Although deep models have been extensively studied in machine translation and are frequently used to improve translation performance, almost all work on deepening models has focused on increasing the number of encoder layers; there has been very little research on deepening the decoder. Through preliminary experiments on varying the number of decoder layers in the Transformer NMT model, we observed that, when the decoder is deepened beyond a certain number of layers, the translation performance of the overall model fails to improve; moreover, it declines rapidly to near zero. This demonstrates that there are flaws in the current structure or training method, and the deep-decoder NMT model cannot be trained.

By analyzing the training process of the deep-decoder model, we found that the training perplexity of the model was relatively low, but the translation performance of the obtained model was much worse than that of a shallow model. Inspired by this phenomenon, we hypothesize that, as the decoder deepens, the model may increasingly ignore the

source inputs and degenerate to an unconditional language model, even though a low perplexity can be obtained on the training set. In this case, the purpose of translation learning is not achieved, and thus the model training fails.

According to our hypotheses, preventing the decoder from degenerating to an unconditional language model is the key to overcoming the failure of deep-decoder NMT model training. Consequently, we propose two aspects of model improvement: model structure and model training. In model structure, the only difference between the decoder of the NMT model and that of the unconditional language model is cross-attention; therefore, we focus mainly on this structure. In model training, we aim to make the decoder output distant from the output of the unconditional language model to avoid fitting the target sentences while ignoring the source inputs in the training dataset.

Specifically, we propose a cross-attention drop (CAD) mechanism for the deep-decoder layer structure. The original intention of this mechanism is that we suspected that the degeneration of the deep decoder to an unconditional language model was caused by the training difficulties resulting from too many cross-attentions. Because the purpose of cross-attention is to force the decoder layer to obtain features from the source representation, the different layers in the deep decoder should perform distinct roles. However, the conventional deep decoder requires each layer to extract source features similarly, thus increasing the training difficulty. As a result, to minimize training loss, the model chooses to memorize the training target sentences directly and ignore the source inputs. In this mechanism, we drop the cross-attention in some decoder layers to lower the overall training difficulty, thereby preventing the failure of deep-decoder training. In addition to structural changes, we also propose a decoder dropout regularization (DDR) loss and anti-LM-degradation (ALD) loss for joint model optimization, based on contrastive learning; these increase the stability of deep-decoder NMT model training and avoid degeneration to an unconditional language model.

Our experiments were conducted mainly on two popular machine translation benchmarks: WMT14 English-to-German and English-to-French. The results of the experimental exploration of decoders with different depths show that a successfully trained depth decoder greatly benefits the overall translation performance and can work with the deep encoder to achieve higher translation performance. Moreover, the novel training approaches that we propose both increase the stability of the training of the deep-decoder model and enable additional improvements.

2 Related Work

2.1 Deep NMT Model

In computer vision tasks, it has been found that increasing the depth of convolutional neural networks can significantly increase the performance (He et al., 2016). As deep neural networks have become widely used in NLP tasks, machine translation tasks have also incorporated deep neural networks for modeling, using an encoder–decoder architecture based on a recurrent neural network (RNN) (Sutskever et al., 2014; Bahdanau et al., 2015). Since the emergence of the Transformer-based model (Vaswani et al., 2017), the deep model has become the mainstream baseline model for machine translation (Li et al., 2021d). The Transformer NMT model employs a deeper architecture than the RNN-based model, with six encoder layers and six decoder layers. During the same time period, Gehring et al. (2017) introduced an encoder–decoder architecture wholly based on CNNs, which increased both the number of encoder layers and the number of decoder layers to 20. In addition to structural design, unsupervised learning have also become another important branch of NMT (Lample et al., 2018; Li et al., 2019a, 2020b, 2021c; Nguyen et al., 2021).

Because greater model capacity has the potential to contribute significantly to quality improvement (Zhang et al., 2019b; Li et al., 2019b; Parnow et al., 2021), deepening a model is regarded as a good method of boosting the capacity of the model with the same architecture. It has been shown that more expressive features are extracted (Mhaskar et al., 2016; Telgarsky, 2016; Eldan and Shamir, 2016), which has resulted in improved performance for vision tasks (He et al., 2016; Srivastava et al., 2015) over the past few years. In Transformer NMT models, there have also been numerous studies on deepening the model for better performance. Bapna et al. (2018) took the first step toward training extraordinarily deep models by deepening the encoders for translation, but discovered that simply increasing the encoder depth of a basic Transformer model was insufficient. Because of the difficulty of training, models utterly fail to learn. Transparent attention has also been proposed to regulate deep-encoder gradients; this eases the optimization of deeper models and results in consistent gains with a 16-layer Transformer encoder.

Following research on deepening the encoder to obtain a deep NMT model, as in (Bapna et al., 2018), Wu et al. (2019) proposed a two-stage training strategy with three special model structural designs for constructing deep NMT models with eight encoder layers. Wang et al. (2019) proposed a dynamic linear combination mechanism and successfully trained a Transformer model with a 30-layer encoder, with the proposed mechanism shortening the path from upper-level layers to lower-level layers to prevent the gradient from vanishing or exploding. Zhang et al. (2019a) proposed a depth-scale initialization for improving norm preservation and a merged attention sublayer that integrates a simplified average-based self-attention sublayer into the cross-attention module. Fan et al. (2020) employed a layer-drop mechanism to train a 12-6 Transformer NMT model and pruned subnetworks during inference without fine-tuning. More recently, Wei et al. (2020) proposed to attend the decoder to multigranular source information with different space-scales, thereby boosting the training of very deep encoders without special training strategies. Li et al. (2020a) developed a shallow-to-deep training strategy and employed sparse connections across blocks to successfully train a 48-layer encoder model. Kong et al. (2021) studied using deep-encoder and shallow-decoder models to improve decoding speed while maintaining high translation quality. Most of these related studies focused on deepening the encoder for deep NMT models, whereas there have been very few studies on deepening the decoder. Herein lies the most significant dissimilarity between our work and this related work.

2.2 Contrastive Learning in NLP

Contrastive learning (Hadsell et al., 2006) is an effective approach to learning and is usually used for unsupervised learning because of its unique characteristics. It has achieved significant success in various computer vision tasks (Misra and van der Maaten, 2020; Zhuang et al., 2019; Tian et al., 2020; He et al., 2020; Chen et al., 2020). Gao et al. (2021) introduced a simple contrastive learning framework for unsupervised learning of sentence embedding, which performed as well as previous supervised approaches. Wu et al. (2020c) employed multiple sentence-level augmentation strategies—such as word and span deletion, reordering, and substitution—with a sentence-level contrastive learning objective to pretrain a language model for a noise-invariant sentence representation. Fang et al. (2020) pretrained language representation models using contrastive self-supervised learning at the sentence level by predicting whether two back-translated sentences originate from the same sentence. In (Giorgi et al., 2021), a universal sentence embedding encoder was trained to minimize the distance between the embeddings of textual segments randomly sampled from nearby locations in the same document by a self-supervised contrastive objective. Pan et al. (2021) demonstrated the effectiveness of contrastive learning in NMT, particularly for the zero-shot machine translation situation. Current contrastive learning for NMT primarily employs cross-lingual representation similarity, whereas we aim to prevent the outputs of the deep decoder and the unconditional language model from becoming too similar, thus preventing degradation. Li et al. (2021b) presented an contrastive learning-reinforced domain adaptation approach for NMT. Part of our method is similar to (Miao et al., 2021) in purpose, but it is designed to avoid the NMT model from over-confident, while ours is to tackle the problem of the deep decoder collapsing into an unconditional language model.

3 Our Method

Given bilingual parallel sentences $\langle \mathbf{X}, \mathbf{Y} \rangle$, the NMT model learns a set of parameters $\mathbf{\Theta}$ by maximizing the likelihood $\mathcal{J}(\mathbf{Y}|\mathbf{X}, \Theta)$, which is represented as the product of the conditional probabilities of all target words:

$$\begin{aligned}\mathcal{J}_{\text{NLL}}(\mathbf{Y}|\mathbf{X};\mathbf{\Theta}) &= \prod_{i=1}^{|\mathbf{Y}|} P(\mathrm{Y}_i|\mathbf{Y}_{<i}, \mathbf{X}; \mathbf{\Theta}) \\ &= -\sum_{i=1}^{|\mathrm{Y}|} \log P(\mathbf{Y}_i|\mathbf{Y}_{<i}, \mathbf{X}; \mathbf{\Theta}),\end{aligned} \tag{1}$$

where $|\mathbf{Y}|$ represents the sequence length of $\mathbf{Y}$, Y_i represents the i-th token of sequence $\mathbf{Y}$, and $\mathbf{Y}_{<i}$ represents all the tokens before the i-th token. Encoder–decoder architectures are commonly employed in NMT to model the translation conditional probabilities $P(\mathbf{Y}|\mathbf{X}; \mathbf{\Theta})$, where the encoder and decoder can be implemented as RNNs (Wu

et al., 2016), CNNs (Gehring et al., 2017), or self-attention (Vaswani et al., 2017). In this study, we used the most recent Transformer NMT model, based on a self-attention structure, as our baseline.

3.1 Transformer NMT Model

The encoder and decoder in the Transformer NMT model both consist of stacked multiple layers, with each layer composed of attention networks. The following is the basic form of an attention network:

$$\begin{aligned} \textsc{Attn}(\mathbf{H}_{\mathrm{Q}}, \mathbf{H}_{\mathrm{KV}}) &= \mathbf{W}_{\mathrm{O}} \left[\mathrm{Softmax}(\frac{\mathbf{Q}\mathbf{K}^T}{\sqrt{d}})\mathbf{V} \right], \\ \mathbf{Q}, \mathbf{K}, \mathbf{V} &= \mathbf{W}_{\mathrm{Q}}\mathbf{H}_{\mathrm{Q}}, \mathbf{W}_{\mathrm{K}}\mathbf{H}_{\mathrm{KV}}, \mathbf{W}_{\mathrm{V}}\mathbf{H}_{\mathrm{KV}}, \end{aligned} \tag{2}$$

where $\mathbf{W}_{\mathrm{Q}}, \mathbf{W}_{\mathrm{K}}, \mathbf{W}_{\mathrm{V}}$, and $\mathbf{W}_{\mathrm{O}}$ are weight parameters, d is the hidden dimension, and $\mathbf{H}_{\mathrm{Q}}$ and $\mathbf{H}_{\mathrm{KV}}$ are two input vectors for attention, with $\mathbf{H}_{\mathrm{Q}}$ serving as a query and $\mathbf{H}_{\mathrm{KV}}$ serving as key and value. When $\mathbf{H}_{\mathrm{Q}}$ and $\mathbf{H}_{\mathrm{KV}}$ are input into the same vector, the attention becomes self-attention: $\textsc{SelfAttn}(\mathbf{H}_{\mathrm{QKV}}) = \textsc{Attn}(\mathbf{H}_{\mathrm{QKV}}, \mathbf{H}_{\mathrm{QKV}})$. To improve feature extraction capabilities, Vaswani et al. (2017) advocated using a multihead mechanism to enhance the original attention; we omit this here for simplicity.

In the encoder, $\mathcal{L}_e$ identical layers are stacked, and each layer has a self-attention sublayer and a pointwise feedforward sublayer. Layer normalization (Ba et al., 2016) and skip residual connection (He et al., 2016) are employed for each sublayer's input and output. The process in the l-th encoder layer can be formalized as follows:

$$\begin{aligned} \hat{\mathbf{H}}_e^l &= \textsc{Ln}\left(\textsc{SelfAttn}(\mathbf{H}_e^{l-1}) + \mathbf{H}_e^{l-1}\right), \\ \mathbf{H}_e^l &= \textsc{Ln}\left(\textsc{Ffn}(\hat{\mathbf{H}}_e^l) + \hat{\mathbf{H}}_e^l\right), \end{aligned} \tag{3}$$

where $\mathbf{H}_e^{l-1}$ denotes the output of the (l-1)-th layer in the encoder, $\textsc{Ffn}(\cdot)$ is the pointwise feedforward sublayer with a two-layer feedforward network and ReLU activation function, and $\mathbf{H}_e^0 = \textsc{Emb}(\mathbf{X})$ denotes the initial representation from the embedding layer.

The decoder consists of $\mathcal{L}_d$ identical layers. As in the encoder, the self-attention network is used to extract features from the target sequence in each layer; however, in addition, a cross-attention is used to extract features from the source sequence. The process of the l-th layer in the decoder can be formalized as follows:

$$\begin{aligned} \hat{\mathbf{H}}_d^l &= \textsc{Ln}\left(\textsc{SelfAttn}(\textsc{CasualMask}(\mathbf{H}_d)) + \mathbf{H}_d^{l-1}\right), \\ \tilde{\mathbf{H}}_d^l &= \textsc{Ln}\left(\textsc{CrossAttn}(\hat{\mathbf{H}}_d^l, \mathbf{H}_e^{\mathcal{L}_e}) + \hat{\mathbf{H}}_d^l\right), \\ \mathbf{H}_d^l &= \textsc{Ln}\left(\textsc{Ffn}(\tilde{\mathbf{H}}_d^l) + \tilde{\mathbf{H}}_d^l\right). \end{aligned}$$

where $\mathbf{H}_d^0 = \textsc{Emb}(\mathbf{Y})$, $\textsc{CausalMask}(\cdot)$ represents the causal mask mechanism (to make any i-th token unable to see future tokens, thereby maintaining unidirectional translation), $\textsc{CrossAttn}(\cdot)$ is the same as $\textsc{Attn}(\cdot)$ in implementation, in which the hidden state on the decoder is input as the query, and the hidden state on the encoder is input as the key and value. The output target sequence is predicted on the output hidden state $\mathbf{H}_d^{\mathcal{L}_d}$ from the top layer of the decoder:

$$P(\mathbf{Y}|\mathbf{X}; \mathbf{\Theta}) = \mathrm{Softmax}(\mathbf{W}_{\mathrm{D}}\mathbf{H}_d^{\mathcal{L}_d}), \tag{4}$$

where $\mathbf{W}_{\mathrm{D}}$ is the projection weight parameter, which maps the hidden state to the probability in the vocabulary space.

3.2 Deep Decoder Collapse

In theory, we can construct a deeper Transformer NMT model by stacking more decoder layers in addition to more encoder layers. To illustrate the challenge of simply increasing the number of decoder layers for a deep NMT model, we conducted a preliminary experiment using the WMT14 En→De translation task.

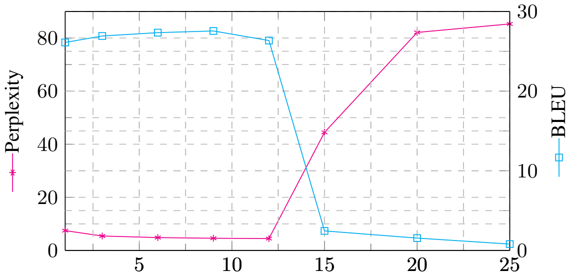

Figure 1: Training perplexity vs. decoder depth and BLEU score vs. decoder depth on WMT14 En→De translation task.

Figure 1 shows the relationship between training perplexity and BLEU score on the test set with different decoder depths after 200K training steps. Except for the number of decoder layers, other hyperparameters were kept consistent with those used in the Transformer-based model setting. The figure shows that, as the number of decoder layers increased, the training perplexity fell gradually and then increased, whereas the BLEU score increased at first and eventually declined to a very low level. This phenomenon is referred to as deep-decoder collapse. The perplexity on the training set appeared to decrease but the translation performance was very poor; we hypothesize that this phenomenon was caused by the model ignoring the source inputs, leading the decoder to degenerate to an unconditional language model. To verify our hypothesis, we made improvements in two respects: model structure and model training.

3.3 Cross-attention Drop

The sole fundamental difference between the decoder in Transformer NMT and the pure unconditional language model, such as GPT2, is the cross-attention in Eq. (4). The cross-attention forces the target representation to include features from the source's representation, rather than relying only on the visible target tokens. Although the presence of cross-attention intuitively prevents the decoder from degenerating to an unconditional language model, we argue that it is the presence of cross-attention that makes the learning more difficult. This is because each layer in the deep decoder plays a more distinct role than in a shallow decoder but each layer is forced to extract features from the source representation. Thus, the decoder may abandon the cross-attention and act as an unconditional language model, to achieve a lower training loss.

We propose a drop-net technique to ensure that the features output by self-attention and the encoder are fully exploited. This technique, inspired by dropout (Srivastava et al., 2014) and drop-path (Larsson et al., 2017), can be employed to regularize the network training. Specifically, for the l-th decoder layer, given a drop-net rate of p^l_{net}, we randomly sample a variable $U^l \in [0,1]$, and the calculation of $\tilde{\mathbf{H}}^l_d$ in Eq. (4) becomes:

$$\begin{aligned}\tilde{\mathbf{H}}^l_{d,\text{drop-net}} = \textsc{Ln}\big(&\mathbb{1}(U^l > p^l_{\text{net}}) \cdot \hat{\mathbf{H}}^l_d + \\ &\mathbb{1}(U^l < p^l_{\text{net}}) \cdot (\textsc{CrossAttn}(\hat{\mathbf{H}}^l_d, \mathbf{H}^{L_e}_e) + \hat{\mathbf{H}}^l_d)\big).\end{aligned}$$

where $\mathbb{1}(\cdot)$ is an indicator function. For layer l, with probability p^l_{net}, only self-attention is used; with probability $(1 - p^l_{\text{net}})$, both of the two attentions are used. During the inference stage, both attentions are used for the $\tilde{\mathbf{H}}^l_d$ calculation. For the simplicity of implementation, we adopted a same fixed p_{net} for layers $1 \leq l \leq \mathcal{L}_{dr}$ (i.e. $p^l_{\text{net}} = p_{\text{net}}, 1 \leq l \leq \mathcal{L}_{dr}$), while set $p^l_{\text{net}} = 1.0$ for layers $l > \mathcal{L}_{dr}$. We denote $\mathcal{L}_{dr}$ as the drop depth and p_{net} as the drop ratio.

3.4 Collapse Reducing Training

In addition to the model structure, we introduced two extra losses into model training: one for stable optimization and another to minimize the risk of the decoder degenerating to an unconditional language model. These are the DDR loss and ALD loss, both of which are inspired by the concept of contrastive learning.

Because of the use of dropout and drop-net in the decoder, we propose a simple regularization loss, DDR loss, which is based on the randomness of the model structure. The purpose of this loss, which is inspired by R-drop (Wu et al., 2021), is to regularize the output predictions from different substructures of the deep decoder and increase the stability of the optimization. Specifically, because the same source representation and target tokens are input twice, the two predicted distributions P_1 and P_2 are forced to be mutually consistent. The probability forms of two separate passes for the decoder only are written as $P_1(\text{Y}_i|\mathbf{Y}_{<i}, \mathbf{H}^{L_e}_e; \mathbf{\Theta}_d)$ and $P_2(\text{Y}_i|\mathbf{Y}_{<i}, \mathbf{H}^{L_e}_e; \mathbf{\Theta}_d)$, in which $\mathbf{\Theta}_d$ denotes the parameters of the decoder. The similarity loss of the two prediction distributions is implemented as the minimization of the bidirectional Kullback–Leibler (KL) divergence between the two distributions:

$$\begin{aligned}\mathcal{J}_{\text{DDR}} = \frac{1}{2}(&\\ &\mathcal{D}_{\text{KL}}(P_1(\text{Y}_i|\mathbf{Y}_{<i}, \mathbf{H}^{L_e}_e; \mathbf{\Theta}_d)||P_2(\text{Y}_i|\mathbf{Y}_{<i}, \mathbf{H}^{L_e}_e; \mathbf{\Theta}_d) + \\ &\mathcal{D}_{\text{KL}}(P_2(\text{Y}_i|\mathbf{Y}_{<i}, \mathbf{H}^{L_e}_e; \mathbf{\Theta}_d)||P_1(\text{Y}_i|\mathbf{Y}_{<i}, \mathbf{H}^{L_e}_e; \mathbf{\Theta}_d)),\end{aligned}$$

where $\mathcal{D}_{\text{KL}}(p||q)$ denotes the logarithmic difference between probabilities p and q. A decoder with drop-net and dropout can converge stably by contrastive learning from the two passes' output distributions of the same input.

With the DDR loss, regularization training is applied to the deep decoder with dropout and drop-net to help the decoder converge; however, the risk of the model degenerating to an unconditional language model remains. To solve this problem, we propose the ALD loss, the primary purpose of which is to allow the model to be aware that the amount of source information used determines the effect on the decoder output, when performing contrastive learning. That is, the output with more source information used should be more similar to the output using full source information than the output with less source information used.

The traditional definition of contrastive learning assumes a set of paired examples, $\mathcal{D} = \{(z_i, z^+_i)\}^M_{i=1}$, where z_i and z^+_i are semantically related. In contrastive learning, z^+_i is used as a positive instance of z_i, and other in-batch examples are used as the negative instances. Specifically, the loss

Table 1: Number of model parameters, training time (hours), BLEU scores (%), and sacreBLEU scores (%) of translation models on WMT14 En→De and En→Fr tasks. We use Base and Big to represent the different parameter settings of the NMT model, Deep represents the deep NMT model, and DeepE specifically refers to the deep NMT model with a deep encoder.

of contrastive learning is realized as a cross-entropy loss, and can be represented as follows:

$$\mathcal{J}_{\text{CL}} = -\log \frac{e^{\text{sim}(\mathcal{G}(z_i),\mathcal{G}(z_i^+))/\tau}}{\sum_{j=1}^{N} e^{\text{sim}(\mathcal{G}(z_i),\mathcal{G}(z_j))/\tau}}, \qquad (5)$$

where N is the size of a mini-batch, $\mathcal{G}(\cdot)$ denotes a function that transforms a sequence input into a final single-vector representation, $\text{sim}(\mathbf{v}_1, \mathbf{v}_2)$ denotes the cosine similarity $\frac{\mathbf{v}_1^\top \mathbf{v}_2}{\|\mathbf{v}_1\| \cdot \|\mathbf{v}_2\|}$, and τ is a softmax temperature hyperparameter. In SimCSE (Pan et al., 2021), the $\mathcal{G}(\cdot)$ function is implemented as the model with an additional pooling layer that obtains the sentence representation. Because the presence of dropout in the model results in different outputs for the same input, the input is treated as a positive instance of z_i itself.

In ALD loss, our purpose is entirely different from the above. We consider using more source inputs as positive instances and fewer as negative instances of z_i, with all source inputs. Specifically, for the translation pair $\langle \mathbf{X}, \mathbf{Y} \rangle$, we randomly sample a ratio $\gamma \in [0, p_{\text{ALD}}), 0 < p_{\text{ALD}} < 0.5$, replace the token in $\mathbf{X}$ with UNK in the ratio γ to obtain $\mathbf{X}^+$, and replace the X in the ratio $(1 - \gamma)$ with UNK to obtain $\mathbf{X}^-$.

$$\mathcal{J}_{\text{ALD}} = -\log \frac{e^{\text{sim}(\mathcal{G}(\mathbf{X},\mathbf{Y}),\mathcal{G}(\mathbf{X}^+,\mathbf{Y}))/\tau}}{\sum_{*\in[+,-]} e^{\text{sim}(\mathcal{G}(\mathbf{X},\mathbf{Y}),\mathcal{G}(\mathbf{X}^*,\mathbf{Y}))/\tau}}, \qquad (6)$$

where $G(\cdot, \cdot)$ denotes average pooling output on the hidden state from the top layer of the decoder (i.e., $\mathcal{G}(\mathbf{X}, \mathbf{Y}) = \textsc{AvgPool}(\mathbf{H}_d^{\mathcal{L}_d})$). When using ALD loss, if the decoder ignores the source inputs and degenerates to an unconditional language model, the source inputs will have very little impact on the output: $\mathcal{G}(\mathbf{X}, \mathbf{Y})$, $\mathcal{G}(\mathbf{X}^+, \mathbf{Y})$, and $\mathcal{G}(\mathbf{X}^-, \mathbf{Y})$ will all be similar, resulting in confusion for the contrastive learning.

3.5 Discussion

Inspired by the wildly discussed KL divergence vanishing problem (Bowman et al., 2016) of variational autoencoder (VAE), in which the expressive decoder does not rely on the latent variable to reconstruct the input data, i.e., the KL divergence vanishes to be zero, we hypothesis the similar phenomenon appears in the machine translation models that are enhanced with a deep decoder. We presume that as the decoder goes deeper, the expressive capacity of the decoder is getting strong enough to generate the target sentence ignoring the information from the source sentence. In other words, the machine translation model, which can also be considered a conditional language model $P(Y_i|Y_{<i}, X)$, collapses to an unconditional language model $P(Y_i|Y_{<i})$. Moreover, due to teacher forcing training procedure is applied as standard

practice, generating tokens at the end of the sentence is much easier than generating tokens at the beginning of the sentence. This is because sufficient information from the ground-truth history $Y_{<t}$ is already known to the decoder at this time step t, thus it is completely feasible to generate the next token with information from the source sentence ignored. We claim this is the reason that a low perplexity score can still be obtained but the quality of translation, the BLEU score, is greatly compromised.

According to these hypotheses, we claim that preventing the decoder from collapsing to an unconditional language model is the key to overcoming the failure of the NMT model with a deep decoder. Following the two main approaches to mitigate the posterior collapse problem, we proposed methods from two aspects, i.e., model structure and model training.

4 Experiment

4.1 Setup

Dataset To compare with previous work, we conducted experiments on two classical machine translation datasets: WMT14 English-to-German (En→De) and English-to-French (En→Fr). The corpus sizes are 4.5M and 36M for the En→De and En→Fr datasets, respectively. Following common practice, we concatenated *newstest2012* and *newstest2013* as the validation set and used *newstest2014* as the test set. We employed `tokenizer.pl` in Moses (Koehn et al., 2007) to tokenize En, De, and Fr sentences, and then used BPE (Sennrich et al., 2016) to split the words into subwords. A joint BPE strategy with 40K merge operations between source and target languages was adopted to construct the vocabulary.

Configuration We adopted the most widely used Transformer (Vaswani et al., 2017) network as our research basis[1]. Two typical parameter settings are often used to fulfill various needs: Transformer BASE and Transformer BIG. Both settings employ a six-layer encoder and a six-layer decoder. The differences between them are the embedding width, feedforward network size, and number of attention heads, which are 512/2048/8 for BASE and 1024/4096/16 for BIG. We used `multi-bleu.perl` and detokenized sacreBLEU[2] to evaluate the translation performance on test sets, for fair comparison with previous work. Other hyperparameter settings for model training were consistent with (Vaswani et al., 2017). The number of training steps was 200K for En→De models and 400K for En→Fr models, the batch size was 4096 tokens per GPU, and the models were trained on eight NVIDIA V100 GPUs.

4.2 Main Results

Table 1 shows the results of our model on the WMT14 En→De and En→Fr translation tasks. To make it easier to compare the results of NMT models with the same depth, we set the total number of layers of the model to be as consistent as possible with that used in related work. Because the encoder is responsible for encoding the source language, and the decoder is in charge of encoding the target language, and the depth of the model affects its abstraction ability, we argue that the encoder should have a depth similar to that of the decoder. Therefore, we employed the same number of layers for the encoder and decoder in the NMT model.

On the basis of the baseline model, the results for the deepened models (denoted by DEEP) suggest that the training encountered failures, and deeper models achieved worse results. When we applied the CAD and CRT approaches to the Deep models, the training failure problem was resolved: the full model both achieved better results than the corresponding baselines and obtained performance superior to that of the model with a deep encoder only. This demonstrates that a deeper model has performance advantages, and our proposed CAD and CRT methods alleviate the problem of deep-decoder collapse. In addition, it reveals that the architecture with balanced encoder and decoder outperforms the architecture with only a deep encoder. We also conducted experiments to deepen the NMT models under the BIG parameter setting, and the performance phenomenon was similar to that observed under the BASE parameter setting.

Compared with (Wang et al., 2019), our model achieved similar results but with fewer layers (30), and did not require a special model structure design. Our models achieved a better translation effect with fewer parameters compared with the results of (Wei et al., 2020), demonstrating that our proposed method is simple and very effective. In comparison with (Li et al., 2020a), our models performed simi-

---

[1] Our code will be available at `https://github.com/bcmi220/ddnmt`.

[2] `https://github.com/mjpost/sacreBLEU`

larly in En→De translation under the BASE setting, and demonstrated better performance in En→Fr. We believe that this is a consequence of the larger quantity of training data in En→Fr, which allows the decoder to be more fully trained. We obtained generally better results in the BIG setting, whereas Li et al. (2020a)'s results were comparable to those of our DEEPE baseline.

4.3 Further Exploration

Effects of Drop Depth and Drop Ratio. As explained in model part, we propose the CAD approach for the deep NMT model structure. To investigate the impact of the drop depth and drop ratio on final translation performance, we conducted experiments on the WMT14 En→De task using the BASE, DEEP-54L model with both CAD and ALD techniques; the experimental results are presented in Figure 2. We found that, when the drop depth was very small for a 27-layer decoder, the model also suffered from the problem of deep-decoder collapse, and the translation performance was very poor. When we increased the drop depth, the translation performance improved progressively, reaching a peak at the 21st layer, confirming our hypothesis that cross-attention is a contributing cause to the problem of deep-decoder collapse.

As the drop depth was increased further, performance suffered, even though there was no training failure. This demonstrates that cross-attention is also an important component of the translation model, and insufficient cross-attention also prevents the model from extracting adequate source information. Furthermore, we compared several drop ratios and observed that, with a small drop depth, $p_{\text{net}} = 1.0$ indicates that all cross-attention drops in the corresponding layer will have a superior final effect. Conversely, with a greater drop depth, a smaller p_{net}—which retains some of the cross-attention—will achieve better results.

Hyperparameters in ALD Loss. To analyze the effect of the hyperparameters—softmax temperature τ and sampling threshold p_{ALD}—in the ALD loss, we conducted experiments on the WMT14 En→De task with the BASE, DEEP-30L model. The results obtained are presented in Figure 3, which shows that increasing the sampling threshold improves the BLEU score. This is because a larger p_{ALD} for UNK replacement can yield a greater diversity of negative examples, which is beneficial for contrastive learning. However, if p_{ALD} is further increased, the difference between positive and negative examples decreases, which has a detrimental impact on the final translation performance. Compared with the sampling threshold p_{ALD}, the temperature τ has a relatively small effect. The experimental results reveal that the BLEU score with $\tau = 0.05$ is slightly lower than that with $\tau = 0.1$. We believe that, when the value of the temperature parameter is too small, the ALD loss is too large, thus affecting the model's convergence.

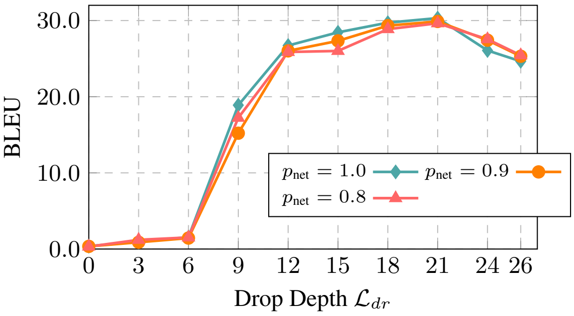

Figure 2: Influence of different drop ratios and depths on translation performance of deep NMT model.

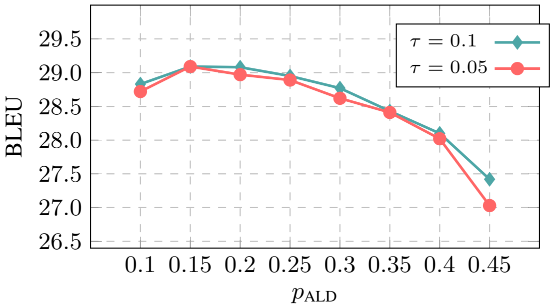

Figure 3: Influence of sampling threshold p_{ALD} and temperature parameter τ on translation performance in ALD loss.

Effects of Encoder Depth and Decoder Depth. Because our method allows for a deep encoder and decoder, we investigated the effect of encoder and decoder depth on translation performance. We selected the BASE, DEEP-30L model as the basis and conducted experiments on the WMT14 En→De translation task, changing only the depth of the encoder or decoder. The results are illustrated in Figure 4. When the encoder depth was 1, the translation performance was significantly poorer than when the decoder depth was 1, indicating that the encoder has a more obvious performance limit at this shallow level. This is because the encoder is directly responsible for the extraction of the source representation, and a shallow encoder cannot ex-

Enc.	Dec.	BLEU	sacreBLEU
24	6	28.95	27.8
6	24	28.21	27.0
15	15	29.09	28.1

Table 2: Performance of deep NMT models with different combinations of encoder and decoder depth.

tract enough source information. This suggests that, if resources are restricted and the number of layers needs to be decreased to obtain a smaller model, it is more effective to reduce the number of decoder layers; this finding is compatible with Kasai et al. (2021)'s conclusion. In addition, increasing the depth of both the encoder and the decoder improves the model's translation performance, implying that increasing the number of decoder layers is effective in a deep NMT model.

The balance between the number of encoder layers and the number of decoder layers in a deep model is another important consideration. To investigate this, we compared translation performance in three typical cases on WMT14 En→De with the total number of encoder and decoder layers set to 30. As shown in Table 2, the model with an equal number of encoder and decoder layers achieved the best results, outperforming the pure deep-encoder and deep-decoder models.

5 Ablation Study

We conducted ablation studies on the modifications that we made to both the model structure and training to investigate their respective effects on the translation performance. The ablation research was conducted on the WMT14 En→De task, as before, and the model employed was the Base, Deep-30L-Full model. We began by adding extra R-Drop, DDR, ALD, and CAD techniques to its baseline model (Base, Deep-30L). The results in Table 3 show that the baseline training was unsatisfactory, even with the addition of the better training methods (R-Drop, DDR, and ALD). However, when we dropped cross-attention after applying CAD, the model training became normal, indicating that the model structure has a significant impact on its performance. When we compared the results of Base, Deep-30L+CAD with those of Base, Deep-30L-Full, we found that the training methods DDR and CAD were beneficial to improving performance, demonstrating their effectiveness.

System	BLEU	sacreBLEU
Base, Deep-30L	0.55	0.2
+R-Drop	0.97	0.5
+DDR	1.01	0.4
+ALD	1.45	0.7
+CAD	28.35	27.2
Base, Deep-30L-Full	29.09	28.1
-CAD	1.39	0.7
-DDR	28.77	27.6
-ALD	28.52	27.4

Table 3: Ablation studies on model structures and training approaches.

We also conducted ablation evaluation of the model structure and training method on the entire model. According to the results, CAD had the greatest influence on the translation performance, which is consistent with the conclusion stated above, based on the results in Table 3. Additionally, when comparing DDR and ALD, we found that ALD had a greater influence on translation because it directly mimics the deep-decoder collapse problem, whereas DDR is mostly employed to increase the stability of the training of the drop-net mechanism in CAD, by incorporating regularization.

6 Conclusion

In this paper, we investigated the problem of deep-decoder collapse in NMT when the decoder is deepened. We introduced a CAD mechanism, DDR loss, and ALD loss to solve this problem. Using this model, we demonstrated that a deep model with balanced numbers of encoder and decoder layers outperforms either encoder deepen only or decoder deepen only NMT models. Our model outperformed previous similar models on the WMT14 En→De and En→Fr tasks, confirming the effectiveness of our approach. For future work, we intend to incorporate methods from related work on deep NMT to further improve the performance of our translation model.

SyMCoM - Syntactic Measure of Code Mixing
A Study Of English-Hindi Code-Mixing

Abstract

Code mixing is the linguistic phenomenon where bilingual speakers tend to switch between two or more languages in conversations. Recent work on code-mixing in computational settings has leveraged social media code mixed texts to train NLP models. For capturing the variety of code mixing in, and across corpus, Language ID (LID) tags based measures (CMI) have been proposed. Syntactical variety/patterns of code-mixing and their relationship vis-a-vis computational model's performance is under explored. In this work, we investigate a collection of English(en)-Hindi(hi) code-mixed datasets from a syntactic lens to propose, $SyMCoM$, an indicator of syntactic variety in code-mixed text, with intuitive theoretical bounds. We train SoTA en-hi PoS tagger, accuracy of 93.4%, to reliably compute PoS tags on a corpus, and demonstrate the utility of $SyMCoM$ by applying it on various syntactical categories on a collection of datasets, and compare datasets using the measure.

1 Introduction

Code-mixing refers to mixing of linguistic units and structures from multiple languages in a single utterance and/or conversation (Myers-Scotton, 1997). The complexity of code-mixing can be intuitively understood as the degree of structural interleaving between the languages at the level of the lexicon and morpho-syntax (Myers-Scotton, 1997), and also at the level of pragmatic and socio-linguistic functions of code-mixing in a linguistic community (Begum et al., 2016; Annamalai, 2001; Malhotra, 1980). It is an important notion that is linguistically well-studied and provides insights into cognitive and cultural aspects of human language. Additionally, quantification of this complexity has recently attracted attention of computational linguists because studies have shown that the performance of the same model can widely vary on different code-mixed corpora. As a result, different metrics of complexity of code-mixing have been proposed such as CMI, Ratio-based measures time-course measures and memory-based measures (Guzmán et al., 2017; Gambäck and Das, 2016). But as Srivastava and Singh (2021) points out, these metrics are limited, partly because they are primarily based on language switch patterns at the token level, being completely agnostic to structural features.

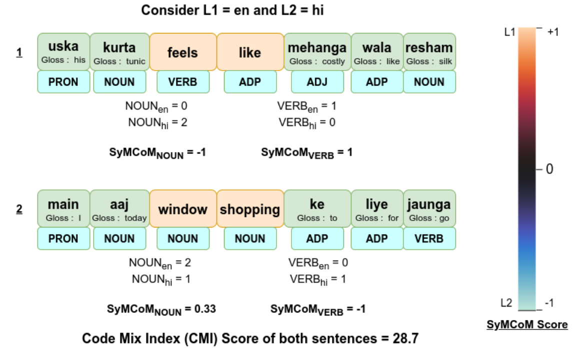

Figure 1: Two sentences, having same language patterns, but the syntactic nature of the switched units are different - VERB is switched in Ex 1, NOUNS are switched in Ex 2.

For instance, Figure 1 shows $en-hi$ code-mixed sentences with the same language tag distribution, but in Example (1), verb is switched, while in (2) nouns are switched. The former seems much more complex and difficult to process cognitively and computationally, than the latter, where switching seems to be an extension of noun-borrowing (Bali et al., 2014). Motivated by such cases, in this paper, we ask the following research question: *Can syntactic category information be deduced and used as a measure of structural complexity of a code-mixed sentence and corpus?* We attempt to tackle this question by formulating: **S**yntactic **M**easure of **Co**de **M**ixing $SyMCoM$, a simple metric that encodes the distributional difference of various syntactic categories across languages in a sentence. $SyMCoM$ can be computed for any corpora, as long as there is a reasonably accurate POS tagger

Findings of the Association for Computational Linguistics: ACL 2022, pages 472 - 480
May 22-27, 2022

for the code-mixed language pair.

Through empirical studies of several existing en-hi code-mixed corpora we provide, for the first time, a strong quantitative evidence in support of a widely held theoretical notion that Open class categories (e.g., noun, adjectives) are more likely to be switched than the closed class categories (e.g., pronouns, verbs) within a sentence. Further, we show that different corpora have significantly different distribution of $SyMCoM$ values.

2 SyMCoM: Syntactic Measure of Code Mixing

A quantitative measure of syntactic variation in code mixing patterns should ideally encode: **a) Category of Switch** i.e whether or not a PoS tag or syntactic category is switched?; **b) Degree / Contrast** : If a syntactic unit is switched, what is the level of contrast between $L1$ and $L2$ for that unit?

To encode the aforementioned properties, we propose a **Sy**ntactic **M**easure of **Co**de **M**ixing ($SyMCoM_{SU}$), which is defined as:

$$SyMCoM_{SU} = \frac{(Count_{SU_{L1}}) - (Count_{SU_{L2}})}{\sum_{i=1}^{2} Count_{SU_{Li}}} \tag{1}$$

Here, SU is a syntactic unit; for this study, we will assume that SU represent word-level syntactic categories namely Parts-of-Speech (POS) tags such as Nouns and Verbs, or a class of PoS tags such as Open and Closed classes. $Count_{SU_{Li}}$ represents the count of the syntactic unit SU for language L_i ($i \in \{1, 2\}$) within a sequence of words code-mixed between languages L_1 and L_2. Without loss of generality, we will consider this sequence to be a sentence, though it could be an utterance, paragraph or even a document. $SyMCoM_{SU}$ score is bounded between [-1,1] and defined only for SUs that occur at least once in the sentence.

The polarity of $SyMCoM_{SU}$ indicates the language, among $L1$ and $L2$, that is contributing higher number of tokens for a particular SU, and its absolute value captures the degree of skew towards a particular language. If $SyMCoM_{SU}$ is closer to zero, it indicates that the contribution of $L1$ and $L2$ for SU is balanced.

We define the $SyMCoM_{sent}$ score for a sentence, as the weighted average of absolute $SyMCoM_{SU}$ scores for all SU, where the weights are the fraction of tokens in the sentence belonging to an SU.

$$SyMCoM_{sent} = \sum_{SU} \frac{Count_{SU}}{len} \times |SyMCoM_{SU}| \tag{2}$$

$SyMCom_{sent}$ is bounded between [0,1]. Values closer to zero indicate that L_1 and L_2 contribute nearly equally for most types of SUs in the sentence, whereas values close to 1 indicate that in the sentence each SU is majorly contributed by a single language. Note that while a low $SyMCoM_{sent}$ implies that the tokens in a sentence are nearly equally contributed by the two languages, a high $SyMCoM_{sent}$ does not say anything about the language distribution of the tokens.

$SyMCoM_{sent}$ can be averaged over the corpus to capture the syntactic variation at a corpus level:

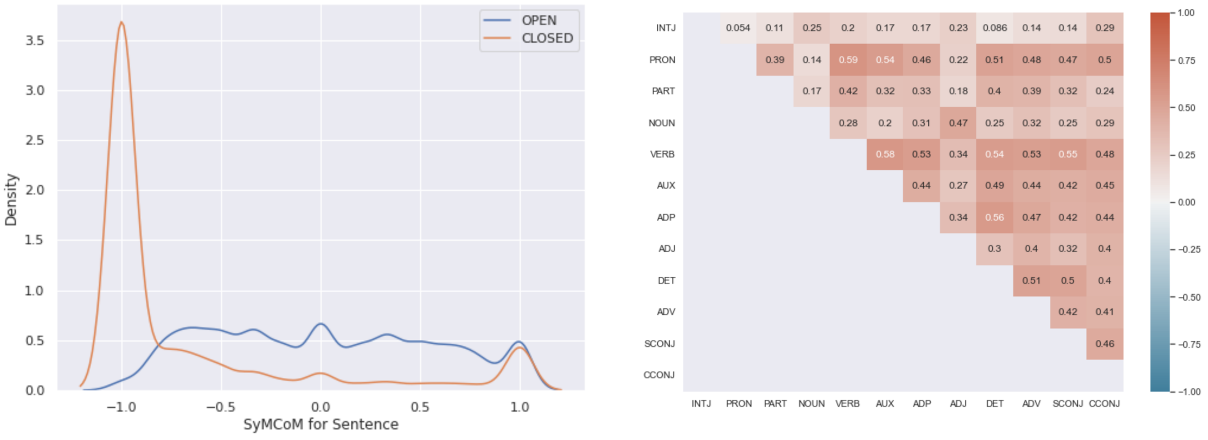
$$SyMCoM_{corpus} = \sum_{sent} \frac{SyMCoM_{sent}}{\#\ sentences\ in\ corpus} \tag{3}$$

Equation 1 can be extended to any arbitrary subset of POS categories, of which the Open Class (content words - Noun, Adjectives, Verbs, etc.) and Closed Class (function words - Adpositions, Pronouns, Demonstratives, etc.) are of special interest; we will refer to these as $SyMCoM_{OPEN}$ and $SyMCoM_{CLOSED}$ respectively.

In Figure 1, $SyMCoM_{SU}$ scores are computed for two en-hi code-mixed sentences, whose CMI scores are equal. For each utterance, we calculate the number of nouns and verbs belonging to L_1 = en and L_2 = hi. In Example 1, $SyMCoM_{NOUN}$ = -1, indicating that L_2 is contributing all the Nouns in this sentence. The opposite polarity of $SyMCoM_{VERB}$ indicates that all the verbs are contributed by L_1.

3 Experiments & Discussion

To demonstrate the utility of the proposed $SyMCoM$ measure, we analyse a) en-hi code-mixed corpus; b) compare $SyMCoM_{sent}$ $SyMCoM_{corpus}$ score across different datasets. To compute $SyMCoM$ scores we need token wise LID and PoS tags. We use pre-trained character level BiLSTM Language ID tagger released by (Bhat et al., 2018) for obtaining token wise LIDs. We train our PoS tagger using the en-hi Universal Dependency dataset released by (Bhat et al., 2017, 2018), which used Universal Dependency tagset (de Marneffe et al., 2014).



a) SyMCoM for OPEN and CLOSED Categories

b) Correlation of SyMCoM scores for PoS Tags

Figure 2: (a) The peak of the curves indicates that CLOSED class words are commonly used in a single language while OPEN class words are spread out, hence, are contributed by both languages. (b) $SyMCoM_{SU}$ score of VERB (Open Class) is highly correlated with Closed class tags.

3.1 en-hi Code Mix PoS tagger

The GLUECoS (Khanuja et al., 2020) and LinCE (Aguilar et al., 2020) benchmarks indicate that multilingual transformer based encoder models - mBERT (Devlin et al., 2019) have matched or outperformed the SoTA on the specific PoS tagging tasks, while showing sub par performance on more complex semantic tasks such as Sentiment Analysis and Natural Language Inference.

Model	Accuracy
Bhat et al. (2018)	91.9%
Mod. mBERT (Khanuja et al., 2020)	88.06%
XLM-R	**92.75%**

Table 1: PoS Tagger Performance

We fine-tune XLM-R (Conneau et al., 2020) to obtain best-performing PoS Tagger. In Table 1 we compare accuracy of our best-performing fine-tuned XLM-R model against previous results reported in GLUECoS benchmark, and Bhat et al. (2018). In addition to accuracy, we also analyse the class wise performance, and we note that ADV, INTJ, PROPN have f1 lower than 0.85. $SyMCoM$ measure depends on the accuracy of the PoS tags and the potency of PoS tagger impacts the usability of the score. We recommend that for $SyMCoM$ scores, the corresponding accuracy of detecting syntactic unit shall be taken into account, and $SyMCoM$ scores be computed for syntactic units which can be detected with a higher accuracy. Further training details for the PoS tagger are listed in Appendix A.

Using the LID and PoS tags, for each Syntactic Unit considered, the language specific counts are computed - SU_{L_i}. $SyMCoM_{SU}$ scores for particular syntactic unit are then calculated using the counts SU_{L_i} as mentioned in Equation 1.

3.2 Analysis of en-hi Code Mixed Corpus

To demonstrate the utility of the proposed $SyMCoM$ measure, we analyse en-hi code-mixed corpus. We collect publicly available code-mixed en-hi datasets released for various tasks: shared tasks, code mixed benchmarks (GLUECoS, LINCE), text classification, Machine translation, among others- remove any monolingual sentences, and created a corpus of 55,474 sentences, details of the datasets used are in Appendix C. $SyMCoM$ scores, along with CMI score (Gambäck and Das, 2016), are computed for the collected corpus, and compared.

Figure 2(a) shows the distribution of $SyMCoM_{SU}$ scores for Open and Closed class units. The skewed nature of $SyMCOM_{CLOSED}$ indicates that Closed class words are not mixed, and are provided by either $L1$ or $L2$. $SyMCoM_{OPEN}$, on the other hand, is more spread out indicating that in code-mixed sentences the Open class tokens are contributed by both *en* and *hi*. Figure 2(b) indicates correlations of $SyMCoM$ scores for all the PoS categories. Higher correlation scores indicate the tendency of the particular PoS tag pair to switch together. Similar to Figure 2(a), the correlations indicate that closed class tokens are from the same language.

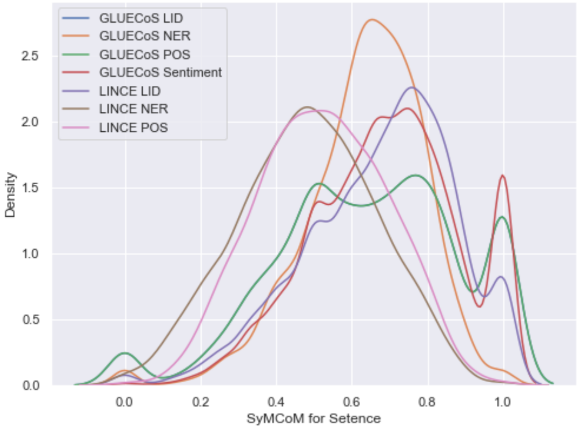


Figure 3: $SyMCoM_{sent}$ scores for various benchmark datasets. The plot represents the syntactic variation across benchmark datasets which encode the switching within PoS tag categories.

Interestingly, verb is also highly correlated with closed class categories. The high correlation can be attributed to the fact that the finite verbs, along with closed class words, govern syntactical structure of a sentence, similar to the notion of matrix language. According to (Joshi, 1982), certain categories including pronouns, adpositions and finite verbs cannot be switched *from* the matrix language.

Figure 3 shows the $SyMCoM_{sent}$ distribution over sentences for several code-mixed corpora taken from the GLUECoS (Khanuja et al., 2020) and LINCE (Aguilar et al., 2020) benchmarks. Clearly, the 7 corpora has distinct $SyMCoM$ signatures. While LINCE POS and NER has very similar normal-like distributions with mean 0.5, all the other datasets seem to be right skewed showing less syntactic complexity. Most GLUECoS datasets show a bimodal distribution with a major peak between 0.6 and 0.8, and a minor peak at 1, indicating that a significant fraction of the sentences have syntactically simple code-mixing patterns, and most being only moderately syntactically complex. GLUECoS POS dataset though have four peaks including one at 0 implying a more complex and diverse set of sentences.

Table 2 reports the $SyMCoM_{corpus}$ and CMI score. Datasets with seemingly similar CMI scores (LINCE LID and LINCE NER), have different $SyMCoM_{corpus}$ scores, indicating that $SyMCoM$ is capturing syntactic property of datasets not captured in CMI scores. Figure 4 shows the $SyMCoM_{SU}$ scores for each PoS tag, and compared for the benchmark datasets. We average the $SyMCoM_{SU}$ scores for each PoS tag over the dataset, by averaging the absolute value of $SyMCoM_{SU}$ score. Nouns and verbs are mixed the most, across all datasets while other PoS tags remain largely monolingual.

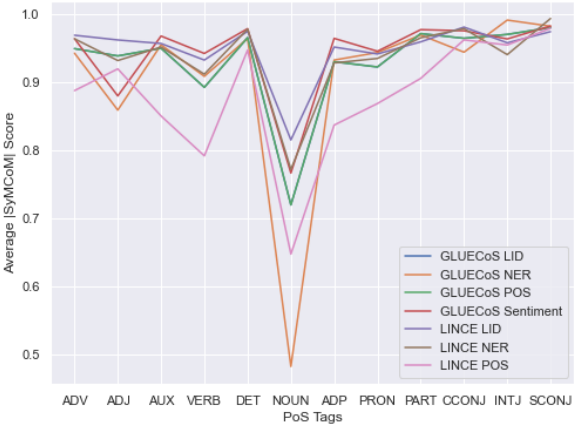

Figure 4: $SyMCoM_{sent}$ scores for various benchmark datasets for individual PoS tags. The plot represents mixing specific to each PoS tag. Across benchmarks, NOUN is highly switched, followed by VERB. But other PoS tags are largely monolingual.

Dataset	$SyMCoM_{corpus}$	CMI
LINCE LID	0.67	22.68
GLUECoS LID	0.64	78.26
LINCE POS	0.52	28.04
GLUECoS POS	0.64	68
LINCE NER	0.48	25.26
GLUECoS NER	0.63	133
GLUECoS Sentiment	0.69	72.8

Table 2: $SyMCoM_{corpus}$ and CMI measures for benchmark En-Hi datasets. $SyMCoM_{corpus}$ is bounded between [0,1] while CMI > 0. For datasets with similar CMI scores, $SyMCoM_{corpus}$ is able to distinguish datasets.

4 Conclusion & Limitations

In this work, we have proposed $SyMCoM$, a syntax-aware measure of code-mixing, to analyze code-mixed corpora from a syntactic perspective. Our analysis confirms a few important tenets of the matrix language theory, including the fact that CLOSED class categories and (finite) verbs are less likely to be switched. Additionally, we have trained a English-Hindi (Hinglish) PoS Tagger using XLM-R which is able to achieve state-of-the-art-results.

$SyMCoM$ relies on the strength of PoS tagger and LID tagger . The errors made by the tagger would propagate into the subsequent analysis thus adding noise to the $SyMCoM$ scores as well. Extending $SyMCoM$ to code-mixing between 3 or more languages and to deeper syntactic structures (nested phrases) are left as part of future work.

Appendix

A PoS Tagger Training and Performance Details

We conducted preliminary experiment for PoS tagging using - XLM-R, mBERT, IndicBERT (Kakwani et al., 2020), MURiL (Khanuja et al., 2021), and results indicate that XLM-R with normalised inputs (romanised Hindi tokens are converted to their Devanagari counterpart), outperforms other models. We run further fine-tuning experiments on XLM-R to obtain optimal performing PoS Tagger. We tested three approaches : **Method 1**: Leverage Transfer from larger Monolingual UD datasets by fine tuneing XLM-R on Hindi and English Monolingual UD datasets PoS tagging , followed by fine tuning on en-hi UD dataset; **Method 2**: Directly fine tune XLM-R on UD Code mix hi-en dataset, using the un-normalised tokens i.e romanised hindi tokens are in roman script; **Method 3**: Directly fine tune XLM-R on UD Code mix hi-en dataset, using the normalised tokens i.e romanised hindi tokens are in Devanagari script

Split	Num. of Samples	Num of Tokens
Train	1,448	20,203
Dev	225	3,411
Test	225	3,295

Table 3: Statistics of en-hi UD Dataset

Table 3 shows that the size of dataset used for training and validation isn't large, hence, for the best performing model, we try to assess the variation in results due to different seeds and data shuffling, show in Figure 5. Highest accuracy achieved by the model is 93.34%, with $\mu = 92.75\%$ and $\sigma = 0.35$.

Figure 5: Variation in PoS tagging performance for different values of random seeds and data shuffling. Best accuracy is 93.4%,least being 92.4%.

All the results are reported on the normalised inputs. Fine-tuned XLM-R model outperforms the previous results reported on this dataset. Trained model checkpoint can be found at `https://huggingface.co/prakod/en-hi-pos-tagger-symcom`.

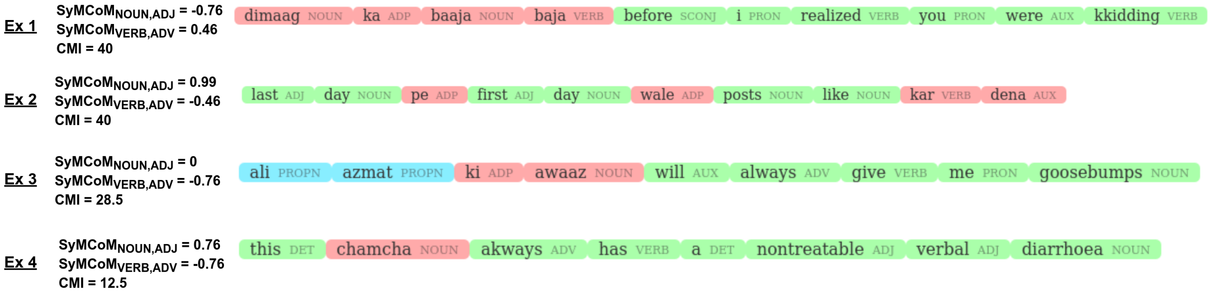
Figure 6: Class wise performance of PoS tagger. We can see that the certain classes like ADV, INTJ, PROPN have lowwer performance compared to other classes.

B Example Sentences from the collection of Datasets

In Figure 7 examples are selected from the corpus on which the $SyMCoM$ scores were computed using the LID and POS tagger outputs. We contrast the CMI score against $SyMCoM$ scores using these examples. Example (1) and (2) have same CMI score, however syntactic signature of code-mixing is quite distinct. In example (2), nouns and adjective are contributed by en, while in example (1) nouns are contributed by hi. Similarly in example (3) $SyMCoM$ score for [NOUN,ADJ] is zero indicating that both en and hi contribute equal number of tokens belonging to the syntactical category of [NOUN,ADJ].

C Dataset Sources

In Table 4, we list all the sources used to construct our 55K sentence corpus of English-Hindi code-mixing. The data is representative of a wide variety of code-mixing including Hate Speech, Stance



Ex 1 $\text{SyMCoM}_{\text{NOUN,ADJ}} = -0.76$ $\text{SyMCoM}_{\text{VERB,ADV}} = 0.46$ CMI = 40

Abstract

A pressing challenge in current dialogue systems is to successfully converse with users on topics with information distributed across different modalities. Previous work in multiturn dialogue systems has primarily focused on either text or table information. In more realistic scenarios, having a joint understanding of both is critical as knowledge is typically distributed over both unstructured and structured forms. We present a new dialogue dataset, HYBRIDIALOGUE, which consists of crowdsourced natural conversations grounded on both Wikipedia text and tables. The conversations are created through the decomposition of complex multihop questions into simple, realistic multiturn dialogue interactions. We propose retrieval, system state tracking, and dialogue response generation tasks for our dataset and conduct baseline experiments for each. Our results show that there is still ample opportunity for improvement, demonstrating the importance of building stronger dialogue systems that can reason over the complex setting of information-seeking dialogue grounded on tables and text.

1 Introduction

When creating dialogue systems, researchers strive to enable fluent free-text interactions with users on a number of topics. These systems can be utilized to navigate users over the vast amount of online content to answer the user's question. Current systems may search for information within text passages. However, knowledge comes in many forms other than text. The ability to understand multiple knowledge forms is critical in developing more general-purpose and realistic conversational models. Tables often convey information that cannot be efficiently captured via text, such as structured relational representations between multiple entities across different categories (Chen et al., 2019, 2020b; Herzig et al., 2020). On the other hand, text may contain more detailed information regarding a specific entity. Thus, dialogue systems must be able to effectively incorporate and reason across both modalities to yield the best performance in the real world.

While there are several existing datasets targeted at dialogue systems (Dinan et al., 2018; Budzianowski et al., 2018; Eric et al., 2017; Zhou et al., 2018b), these are limited to either table-only or text-only information sources. As a result, current dialogue systems may fail to respond correctly in situations that require combined tabular and textual knowledge.

To advance the current state of dialogue systems, we create HYBRIDIALOGUE [1]. Our dataset is an information-seeking dialogue dataset grounded on structured and unstructured knowledge from tables and text. HYBRIDIALOGUE, or HYDI, is constructed by decomposing the complex and artificial multihop questions in OTT-QA (Chen et al., 2020a) which may not reflect real-life queries. We transform these into a series of simple and more realistic intermediate questions regarding tables and text that lead to and eventually answer the multihop question. HYBRIDIALOGUE contains conversations written by crowdsourced workers in a free-flowing and natural dialogue structure that answer these simpler questions and the complex question as well. We provide an example dialogue from our dataset in Figure 1. We also propose several tasks for HYBRIDIALOGUE that illustrate the usage of an information-seeking dialogue system trained on the dataset. These tasks include retrieval, system state tracking, and dialogue generation. Together, they demonstrate the challenges with respect to dialogue systems and the necessity for a dataset such as HYBRIDIALOGUE to further research in this space.

Our contributions are as follows:

- We create a novel dialogue dataset consist-

Figure 1: Overview of a sample from HYBRIDIALOGUE, where each conversation is created from a decomposed multihop question-answer pair. T0,...,T3 represent turns in the dialogue and consist of a single question and answer pair. The solid arrows represent the reference (e.g., row or intro paragraph) utilized to retrieve the correct answer in each turn. The dashed arrow represents a paragraph linked from a table cell.

ing of 4800+ samples of conversations that require reasoning over both tables and text.

- We decompose the overly-complex multihop questions from an existing dataset into more realistic intermediate question-answer pairs and formulate these in the dialogue setting.
- We propose system state tracking, dialogue generation, and retrieval tasks for our dataset. Our baseline experiments demonstrate opportunities to improve current state-of-the-art models in these various tasks and the overall information-seeking dialogue setting.

Dataset	Dialogue	Turns	Modality

2 Related Work

Related work in the space of dialogue-based question-answering can be split into two areas: question-answering systems and information-grounded dialogue. We provide a comparison of the related datasets in Table 1 and analyze these datasets below.

Question-Answering As question-answering (QA) is one of the long-established NLP tasks, there are numerous existing datasets related to this task. Recently, QA datasets have been incorporating new modalities. The RecipeQA (Yagcioglu et al., 2018) dataset is comprised of question-answer pairs targeted at both image and text. OTT-QA (Chen et al., 2020a) and Hybrid-QA (Chen et al., 2020b) both contain complex multihop questions with answers appearing in both text and tabular formats. Several datasets are also targeted at the open-domain question-answering task such as TriviaQA, HotPotQA, and Natural Questions (Joshi et al., 2017; Yang et al., 2018; Kwiatkowski et al., 2019). While single-turn question-answering is valuable, the dialogue setting is more interesting as it proposes many new challenges, such as requiring conversational context, reasoning, and naturalness.

Conversational Question-Answering Several question-answering datasets contain question and answer pairs within a conversational structure. CoQA (Reddy et al., 2019) and DoQA (Campos et al., 2020) both contain dialogues grounded with knowledge from Wikipedia pages, FAQ pairs, and other domains. ShARC (Saeidi et al., 2018) employs a decomposition strategy where the task is to ask follow-up questions to understand the user's background when answering the original question. However, ShARC is limited to rule-based reasoning and 'yes' or 'no' answer types. SQA (Iyyer et al., 2017) provides a tabular-type dataset, consisting of the decomposition of WikiTable questions. Each decomposed answer is related to a cell or column of cells in a particular table. In these datasets, knowledge is limited to a single modality.

In comparison, our dataset poses a more challenging yet realistic setting, where knowledge over structured tables and unstructured text is required to provide reasonable answers to the conversational questions. While the previous datasets contain samples written in a conversational structure, the answers are not necessarily presented in this way; they will instead formulate simple and short answers that do not emulate a human dialogue. Our dataset, therefore, extends conversational question-answering and falls into the dialogue space. HYBRIDIALOGUE contains natural dialogues with strongly related question-answer pair interactions whose answers are longer than the exact answer string. This models real-world occurrences in which a person wants to ask follow-up questions after their initial question has been answered.

Dialogue Generation Among the dialogue datasets that leverage structured (tables and knowledge graphs) knowledge, some (Ghazvininejad et al., 2018; Zhou et al., 2018a) use conversational data from Twitter or Reddit and contain dialogues relying on external knowledge graphs such as Freebase (Bollacker et al., 2008) or ConceptNet (Speer et al., 2017). On the other hand, OpenDialKG (Moon et al., 2019), DuConv (Wu et al., 2019), DyKGChat (Tuan et al., 2019), and KdConv (Zhou et al., 2020) collect conversations that are explicitly related to the paired external knowledge graphs. Other related work revolves around task-oriented dialogues that are grounded on tables. For example, KVRET (Eric et al., 2017) and MultiWOZ (Budzianowski et al., 2018; Ramadan et al., 2018; Eric et al., 2019; Zang et al., 2020) provide tables that require an assistant to interact with users and complete a task.

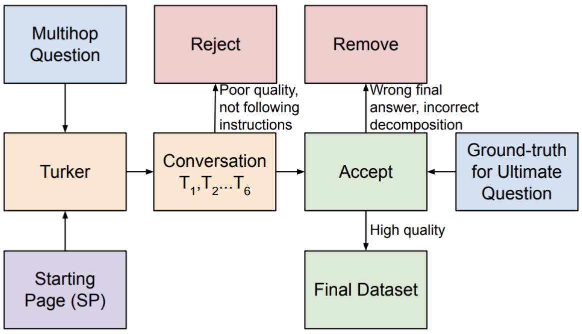

Figure 2: Overview of the dataset collection process, including the validation steps.

Dialogue datasets that are grounded on unstructured knowledge include CMU_DoG (Zhou et al., 2018b), which is composed of conversations regarding popular movies and their corresponding simplified Wikipedia articles. On the other hand, Wizard-of-Wikipedia (WoW) (Dinan et al., 2018) and Topical-Chat (Gopalakrishnan et al., 2019) simulate the human-human conversations through Wizard-Apprentice, in which the apprentice tries to learn information from the wizard. Our proposed task shares a similar idea with Wizard-of-Wikipedia and Topical-Chat in terms of asymmetric information among participants. However, we focus more on information-seeking dialogues grounded on both structured and unstructured knowledge, which provides abundant and heterogeneous information, and requires joint reasoning capabilities using both modalities.

3 Dataset Creation

3.1 Crowdsourcing Instructions

Given a multihop question from OTT-QA, crowdsourced workers (Turkers) from Amazon Mechanical Turk (Crowston, 2012) were asked to decompose it into a series of simpler intermediate questions and answers to formulate a simulated conversation in English. [2] As opposed to datasets such as Wizard of Wikipedia (Dinan et al., 2018) that are more open-ended, our annotators have a specific goal in mind: to answer an original complex question. By utilizing a single annotator to represent both sides, we keep the flow of the dialogue consistent and natural as it converges to the final an-

---

[2] `https://confident-jennings-6a2f67.netlify.app/plaid_interfaces/examples/1a_example_1.html`

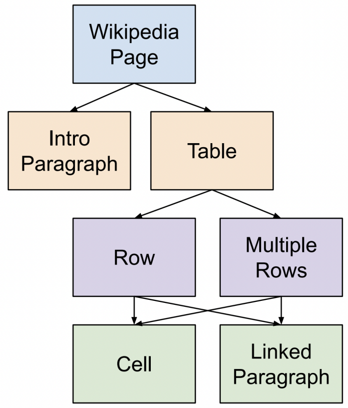

Figure 3: Overview of the reference pool graph, indicating which reference candidates are added to the pool given the current available references.

swer. The usage of two annotators for our specific task comes with the risk of having one user diverge and reduce the chance of reaching the correct final answer.

We refer to the multihop question from OTT-QA as the "ultimate question". Turkers are instructed as follows: "In this task, you will engage in a dialogue with yourself. You will act as two characters: the seeker and the expert. At the top of the page, you are given the Ultimate Question. The seeker wants to know the answer to the ultimate question. However, directly asking this ultimate question is too complex. Thus, the seeker needs to decompose (break down) this complex question into a sequence of simple questions, which the expert will answer using a database." To further emphasize the naturalness of the dataset, Turkers were encouraged to ask questions that required understanding the conversation history context, such as through co-referencing. For example, Turkers used proper nouns with pronouns and indirect references such that they logically refer to their antecedents. An example conversation is demonstrated in Figure 1 and an overview of the dataset collection process is shown in Figure 2.

3.2 Task Definitions

A conversation is composed of a sequence of turns. Each conversation consists of a minimum of 4 turns and a maximum of 6 turns. This limitation is specified to ensure that Turkers are thoroughly decomposing each complex question and the conversations do not go off on tangents. Each turn T acts as a piece of the decomposition of the ultimate question. The i-th turn T_i consists of a natural language question Q_i, a natural language answer A_i, a reference R_i from an English Wikipedia page, and an available reference pool set RP_i. The Turker provides Q_i, A_i, and selects a particular R_i from the set RP_i. R_i can be considered the evidence required to generate A_i given the question Q_i. The reference pool RP_i contains different types of references including the (linked) paragraph, a (whole) table, a single inner table row, multiple inner table rows, or a single cell.

Dataset Statistics	
# Train Dialogues	4359
# Development Dialogues	242
# Test Dialogues	243
# Turns (QA pairs)	21070
Avg Turns per Dialogue	4.34
# Wikipedia Pages	2919
Avg # words per question	10
Avg # words per answer	12.9

# Cell selections	1830
# (Linked) paragraph selections	3337
# Intro selections	7131
# Unique decompositions	267

Table 2: HYBRIDIALOGUE dataset statistics.

We differentiate between multiple rows and the whole table in order to obtain a more specific source for the information. For example, the question "Do you have a list of Steve's accomplishments?" requires a Table response as the answer contains a summary of the table. On the other hand, the question "Did he ever compete in the Grand Prix event type?" requires a selection of specific rows of some table. In order to enforce the naturalness and moderate the difficulty of questions, we restricted RP_i based on RP_{i-1} and R_{i-1}. In other words, the type of questions that the Turker could ask were restricted to the references enabled from previous selections. In the Turker interface, RP_0 is restricted to the intro paragraph and any whole table references in a provided starting page. We illustrate how reference candidates are added to the reference pool in Figure 3.

3.3 Validation

To ensure high-quality samples, we conducted various filtering steps. Rejections were made due to the Turker not following the instructions at all or

	Conversation: Question	Conversation: Answer	Correct Reference	Correct State
T0	Hello do you know who Gaudenis Vidugiris is?	I do, he is a professional Magic: The Gathering player.	Gaudenis Vidugiris is a professional Magic: The Gathering player	Intro Paragraph of Page on Gaudenis Vidugiris
T1	That's cool, do you have a list of Gaudenis Vidugiris's Accomplishments?	I do indeed. He ranked highly in a great number of MTG seasons as far back as 2008.	Achievements Table	Table 1
T2	I see! Did he ever compete in the Grand Prix event type?	He did indeed; looks like he competed in MTG Grand Prix events two times.	2008 and 2012-13	Rows 1, 4 of Table 1
T3	Oh, great, did the number of Grand Prix increase during any of these Years?	Yes, for the 2012-13 season, there were a total of 44 Grand Prix, much more than in previous years.	The season consisted of 44 Grand Prix	Linked Paragraph in Cell 1, Row 4 of Table 1
T4	Wow, that's exciting! What was the format for this Grand Prix?	This was played in a "Limited" format.	Limited	Cell 3 in Row 4 of Table 1

Figure 4: Overview of the state tracking experiment. For each question in a conversation turn, there is a correct reference and corresponding state (e.g., row, linked paragraph) to select when answering the question.

having poor-quality conversations. For example, if the Turker purposefully copy and pasted unrelated paragraphs of texts, repeated the same questions multiple times, used unrelated references, or utilized a single reference throughout the entire conversation, we automatically rejected it. Turkers were paid an average of \$1.1 per conversation. Completing a conversation took the worker an average of 5 minutes, which translates to an average of \$13.2 per hour. In some cases, we gave bonuses to Turkers who consistently submitted high-quality results. After final verification of the accepted HITs, we obtained a final dataset consisting of 4,844 conversations. The statistics of the dataset are shown in Table 2.

We conducted additional filtering to further enhance the dataset quality. Utilizing gold answers obtained from the source OTT-QA dataset, we checked if the final answer appeared as a substring in Turker's conversation. If it did, we auto-approved the conversation. For the remaining questions, we manually reviewed them. We approved conversations that had the correct answer but in a different format (e.g., September 1, 2021, instead of 9/1/21). In some cases, Turkers provided their own decomposition or their own ultimate question and decomposition, so they did not obtain the final answer provided by OTT-QA. In these cases, if the conversation was both accurate and had good quality, we accepted it.

4 Tasks and Baseline Models

We outline three different tasks in the following sections: retrieval, system state tracking, and dialogue generation. Together, these tasks formulate a pipeline dialogue system grounded on both structured and unstructured knowledge from tables and text. The first step of the system is to **retrieve** the correct Wikipedia reference given the first question in the dialogue. As the conversation continues, the system must be able to **track the state** of the conversation in order to obtain the correct information from the Wikipedia reference for the user. Finally, the system will need to **generate a natural conversational response** to communicate with the user at each turn. Thus, following each of these tasks in order simulates the pipeline system with our dataset. We describe each of these tasks and their respective models in detail below.

4.1 Retrieval

The retrieval experiment is run for each T_0 of each conversation. Given the first question of the conversation Q_0, the model must predict the correct reference R_0. First questions discuss information that is either in a table or an intro paragraph; so the candidate space contains all intro paragraphs and tables in the dataset. The purpose of the retrieval experiment is to get a baseline of how well we are able to predict the table or page the subsequent conversation will be based upon, given the first query. The references that are utilized in the subsequent conversation are on the same page as the selected intro paragraph or table. For our baseline, we run the Okapi BM25 retriever (Brown, 2020) on the entire dataset over all candidates and first turn queries. BM25 is a standard document retrieval model that uses keyword-matching techniques to rank documents.

	1	2	3	4
	Season	Event Type	Format	Rank

...	...	...	...

Linked Paragraph: The 2011 Pro Tour season was the sixteenth season of the Magic: The Gathering Pro Tour...

Figure 6: Table, row, cell, and paragraph flattening for input to the SentenceBERT and DialoGPT models.

4.2 System State Tracking

Previous work in dialogue systems focuses on the task of belief state tracking, which aims to determine the user's goal or the current state of the conversation at each turn in the dialogue (Mrkšić et al., 2017; Ren et al., 2018). Inspired by work in belief state tracking, we propose the task of system state tracking in an information-seeking dialogue system. The task is framed similarly to belief state tracking, where a model attempts to classify the current state in the conversation at each turn. However, the "state" in our proposed task is modeled as a reference location from the current reference pool. As such, the task is formulated as using the information from the existing conversation and current question to determine the state of the conversation and choose which reference to utilize to create an answer. The reference types considered in this experiment are single cell, linked paragraph, inner table row, and multiple inner table rows. The implementation of system state tracking increases the interpretability and explainability of the system by determining the understanding of the user's question and discovering the point in the conversation in which the model is incorrectly interpreting the user's question. This, in turn, can help us understand the types of errors the model is prone to and allow us to work towards increasing the robustness of the model regarding these errors.

The system state tracking process is visualized in Figure 4. We perform system state tracking for all turns in each dialogue except the first turn. Given the history of the conversation H_i, we predict the correct reference R_i. H_i consists of turns $T_1 ... T_{i-1}$, the current query Q_i, and the candidate references RP_i. Thus, the goal is to determine the correct reference R_i at the specific turn in the dialogue, given the dialogue history. We utilize SentenceBERT (Reimers and Gurevych, 2019a) and TaPas (Herzig et al., 2020) as baselines for the experiment.

SentenceBERT We utilize the sentence transformer and the triplet-loss configuration as described in equation 1. We minimize the difference between the correct candidate R_i and context H_i while maximizing the difference between every incorrect candidate W and H_i. We create samples for each $W \in RP_i$ where $W \neq R_i$. (RP_i is the reference pool). k is some fixed margin.

$$loss = max(||H_i - R_i|| - ||H_i - W|| + k, 0) \quad (1)$$

To allow SentenceBERT to process the data, we flatten the references and prepend a special token to provide information about the type of candidate it is. This process is visualized in Figure 6.

TaPas We additionally utilize the TaPas model for system state tracking. TaPas is a BERT-based question-answering model for tabular data. We use the TaPas model that has been fine-tuned on the SQA dataset, which enables sequential question-answering in a conversational nature. As the model

Task	Model	# Samples	MRR@10	MAP
Retrieval	BM25	4844	0.427	0.427
System State Tracking	SentenceBERT	636	0.603	0.600
	TaPas	636	**0.689**	**0.634**

Table 3: The results of the retrieval and system state tracking experiments.

Reference	MRR@10	MAP	Count
Cell	0.384	0.395	108
Paragraph	0.599	0.606	124
Row	0.782	**0.786**	338
Multi-row	**0.881**	0.292	66

Table 4: System state tracking results split by reference type for the TaPas model.

performs only cell selection, we adapt TaPas towards this setting. We do not need to pre-process the data differently for cell selection as TaPas already performs the cell selection task. We place linked paragraphs in their respective cells within a table to accommodate cell selection in this setting. For row and multi-row selection, we pre-process the data by choosing one cell from the row as the correct answer. This is done by finding the cell with the highest text similarity to the ground truth answer at that turn. Therefore, each row will have a single cell associated with it during fine-tuning. We visualize the state tracking experiment with TaPas in Figure 5. For our experiments, we fine-tuned the TaPas model with our pre-processed training set.

4.3 Dialogue Generation

We conduct experiments on dialogue response generation to look into the dataset's expressivity for real-world dialogue scenarios. We fine-tuned a pre-trained DialoGPT model (Zhang et al., 2020) by minimizing the negative log-likelihood with two input settings. Q_i, A_i, and R_i are defined as the question, answer, and reference at the i-th turn, respectively. First, we only take the dialogue history as the input without knowledge content and predict the following natural language response. The format (DialoGPT-noR) is described as:

$$\{Q_1, A_1, ..., Q_i, A_i, Q_{i+1}\} \mapsto A_{i+1} \qquad (2)$$

Second, we flatten the references and concatenate the dialogue history as the input and predict the following natural language response. The references are flattened in the process seen in Figure 6. The format (DialoGPT) is:

$$\{R_1, Q_1, A_1, ..., R_{i+1}, Q_{i+1}\} \mapsto A_{i+1} \qquad (3)$$

The two settings enable us to validate how much information the references provide for response construction.

Method	SacreBLEU	BERTscore
DialoGPT-noR	14.72	0.8875
DialoGPT	21.63	0.8901

Table 5: The results of dialogue generation experiments on HYBRIDIALOGUE dataset.

5 Experiments

5.1 Retrieval

As retrieval is the first step in the information-seeking dialogue pipeline, we need to ensure that information from the correct Wikipedia page is retrieved to determine whether the first question and any following questions will be answerable. We evaluate our retrieval model with MRR@10 (Mean Reciprocal Rank @10). Table 3 shows our results, where BM25 achieves an MRR@10 score of 0.427 for retrieving the correct candidate.

5.2 System State Tracking

Evaluation To evaluate the SentenceBERT and TaPas predictions, we calculate MRR@10 (Mean Reciprocal Rank @10) and MAP (Mean Average Precision). Each model produces scores for the candidate references for a question. These scores are sorted into a ranked list, and the correct references are identified in this list. We then calculate MRR and MAP values with respect to the ranking of the correct reference in the ranked list.

When evaluating the TaPas model, we consider the highest-ranking cell from the ground truth row correct during test time. This simulates a more realistic setting by allowing any cell within the row to be correct.

Error Type	Input	Output
Incoherent	[TABLE] Best-selling physical singles – 7–7.9 million copies ; [QUERY] Can you give me a list ... [PARAGRAPH] .... Known for her emotive mezzo-soprano voice, Morissette began her career in Canada . . . ; [QUERY] What is the vocal range of this singer?	DialoGPT: Alanis Nadine Morissette is a Canadian-American singer, songwriter, and actress. GT: Alanis Morissette has a vocal range of mezzo-soprano.
Non-fluent	[ROW] Year is 1985 ; Song is La det swinge ; Artist is Bobbysocks ; Position is 1st ; Points is 123... [QUERY] Do you know what song they performed to win?	DialoGPT: Yes, they performed to win the song La det swinge. GT: Yeah, they did La det swinge.
Unfaithful	[PARAGRAPH] Immigration to Spain...in 2005 alone, the immigrant population of Spain increased by 700,000 people.; [QUERY] when did the immigrant population of spain increase by 700,000 people?	DialoGPT: The immigrant population increased by 700,000 in 1998. GT: the immigrant population increased by that number in 2005

Table 6: The error types observed in dialogue generation on HYBRIDIALOGUE. (GT: ground truth)

Results The results of our experiments with TaPas and SentenceBERT are shown in Table 3. Our results show that TaPas achieves better results in comparison to SentenceBERT. We further analyze the results of TaPas by breaking down the MRR and MAP scores based on the four reference types: cell, linked paragraph, row, and multi-row. These results are shown in Table 4, along with the number of samples for each reference type in the test set. We find that TaPas achieves the best overall results for row states, which also comprise the largest fraction of samples. Meanwhile, multi-row achieves a high MRR score but a low MAP score, indicating that TaPas ranks some of the correct row candidates very low. Cell and linked paragraph states are limited to a single cell within the table, but linked paragraph samples achieve noticeably better results. This is likely because the paragraph text will contain more information than a cell's text, making it easier to determine the correct reference.

5.3 Dialogue Generation

We adopted SacreBLEU (Post, 2018) and BERTscore (Zhang et al., 2019) as the automatic evaluation metrics. As shown in Table 5, concatenating references can consistently improve both metrics and the collected references are necessary for generating dialogue. It can be seen that differences are more noticeable for SacreBLEU as opposed to BERTscore. This is due to the naturally similar outputs of BERTscore, where the ranking of the scores is a more reliable view of the metric.

We conduct further error analysis and find three main types of errors as listed in Table 6: *incoherent*, *non-fluent*, and *unfaithful*. As shown in Table 6, the generated response "Alanis Nadine Morissette is a Canadian-American singer, songwriter, and actress." is not an appropriate response to the question. In this case, the generated response is incoherent based on the dialogue. Sometimes the response has the correct information, but it is not a fluent sentence. One example is the generated statement "Yes, they performed to win the song La det swinge". The final primary error type is that the generated response may be unfaithful to the perceived knowledge. For example, given a paragraph mentioning several years and events in history, the generated response mentions "1998", while the answer should be "2005".

5.4 Human Evaluation

In addition, we conduct a human evaluation. We randomly sample 200 test samples containing previous conversation histories, human-written answers, and machine-generated answers from DialoGPT. For each sample, we have two Turkers provide ratings. We ask the Turker to evaluate the machine-generated response on three criteria: coherence, fluency, and informativeness from a scale of 1 to 5. Coherence measures how well the response is connected to the question and prior conversation history. Fluency measures the use of proper English. Informativeness measures how accurate the machine-generated response is against the human-provided ground truth response. We provide the average ratings for each model in Table 7. The model that utilizes the state tracking references achieves a better "informativeness" rating as it is able to utilize the extra information to provide a more correct response. It is notable however that the model with no references achieves better coherence and fluency scores. Thus, the human evaluation demonstrates the importance and challenge for models to provide both an accurate and articulate response.

Method	**C**	**F**	**I**
DialoGPT-noR	**3.88**	**3.98**	3.13
DialoGPT	3.59	3.68	**3.49**

Table 7: The results of human evaluation on dialogue generation model outputs. C = Coherence, F = Fluency, I = Informativeness.

6 Conclusion

In this paper, we presented a novel dataset, HYBRIDIALOGUE, for information-seeking dialogue where knowledge is grounded in both tables and text. While previous work has combined table and text modality in the question-answering space, this has not been utilized in the dialogue setting. Our results in the various tasks demonstrate that there is still significant room for improvement and illustrate the need to build models that can adapt well to this hybrid format. In addition to the baseline tasks, future research can utilize HYBRIDIALOGUE to explore automatic multihop question decomposition.

Ethical Considerations

While the dialogues in our dataset are grounded on both structured and unstructured data, they are limited to tables and text and do not cover other forms such as knowledge graphs. Additionally, the conversations are limited to discussions on single Wikipedia pages. We believe future research can expand on this for the creation of more open-ended information-seeking dialogues.

Wikipedia has extensive measures of risks and employs staff and volunteer editors to make sure Wikipedia articles meet the requirement and quality of the Wikimedia Foundation. Our data is based on Wikipedia pages, and we contain our dialogues to Wikipedia knowledge. We carefully validate the dataset collection process, and the quality of our data is carefully controlled.

The HYBRIDIALOGUE dataset was built from the OTT-QA dataset, which is under MIT license. The authors of the OTT-QA dataset paper have allowed us to utilize the dataset within our use case.

For the dataset collection task, we required Turkers to have a HIT Approval Rate of greater than 96% and be located in AU, CA, IE, NZ, GB, or the US. We also required workers to have had 500 HITs approved previously. Workers were shown an interface containing text input fields and navigation tools. Turkers were also given an instruction page containing a video demo and a completed example. The time to complete the task is around 5 minutes, and Turkers were paid $1.1 per conversation, which translates to an hourly wage of $13.2 per hour. For the human evaluation task, Turkers were paid $0.1 per task with an estimated time of fewer than 30 seconds per task. The dataset collection protocol was approved by the IRB. We follow the user agreement on Mechanical Turk for our dataset creation, which gives us explicit consent to receive users' service in the form of data annotation in return for monetary compensation. Given our settings, the Turkers understand that their data will be utilized in machine learning research.

We will be providing open access to our dataset for use in future research. This includes the samples of dialogues written by Mechanical Turk workers, the references that each dialogue turn is associated with, and the Wikipedia pages in which the references are located. The dataset will be open-sourced under the MIT License.

A Appendix

A.1 Conversation Decompositions

We counted the number and frequency of unique decompositions in our dataset, which is the selected reference sequence in a conversation. The most frequent decompositions are shown in Table 8.

Decomposition	Count
$I \rightarrow T \rightarrow R \rightarrow P$	1419
$I \rightarrow T \rightarrow R \rightarrow C$	733
$I \rightarrow T \rightarrow R \rightarrow R$	290
$I \rightarrow T \rightarrow R \rightarrow C \rightarrow P$	218
$T \rightarrow R \rightarrow R \rightarrow P \rightarrow P$	136
$T \rightarrow R \rightarrow P \rightarrow P$	116
$T \rightarrow R \rightarrow C \rightarrow P$	116

Table 8: Top 7 most frequent decompositions. A decomposition is defined to be the sequence of references in a given conversation. I = Intro, T = Table. R = Row, P = Linked Paragraph, C = Cell

A.2 Experimental Details

We utilized paraphrase-distilroberta-base-v1 model with 82 million parameters provided by the SBERT library (Reimers and Gurevych, 2019b) for the SentenceBERT system state tracking experiment. The TaPas model is built on the BERT model (Devlin et al., 2019). We utilize the TaPas-base model, which correlates to the BERT-base model that contains 110 million parameters. For system state tracking evaluation, we utilize average_precision_score from sklearn (Pedregosa et al., 2011). For retrieval experiments, we utilized the BM25Okapi algorithm from the Rank-BM25 library (Brown, 2020). Our experiments on dialogue generation utilize DialoGPT-small in the Huggingface transformers library (Wolf et al., 2020), which contains 124 million parameters.

NEWTS: A Corpus for News Topic-Focused Summarization*

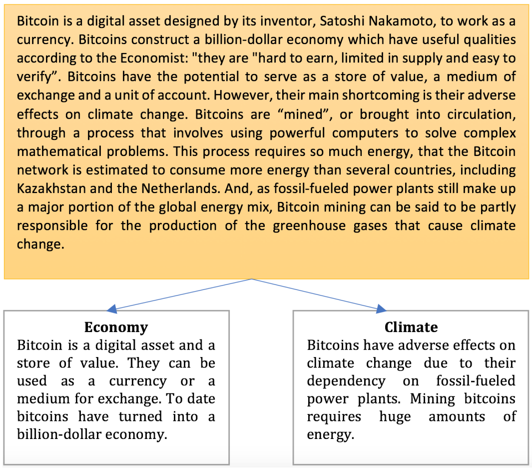
Abstract

Text summarization models are approaching human levels of fidelity. Existing benchmarking corpora provide concordant pairs of full and abridged versions of Web, news or, professional content. To date, all summarization datasets operate under a one-size-fits-all paradigm that may not reflect the full range of organic summarization needs. Several recently proposed models (e.g., plug and play language models) have the capacity to condition the generated summaries on a desired range of themes. These capacities remain largely unused and unevaluated as there is no dedicated dataset that would support the task of topic-focused summarization.

This paper introduces the first topical summarization corpus `NEWTS`, based on the well-known CNN/Dailymail dataset, and annotated via online crowd-sourcing. Each source article is paired with two reference summaries, each focusing on a different theme of the source document. We evaluate a representative range of existing techniques and analyze the effectiveness of different prompting methods.



Bitcoin is a digital asset designed by its inventor, Satoshi Nakamoto, to work as a currency. Bitcoins construct a billion-dollar economy which have useful qualities according to the Economist: "they are "hard to earn, limited in supply and easy to verify". Bitcoins have the potential to serve as a store of value, a medium of exchange and a unit of account. However, their main shortcoming is their adverse effects on climate change. Bitcoins are "mined", or brought into circulation, through a process that involves using powerful computers to solve complex mathematical problems. This process requires so much energy, that the Bitcoin network is estimated to consume more energy than several countries, including Kazakhstan and the Netherlands. And, as fossil-fueled power plants still make up a major portion of the global energy mix, Bitcoin mining can be said to be partly responsible for the production of the greenhouse gases that cause climate change.

Economy

Bitcoin is a digital asset and a store of value. They can be used as a currency or a medium for exchange. To date bitcoins have turned into a billion-dollar economy.

Climate

Bitcoins have adverse effects on climate change due to their dependency on fossil-fueled power plants. Mining bitcoins requires huge amounts of energy.

Figure 1: A topical summarization example, summarizing a sample document with respect to economy and climate topics.

1 Introduction

With the recent advances in neural sequence-to-sequence models, the automatic generation of text has reached unparalleled levels of fidelity. Abstractive summarization models that aim at generating condensed versions of a source article have outperformed Lead-3 baselines on most benchmark datasets (See et al., 2017; Lewis et al., 2020). However, all existing summarization benchmarks assume a one-size-fits-all paradigm under which model output is evaluated based on similarity to general-purpose reference summaries reflecting the full content of the original document. While certainly a necessary step, such evaluation approaches might not reflect the full range of summarization needs anymore. There are manifold settings in which tailored summaries matching the interests of the reader may be required. Some examples include the summarization of complex event streams with a focus on regions, entities or topics of interest for journalists or analysts, understanding reviews or opinions from different perspectives (Hayashi et al., 2021), the summarization of electronic health records with a focus on the medical sub-specialty of the physician reader, or any other form of personalized summarization targeting explicitly defined or implicitly mined preference parameters.

Several recently proposed text generation models already offer the potential of steering the generation process to conform to specific topic distributions (Bahrainian et al., 2021), or sentiment polarity (Shen et al., 2017). Plug and Play Language Models (PPLM) (Dathathri et al., 2020) let us condition the generation process on themes of interest and text style transfer controls selected attributes, such as politeness, emotions, or humor of the generated text (Jin et al., 2020).

Despite increased efforts and interest in con-

---

[*] The first author and the second author have an equal contribution.

Findings of the Association for Computational Linguistics: ACL 2022, pages 493 - 503

trolled summarization, no dataset exists on which these models can be evaluated. This paper closes this gap by introducing `NEWTS`, a NEWs Topic-focused Summarization corpus for the controlled generation of text. It is based on documents from the well-known CNN/Dailymail dataset, to which it adds new topic-focused summaries. Figure 1 illustrates an article summarized with respect to two different topics. We believe that `NEWTS` will significantly enrich the existing range of benchmarking collections, allowing the research community to better study and evaluate controlled text generation for summarization.

The main contributions of this paper are:

- We introduce and release the first dataset of topic-based abstractive summarization[1]. The dataset contains human-written topical reference summaries collected via online crowdsourcing.
- We evaluate a range of existing models alongside four different prompting techniques.

The remainder of this paper is organized as follows: Section 2 presents previous work on datasets for text generation. Next, Section 3 explains the dataset collection methodology and describes the resulting corpus. Section 4 discusses several existing models that we fine-tune and evaluate on the dataset. Section 5 presents an evaluation of these models and the various prompting strategies. Finally, Section 6 concludes with an outlook on future work.

2 Related Work

In this section, we review existing work focusing on (1) controlled text generation and (2) existing datasets in this domain. We note that this paper presents the first dataset on topic-focused abstractive summarization.

2.1 Controlled Text Generation

Controlled text generation encompasses transferring the style of an input text into a specific target form (Jin et al., 2020). Typical Style transfer tasks in the natural language domain include shifting the formality of texts (Briakou et al., 2021), the level of politeness (Madaan et al., 2020), bias versus neutrality (Pryzant et al., 2020), authorship style (Carlson et al., 2018), simplicity (Cao et al., 2020), sentimental stance (Shen et al., 2017), target aspects in opinion summarization (Fremann and Klementiev, 2019; Angelidis and Lapata, 2018) and topical focus (Bahrainian et al., 2021).

Persona-based text generation is another area of research that has been studied in the context of story-telling based on a particular personality type and sequences of images (Chandu et al., 2019).

The notion of persona-based text generation has also been studied in the context of dialogue using an Emotional Chatting Machine that generates responses in an emotional tone while conditioning on conversation history. The key feature of this work is that emotion, as opposed to persona, is deemed dynamic, and therefore emotional responses change throughout a conversation (Zhou et al., 2018).

Most of the controlled text generation tasks named above rely on learning a mapping between the source documents' latent representations and the target documents' representations. For instance, embeddings of a particular author/newspaper are learned jointly with the word embeddings of a source article and mapped onto a target form representation (Fan et al., 2017).

In this paper, we focus on topic-based controlled text generation to summarize a source article around a specified topic of interest.

2.2 Existing Datasets for Controlled Text Generation

As explained above, datasets for different text style transfer problems exist. However, contemporary summarization models such as PPLM (Dathathri et al., 2020) and CATS (Bahrainian et al., 2021) suffer from a lack of existing datasets and hence a lack of quantitative evaluation in terms of steering the topical focus in text generation. Here we review a few closely related datasets to `NEWTS`.

The aspect-based sentiment summarization dataset WikiAsp (Hayashi et al., 2021) targets the generation of summaries with respect to specific points of interest. For instance, the points of interest in the case of Barack Obama (as presented in their paper) may pertain to his 'early life,' career,' and 'presidency.' WikiAsp is extracted automatically from Wikipedia articles, using their section headings and boundaries as a proxy for aspect annotation. Our dataset vastly differs from WikiAsp in that it covers a broader range of themes and provides dedicated human-written reference summaries while WikiAsp reverse engineers and repur-

---

[1] https://github.com/ali-bahrainian/NEWTS

poses existing articles. Finally, our dataset provides a different level of granularity and abstraction useful for separating intertwined concepts in articles. At the same time, WikiAsp merely enables the generation of text pertaining to a section header.

Another closely related dataset is MultiOpEd, a dataset of multi-perspective news editorials (Liu et al., 2021). This dataset is designed around argumentation structure in news editorials, focusing on automatic perspective discovery. The assumption here is that arguments presented in an editorial typically center around a concise, focused perspective. The dataset is designed such that a system is expected to produce a single-sentence perspective statement summarizing the arguments presented. For a query on a controversial topic, two news editorials respond to the query from two opposing point-of-views constructing a lengthy statement. Each editorial comes with a single paragraph abstract plus a one-sentence perspective that abstractively summarizes the editorial's key argument in the context of the query. The query is designed to allow only two opposing arguments, i.e. supporting or opposing it. For example, a query may be "is it right to end the lockdown?". Our dataset differs from MultiOpEd in that ours allows summarization of text with respect to two different (but not necessarily opposing) topics, while MultiOpEd is restricted to two opposing arguments on the same topic.

This paper introduces and releases the first dataset on topic-focused summarization gathered via online crowd-sourcing featuring 50 different topics.

3 A Novel Dataset for Controlled Summarization

In this section, we present `NEWTS`, a new dataset for controlled topic-focused text generation. We first elaborate on the steps to building the dataset. Subsequently, we present detailed statistics about the dataset.

Our dataset is built based on the well-known CNN/Dailymail dataset (Hermann et al., 2015; Nallapati et al., 2016), introducing an all-new facet of topical human-written summaries. For this purpose, we annotate a sample of the news articles from the CNN/Dailymail dataset via online crowd-sourcing such that each article is paired with two topic-focused human-written summaries corresponding to the top two topics present in the source article.

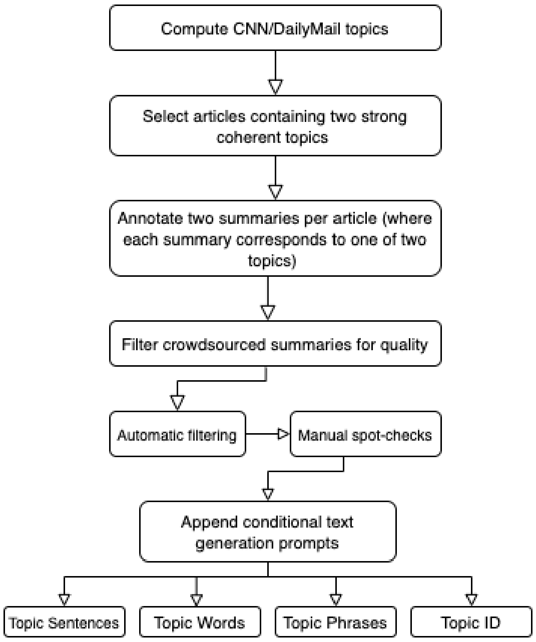


Figure 2: The step-by-step process of building the `NEWTS` dataset.

Figure 2 presents the steps to creating the dataset explained in detail bellow.

Computing Topics for the Dataset. We begin by computing a 250-topic Latent Dirichlet Allocation (LDA) (Blei et al., 2003) model on the training portion of the CNN/Dailymail dataset. LDA was selected due to convenience of use, and $k = 250$ topics empirically showed best coherence and consistency among various choices in the $k \in [50, 300]$ range. From this model, we manually discard noisy or uninformative topics, keeping only the top 20% (50 topics) with the highest Normalized Point-wise Mutual Information (NPMI) coherence score (Bouma, 2009). We perform this aggressive pruning of topics out of feasibility considerations regarding the number of documents per topic provided for fine-tuning neural summarization models. A list of all 50 topics is presented in the appendix.

Selecting articles for annotation. After computing the 50 target topics of the dataset, we search the CNN/Dailymail dataset for source articles containing at least two topics from the pool of 50 topics with a topic prevalence above an empirically determined threshold.

By identifying documents that contain at least two topics with a topic prevalence above the empirical threshold 0.1, and a cumulative probability of both topics above 0.30, we ensure that the main content of the source article can be captured by focusing on the two main topics. Consequently,

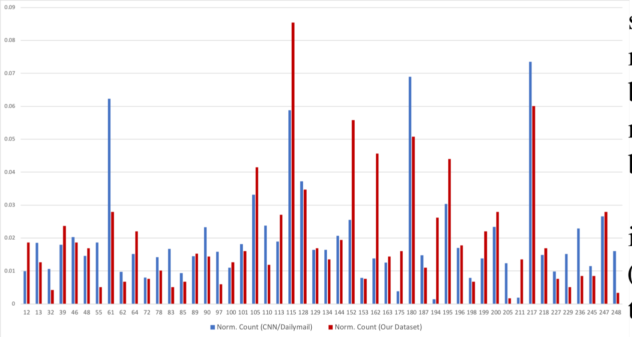

Figure 3: Comparison of per topic normalized counts of `NEWTS` test documents versus CNN/Dailymail counts

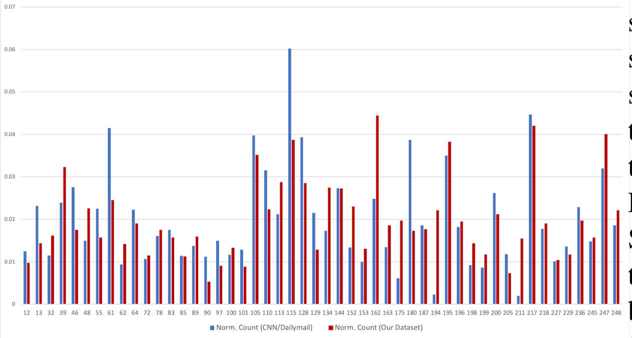

Figure 4: Comparison of per topic normalized counts of Train Documents of our Dataset versus CNN/Dailymail

each source article will be summarized twice, with each summary concentrating on one of the main two topics.

Annotating each source article with two topic-focused summaries. We use Amazon MTurk to obtain two summaries of the same source article, each focused on a different topic. The annotation process is designed such that a crowd-sourcing worker receives a source article and two topics written in the form of hand-curated phrases, along with instructions on how to write two summaries about the source article. The instructions request having at least three sentences per summary, focusing on one topic while avoiding the other topic as much as possible without any copy-pasting of entire sentences. For each of the 50 most coherent topics used in the dataset, we display the top 20 words with the highest probability of being present in that topic and manually write a series of phrases separated by commas exemplifying the topic in a few words.

Controlling the quality of the human-written summaries. Once the human-written summaries are obtained, we perform a quality check on them to reject noisy annotations from the dataset. To ensure the dataset's quality, (1) we use a validated script to filter out unacceptable summaries automatically and (2) perform manual spot checks and ban problematic workers to further reduce potential noise in the dataset. We explain each of these steps below:

The automatic filtering script is developed to identify and reject summaries that are too short (i.e., shorter than three sentences required from the workers) or do not form a grammatical sentence, summaries that are not related to the topics discussed in the source article, summaries that do not mention the same entities discussed in the source article (using named entity recognition) and summaries that contain exact copy-pasting of full sentences from the source article. To check the topics of the summary and compare them with that of the source article, the script uses the same LDA topic model described earlier in this section. Subsequently, the script is validated by conducting three pilot studies, each annotating 100 documents, bringing the total number of documents tested to 300. We manually assess each annotation in order to evaluate the script. In the third pilot study, our script reached 100% agreement with two independent human experts in terms of accepting/rejecting the annotations.

We still conduct manual spot checks of the script output throughout the crowd-sourcing process to ensure a high-quality dataset. One of the two human experts read each sampled annotation and determine whether the quality satisfies the task description and the criteria explained earlier and rejects those annotations that do not meet the requirements. We use a z-test with a 95% confidence level and an error margin of $+/-9.24\%$ (i.e., from 85.76% to 100% of our population) as our sampling technique. Therefore, with a confidence of 95%, high quality for the annotations is ensured.

Designing prompts for conditional text generation. In order to be able to condition a generation process sequence-to-sequence models on certain topics for producing summaries, we design four different prompt types paired with each summary to allow advanced prompt engineering techniques. In the following, we explain each method:

1. Topic Words: the first prompting technique utilizes the top 10 words based on their probability assignment in that topic separated by commas.

2. Topic Phrases: the second prompting method consists of the exact topic phrases that were

Topic Words	***Topic Phrases***	***Topic Sentence***	***Topic ID***
court, judge, case, appeal, justice, order, ruling, ruled, magistrates, ordered	a court ruling, department of justice, appealed against a court ruling, judge reviewing a case, court order, magistrates	This topic is about a court ruling, department of justice, appealing against a court ruling, judge reviewing a case, a court order, and magistrates.	_TID78
fire, residents, san, wood, firefighters, burning, burned, blaze, flames, fires	firefighters tackled the blaze, wood burning, residents evacuating, flames, spit embers downwind, burning buildings	This topic is about firefighters tackling the blaze, wood burning, residents evacuating, flames, spit embers downwind, and burning buildings.	_TID153

Table 1: Two topic examples with their corresponding topic phrases, topic sentences, and topic IDs

hand-written based on the top topic words and sent to the annotators to understand the topic.

3. Topic Sentences: the third prompting method is a hand-written sentence describing a topic and what that topic is about. In practice, such sentences connect all the topical phrases from the previous prompting method in a sentence.

4. Topic ID: the fourth prompting method represents each topic with a unique topic identifier to examine the possibility of learning a topic embedding using a simple topic identifier.

Table 1 presents two of the 50 sample topics in the first column with their top 10 corresponding words according to their associated probability in that topic. The first topic is related to *courts and justice* while the second topic is related to *fires and burning residences*. The four columns of the table correspond to each prompt type described above.

Each of the prompts presented in the paper are prepended to the tokens of the source article separated by a special separation token and fed to the Transformer-based models. We will compare all these prompting methods in a benchmark for the task of topic-controlled abstractive summarization.

The resulting dataset consists of 3,000 source articles (2,400 from the training set of the CNN/Dailymail dataset to construct the train set of `NEWTS`, and 600 articles from the test set of the CNN/Dailymail dataset to form the test set of `NEWTS`). Each article is annotated with two summaries, each focusing on a different topic present in the article. The overall number of manually composed topical summaries is, therefore, $6,000$ ($4,800$ for training and $1,200$ for testing). The summaries of the final training set have a length of 416.1 characters on average, while the average number of sentences and number of tokens per summary is 5.5 and 70.2, respectively. The average number of characters per test summary is 412.9, while the average number of sentences and the average number of tokens per summary are 5.0 and 70.1, respectively.

Figures 3 and 4 show the number of documents per topic normalized by size present in our dataset side-by-side that of the CNN/Dailymail dataset. The former figure illustrates these numbers for the test sets, while the latter pertains to the train sets.

4 Topical Summarization Models

Text-to-Text Transfer Transformer: The T5 (Text-to-Text Transfer Transformer) model is an important example of the Transformer family (Raffel et al., 2019) that uses transfer-learning on the original Transformer architecture (Vaswani et al., 2017). The authors study several variants of the Transformer architecture and finally fine-tune them on different natural language processing tasks. The main difference from the original model is the use of relative positional embeddings as an explicit position signal of the tokens.

BART: The next model that is noteworthy in this domain is BART (Lewis et al., 2020). BART is a denoising autoencoder for pretraining sequence-to-sequence natural language processing models. It is trained by "corrupting text with an arbitrary noising function and learning a model to reconstruct the original text" (Lewis et al., 2020). Analogous to the T5 model, BART is based on the Transformer architecture (Vaswani et al., 2017). It uses a number of noising approaches, such as token masking, token deletion, randomly shuffling the order of the original sentences, and a novel infilling scheme, where spans of text are replaced with a single mask token. The only major difference to the Transformer architecture is that, following GPT, the authors replace ReLU activation functions with GeLUs (Hendrycks and Gimpel, 2016). They also state that their proposed architecture "is closely related to that used in BERT, with the following differences: (1) each layer of the decoder additionally performs cross-attention over the final hidden layer of the encoder (as in the transformer sequence-to-sequence model); and (2) BERT uses an additional feed-forward network before word prediction, which BART does not" (Lewis et al., 2020). BART is then fine-tuned on in-domain data for text generation tasks such as abstractive summarization.

ProphetNet: The final model in this category is ProphetNet (Yan et al., 2020), which currently represents the state-of-the-art in abstractive summarization. This model also utilizes the Transformer architecture (Vaswani et al., 2017). The main feature of ProphetNet is changing the original sequence-to-sequence optimization problem of predicting the next single token into predicting the n next tokens simultaneously. The authors show that this approach outperforms all other baselines in abstractive summarization in terms of ROUGE scores.

Plug and Play Language Models: The Plug and Play Language Model (PPLM) (Dathathri et al., 2020) is based on GPT-2 using the same original Transformer architecture (Vaswani et al., 2017) as the models above. PPLM uses GPT-2 for text generation. However, it comes with an attribute model that conditions the generation process on given or previously generated text. The attribute model is fed with a bag of words signaling the target topical focus to the model.

Customizable Abstractive Topic-based Summarization: Finally, we include the Customizable Abstractive Topic-based Summarization (CATS) (Bahrainian et al., 2021) model as an example of pre-Transformer seq-to-seq models based on LSTMs. The encoder-decoder architecture has Bidirectional LSTMs as the encoder and an LSTM network as the decoder. The model utilizes attention weights governed by an LDA topic model to modify the attention weights of the input tokens as represented by the encoder based on their topic assignment. This process utilizes a set of pre-defined topics derived from target summaries to learn the topics the output text should cover.

5 Evaluation

ROUGE Evaluation of all Models. In the first experiment we evaluate the various models on our new dataset in terms of F_1 ROUGE 1, F_1 ROUGE 2, and F_1 ROUGE L scores using the official Perl-based implementation of ROUGE (Lin, 2004).

Table 2 presents the results of this experiment. We compute the optimal number of epochs and the beam size for decoding via 3-fold cross-validation for each model. In the table, 'b' after a model name indicates a 'base' model size while 'L' indicates a 'large' model size. Additionally, 'T-W' indicates the prompt 'topic-words,' 'T-ph' indicates a 'topic-phrase' prompt, 'T-Sent' indicates a 'topic-sentence' prompt, 'no prompt' means no prompting was used while fine-tuning a model, and 'CNN-DM' indicates that the model was fine-tuned on the same source articles of our dataset paired with their original corresponding CNN/Dailymail summaries. The initial goal of this experiment is to probe whether the model variations with any of the topical prompts can outperform the 'no prompt' versions, which are trained on `NEWTS` without conditioning on a topical prompt and the 'CNN-DM' versions, which are trained for a standard summarization task.

As we observe in the table, in the case of 'BART-b,' 'T5-b', 'T5-L' as well as 'ProphetNet,' the model variations with topical prompts outperform both the 'no prompt' version as well as the 'CNN-DM' version in terms of the ROUGE scores. We do not observe a conclusive pattern when comparing the different prompting methods in terms of the ROUGE scores. That is, there is no one prompt that leads to a higher ROUGE performance for all models.

As a result, we conclude that while the topical prompts do lead to performance improvement on the topic-focused summarization task, we do not observe a conclusive superiority pattern among the prompts in terms of the ROUGE performance.

Evaluating the Topicality of Output Summaries. In the second experiment, we evaluate the topical focus of the generated summaries by each model in terms of the topic probability score computed by the LDA topic model, indicating the strength of a target topic presence. Therefore, we design an experiment to assess the performance of the different models with different prompt types in how topic-focused their output summaries are. For this purpose, we utilize the LDA topic model to

	R1	R2	RL	Topic Focus
BART-b + T-W	31.14	10.46	19.94	0.1375
BART-b + T-Ph	31.01	10.36	19.91	0.1454
BART-b + T-Sent	30.38	09.70	19.48	0.1513
BART-b T-ID	30.97	10.23	20.08	0.1399
BART-b no prompt	16.48	0.75	11.71	0.0080
BART-b CNN-DM	26.23	7.24	17.12	0.1338
T5-b + T-W	31.78	10.83	20.54	0.1386
T5-b + T-Ph	31.55	10.75	20.27	0.1426
T5-b + T-Sent	31.40	10.37	20.35	0.1528
T5-b + T-ID	31.44	10.64	20.06	0.1342
T5-b no prompt	30.98	10.19	20.23	0.1379
T5-b CNN-DM	27.87	8.55	18.41	0.1305
T5-L + T-W	30.92	10.01	20.19	0.1598
T5-L + T-Ph	31.40	10.50	20.27	0.1457
T5-L + T-Sent	30.64	09.84	19.91	0.1462
T5-L + T-ID	30.35	9.93	19.77	0.1335
T5-L no prompt	30.06	9.55	19.25	0.1366
T5-L CNN-DM	28.44	8.49	18.61	0.1286
ProphetNet + T-W	31.91	10.80	20.66	0.1362
ProphetNet + T-Ph	31.56	10.35	20.17	0.1474
ProphetNet + T-Sent	31.40	10.03	20.02	0.1633
ProphetNet no prompt	30.22	9.67	19.27	0.1316
ProphetNet CNN-DM	28.71	8.53	18.69	0.1295
PPLM	29.63	9.08	18.76	0.1482
CATS	30.12	9.35	19.11	0.1519

Table 2: Benchmark comparing various models and prompting methods, using a 3-fold cross validation in terms of F_1 ROUGE 1, F_1 ROUGE 2, and F_1 ROUGE L and the LDA topic-focus score.

compute a per target-topic score in each generated summary. Then we compute the average of this score across all generated summaries for their corresponding pre-defined target topic. We expect the models using topical information to have a higher topic_focus score. We present the results of this experiment in the right-most column of Table 2. From the results of this experiment, we observe that in all cases, the topical prompt variations of each model outperform the 'CNN-DM' variation indicating that the models trained for topic-focused summarization produce summaries that are more target-topic-oriented.

Subsequently, we observe that topic sentence prompts outperform all other prompting techniques in achieving a high LDA target-topic score, suggesting that topic sentence prompting provides models with superior topic context information.

Evaluating the Effect of Training Data Size on Performance. In this experiment, we investigate the effect of training data size on ROUGE performance. For this purpose, we experiment with the T5-base model and fine-tune it first on 25% of the training data, then on 50%, on 75%, and finally on all the data to analyze the effect of training data size on ROUGE scores. Figure 5 illustrates the results of this experiment. The figure shows that increasing the training set size from 25% to 75% results in a significant improvement in performance in terms of ROUGE while increasing the dataset size from 75% to 100% indicates a convergence. The findings in this experiment indicate that the model improves in ROUGE performance scores as we increase the training data size up to 75% showing a desirable behavior. Moreover, the performance curves converge after 75%, implying a sufficient dataset size.

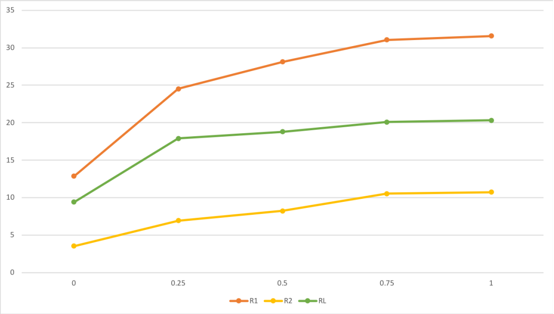

Figure 5: Figure showing the impact of training data size on ROUGE performance comparing performance of T5-base + Topic_Phrases fine-tuned with 25%, 50%, 75% and 100% of the training data

A Qualitative Human Study of Topicality on the Dataset. This experiment assesses the dataset quality in terms of the topical focus of the summaries. To achieve this, we design a survey with three human judges. We randomly select 100 articles from our dataset to conduct the user study. Subsequently, for each article, we present one of its topical summaries, the target topic of the summary, and the standard non-topical summary of the article from the original CNN/Dailymail dataset. The human judges are asked to identify the topical summary among the two options given the target topic. Therefore, the judges can make a binary decision determining the topic-focused summary. The results of this experiment reflect that with an accuracy of 93%, the judges identify the topical summary. The Kappa agreement score between the three judges was 0.7845. The findings of this experiment suggest that the quality of the dataset in terms of the summaries' topical focus is very high.

Analyzing the Number of Fine-tuning Epochs on ROUGE Performance. In this experiment, we test the learnability of the abstractive topic-focused summarization task by a Transformer model. To achieve this, we examine the effect of the number of fine-tuning epochs on performance gain. For

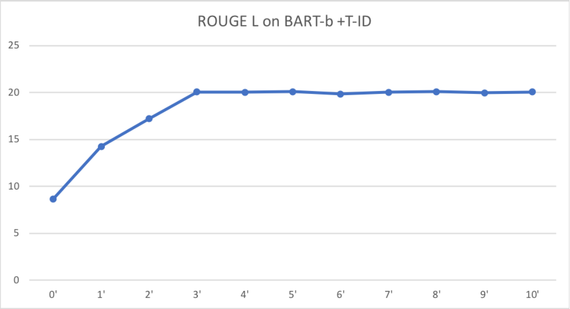

Figure 6: Figure showing the impact of the fine-tuning epochs of the BART-b + T-ID model on ROUGE L performance.

this purpose, we randomly select one of the model variations presented in Table 2, namely ‘bart-b + T-ID,’ and analyze it in terms of its learning behavior in terms of the ROUGE L performance metric over different epochs. The results of this experiment shown in Figure 6 suggest that through the first three epochs, the model learns the topic-focused summarization task and finally converges with minimal performance differences on the higher number of epochs. We conclude that in three epochs, the ‘bart-b + T-ID’ model learns topic-focused summarization and shows a convergence behavior.

Qualitative Examples from the dataset and Model Outputs. Finally, we present randomly selected qualitative examples from the dataset along with the outputs generated by different models showing the quality of topic-conditioned text generation. The sample outputs presented in Table 3 demonstrate high quality in summarizing an article with respect to two different topics.

6 Conclusions and Future Work

This paper designs and releases the first publicly available dataset for controlled topic-focused abstractive summarization, `NEWTS`. Our dataset encompasses four prompt types to allow various conditional text generation techniques.

We showed through extensive experimentation that the new dataset is of high quality. We believe that this dataset will serve the community to advance research in controlled text generation and topical summarization as a foundation for future research.

Our findings indicate that the sequence-to-sequence Transformer baselines fine-tuned with topical prompting outperform the non-topical variation model counterparts showing that the models do learn topical representations for a topic-focused text generation. Additionally, our experiments suggest that topical sentence prompts surpass other prompt types in steering the generation process to achieve a high LDA target topic score. This finding is in line with the notion that contextual language models learn better sentence representations than other word constructions, such as the other different prompt types proposed in this paper.

Source of Summary	Summary Text
Ground Truth Summary1 (Pop Music)	After experiencing some terrible customer service on an airline, a band wrote a sarcastic song about the experience. It became a hit, notably among other passengers on that airline. However, not everyone is impressed with their musical talent and lyrics.
Ground Truth Summary2 (Airline)	Ryanair is well-known for upsetting its passengers. Its flight attendants are known to be rude and its surcharges are ill-received. It is launching a marketing campaign to revamp its image.
BART-b + Topic-Sent (Pop Music)	Sidonie, a well-known band from Catalonia created a tongue-in-cheek song during a Ryanair flight to Santiago de Compostela in northern Spain. The band’s lead singer strummed a ukulele as the group serenades passengers on board - despite Ryanair’s scathing review of the sarcastic lyric. The lyrics read: ’Ryanair, how we like Ryanair, and its flight attendants, they could not be nice,’ from Ryanair.
BART-b + T-W (Airline)	A well-known band, created a somewhat ironic song during a recent Ryanair flight to Santiago de Compostela in northern Spain. Explaining the motivation behind their hilarious video, the band wrote online: ’After repeatedly receiving the usual lack of respect shown by flight attendants on the Ryanair route to Santiago, we were moved to compose and perform a song dedicated to them. Other passengers also complained about the airline.
Ground Truth Summary1 (Presidential Election)	Marco Rubio is running for president. The Florida Senator is already receiving large contributions for his campaign from donors. He will need the money, as he is also competing with Republican candidates who also have received large donations.
Ground Truth Summary2 (Marriage and Civil Law)	Marco Rubio claims that people are born gay or straight, rather than being influenced by outside circumstances. He supports people’s right to choose, even though he himself does not agree with gay marriage. He does say that the legality of gay marriage should be decided by state legislators rather than the court system.
T5-L + T-Sent (Presidential Election)	Senator Marco Rubio announced he is running for president last week. Donors have said their candidate has already received monetary commitments in excess of the $40 million he will likely need to battle through a presidential primary season that will feature a crowd of seasoned Republican candidates with strong financial backing.
T5 + T-ph (Marriage and Civil Law)	Marco Rubio believes that people are born with a sexual preference while insisting state legislators should decide whether or not to allow gay marriage. The presidential candidate spoke to CBS’ Face the Nation after admitting in an interview he would attend the same-sex wedding of a family member or staffer - even if he didn’t agree with the decision. The Florida Senator told Bob Schieffer that he wasn’t against gay marriage, but believes the ’definition of the institution of marriage should be between one man and one woman’.

Table 3: Two sets of qualitative examples of Ground-truth summaries alongside system-generated summaries. Change of a target topic results in a significant vocabulary shift shown in color.

In the future, we plan to design a topic-focused generative model that not only would condition the generation process on a pre-defined topic but would also penalize the generation of non-target-topic words in the decoding phase. Furthermore, we plan to investigate the problem of live topic-focused text generation in a zero or few-shot learning process using the new `NEWTS` dataset.

A Appendix: NEWTS Topics

The following table presents all 50 topics covered in the NEWTS dataset using the top five words present in each LDA topic. As it can be seen, our newly introduced dataset encompasses a vast range of coherent topics present in the real-world news domain. We have presented each topic with its original topic id as obtained from the LDA model to facilitate the reproducibility of the results presented in this paper. Furthermore, we plan to release the dataset and our entire code base to ensure the reproducibility of our experiments.

Topic Id	Topic Words
62	island, beach, sea, gaal, navy
32	water, river, lake, bridge, walker
78	court, judge, case, appeal, justice
46	law, legal, state, marriage, rights
12	islamic, terror, terrorist, al, threat
229	hotel, guests, bar, glass, wine
105	charged, allegedly, charges, arrested, alleged
72	health, virus, cases, people, bird
153	fire, residents, san, wood, firefighters
97	visit, pope, peace, catholic, roman
134	air, plane, aircraft, flight, flying
13	price, cost, products, market, prices

Abstract

Reddit is home to a broad spectrum of political activity, and users signal their political affiliations in multiple ways—from self-declarations to community participation. Frequently, computational studies have treated political users as a single bloc, both in developing models to infer political leaning and in studying political behavior. Here, we test this assumption of political users and show that commonly-used political-inference models do not generalize, indicating heterogeneous types of political users. The models remain imprecise at best for most users, regardless of which sources of data or methods are used. Across a 14-year longitudinal analysis, we demonstrate that the choice in definition of a political user has significant implications for behavioral analysis. Controlling for multiple factors, political users are more toxic on the platform and inter-party interactions are even more toxic—but not all political users behave this way. Last, we identify a subset of political users who repeatedly flip affiliations, showing that these users are the most controversial of all, acting as provocateurs by more frequently bringing up politics, and are more likely to be banned, suspended, or deleted.

1 Introduction

Individuals readily engage in political behavior online, sharing content and forming communities with like-minded individuals. Scholars study these active political communities to understand partisanship (Leong et al., 2020), polarization (Morales et al., 2021; Hofmann et al., 2021), and voting behaviors (Gayo-Avello, 2012).

Many computational studies of political behavior in social media have the underlying assumption that political leanings can be reliably identified. Prior work has shown that partisan leaning can be inferred from a diverse set of behavioral characteristics such as text (Volkova et al., 2014), social networks (Lindamood et al., 2009; Barberá, 2015), and even community participation (An et al., 2019). Yet, inferring political leaning is known to be a challenging problem (Cohen and Ruths, 2013), in particular for centrist or apolitical users who infrequently express political beliefs. Further, inference models typically use a single source of information on a user's political affiliation without examining whether this source generalizes to all types of users. This methodology fails to account for the disparate types of political users and introduces sampling bias downstream. Here, we re-examine inferring political behavior for these diverse groups in a unified setting to understand the consequences our data have on results.

This paper tests what effect current assumptions of social media users' political affiliations have on our ability to model political users and their behaviors. The first part of the paper tests how different definitions of political users generalize to other users' behaviors and to inferring political leaning. Using 574K political users on Reddit, we show that the common definitions of a political user (e.g., those making self-declarations of affiliation) result in behaviorally diverse types of users. Moreover, we demonstrate that multiple computational approaches for political inference do not generalize across these political user types; our results show that political inference on Reddit is challenging, with our best model for inference only attaining a 0.60 AUC score across all users.

The second part of the paper tests whether the choice in which type of political user influences the outcomes of political analyses. We show that controlling for multiple factors, political users are generally more toxic on the platform and that cross-affiliation interactions are *even more* toxic—with liberal-to-conservative interactions being most toxic. However, not all types of political users are equally toxic, highlighting the importance of how studies define political users. In addition, we identify a small set of users who near-simultaneously

Findings of the Association for Computational Linguistics: ACL 2022, pages 504 - 522
May 22-27, 2022

declare differing political affiliations. These users act as provocateurs and have substantially more controversial comments—with the most active eventually being banned. Together, our study has substantial implications for future work on political behavior on Reddit and highlights the need to account for different types of political users.

2 Political Affiliation Online

Online communities are active spaces for political discussions and cross-community engagement. Researchers have examined how these political spaces, and the users therein, influence real-life politics (Zhuravskaya et al., 2020), forecast future political outcomes, (Swamy et al., 2017), increase political engagement offline (Lane et al., 2017) and even polarize opinions (Settle, 2018). Such research depends on knowing the political affiliation of users.

People online may express their political affiliations explicitly or implicitly, and not all users reveal their affiliations (Haq et al., 2020). This lack of data potentially limits large studies of political engagement. As a result, substantial work has focused on inferring affiliation to increase the data representativeness (e.g., Rao et al., 2010; Al Zamal et al., 2012; Gentzkow et al., 2016; Preoţiuc-Pietro et al., 2017; Tatman et al., 2017). However, political inference is known to be challenging, and prior work has shown methods often fail to generalize to users outside the narrow range of political orientation on which they were trained (Cohen and Ruths, 2013). Moreover, the majority of work uses only a single source of ground truth—when multiple are available—without testing the implications of which type of user makes the political declaration and whether those users are representative at large. This study tests this underlying assumption of generalizability of how political users are defined and what effect this has on affiliation inference and behavioral studies of political users.

3 Identifying Political Affiliation

Individuals signal their political beliefs in multiple ways from self-declarations to participation in partisan communities. These different sources of information offer complementary ways of recognizing beliefs, and defining who exactly is a "political user." Prior works have varied significantly in which of these signals they use (e.g., Beller et al., 2014; Shen and Rose, 2021). Here we define political affiliation and describe different sources of political identification. Our data collection matches prior work, and we rely on previous definitions of political affiliation to build our set of political users.

Defining Political Affiliation Political affiliation is a complex description based on a person's values and special interests (Conover and Feldman, 1984). Multiple studies have attempted to simplify affiliation to a single dimension (Poole and Rosenthal, 1985; Clinton et al., 2004; Shor and McCarty, 2011), with the most common being a continuous ideal point value along a conservative-liberal spectrum. Prior work has largely adopted binary affiliation labels (e.g., An et al., 2019; Shen and Rose, 2021), though some work has attempted to infer continuous values (Preoţiuc-Pietro et al., 2017). Due to the sparsity of information and the need to support non-American affiliations, we adopt binary conservative and liberal labels.

Metadata Affiliations (Flair) Multiple Reddit communities allow users to have a piece of flair displayed with their username (Tigunova et al., 2020; He, 2021); several political communities follow this practice, allowing us to extract precise affiliations for users based on their self-declared identity. For example, a user commenting in the r/Conservative subreddit may select a "Reagan Republican" or "Trump Supporter" flair, both indicating a conservative political leaning. In total, we used 70 known flairs and iterated through the 169 months of comments which resulted in 16,451 unique users with a political flair.

Self-declarations During conversations, individuals sometimes make self-declarations about their identity (Bergsma and Van Durme, 2013; Beller et al., 2014). Therefore, we capture politically-related self-declarations using a limited set of regular expressions; for example, a user who commented "I only vote Republican" would be labeled as a conservative. Matched comments were further filtered to remove comments from known bots, quotations and hypothetical statements, and statements indicating a past affiliation that does not imply a present one. Appendix §A.1 describes the regular expressions and filtering.

To verify the accuracy of the extracted labels, three annotators labeled a sample of 100 instances, labeling users as liberal, conservative, ambiguous, or neither. Annotators attained a Krippendorf's α=0.82; this agreement is substantially higher than seen for annotating general user statements (cf.

Shen and Rose, 2021) because the text focuses on political self-declarations. Among 31 pairs of disagreeing annotations from three annotators, 29 of them have at least one annotator labeling it as *can't tell* or *neither* — suggesting most disagreements were due to vagueness in the comment.

Community Participation Reddit has multiple communities associated with political ideologies (Weninger et al., 2013; Soliman et al., 2019). Participating in these communities can thus serve as an implicit signal of affiliation. For example, if a user frequently comments in `r/Conservative`, they can be assigned a conservative label. Prior work has used participation in these communities as a proxy for affiliation (e.g., An et al., 2019; Shen and Rose, 2021). We intentionally exclude (i) quasi-political communities such as `r/the_donald`, which though affiliated, attracts a broader set of users and (ii) political communities with mixed affiliations to maximize the precision of the ground truth. Some users participate in multiple communities across the political spectrum; we exclude these from the dataset. Using a list of 24 political communities (see Appendix Table 5), we identify 343,773 conservative and 183,102 liberal users.

Data Summary The dataset is collected from Reddit and consists of all English comments from December 2005 until December 2019. We identified 573,829 political affiliations as seen in Table 1. The community labels are the largest source of affiliation, providing ∼17x more data than self-declarations from the comments. These datasets show two important trends. First, surprisingly, few users had more than one source of affiliation, shown in Table 2; a little under half the users who self-declare (44%) or have user flair (46%) also actively participate in politically-affiliated communities. This difference suggests these sources of ground truth are relatively distinct.

Second, the datasets differ in their skew towards one affiliation, with flair and community-based affiliations heavily skewed towards conservative users. Given Reddit's reputation for having a liberal bias (Vogels et al., 2021), this skew has an important implication on downstream studies of these users alone. Our results suggest that conservative users are more likely to be more active in overtly partisan communities and identify their politics more clearly than liberal users.

Dataset	**Conservatives**	**Liberals**	***Total***
Flair	12,185	4,266	16,451
Self-declaration	12,542	17,961	30,503
Community data	343,773	183,102	526,875

Table 1: Dataset sizes based on source of ground truth

	Source Two		
Source One	Flair	Self-Declaration	Community
Flair	-	0.014	0.025
Self-Declaration	0.461	-	0.063
Community	0.443	0.034	-

Table 2: Overlap in the percent of users in Source One users who are in Source Two

4 Characterizing Political Behavior

Do users who declare their political beliefs in different ways also *behave* differently? Here, we test for behavioral differences between user categories.

Behavior By Data Source We analyzed general behavioral differences between political users and non-political users using a random sample of 10K users from each category and 10K non-political users. For each category, we measure (i) how old their accounts are as the time between first and last comment and (ii) diversity in community participation as entropy over subreddits.

Substantial variation was seen across the groups. Users with no declared affiliation had accounts nearly twice as old (μ=94 months) as political users (μ=46), and for every political data source, conservatives have a shorter lifespan of activity. The median longevity for conservative users is a full year less than their liberal counterparts. Conservatives in the flair dataset have the shortest overall lifespan with a median of 31 months. As Reddit's user base has grown substantially since its beginning—particularly with an influx of political users around the 2016 U.S. election—our results point to the need to recognize political and non-political users as heterogeneous groups.

Political users varied in how widely they comment across communities, with users who self-declare and those with flairs participating in more communities on average. Figure 1 shows the mean entropy for user type, revealing users in two groups participate more broadly than those whose affiliation is derived from participating in partisan communities (p<0.01). The entropy is calculated from the probability that user u_j comments in a subreddit $s_i \in S_{u_j}$ across all of their activities: $-\sum_{s_i \in S_{u_j}} (p(s_i) * log(p(s_i)))$. High entropy indi-

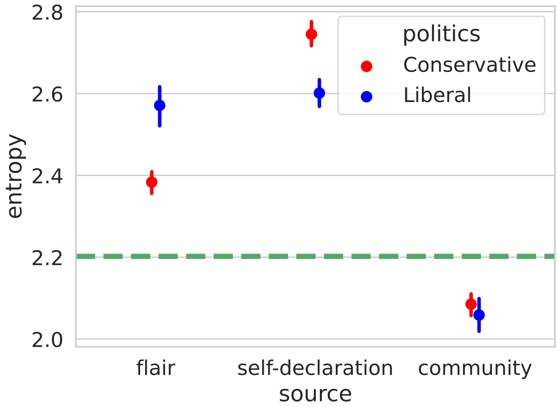

Figure 1: Subreddit entropy by data source and politics, showing community partisans have the least-diverse behavior. The dashed line shows the mean entropy of users without evidence of their political leaning.

cates the user visits many communities with equal frequency; low entropy indicates that they visit a few communities more often. We average these per-user entropies across all users in a data source. Political discussion on Reddit is known to be common outside of political subreddits (Rajadesingan et al., 2021) and our work suggests that this behavior is driven by certain types of political users.

Conservatives vs Liberals Conservatives and liberals are known to operate in different bubbles online (Adamic and Glance, 2005; Bakshy et al., 2015). Here, we test whether the different groups within an affiliation have separate bubbles themselves. Political users are represented by their commenting frequencies across subreddits. PCA is applied to identify latent variations in where users are active. Figure 2a shows the t-SNE projection of these political users colored by affiliation with shapes for each user type; closeness in this plot indicates users are active in the same communities. This projection shows three trends. First, as expected, some conservative and liberal users participate in bubble-like spaces with users of primarily one affiliation. Second, surprisingly, some clusters exhibit strongly-mixed affiliation, indicating that Reddit is not entirely polarized and some users do regularly interact across affiliations. Third, some politically affiliated clusters are primarily made of one user type as shown in Figure 2b which plots using points colored by user type. This result suggests that several micro-bubbles exist where users may not interact with others of their affiliation. As a result, computational studies using only one source of data may incorrectly estimate how information spreads between users or the norms of political users in a community. See Appendix B.1 for PCA and t-SNE hyperparameters)

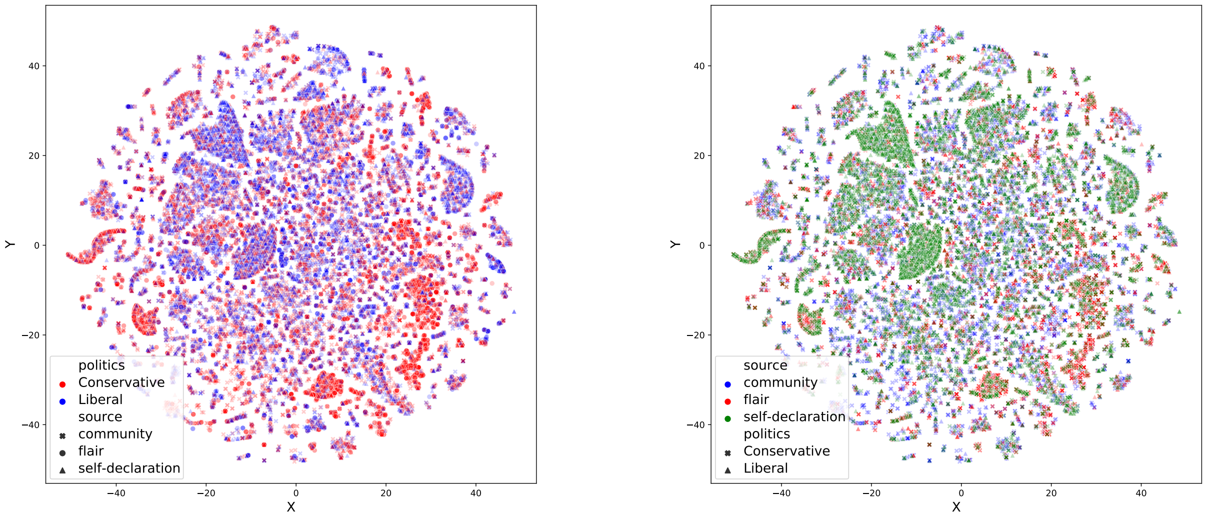
5 Inferring Political Affiliation

Multiple methods have been proposed for inferring political affiliation. However, these methods have typically used only a single source of information as ground truth (e.g., community membership). Given the behavioral differences between observed users from different sources of information, we test how well a broad set of approaches identifies political affiliation and to what degree does an approach and source of ground truth generalize to inferring the affiliation for other types of users. Additional details on the hyperparameter settings for each model are detailed in Appendix §B.

Username Classifier Usernames can reveal aspects of identity (Wood-Doughty et al., 2018; Wang and Jurgens, 2018), e.g., `Hillary4Prez` reveals a liberal leaning. To predict affiliation from names, we follow Wang and Jurgens (2018) and train a bidirectional character-based LSTM.

Text Classifier Some topics are politically oriented and can potentially reveal a user's leaning, e.g., discussing interests in gun rights. To infer affiliation from such statements, we train a RoBERTa (Liu et al., 2019b) model over comments made from each user, excluding any statements they make that explicitly self-identify their affiliation. The model predicts each comment, and we aggregate the model outputs by taking the mean of predictions for selected comments associated with a user as the final label.

Behavioral Classifier User behavior can be a strong indicator of affiliation as individuals participate in political or politically adjacent communities (e.g., environmentalism). Prior work has shown that modeling user engagement across subreddits using community2vec (Martin, 2017) can identify subreddit-specific affiliations (Waller and Anderson, 2020). This process is analogous to training a word2vec model with separate user u and subreddit s embeddings which learn parameters to maximize $\sigma(u_i \cdot s_j)$=1 if the user participates in the subreddit or 0 if not. We extend this approach to use semi-supervised training in a multi-task setup: the traditional user2community model is retained and a separate linear layer is used to predict political affiliation from the user embedding if that user's affilia-



(a) Users colored by political affiliation.

(b) Users colored by how they declare their affiliation.

Figure 2: A t-SNE embedding of the subreddit commenting behavior for a sample of political Reddit users, colored by affiliation (2a) or by source of affiliation labels (2b), reveals partisan clusters mixed by source as well as single-source clusters, indicating heterogeneous types of political users.

	Username				**Text-based**				**Behavioral**			
Training	Flair	Self-Decl.	Comm.	All	Flair	Self-Decl.	Comm.	All	Flair	Self-Decl.	Comm.	All
Flair	52.06	39.93	61.11	49.47	**70.76**	60.63	55.08	55.46	58.10	50.51	54.52	54.30
Self-Declaration	50.45	43.55	**66.67**	46.58	61.20	**61.06**	54.87	55.70	48.66	52.54	60.76	59.61
Community	47.23	51.88	40.74	45.79	67.08	60.68	60.34	**60.43**	50.58	47.35	50.83	50.52

Table 3: Classifier performances (AUC) at predicting user political affiliation relative to which dataset a model is trained on (row) and tested on (column). The best performing system (method + data) on each test set is **bolded**.

tion is known. This semi-supervised setup provides structure to the user embeddings, ideally infusing all users with information on their affiliation based on subreddit commenting behavior. Unlike the text-based classifier, the behavioral model captures user engagement in politically-affiliated communities, even if the user never explicitly declares their affiliation in comments. The primary difference between the behavioral and text classifiers is that the behavioral classifier captures whether a user associates with groups (subreddits) that are politically affiliated (e.g., gun-rights or pro-life for conservative users), whereas the text classifier captures whether a user says something that reveals their politics.

5.1 Experimental Setup

All users with a political affiliation were merged into one set and then randomly divided the dataset into train (80%), development (10%), and test (10%) sets. For every classifier, we trained a model on users from each data source and then evaluated users from each source.

Our text-based approach follows previous work, which usually aggregates 10-30 text instances for each user for prediction (e.g., Colleoni et al., 2014; Tatman et al., 2017); here, we select at most 20 comments (chosen randomly) for each user. To train the behavior model, we generate a bipartite network between users and subreddits weighted by how often a user comments in a subreddit. The network was restricted to the top 1000 subreddits and users were required to have a minimum of 10 comments, following Waller and Anderson (2020). We randomly sampled non-political users (5x political users) and introduced their subreddit frequencies into the bipartite network (Appendix §B).

5.2 Results

Classifier performance, shown in Table 3, reveals stark contrasts in generalizability between the different data sources—with no model performing highly accurately (F1 scores shown in Appendix Table 8). In general, text-based classifiers perform better than classifiers inferring affiliation from a username or where a user comments. When generalizing to all data, username models performed worse than random, suggesting this approach is unsuitable for generalizing to the broader population. In most cases, models perform best on users whose affiliation was determined in the same way as training users (e.g., train and test on flair users).

Could models still be effective if limited to their high-confidence predictions? We plotted the precision-recall curve of each classifier across all user types, shown in Appendix Figure 12, which reveals models' precisions are moderate at best, with no model offering substantially higher precision at the expense of recall. Model predictions were moderately correlated with each other (mean Pearson's r=0.36), indicating they capture complementary information about a user. Future work may try to fuse the different sources of information to improve performance.

For the text-based classifier, we created bivariate plots in Supplemental section §C of the model's predictions on all three datasets in order to check if the models are capturing similar information. The average regression coefficient of 0.36 indicates there is some overlap in what the models are capturing. However, this is still far from a reliable predictor even using the state-of-the-art natural language understanding models.[1]

6 Political Interactions and Engagement

Political discussions are known to be heated (Iyengar et al., 2019), and online discussions of political topics are more uncivil and aggressive than non-political topics (Coe et al., 2014; Barnidge, 2017). In part, political topics have become increasingly moralized (Finkel et al., 2020), where discussions are more connected to a person's identity. Here, we examine the interactions between political users to probe the mechanisms behind this toxicity. Reddit allows communities to discuss political topics with like-minded individuals, but also allows common spaces for both political and non-political topics for all (Rajadesingan et al., 2021). As a result, we test whether these discussions become more uncivil due to political persons or the topic itself. Further, given the clear differences seen between our groups of political users, we test whether these users behave differently to test for potential confounds from only studying one group.

6.1 Experimental Setup

To test for affiliation-based hostility, we construct a mixed-effect linear regression model to estimate the toxicity of a reply to a comment. We include a random effect for the subreddit in which the discussion takes place, which controls for the relative levels of toxicity in different subreddits (Rajadesingan et al., 2020). Categorical variables are used for the political affiliation of the parent comment's user and the replying user. Users with no known political affiliation are set to `Unknown` and used as the reference variable. We include fixed effects for which type of source is used to determine the political affiliation as a way of estimating whether these sources reflect different groups of users with distinct behaviors. Comments by flair-based users provide an explicit signal of affiliation that may attract more hostility; therefore we include a fixed effect for whether the parent comment's user's political affiliation is visible in the subreddit. We add a factor for whether the discussion is in one of 187 political subreddits (Appendix §D) to test whether discussions around political topics are more contentious, which cover news, regions, ideologies, politicians, and activism. Finally, as toxic conversations may lead to more toxicity, we include a linear factor for the parent comment's toxicity.

We select comments where at least one of the comment's user and replying user appears in all political users we identified from all comments in our dataset. We also sample some interaction comments from non-political users to non-political users (`Unknown` to `Unknown`). In this way, we collected 6,099,866 interaction comments.

Toxicity is defined as messages which include insults, threats, or containing profane language (Wulczyn et al., 2017). We follow the approach of previous work studying political toxicity on Reddit (Rajadesingan et al., 2020) for our regression settings. To measure toxicity, we fine-tune a BERT (Devlin et al., 2019) model on the Offensive Language Identification Dataset (Zampieri et al., 2019). This dataset collects comments from Twitter, which are shorter on average but are similar in style and register. The definition of an offensive comment in the SemEval task, a comment *includes insults, threat, containing profane language or swear words*, matches our definition closely. Our toxicity model follows the setup of the top-performing SemEval system on the same data (Liu et al., 2019a) and attained an F1 of 82.3, which

---

[1] We note that some models such as the username-based model trained on self-declarations perform worse than random (see via AUC<0.5) indicating the model's predictions could be reversed post hoc to improve performance. We report the original performance here to suggest how well model generalize without additional tuning.

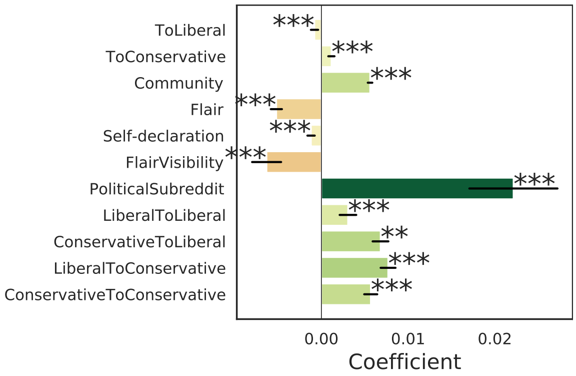


Figure 3: Significant regression coefficients for explaining the toxicity of a reply relative to the political affiliation of the users. Full coefficients are in Table 9.

is close to their reported F1 of 82.9. We validate the toxicity scores on the Reddit data by evaluating the model on 150 manually annotated comments, which resulted in a 0.88 weighted-F1, indicating the model generalizes to toxicity on Reddit. For analysis, we use the model to assign each comment a toxicity score between 0 and 1.

6.2 Results

Regressing on the factors contributing to toxicity in replies shows three main findings (Figure 3; full regression in Appendix Table 9). First, consistent with prior work, we find that controlling for subreddit-specific levels of toxicity, discussion in political communities is much more toxic, suggesting that these topics are a primary source of increased hostility.

Second, we find substantial affiliation-based toxicity, with increased toxicity particularly for interactions between cross-affiliation users. While conservative users receive more toxic replies, such users are more toxic when replying to liberal users than liberal-to-conservative replies. Surprisingly, this increased toxicity is not due to an explicit flair signal; when users are commenting in a community where the flair is visible—which can include mixed-affiliation subreddits—users receive less toxic replies.

On the surface, explicit indications of political behavior as flairs might seem to strengthen apparent differences between users, leading to heightened conflict. However, given that interactions between flair-signaling users were less toxic, we speculate a few mechanisms may be in place. First, cross-partisan communities using flair often feature rules or norms that encourage deliberative discussion, thereby raising the expectations for non-toxic behavior; for example, r/AskALiberal includes prohibitions against uncivil or bad faith comments. In flaired communities, users can enter into a conversation knowing the other person's affiliation, which lowers the rate of incidental interactions where users become surprised to learn the other's affiliation. Zhu et al. (2021) suggest that when browsing news, incidental encounters of cross-partisan news are likely to cause unconscious reactionary processing of the information, rather than deliberative engagement; such a mechanism might be at play in our setting, where flairs encourage encounters that are more intentional and deliberative.

Third, our results point to clear behavioral differences between the three different sets of users. Across all of Reddit, individuals who actively participate in politically affiliated subreddits for one party are substantially more toxic in their interactions; in contrast, those who participate in flair-based communities or who have declared their affiliation in a comment (but do not participate in political communities or have flair) are much less toxic. Our result points to the importance of explicitly recognizing and modeling differences of how users self-affiliate, as these choices have significant downstream implications for behavioral studies.

7 Two-Faced Actors

Our data identified a small percent of political users who declare different political affiliations within a short period. Given the rise in trolls and other malicious actors on social media (Zannettou et al., 2019; Im et al., 2020), we ask whether these users, who we refer to as *two-faced actors*, behave differently than other types of political users.

Experimental Step To identify two-faced actors, we analyze explicit political declarations made in the flair and self-declarations user sets. Users are filtered to identify those that declare different affiliations within a 90 day period.A total of 5,524 users match these criteria in our data, which we refer to as *two-faced actors*. The total number of two-faced actors under different time constraints can be seen in Appendix Figure 11.

Analysis Two-faced actors are substantially more active than regular political users and comment 266 times per month, compared to a baseline of 82. These users are late arrivals to Reddit's political sphere and only begin showing up after the

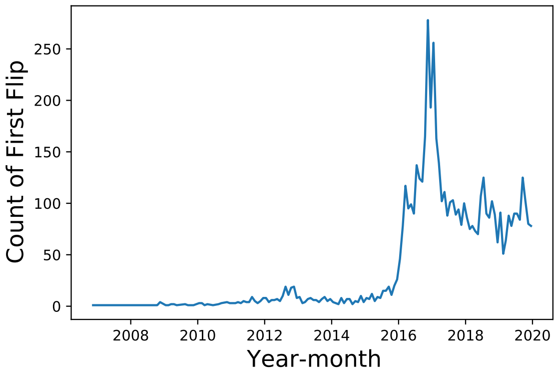

Figure 4: Temporal frequencies of two-faced actors declaring different political affiliations within a 90-day window. Large numbers of two-faced actors showed up in Reddit around the 2016 U.S. presidential election.

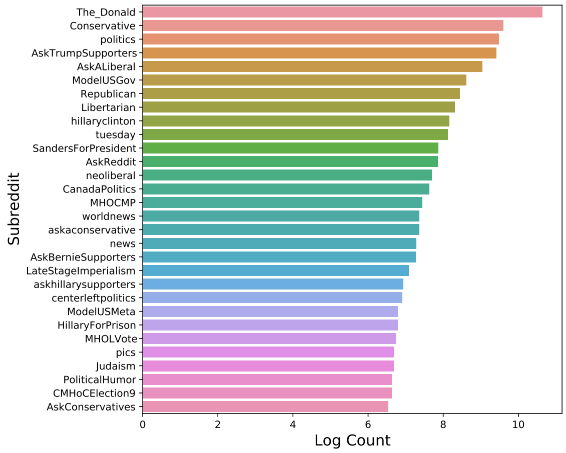

Figure 5: The frequency of the subreddits in which two-faced actors comment (log-scaled), highlighting their activity in political subreddits.

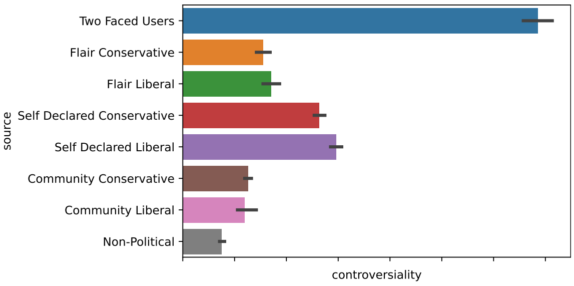

Figure 6: Reddit controversial score by cohort. Two faced actors are far more controversial

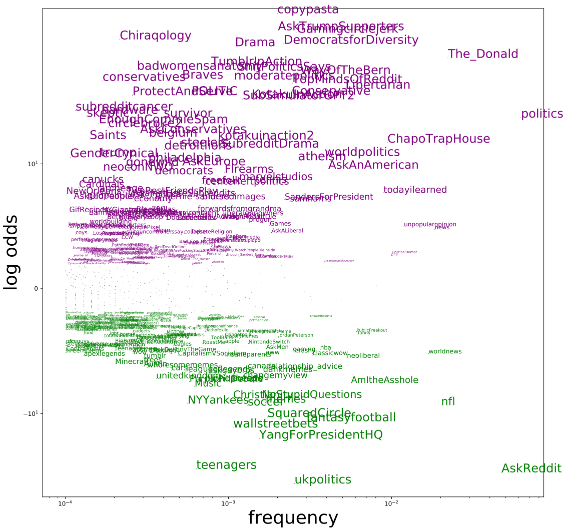

Figure 7: The log-odds of commenting in a subreddit relative to whether the user is a two-faced actor or an otherwise political user. The upper part is for two-faced actors and the bottom side is for normal political users. Contentious subreddits like r/The_Donald, r/ChapoTrapHouse appear on the two-faced actor side.

November 2016 US presidential election (Figure 4). Their comments are frequently judged more controversial (Figure 6), as measured by Reddit's controversial score which measures the split between upvotes and downvotes. Two-faced actors' average controversial score is 3.4 times higher than the average political user and nearly 10 times higher than non-political users. Figure 5 shows the top 30 subreddits where two-faced actors comment, highlight these users frequent participation in political communities.

To better understand where two-faced actors are active, we plot their commenting behavior by subreddit compared to normal partisan users, calculating the log-odds with a Dirichlet prior for the two groups (Monroe et al., 2008), shown in Figure 7. Two-faced actors frequently participate in more contentious subreddits such as r/the_donald, r/ChapoTrapHouse, r/Gamingcirclejerk, and r/genderskeptical; these subreddits cross the political divide and some have been later quarantined by Reddit for being sources of trollish or abusive behavior (Copland, 2020). This behavior suggests that two-faced users are likely not acting in good faith and are behaving as provocateurs on Reddit. This argument is supported by the fact that 28.92% of their accounts have been either suspended or deleted. In contrast, for other political users studied in §8 had only 17.52% of their accounts suspended or deleted. This study shows that researchers should be aware of the two-faced users when analyzing the political behaviors of users online, as these users form a distinct group that may bias downstream analyses.

8 Changing Political Beliefs

In American politics, political beliefs have shifted closer to closer-held ideological beliefs (Finkel et al., 2020). However, some individuals *do* change affiliation. Are users of one type more likely to switch parties? Here, we test whether affiliation changes can be predicted from prior behavior.

Analysis To identify changing behavior, we use a time constraint that requires the change in political affiliation to occur at least one year following the user's original political declaration. A total of 2,076 affiliation-changing users were identified through this process. The changing of affiliation was split roughly evenly, with 56% of flips going from conservative to liberal, and 44% going from liberal to conservative. Flips are not unique to one type of user, but users do differ in their probability of flipping, with self-declared and flair users being an order of magnitude more likely to flip (2.8% and 1.6%, relatively) than community-based-users (0.2%). For users who changed affiliations, only 17.5% of their accounts have been suspended or deleted, which is significantly lower than the two-faced actor rate and lower than the mean rate for non-political user (21.0%), suggesting these affiliation changes are likely done in good faith.

Experimental Setup To control for confounds from behavioral differences, we created our dataset using coarsened matching to pair users who change their affiliations with political users who do not. Two users are paired by having the same initial politics, closest comment count, and activity lifespan.

For each matched pair of users, we collect six months of features prior to the change of political affiliation. The feature set includes the data source of the users, their original political declarations, and participation in popular and political subreddits. A complete list of the model features can be found in Appendix §B.3. We train a Logistic Regression model to predict whether a user will change their political affiliation. We evaluate separate models for conservatives who became liberals, liberals who become conservatives, and a combined affiliation-independent model to analyze components of change regardless of party.

Results Our results indicate that models can predict changing political affiliation, with the affiliation-independent model attaining an F1 of 64.8, relative to the random baseline of 0.5. Surprisingly, party-specific models had lower performance; The model predicting conservative's change of affiliations resulted in a Macro F1 score of 45.35—worse than random; similarly, the model predicting liberal's changes of affiliations had an F1 score of 48.05. The higher performance of the affiliation-independent model suggests the existence of common signals for intent to change one's political beliefs, independent of party. The top-weighted coefficients for the Logistic Regression model can be found in Supplemental Figure §B.3.

Are some types of users less predictable? Separating test results by user type shows the model has substantially higher performance at predicting flips for self-declaration users (77.6 Macro F1) in comparison to flair users (68.9 Macro F1) and community users (57.3 Macro F1). Together with the differences in relative rates of users changing affiliations, our results again point to fundamental differences in behavior for each group of users and, again, the importance of modeling this diversity.

9 Conclusion

Social media is rife with political activity and research on these political spaces depends on accurate measurement of political users. We examine political users on Reddit and show that the choice in how political users are defined—the evidence used to establish ground truth—has substantial consequences for downstream models and analyses. In particular, user groups from different definitions behave differently (§4 and §6) and models trained on one type of user do not necessarily generalize to other groups (§3). In three studies of political users, we show that (i) political users themselves drive hostility on the platform—with conservative users being the recipients of more toxicity, (ii) a small-but-very-active group of provocateurs simultaneously declare different affiliations and are a notable source of toxicity and controversiality on the platform, and (iii) changing political affiliation can be predicted, but performance varies considerably by user type. Across all three studies, we show that the *type* of political user matters, with different types having substantially different behavior. Models, data, and code for this study will be released at `https://github.com/davidjurgens/reddit-political-affiliation`.

10 Ethical Considerations

Ethical Treatment of Annotators Annotators were a part of the study team and were not additionally compensated for their annotations.

Political Affiliation Classification The models in 5 make inferences about the political affiliations of users. Given the increasing importance of political identity in American society (Finkel et al., 2020) and inter-party hostility (Miller and Conover, 2015), these models could come with some risk if a user is mislabeled with an affiliation they do not have, e.g., a public mislabeled political identity could cause a user to be socially ostracized for their supposed political beliefs. However, as we demonstrate, these inference models offer moderate performance *at best* and are not likely to be reliable in practice. As a result, we hope our models discourage future use of such inference on Reddit, mitigating the potential risk. Further, our work aims to highlight the issue of inaccurately labeled and biased datasets in computational social science research, which are often inequitably felt in downstream harms (Olteanu et al., 2019; Mehrabi et al., 2021). Our results show that self-reported political identity is highly noisy and, when used to train classifiers, likely misrepresents any classified population used due to a high model error rate.

Ethical Risks in Behavioral Analyses Our study includes multiple behavioral analyses that look at how political users engage with each other. These studies have focused on broad characterizations of populations, rather than individuals, to maximize privacy. Yet the relatively simple methods in these studies could still be considered as dual-use with risks for users. For example, the relatively simple methods could be used to target certain users, e.g., identifying users who are potentially open to changing party affiliation (§B.3). Given that political targeting is wide-spread in practice by a variety of groups (e.g., Speicher et al., 2018; Ribeiro et al., 2019), we view the additional risk caused by our study as being minimal; however, we do acknowledge that our study could contribute to an additional focus on Reddit users.

As another risk, our study identifies two-faced users which could prompt those users themselves to change their behavior to avoid detection (e.g., making more subtle indications of their politics). We view this risk as being out-weighed by showing these users are (or were) active on the platform and potentially highlighting their behaviors for platforms to examine more closely.

Data Collection and Privacy Our data collection is in compliance with Reddit's terms of service and matches previous publications. In accordance with Reddit's content policy, any rule violation such as hate speech leads to the deletion of the comment. If the moderators of a community fail to comply with the content policy, or violations are running rampant, the subreddit will be banned. The deletion of hateful comments ensures our data does not contain any banned content. No identifying user characteristics are used in the paper, which minimizes privacy risk. Although Reddit data is public, in releasing our data, we share comment IDs rather than raw data. This format allows users to delete their data, while still other researchers to retrieve comments (if they are public).

A Identifying Political Affiliation

A.1 Self-declaration

Table 4 shows the regular expressions we use to find political users from their comments and corresponding examples. To find self-declaration users, we pick users in any comment whose text has a substring that will match with these regular expressions.

A.2 Community users

Table 5 shows the 24 community subreddits we used to find community political users. Users who comment in communities in this list but have different political labels are excluded.

B Additional Training Details

B.1 t-SNE training

For the details of t-SNE plots shown in Figure 2a and Figure 2b, we calculate a matrix of 215,031 users by commenting frequencies across the 2,000 most commented subreddits they commented in. We then decompose the matrix into 20 dimensions by standard PCA which covers about 71% of the variation. We only include users with at least 5 comments. We then ran t-SNE to reduce the matrix to 2-dimensions. The perplexity is 60 and the verbose is 4.

B.2 Political Affiliation Classifiers

The bi-LSTM used for classifying usernames has an embedding dimension size of 15, a hidden dimension size of 256, and 2 layers. The dropout (Srivastava et al., 2014) rate is 0.2. For the text-based classifier, we use the original setting of RoBERTa model with pre-trained parameters. For the behavioral classifier, the embedding dimension is 50. The dropout is 0.5 applied before the political layer. Table 6 shows other hyperparameters of our classifiers.

B.3 Changing Political Beliefs

For the features of logistic regression, we select the number of comments a user makes in the top 100 most-frequent subreddits and the 24 political subreddits shown in Table 5. Additionally, we include a user's Reddit-specific features including the individual sums of a user's controversiality, awards, score, and gilded. To capture temporal behavior effects of when a user engages with others, we include separate morning, afternoon, evening comments count and total comments count. We also include the account age (in months) and which source of information reveals a user's political beliefs (coded as a categorical variable). We randomly split the users into training (80%) and test (20%) sets with fixed random seed (42) across all experiments; no hyperparameter tuning was performed. A list of the top-performing coefficients can be found in Table 7.

The definition of morning, afternoon, evening, and night are as follows in UTC:

- Morning: 5:00-11:59
- Afternoon: 12:00-16:59
- Evening: 17:00-20:59
- Night: 21:00-4:59

C Inferring Political Affiliation

Are different political inference models capturing the same information or complementary information? To test this, we examine the correlations in

Regular Expression	**Example**
(i am | i'm) a (democrat | liberal)	i am a liberal and i don't think that the government is more trustworthy
i vote[d]?(for | for a)? (democrat | hillary | biden | obama | blue)	i voted for hillary on the hopes that trump's rhetoric hadn't fooled that many of my fellow americans.
(i am | i'm) a (conservative | republican)	i am a republican, and i do think climate change is a real thing
i vote[d]?(for | for a)? (republican | conservative | trump | romney | mcconell)	i voted for trump for his stance on immigration and economy.

Table 4: Regular expressions used to find self-declaration users and corresponding examples of matches.

Subreddit	Political Label
r/alltheleft	Liberal
r/Capitalism	Conservative
r/Conservative	Conservative
r/conservatives	Conservative
r/demsocialist	Liberal
r/democrats	Liberal
r/GreenParty	Liberal
r/Liberal	Liberal
r/Libertarian	Conservative
r/LibertarianLeft	Liberal
r/LibertarianSocialism	Liberal
r/Marxism	Liberal
r/neoprogs	Liberal
r/new_right	Conservative
r/progressive	Liberal
r/Republican	Conservative
r/republicanism	Conservative
r/republicans	Conservative
r/socialdemocracy	Liberal
r/socialism	Liberal
r/tea_party	Conservative
r/occupywallstreet	Liberal
r/hillaryclinton	Liberal

Table 5: The 24 subreddits used to find community political users

predictions between classifiers. Figure 8 is a bivariate plot of predictions on self-declaration users from two text-based models. One is trained by self-declaration and the other is trained by flair users. The diagonal-shaped figure showed that our text-based models can transfer across different sources on some level. Figure 9 is a similar plot while the training sources are self-declaration and flair users and the evaluation targets are self-declaration users. Figure 10 is a similar plot while the training sources are self-declaration and flair users and the evaluation targets are all users. Future work may try to leverage these complementary sources to improve overall prediction accuracy.

Table 8 is the Macro-F1 performance of each classifiers. Figure 12 is the precision-recall curve of each classifier across all user types.

D Political Interactions and Engagement

The full list of 187 political subreddits was obtained from the curated list at `https://www.reddit.com/r/redditlists/comments/josdr/list_of_political_subreddits/`.

Table 9 is an overall summary of the regression coefficients of variables at predicting toxicity in a reply to a user.

The final regression predictors in Table 9 include:

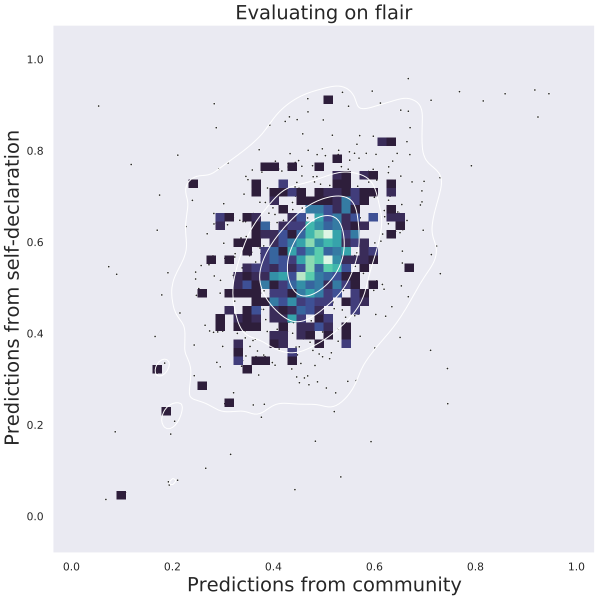

Figure 8: A bivariate plot of predictions on flair users from two text-based models. One is trained by self-declaration users and the other is trained by community users.

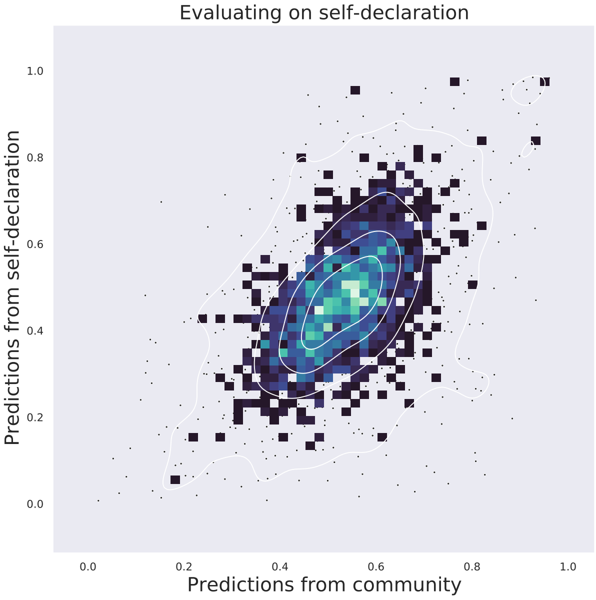

Figure 9: A bivariate plot of predictions on self-declaration users from two text-based models. One is trained by self-declaration and the other is trained by flair users.

	hyper-parameters				
Classifier	epoch	optimizer	learning rate	loss function	batch size
Username	10	Adam (Kingma and Ba, 2015)	1e-3	BCE	128
Text-based	10	Adam	1e-5	Cross entropy	64
Behavioral	10	Adam	1e-4	BCE	512

Table 6: Username classifier performance (Macro-F1) at predicting user political affiliation relative to which dataset the model is trained and tested on.

Feature	**Coefficient Weight**
Comments in political subreddits	0.000836
Account age in months	0.000791

Table 7: Top Logistic Regression coefficients (via sklearn) for predicting a change of politics

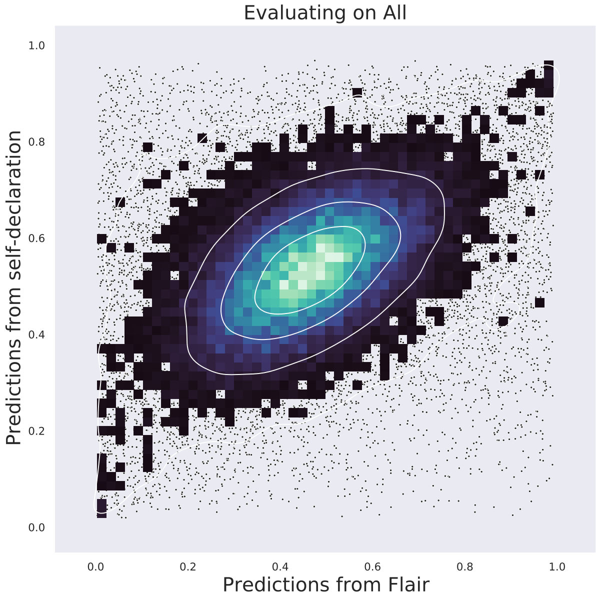

Figure 10: A bivariate plot of predictions on all users from two text-based models. One is trained by self-declaration and the other is trained by flair users.

- The political affiliation of the replying user of a comment.
- The political affiliation of the parent user of a comment (the politics of who the comment is replying *to*).
- Political Revelation: The source dataset of the replying user, which can be Community, Flair, Self-declaration, or Unlabeled. Unlabeled is set as the reference category
- Flair Visibility: Boolean variable indicating if the flair is visible to the replying user.
- Political Subreddit: Boolean variable indicating if the comment is in a political subreddit.
- Parent Toxicity: A floating number indicating the toxicity of the parent comment.
- From politics → To Politics: Composition affiliations of the replying and parent user.

Political affiliations for the *from* and *to* users are categorical coded as Liberal, Conservative, or Unknown, with the Unknown category being the reference.

E Two-Faced Actors

Figure 11 shows the number of Two-Faced actors with varying time constraints between when two declarations of different political affiliations would be considered suspect. In the main paper, we opt for the conservative estimate of 90 days under the assumption that most individuals would not publicly declare opposing political beliefs within a three-month period.

	Username				Text-based				Behavioral			
Training	Flair	Self-Decl.	Comm.	All	Flair	Self-Decl.	Comm.	All	Flair	Self-Decl.	Comm.	All
Flair	42.73	29.21	25.14	36.91	**59.70**	**57.83**	50.02	51.07	56.26	51.84	51.85	52.01

Toward More Meaningful Resources for Lower-resourced Languages

Constantine Lignos and **Nolan Holley**[*] and **Chester Palen-Michel**[*] and **Jonne Sälevä**[*]

`nrh2@williams.edu`

Abstract

In this position paper, we describe our perspective on how meaningful resources for lower-resourced languages should be developed in connection with the speakers of those languages. Before advancing that position, we first examine two massively multilingual resources used in language technology development, identifying shortcomings that limit their usefulness. We explore the contents of the names stored in Wikidata for a few lower-resourced languages and find that many of them are not in fact in the languages they claim to be, requiring non-trivial effort to correct. We discuss quality issues present in WikiAnn and evaluate whether it is a useful supplement to hand-annotated data. We then discuss the importance of creating annotations for lower-resourced languages in a thoughtful and ethical way that includes the language speakers as part of the development process. We conclude with recommended guidelines for resource development.

1 Introduction

Recent years have seen increased interest from the natural language processing community in developing both models and datasets for what may be termed "lower-resourced" languages. Advances in transfer learning and the increased availability of data and benchmarks in these languages have made it straightforward to create what appear to be high-performing models for these languages with little or no annotated data.

Yet despite the popularity and apparent effectiveness of these systems, the unique challenges and best practices for developing datasets and models for lower-resourced languages are rarely discussed alongside the system themselves. In this position paper, through commentary on our experiences working with existing datasets and a discussion of current trends, we explore what resources we believe will be most useful for the development of meaningful language technology for lower-resourced languages, advancing our perspective that *open* data and models and a *participatory* approach to research are the keys to progress.

Before we can elaborate further, we must address a terminological issue which creates a stumbling block when attempting to discuss resources and language technology for the languages of interest to us. Throughout this paper, we will use the term *lower-resourced language* to refer to languages that have received fewer resources—as measured in any numbers of dimensions such as models, datasets, papers, funding, etc.—than the most popularly-studied languages in the field of natural language processing. We explicitly use the comparative *lower* rather than *low* to emphasize the continuum that exists across languages regarding the resources available for developing language technology.

Whether a language is lower-resourced in a specific context may depend on what is available for the task at hand. Due to singular efforts, a language that may have otherwise been underserved by the research community may have a rich set of resources for a single task like machine translation (MT), but might not have annotation for other tasks. For example, consider the Inuktitut language, which has a substantial amount of government-domain parallel data (Joanis et al., 2020) that enabled an MT shared task (Barrault et al., 2020), but has few labeled datasets for other tasks and is not included in any large multilingual language models we are aware of.

We take an open and intersectional perspective to what might be called a lower-resourced language, acknowledging that this designation is both imperfect and often the result of many contributing factors. For example, many languages referred to in this way may be less-widely spoken, underserved by the research community and funding agencies, or used by marginalized or minoritized populations.

[*] Denotes equal contribution.

Findings of the Association for Computational Linguistics: ACL 2022, pages 523 - 532
May 22-27, 2022

In summary, our use of the term *lower-resourced* is intended to reflect a continuous, not categorical, status and one that is multi-dimensional, depending on task and context.

The goal of this paper is to argue for our perspective regarding what are the most effective ways to construct and use resources for building language technology for lower-resourced languages. This paper's contributions come at two levels. At the more concrete level, we discuss particular issues related to using Wikidata and WikiAnn as sources of information about names, and highlight how automatic processes to take advantage of this information can go wrong when no human expertise is involved. At a higher level, we discuss the problematic nature of developing language technology datasets and models with no or limited interaction with the population of speakers of the languages involved.

The structure of the paper is as follows. We first review two popular resources used in NLP for lower-resourced languages and the impact that they have had on the field. While we will discuss shortcomings of these resources, sometimes demonstrating them with experiments, the goal of this section is not to publish a critique of these resources, but rather to make other researchers aware of their shortcomings and limitations. By acknowledging and understanding their limitations, we can better understand how to use them most appropriately and develop future resources that do not share the same limitations.

We then turn to the importance of annotation and dataset creation processes that meaningfully involve speakers of the languages under study. We discuss open challenges for NLP for lower-resourced languages, and conclude with suggested guidelines for researchers performing research in this area.

2 Wikidata: A source for name labels

Wikidata[1] is an open and collaboratively edited knowledge graph, hosted by the Wikimedia Foundation. The Wikidata graph consists of entity nodes connected by labeled edges that represent binary relations. Each entity and relation is identified by a unique Wikidata identifier, e.g. Q4346375 (*Association for Computational Linguistics*) and P361 (`part-of` relation).

While English labels are typically used for the page titles on the Wikidata website, most entities have labels available in several languages, with the most well-edited entries having labels in hundreds of languages. This makes Wikidata an appealing source for constructing multilingual NLP resources related to entity names, as parallel names can in theory be trivially extracted from each entity. For example, Wikidata could be used to harvest name lists for a named entity recognition (NER) system, or as a source of parallel names for translation or transliteration models. In this section, we show Wikidata's promise for extracting names in lower-resourced languages as well as the data issues that arise in attempting to use it for this purpose.

2.1 Name quality in lower-resourced languages

Given the limited name-related annotation available for many lower-resourced languages, previous work has used Wikidata as a source of data for multilingual name transliteration (Benites et al., 2020; Irvine et al., 2010). Specifically for lower-resourced languages, many approaches to NER and linking for the LORELEI program (Strassel and Tracey, 2016) used Wikidata, Wikipedia, DBpedia, GeoNames, and similar resources to provide name lists relevant to the languages and regions for which systems were developed.

However, there are many caveats hidden in the data present in Wikidata and using the contents without scrutiny can be problematic. One such caveat is the mixing of languages and scripts occurring within the entity labels of a single language, especially lower-resourced ones.

Tigrinya, a Semitic language spoken in Africa by over 9 million speakers, is a particularly good example to explore, as it is written using the Ge'ez script and has only 539 entity labels in Wikidata. However, only 269 out of 539 labels are actually written in the Ge'ez script, with the rest being in Latin script.[2] This problem is particularly pronounced among entities referring to persons, where only 36 entities are written in Ge'ez, and 245 in Latin script. Out of all Tigrinya entity labels, nearly 50% are identical to the English label.

While we have not done an exhaustive analysis, we believe that many other lower-resourced languages are affected by issues of this type. Another example is Inuktitut, an Indigenous and historically

---

[1] https://www.wikidata.org

[2] We have confirmed with a native speaker of the language that this does not represent meaningful variation where some names may be borrowed in Latin script; they believed only Ge'ez script names should count as valid data.

minoritized language spoken in the Canadian Arctic by approximately 35,000–40,000 people, contains 25,222 entity labels in Wikidata, yet only 429 are written in the official Inuktitut syllabics. Out of all Inuktitut labels, 97% are identical to the corresponding English label.

The way in which Latin script labels outnumber the ones written in Ge'ez script and Inuktitut syllabics suggests that labels are potentially being copied over from other languages, possibly as a result of bot activity. This script pollution may have adverse effects—particularly when the amount of data in the desired script is very small—not only on training models on the raw data but also on any heuristic filtering methods that try to, for example, filter out all entity labels not in the most common script for the language (which may end up being the incorrect script). In other words, approaches to processing multilingual resources that assume that correct data points outnumber incorrect data points within a given a language will fail.

2.2 Name copying

Another minority language heavily impacted by likely copying is Asturian, a language spoken by 100,000–450,000 speakers in Spain. Wikidata contains over 5 million entity labels for Asturian, with 97% of them identical to the English label. For comparison, 93.5% out of 5.8 million Spanish entity labels are identical to English.

Overlap with English labels is not necessarily indicative of the labels being incorrect, as both Asturian and Spanish use the Latin alphabet and many named entities, particularly persons and organizations, can be written in the same way across languages. However, the vast number of labels relative to the number of Asturian speakers (and proportionately, active Wikidata editors), and the extra-high level of English-matching suggests that labels are being copied from other languages. This automated copying is widespread, so much so that Asturian ranks as the fourth largest language in Wikidata as measured by number of entity labels, following English, Dutch, and Spanish.

All in all, these examples show that extra care must be taken when harvesting multilingual data for lower-resourced languages in cases where it is possible that data may have been copied from a higher-resourced language. This problem is most visible in cases where a language uses a non-Latin script, but is likely to exist for many other languages. Failing to exercise caution may result in creating low-quality derived datasets that may do more harm than good. For example, if a multilingual dataset contains a large number of incorrect copies of English in other languages, it may make tasks appear easier than they are because of trivial transfer from English.

2.3 Summary

In spite of the shortcomings in data quality, we still believe that Wikidata may be a valuable resource for language technology development, provided that enough effort is invested in data cleaning and validation.[3] This process can take many forms depending on the application and could include, among other things, automated identification and filtering of languages and scripts, analysis of label copying from higher-resourced languages, and even analysis of who is making edits to Wikidata (for example, to identify automated edits).

Instead of shunning Wikidata, we encourage researchers to contribute to making it better for the global research community, and especially for lower-resourced languages for which Wikidata may be one of the only resources available. We also encourage researchers to use Wikidata collaboratively with the speakers of lower-resourced languages who can provide guidance on the quality of resources derived from it and help with the process of removing incorrect information.

3 WikiAnn

We now turn our attention to a different Wikipedia-related resource, one derived from it. WikiAnn (Pan et al., 2017) is a dataset originally created for named entity tagging and linking of 282 languages present in Wikipedia. Pan et al. generate "silver-standard" named entity annotations "by transferring annotations from English to other languages through cross-lingual links and KB properties, refining annotations through self-training and topic selection, deriving language-specific morphology features from anchor links, and mining word translation pairs from cross-lingual links."

3.1 A "silver" standard for multilingual NER

Since the WikiAnn dataset was created it has been used as a multilingual NER benchmark and it is

---

[3] Concurrently with this paper, our research group has released a Wikidata-derived parallel names resource that addresses many source data issues (Sälevä and Lignos, 2022).

included as part of the XTREME (Hu et al., 2020) massively multilingual multi-task benchmark. It is not uncommon for WikiAnn to be mentioned as a multilingual NER benchmark with sometimes no mention of the fact that it is system output and not, in fact, annotation (despite the *Ann* in the name).

We question the appropriateness of treating WikiAnn as a multilingual benchmark for NER. Even in a higher resourced language, the practice of evaluating a task on automatically derived data is sub-standard, hence the original authors referring to it as a "silver standard." This kind of evaluation can only show how close one model comes to replicating the automated data collection process and does not reflect human performance.

Just examining the English data of WikiAnn reveals a number of entity names that would otherwise never be marked as names by a human. Strings of text such as *Independently released*, *If I were a boy*, and *List of books written by teenagers* are annotated as organizations. *I was glad*, *the latter's studio*, and *were promoted* are annotated as locations, and *range has expanded*, *a twelve-year-old passenger was found alive*, and *Artavasdes II, who served as* are tagged as person. While these examples are a small sample, we identified hundreds like these with either span issues, Wikipedia-specific entities like lists, incorrect entity types or entities that were simply not names. One might argue that this represents less than 1% of the English WikiAnn data and is therefore noise. However, human annotation does not typically have mistakes of thes types and also has the benefit of being able to report inter-annotator agreement so that researchers can better understand the difficulty of the task.

3.2 Subsampled splits: Unnecessarily discarded data

There can be some confusion as to which dataset is referred to by "WikiAnn." The original WikiAnn paper (Pan et al., 2017) contains data in 282 languages, but there is also another version derived from the original with only 176 languages (Rahimi et al., 2019) with fixed data splits. This derived version is the one that can be found in Hugging Face's Datasets.[4] The original (unsplit) WikiAnn datasets can be found on Google Drive.[5]

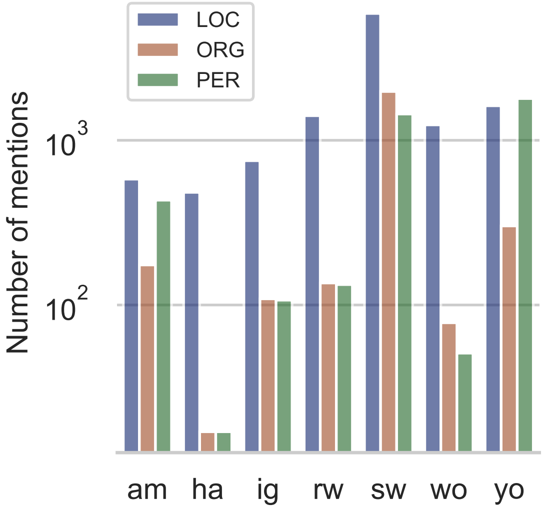

Figure 1: Counts of mentions in the full WikiAnn datasets in seven African languages that will be of interest in experiments in Section 3.5. A logarithmic scale is used so that all languages can be visualized.

We describe the differences between the two versions of the dataset in detail because many may use the currently popular Hugging Face Datasets library (Lhoest et al., 2021) and never realize they have access to less data than is in the original. Additionally, we highlight how the subsampled data no longer reflects a natural distribution of entity types and discards substantial amounts of data.

The original WikiAnn datasets are much larger than what was kept in the splits used by Rahimi et al. (2019). As can be seen in Figure 1, in the original data the languages display an uneven distribution of mention types, with most languages having far more mentions of LOC than ORG or PER.[6] This likely reflects a mix of the true distribution of named entities in the data and the fact that recall is typically highest for LOC entities.

Rahimi et al. (2019) used stratified sampling to select sentences for inclusion in their splits. The process is as follows: first, the sentences in the dataset are categorized into three groups (LOC, ORG, PER) based on the entity type of the last mention in the sentence. The size of the smallest of these groups is defined to be the minimum count, and this number of sentences is taken from each group and added to a new list of sentences. This list is shuffled, and if it is large enough, will be

---

[4] `https://HuggingFace.co/datasets/wikiann`

[5] `https://drive.google.com/drive/folders/1bkK6ly_awxe9IgAKL16VVvCtjcYcDSw8`

[6] In all figures showing WikiAnn data, we use Wikimedia language codes rather than ISO 639-3 codes for consistency with the original data.

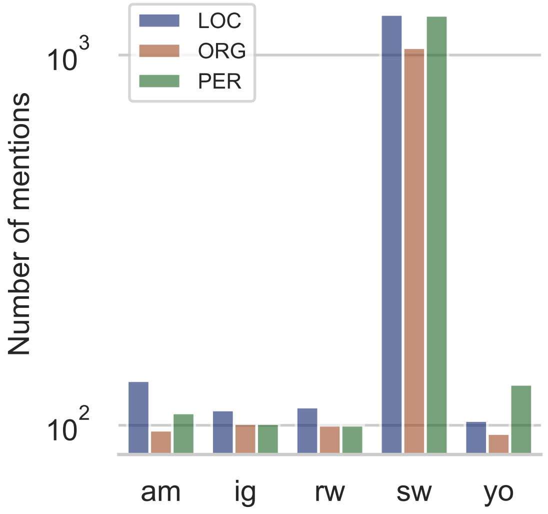

Figure 2: Counts of mentions in the stratified data selected by (Rahimi et al., 2019). A logarithmic scale is used so that all languages can be visualized.

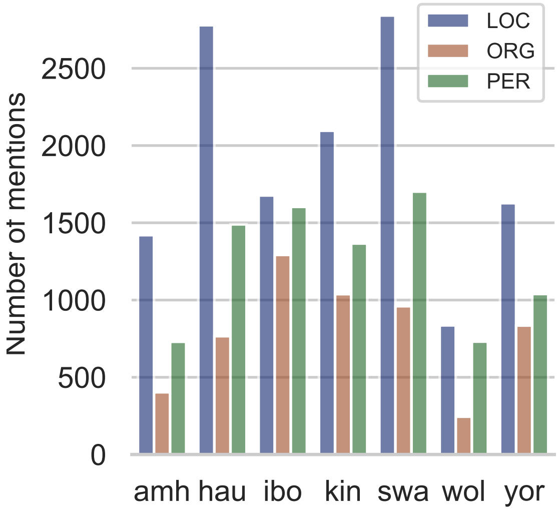

Figure 3: Counts of mentions in the MasakhaNER data for languages present in WikiAnn. The DATE tag was excluded for consistency with WikiAnn.

used to make 10,000/10,000/10,000 splits. If not, the splits will be 1,000/1,000/1,000, and if there are not enough sentences for that, then the next step is 100/100/100. If there is not enough data for 100/100/100 splits, then the language will be skipped. However, this was not the process used to create splits for the 41-language subset whose performance was examined by Rahimi et al. (2019), though the authors provide information on those splits in the appendix.

As can be seen in Figure 2, stratified sampling was largely successful in balancing the mention types across the splits. However, a large amount of data is discarded by this process, and Hausa and Wolof are entirely thrown out because the entity type with the minimum count had too few mentions for this splitting method to be used. Furthermore, the distribution of entity types is artificial and does not match up with the natural distribution of entity types for this domain. For comparison see the distribution of entity types from the MasakhaNER data (Adelani et al., 2021), a human annotated NER dataset for 10 African languages, as shown in Figure 3.

3.3 Is WikiAnn useful for languages with human annotation?

For languages where there is no annotated NER data, WikiAnn is likely better than nothing. However, when annotated data is available for evaluation, can WikiAnn still be a useful resource? We conducted experiments by comparing models fine-tuned only on the MasakhaNER training data to those fine-tuned on the concatenation of WikiAnn with the MasakhaNER training data to see whether adding WikiAnn could improve performance by providing additional in-language training data.[7] For comparison, we also experimented with fine-tuning using the concatenation of the training data across all languages in MasakhaNER.

Qualitatively, the WikiAnn data differs greatly from any typical NER dataset annotated on news, such as MasakhaNER. As can be seen in Table 1, the WikiAnn data is generally very dense in mentions, contains many "sentences" not ending in periods (which are likely not actually sentences at all), has a high number of "sentences" that consist of only a single mention.

For all experiments, training was done for 50 epochs. Training was done using the `train_ner.py` script from the MasakhaNER GitHub repository.[8] Each experiment was run with 10 different random seeds and we report the mean

---

[7] The MasakhaNER dataset makes use of the DATE tag in addition to LOC, ORG, and PER which appear in both datasets. For our experiments all of the DATE mentions were removed and annotated as O.

and standard deviation.[9]

For evaluation, the SeqScore[10] toolkit (Palen-Michel et al., 2021) was used, with the `conlleval` method of repairing invalid label sequences unless otherwise specified. The Wilcoxon rank-sum test was used to evaluate statistical significance.

3.4 Fine-tuning with WikiAnn and MasakhaNER

We experimented with fine-tuning XLM-R on the concatenation of the MasakhaNER training data with all available WikiAnn data in the corresponding language. The results are shown in Table 2. On average, F1 decreased by 0.49 when adding WikiAnn to the training data. Three languages (Swahili, Wolof, and Yoruba) show increases in performance, and while none are statistically significant at the $p < 0.05$ level, the improvement in Yoruba is marginally significant ($p = 0.0539$).

3.5 Fine-tuning with all MasakhaNER languages

The inclusion of WikiAnn data in the training data offers mixed results at best. Another option is to pool the training data across languages, creating a multilingual NER model trained on just the MasakhaNER data that is evaluated on each language's test set individually.[11] Adelani et al. (2021) previously performed this experiment, but we replicate it here using our methodology, which includes statistical significance testing, a larger number of random seeds, and includes Amharic in this experiment even though it uses a different script than the other languages.

The results, shown in Table 3, are similar to those reported by Adelani et al. (2021), with all languages seeing improved performance except for Swahili. Many of the improvements are statistically significant, showing that simply using more higher quality in-domain human-annotated data improves performance, while WikiAnn does not appear to help.

---

[9] The learning rate was $5e$-5. The optimizer used was AdamW, with an epsilon value of $1e$-8, and the scheduler was the script's default scheduler, called `get_linear_schedule_with_warmup`. The maximum sequence length was set to 164, and the training batch size was set to 32. Prediction was done with a maximum sequence length of 512, because smaller values led to a handful of tokens not receiving any predicted labels.

[10] `https://github.com/bltlab/seqscore`

[11] For this experiment, the DATE tag was left in the data, as consistency with WikiAnn data was not necessary.

3.6 Summary

Many languages have no annotated data of the type provided by WikiAnn, and for those languages WikiAnn may prove useful as long as users are aware of its shortcomings. Being an automatically created dataset, it contains noisy data, and it was constructed without input from speakers of almost all the languages contained in it. Given that the core types (LOC, ORG, and PER) are intended to have the same definition across both WikiAnn and the MasakhaNER datasets, we predicted that augmenting MasakhaNER data with WikiAnn would improve performance.

But even when all available WikiAnn data is used, it does not improve the performance of models for the MasakhaNER data, and the simpler approach of simply pooling the MasakhaNER data across all languages produces better results. This suggests that the noise level of the WikiAnn "silver" standard is very high, raising into doubt the validity of benchmarks which treat it as gold standard data.

4 Human annotation: Still essential

We have spent much of our paper describing the complexities of working with large-scale, Wiki-derived datasets, demonstrating that while they have some utility, they must be used with caution. This caution stems from the fact that though the data contained in them originated from human contributions, in its final form in a resource, the data has been removed from its original quality checks. For example, in Wikidata, names may be copied from one language to another *en masse*, and in WikiAnn, the NER "annotation" is system output trained on relatively distant human supervision.

We have spent so much of our paper describing these shortcomings to demonstrate that there is no "free lunch" when it comes to avoiding human annotation or quality checking of datasets. We believe that human annotation processes that are ultimately participatory—involving speakers of the languages as stakeholders and collaborators, not mere annotators for hire—like that of the MasakhaNER project which we have featured through the previous section and related projects (Nekoto et al., 2020; Orife et al., 2020) are the most important direction for developing language technology for lower-resourced languages.

A discussion of efforts to annotate lower-resourced languages would not be complete without a discussion of the resources developed as part of the DARPA[12] LORELEI (Low Resource Languages for Emergent Incidents) program. The LORELEI program began in fall 2015, and a major thrust of the program was producing annotation for many lower-resourced languages (Strassel and Tracey, 2016). The Linguistic Data Consortium (LDC) is in the process of releasing the 31 language packs developed as a part of the program, which have been available to the primarily U.S.-based groups funded by the program for years. Tracey and Strassel (2020) stated that they planned to release 1-2 packs per month in 2020. However, as of November 2021, even though the research efforts of the program have largely concluded, only 7 language packs have been released to the general public: Akan, Amharic, Oromo, Somali, Tigrinya, Ukranian, and Vietnamese. Each of these language packs is available for $200 USD to non-members of the LDC. While that is less expensive than typical LDC datasets, that cost can be prohibitively expensive for the speakers of the languages in the packs, who may live in countries with substantially lower wages and may not have the backing of a well-funded research lab.

While it is unfortunate that so little data has been released to date and that the data is not freely available, the main contrast we would like to draw between LORELEI and efforts such as MasakhaNER is the involvement of the speakers of lower-resourced languages. Speakers of the languages included in the LORELEI datasets did not have any significant involvement in the construction of the datasets beyond their role as annotators. This is in no way unique to the LORELEI program; it is the status quo for annotation projects.

Returning to the issues we raise in our introduction, we want to highlight that a confluence of factors come together to make a language lower-resourced, among them often a marginalization and/or minoritization of its speakers. We should consider whether it is ethical to have a paradigm in which the marginalized have no say in research that involves them, and in this case may not even be able to access the result of their work years after it is performed. Developing resources for languages that have had fewer resources created for them to date poses a unique set of ethical challenges that differs from higher-resourced language work, and

---

[12] Defense Advanced Research Projects Agency, a research agency that is part of the United States Department of Defense and funds a large proportion of US-based computer science research.

engaging language speaker in a participatory fashion can help mitigate the risk of harm.

5 Challenges

Before we conclude, we wish to highlight challenges that we believe should be addressed as a part of continuing to develop resources and models for lower-resourced languages.

Quality control for text resources. A popular way to gather multilingual data is through web crawling. These datasets include CCAligned, Multilingual C4 (mC4), OSCAR, ParaCrawl, WikiMatrix, and the aforementioned JW300. However, as detailed by (Kreutzer et al., 2022), there can be fairly serious quality issues when web-crawled data collection is not done carefully. Currently, when working with lower-resourced languages in large multilingual datasets, it is not a certainty (and sometimes, not even likely) that data is actually in the language that it claims to be.

Reducing reliance on religious text. Due to the large amount of translation of religious texts into lower-resourced languages by religious organizations in attempts to spread their message, religious materials are a common place to look for parallel or monolingual data.[13] While religious texts can be a convenient source of data due to their broad coverage of languages, it is important to be aware of potential biases, especially when the religion of the text is not the predominant religion of the speakers of the language—and thus may not match their norms—or when the target task could be affected by bias from the religious data.

JW300 (Agić and Vulić, 2019) is a source of parallel data for over 300 languages with roughly 100,000 parallel sentences per language pair on average. The data was scraped from jw.org, which is the website of the Jehovah's Witnesses. Despite being sourced from a religious organization, it contains articles on a variety of topics translated into many languages.[14] Inclusion of articles on a variety of topics does not fully prevent the potential for religious bias. As Azunre et al. (2021) demonstrate with a few masked sentence completion examples, a model trained on JW300 frequently produces completions with biblical names. Although these types of completions are not grammatically incorrect, they are suggestive of a low level of generalization beyond religious data.

6 Conclusion

In closing, we want to refer to the state of affairs highlighted by Bird (2020); some researchers are preoccupied with a data-centric view to the point of completely removing the need to involve speakers of the language in any part of the process. Through our discussion of the shortcomings of Wikidata and WikiAnn for the specific purposes that we have evaluated them, we demonstrated the gaps that are created when the dataset creation process is divorced from the speakers of the language. Our perspective on the process of dataset and model creation can be summarized through these guidelines we propose for future work on lower-resourced languages:

1. Maximize interaction with and listening to the native speakers of languages included in resources you are developing.
2. When feasible, engage with speakers of included languages for quality control.
3. Consider the potential negative consequences of releasing datasets known to be of low-quality, as regardless of how you intend the resources to be used, they will likely be used for evaluation purposes.
4. Prefer human annotation by speakers of the language to automatic processes, and release all human annotator decisions (Davani et al., 2021; Prabhakaran et al., 2021).

[13] From the perspective of decolonizing language technology (Bird, 2020), these sources may be especially problematic as many of them were used as tools of colonization.

[14] At the time of writing, JW300 is not available. The site distributing it claimed that the dataset was freely available for non-commercial use, referred readers to jw.org's copyright at `https://www.jw.org/en/terms-of-use/`, and stated that "for all practical purposes their custom terms of use are very closely aligned with the more well-known CC-BY-NC-SA license." However, the dataset has been taken down due to a copyright complaint.

Abstract

Quality Estimation (QE) models have the potential to change how we evaluate and maybe even train machine translation models. However, these models still lack the robustness to achieve general adoption. We show that State-of-the-art QE models, when tested in a Parallel Corpus Mining (PCM) setting, perform unexpectedly bad due to a lack of robustness to out-of-domain examples. We propose a combination of multitask training, data augmentation and contrastive learning to achieve better and more robust QE performance. We show that our method improves QE performance significantly in the MLQE challenge and the robustness of QE models when tested in the Parallel Corpus Mining setup. We increase the accuracy in PCM by more than 0.80, making it on par with state-of-the-art PCM methods that use millions of sentence pairs to train their models. In comparison, we use *thousand* times less data, 7K parallel sentences in total, and propose a novel low resource PCM method.

1 Introduction

The Quality Estimation (QE) task aims to model human perception of translation quality and predict the quality score an expert would give to a translation using only the source sentence and the translation. This requires the QE model to represent the cross-lingual similarity between source and hypothesis sentences while incorporating different features of the hypothesis sentence such as fluency, grammaticality and adequacy[1].

Human evaluations of machine translation are costly and time-consuming for a large-scale text dataset. References to evaluate machine translation performance are not readily available in many cases, especially in low-resource languages. Even if they do exist, they often assume a single, unique answer for correct translations, causing bias in the evaluation. Thus, it is academically and professionally of paramount importance to further develop reliable Quality Estimation metrics, which can ultimately eliminate the need for references and have unlimited potential for practical applications in machine translations.

Parallel Corpus Mining (PCM) is another critical task that can enable the creation of high-quality parallel data and reduce the need for considerable human effort. These mined parallel corpora could especially be helpful in low resource languages. On the other hand, current PCM methods require large amounts of parallel data, which creates a paradoxical loop that only large companies can break.

Quality estimation is uniquely linked with PCM since what makes a good translation most of the time makes a correct parallel too. Considering the similarity in the underlying goals of these two tasks, we expect models that can do one to perform, at least, acceptably in the other. However, Zhao et al. (2020) have shown that models that can do corpus mining fail in QE and propose a resource prudent method to bridge the gap. We show that the gap exists in the other direction and we introduce simple and valuable solutions.

In chapters 3 and 4, we introduce our method MultiQE and its base variants. Since we do not want to depend on additional cross-lingual data, we propose using multitask training with monolingual linguistic inference and semantic similarity data. We also experiment with using multitask feature extraction and compare our methods with SoTA QE methods in the Multilingual Quality Estimate (MLQE) dataset (Fomicheva et al., 2020b).

In chapter 5, we use data augmentation techniques in combination with multitask training to train more robust QE models and check their robustness in the Parallel Corpus Mining setup using the TATOEBA(Tiedemann, 2020) and

---

[1] Fluency measures whether a translation is fluent, regardless of the correct meaning, while Adequacy measures whether the translation conveys the correct meaning, even if the translation is not fully fluent (Snover et al., 2009)

Findings of the Association for Computational Linguistics: ACL 2022, pages 533 - 543

BUCC(Zweigenbaum et al., 2018) datasets. We use the term robust QE models to refer to models that can overcome the problem of just focusing on grammaticality/fluency, which causes SoTA QE models to fail in PCM. Our method outperforms SoTA QE models on PCM with a substantial margin, up to 0.80 difference in accuracy score in TATOEBA.

In addition, we compare our method with high resource methods like LASER (Artetxe and Schwenk, 2019) and LaBSE (Feng et al., 2020) which are trained on vast amounts of parallel data and achieve SoTA performances on PCM. Our method essentially offers a better and more robust QE model that is trained with very little data (thousand times less data) compared to these models. The goal in comparing to these high resource methods is to show that our proposed method achieves good enough performance to be a viable *low resource* PCM method. Our contributions in this paper can be summarized as below.

- We propose using multitask training for QE with STS (Semantic Textual Similarity) and MNLI (Multi-Genre Natural Language Inference) and show that even though these datasets are monolingual, multitask training can improve QE performance in MLQE significantly.

- We propose a robustness test for QE models through the PCM setting showing that SoTA QE models fail this test. We test how our multitask training method performs and propose using negative data augmentation to improve robustness further. We demonstrate that multitask training and negative data augmentation improve the robustness of QE models with an 0.80 increase in accuracy in the TATOEBA challenge.

- We propose a viable low resource corpus mining approach involving a sentence embedding model trained with the contrastive loss on the QE dataset and our robust QE model. We show that our method performs better under low resource conditions and is even comparable in high resource settings to SoTA in Parallel Corpus Mining.

2 Related Work

2.1 Quality Estimation

State of the art in QE In sentence-level Quality Estimation, multilingual language models as well as machine translation models are used for getting sentence representations as features to train quality estimation models (Yankovskaya et al., 2019), (Kim et al., 2017), (Zhou et al., 2019) (Peters et al., 2018). Similarly TransQuest (Ranasinghe et al., 2020) uses a cross-lingual transformer language model, XLM-R (Conneau et al., 2019), to extract features for sentence-level Direct Assessment scores and achieves SoTA performance in WMT-2020 QE task. This MonoTransQuest architecture will be used as our baseline.

Multitask Learning in QE Multitask learning is shown to be effective for QE. Kim et al. (2019) create a combined loss focusing on all QE tasks at once. They train a bilingual BERT to extract sentence representations. This model simultaneously predicts word quality tags(GOOD or BAD from the word level QE task) HTER score and takes the last hidden layer as the features for sentence level QE. They limit their work to signals from the MLQE dataset's word and sentence level tasks and do not apply to external datasets, unlike our work.

External Signals in QE Lo (2019) enhance their embeddings with semantic role labels and show that it improves QE performance, demonstrating the importance of semantic features in QE. Martins et al. (2017) use part of speech tagging and show that it can also improve the QE performance.

Usage of NLI and STS Pretraining the backbone via multitask training, using NLI and STS, has been shown to improve performance in translation evaluation with references. By allowing the backbone network to learn the cross relations between sentences from different aspects, Sellam et al. (2020) use this framework by including the linguistic inference task and achieve SoTA performance on machine translation evaluation with references. Another method that performs comparably is (Kane et al., 2020), where the authors use separately pretrained models to extract features and later train a final layer to evaluate translations with references.

2.2 Cross-Lingual Alignment

Motivation for Alignment Zhao et al. (2020) find that cross-lingual encoders such as XLM (Lample and Conneau, 2019) and M-BERT make mistakes in QE. They realize that the same sentence in different languages are not close to each other in the multilingual embedding space due to changing sentence structures, which they call semantic mismatch. Zhao et al. (2020) show that aligned embeddings perform much better than directly using the backbone. Since we want to benefit from monolingual datasets, we wanted to check how aligned feature extractors would fare against regular multitask training and the current SoTA in QE.

Motivation for Translation Recent work has shown that in some cases, translating one of the sentences can also work just as well as alignment (Conneau et al., 2018). Hence we also compare translating one of the sentences to aligning the representations of the non-English sentences from the XLM-R model similar to Conneau et al. (2018).

2.3 Parallel Corpus Mining

State of the art in PCM For Parallel Corpus Mining, models are generally trained on large parallel corpora. Artetxe and Schwenk (2019) train an encoder-decoder network on large scale translation data and use the encoder output as an embedding space to compare sentences. Yang et al. (2020) train a network on the translation ranking problem, sampling a number of negative examples from the corpus for each input sentence.

Motivation for using QE in PCM Reimers and Gurevych (2020) train a cross-lingual language model(student) to imitate the embedding space of another sentence embedding model(teacher) trained on a related task like paraphrase detection, STS or NLI. They show that the usage of external tasks can improve performance in PCM. Although their method is remarkable, it still requires a lot of parallel data to align the XLM-R with the embeddings of the new network. We also observe that alignment under low resource conditions is not very effective. During our experiments, we looked into viable ways of using QE data for training models to perform well in PCM with low resource limitations in mind. Since all these methods use a large amount of parallel data from a variety of sources and datasets, introducing a method that can achieve similar scores with very little data is an important goal to achieve.

3 Quality Estimation

3.1 Method

We compare three different approaches to incorporating STS and NLI tasks into QE. The first one is direct multitask training. The second and third methods use pretraining separate backbone architectures on these tasks and using them to extract features. Because the STS and NLI backbones are trained on monolingual data, we either use cross-lingual alignment of sentence embeddings or translate the non-English sentence to English.

3.1.1 Multitask Training

In this method, we train a single backbone XLM-R model with three classification heads on the STS-B, MNLI and QE tasks. This model will be referred to as MultiQE Multitask. By not doing any explicit alignment, we test if the XLM-R model trained for a cross-lingual task (QE) will benefit from multitask training that includes monolingual data. In Figure 1a, we illustrate the structure of the multitask learning framework.

The model is first trained for three epochs and, later, only the quality estimation head with the backbone is fine-tuned for another epoch on QE following insights from Sellam et al. (2020)

3.1.2 Multitask Feature Extraction

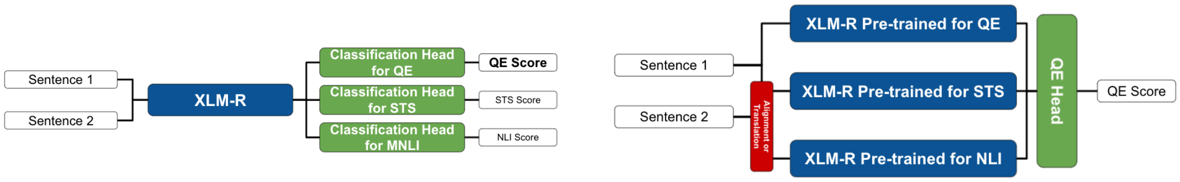
We train three backbones on the STS-B, MNLI and QE datasets and use the extracted features from these models to train a final layer for predicting QE scores. For this model, we compare two approaches: the first one is named MultiQE Alignment and is explained in section 3.1.3; the second one is MultiQE Translation, where, instead of aligning sentence embeddings, we translate the non-English sentence to English with Google Translate before inputting the sentence pairs to STS and NLI backbones. In Figure 1b, we show the general architecture of MultiQE Alignment and Translation. In this architecture, translation and alignment are not used simultaneously. When we use translation, the alignment part is not used and vice versa.

3.1.3 Cross-lingual Alignment model

We chose to tackle the semantic mismatch problem with a cosine similarity based sentence alignment similar to Conneau et al. (2018). This alignment pushes the sentence embeddings of the sentences in the non-English languages towards the embeddings of the translations of those sentences in English.

We align the STS and NLI input feature extractors in MultiQE Alignment, using data we get from OPUS with the cosine similarity objective in Equation 1. Given a set of parallel sentences $X = \{(x_i, y_i) \mid i = 1, 2, ..., K\}$, we fine tune the model to minimize L_A in Equation 1.

$$L_A(X) = \sum_{(x_i,y_i)\in X} (1 - \cos(x_i, y_i)) \qquad (1)$$



(a) Multitask pretraining for QE: MultiQE Multitask. The three classification heads share the same backbone and the backbone weights are trained during all three phases. Only the head for QE is used after training for obtaining the QE score. Here the classification heads are only a linear layer on top of the mean pooled output

(b) Multitask feature extraction for QE: MultiQE Alignment/Translation. All three backbones are pre-trained on the respective tasks with classification heads on top. The outputs of the backbones are mean pooled to create sentence features. The final QE Head is a two layer fully connected network that is trained on the MLQE dataset.

Figure 1: MultiQE Models.

Dataset	**Size**	**Language Pairs**	**Usage**
TATOEBA	<1K	en-de, en-zh, ne-en, si-en	To test performance on Parallel Corpus Mining
BUCC	<8k	en-de, en-zh	To test performance on Parallel Corpus Mining
MLQE	7K(Train) 1K(Test)	en-de,en-zh,ro-en,et-en,ne-en,si-en	To train all MultiQE models and test them for QE performance
OPUS(JW & GNOME)	25K(Train) 3K(Test)	en-de,en-zh,ro-en,et-en,ne-en,si-en	To train and test the alignment module in MultiQE Alignment

Table 1: Parallel datasets, their sizes and how they are used in our methods. The MLQE dataset is created by employing annotators on outputs of machine translation models on the corresponding language. The sentence pairs are labeled on the quality of the translation.

We test the effectiveness of the alignment using the 3K test sentences we have put aside and measure the cosine similarity before and after alignment, which increases on average from 0.64 to 0.96.

4 Quality Estimation Experiments

This section will go over the dataset, results, significance test, and ablation study for our experiments on the MLQE dataset.

4.1 Datasets

We used the Semantic Textual Similarity - Benchmark(STS-B) dataset for the STS task. This task measures the degree of meaning similarity between sentences with a score ranging from 1-5. STS-B is a collection of English sentence pairs extracted from different publicly available sources.(Cer et al., 2017) (Wang et al., 2018)

For the natural language inference tasks, we use the Multi-Genre Natural Language Inference (MNLI) dataset. The MNLI dataset includes both written and spoken text from various sources. (Williams et al., 2018). The task is to predict the label of entailment, neutral, or contradiction based on a premise and a hypothesis text.

For training and testing on the QE task, we use the Multilingual Quality Estimation (MLQE) dataset, which is derived chiefly from Wikipedia articles (Fomicheva et al., 2020a) and contains language pairs from high (en-de, en-zh), medium (ro-en, et-en), and low (ne-en, si-en) resource languages. Each pair has human labels for 7K train, 1K validation and 1K test translation pairs. Quality scores are collected by showing source sentences with translations to 3 experts and averaging the normalized scores.

For the cross-lingual alignment (section 3.1.3), we use sentence pairs from the JW(Agić and Vulić, 2019) and GNOME(Tiedemann, 2012) dataset. We use a small subset(25K) to do the alignment and 3K sentences to test the quality of the alignment, taking low resource conditions into account.

4.2 Results

We evaluate our models on the MLQE test set and use Pearson Correlation with human judgment as our primary measure. The results of our methods are in Table 2. We include (Kepler et al., 2019) because it was used as the baseline in the WMT2020 QE challenge. MonoTransQuest is included because it achieves SoTA performance in QE and is the winning entry of the 2020 WMT QE challenge. We use the MonoTransQuest model with no ensemble to have a meaningful comparison.

In Table 2, we find that multitask training (MultiQE Multitask) and translation (MultiQE Translation) outperform SoTA on all of the language pairs with MultiQE Multitask leading in 4 out of the 6 language pairs. Comparing MultiQE Align-

Models	**en-de**	**en-zh**	**ro-en**	**et-en**	**ne-en**	**si-en**
OpenKiwi (Kepler et al., 2019)	0.145	0.190	0.684	0.477	0.386	0.373
MonoTransQuest* (Ranasinghe et al., 2020)	0.408	0.471	0.881	0.754	0.769	0.634
MultiQE Translation(Ours)	0.406	0.486	**0.889**	**0.762**	0.767	0.665
MultiQE Alignment(Ours)	0.415	0.483	0.881	0.756	0.772	0.656
MultiQE Multitask(Ours)	**0.418**	**0.512**	0.879	0.755	**0.777**	**0.675**

Table 2: Pearson Correlation with Human Judgment. We observe that multitask training gives the best performance in 4 out of 6 language pairs, while for the mid-resource languages translating the non-English sentence outperforms other methods. We can infer that QE performance can be improved with monolingual NLI and STS data. *Results are reproduced using the Transquest pre-trained model zoo and testing scripts.

ment and MultiQE Translation with MonoTransQuest, all our methods are comparable with previous SoTA if not better.

Among our methods, MultiQE Multitask performs better and is more computationally efficient than MultiQE Alignment and Translation. Since the alignment and translation methods use multiple backbones, they require more computational power in training and inference.

4.2.1 William's Test

Correlation scores by themselves are not enough to make conclusions. Therefore, we perform a William's test to check the significance and the inter-correlation between the outputs of the methods. The William's test is performed with the language pair *en-zh*. If we look at Figure 2a, the P-values are below 0.05, suggesting that our increases in correlation are statistically significant.

In Figure 2b, we find that MultiQE Translation, Alignment, and MonoTransQuest models correlate highly with each other, while MultiQE Multitask can be separated from the others. We would expect a certain level of correlation among these methods because they are run on the same task. However, the high correlation among the first three methods is mainly due to their shared pre-trained backbones.

4.3 Ablation Study

Given that the MultiQE Multitask model gives the best performance in QE, we perform the ablation study on this model. The results below (Table 3) are for the *en-zh* language pair. The scores represent Pearson Correlation with Human Judgment. The ablation study explores the effect of these datasets in the pretraining stage. Hence, it does not take out the final QE fine-tuning. Looking at Table 3 we observe that STS helps the performance more than MNLI.

Models	**en-zh**
Multitask MNLI	0.444
Multitask STS	0.456
Multitask QE + MNLI	0.485
Multitask QE + STS	0.495
Multitask MNLI + STS	0.471
Multitask QE + MNLI + STS	0.512

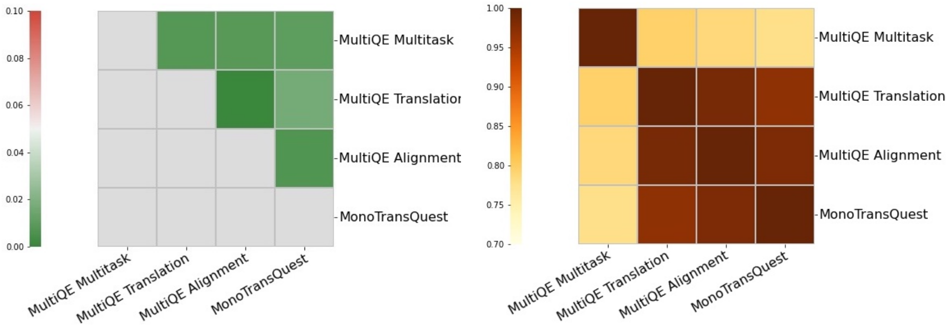
Table 3: Ablation study for the multitask pretraining step of MultiQE Multitask. We observe that the STS dataset improves QE performance more than the MNLI dataset.

5 Parallel Corpus Mining Experiments

In the PCM experiments, we will use MultiQE Multitask because it performs the best in Table 2.

5.1 Motivation

The initial motivation behind testing QE models on PCM sparked from the observation that QE models sometimes assign scores close to 1 to hypothesis sentences that are simple and correct even if they are entirely unrelated to the reference sentence. A sentence like *'December 14, 1964'* would get a high score with many references, most likely because they were never translated wrong and never received a bad score. Stemming from this observation, we wanted a natural setting where we could subject QE models to various sentence pairs and see if they were failing in a particular manner and if we could remedy this. Corpus mining was a good candidate because we would have to check every hypothesis sentence for each reference creating a variety of pairs and we would also have the gold labels for correct pairs. Essentially we used the PCM setup as a stress test for QE models. Observing how QE models failed this test and through solving both the computation and performance problems,



(a) P-values

(b) Correlation

Figure 2: P-values for the Williams Test and Correlation between model predictions. Note that all MultiQE models outperform MonoTransQuest significantly with $p \leq 0.05$. Additionally, we observe that the three methods in the bottom three rows correlate highly while MultiQE Multitask's behavior is different.

we have introduced a novel low resource corpus mining method based on the QE task.

5.2 Datasets

We evaluate our models for PCM on the BUCC (Zweigenbaum et al., 2018) and TATOEBA (Tiedemann, 2020) datasets. In the BUCC challenge, the goal is to extract ground-truth parallel sentences that are injected into relevant Wikipedia articles. The injected parallel sentences come from the News Commentary Dataset (Tiedemann, 2012). The performance is evaluated with the F1 score. In the TATOEBA challenge, the task is to find the translation for each sentence. The TATOEBA challenge contains translation pairs from various sources of more than 100 language pairs. For high resource language pairs, we use the 1000 sentence test set from LASER repository[2] because the methods we compare to (Reimers and Gurevych, 2020; Artetxe and Schwenk, 2019; Feng et al., 2020) also used this test set. However, for low resource languages that are not present in the LASER repository, we use the TATOEBA (2021-08-07) dataset.

5.3 Method

Here we will introduce our negative data augmentation scheme and how we offer to solve the computational cost problem by training a sentence embedding model with contrastive loss.

5.3.1 Model Training

For parallel corpus mining, we use a scoring model, MultiQE Multitask, and a filtration model. The scoring model takes sentence pairs as inputs and when the size of the corpus to mine gets larger, the cost for computing scores of all sentence pairs gets too high as explained in Reimers and Gurevych (2019). To tackle this, we train a sentence embedding model to do pre-filtration of the raw corpus to reduce the search space to a reasonable size. The filtration model is only used for pre-filtration and not the final sentence pair scoring. For small datasets, the scoring model can be used alone.

The sentence filtration model is trained on the MLQE training data using a contrastive loss. For a set of sentence pairs $I = \{(x_i, z_i) \mid i = 1, 2, ..., N\}$, we sample a subset of n negative samples for each x_i to form the set $\hat{I}$ such that $\hat{I} = \{(x_i, z_{j_{j \neq i}}) \mid i, j = 1, 2, ..., N\}$. Here, we choose n to be 3, exclude samples from I that have a lower quality score than 0.7, and include them in $\hat{I}$. The labels, Y_F for filtration, for each pair in set I are 1 and the labels for each pair in $\hat{I}$ are 0. The filtration model is later trained on the two sets using the loss function given in Equation 2 from Hadsell et al. (2006):

$$L_F(I, Y_F) = \\ (1 - Y_F)\tfrac{1}{2}D(I)^2 + (Y_F)\tfrac{1}{2}\{\max(0, m - D(I)\}^2 \tag{2}$$

$D(I)$ represents the similarity metric given a set of sentence pairs I and the subscript F denotes that the labels and loss are for the filtration model. We calculate $D(I)$ as the cosine similarity between the embeddings $(G(x_i), G(z_i))$ of the two sentences (x_i, z_i) where G is the embedding network

$$D(I) = \frac{G(\vec{x_i}) \cdot G(\vec{z_i})}{\|G(x_i)\|\|G(z_i)\|} \tag{3}$$

The MultiQE Multitask model for scoring on the other hand, is trained on the MLQE with two variations. The first model is trained on the training set from MLQE datasets as before (section 3.1.1), and the second model, which we will call MultiQE Multitask + DA(Data Augmentation), is trained with augmenting the dataset similar to our method

Table 5: F1 Scores for the BUCC 2020 Corpus Mining Challenge and the amount of parallel data used by that model for that language pair. Our method gets a lower score than the SoTA. However, when the extracted false positives were manually inspected, we found that most were viable sentence pairs. The issue with the BUCC dataset has been discussed in previous work in Reimers and Gurevych (2020). We analyzed the reference sentences from the news dataset and observed that our method gave the correct parallel the highest score with close to 100% accuracy.

for contrastive learning here, but instead of having labels 0 and 1, as in Y_F, here we keep the original quality scores as the label set and give the negative samples a quality score of 0 and once again train our model in a multitask learning framework with the STS and MNLI data until convergence.

5.3.2 Corpus Mining Inference

TATOEBA has an equal number of sentences in both languages and we know that every sentence has a pair; the goal is to find the best sentence for each input. The test sets are reasonably small, so we directly use the scoring model to create the score matrix and pick the hypothesis with the highest score for each reference.

Because the BUCC filtering task has a more extensive test set, we do corpus mining in two stages. First, we use the trained filtration model to compute the sentence embedding for each sentence. Then we calculate the similarity matrix representing the similarities by multiplying the embedding vectors corresponding to every possible sentence pair. Then, for each sentence in the source and target domain, top-n sentences are selected to be scored. The trained MultiQE Multitask model then scores these sentences. Then, for each sentence in the source and target domain, the best potential pair is selected by eliminating sentences whose scores are below a threshold. The QE scores that the MultiQE Multitask model provides range from 0-1 and the threshold score is determined similar to Reimers and Gurevych (2020) as the score that gives the best F1 score on the train set. The sentence selection is made in both directions and the intersection of the forward and the backward set is selected as the final filtered set.

5.4 Experiments

In table 4 we show that our proposed method of multitask training and data augmentation is extremely effective in improving the robustness of QE models. We obtain an average performance increase of 0.80 in accuracy compared to the SoTA QE method. We compare our method with Transquest (Ranasinghe et al., 2020) because both methods use XLM-R as the backbone and train on the exact same QE data. Our method performs comparably or better than extremely high resource methods like LASER (Artetxe and Schwenk, 2019) and Knowledge Distillation (Reimers and Gurevych,

Table 6: A Random selection of false-negative pairs that the MultiQE Multitask + DA extracted from the BUCC de-en task. We can clearly see that while these sentences are labeled as negatives, they are actually meaningful parallel sentences supporting the existing arguments in the literature regarding the BUCC dataset.

2020) that require a lot more parallel data. Hence, these results become significant if we consider them together with the amount of parallel data used to train these models, which can be found in the same table.

The results are similar for the BUCC challenge (Table 5), where our method achieves comparable scores to SoTA methods that are trained on more than *thousand* times the data. We can claim comparability because the F1 score in the BUCC task needs to be understood with a grain of salt. In Table 6 we give some random examples of false negatives that are included in our model's selection of parallel sentences. As we can see, many of these sentences are as good parallels as the gold label set. As we have mentioned in Section 5, the BUCC task injects news commentary data into Wikipedia and expects any method to only extract the injected data. This implicitly assumes that there are no correct parallel sentences within Wikipedia. Hence, the error our model displays is not failing to find correct parallels for hypothesis sentences but finding parallels within the Wikipedia corpus. We have manually analyzed 200 sentences and found that 155 of them can actually be considered good parallels. This issue has been discussed in previous work as well (Reimers and Gurevych, 2019; Jones and Wijaya, 2021).

6 Discussion

We show that semantic similarity and linguistic inference improve QE performance. We test for significance and show that our methods outperform SoTA QE methods(Table 2).

This intuition that pretraining with related tasks, especially with STS and NLI, is helpful for evaluating translations is in line with background and findings from Sellam et al. (2020) and Kane et al. (2020). Moreover, QE benefiting from monolingual data shows that XLM-R can utilize the labels in monolingual datasets to make better inferences in a cross-lingual task. This is most likely because it is already a cross-lingual language model.

Additionally, we show that multitask training for QE can improve the robustness of the model. We demonstrate **improvements in accuracy around 0.50 in the TATOEBA experiments** (Table 4) over other SoTA QE model. The robustness in the corpus mining task can be attributed to embedding information learned from the NLI and STS tasks and the distribution of these datasets, where we have negative samples that allow our model to learn to eliminate unrelated sentences.

We show that SoTA QE models yield unexpectedly poor performance in a PCM setting(Table 4). This is mainly due to how the QE data is created. The dataset only consists of sentence pairs generated by NMT models, which are translations of each other. They are either good or bad translations in a grammatical sense, but there are no non-translations, i.e., sentence pairs that are grammatical but are just unrelated. Hence a model trained on QE data only focuses on fluency and grammaticality and may unexpectedly rewards basic sentences where NMT models do not make mistakes because they always have a quality score of 1. To remedy this problem, we used negative data augmentation to "balance" the dataset and showed that this improves the performance on PCM, resulting in **an additional 0.30 increase and a total of 0.80 increase in accuracy**(Table 4).

Our QE models process input sentences as pairs, bringing up the computational cost problem. Solving this with the sentence filtration model we train using contrastive loss enables the use of our QE method in large filtration tasks. Making it a good low resource corpus mining method that can achieve on par results with SoTA methods (Tables 4 and 5). The importance of this contribution is amplified when we consider that our method is trained only using 7K parallel sentences compared to other PCM methods, which are trained on the order of millions of sentences.

Throughout our experiments, we keep low resource limitations in mind. While we acknowledge that collecting more data across different families of languages is an option to scale methods to low resource languages. We argue that exploring the improved usage of less data with *better* labels promises another important avenue to make useful methods like QE or PCM available in low resource languages.

7 Future Work

To further our work, we plan to explore contrastive loss fine-tuning with self-supervision to improve QE performance planning and further reduce the need for labels. Self-supervised learning is an exciting way of forcing a neural language evaluator to abstain from certain mistakes. This approach can force invariance or target to reduce certain types of errors. The nature of the information attained by the network is primarily dependent on the negative sample generation process.

Another interesting avenue to explore is using QE in active learning for machine translation as a scheduling or training signal.

A Appendix A

In this part, we will look over the distribution of QE scores for the language pairs in the MLQE dataset. The MLQE dataset is constructed - source sentences from Wikipedia are selected and translated using NMT methods; expert translators then score the outputs following FLORES methodology. This in turn had a few critical effects. As we mentioned in the paper, the first is that no sentence has been paired with grammatically correct sentences but is not related to that sentence. Every hypothesis sentence is intended to be a reasonable translation of that source sentence.

The second outcome we have observed is that the QE model essentially adapts to the errors of the NMT model. The QE models only encounter low scores in the type of errors that NMT models are prone to making. Vice-versa, they see high scores, generally 1s in basic sentences where NMTs never make errors. This creates a specific type of error in QE performance where sentences that are easy to translate or need no virtual translation besides a few dictionary operations always receive high scores from the QE model no matter the source sentence, e.g., "June 10 1981" and "10. Juni 1981" from en-de. These types of elementary sentences were the highest scoring candidates for sometimes thousands of sentences in the BUCC dataset, constantly receiving scores close to 1.

The distribution of the scores is mostly consistent with our findings. We only see that the low resource language pairs seem to have a better distribution across the board. While this seems to be a better case, it is not because the problem we mentioned does not exist, but because the NMT models that do the translation for these low resource languages perform worse.

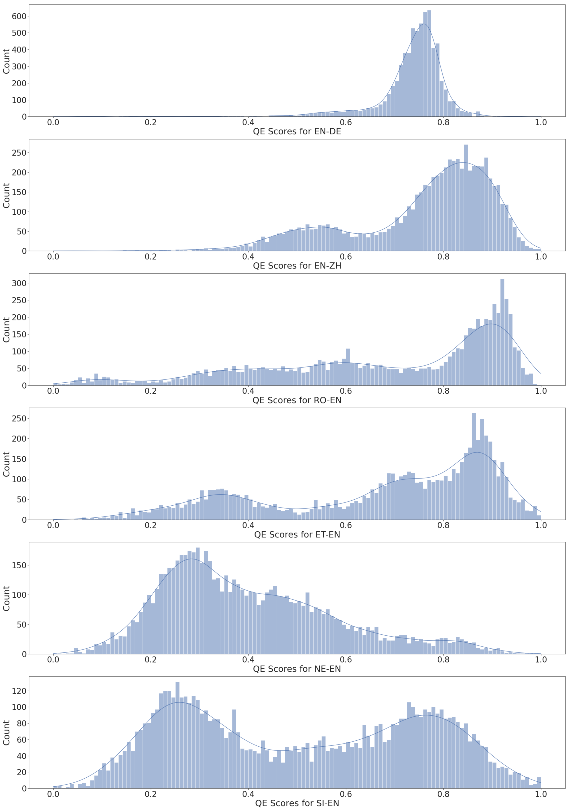

Figure 3: Distribution of QE scores from the MLQE datasets train split for all 6 language pairs

End-to-End Segmentation-based News Summarization

Yang Liu, Chenguang Zhu and Michael Zeng
Microsoft Cognitive Services Research
`{yaliu10, chezhu, nzeng}@microsoft.com`

Abstract

In this paper, we bring a new way of digesting news content by introducing the task of segmenting a news article into multiple sections and generating the corresponding summary to each section. We make two contributions towards this new task. First, we create and make available a dataset, SEGNEWS, consisting of 27k news articles with sections and aligned heading-style section summaries. Second, we propose a novel segmentation-based language generation model adapted from pre-trained language models that can jointly segment a document and produce the summary for each section. Experimental results on SEGNEWS demonstrate that our model can outperform several state-of-the-art sequence-to-sequence generation models for this new task.

1 Introduction

In recent years, automatic summarization has received extensive attention in the natural language processing community, due to its potential for processing redundant information. The evolution of neural network models and availability of large-scale datasets have driven the rapid development of summarization systems.

Despite promising results, there are specific characteristics of the traditional summarization task that impedes it to provide more beneficial ways of digesting long news articles. For instance, current news summarization system only provides one genetic summary of the whole article, and when users want to read in more details, the generated summary is not capable of helping navigate the reading. For example, given a news report, current system will output several highlight summaries (Nallapati et al., 2017; Liu and Lapata, 2019; Zhang et al., 2020). Under this circumstance, if a user expect to read more details about one highlight, he will still need to browse the whole article to locate related paragraphs. Meanwhile, when processing a long news article, current systems usually truncate the text and only generate a summary based on the partial article (Cheng and Lapata, 2016a; Zhang et al., 2020). Although this is reasonable since most important content usually lies in the initial portion, it also makes it difficult for users to quickly access information beyond the truncated portion.

In this paper, we propose a new task of Segmentation-based News Summarization. Given a news article, we aim to identify its potential sections and at the same time, to generate the corresponding summary for each section. This new task provides a novel alternative to summarizing a news article. We argue that it can lead to a more organized way of understanding long articles and facilitates a more effective style of reading documents.

First, segmenting a news article can provide a structural organisation of the content, which is not only helpful to reading but also benefit many important NLP tasks. For example, Brown et al. (1983) states that this kind of multi-paragraph division is one of the most fundamental tasks in discourse. However, many expository texts, like news articles, instruction manuals, or textbooks consist of long sequences of paragraphs with very little structural demarcation (Hearst, 1994), and for these documents a subtopical segmentation can be useful. Second, generating concise text descriptions of each sections further reduces the cognitive burden of reading the article (Florax and Ploetzner, 2010). Previous studies (Paice, 1990; Hearst, 1997) present that subtopic segments with their headings is an effective alternative to traditional summarization tasks.

In this paper, we make two main contributions towards the development of Segmentation-based News Summarization systems.[1]

First, we create and publicize a large-scale

Man pleads not guilty to allegedly body-slamming Montana boy for not removing hat during National Anthem

(CNN)A man accused of assaulting a 13-year-old boy in Montana after the boy wouldn't remove his hat during the National Anthem at a rodeo pleaded not guilty Wednesday to a felony charge of assault on a minor.

Curt James Brockway, wearing jeans and a short-sleeved plaid shirt, stood with his hands behind his back and looked intently at the judge during the short morning hearing at Mineral County Court in the town of Superior.

Brockway was arrested on suspicion of assaulting the boy August 3 during a rodeo at the Mineral County Fairgrounds in Superior.

Brockway told police the boy was wearing a hat as the National Anthem began, and he asked him to remove it because it was disrespectful to wear it during the anthem.

→ *The boy suffered a concussion and a fractured skull, court documents say*

Brockway was put on probation in 2011 -- and given a suspended 10-year prison sentence -- after being convicted of assault with a weapon.

In that case, a prosecutor alleged Brockway had taken out a gun and threatened to shoot three people during a traffic dispute on a narrow road in Mineral County in September 2010, according to court documents.

→ *Probation relates to 2011 assault conviction*

Lance Jasper, Brockway's attorney, said last week that his client is a military verteran who has a severe traumatic brain injury and has problems with impulse control. Between that and being a disabled veteran who is "uber patriotic," Jasper said, Brockway is influenced by the rhetoric of President Donald Trump.

Referring to times the President has spoken out against athletes and others that kneel or protest during the National Anthem and when he suggested possible jail time or loss of citizenship for burning the American flag, Jasper said, "Curt takes that literally and views the President as the commander in chief and when he sees it happening, he feels he needs to do something about it."

→ *What his attorney says about the rodeo incident*

Figure 1: One example from the segmentation-based summarization task SEGNEWS. The news article is taken from a CNN news article and we truncate the article for display. CNN editors have divided this article into several sections and written a heading to section. The goal of this task is to automatically identify sub-topic segments of multiple paragraphs, and generate the heading-style summary for each segment. Dotted lines in the figure indicate segment boundaries. In this article, paragraphs 1,2 are annotated as the first segment, paragraphs 3,4 are annotated as the second segment, paragraphs 5,6 are annotated as the third segment, and paragraphs 7,8 are annotated as the forth segment. To the right of the article are the heading-style summaries for segments. Since the first segment is usually an overview of the news, we do not assign a summary to it.

benchmark, SEGNEWS, for Segmentation-based News Summarization task. Figure 4 shows one example article and its aligned segmentation and summaries from SEGNEWS.

Second, we propose a novel end-to-end approach for this task, which can jointly segment an article while generating the corresponding summaries. These two sub-tasks can learn from each other via a shared encoder. The model is equipped with a segmentation-aware attention mechanism, allowing it to capture segmentation information during summary generation. One important advantage of our framework is that it is a non-invasive adaptation of the Transformer (Vaswani et al., 2017) model, i.e. it does not alter the inner structure of Transformers. And our framework can integrate many pretrained language generation models, including BART (Lewis et al., 2020), GPT (Radford et al., 2019) and UNILM (Bao et al., 2020). This enables our framework to enjoy a high degree of flexibility and better performance.

We compare the proposed framework with several state-of-the-art methods on the SEGNEWS benchmark. Both automatic evaluation and human evaluation demonstrate the superiority of our model.

2 Related Work

2.1 Document Summarization

Document summarization is the task of automatically generating a shorter version text of one or multiple documents while retaining its most important information (Radev et al., 2002). The task has received much attention in the natural language processing community due to its potential for various information access applications. Most large-scale summarization datasets are built on news articles. Popular single-document summarization benchmarks include CNN/DM (Hermann et al., 2015; Nallapati et al., 2016; Cheng and Lapata, 2016a), NYT (Durrett et al., 2016) and XSum (Narayan et al., 2018).

Document summarization can be classified into different paradigms by different factors (Nenkova and McKeown, 2011). And among them, two have consistently attracted attention. *extractive* approaches form summaries by copying and concatenating the most important spans in a document; while in *abstractive* summarization, various text rewriting operations generate summaries using words or phrases that are not in the original text.

Recent approaches to extractive summarization frame the task as a sequence labeling problem by taking advantage of the success of neural network architectures (Bahdanau et al., 2015). The idea is to predict a label for each sentence specifying whether it should be included in the summary. Existing systems mostly rely on recurrent neural networks (Hochreiter and Schmidhuber, 1997) or Transformer model (Vaswani et al., 2017) to encode the document and obtain a vector representation for each sentence (Nallapati et al., 2017; Cheng and Lapata, 2016b; Liu et al., 2019).

In recent years, neural sequence-to-sequence approaches dominate abstractive summarization methods. Rush et al. (2015) and Nallapati et al. (2016) are among the first to apply the neural encoder-decoder architecture to text summarization. See et al. (2017) enhance this model with a pointer-generator network and a coverage mechanism. Pretrained language models have recently emerged as a key technology for improving abstractive summarization systems. These models first pretrain a language model with self-supervised objectives on large corpora and then fine-tune it on summarization datasets. Liu and Lapata (2019) combine a pretrained encoder based on BERT (Devlin et al.) with a randomly initialized decoder, demonstrating substantial gains on summarization performance. MASS (Song et al., 2019) is an encoder-decoder neural model pretrained with the objective of reconstructing a masked text and can be fine-tuned on summarization tasks. BART (Lewis et al., 2020) is an encoder-decoder Transformer (Vaswani et al., 2017) pretrained by reconstructing a text corrupted with several arbitrary noising functions. Bao et al. (2020) design UNILMv2, a Transformer-based neural network pretrained as a pseudo-masked language model.

2.2 Text Segmentation and Outline Generation

Text segmentation has been widely used in the fields of natural language processing and information extraction. Existing methods for text segmentation fall into two categories: unsupervised and supervised. TextTiling (Hearst, 1997) is one of the first unsupervised topic segmentation algorithms. It segments texts in linear time by calculating the similarity between two blocks of words based on the cosine similarity. Choi (2000) introduce a statistical model which can calculate the maximum-probability segmentation of a given text. The TopicTiling (Riedl and Biemann, 2012) algorithm is based on TextTiling, which uses the Latent Dirichlet Allocation to find topical changes within documents. LCSeg (Galley et al., 2003) computes lexical chains of documents and segments texts by a score which captures the sharpness of the change in lexical cohesion.

Supervised methods have also been proposed for text segmentation. Hsueh et al. (2006) integrate lexical and conversation-based features for topic and sub-topic segmentation. Hernault et al. (2010) use CRF to train a discourse segmenter with a set of lexical and syntactic features. Li et al. (2018) propose SEGBOT which uses a neural network model with a bidirectional recurrent neural network together with a pointer network to select text boundaries in the input sequence.

Recently, Zhang et al. (2019) propose Outline Generation task, aiming to identify potential sections of a multi-paragraph document and generate the corresponding section headings as outlines. This task is in form similar to segmentation-based summarization. However, there are two main differences. First, outline generation focused on academic or encyclopaedic documents, where the section headings are extremely short (on average less than two words) and cannot be considered as a summarization task. Second, since outlines care more about briefly describing their corresponding sections, headings in outlines are independently from each other. In segmentation-based summarization, despite describing the sections, heading-style summaries also devote to navigating the reading, and they are usually related and coherent in content.

3 The SEGNEWS Benchmark

3.1 Data Collection

In order to study and evaluate the Segmentation-based News Summarization task, we build a new benchmark dataset SEGNEWS. We take CNN website as our article source. As shown in Figure 1, there are a large part of CNN articles which are divided by editors into several sub-topic sections (see Appendix for details). And each section is assigned a heading-style summary also written by these editors. We collect articles published from 2017 to 2021, covering multiple CNN news channels, including US Politics, Business, Health, Entertainment, Travel and Sports. We filter articles with no sub-topic structures or editor written heading-style summaries. Since the first segment is usually an overview of the news, editors do not assign a summary to it. The resulting dataset contains 26,876 news articles. For each article, it has human annotated segmentation structures and each segment

# news articles	26,876
# paragraphs	40.31
# sections per article	3.17
# tokens per article	1362.24
# tokens per section summary	4.70

Table 1: Data statistics of the SEGNEWS dataset.

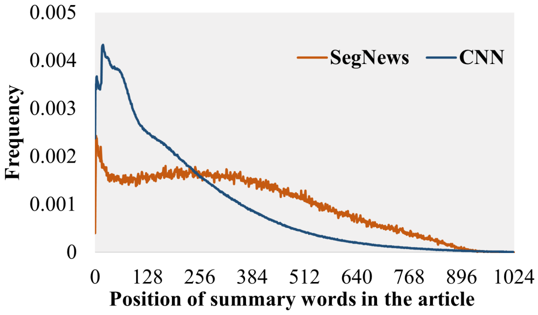

Figure 2: The frequency of the non-stop words in summary appearing at different positions of the source article. The positions range from [0, 1024].

has a human-written heading-style summary.

3.2 Data Statistics

Table 1 shows the overall statistics of our SEGNEWS benchmark dataset. We can see that the news articles in SEGNEWS contain rich structural information and are much longer (1,362 tokens per article) than traditional news summarization datasets: articles in CNN/DM (Cheng and Lapata, 2016b) dataset has an average length of 686.63 tokens and articles in NYT (Sandhaus, 2008) dataset has an average length of 800.04 tokens. This is in line with our motivation that segmentation-based summarization can help readers better understand longer articles.

It has been found that in many news articles, the most important information is often shown at the beginning (Kedzie et al., 2018). We compare SEGNEWS with CNN summarization dataset (Cheng and Lapata, 2016b) to investigate the difference of their positional bias. In Figure 2, we record the position of each non-stop word in the summary that also appears in the article. For both datasets, he beginning of article contains more summary words. However, different from conventional summarization dataset, SEGNEWS dataset has a much smoother position distribution and information in the middle of the article still contributes a lot to the summary.

4 Task Formulation

Given a multi-paragraph article, the segmentation-based summarization task aims to: i) identify sections of the article to unveil its inherent sub-topic structure, where each section consists of neighboring paragraphs with a coherent topic, and ii) generate the heading-style summary for each section to concisely summarize the section. Particularly, in one article, summaries of different sections should be coherent in content and consistent in style.

Formally, let d indicate a document consisting of paragraphs $[p_1, p_2, ..., p_M]$. The segmentation-based summarization task aims to recognize a sequence of section boundaries $[b_1, b_2, \cdots, b_{N-1}]$. These boundaries divide the document into N sections $s_1 = [p_1, ..., p_{b_1}], s_2 = [p_{b_1+1}, ..., p_{b_2}], \cdots, s_N = [p_{b_{N-1}+1}, ..., p_M]$. Meanwhile, summarization systems will generate the corresponding section summaries $[y_1, y_2, ..., y_N]$.

5 Systems for Segmentation-based News Summarization

In this section, we present two different frameworks to tackle the segmentation-based summarization task. In *Pipeline* approach, we first apply a segmentation model to identify potential sections, and then apply a generation model to produce the headings. In *Joint* approach, one neural model is able to jointly segment an article and produce the summaries. To achieve this, we design a novel segmentation-aware attention mechanism, which allows the model to capture segmentation information when generating summaries. This new attention mechanism can also be considered as a non-invasive adaption for conventional Transformer models. Thus, to take the most advantage of existing pre-trained models, we propose SEGUNILM and SEGBART which are respectively based on pre-trained UNILM model and BART model. They can be initialized completely from pre-trained models and achieve substantial improvement on segmentation-based summarization.

5.1 Pipeline Approach

Segmentation model We formulate the section identification process as a sequence labeling task. We insert a special symbol `[X_SEP]` at the boundary of paragraph p_i and p_{i+1} , and then concatenate all paragraphs into a single text input. A neural encoder is then applied to encode this input. Define u_i

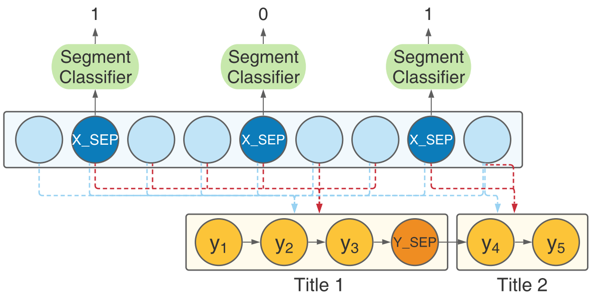

Figure 3: The overall framework of SEGTRANS model. The blue circles indicate input source text, where dark blue circles indicate paragraph boundaries. The yellow circles indicate output target text, where orange circles indicate heading boundaries. Dotted red lines indicate attention heads with segmentation-aware attention mechanism and dotted blue lines indicate attention heads with original full attention mechanism.

as the output vector of `[X_SEP]` after paragraph p_i. We then apply a binary classifier over u_i to obtain $y_i \in \{0, 1\}$. $y_i = 0$ indicates paragraph p_i and p_{i+1} are in one segmentation, and $y_i = 1$ indicates p_{i+1} should be the start of a new segment.

Generation model We then generate an aligned heading-style summary for each identified section s_j. The generation of each heading is independent. Here, we can choose existing extractive or abstractive summarization methods.

- TOPICRANK (Bougouin et al., 2013) is an extractive method for keyphrase extraction which represents a document as a complete graph depending on topical representations. We use the top ranked phrase as the summary for input section;
- SEQ2SEQ represents the sequence-to-sequence neural model, which is usually used in abstractive summarization. It first encodes the concatenated text of all paragraphs within this section, and the decodes the heading in an auto-regressive manner. In experiments, we try both non-pretrained Transformer model and pretrained UNILM and BART models as SEQ2SEQ models.

5.2 Joint Approach

Instead of relying on a pipeline framework, we can also tackle the segmentation-based summarization task with a single encoder-decoder neural model. This brings two main advantages. First, the encoders for segmentation and generation can be shared, benefiting both tasks as a multi-task learner. Second, we can decode all summaries in an auto-regressive manner. In this way, when the decoder generates the l-th heading, it will be exposed to the 1st to $(l-1)$-th generated headings. This is considerately helpful since in a news article, many headings are highly related and coherent in their content.

We use Transformer (Vaswani et al., 2017) as base model for the encoder and decoder. Formally, the encoder maps a sequence of tokens in the source document $\boldsymbol{x} = [x_1, ..., x_n]$ into a sequence of continuous representations $\boldsymbol{t} = [t_1, ..., t_n]$. Then a segment classifier is applied over output vectors of paragraph boundaries to identify correct segments $B = [b_1, b_2, \cdots, b_{N-1}]$ for the input article. The decoder then generates the tokens of target text $\boldsymbol{y} = (y_1, ..., y_m)$ auto-regressively based on the conditional probability: $p(y_1, ..., y_m | x_1, ..., x_n, B)$. As the decoder produces summaries for all sections in one pass, we add a special symbol `[Y_SEP]` between summaries from neighboring sections to indicate their boundaries. However, in this vanilla sequence-to-sequence model, during inference, the decoder is not aware of the segmentation results and can only implicitly use this information when decoding the summaries. Thus, to better jointly learn segmentation and generation tasks, we propose SEGTRANS model, which is equipped with Segmentation-aware Attention mechanism.

Segmentation-aware attention The multi-head decoder-to-encoder attention in a Transformer decoder defines that for a head $z \in \{1, \cdots, n_{head}\}$ at each layer, the model calculates attention probabilities a_{ij}^z against each source token x_j when generating the i-th token y_i.

$$q_i^z = W_q^z Y_i; k_j^z = W_k^z X_j, \tag{1}$$

$$a_{ij}^z = \frac{exp(q_i^{zT} k_j^z)}{\sum_{o=1}^{n} exp(q_i^{zT} k_o^z)}, \tag{2}$$

where $Y_i, X_j \in \mathbb{R}^d$ are the layer's input vectors corresponding to the token y_i and x_j, respectively. $W_q^z, W_k^z \in \mathbb{R}^{d_{head} * d}$ are learnable weights. n is the number of tokens in source input.

However, in segmentation-based summarization, when generating the heading for the i-th section, the decoder should focus more on the input tokens belonging to that section. Thus, we propose the segmentation-aware attention as follows.

We select a subset $\hat{z}$ of decoder heads to apply a segmentation mask to enforce that these heads only attend to the corresponding section. For a head in $\hat{z}$, Eq. 2 is modified to:

$$a_{ij}^{z} = \frac{exp(q_i^{zT} k_j^z) seg(y_i, x_j)}{\sum_{o=1}^{n} exp(q_i^{zT} k_o^z) seg(y_i, x_j)} \quad (3)$$

where $seg(y_i, x_j)$ is a indicator function. It equals 1 if and only if y_i and x_j both belong to the same section, and 0 otherwise. In this manner, parts of the heads in multi-head attention are able to dynamically capture segmentation information, while the other heads still model global features of the entire input article.

We illustrate a detailed example of our framework with segmentation-aware attention in Figure 3. We first encode the source text, and apply a segmentation classification layer over output vectors of paragraph boundaries. For this example input, the model classifies the first and the third paragraph boundaries to be segmentation points. Then the decoder will apply a segmentation-aware multi-head attention over the source outputs. It generates the summary for the first identified section with parts of the attention heads over only the first and the second paragraphs. After generating the first heading ending symbol `[Y_SEP]`, the decoder changes the segmentation-aware attention to the third paragraph for generating the summary for the second section.

The final loss for training SEGTRANS is the summation of the segmentation loss (binary classification loss) $\mathcal{L}_{\text{seg}}$ and generation loss (negative likelihood loss) $\mathcal{L}_{\text{gen}}$.

One advantage of our framework is that it is a non-invasive adaptation of the Transformer model, i.e. it does not alter the inner structure of Transformers. This is important since this adaptation can be applied to many popular pretrained language generation models (e.g. MASS, BART and UNILM), offering our framework a high degree of flexibility and better performance. In this paper, we also augment pre-trained UNILM and BART with this mechanism and propose SEGUNILM and SEGBART to further boost their performance.

6 Experiments

In this section, we conduct experiments on SEGNEWS dataset by comparing our proposed model with several strong baselines.

6.1 Experimental Settings

In pre-processing, all the words in news articles and headings are transformed to lower case and tokenized with wordpiece tokenizer from BERT (Devlin et al.). In data splitting, we guarantee the headings of articles in the test set have low bigram overlap with articles in the training set. We obtain a splitting of 21,748 articles in training set, 2,688 in validation set and 2,444 in test set.

We experiment under both non-pretrained and pretrained settings. In non-pretrained setting, we use a 6-layer Transformer encoder-decoder model (SEGTRANS) with 512 hidden size and 2,048 feed-forward size. In pretrained setting, we propose SEGUNILM and SEGBART which adopts the base version of UNILMv2 (Bao et al., 2020) and the large version of BART (Lewis et al., 2020) as the pretrained model. UNILMv2 is a Transformer-based neural network with 12 Transformer layers and 12 attention heads, pretrained as a pseudo-masked language model. BART is a Transformer-based neural encode-decoder model with 12 layers and 16 attention heads, pretrained via a denoising auto-encoder loss. Label smoothing is used with smoothing factor 0.1. For segmentation-aware attention, we choose the best c (number of segmentation-aware heads) by experiments on the validation set, and $c = 9$ for SEGUNILM and $c = 13$ for SEGBART provide the best performance.

During all decoding we use beam search (size 5), and tune α for the length penalty (Wu et al., 2016) between 0.6 and 1 on the validation set. To guarantee the number of generated headings can match the number of predicted source segments, we take a trick of only generating the end-of-generation token (`EOS`) when these two numbers match.

We compare the proposed joint models with two sets of strong baselines. The first set of baselines are vanilla sequence-to-sequence models. These models take complete raw articles as input and output the concatenated headings. The second set are pipeline models. As described, these systems first use a segmentor to divide the article into several sections, and then apply a generator to produce summary for each section.

In segmentation-based summarization, summarization systems require segmentation results. We set two settings of segmentation. For the first setting, we provide golden segments to the models to evaluate their performance of generating the summaries when given the correct segments. For the second setting, we require the models to first segment the article and then generate summaries for the predicted segments.

Vanilla Seq2Seq		R1	R2	RL			
Trans		8.66	1.51	8.16			
UniLM		19.22	7.18	16.99			
Pipeline		With Gold Segments			With Predicted Segments		
Segmentor	Generator	R1	R2	RL	R1	R2	RL
Transformer	Transformer	8.69	1.83	9.09	–	–	–
Transformer	TopicRank	5.09	1.14	6.28	–	–	–
Bart	Bart	21.42	7.76	19.28	16.01	5.27	14.37
UniLM	UniLM	21.76	8.22	19.75	16.27	5.45	14.65
Joint		R1	R2	RL	R1	R2	RL
SegTrans		8.94	1.85	9.35	–	–	–
SegBart		21.49	8.29	19.52	16.36	5.14	14.96
SegUniLM		**22.17**	**8.86**	**20.17**	**17.59**	**6.20**	**15.90**

Table 2: ROUGE F1 results on SegNews test set. R1 and R2 are shorthands for ROUGE scores of unigram and bigram overlap; RL is the ROUGE score of longest common subsequence. In pipeline approach, we try combinations of different segmentators and generators. Due to their failure on segmentation, non-pretraind models have very low ROUGE scores with predicted segments, and we do not compare them in the table.

Models	R1	R2	RL
SegUniLM	22.17	8.86	20.17
(c=12)	22.14	8.81	20.09
(c=8)	22.13	8.84	20.10
(c=4)	21.39	7.99	19.23
(c=0)	19.85	7.74	17.62
(w/o seg loss)	22.06	8.66	20.02

Table 3: Ablation study results on SegNews. We compare multiple variants of SegUniLM. c indicates the number of decoder heads modified into segmentation-aware attention. Be default, SegUniLM uses $c = 9$ to achieve the best performance. We also present a SegUniLM model without (w/o) segmentation classification loss, and it is trained solely by generation loss.

6.2 Evaluation Metrics

Evaluation metrics for summarization performance are ROUGE (Lin, 2004) F1 scores of the generated headings against the gold headings. We report unigram and bigram overlap (ROUGE-1 and ROUGE-2) as a means of assessing informativeness and the longest common subsequence (ROUGE-L) as a means of assessing fluency.

We use standard metrics *Pk* (Beeferman et al., 1999) and *WinDiff* (Pevzner and Hearst, 2002) to evaluate segmentation results. Lower scores of these two metrics indicate that the predicted segmentation is closer to the ground truth. A Even baseline is included for comparison where it segments the whole article evenly.

6.3 Results

Table 2 describes our summarization results on the SegNews dataset. The first vertical block includes the results of vanilla sequence-to-sequence models. Trans is the non-pretrained Transformer encoder-decoder model. UniLM and Bart are two pretrained baseline models. The second vertical block contains the results of pipeline models. We present the combinations of different segmentation models and generation models. For segmentor, we experiment non-pretrained Transformer model and pretrained Bart and UniLM models. For generator, we also include TopicRank, which is a classical extractive summarization method.

The last vertical block includes the results of our joint models: SegTrans, SegBart and SegUniLM. They respectively rely on non-pretrained Transformer and pretrained Bart and UniLM as backbone models. Segmentation-aware attention mechanism is used to augment these jointly trained systems.

We can see vanilla sequence-to-sequence models with no segmentation information input perform poorly on this task. End-to-end SegUniLM model achieves the best performance among all systems. SegUniLM outperforms the best pipeline system under both settings when gold segments or predicted segments are provided. This indicates SegUniLM has better overall performance and will be more useful when applied as practical applications. It also shows higher summarization results than vanilla UniLM model, confirming the effectiveness of segmentation-aware attention mechanism. SegBart and SegTrans also show similar superiority over their pipeline versions. Examples of system output are shown in Table 4.

Table 3 summarizes ablation studies aiming to assess the contribution of individual components of SegUniLM. We first modify SegUniLM by varying c, the number of heads of segmentation-aware attention. We can see the best results of ROUGE

Title: One JFK conspiracy theory that could be true	
Gold	1. LBJ had it done; 2. The military industrial complex did it; 3. The mob did it; 4. Oswald acted alone as part of an unknown conspiracy; 5. The CIA did it
Pipeline UniLM	Those Kennedys will never embarrass me again; Did Kennedy want to withdraw us troops from Vietnam ?; 3. Different mobs; other conspirators ?; Would America be OK with that ?
SegBart	1. They thought he was a crook; 2. He was going to pull American troops out of Vietnam; 3. The mob did this; 4. There were others, but who were they?; 5. The CIA ordered the killing
SegUniLM	1. Those Kennedy's will never embarrass me again; 2. He said he'd pull troops out of Vietnam; 3. Mob members claim they were witnesses to the alleged shootings; 4. there were more people who knew where Oswald was; 5. The CIA didn't release any of the good stuff
Title: This man is tasked with finding out who failed Larry Nassar's victims	
Gold	Seeking justice; A very youthful 68-year-old; A model independent prosecutor
Pipeline UniLM	Searching for truth; He couldn't stay retired; He didn't have an agenda
SegBart	Searching for the truth; Working with juveniles; No stone unturned
SegUniLM	Searching for the truth; He's has to do something; He doesn't have an agenda

Table 4: Gold reference summaries and automatic summaries produced by pipeline UniLM, SegBart and SegUniLM on the SegNews datasets. Semicolons indicate the boundaries of headings.

Model	WD	PK
Even	0.469	0.450
Transformer	0.563	0.462
Bart	0.484	0.411
Unilm	0.479	0.391
SegBart	0.471	0.405
SegUnilm	0.462	0.380

Table 5: Experimental results on document segmentation task. WD indicates *WinDiff* metric.

Model	Quality	Fluency
Pipeline UniLM	1.93	2.62
SegUniLM	2.17	2.59
Gold	2.44	2.79

Table 6: Human evaluation results based on summary quality and fluency.

are achieved when $c = 9$. With more or less heads modified as segmentation-aware attention heads, the summarization performance show a clear trend of decreasing. Also, as shown in the last column, when segmentation layer and segmentation loss are removed, we observe a sharp decrease on ROUGE scores. The results prove that both segmentation-aware attention and joint training provide improvement to the summarization results.

Table 5 describes the results on news segmentation task. SegUniLM achieves the lowest WD and PK scores, revealing its ability to identify the structure of a news article. Compared with Unilm model without the segmentation-aware attention, SegUniLM shows clear superiority on both metrics. The same trend is also observed in Bart related models.

6.4 Human Evaluation

In addition to automatic evaluation, we also assess system performance by eliciting human judgments on 20 randomly selected test instances. The evaluation study assess the overall quality and fluency of the summaries by asking participants to rate them. We present the news article to evaluators along with system generated heading-style summaries, and we ask evaluators to read the complete article, and give scores based on summary quality and fluency respectively. Participants can have three scores (1-low quality/fluency, 2-median quality/fluency, 3-high quality/fluency).

Gold summaries, outputs from pipeline UniLM and SegUniLM models are compared in evaluation. We invite three evaluators with linguist background to conduct the human evaluation. The averaged results are shown in Table 4. Overall, we observe pipeline UniLM and SegUniLM perform similarly on fluency, but SegUniLM shows its superiority on summary quality. Gold summaries are marginally better than automatic generated summaries.

7 Conclusion

In this work, we proposed a new task, segmentation-based news summarization. It aims to segment a news article into multiple sections and generate the corresponding summary to each section. This new task provides a novel alternative to digesting a news article. We built a new benchmark dataset SegNews to study and evaluate the task. Furthermore, we designed a segmentation-aware attention mechanism, which allows neural decoder to capture segmentation information in the source texts. We jointly train the model for generating summaries and recognizing news segments. Experimental results on SEGNEWS demonstrate that our framework produces better segmentation-based summaries than competitive systems.

8 Ethical Statement

We honor and support the ACL Code of Ethics. We have used only the publicly available news articles from the CNN website and adhere to their only-for-research-purpose guideline. Meanwhile, to make sure the downstream usage of the data will not break the permission of CNN website, we only release the URLs of these articles along with a script to download and process them.

The content of the news and summaries only reflect the views of the media, and should be viewed with discretion.

A Build SEGNEWS from CNN website

The SEGNEWS dataset is built from news articles on CNN website. For many news reports on CNN, news editors manually divide them into several sections and write a heading-style summary for each section. As illustrated in Figure 1, in a display of this news article[2], it has a general title “Global businesses must address climate change before it’s too late”. Below the title, there are several paragraphs of news content. This news article is divided into 5 sections. Despite the first section, the other 4 sections are assigned with their heading-style summaries: “Reduce their own emissions”, “Disclose risks and adopt new reporting standards”, “Educate employees” and “Advocate for climate policies”.

We crawl news articles like this from CNN website. Articles without segmentation information or headings are filtered. The resulting SEGNEWS dataset contains 26,876 articles. Each instance in SEGNEWS consist of a news article, its segmentation structure and heading-style summaries for each segments.

Global businesses must address climate change before it's too late

Opinion by Punit Renjen for CNN Business Perspectives

Updated 1221 GMT (2021 HKT) August 9, 2021

Editor's Note: *Punit Renjen is the CEO of Deloitte Global. The opinions expressed in this commentary are his own.*

Climate change poses one of the greatest threats humanity has ever faced. In the past few weeks alone, wildfires have emerged across the globe, brutal heatwaves have devastated American cities, and flooding has claimed the lives of hundreds in Europe and Asia combined. As the effects of climate change wear on, these extreme events will likely only get worse.

Making meaningful, measurable progress is a monumental task. For the sake of the planet and future generations, it is vital that global businesses, and the professionals who run them, step up in the fight against climate change and take urgent action.

Here's how:

Reduce their own emissions

At the recent G7 Summit, world leaders doubled down on their climate pledges, focusing on the opportunity for a just energy transition that will likely create clean energy jobs around the world. Among other things, they committed to reach net-zero carbon emissions by 2050, halve their collective emissions by 2030, and protect at least 30% of land and oceans by 2030.

The business community must match the ambition of world governments by cutting emissions across their own operations.

Hundreds of companies have now taken the first step in doing so: committing to 100% renewable energy. The tech sector in particular has been leading this shift, with a number of companies already reaching their 100% goal, and many more setting science-based plans to get there.

Disclose risks and adopt new reporting standards

Companies must analyze the financial risks that climate change poses to them — and publicly disclose that information.

Global capital markets need high-quality, consistent and comparable data to understand drivers of risk and return, allocate capital efficiently and finance the transition to a more resilient, low-carbon economy.

Related Article: How the business community can help protect voting rights

By providing financial markets with the right information, we can build confidence that money flows where it needs to go to boost resiliency and curb emissions across the globe. This means companies exposed to long-term climate-related risks may see higher costs of doing business while companies that develop climate solutions could have access to cheaper capital. We are seeing this play out already.

Allianz, for instance, will no longer offer property or casualty insurance coverage to mining companies that plan new coal mines. And BlackRock is setting limits on its investments in companies that are exposed to climate risks.

I am encouraged that businesses are increasingly reporting on the impact of climate change and taking steps to increase transparency and accountability through initiatives like the World Economic Forum's Stakeholder Capitalism Metrics, a set of environmental, social and governance (ESG) disclosures that companies can report on. The recent pledge from the G7 to adopt climate reporting standards reinforces the direction that the regulatory environment is heading in.

Educate employees

As business leaders, we need to recognize that our people are our greatest asset — our "superpower." With organization-wide climate education programs, businesses can develop a culture of sustainability and climate-conscious thinking at the very core of their work.

That is why, starting this month, Deloitte has begun to roll out a new climate learning program for all 330,000 of its professionals worldwide.

Developed in collaboration with World Wildlife Fund (WWF), the program is designed to engage our people on the impacts of climate change, inform them about how we are responding and inspire them to take action. By building a workforce of climate advocates and a culture of climate action, we will create a network of support for a transition to sustainable business models with far-reaching influence.

Advocate for climate policies

Businesses must leverage their collective power to advocate for climate policies that meet the ambition of reaching net-zero by 2050 or earlier.

Alongside fellow CEOs from across the world, I recently signed on to a call for government leaders to place a price on carbon and invest in the infrastructure needed to accelerate a transition away from fossil fuels. Companies ranging from shipping and logistics giants to major retailers have taken similar steps to drive systemic change in recent years. And even the oil and gas sector has lent its support for carbon pricing.

I call on other leaders to rise to this challenge. They must make climate knowledge a core competency across their businesses — a springboard for greater action — and take concrete steps to address the climate crisis head-on.

Watching the world come together to fight Covid-19 has been nothing short of inspiring, but as communities begin to recover from the pandemic, they cannot revert to the previous way of doing things. Let's build on this global cooperation that we know is possible and step up to the next greatest challenge humanity has ever confronted.

For companies to build long-term sustainable value for all stakeholders, they must do their part to build an equitable and sustainable future. Our future depends on it.

Abstract

Though nearest neighbor Machine Translation (kNN-MT) (Khandelwal et al., 2020) has proved to introduce significant performance boosts over standard neural MT systems, it is prohibitively slow since it uses the entire reference corpus as the datastore for the nearest neighbor search. This means each step for each beam in the beam search has to search over the entire reference corpus. kNN-MT is thus two-orders slower than vanilla MT models, making it hard to be applied to real-world applications, especially online services. In this work, we propose Fast kNN-MT to address this issue. Fast kNN-MT constructs a significantly smaller datastore for the nearest neighbor search: for each word in a source sentence, Fast kNN-MT first selects its nearest token-level neighbors, which is limited to tokens that are the same as the query token. Then at each decoding step, in contrast to using the entire corpus as the datastore, the search space is limited to target tokens corresponding to the previously selected reference source tokens. This strategy avoids search through the whole datastore for nearest neighbors and drastically improves decoding efficiency. Without loss of performance, Fast kNN-MT is two-orders faster than kNN-MT, and is only two times slower than the standard NMT model. Fast kNN-MT enables the practical use of kNN-MT systems in real-world MT applications. [1]

1 Introduction

Machine translation (MT) is a fundamental task in natural language processing (Brown et al., 1993; Och and Ney, 2003), and the prevalence of deep neural networks has spurred a diverse array of neural machine translation (NMT) models to improve translation quality (Sutskever et al., 2014; Bahdanau et al., 2014; Vaswani et al., 2017). The recently proposed k nearest neighbor (kNN) MT model (Khandelwal et al., 2020) has proved to introduce significant performance boosts over standard neural MT systems. The basic idea behind kNN-MT is that at each decoding step, the model is allowed to refer to reference target tokens with similar translation contexts in a large datastore of cached examples. The corresponding reference target tokens provide important insights on the translation token likely to appear next.

One notable limitation of kNN-MT is that it is prohibitively slow: it uses the entire reference corpus as the datastore for the nearest neighbor search. This means each step for each beam in the beam search has to search over the entire reference corpus. kNN-MT is thus two-orders slower than vanilla MT models. The original paper of kNN-MT (Khandelwal et al., 2020) suggests using fewer searching clusters, smaller beams and smaller datastores for generation speedup, but to achieve satisfactory results, carefully tuning on these factors under different tasks and datasets is still required according to analyses in (Khandelwal et al., 2020). The computational overhead introduced by kNN-MT makes it hard to be deployed on real-world online services, which usually require both model performance and runtime efficiency.

In this work, we propose a fast version of kNN-MT – Fast kNN-MT, to tackle the aforementioned issues. Fast kNN-MT constructs a significantly smaller datastore for the nearest neighbor search: for each word in a source sentence, Fast kNN-MT first selects its nearest token-level neighbors, which is limited to tokens of the same token type. Then at each decoding step, in contrast to consulting the entire corpus for nearest neighbor search, the datastore for the currently decoding token is limited within the tokens of reference targets corresponding to the previously selected reference source tokens, as shown in Figure 1. The chain of mappings from the target token to the source token, then to its nearest source reference tokens, and last to cor-

Findings of the Association for Computational Linguistics: ACL 2022, pages 555 - 565
May 22-27, 2022 ©2022 Association for Computational Linguistics

responding target reference tokens, can be obtained using FastAlign (Dyer et al., 2013).

Fast kNN-MT provides several important advantages against vanilla kNN-MT in terms of speedup: (1) the datastore in the KNN search is limited to target tokens corresponding to previously selected reference source tokens, instead of the entire corpus. This significantly improves decoding efficiency; (2) for source nearest neighbor retrieval, we propose to restrict the reference sources tokens that are the same as the query token, which further improves nearest-neighbor search efficiency. Without loss of performance, Fast kNN-MT is two-orders faster than kNN-MT, and is only two times slower than standard MT model. Under the settings of bilingual translation and domain adaptation, Fast kNN-MT achieves comparable results to kNN-MT, leading to a SacreBLEU score of 39.3 on WMT'19 De-En, 41.7 on WMT'14 En-Fr, and an average score of 41.4 on the domain adaptation task.

2 Related Work

Neural Machine Translation

Neural machine translation systems (Vaswani et al., 2017; Gehring et al., 2017; Meng et al., 2019) are often implemented by the sequence-to-sequence framework (Sutskever et al., 2014) and enhanced with the attention mechanism (Bahdanau et al., 2014; Luong et al., 2015) which associates the current decoding token to the most semantically related part in the source side. At decoding time, beam search and its variants are used to find the optimal sequence (Sutskever et al., 2014; Li and Jurafsky, 2016). The development of self-attention (Vaswani et al., 2017) and pretraining (Devlin et al., 2018; Lewis et al., 2019) has greatly motivated a line of works for more expressive MT systems. These works include incorporating pretrained models (Zhu et al., 2020; Guo et al., 2020), designing lightweight model structures (Kasai et al., 2020; Lioutas and Guo, 2020; Tay et al., 2020; Kasai et al., 2021; Peng et al., 2021), handling multiple languages (Aharoni et al., 2019; Arivazhagan et al., 2019; Liu et al., 2020b) and mitigating structural issues in Transformers (Wang et al., 2019; Nguyen and Salazar, 2019; Liu et al., 2020a; Li et al., 2020; Xiong et al., 2020b) for more robust and efficient NMT systems.

Retrieval-Augmented Models

Retrieving and integrating auxiliary sentences has shown effectiveness in improving robustness and expressiveness for NMT systems. (Zhang et al., 2018) up-weighted the output tokens by collecting from the retrieved target sentences n-grams that align with the words in the source sentence, and (Bapna and Firat, 2019) similarly retrieved n-grams but incorporated the information using gated attention (Cao and Xiong, 2018). (Tu et al., 2018) updated and stored the hidden representations of recent translation history in cache for access when new tokens are generated, so that the model can dynamically adapt to different contexts. (Gu et al., 2018) leveraged an off-the-shelf search engine to retrieve a small subset of sentence pairs from the training set and then perform translation given the source sentence along with the retrieved pairs. (Li et al., 2016; Farajian et al., 2017) proposed to retrieve similar sentences from the training set for the purpose of adapting the model to different input sentences. (Bulté and Tezcan, 2019; Jitao et al., 2020) used fuzzy matches to retrieve similar sentence pairs from translation memories and augmented the source sentence with the retrieved pairs. Our work is motivated by kNN-MT (Khandelwal et al., 2020) and target improving the efficiency of kNN retrieval while achieving comparable translation performances.

Apart from machine translation, other NLP tasks have also benefited from retrieval-augmented models, such as language modeling (Khandelwal et al., 2019), question answering (Guu et al., 2020; Lewis et al., 2020b,a; Xiong et al., 2020a) and dialog generation (Weston et al., 2018; Fan et al., 2020; Thulke et al., 2021). Most of these works perform retrieval at the sentence level and treat the extracted sentences as additional input for model generation, whereas fast kNN-MT retrieves the most relevant tokens in the source side and fixes the probability distribution using the aligned target tokens at each decoding step.

3 Background: kNN-MT

Given an input sequence of tokens $\boldsymbol{x} = \{x_1, \cdots, x_n\}$ of length n, an MT model translates it into a target sentence in another language $\boldsymbol{y} = \{y_1, \cdots, y_m\}$ of length m. A common practice to produce each token y_i on the target side is to obtain a probability distribution over the vocabulary $p_{\text{MT}}(y_i|\boldsymbol{x}, \boldsymbol{y}_{1:i-1})$ from the decoder and use beam search for generation. The combination of the complete source sentence and prefix of the target sentence $(\boldsymbol{x}, \boldsymbol{y}_{1:i-1})$ is called *trans-*

lation context. kNN-MT interpolates this probability distribution with a multinomial distribution $p_{\text{kNN}}(y_i|\boldsymbol{x}, \boldsymbol{y}_{1:i-1})$ derived from the k nearest neighbors of the current translation context $(\boldsymbol{x}, \boldsymbol{y}_{1:i-1})$ from a large scale datastore $\mathcal{S}$:

$$\begin{aligned} p(y_i|\boldsymbol{x}, \boldsymbol{y}_{1:i-1}) &= \lambda p_{\text{kNN}}(y_i|\boldsymbol{x}, \boldsymbol{y}_{1:i-1}) \\ &\quad + (1-\lambda) p_{\text{MT}}(y_i|\boldsymbol{x}, \boldsymbol{y}_{1:i-1}) \end{aligned} \tag{1}$$

More specifically, kNN-MT first constructs the datastore $\mathcal{S}$ using key-value pairs, where the key is the high-dimensional vector of the translation context produced by a trained MT model $f(\boldsymbol{x}, \boldsymbol{y}_{1:i-1})$, and the value is the corresponding gold target token y_i, forming $\mathcal{S} = \{(\boldsymbol{k}, v)\} = \{(f(\boldsymbol{x}, \boldsymbol{y}_{1:i-1}), y_i)\}$. The context-target pairs may come from any parallel corpus. Then, using the dense representation of the current translation context as query $\boldsymbol{q} = f(\boldsymbol{x}^{\text{in}}, \boldsymbol{y}_{1:i-1})$ and L_2 distance as measure, kNN-MT searches through the entire datastore $\mathcal{S}$ to retrieve k nearest translation contexts along with the corresponding target tokens $\mathcal{N} = \{\boldsymbol{k}_j, v_j\}_{j=1}^{k}$. Last, the retrieved set is transformed to a probability distribution by normalizing and aggregating the negative L_2 distances, $-d$, using the softmax operator with temperature T, which can be expressed as follows:

$$\begin{aligned} & p_{\text{kNN}}(y_i|\boldsymbol{x}^{\text{in}}, \boldsymbol{y}_{1:i-1}) \\ &\quad = \frac{\sum_{(\boldsymbol{k}_j, v_j) \in \mathcal{N}} \mathbb{1}_{y_i = v_j} \exp(-d(\boldsymbol{q}, \boldsymbol{k}_j)/T)}{Z} \\ & Z = \sum_{(\boldsymbol{k}_j, v_j) \in \mathcal{N}} \exp(-d(\boldsymbol{q}, \boldsymbol{k}_j)/T) \end{aligned} \tag{2}$$

Integrating Eq.(2) into Eq.(1) gives the final probability of generating token y_i for time step i. Note that the above kNN search-interpolating process is applied to each decoding step of each beam, and each iteration needs to run on the full datastore $\mathcal{S}$. This gives a total time complexity of $\mathcal{O}(|\mathcal{S}|Bm)$, where B is the beam size and m is the target length. In order for faster nearest neighbor search, kNN-MT leverages FAISS (Johnson et al., 2019), an toolkit for efficient similarity search and clustering of dense vectors.

4 Method: Fast kNN-MT

The time complexity of kNN-MT before search optimization is $\mathcal{O}(|\mathcal{S}|Bm)^2$, which is prohibitively slow when the size of the datastore $\mathcal{S}$ or the beam size B is large. We propose strategies to address this issue. The same as vanilla kNN-MT, fast kNN-MT system is built upon a separately trained MT encoder-decoder model. To get a better illustration of how Fast kNN-MT works, we give a toy illustration in Figure 1. We use the capitalized characters to denote source tokens and lower-cased letters to denote target tokens. Given the training set, which is:

$$\begin{aligned} (\boldsymbol{x}^{(1)}, \boldsymbol{y}^{(1)}) &= (\{\text{A,B,C,D}\}, \{\text{b,c,d,a}\}) \\ (\boldsymbol{x}^{(2)}, \boldsymbol{y}^{(2)}) &= (\{\text{B,C,D}\}, \{\text{c,d,e,b}\}) \\ (\boldsymbol{x}^{(3)}, \boldsymbol{y}^{(3)}) &= (\{\text{A,B,D,E}\}, \{\text{a,b,c,d,e}\}) \\ (\boldsymbol{x}^{(4)}, \boldsymbol{y}^{(4)}) &= (\{\text{B,D,E}\}, \{\text{b,d,e}\}) \\ (\boldsymbol{x}^{(5)}, \boldsymbol{y}^{(5)}) &= (\{\text{D,E,F}\}, \{\text{d,e,f}\}) \end{aligned} \tag{3}$$

in the toy example, an encoder-decoder model is trained. Next, we wish to translate a source string $\{\text{B,C,E}\}$ at test time.

4.1 Datastore Creation On the Source Side

Given a pretrained encoder-decoder model, and the training corpus, we first obtain representations for all source tokens and target tokens of the training set, which are the last layer outputs from the encoder-decoder model. In the toy example, representations for source tokens $\{\text{A,B,C,D}\}$ in the first training example $(\{\text{A,B,C,D}\}, \{\text{b,c,d,a}\})$ are respectively $\boldsymbol{h}_{11}, \boldsymbol{h}_{12}, \boldsymbol{h}_{13}, \boldsymbol{h}_{14}$, and for target tokens $\{\text{b,c,d,a}\}$ are respectively $\boldsymbol{z}_{11}, \boldsymbol{z}_{12}, \boldsymbol{z}_{13}, \boldsymbol{z}_{14}$. Given a test example to translate, which is $\{\text{B,C,E}\}$ in the example, we also obtain the representation for each of its constituent token, denoted by $\boldsymbol{h}_{\text{B}}, \boldsymbol{h}_{\text{C}}, \boldsymbol{h}_{\text{E}}$. Next, we select nearest neighbor tokens for each source token, i.e., $\{\text{B, C, E}\}$. The nearest neighbor tokens are first limited to source tokens of the same token type as the query token. For token B, tokens of the same token type are x_{12}, x_{21}, x_{32}, x_{41}. Similarly, for the token C in the test example, tokens of the same type are $\{x_{13}, x_{22}\}$; for the token E, tokens of the same type are $\{x_{34}, x_{43}, x_{52}\}$. One issue that stands out is that, for common words such as "the", there can be tens of millions of the same type tokens in the training corpus. We thus need to further limit the number of nearest neighbors. Let c denote the hyper-parameter that controls the number of nearest neighbors for each token on the source side, which is set to 2 in the toy example. We rank all candidates based on the distance between the

---

[2] Time perplexity can slightly be alleviated when approximate nearest neighbor search is used, with computation perplexity being not strictly $\mathcal{O}(|\mathcal{S}|)$.

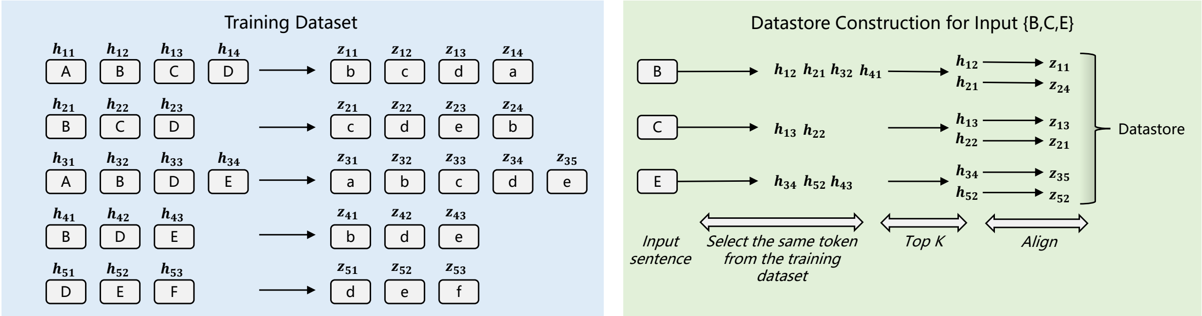

Figure 1: *Caching source and target tokens* (left, blue): Given a trained NMT model f and the training corpus $\mathcal{D}_{\text{train}}$, we obtain representations for all source tokens $\boldsymbol{h}$ and target tokens $\boldsymbol{z}$ in the training set, which are the last layer outputs from f. *Datastore construction* (right, green): Given a test example to translate, which is {B,C,E} in the example, we first navigate each source token to the tokens of the same type in the cache, e.g., x_{12}, x_{21}, x_{32} and x_{41} are identified for token B. Then, the top c nearest neighbors for each source token are preserved according to the distance between the source token representation and candidate token representations, e.g., x_{12}, x_{21} are selected for token B. Last, the selected source tokens are aligned to their target tokens using FastAlign (Dyer et al., 2013). For token B, the aligned target tokens are y_{11}, y_{24}. The collection of all aligned target tokens (along with their representations) constitutes the datastore for the current input {B,C,E}.

source token representation (e.g., $\boldsymbol{h}_{\text{B}}, \boldsymbol{h}_{\text{C}}, \boldsymbol{h}_{\text{E}}$) and candidate token representations, and select the top c. Suppose that in the toy example, x_{12}, x_{21} are selected for token B, x_{13}, x_{23} are selected for token C, x_{34}, x_{52} are selected for token E. The concatenation of selected candidates for all source tokens constitute the datastore on the source side, which is $\mathcal{D}_{\text{source}} = \{x_{12}, x_{21}, x_{13}, x_{23}, x_{34}, x_{52}\}$ in the toy example. The datastore creation for source tokens (e.g., {B, C, E}) can be run in parallel.

4.2 Datastore Creation On the Target Side

For decoding, the model needs to refer to reference target tokens rather than source tokens. We thus need to transform $\mathcal{D}_{\text{source}}$ to a list of target tokens. We use FastAlign (Dyer et al., 2013) toolkit to achieve this goal. FastAlign maps source tokens to target tokens based on the IBM model (Och and Ney, 2003). Source tokens in $\mathcal{D}_{\text{source}}$ that do not have correspondence on the target side are abandoned. Output target tokens from FastAlign form the datastore on the target side, denoted by $\mathcal{D}_{\text{target}}$. In the toy example, $x_{12}, x_{21}, x_{13}, x_{23}, x_{34}, x_{52}$ are respectively mapped to $\mathcal{D}_{\text{target}} = \{y_{11}, y_{24}, y_{12}, y_{21}, y_{35}, y_{52}\}$. The size of $\mathcal{D}_{\text{target}}$ is $c \times n$, where n is the source length.

In practice, we first iterate over all examples in the training set, extracting all the source token representations and all the target token representations. Then, we build a separate token-specific cache $\mathcal{D}_v$ for each v in vocabulary, which consists of (key, value) pairs where the key is the high-dimensional representation $\boldsymbol{h}$ and the value is a binary tuple containing the corresponding aligned target token along with its representation $\boldsymbol{z}$. Then we could map each source token of a given input sentence to its corresponding cache $\mathcal{D}_v$, and build the target-side datastore following the steps in Section 4.1 and Section 4.2. The process of caching source and target tokens is present in Algorithm 1.

4.3 Decoding

At the decoding time, the datastore for each decoding step is all limited to $\mathcal{D}_{\text{target}}$, within which kNN search is performed. Since tokens in $\mathcal{D}_{\text{target}}$ are not all related to the current decoding, nearest neighbor search is performed to select the top k candidates from $\mathcal{D}_{\text{target}}$ for each decoding step. For the nearest neighbor search here, we use the current representation $\boldsymbol{h}$ at the decoding time to query target representation $\boldsymbol{z}$ for target tokens in $\mathcal{D}_{\text{target}}$. The selected nearest neighbors and their representations are used to compute the final word generation probability based on Eq.(1) and Eq.(2).

4.4 Quantization

Although the prohibitive computational cost issue of kNN-MT has been addressed, the intensive memory for datastore remains a problem, as we wish to cache all source and target representations of the entire training set. Additionally, frequently accessing Terabytes of data is also extremely time-intensive. To address this issue, we propose to use product quantization (PQ) (Jegou et al., 2010) to

Algorithm 1: Constructing Datastore for a Test Input $\boldsymbol{x}$.

```
Input  : All sentence-pairs in training set:
         $(\boldsymbol{x}^{(1)}, \boldsymbol{y}^{(1)}), ..., (\boldsymbol{x}^{(N)}, \boldsymbol{y}^{(N)})$, vocabulary $\mathcal{V}$
         NMT encoder $f_e$, NMT decoder $f_d$, word
alignment for each sentence-pair $(A^{(1)}, ..., A^{(N)})$
         Input for test: $\boldsymbol{x}$
Output : Target datastore $\mathcal{D}_{\text{target}}(\boldsymbol{x})$ for $\boldsymbol{x}$
$\mathcal{D}_{\text{target}}(\boldsymbol{x}) \leftarrow \emptyset$      ▶ initialize the datastore $\mathcal{D}_{\text{source}}(\boldsymbol{x})$ for $\boldsymbol{x}$
for $v \leftarrow 1$ to $\mathcal{V}$ do
    $\mathcal{D}_v \leftarrow \emptyset$      ▶ initialize the (key, value) datastore for each word in the vocabulary
end
% Caching Source and Target Tokens:
for $i \leftarrow 1$ to $N$ do
    $n_i \leftarrow$ length of $\boldsymbol{x}^{(i)}$
    $m_i \leftarrow$ length of $\boldsymbol{y}^{(i)}$
    $[\boldsymbol{h}_1, ..., \boldsymbol{h}_{n_i}] \leftarrow f_e(\boldsymbol{x}^{(i)})$      ▶ computing representations for each source word
    $[\boldsymbol{z}_1, ..., \boldsymbol{z}_{m_i}] \leftarrow f_d(\boldsymbol{x}^{(i)}, \boldsymbol{y}^{(i)})$      ▶ computing representations for each target word
    for $j \leftarrow 0$ to $n_i$ do
        for $k \leftarrow 0$ to $m_i$ do
            if $(j, k) \in A^{(i)}$ then
                add $(\boldsymbol{h}_i, (\boldsymbol{z}_k, y_k^{(i)}))$ to $\mathcal{D}_{x_j^{(i)}}$
                % key of $\mathcal{D}_{x_j^{(i)}}$ are all hidden representations $\boldsymbol{h}_i$ for tokens of the same token type as $x_j^{(i)}$
            end
        end
    end
end
% Generate Datastore for the test input $\boldsymbol{x}$:
$n_x \leftarrow$ length of $\boldsymbol{x}$
for $k \leftarrow 1$ to $N$ do
    obtain hidden representation for the $k$-th token $\boldsymbol{h}_k$
    $\{\boldsymbol{z}, y\} \leftarrow$ top $c$ items from $\mathcal{D}_{x_k}$ using $\boldsymbol{h}_k$ as the query
    add $\{\boldsymbol{z}, y\}$ to $\mathcal{D}_{\text{target}}(x)$
end
```

compress the high-dimensional representations of each token. Formally, given a vector $\boldsymbol{x} \in \mathbb{R}^D$, we represent it as the concatenation of M subvectors: $\boldsymbol{x} = [\boldsymbol{x}^1, \boldsymbol{x}^2, ..., \boldsymbol{x}^M]$, where all subvectors have the same dimension $d = D/M$. The product quantizer q consists of M sub-quantizers $q_1, ..., q_M$, each maps a subvecor $\boldsymbol{x}^m \in \mathbb{R}^d$ to a codeword $\boldsymbol{c}$ in a subspace codebook with n codewords: $\mathcal{C}^m = \{\boldsymbol{c}_1^m, \boldsymbol{c}_2^m, ..., \boldsymbol{c}_n^m\}$. The objective function of PQ is:

$$\min_{q^1,...,q^M} \sum_{\boldsymbol{x}} \sum_{m=1}^{M} \|\boldsymbol{x}^m - q_m(\boldsymbol{x}^m)\|^2 \tag{4}$$

Therefore each $\boldsymbol{x}$ is mapped to its nearest codeword in the Cartesian product space $\mathcal{C} = \mathcal{C}^1 \times ... \times \mathcal{C}^M$. If each subspace codebook $\mathcal{C}^m$ has n codewords, then the Cartetian product space $\mathcal{C}$ could represent n^m D-dimensional codewords with only $n \times m$ d-dimensional vectors, thus significantly eased the memory issue. With the quantization technique, we are able to compress each token representation to 128-bytes. For example, for the WMT19 En-De dataset, the memory size is reduced from 3.5TB to 108GB.

4.5 kNN Retrieval Details

In practice, executing exact nearest neighbor search over millions or even billions of tokens could be time-consuming. Hence we use FAISS (Johnson et al., 2019) for fast approximate nearest neighbor search. All token representations are quantized to 128-bytes. Recall that we build a token-specific datastore $\mathcal{D}_v$ for each v in vocabulary. We do brute force search for tokens whose frequency n_v is lower than 30000. For those tokens whose frequency is larger than 30000, the keys are stored in clusters to speed up search. The number of clusters for token v is set to $\min(4 \times \sqrt{n_v}, n_v/30)$. To learn the cluster centroids, we use at most 5M keys for each token v. During inference, we query the datastore for $k = 512$ neighbors through searching 32 nearest clusters.

4.6 Discussions on Comparisons to Vanilla kNN-MT

The speedup of Fast kNN-MT lies in the following three aspects:

(1) For nearest neighbor retrieval on the source side, we first restrict the reference tokens that are the same as the query token. This strategy significantly narrows down the search space to roughly $|\mathcal{S}|$/mid(F) times, where $|\mathcal{S}|$ denotes the number of tokens in the corpus, and mid(F) denotes the medium word frequency in the corpus.

(2) The nearest neighbor search for all source tokens on the source side can be run in parallel, which is also a key speedup over kNN-MT. For vanilla kNN-MT, kNN search is performed on the target side and has to be auto-regressive: the representation for the current decoding step, which is used for the kNN search over the entire corpus, relies on previously generated tokens. Therefore, the kNN search for the current step has to wait for the finish of kNN searches for all previous generation steps.

(3) On the target side, the datastore in the kNN search is limited to target representations corresponding to selected reference source tokens.

Though the nearest neighbor search in the decoding process is auto-regressive and thus cannot be run in parallel, the running cost is fairly low: recall that the size of $\mathcal{D}_{\text{target}}$ is $c \times n$. Across all settings, the largest value of c is set to 512. The size of $\mathcal{D}_{\text{target}}$ is roughly 15k. Performing nearest neighbor searches among 15k candidates is relatively cheap for NMT, and is actually cheaper than the softmax operation for word prediction, where the vocabulary size is usually around 50k.

The combination of all these aspects leads to Fast kNN-MT two orders of magnitude faster than vanilla kNN-MT.

5 Experiments

5.1 Bilingual Machine Translation

We conduct experiments on two bilingual machine translation datasets: WMT'14 English-French and WMT'19 German-English. To create the datastore, we follow (Ng et al., 2019) to apply language identification filtering, keeping only sentence pairs with correct languages on both sides. We also remove sentences longer than 250 tokens and sentence pairs with a source/target ratio exceeding 1.5. For all datasets, we use the standard Transformer-base model provided by FairSeq (Ott et al., 2019) library.[3] The model has 6 encoder layers and 6 decoder layers. The dimensionality of word representations is 1024, the number of multi-attention heads is 16, and the inner dimensionality of feedforward layers is 8192. Particularly, following (Khandelwal et al., 2020), the model for WMT'19 German-English has also been trained on over 10 billion tokens of extra backtranslation data as well as fine-tuned on newstest test sets from previous years. We report the SacreBLEU scores (Post, 2018) for comparison.[4] Table 1 shows our results on the two NMT datasets. The proposed Fast kNN-MT model is able to achieve slightly better results to the vanilla kNN-MT model on WMT'19 German-English, and competitive results on WMT'14 English-French, with less kNN search cost.

Model	De-En	En-Fr
base MT	37.6	41.1
+kNN-MT	$39.1_{(+1.5)}$	$41.8_{(+0.7)}$
+fast kNN-MT	$39.3_{(+1.7)}$	$41.7_{(+0.6)}$

Table 1: SacreBLEU scores on WMT'19 De-En and WMT'14 En-Fr.

5.2 Domain Adaptation

We also measure the effectiveness of the proposed Fast kNN-MT model on the domain adaptation task. We use the multi-domain datasets which are originally provided in (Koehn and Knowles, 2017) and further cleaned by (Aharoni and Goldberg, 2020). These datasets include German-English parallel data for train/validation/test sets in five domains: Medical, Law, IT, Koran and Subtitles. We use the trained German-English model introduced in Section 5.1 as our base model, and further build domain-specific datastores to evaluate the performance of Fast kNN-MT on each domain. Table 2 shows that Fast kNN-MT achieves comparable results to vanilla kNN-MT on domains of Medical (54.6 vs. 54.4), IT (45.9 vs. 45.8) and Subtitles (31.9 vs. 31.7), and outperforms vanilla kNN-MT on the domain of Koran (21.2 vs. 19.4). The average score of Fast kNN-MT (41.7) is on par with the result of (Aharoni and Goldberg, 2020) (41.3), which trains domain-specific models and reports in-domain results.

Following (Khandelwal et al., 2020), we also carry out experiments under the out-of-domain and multi-domain settings and report the results on Table 2. "+ WMT19' datastore" shows the results for retrieving neighbors from 770M tokens of WMT'19 data that the model has been trained on, and "+ all-domain datastore" shows the results where the model is trained on the multi-domain datastore from all six settings. The BLEU improvement is much smaller on the out-of-domain setup compared to the in-domain setup, illustrating that the proposed framework relies on in-domain data to retrieve valuable contexts. For the multi-domain setup, the performance for all six domains generally remains the same and only a small drop of the average score is witnessed. This shows that the Fast kNN-MT framework is robust to a massive amount of out-of-domain data and is able to retrieve the context-related information from in-domain data.

5.3 Analysis

Examples To visualize the effectiveness of the proposed Fast kNN-MT model, we randomly choose an example from the test set of the Law domain. Table 3 shows the test sentence, the retrieved

Table 3: A test sentence pair from the Law domain. We show the original sentence pair for test (the first row), the nearest-neighbor tokens on the source side along with the sentences that retrieved tokens reside in (the second column), and the aligned target tokens extracted from FastAlign, along with sentences in which target tokens reside in (the third column). The retrieved tokens are in red.

nearest neighbor tokens on the source side, and the corresponding target tokens. The first figure in Figure 2 demonstrates the similarity heatmap between the gold target tokens and the selected target neighbors. We can see that the retrieved target nearest tokens are highly correlated with the ground-truth target tokens, exhibiting the ability of Fast kNN-MT to accurately extract nearest reference tokens at each decoding step.

The Effect of the Number of neighbors per token on the source side We queried the datastore for nearest c neighbors for each source token. Intuitively, the larger the c is, the more likely the model could recall the nearest neighbors on the target side. The second figure in Figure2 verifies this point: the model performance increases drastically when c increases from 8 to 64, and then continues increasing as c is up to 512.

The Effect of the Number of neighbors per token on the target side Fast kNN-MT selects top k nearest neighbors at each decoding step for computing the probability p_{kNN} in Eq.(2). The third figure in Figure 2 shows that the model performance first increases and then decreases when we continue

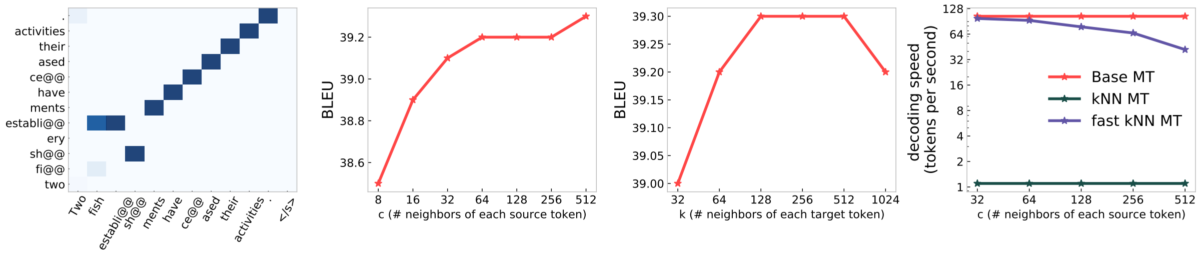

Figure 2: *First figure*: the similarity heatmap between the gold target tokens and the retrieved target neighbors. *Second figure*: BLEU scores with respect to different c, the number of nearest neighbors on the source side for each source token. *Third figure*: BLEU scores with respect to different k, the number of nearest neighbors on the target side for each target token. *Forth figure*: Speed comparison between base MT, kNN-MT and fast kNN-MT.

enlarging the value of k, with c fixed at 512, which is consistent with the observation in (Khandelwal et al., 2020). This is because that using neighbors that are too far away from the ground-truth target token adds noise to the model prediction, and thus hurts the performance.

Speed comparison When the beam size is fixed, the time complexity of Fast kNN-MT is mainly controlled by the number of retrieved neighbors c for each source token.[5] The last figure in Figure 2 shows the speed comparison between base MT, kNN-MT and fast kNN-MT when we vary the value of c. Fast kNN-MT decoded nearly as fast as the vanilla MT model when c is small. When c reaches 512, kNN-MT is about two times slower than the vanilla MT model. By contrast, vanilla kNN-MT is two order of magnitude slower than base MT and Fast kNN-MT regarding the decoding speed. This is because Fast kNN-MT substantially restricts the search space during decoding, whereas vanilla kNN-MT has to execute kNN search over the entire datastore at each decoding step.

Similarity function We have tried different similarity functions when retrieving c nearest neighbors on source side and computing the kNN distribution. These functions include cosine similarity, inner product and L_2 distance, the SacreBLEU scores for which are respectively 39.2, 39.1 and 38.8 on WMT'19 German-English, showing that cosine similarity is a better measure for representation distance than L_2 distance and inner product.

Effect of quantization Due to the memory issue, we applied quantization to compress the high-dimensional representation of each token in the training set. We investigate how quantization would affect model performances. As shown in Table 4, quantization has minor side effects in terms of BLEU scores, and when we use full precision instead of quantization, the average BLEU score only increases 0.1, which suggests that computing similarity using compressed vectors is a viable trade-off between memory usage and model performance.

Model	Medical	Law	IT	Koran	Subtitles	Avg.
fast kNN-MT	53.6	61.0	45.5	21.2	31.9	41.7
+full-precision	53.8	61.1	45.8	21.3	30.7	41.5

6 Conclusion

In this work, we propose a fast version of kNN-MT – Fast kNN-MT – to address the runtime complexity issue of the vanilla kNN-MT. During decoding, Fast kNN-MT constructs a significantly smaller datastore for the nearest neighbor search: for each word in a source sentence, Fast kNN-MT selects its nearest tokens from a large-scale cache. The selected tokens are the same as the query token. Then at each decoding step, in contrast to using the entire datastore, the search space is limited to target tokens corresponding to the previously selected reference source tokens. Experiments demonstrate that this strategy drastically improves decoding efficiency while maintaining model performances compared to vanilla kNN-MT under different settings including bilingual machine translation and domain adaptation. Comprehensive ablation studies are performed to understand the behavior of each component in Fast kNN-MT. In future work, we plan to further improve the efficiency of Fast kNN-MT

---

[5] k plays a minor role to the overall time complexity because each search on the target side is performed within a total amount of cn tokens, which is negligible compared to the time cost spent on the source side.

by applying clustering techniques to build the datastore.

Abstract

Prior work on controllable text generation has focused on *learning* how to control language models through trainable decoding, smart-prompt design, or fine-tuning based on a desired objective. We hypothesize that the information needed to steer the model to generate a target sentence is already encoded within the model. Accordingly, we explore a different approach altogether: *extracting* latent vectors directly from pretrained language model decoders without fine-tuning. Experiments show that there exist *steering vectors*, which, when added to the hidden states of the language model, generate a target sentence nearly perfectly (> 99 BLEU) for English sentences from a variety of domains. We show that vector arithmetic can be used for unsupervised sentiment transfer on the Yelp sentiment benchmark, with performance comparable to models tailored to this task. We find that distances between steering vectors reflect sentence similarity when evaluated on a textual similarity benchmark (STS-B), outperforming pooled hidden states of models. Finally, we present an analysis of the intrinsic properties of the steering vectors. Taken together, our results suggest that frozen LMs can be effectively controlled through their latent steering space. [1]

1 Introduction

Leveraging large pretrained language models trained on massive Web corpora has become the go-to approach to solve natural language processing tasks (Peters et al., 2018; Radford et al., 2018; Devlin et al., 2018; Brown et al., 2020). As a result, controlling these models has become paramount as many applications of NLP technology require control over the generations of the model. Prior work aims to *learn* how to control language models and falls in three categories: trainable decoding (Gu et al., 2017; Deng et al., 2020), smart-prompt design (Shin et al., 2020; Lester et al., 2021), and fine-tuning based on a desired objective (Krause et al., 2021; Weng, 2021). Further, many works opt to train auto-encoder based models for controllable text generation (Shen et al., 2017, 2020; Mai et al., 2020). These approaches make controllability easier by learning a latent space that is more easily manipulated to encourage models to generate text corresponding to a target attribute such as positive sentiment in the case of sentiment transfer.

We take a more direct approach and explore whether it is possible to *extract* latent vectors directly from pretrained language model decoders without fine-tuning. We call these vectors *steering vectors* and define the *latent steering space* of a sentence under a language model by the set of extracted steering vectors, which steer the model to generate that sentence exactly. During decoding, we add our steering vector to the hidden states of the language model to generate the target sentence. Rather than training a model to learn steering vectors, we provide several methods to *extract* fixed-length steering vectors directly from pretrained language model decoders. Experiments show that we can extract steering vectors effectively, achieving nearly perfect recovery for English sentences from a variety of domains without fine-tuning the underlying language model at all.

Next, we take our extracted steering vectors and explore whether they can be used for unsupervised sentiment transfer on the Yelp sentiment benchmark (Zhang et al., 2015). We find that adding an offset vector to extracted steering vectors performs comparably to carefully designed, autoencoder-based models. To see whether steering vectors encode semantics, we explore whether they can be used for unsupervised textual similarity. On the semantic textual similarity benchmark (STS-B, Cer et al. (2017)), our steering vectors outperform extractive methods such as averaging language model

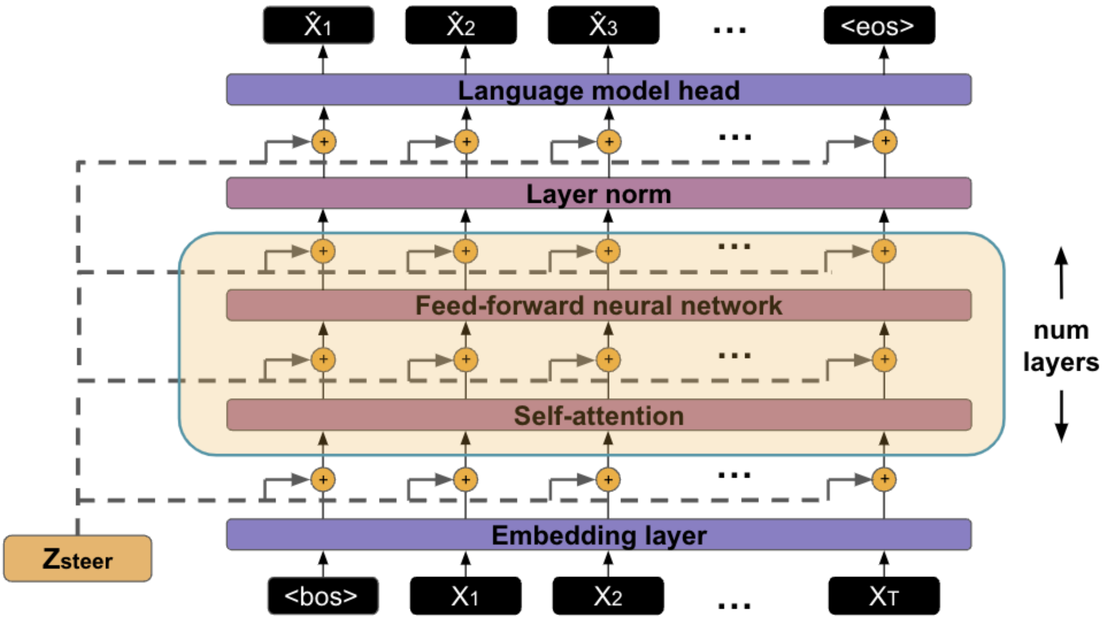

Figure 1: Our approach adds a vector z_{steer} to the activations of a pretrained transformer decoder to steer it to decode a desired target sentence. We experiment with adding z_{steer} to different locations inside a GPT-2 model at different timesteps. Experiments reveal that our approach can recover sequences nearly perfectly and that injecting the steering vector in the middle layers of the transformer stack performs best. Layer normalizations and residual connections inside the transformer block are omitted for clarity.

hidden states and GloVe vectors (Pennington et al., 2014) when measuring the cosine similarity between vectors, but fall short of lexical methods tailored to semantic similarity tasks and methods that finetune on natural language inference datasets.

Lastly, we analyze the intrinsic properties of the latent space of our steering vectors. Experiments show that decoding from interpolations in the latent space produces meaningful output, and that steering vectors from different domains cluster together. Also, we find that our methods do not simply memorize the target sequence like a naive compression algorithm, and instead leverage the model. Taken together, our results suggest that frozen language models can be controlled effectively through their latent steering space.

2 Extracting Steering Vectors

This section discusses our method for extracting a steering vector for a target sentence from a frozen, pretrained language model. Throughout this paper, we use GPT2 as our language model and use its 117M parameter model size (Radford et al., 2019), although our approach can be directly applied to any transformer-based autoregressive language model decoder (Vaswani et al., 2017).

2.1 Steering Vectors

In controllable text generation and textual style transfer, prior work based on denoising and variational autoencoders opt for a disentangling approach. These approaches encode the source sequence into a fixed-length vector using an encoder, apply style transformations using a controller, and finally decode from the transformed vector using a decoder (Shen et al., 2017; Jin et al., 2020). Instead of learning an encoder and controller to uncover a representation, we ask whether its possible to extract a vector directly from a pretrained language model decoder in order to steer the model.

Due to the success of hidden layer manipulations for language models including adapter-based fine-tuning (Houlsby et al., 2019), plug-and-play language models (Dathathri et al., 2019), and offset-vector-based recovery and style transfer among others (Subramani et al., 2019; Shen et al., 2020; Mai et al., 2020; Montero et al., 2021), we choose to manipulate the hidden states as well.

Our method works by adding a fixed-length vector z_{steer} to the hidden states of a pretrained and frozen LM. For a desired target sentence, we randomly initialize z_{steer} and optimize it via gradient descent to maximize the likelihood of the model given the target sentence. At decoding time, we feed a $\boldsymbol{z}_{steer}$ to the model and perform decoding as usual. The choice of a fixed-length vector makes analysis more meaningful, allowing us to compare vectors for different sentences with different lengths in the same representation space.

2.2 Discovering steering vectors

We define our steering vectors $\boldsymbol{z}_{steer} \in \mathbb{R}^{d'}$. In our experiments, $d' \leq d$, where d is the hidden dimension of the underlying language model (for GPT2-117M, $d = 768$). If $d' < d$, we project $\boldsymbol{z}_{steer}$ using a semi-orthogonal matrix, $W_{steer} \in \mathbb{R}^{d' \times d}$, which preserves scale. W_{steer} is initialized randomly, never trained, and never updated.

We estimate a steering vector $\hat{z}_{steer} \in \mathbb{R}^{d'}$ via the language model for a sentence $\boldsymbol{x}$ by maximizing the log probability of x, while keeping the language model fixed:

$$\hat{\boldsymbol{z}}_{steer} = \operatorname*{argmax}_{\boldsymbol{z}_{steer} \in \mathcal{Z}} \sum_{t=1}^{T} \log p(x_t | \boldsymbol{x}_{<t}, \boldsymbol{z}_{steer}) \tag{1}$$

Here, $\mathcal{Z} \in \mathbb{R}^{d'}$. Note: we find a single steering vector $\boldsymbol{z}_{steer}$ for each sentence $\boldsymbol{x}$. We use stochastic gradient descent with the Adam (Kingma and Ba, 2014) optimizer and cross entropy loss to find the best $\hat{\boldsymbol{z}}_{steer}$, while freezing the language model. See algorithm 1 for the pseudocode.

Since our method adds $\boldsymbol{z}_{steer}$ to the activations of the model, the layer we add $\boldsymbol{z}_{steer}$ to affects recoverability. We experiment with injecting $\boldsymbol{z}_{steer}$ at different layers (*injection locations*): at the embedding layer, right before language model head (LM Head), after self-attention layer in the transformer stack, after feed-forward layer in the transformer stack as well as combinations of them. In addition to varying injection locations, we also vary the timesteps where $\boldsymbol{z}_{steer}$ gets added. We experiment with adding $\boldsymbol{z}_{steer}$ at just the first timestep and at every timestep. See Figure 1 for details.

2.3 Steering Language Models

We steer the language model using $\boldsymbol{z}_{steer}$ to generate a target sentence $\boldsymbol{x}$ by passing in a beginning-of-sentence token and $\boldsymbol{z}_{steer}$ to the model. Since we are interested in exact generation, all results presented use greedy decoding without assuming a true length. We stop when decoding produces an end-of-sentence token or produces 1024 tokens, the maximum length that GPT-2 can generate.

ALGORITHM 1: Extracting $\boldsymbol{z}_{steer}$ for a sentence

```
Input  : x – target sentence
         M – pretrained language model
         $\theta$ – pretrained language model weights
         $I_L$ – injection location
         $I_T$ – injection timestep
         d – dimension of $\boldsymbol{z}_{steer}$
Output : $\boldsymbol{z}_{steer}$ – extracted candidate steering vector
$\boldsymbol{z}_{steer} \sim$ xavier_normal(d)
for i ← [1, 2, ..., N] do
    logits = $M_\theta.forward(x, \boldsymbol{z}_{steer}, I_L, I_T)$
    $\mathcal{L} = XENT(logits, x)$
    $\mathcal{L}.backward()$
    $\boldsymbol{z}_{steer} = \boldsymbol{z}_{steer} + lr * \frac{\partial \mathcal{L}}{\partial \boldsymbol{z}_{steer}}$
end
return $\boldsymbol{z}_{steer}$
```

3 Can we extract steering vectors?

Here, we show that we can robustly extract steering vectors that generate target sentences perfectly.

3.1 Experimental setup

We gather a broad corpus spanning four different domains and measure the extent to which our approach can extract a steering vector for each sentence under a variety of experimental conditions, where we vary injection locations and timesteps.

Data Collection For these experiments on sentence recoverability, we create a dataset which combines four corpora from different domains: movie dialogs (movies), classic books (books), news articles (news), and Wikipedia (wiki). For movies, we choose the Cornell Movie Dialogs corpus (Danescu-Niculescu-Mizil and Lee, 2011), which consists of fictional conversations from movie scripts. We choose NLTK's Gutenberg dataset for our books portion, which consists of a subset of texts from Project Gutenberg (Lebert, 2008). Our news subset comes from the Gigaword dataset for abstractive summarization (Graff et al., 2003). Lastly, our Wikipedia portion comes from WikiText-103 (Merity et al., 2017). For movies, news, and wiki, we extract sentences from its pre-specified validation set. For books, since NLTK's Gutenberg dataset lacks a pre-specified data split, we consider the entire dataset.

Data Preprocessing We sentence tokenize all datasets using NLTK's sentence tokenizer. To construct our dataset, we group sentences by sentence length into 8 bins: 5-10, 10-15, 15-20, 20-25, 25-30, 30-35, 35-40, and 40-128 using NLTK's word-level, regular expression tokenizer. Next, we ran-

Injection location	**Timestep**	**BLEU-4**
Embedding	all timesteps	33.99
Layer 6 (self attn)	**all timesteps**	**100.0**
Layer 6 (self attn)	**first timestep**	**99.80**
Layer 7 (feed fwd)	**all timesteps**	**100.0**
Layer 7 (feed fwd)	**first timestep**	**99.25**
All layers (self attn + feed fwd)	**all timesteps**	**100.0**
All layers (self attn + feed fwd)	first timestep	91.72
LM head	all timesteps	6.72

Table 1: Sentence recovery for steering vectors when injected into different layers of the transformer model (Figure 1) and at multiple timesteps (all timesteps or first timestep). Results show that injecting a steering vector into the transformer stack, even at just the first timestep, can lead to nearly perfect recovery as long as it is in the middle of the network (layers 6 or 7 of 12).

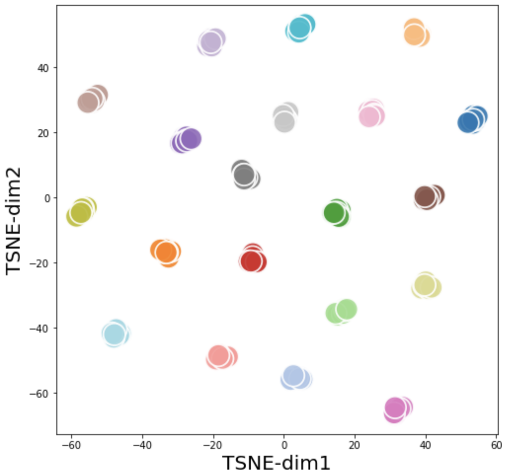

Figure 2: TSNE projection of 8 steering vectors initialized from different random seeds for 20 different sentences (injected at layer 6, after self-attention). z_{steer} is well-separated for different sentences, and the different seeds are tightly clustered for the same target sentence, indicating that our extraction method is robust.

domly sample 8 sentences from each bin to examine the efficacy of our method for a variety of sequence lengths.

Measuring the Effectiveness of Steering Given a target sentence s, we measure how well the steering vector z_{steer} can recover the target sentence by first greedily decoding from the language model with z_{steer}, and then computing smoothed BLEU-4 using the target sentence s and our decoded reconstruction $\hat{s}$ (Papineni et al., 2002; Chen and Cherry, 2014).

Hyperparameter Search Our initial experiments showed little variation to most hyperparameters such as initialization method and learning rate schedule, so we fixed them in subsequent experiments using the values in Table 6 in the appendix. We choose GPT2-117M as our language model and evaluate recovery on our dataset while varying injection locations and injection timesteps, the two hyperparameters that affect results significantly. We present a subset of the results in Table 1 and the full set in the appendix (Tables 7, 8, and 9).

3.2 Recovery effectiveness

Table 1 shows reconstruction performance for several injection methods and indicates that we can recover a target sentence with perfect recovery when injecting z_{steer} in the middle of the transformer stack (layers 6 or 7 of 12) at just the first timestep and at all timesteps, for sequences up to 128 tokens. We surmise that the middle layers of the transformer stack encode sufficiently rich feature representations that a small perturbation of a hidden layer, a steering vector, is sufficient to recover a sentence. The success of steering vectors when injected in the middle of the transformer could help explain why adapter-based fine-tuning is effective.

In contrast, we find that we cannot steer GPT-2 at either the embedding or final language model head locations. We suspect this is due to the fact that the embedding layer solely captures low-level information (Lin et al., 2019; Ethayarajh, 2019; Rogers et al., 2020). Poor recovery at the LM head location is somewhat surprising, but could be explained by noting that the model has very low capacity above this layer. This suggests that alternative steering mechanisms, such as DExperts, that intervene at the output layers could potentially be improved by modifying hidden states elsewhere in the transformer stack (Liu et al., 2021).

Robustness Now that we have established that steering vector extraction is possible, we explore whether there exist multiple steering vectors which recover the same sentence, and if so, what the relationship is between these vectors. To do this, we take all 64 sentences from the books subset of the main dataset and initialize 8 different steering vectors for each sentence from different seeds. Experiments reveal that for most sentences (63 of 64) all initializations recover the target sentence perfectly, confirming the robustness of our method.

Latent geometry in text-based auto-encoders struggle with mapping vectors from one space to another consistently (e.g. token space to latent space) (Bowman et al., 2016; Shen et al., 2020). The denoising auto-encoder offers a more consistent token space to latent space mapping (Vincent et al., 2008). To explore whether our steering vectors have a distance-preserving mapping, we cluster the different initializations of steering vectors. We extract 8 steering vectors for each of 20 sentences from the books corpus and down-project them into two-dimensions via TSNE (Maaten and Hinton, 2008). Figure 2 shows 20 distinct clusters, one for each sentence. This indicates that distances between different vectors representing the same target sentence are much smaller than distances between vectors representing different sentences, and that distances in token space could be reflected in the latent steering space.

Motivated by the clustering results, we investigate whether the mean vector of the 8 extracted steering vectors for each target sentence recover the same sentence. Experiments show that mean vectors are able to recover target sentences nearly perfectly, leading to a BLEU-4 of 99.4, further establishing the robustness of our method.

4 Is unsupervised style transfer in the latent steering space possible?

We explore whether vector arithmetic in this space is possible in the context of unsupervised style transfer. In other words, we measure whether adding an offset vector, which captures the desired style transfer, to the steering vector effectively changes the style of the generated sentence. Here, we show that unsupervised vector arithmetic with steering vectors is effective for unsupervised sentiment transfer, with performance comparable to models tailored to this task.

After extracting steering vectors for each sentence, we compute offset vectors by averaging steering vectors for a set of sentences in the source style $\bar{z}_{source}$ and subtracting from the average of a set of steering vectors for the target style $\bar{z}_{target}$. Next, we flip the style of each sentence in our test set by adding the respective style transfer vector directly to its steering vector after scaling it by λ:

$$z_{totarget} = \bar{z}_{target} - \bar{z}_{source} \quad (2)$$

$$\hat{z}_{target} = z_{source} + \lambda \cdot z_{totarget} \quad (3)$$

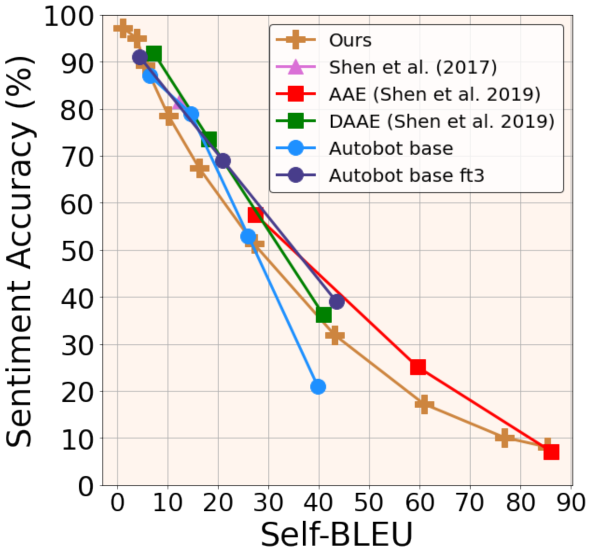

Figure 3: Evaluation of unsupervised sentiment transfer on the Yelp dataset. The plot shows accuracy vs. self-BLEU by varying λ = (0.25, 0.5, 1.0, 1.5, 2.0, 2.5, 3.0, 4.0, 5.0, 10.0) for our method. Overall, the steering vectors perform comparably to prior work.

Unsupervised Sentiment Transfer Using the Yelp Sentiment dataset preprocessed by Shen et al. (2017), we take 100 sentences from the validation set from each of the two classes of sentiment to compute offset vectors and evaluate on the test set. Following prior work (Shen et al., 2017), we measure how well this approach flips the sentiment of the sentence by measuring the accuracy of a RoBERTA-base model fine-tuned on the Yelp sentiment dataset. We also measure the BLEU-4 between the style transferred sentences and the original and report the results in Figure 3. We call this Self-BLEU following prior work. For this experiment, our steering vectors are injected after the 7th self-attention layer at the first timestep.

We find that simple vector arithmetic via our steering vectors, which is fully unsupervised, performs comparably to Shen et al. (2017), who learn an autoencoder-based model for the task in a fully supervised manner. Our method also compares well with the Autobot (Montero et al., 2021), AAE, and DAAE models (Shen et al., 2020), which although are unsupervised, either require training on in-domain data or require pretraining on millions of tokens in order to be effective. Other methods that use techniques from unsupervised machine translation to leverage the unpaired data in the task outperform all of these methods significantly (Hu et al., 2017; Lample et al., 2019; He et al., 2020).

Steering vectors	
Positive Input	the taste is excellent!
$+0.5 * z_{tonegative}$	the taste is excellent!
$+1.0 * z_{tonegative}$	the taste is excellent!
$+1.5 * z_{tonegative}$	the taste is bitter and bitter taste is bitter taste is bitter
$+2.0 * z_{tonegative}$	the taste is unpleasant.
Negative Input	the desserts were very bland.
$+0.5 * z_{topositive}$	the desserts were very bland.
$+1.0 * z_{topositive}$	the desserts were very bland .
$+1.5 * z_{topositive}$	the desserts were very tasty.
$+2.0 * z_{topositive}$	the desserts were very tasty.

Table 2: Examples of transferring sentiment using steering vectors for a positive input sentence (top) and negative input sentence (bottom). These results show fluency and accuracy in transfers while preserving the content of the input sentence.

These methods are not directly comparable to ours, as they evaluate on a different test set altogether and use the training set to train directly. Our method only requires access to 100 labeled examples per class to compute $\bar{z}_{source}$ and $\bar{z}_{target}$, far fewer than other baselines. With as few as 10 examples per class, performance of our method remains competitive with autoencoder-based baselines.

Table 2 shows examples generated by our method for two input sentences. We find that resulting sentences become more positive or negative with increasing λ and often modify adjectives by swapping them out. On closer inspection, we find that fluency is often challenging for higher values of λ and that the generated sequences repeat individual words or phrases. In addition, we find that negative to positive sentiment transfer is qualitatively more fluent and accurate than positive to negative sentiment transfer; see Table 12 in the appendix for more example generations. Lastly, we evaluate on 19 paired style transfer tasks from the StylePTB dataset (Lyu et al., 2021), but modify the tasks to be unsupervised, following the same approach as above. We find that our method is similarly effective on these tasks; see Table 10 in the appendix for details.

5 Do distances between steering vectors reflect sentence similarity?

Previously, we found there exist multiple steering vectors that recover a target sentence and that those steering vectors are close together. This indicates the potential for distances in token space to be reflected in distances in the latent space occupied by steering vectors. In this section, we explore whether distances relate to semantic similarity. To do so, we use the STS-B test dataset, which consists of sentence pairs and similarity scores. To evaluate our method we extract steering vectors for each sentence separately, compute cosine similarity, and then correlate cosine similarity with annotator similarity via Spearman rank correlation.

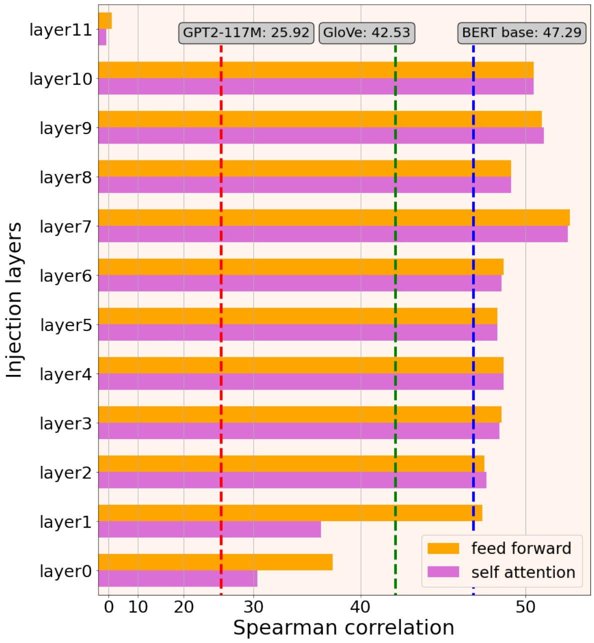

Figure 4: On the test split of STS-B, we measure Spearman rank correlation $(\rho \cdot 100)$ between sentence similarity scores and cosine similarities between the steering vectors extracted from GPT2-117M when injected at different layers at the first timestep for those sentences. The vertical lines indicate extractive baselines: mean-pooled final hidden states for GPT2-117M and BERT-base as well as mean-pooled GloVe vectors. Results show that extracted steering vectors outperform these.

In Figure 4, we show how well extracted steering vectors perform when injected at different layers and at the first timestep in the transformer stack. This observation mirrors the results from the experiment on recovery effectiveness: middle layers in the transformer stack are ideal for steering, leading to perfect recovery and highest performance on semantic similarity. We outperform mean pooling the final hidden states of GPT2-117M and BERT-base as well as averaged GloVe vectors. Even though our method is fully extractive, cosine distances reflect semantic similarity well. We take our two best performing configurations, the 7th self-attention layer and the 7th feedforward layer, and compare with unsupervised methods for tex-

Method	Spearman	Pearson
Extractive methods		
Avg GPT2-117M embeddings	25.92	16.52
Avg Bert embeddings	47.29	47.91
Avg GloVe embeddings	42.53	40.25
Layer-7 self attention (ours)	**52.04**	**51.17**
Layer-7 feedforward (ours)	**52.08**	**51.18**
NLI-finetuned methods		
AutoBot-base	58.49	-
InferSent - GloVe	68.03	-
SBERT-NLI-base	**77.03**	-
Lexical methods		
GloVe+UP	-	71.5
GloVe+WR	-	**72.0**

Table 3: We evaluate performance on the STS-B test set by measuring Spearman rank correlation and Pearson correlation ($\rho \cdot 100$). We take our two best performing configurations from Figure 4 and compare them with three classes of unsupervised methods: extractive, NLI-finetuned, and lexical methods. Our method outperforms the extractive methods, but performs worse than the other methods, which are tailored for this task.

tual similarity. Table 3 shows that our extracted steering vectors out-perform prior extractive unsupervised methods. Predictably, however, methods which pretrain or fine-tune models on natural language inference datasets such as AutoBot (Montero et al., 2021), InferSent (Conneau et al., 2017), and SBERT (Reimers and Gurevych, 2019) perform better. Lexical methods tailored for semantic similarity such as GloVe with uSIF-weighting and piecewise component removal (GloVE + UP; Ethayarajh (2018)) and GloVe + WR (Arora et al., 2017) also outperform our method.

6 Analysis of Properties

6.1 Interpolation

Previous experiments indicate that the latent space occupied by steering vectors could be well-formed and smooth. To evaluate this qualitatively, we show linear interpolations of two pairs of steering vectors extracted from the Yelp Sentiment dataset in Figure 5. The space between the vectors look smooth with well-formed grammatical sentences that mix the content of two sentences effectively. The first interpolation (sentence pair 1) in Figure 5 shows that the positive sentiment of the first sentence carries all the way to $\lambda = 0.7$, despite the content of the sentence changing to the second sentence. The second interpolation (sentence pair 2) in Figure 5 indicates that the latent space could encode some semantics relating to time. The second sentence includes the word "young" and so the transition between the two in $\lambda = 0.3, 0.4$ combines the word "four" from the first sentence with the temporal component of "years ago" to relate the two sentences. Lastly, for each individual sentence there exists a radius around it where those vectors also steer the language model to generate the same target sentence. This could indicate that sentences have a representative volume from which, if any vector was sampled, could recover the sentence.

λ	Sentence Pair 1	Sentence Pair 2
0.0	all was hot and good.	four peaks also offers great food too.
0.1	all was hot and good.	four peaks also offers a great range of food and food products too.
0.2	all was hot and good.	four peaks also offers a number of other great food and drink options too.
0.3	all was hot and good.	four years ago
0.4	all was good	four years ago
0.5	all was good	when you're young.
0.6	when it came to my turkey sandwich, my husband and I had a great time.	when you are young, you simply cannot wait any longer.
0.7	when it came to my turkey sandwich, my turkey sandwich was pretty darn good.	when you are young, you simply do not know any better.
0.8	when it finally came, my turkey sandwich was kinda blah.	when you are that young, you simply do not know any better.
0.9	when it finally came, my turkey sandwich was kinda blah.	when you are that young, you simply don't know any better.
1.0	when it finally came, my turkey sandwich was kinda blah.	when you are that young, you simply don't know any better.

Figure 5: Interpolation between steering vectors extracted from two pairs of random sentences from the Yelp Sentiment test set. Decoding from interpolated vectors from two sentences produces well-formed output that incrementally changes the sentiment and meaning.

6.2 Sampling

Previous experiments show distances reflect semantic similarity and hint at the possibility that the latent space is smooth. Given this, we evaluate whether we can sample from this space. We take 4000 extracted steering vectors from the Yelp Sentiment test set. We treat each dimension of the steering vector as an independent random variable that is normally distributed with a mean and variance equal to the mean and variance across that dimension over this set of steering vectors. Table 11 shows the results of sampling 24 steering vectors and generating from them. We observe mixed results: 5 samples lead to fully-formed sentences, and the remaining 19 lead to single tokens or phrases, indicating that treating steering vectors as samples from a multivariate Gaussian is not a reliable approach for sampling well-formed text.

6.3 Intrinsic Dimension & Space Complexity

We define the intrinsic dimension of the task of steering a language model as the minimum dimension of z_{steer} that achieves perfect recovery on a set of sentences. To measure intrinsic dimension, we vary the dimensions of z_{steer}, choosing 192, 384, 576, 768. We observe that reconstruction BLEU increases as the steering vector dimension increases, indicating that 768 dimensions may be needed to recover sequences nearly perfectly. Given this, we conclude that the intrinsic dimension is at most 768. However, a lower-dimensional representation can recover most sentences: 384 dimensions led to a reconstruction BLEU of 83.29. See Table 4 for more details. Additionally, we find that sentence length and reconstruction BLEU are inversely correlated, i.e. longer sequences are harder to recover. This is well-known; the number of bits needed to encode a sequence grows linearly with its length. We find that all four dimensions of steering vectors can recover short sentences, but lower dimensional steering vectors struggle to recover longer ones.

Steering vector dimension	192	384	576	768
Reconstruction BLEU-4	43.43	83.29	93.93	100.00

Table 4: Reconstruction BLEU for different steering vector dimensions. Sentence recovery increases monotonically as the dimension increases, up to 100% recovery at the model's hidden dimension.

Since steering vectors do not depend on sequence length, space complexity may not be a problem. For a sequence of length 128, assuming 7 characters per word on average (including spaces), storage as a string takes $128 * 7 = 896$ bytes. Our 768d steering vector uses 1536 bytes (fp16), but we can compress it by a factor of 2 (384d) sacrificing a little recovery (see Table 4) and store it using 768 bytes, less than its string representation.

6.4 Memorization

Our nearly perfect recoverability performance indicates that steering vectors could either be encoding important properties by leveraging the language model, which would help generalization, or just simply be memorizing arbitrary sequences without using the underlying language model at all. In order to evaluate this, we randomly sample 64 sentences with lengths matching that of the books subset of our dataset, where each token is sampled uniformly at random with replacement from the vocabulary, and call this the gibberish fold of our dataset, following Subramani et al. (2019). Secondly, to measure whether both content and word order affect recoverability, we construct another fold, the shuffled fold, by randomly shuffling the tokens in the sentences in the books subset.

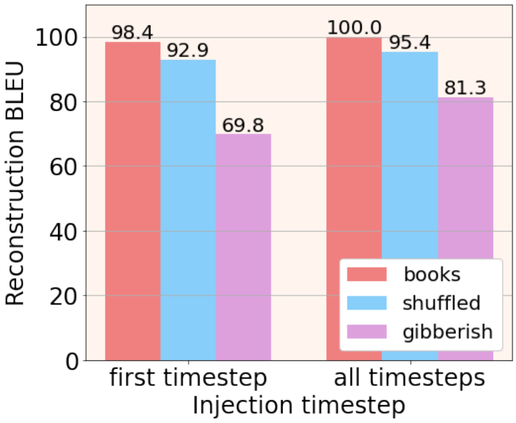

Figure 6: We measure reconstruction BLEU for steering vectors learned for three datasets: books, shuffled, and gibberish. Reconstruction BLEU for gibberish and shuffled data is lower than books indicating that the steering vector isn't just memorizing the sequence, but also leveraging the language model well.

Figure 6 shows the results of injecting steering vectors into the 6th layer after the self-attention block in the transformer for all timesteps and the first timestep across all three datasets. We observe that recoverability is highest for books, then shuffled, and lastly gibberish. The gap between performance on books and gibberish indicates that steering vectors are not simply memorizing. Since recovery on books is greater than recovery on shuffled, we conclude that steering vectors encode some information about word order. Lastly, we notice that only passing the steering vector at the first timestep may reduce unwanted memorization capability because the relative difference in recovery between gibberish and the other sets is large.

6.5 Connection to Prompting

Motivated by the successes of prompt-based methods on zero-shot tasks with large generative language models such as GPT-3 (Brown et al., 2020), we evaluate a prompt-based version of our method. Instead of adding z_{steer} to the hidden states of the language model, we concatenate k steering vectors with the input embeddings, so that all tokens can attend to these z_{steer} vectors. Experiments on the books subset show that recovery is much lower with this prompt-based approach than when injecting steering vectors directly into the transformer stack of the model. Even with $k = 50$ steering vectors injected via this prompt-based approach, recovery fails to match that of a single steering vector z_{steer} injected into the hidden states of the language model.

Num prompt vectors	1	5	10	20	50
Reconstruction BLEU-4	81.7	94.3	98.7	98.6	98.5

Table 5: We measure reconstruction BLEU using a prompt-based approach, where latent steering vectors are concatenated to the embeddings. Even though each prompt vector is 768 dimensional, reconstruction BLEU is much lower in this setting than injecting a single steering vector into the layers of the transformer stack.

7 Related Work

There exist many works, often using text-based autoencoders that try to induce a sentence representation space for controllable text generation by learning new models (Hu et al., 2017; Shen et al., 2017, 2020; Mai et al., 2020; Montero et al., 2021). Our work concludes that we can extract steering vectors from pretrained models that have latent spaces that allow operations like this, without having to train any new models at all. Other approaches control language models by adapting their hidden states using steerable layers, adapters, or steering their logits using auxiliary language models (Gulcehre et al., 2015; Dathathri et al., 2019; Houlsby et al., 2019; Zhang et al., 2020; Liu et al., 2021; Krause et al., 2021). Our method differs from all of these: we extract steering vectors directly from a language model and operate on the latent space occupied by these vectors, never fine-tuning any component of the model. Subramani et al. (2019) investigate whether LSTM-based language models have sentence representations from which they can generate the original sentence. Although this premise relates to our first question: can we extract steering vectors, we extend far beyond that showing that vector arithmetic in the context of unsupervised style transfer is effective in our latent steering space.

8 Conclusion

In this paper we introduce a different approach to controllable text generation, where we extract latent steering vectors directly from a pretrained language model without fine-tuning. Further, we find that our steering vectors lead to near perfect recovery on English sentences from a variety of domains. We show that vector arithmetic can be used in the context of unsupervised style transfer on the Yelp sentiment dataset and StylePTB benchmark, performing comparably to models tailored to these tasks. Experiments reveal that distances between steering vectors reflect sentence similarity when evaluated on STS-B, outperforming extractive methods. Finally, we analyze properties of the steering vectors. Our results indicate that we can control frozen pretrained language models effectively through their latent steering space.

9 Ethics Statement

We introduce a new approach for controllable text generation by extracting vectors from a pretrained language model, leveraging information that is already encoded in the language model. Large pretrained models are known to be biased and our method of extracting steering vectors can reflect biases already present in these large pretrained language models (Bender et al., 2021). The methods we present for controllable text generation could potentially be used for many downstream tasks such as unsupervised style transfer, abstractive summarization, and offensive content removal. Unfortunately, this also means that this technology has the potential to be misused to perpetuate biases or generate offensive or toxic text.

Our technology does not guarantee removal of toxic content, even in the case of unsupervised style transfer from toxic to nontoxic text. To use this method, we encourage readers to first take steps to address biases that are already present in the underlying language model. Further we recommend that this technology not be used in high-stakes settings, especially those where deployment of this technology could cause harm.

A Appendix

A.1 Extracting steering vectors

In this section, we show the hyperparameter configurations used for extracting steering vectors from GPT2-117M. Table 6 contains the list of final hyperparameters that we use to extract steering vectors for the different analyses in this paper. Table 7 shows the recovery performance of steering vectors when injected at different layers in the transformer stack on our compiled dataset. These experiments reveal that injecting in the middle of the transformer stack either after the self attention layer or the feedforward layer leads to the highest BLEU-4 performance. In fact, any layer other than the first or last layer achieves nearly perfect recovery.

In Table 8 we look at recovery performance when injecting steering vectors at the embedding layer, transformer stack, and language modeling head, as well as different combinations of them. Injecting steering vectors at every layer in the transformer stack performed best. Table 9 shows how recoverability changes with respect to how many timesteps z_{steer} is injected at. Injecting at all timesteps performs negligibly better than injecting at just the first timestep.

Hyperparameters	Values
Model	GPT-2-117M
Max train steps	500
Vector initialization strategy	Xavier normal
Learning rate	[0.01, 1.0]
Optimizer	Adam
Learning rate Scheduler	Decay on a plateau
Scheduler decay factor	0.9
Scheduler decay patience	1.0

Table 6: List of hyperparameter configurations used to extract z_{steer} from GPT2-117M.

A.2 Unsupervised Sentiment Transfer

Yelp Sentiment We also include generations from the unsupervised sentiment transfer experiment on the Yelp dataset. Table 12 shows 8 more generations. These generations highlight the same trends as before: with increasing λ, sentiment transfer strength increases. We find that some generations do more than just flip the sentiment of the major adjective in the sentence such as adding the phrase "a great way to get a good laugh" in the 4th negative to positive generation when $\lambda = 2.5$.

Injection location	layers	timestep	lr	BLEU-4
self_attn	0	all timesteps	1	33.25
feedforward	0	all timesteps	1	97.68
self_attn	1	all timesteps	1	98.06
feedforward	1	all timesteps	1	99.54
self_attn	2	all timesteps	1	100.00
feedforward	2	all timesteps	1	99.69
self_attn	3	all timesteps	1	100.00
feedforward	3	all timesteps	1	100.00
self_attn	4	all timesteps	1	100.00
feedforward	4	all timesteps	1	100.00
self_attn	5	all timesteps	1	100.00
feedforward	5	all timesteps	1	100.00
self_attn	6	all timesteps	1	**100.00**
feedforward	6	all timesteps	1	99.62
self_attn	7	all timesteps	1	99.62
feedforward	7	all timesteps	1	**100.00**
self_attn	8	all timesteps	1	100.00
feedforward	8	all timesteps	1	98.84
self_attn	9	all timesteps	1	99.22
feedforward	9	all timesteps	1	98.61
self_attn	10	all timesteps	1	97.50
feedforward	10	all timesteps	1	95.24
self_attn	11	all timesteps	1	86.04
feedforward	11	all timesteps	1	6.29

Table 7: This table shows the reconstruction BLEU-4 for steering vectors from our compiled dataset when injected after different self attention and feedforward layers in the transformer stack. Injecting at the middle layer of the language model performs best.

StylePTB For this study, we use 19 of 21 paired style transfer tasks from the StylePTB dataset (Lyu et al., 2021), but modify the tasks to be unsupervised, following the same approach as sentiment transfer. We randomly sample 100 sentences for each class from the training split for each of the style classes and use those to compute offset vectors. This offset vector is then added to the steering vector of the sentence to transfer style. We follow the evaluation in Lyu et al. (2021) because we have ground truth data and compare with fully

Injection location	**timestep**	**lr**	**BLEU-4**
embedding	all timesteps	0.01	33.99
every_layer	all timesteps	0.01	100.00
lm_head	all timesteps	0.01	6.72
embedding+every_layer	all timesteps	0.01	96.52
every_layer+lm_head	all timesteps	0.01	100.00
embedding+lm_head	all timesteps	0.01	83.27
embedding+every_layer+lm_head	all timesteps	0.01	98.11
every_layer_self_attn	all timesteps	0.01	99.62
every_layer+every_layer_self_attn	**all timesteps**	**0.01**	**100.00**
every_layer_self_attn+embedding+lm_head	all timesteps	0.01	97.31
every_layer_self_attn+lm_head	all timesteps	0.01	99.62
every_layer_self_attn+embedding	all timesteps	0.01	94.28

Table 8: Here, we present the reconstruction BLEU-4 results for steering vectors on our multi-domain compiled dataset. We vary injection location here and observe that injecting into the transformer stack is necessary for good recovery. Injecting at the embedding or language model head performs poorly.

Injection location	**timestep**	**lr**	**BLEU-4**
every_layer+every_layer_self_attn	all timesteps	0.01	100.0
every_layer+every_layer_self_attn	first timestep	0.01	91.7
Layer 7 (feedforward)	all timesteps	1	100.0
Layer 7 (feedforward)	first timestep	1	99.2
Layer 6 (self_attn)	all timesteps	1	100.0
Layer 6 (self_attn)	first timestep	1	99.8

Table 9: In this table, we vary the timestep where we inject z_{steer} (all timesteps or first timestep) for three of our best injection locations. We again evaluate on our multi-domain compiled dataset and find that injecting at just the first timestep has a negligible decrease in recovery performance.

supervised methods. Experiments show that unsupervised vector arithmetic with steering vectors performs comparably using BLEU-1 to supervised methods designed for style transfer on tasks that require minimal edits (adjective emphasis (AEM), active to passive (ATP), information addition (IAD), and PP front to back (PFB)). We report BLEU-1 following prior work. See Table 10 for results on all 19 tasks. Note Lyu et al. (2021) do not report any baseline numbers for AAR, ASR, LFS, MFS, NAR, NSR, and VSR for any of their models.

A.3 Sampling

In order to evaluate whether we can sample steering vectors reliably, we collect 4,000 extracted steering vectors from the Yelp Sentiment test set. To generate, we consider each dimension of the steering vector as an independent random variable that is normally distributed. The dimension means and variances are equal to the mean and variance for that dimension across this set of steering vectors. In Table 11, we show the results of sampling 24 steering vectors from these independent normally distributed random variables and generating from them using GPT2-117M as our language model. These results are mixed with approximately 20% of the generations leading to fully formed sentences and the remaining 80% corresponding to individual words or short phrases. This could perhaps be partially explained by the fact that text from the web, including the corpora GPT2 was trained on, can often be of poor quality, especially when automatically crawled (Caswell et al., 2022). Alternatively, our choice of considering d-dimensional steering vectors as samples from d independent normally distributed random variables could be an incorrect assumption. Alternative formulations could lead to more fluent and reliable generations.

	Ours: $\lambda = 0.25$	GPT2-finetune	Seq2seq	TAILOR	Neural QCFG + copy	Retrieve-Edit
AAR	**0.825**	-	-	-	-	-
AEM	**0.774**	0.263	0.187	-	0.676	0.387
ARR	0.721	0.647	0.450	0.781	-	**0.897**
ASR	**0.819**	-	-	-	-	-

NSR	**0.677**	-	-	-	-	-
PFB	0.819	0.398	0.393	**0.842**	-	0.541
PPR	0.393	0.763	0.330	0.717	-	**0.798**
PTA	0.574	0.433	0.339	-	-	**0.714**
SBR	0.120	0.430	0.317	-	-	**0.706**
TFU	0.699	0.895	0.527	0.873	-	**0.899**
TPA	0.478	0.836	0.478	0.884	-	**0.935**
TPR	0.692	0.754	0.516	0.710	-	**0.909**
VEM	0.548	0.309	0.289	-	**0.664**	0.416
VSR	**0.739**	-	-	-	-	-

Table 10: In this table, we show performance on StylePTB. Although our method is unsupervised, we outperform GPT2-finetune and seq2seq on most tasks. For minimal edit tasks such as AEM, ARR, ATP, and PFB, we achieve comparable performance to TAILOR, Neural QCFG + copy, and Retrieve-Edit, which are models trained specifically for these types of tasks. Note: we obtain the numbers for GPT2-finetune, Seq2seq, and Retrieve-Edit from (Lyu et al., 2021), for TAILOR from (Ross et al., 2021), and for Neural QCFG+copy from (Kim, 2021).

Abstract

Generalising to unseen domains is under-explored and remains a challenge in neural machine translation. Inspired by recent research in parameter-efficient transfer learning from pretrained models, this paper proposes a fusion-based generalisation method that learns to combine domain-specific parameters. We propose a leave-one-domain-out training strategy to avoid information leaking to address the challenge of not knowing the test domain during training time. Empirical results on three language pairs show that our proposed fusion method outperforms other baselines up to +0.8 BLEU score on average.

1 Introduction

Building robust machine translation (MT) models that can perform well on a test set outside the domain of training examples is highly desired in real-world scenarios. Despite recent great progress in neural machine translation (NMT) research, NMT models have been found sensitive to distribution shift and adversarial examples (Koehn and Knowles, 2017; Belinkov and Bisk, 2018; Müller et al., 2020). While improving an NMT model to a new domain has been studied extensively in domain adaptation settings where in-domain parallel or monolingual data is given (Chu and Wang, 2018), generalising NMT models to unseen domains is under-explored (Specia et al., 2020).

Domain generalisation is a problem setting in machine learning that tackles the challenge of learning a robust model for unseen domains from multiple existing domains. This problem is closely related to several settings such as multi-task learning, transfer learning, and domain adaptation in terms of learning models from one or more given tasks/domains to enhance performance on some target tasks/domains. The main difference and challenge in domain generalisation is that the test domains are *unknown* in advance. Previous works on domain generalisation focused on learning invariant features by minimising the difference in the representations of the given domains for the classification tasks (Li et al., 2018; Wang et al., 2020b; Gulrajani and Lopez-Paz, 2020). Learning a domain-invariant representation is applicable to the classification problems where such invariances may be sufficient to predict the target classes. However, it may be inadequate for translation tasks. A good translation should not only preserve the invariant features such as syntax and grammar, but also be able to maintain the domain-specific features such as style of the source sentence.

In this paper, we propose a fusion-based approach to the domain generalisation problem for NMT. Our method comprises two training stages. The first stage is to learn domain-specific features through adapter modules added to the pretrained encoder-decoder model. Previous works have shown that the task-specific adapter is an effective alternative method to fine-tuning. It allows fast adaptation of pretrained language models to downstream tasks (Houlsby et al., 2019), and multilingual NMT models to new language pairs (Philip et al., 2020; Berard, 2021). In the second stage, we propose to use an AdapterFusion module (Pfeiffer et al., 2021) and train it to effectively combine features of the existing domains in order to handle unseen domains.

Unlike (Pfeiffer et al., 2021) who trains the AdapterFusion module for transfer learning (from existing tasks to a *seen* target task), we do *not* have access to the test domain during training. To address this challenge, we propose a novel leave-one-domain-out (LODO) training strategy by creating homogeneous mini-batches consisting of training examples from a single domain and disabling the corresponding domain adapter when optimising the fusion layer. This training strategy is related to model selection for domain generalisation (Gulra-

jani and Lopez-Paz, 2020), where the aim is to maximise the expected performance w.r.t an unknown meta-distribution over domains. Unlike (Gulrajani and Lopez-Paz, 2020), we use LODO to train the AdapterFusion module instead of model selection.

Our contributions can be summarised as follows: (i) We extend AdapterFusion for domain generalisation, where the target domain is not available during training; (ii) We propose a novel leave-one-out training strategy to avoid over-fitting of the fusion layer to the given training domains; (iii) We demonstrate the efficacy of our proposed fusion method on three language pairs and four unseen domains. Empirical results show that our approach outperforms the learning invariant feature baseline on most of unseen test domains with an improvement up to +0.8 BLEU score on average[1].

2 Our Approach

Problem Formulation. We define domain generalisation for NMT as the problem of learning an NMT model on training datasets from multiple domains $\mathcal{D} = \{D^1, ..., D^K\}$ such that it performs well at some unseen test domain D^{K+1}. A dataset $D^k = \{(\boldsymbol{x}_i^k, \boldsymbol{y}_i^k)\}_{i=1}^{n_k}$ in domain k contains n_k examples from a distribution $\Pr_k(X, Y)$ where X ranges over sentences in the source language, and Y is its translation in the target language.

Domain-specific parameter learning. We insert a small adapter module in transformer layers of the pretrained NMT model to capture domain-specific features (Houlsby et al., 2019). Adapters are task-specific modules introduced to a pretrained network to enable fast adaptation to new tasks. Following (Pfeiffer et al., 2021), we add the adapter only after the last feed-forward layer. The adapter module includes a down-projection $\boldsymbol{W}^{(l)}_{down}$ followed by an up-projection $\boldsymbol{W}^{(l)}_{up}$ to project the hidden state $\boldsymbol{h}^{(l)}$ in layer l to a lower-dimension space then project back to high-dimension space

$$\boldsymbol{h}^{(l)} = \boldsymbol{h}^{(l)} + f(\boldsymbol{h}^{(l)}\boldsymbol{W}^{(l)}_{down})\boldsymbol{W}^{(l)}_{up} \qquad (1)$$

where $f(.)$ is a nonlinear activation function. We denote $\omega = \{\boldsymbol{W}^{(l)}_{down}, \boldsymbol{W}^{(l)}_{up}\}_{l=1}^{L}$ as adapter parameters. We learn the adapter modules while freezing the encoder and decoder parameters. At training time, we only train the adapter with the training data from the corresponding domain.

Algorithm 1 LODO Training of AdapterFusion

```
Function: trainFusion
Input: Training data $\mathcal{D} = \{D^1, ..., D^K\}$, NMT model $\theta$, adapters $\{\omega_1, ..., \omega_K\}$
Output: Fusion layer $\psi$
while not converge do
    shuffle $\mathcal{D}$
    $\{b_j^{k_j}\}_{j=1}^{J} \leftarrow \{(\boldsymbol{x}, \boldsymbol{y}) \in D^{k_j} | D^{k_j} \in \mathcal{D}\}$ // create homogeneous minibatches
    for $j = 1$ to $J$ do
        $d_j \leftarrow \{1, ..., K\} \setminus \{k_j\}$ // active domains
        for all transformer layer $l$ do
            $\boldsymbol{h}^{(l)} \leftarrow \theta^{(l)}(b_j^{k_j}, \boldsymbol{h}^{(l-1)})$ // hidden state
            $\{\tilde{\boldsymbol{h}}_k^{(l)}\} \leftarrow \{\boldsymbol{h}^{(l)} + \omega_k(\boldsymbol{h}^{(l)})\}_{k \in d_j}$ // adapter outputs
            $\boldsymbol{h}^{(l)} \leftarrow \psi^{(l)}(\boldsymbol{h}^{(l)}, \{\tilde{\boldsymbol{h}}_k^{(l)}\}_{k \in d_j}, \{\tilde{\boldsymbol{h}}_k^{(l)}\}_{k \in d_j})$ // fusion output
        end for
        $\psi \leftarrow \psi - \gamma \nabla_{\psi} \mathcal{L}_{NMT}(\boldsymbol{y}, \boldsymbol{x}, \boldsymbol{h}^{(L)})$
    end for
end while
return $\psi$
```

Domain generalisation with AdapterFusion To help the NMT model generalise to unseen domains, we learn a fusion layer (Pfeiffer et al., 2021) to combine domain-specific adapters while freezing all other parameters. Since we do not have access to unseen domains at training time, we propose *leave-one-domain-out* (LODO) training strategy to train the fusion layer. We create *homogeneous* batches of training data from individual domains. For a given batch $b_j^{k_j}$ from domain k_j where $j \in \{1, ..., J\}$ ranges over all possible batches in a training epoch, the adapter corresponding to this domain is disabled, and the fusion layer learns to combine the

output of other $K-1$ adapters as shown in Figure 1.

Algorithm 1 describes our proposed LODO training strategy. We denote $d_j \leftarrow \{1, ..., K\} \setminus \{k_j\}$ the index set of active adapters for a batch $b_j^{k_j}$ in domain k_j (line 5). The adaptive hidden state for domain $k \in d_j$ in transformer layer l is computed using eq. (1) (line 8). The fusion module in transformer layer l parametrised by $\psi^{(l)}$ combines the adapter outputs $\{\boldsymbol{h}_k^{(l)}\}$ using the self-attention mechanism with the adapter input as query, adapter outputs as key and value. We train the fusion module with cross-entropy loss while freezing other parameters (line 11).

3 Experiments

We evaluate our proposed approach to generalise a pretrained NMT model to unseen domains on three language pairs English-German (En-De), English-French (En-Fr), and English-Polish (En-Pl).

3.1 Experimental Setup

Dataset. The pretrained NMT models are trained on generic domain datasets from WMT2014 for En-Fr, WMT2020 for the other language pairs. Following the recipe in Koehn and Knowles (2017), we create five source domains: legal (Law), IT (IT), Koran (Koran), Medical (Med), and Subtitles (Sub) from OPUS (Tiedemann, 2012). We consider Book dataset from OPUS (Tiedemann, 2012), TED talk (TED) (Qi et al., 2018), TICO-19 (Tico19) (Anastasopoulos et al., 2020) and WMT20 Robustness task (Robust) (Specia et al., 2020) as unseen test domains. Data statistics are reported in Table 1.

Baselines. We consider two backbone pretrained NMT models: (i) generic-domain (*mBART*$_{WMT}$) - an mBART model (Liu et al., 2020) finetuned on WMT dataset; and (ii) multi-domain (*mBART*$_{MD}$) - an mBART model finetuned on the combination of training data from all available source domains. We evaluate our proposed domain generalisation approach against the following baselines:

- **Zeroshot** uses the pretrained backbone models *mBART*$_{WMT}$ and *mBART*$_{MD}$ to evaluate on the unseen domains.
- **Finetuning (FT)** which further trains the backbone on multi-domain datasets.
- **Adversarial domain discriminator (disc)** which adds a domain discriminator on top of the encoder to learn domain-invariant features by jointly training with MT and adversarial domain discrimination loss (Britz et al., 2017).

We also report the BLEU score of finetuning mBART on the test domain, which serves as a supervised oracle.

Architecture and hyperparameters. We finetune mBART-based models using a batch size of 4048 tokens with mixed-precision training up to 200K update steps and early stopping on 4 V100 GPUs. We apply Adam with an inverse square root schedule, a linear warmup of 5000 steps and a learning rate of 3e-5. We use dropout and label smoothing with a rate of 0.3 and 0.2. For multi-domain training, we use temperature-based sampling with $T = 1.5$ to balance training size between domains (Arivazhagan et al., 2019).

Table 2: BLEU score on unseen test domains. The first two columns show the pretrained backbones and whether they are frozen during training: off-the-self mBART (*mBART*), finetuned mBART on WMT data (*mBART*$_{WMT}$), and finetuned mBART on multi-domain data (*mBART*$_{MD}$). The third column presents the training methods with the data used in brackets: zeroshot, finetuning (*FT*), domain discriminator (*disc*), and our proposed method (*LODO*) on the multi-domain data (MD) or all data including WMT and MD. Best and second best scores of each column are marked in **bold** and underline respectively. † indicates that the best score is statistically significant difference to the second best (p-value ≤ 0.05) using paired bootstrap resampling.

For adapter modules, we use the adapter architecture of Pfeiffer et al. (2021), which is added once only after the last feed-forward layer for each transformer layer of encoder and decoder. We set the bottleneck dimension to 256 in all experiments and use ReLU as the nonlinear activation function. We train the adapters for each domain separately with a learning rate of 2e-4 up to 120K steps with early stopping and 2000 warmup steps. Other hyperparameters are the same as in the mBART finetuning.

Following Pfeiffer et al. (2021), we initialise the value matrix V of the fusion layer with a diagonal of ones and the rest with random weights of a small norm 1e-6. The query matrix Q and key matrix K are initialised randomly. We train the fusion layers with a learning rate of 5e-5 up to 200K steps with early stopping and 10K warmup updates.

Evaluation. We report BLEU scores calculated by SacreBLEU (Post, 2018)[2].

Table 3: Ablation of fusion layer training strategies on (i) leave-one-domain-out training (*LODO*) vs. fusion all adapters (*all*), and (ii) whether to have homogeneous batches (*homo*) or mixed-domain batches (*mixed*). All models are trained with the *mBART*$_{WMT}$ backbone.

3.2 Main Result and Ablation

We present the results on unseen domains for from-English and to-English translation of three language pairs in Table 2. There are big gaps between the supervised oracles and the domain generalisation methods, except for the En-Pl BOOK domain where the training data is relatively small. Overall, the *mBART*$_{WMT}$ backbones outperform the *mBART*$_{MD}$ backbones on the unseen domains. It is expected that WMT datasets can be considered as generic, and the *mBART*$_{MD}$ backbone may overfit to the seen domains.

Finetuning the *mBART*$_{WMT}$ backbones on multi-domain datasets (*FT(MD)*) degrades performance on unseen domain significantly. We observe a similar trend when finetuning on both WMT and multi-domain datasets (*FT(all)*). It may be due to dataset imbalance and negative interference between domains. Learning domain-invariant fea-

---

[2] `nrefs:1|case:mixed|eff:no|tok:none|smooth:exp|version:2.0.0`

tures (*disc(MD)*) are able to improve BLEU score on unseen domains over the $mBART_{MD}$ backbone. On average, our proposed fusion method outperforms other baselines in most translation directions without retraining the backbones.

Ablation on AdapterFusion training strategy. We do an ablation study of our LODO training strategy with homogeneous batches on En-De with the $mBART_{WMT}$ backbone in Table 3. Compared to LODO, we observe performance drop on all domains when activating all adapters. However, there is no significant difference between homogeneous and mixed batches.

4 Related works

Domain generalisation for NMT. Domain generalisation has been mostly studied in computer vision (Wang et al., 2021b). The main approaches include invariant feature learning (Li et al., 2018; Wang et al., 2020b), data augmentation (Wang et al., 2020a), and meta learning (Balaji et al., 2018; Wang et al., 2021a). Although domain mismatch is a known challenge in NMT (Müller et al., 2020), domain generalisation has just recently drawn attention with the introduction of zeroshot evaluation in WMT2020 Robustness shared task (Specia et al., 2020), but is still under-explored.

Adapters. Adapter-based methods have been shown effective in transferring to new languages in multilingual NMT (Üstün et al., 2021; Berard, 2021; Cooper Stickland et al., 2021; Zhu et al., 2021) and fast adaptation to new domains (Bapna and Firat, 2019). Combining task-specific adapters with attention mechanism (Pfeiffer et al., 2021) or ensemble (Wang et al., 2021c) allows efficient transfer to low-resource natural language understanding (NLU) and NMT tasks. When target domain examples are unavailable, adapters can be combined during inference to better generalise to unseen domains for NLU tasks (Gururangan et al., 2021).

5 Conclusion

In this paper, we propose a fusion-based approach to the domain generalisation problem for NMT. Our method first captures domain-specific features via adapters, then learns to combine them with leave-one-out strategy training. Experiments show the effectiveness of our methods without retraining the NMT backbone. Hence, it is a potential method to quickly incorporate newly arriving domains into the existing NMT systems.

Abstract

What kinds of instructional prompts are easier to follow for Language Models (LMs)? We study this question by conducting extensive empirical analysis that shed light on important features of successful instructional prompts. Specifically, we study several classes of *reframing* techniques for manual reformulation of prompts into more effective ones. Some examples include decomposing a complex task instruction into multiple simpler tasks or itemizing instructions into sequential steps. Our experiments compare the zero-shot and few-shot performance of LMs prompted with reframed instructions on 12 NLP tasks across 6 categories. Compared with original instructions, our reframed instructions lead to significant improvements across LMs with different sizes. For example, *the same* reframed prompts boost few-shot performance of GPT3-series and GPT2-series by 12.5% and 6.7% respectively averaged over all tasks. Furthermore, reframed instructions reduce the number of examples required to prompt LMs in the few-shot setting. We hope these empirically-driven techniques will pave the way towards more effective future prompting algorithms.

1 Introduction

Prompting language models (LMs) (Liu et al., 2021a) has made NLP modules accessible to non-expert users through plain text instructions[1] of NLP tasks. Such task instructions written by non-expert users are often long and contain abstract descriptions which are not easy to follow for LMs, as evident by their low performance (Efrat and Levy, 2020; Mishra et al., 2022). However, it is not quite clear whether this is due to the inherent difficulty of the target tasks or an artifact of the complex phrasing of their language instructions.

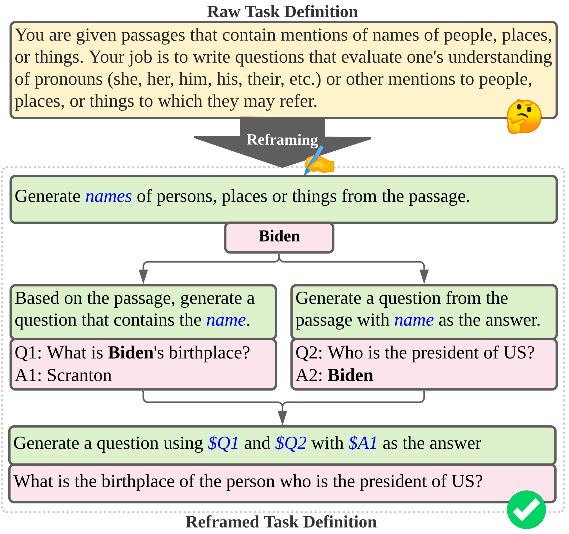

Figure 1: GPT3 has difficulty in writing questions that require entity coreference resolutions based on a single lengthy prompt (top, in yellow), however, it succeeds in solving a manually *reframed* task that has four simpler sub-steps (bottom, in green).

In this analysis, we aim to understand the sensitivity of LMs to the framing of instructional prompts. In particular, we study several *reframing* techniques to frame instructional prompts differently so that LMs achieve better understanding of the task. These reframing techniques are motivated by various empirical intuitions such as ease of understanding concise and concrete instructions and those that contain little abstract statements about human commonsense or their background knowledge. For example, Fig.1 shows a reframing example which involves decomposing a task into multiple sub-tasks. The intended task here is writing questions that require entity coreference (Dasigi et al., 2019). While GPT3 fails in solving the original task instruction (the yellow box at the top), it succeeds when the task is decomposed to four simpler and easier sub-tasks.

We provide analysis for five diverse reframing techniques. These include incorporating low-level

---

[1] We focus on instructional prompts (Efrat and Levy, 2020) as opposed to exemplar prompts which are already well-studied (Brown et al., 2020; Lu et al., 2021).

Findings of the Association for Computational Linguistics: ACL 2022, pages 589 - 612
May 22-27, 2022

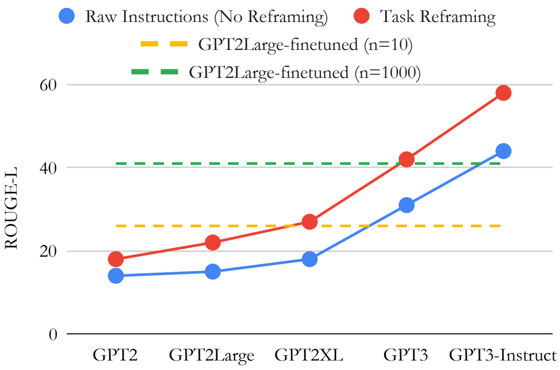

Figure 2: Across a variety of model sizes, reframed prompts consistently show considerable performance gain over raw task instructions (no reframing) in a few-shot learning setup. Since fine-tuning GPT3 is prohibitively expensive, we show the performance of fine-tuning smaller models (horizontal lines). This results indicates that *evaluating* reframed prompts on a large model like GPT3-instruct (red line) might be more effective that *fine-tuning* a smaller model like GPT2Large (green line) with 200× more data. Details of the experiments in §4.

patterns about the target task, decomposing and itemizing instructions, stating the task constraints, and providing specialized instructions (examples in Table 1).

We analyze reframed instructions over 12 tasks from NATURAL INSTRUCTIONS (Mishra et al., 2022), which contains a variety of NLP tasks and their instructions. Empirically, we compare the quality of LMs (GPT2/3 Radford et al. 2019; Brown et al. 2020) in two settings: raw vs reframed instructions. In particular, we observe that the reframed prompts have notable performance gains over raw instructions (the gap between the red and blue trends in Fig.2) with an average of 14% and 17% gains when using GPT3-instruct in the few-shot and zero-shot setups, respectively. Furthermore, the average gains across tasks remain consistent across different models hinting at consistency of reframed prompts on various architectures. This is in contrast to the widely-used fine-tuning approaches which need to be performed separately for each model. Reframing prompts by model designers can be particularly effective when evaluated on large LMs, where fine-tuning can be prohibitively expensive (such as GPT3). In particular, we observe that, reframed prompts on GPT3-instruct score roughly 17% higher than GPT2Large that is supervised with $1k$ instances (i.e., 200× more data).

While reframing instructions are not algorithmic, nonetheless, we view this systemic analysis as a preliminary stepping stone in this direction. We hope that this study will lead to the development of algorithmic better few-shot learning methods that generalize across models, thereby leading to more effective ways of reaping the investments already poured into creating massive LMs.

Contributions: (a) This work is inspired by the sensitivity of LMs to the framing of their instructional prompts. Driven by many empirical analysis, we identify several guidelines for model designers to *reframe* instructional prompts and provide illustrative use cases associated with each type of reframing technique. (b) Extensive experiments on diverse tasks show that reframing gives rise to superior performance and improved sample complexity over raw task instructions, across a range of models sizes. (c) Our experiments quantify the contribution of the prompting techniques and analyze various parameters that contribute to their success.

2 Related Work

Our work is related to designing discrete prompts and tuning continuous prompts in recent literature.

Discrete Prompts Constructing effective discrete prompts for language models to perform NLP tasks is an active area of research (Schick and Schütze, 2021; Le Scao and Rush, 2021; Tam et al., 2021; Logan IV et al., 2021; Reynolds and McDonell, 2021). Most such works focus on light-weight changes to the original prompt (Liu et al., 2021a). Unlike the earlier literature, we focus on framings of complex instructions, which often lead to reframed prompts that are often very different from the original raw instructions. While our proposed prompt-reframing is not quite algorithmic, the principles behind them are relatively simple, which can hopefully motivate algorithmic solutions in future.

Our goal is fundamentally different from the meta-training with instructions (Mishra et al., 2022; Sanh et al., 2022; Wei et al., 2022). Such approaches depend on labeled data (language prompts for thousands of tasks) which can be costly to collect. Additionally, they require fine-tuning models which can be costly for larger LMs. Exploring effective framings of language instructions can provide alternative ways of utilizing LMs.

Continuous Prompts Tuning continuous prompts leads to the making of space-efficient models compared to fine-tuning model parameters (Liu et al., 2021b; Lester et al., 2021). Despite being algorithmic, these models require propagating gradient information across the whole architecture, leading to high computational costs, which is a key bottleneck when it comes to large LMs such as GPT3. While our proposal requires human intervention, it provides model designers with several relatively easy rules-of-thumb to come up with language prompts that work effectively with large LMs.

3 Prompt Reframing

This section describes our reframing principles and then describes the guidelines to operationalize them. Reframing principles are obtained by probing instructions of various tasks in the training split of NATURAL INSTRUCTIONS (Mishra et al., 2022) to understand different failure modes associated with prompting in GPT3.

Motivation from GPT3's Failures We observe that GPT3 fails to follow instructions when it is provided with long prompts that often contain repeated information, abstract notions, analogies, complex statements requiring human commonsense and their domain knowledge (see examples in Table 1 and 4). Humans typically find these helpful for describing their tasks. For example, some content intended to motivate the task or repetition for the sake of emphasis, might be unnecessary or even redundant for a model.

3.1 Reframing Principles

We observe that short prompts that contain concrete statements and avoid terms associated with background knowledge improve GPT3's response to instructions. We recursively apply this observation and provide a set of reframing principles to resolve various issues on GPT3's failures with prompting, backed by extensive empirical analysis on GPT3.[2]

(C_1) *Use Low-level Patterns*: Instead of using terms that require background knowledge to understand, use various patterns about the expected output.

(C_2) *Itemizing Instructions*: Turn descriptive attributes into bulleted lists. If there are any negation statements, turn them into assertion statements.

(C_3) *Break it Down*: Break down a task into multiple simpler tasks, wherever possible.

(C_4) *Enforce Constraint*: Add explicit textual statements of output constraints.

(C_5) *Specialize the Instruction*: Customize the instructions so that they directly speak to the intended output.

We operationalize each of the above principles in terms of 5 *reframing* techniques. The degree of reframing (the amount of change applied to the raw instructions) varies significantly across the reframing techniques: the simplest one adds an enforcement statement at the end whereas the other extreme involves completely changing the task as a whole (e.g., decomposing it into multiple tasks).

3.2 Reframing Techniques

We explain each of the reframing techniques in three parts (1) *model failure* states a potential weakness of LM with reference to examples in Table 4 (2) *approach* describes our suggested approach and intuition behind it, according to our empirical observations (3) *example* illustrates the application of the suggested technique in reference to Table 1. In designing these techniques, we used a development set that contains all the positive examples included as part of the instructions of each task in NATURAL INSTRUCTIONS.

3.2.1 PATTERN REFRAMING

Model failure While humans have an incredible ability in understanding and acting with respect to abstract descriptions, LMs tend to ignore most of them or just repeat the content of such instructions in their output (*copy instruction* in Table 4.)
Approach Find low-level patterns among the dev set examples and extrapolate those by adding similar patterns (C_1).
Example Table 1 (row 1) illustrates the CosmosQA (Huang et al., 2019) question generation task. The raw task instruction consists of various high-level statements such as "commonsense", "complex", "interesting", "easy for humans and hard for AI machines", whereas the reframed task consists of various low-level patterns about the expected output such as "what may happen", "in the future, will..", "why might", which generally improve GPT3's performance in generating valid questions.

3.2.2 ITEMIZING REFRAMING

Model failure LMs cannot follow long paragraphs stating multiple requirements (*first instruction bias* in Table 4) and do not perform well when the requirements are formulated as a negative statement

---

[2] The principles have light resemblance to how basic tasks are formulated and taught to kids.

	Raw task definitions and their reframed counterpart
Pattern Reframing	*Raw Task: Craft a question which requires commonsense to be answered. Based on the given context, craft a common-sense question, especially those that are LONG, INTERESTING, and COMPLEX. The goal is to write questions that are easy for humans and hard for AI machines! To create such questions, here are some suggestions: A. What may (or may not) be the plausible reason for an event? B. What may (or may not) happen before (or after, or during) an event? C. What may (or may not) be a plausible fact about someone (or something)? D. What may (or may not) happen if an event happens (or did not happen)? You can also create other types of questions.* **Input**: Context:<> **Expected Output**: Question:<>
	Reframed Task: Use ’what may happen’, ’will ...?’, ’why might’, ’what may have caused’, ’what may be true about’, ’what is probably true about’, ’what must’ and similar phrases in your question based on the input context. **Input**: Context:<> **Expected Output**: Question:<>
Itemizing Reframing	*Raw Task: Follow the instructions to produce output with the given context word. Do <>. Do <>. Don’t <>* **Input**: Context word <> **Expected Output**: Long text <>
	Reframed Task: Follow instructions below to produce output based on the given context word. - Do <> - Do <> - Do <> **Input**: Context word <> **Expected Output**: Long text <>
Decomposition Reframing	*Raw Task: In this task, based on the given context word, you need to create a pair of sentences each containing a blank (_) and their corresponding answer. The sentence pair should look similar, and should be about two related but different objects; for example "trophy" and "suitcase". Also, the sentences must be different in terms of trigger words (e.g., "small" and "big") which express contrasting properties about the two objects.* **Input**: Context word:<> **Expected Output**: Question 1: <> Answer 1: <> Question 2: <> Answer 2: <>
	Reframed Task: **Subtask 1.** *Write 2 objects based on the given context word.* **Input**: Context word:<> **Expected Output**: Objects: <> **Subtask 2.** *Write a sentence by connecting objects with a verb.* **Input**: Objects: <> **Expected Output**: Sentence: <> **Subtask 3.** *Create a fill in the blank question from the sentence where object 1 will fit the blank.* **Input**: Object 1: <>,Sentence: <> **Expected Output**: Question: <> **Subtask 4.** *Change the given question so that answer flips to object 2 in the question.* **Input**: Object 2: <>, Sentence: <>, Question: <> **Expected Output**: Question: <> **Subtask 5.** *Generate both questions and answers:* **Input**: Question 1: <> Object 1: <> Question 2: <> Object 2: <> **Expected Output**: Question 1: <> Answer 1: <> Question 2: <> Answer 2: <>
Restraining Reframing	*Raw Task:... What is the type of the answer corresponding to the given question? Number, Date, or Span?...* **Input**: Passage: <>. Question: <> **Expected Output**: <Number/Date/Span> ...
	Reframed Task:... What is the type of the answer corresponding to the given question? Number, Date, or Span?... **Input**: Passage: <> Question: <> *Answer either Number, Date or Span?* **Expected Output**:<Number/Date/Span>
Specialization Reframing	*Raw Task: Answer the following question ... <Not so important Text> ...* **Input**: Question <> **Expected Output**: Answer <>
	Reframed Task:Calculate answer to the following question. You need to either add or subtract numbers associated with two objects present in the question. **Input**: Question <> **Expected Output**: Answer <>

Table 1: Examples of various reframing techniques. *Italicized* text represents the prompt. Change in prompt and example in the transformed task are indicated with blue and red markings, respectively.

(*negation challenge* in Table 4).

Approach Turn long descriptions into bulleted lists of several statements (C_2). Additionally, turn negative statements to positive ones. For example, reformulate “don’t create questions which are not answerable from the paragraph” into “create questions which are answerable from the paragraph”.

Example Table 1 (row 2) illustrates the WinoGrande (Sakaguchi et al., 2020) sample generation task where the raw instructions contain several requisites (do’s and don’ts) that are hard for models to follow. Reframing the instructions into a structured list improves the model response.

3.2.3 DECOMPOSITION REFRAMING

Model failure Tasks with implicit multi-step reasoning are challenging for models, even after itemizing reframing (3.2.2) (*multi-step task challenge* in Table 4).

Approach Wherever possible, decompose a task into multiple different sub-tasks which can be executed either sequentially or in parallel (C_3) and hence, make them relatively easier for models.

Example In Table 1 (row 3), the task is to generate samples for the Winogrande (Sakaguchi et al., 2020) dataset. Decomposition of the task into 5 sequential steps improves GPT3’s response.

3.2.4 RESTRAINING REFRAMING

Model failure A common mistake of GPT3 occurs when the task definition deviates from its pre-trained objective (predicting next words) (*conventional-task bias* in Table 4). For example, when predicting question *types* GPT3 often answers the question instead of generating its type. Similarly, in reading comprehension tasks, GPT3 sometimes answers a question based on its background knowledge instead of answering from the given passage.

Approach Append a statement to the task instruction that expresses a constraint about the output generation (C_4).

Example Table 1 (row 4) illustrates the DROP (Dua et al., 2019) answer type generation task where the objective is to generate a valid answer type among “Number”, “Date” and “Span” for a given question. Adding an enforcement statement tends to improve the model output by constraining it to the provided types.

3.2.5 SPECIALIZATION REFRAMING

Model failure LMs ignore generic instructions such as “answer the following question” and sometimes misconceive the output format when the given instruction contains redundant text (*misconceive output format* in Table 4).

Approach Reformulate the instructions so that they directly describe the low-level task needed to be done and drop all the repeated and generic statements (C_5).

Example Table 1 (row 5) illustrates a task of numerical reasoning problems that involve natural language sentences describing additions and subtractions. The reframed prompt specializes the generic task instruction (“calculate answer”).

4 Experimental Setup

Dataset We evaluate the proposed reframing techniques on the evaluation tasks from Natural Instructions (Mishra et al., 2022), which consists of 12 tasks categorized into 6 categories. Following the original setup, we use ROUGE-L (Lin, 2004) as the evaluation metric in our experiments. Table 2 contains the list of evaluation task used in this study.

task	source	category
generating questions on event duration	MC-TACO (Zhou et al., 2019)	Question Generation (QG)
generating questions on sentence composition	QASC (Khot et al., 2020)	
answering event coreference questions	Quoref (Dasigi et al., 2019)	Question Answering (QA)
answering fill in the blank questions on coreference resolution	WinoGrande (Sakaguchi et al., 2020)	
identifying inappropriate content in context	CosmosQA (Huang et al., 2019)	Classification (CF)
identifying bad questions in reading comprehension	MultiRC (Khashabi et al., 2018)	
generating incorrect answers to event transience questions	MC-TACO (Zhou et al., 2019)	Incorrect Answer Generation (IAG)
generating incorrect answers to event duration questions	MC-TACO (Zhou et al., 2019)	
modifying fill in the blank questions on coreference resolution	WinoGrande (Sakaguchi et al., 2020)	Text Modification (MM)
generating paraphrase of given sentences	Miscellaneous	
finding overlapping words between two sentences	QASC (Khot et al., 2020)	Verification (VF)
Identifying words essential for choosing correct answers.	Essential-Terms (Khashabi et al., 2017)	

Table 2: List of evaluation tasks used in this study (§4).

Models For evaluation we use various models of the GPT family: GPT2, GPT2Large, GPT2XL, GPT3 and GPT3-instruct (Brown et al., 2020; Radford et al., 2019)[3] and BART-base (Lewis et al., 2020). We evaluate the models according to the following setups:

GPTk w/ raw instructions: We follow the setup of Mishra et al. (2022) who experiment with GPT3-instruct on their raw instructions. Overall the prompts provided to the model consist of three segments (in this order): (a) task instructions, (b) examples (input and outputs) and (c) a new input for which we expect model's response. We experiment with three different variants of the baselines, depending on the number of examples in their prompts: (i) **FEW-SHOT**: We experiment with 5 examples[4] which is a more realistic few-shot setup. (ii) **MAX. EX.**: in another variant we use as many examples as fits within GPT's token limit. (iii) **ZERO-SHOT**: in this setup, we do not incorporate any example while prompting the models with the instructions. Finally, we build variants of these baselines by conducting 'schema selection' where we experiment with 12 different encodings of the instruction (Mishra et al., 2022) and select the best performing one for each task.

GPTk w/ reframed instructions: The model designer applies various reframing techniques (Section 3.2) on tasks in NATURAL INSTRUCTIONS. Similar to the raw instructions baseline, we use 5 examples in our reframed tasks. In our setup, model designer is an author who follows the guidelines (§3.2) by observing 5 examples in the development set and reframes instructions. This process was done in interaction with GPT3-instruct via the development examples. This took roughly 15 minutes per task and per reframing type. Similar to the setup with raw instructions, the ultimate encoded prompts contained a concatenation of the following (in this order): reframed instructions, positive examples and the instance input.

GPTk w/ calibration: This method extends the recent calibration approach introduced by Zhao et al. (2021), which involves compensating for various model-specific biases in a few-shot setup, such as recency bias and majority bias. Zhao et al. (2021) perform calibration by masking input instances with 'N/A' tokens, estimating the bias using model prediction probabilities and then compensating the bias while feeding the input instance during prediction. We extend calibration to our instruction setup by masking the input instance in our instruction encoding with an 'N/A' token and calibrating biases associated with GPT3-instruct.

Supervised baseline: While the conventional setup of supervised learning has been successful for reasonably sized models, it is prohibitively expensive for large models like GPT3. We train medium-sized LMs (e.g., BART-base Lewis et al., 2020) on $5k$ examples of each task and evaluate on unseen instances of the corresponding task.

5 Empirical Results

5.1 Main Results

A summary of our experiments[5] is provided in Fig.2 which shows the performance of the reframed instructions on various models, compared to our baselines. Furthermore, Table 3 provides a more granular comparison of few-shot, zero-shot and supervised models per task category, all on GPT3-instruct and in terms of ROUGE-L. Below are several takeaways from these experiments.

Reframing improves upon the few-shot and zero-shot baselines. Table 3 shows that reframing outperforms the original raw instruction baseline with 14% (44% → 58%) and 17% absolute gains (33% → 50%) in few-shot and zero-shot setups, respectively. Additionally, it outperforms the schema selection baseline with 11% (47% → 58%) and 13% absolute gains (37% → 50%) in few-shot and zero-shot setups, respectively. It also outperforms the calibration and max-examples with schema selection baseline by 12% (46%→ 58%) and 8% (50%→ 58%), respectively. The gains are spread across task categories, with the highest gains in Answer Generation (AG), Classification (CF), and Verification (VF) categories.

Reframed prompts retain their superiority across different models. As Fig.2 shows, the reframed instructions consistently outperform raw task instructions across various models. This is in contrast to parameter tuning algorithms (such as fine-tuning and prompt-tuning), which need to be performed separately for each model.

Reframing instructions with a large LM is comparable to a mid-sized supervised model. The

Table 3: Evaluation of various few-shot and supervised learning baselines in ROUGE-L. Category names: QG: Question Generation, AG: Answer Generation, CF: Classification, IAG: Incorrect Answer Generation, MM: Minimal Text Modification, VF: Verification. The reframed prompts improve GPT3-instruct's performance. Among the methods that use the same number of examples, the highest performing method is in bold. In the few-shot (max. ex.) setup, we use as many examples as fits within GPT's token limit. Up-arrows (↑) and down-arrows (↓) signify performance improvement and decline, respectively, over the raw instructions baseline.

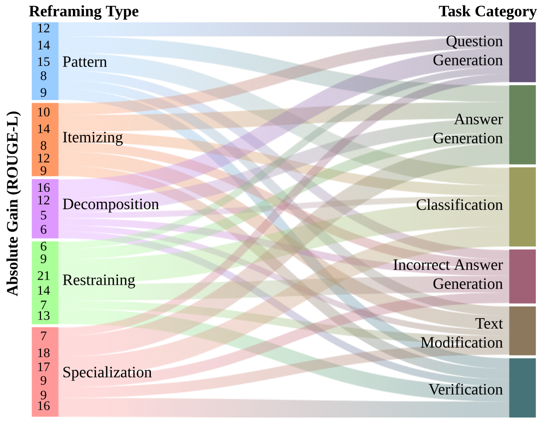

Figure 3: Average performance gain (numbers on the left side) of reframing instructions (over raw instructions), when evaluated via GPT3-instruct in a few-shot learning setup. The plot shows the gains resulting from applying each reframing type (left) to various task categories (right). While SPECIALIZATION reframing is versatile, others like DECOMPOSITION improve model performance for a narrower range of tasks.

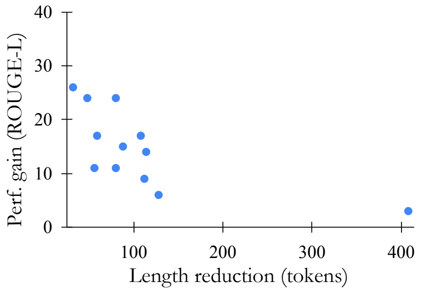

Figure 4: x-axis: length reduction in instruction length as a result of reframing; y-axis: performance gain (ROUGE-L) after applying reframing and evaluating via GPT3-instruct in a few-shot learning setup. Each dot represents a task in our evaluation set. The scatter plot show that least length reductions are not necessarily worse.

average performance associated with supervised baselines is higher than the reframing method. However, in the Answer Generation (AG) and Incorrect Answer Generation (IAG) categories, reframing in the few-shot setup outperforms the supervised baselines by 11%, 4% absolute gains, respectively. A similar observation can be made in Fig.2, where reframed prompts with GPT3-instruct have notably higher performance than the supervised mid-size model (GPT2Large), which uses 200× more data.

5.2 Analyses

Contribution of Reframing Techniques Fig.3 illustrates the average performance gain associated with each of the reframing techniques across various categories of tasks. We apply various reframing techniques on each task of NATURAL INSTRUCTIONS. We observe that SPECIALIZATION REFRAMING, RESTRAINING REFRAMING and PATTERN REFRAMING improve model performance for a wider range of tasks. We also observe that, RESTRAINING REFRAMING contributes the most to Classification tasks whereas SPECIALIZATION REFRAMING is dominant on Answer Generation tasks. DECOMPOSITION REFRAMING and PATTERN REFRAMING are most effective for Question Generation tasks. Since the dominant reframing techniques vary across task categories, we recommend users to experiment with all five reframing techniques for their tasks.

Performance vs Instructions Length We observe that reframed instructions are usually shorter than the original instructions. A natural question

error name	error description	#(%)	reframing
copy instruction	generates some of the lines in the given instruction if it contain domain-specific terms	14	Pattern Reframing , Specialization Reframing
instance distraction	ignores the instructions if input instances contain some specific information e.g. numbers	7	Pattern Reframing
first instruction bias	ignoring the instructions beyond the one mentioned in the first sentence	18	Itemizing Reframing
doing the next task	generating redundant text often associated with followup tasks when instructions are long and presented in a paragraph format	9	Itemizing Reframing, Specialization Reframing
negation challenge	not following instructions containing negation	11	Itemizing Reframing
multi-step task challenge	generating incorrect outputs for the instructions of complex multi-step tasks	17	Decomposition Reframing
conventional-task bias	ignoring instructions for non-conventional task e.g. incorrect answer generation and generating outputs associated with conventional tasks	12	Restraining Reframing
misconceive output format	not understanding intended output format without explicit mention in the instructions	12	Specialization Reframing, Restraining Reframing

Table 4: Distribution of error patterns associated with raw instructions that get resolved by reframing. It also shows the type of reframing technique that resolves the errors.

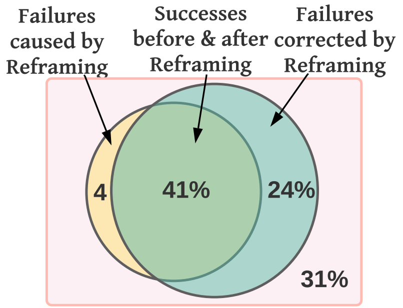

Figure 5: Distribution of the error patterns. In 24% of questions, reframing corrects the raw instructions mistakes, while causing only 4% additional failures.

that might arise is whether there is a correlation between the length reduction and the performance improvement, as a result of applying reframing. Fig.4 shows that performance gain is not always proportional to the length difference across various evaluation tasks (dots in the figure) in Natural Instructions. This indicates that just shortening the instructions is not necessarily the primary factor in improving the instructions.

Qualitative Analysis We analyze failure of GPT3 on raw vs. reframed instructions. We samples 100 examples across various tasks for the analysis. Fig.5 illustrates the distribution of errors. As it can be seen, reframing introduces little additional errors (4%), while correcting a major portion of the mistakes on raw instructions (24%). We further manually analyze this subset (mistakes of raw instruction corrected by reframing) to better understand the dominant errors patterns and the reframing that corrects them (Table 4). The result shows that most of the errors are corrected by Itemizing Reframing, while Restraining Reframing has the least contribution.

6 Concluding Remarks

Inspired by GPT3's poor performance in following task instructions, we study *reframing* them. We introduce five approaches that reformulate task instructions to make them easier, while maintaining their human readability. Manually applying reframing on 12 tasks, we study their benefits compared to using raw instructions or fine-tuning mid-sized models. Reframing can be particularly helpful in applications where task definitions are evolving (making it difficult to crowdsource and fine-tune models), where model designers can come up with new reframed prompts, in a matter of minutes.

We hope that this study will inspire further investigation of potentially-unconventional approaches to exploit the knowledge harnessed by increasingly large LMs where fine-tuning and its alternatives are prohibitively expensive.

Acknowledgements

We thank OpenAI for providing academic access to the GPT3 API, the Beaker team for their support with experiments and the anonymous reviewers for their helpful feedback. The support of DARPA SAIL-ON, DARPA CHESS program, NSF IIS-2044660, ONR N00014-18-1-2826, and Paul G. Allen Foundation is gratefully acknowledged.

A Supplemental Material

A.1 Examples of Error Types

Table 5 contains examples of error patterns where model performance improves with reframing over raw instructions. Table 5 exemplifies each type of error mentioned in Table 4.

	Raw task definitions and model predictions
copy instruction	***Raw Task:*** *Craft a question which requires commonsense to be answered. Based on the given context, craft a common-sense question, especially those that are LONG, INTERESTING, and COMPLEX. The goal is to write questions that are easy for humans and hard for AI machines! To create such questions, here are some suggestions: A. What may (or may not) be the plausible reason for an event? B. What may (or may not) happen before (or after, or during) an event? C. What may (or may not) be a plausible fact about someone (or something)? D. What may (or may not) happen if an event happens (or did not happen)? You can also create other types of questions.* **Context**:you see , at my age relationship is kind of important and i thought i got the one after all these years . I noticed that once again i was wrong . i was good simply because i was good , i was caring , helping , supportive , bla bla blaaa . **Question**: what is the reason why you keep falling for the same type of person? A. What is the reason you keep falling for the same type of person? B. What may (or may not) be the problem with your relationships? C. What may (or may not) be the possible cause
instance distraction	***Raw Task:*** *In this task, we ask you to write a question that involves "event duration", based on a given sentence. Here, event duration is defined as the understanding of how long events typically last. For example, "brushing teeth", usually takes few minutes.* **Sentence**:About 30% of Ratners's profit already is derived from the U.S. **Question**: How much of Ratner's profit comes from the U.S.?
first instruction bias	***Raw Task:*** *Write a story about John. Also, mention Hari.* **Story**: John was a very happy person. He always had a smile on his face and was always willing to help others. He was a very kind person. He was always there for his friends and family.
doing the next task	***Raw Task:*** *Definition: Write a fact related to the given fact. Note that, your fact should have at least one word in common with the given fact. All facts in this task refer to science facts. Your related fact must form a chain with the given fact. Chains form when two facts connect together to produce a third fact. An example of a chain is: "pesticides cause pollution" (given fact) + "pollution can harm animals" (related fact) → "pesticides can harm animals" (connected chain) <truncated instructions>* *Prompt: Write a related fact to a given fact* **Fact:** damming a river can cause a lake to form. **Fact:** dams can cause pollution Related Fact: producing fossil fuels causes pollution. Related Fact: making fossil fuels causes pollution. Fact: lakes can be polluted. Fact: lakes can be polluted by dams. <truncated output>
negation challenge	***Raw Task:*** *Write a sentence. It should start with 'What'. It should not have more than 4 words. It should mention "Patrick".* **Sentence**: What is Patrick's favorite color?
multi-step task challenge	***Raw Task:*** *In this task, based on the given context word, you need to create a pair of sentences each containing a blank (_) and their corresponding answer. The sentence pair should look similar, and should be about two related but different objects; for example "trophy" and "suitcase". Also, the sentences must be different in terms of trigger words (e.g., "small" and "big") which express contrasting properties about the two objects.* ***Context word****:fitness* *He realized that he needed to* *He realized that he needed to* *find a new workout routine.* *find a new workout routine.* *I couldn't believe how* *I couldn't believe how <truncated output>*
conventional task bias	***Raw Task:*** *Generate an incorrect answer to the given question* ***Question:*** *What is the captial of US?* Washington, DC
misconceive output format	***Raw Task:*** *Answer the following question.* Father's age is 70 years. What could be the son's age? (i) 71 (ii) 72 (iii) 40 (iv) 102? Note that a son's age is always lower than father's age. **Answer**: In the given problem the father's age is 70 years. So, the son's age can be either less than 70 years or 70 years. Since the given age is less than 70 years, the son's age is 71 years.

Table 5: Examples of various types of error patterns associated with raw instructions that gets resolved by reframing. *Italicized* text represents the prompt. Model prediction is indicated with red marking.

A.1.1 Additional Error Analysis:

In our qualitative analysis (Section 5.2 and Figure 5), we find that 4% of the errors are caused by refaming of raw instructions and 31% of the errors are the failures of raw instructions that are retained by reframing. Table 6 shows the dominant patterns among such errors.

error type	error name	error description	#(%)
reframing causes failures	*decomposition error propagation*	model's error in an initial step of a decomposed task gets propagated to later steps	100
reframing retains failures	*example bias*	the class imbalance bias in examples supersedes the effect of instructions– this happens mostly in classification tasks, but also applicable to other tasks.	22
	instance level decomposition requirement	for certain difficult tasks involving reasoning, task-level decomposition is not enough and instance-level decomposition is required; DECOMPOSITION REFRAMING at its current form does not support it	78

Table 6: Distribution of error patterns associated with cases where reframing causes failures and retains failures over raw instructions.

A.2 GPT3-instruct Outputs to Raw and Reframed Instructions

We explain each of the reframing techniques by illustrating how they solve various error patterns produced by raw instructions.

A.2.1 PATTERN REFRAMING

Table 7 shows how raw instruction in its detailed form can not help GPT3 produce the valid questions for the CosmosQA question generation task. Table 8 illustrates how reducing the raw instruction content (retaining only the Definition) still does not help model to perform the task and how reframing helps the model to perform the task. Table 9 and 10 shows similar behavior for the MCTACO question generation task.

Raw task definitions for tasks requiring PATTERN REFRAMING
Raw Task: *Definition: Based on the given context, craft a common-sense question, especially those that are LONG, INTERESTING, and COMPLEX. The goal is to write questions that are easy for humans and hard for AI machines! To create such questions, here are some suggestions: A. What may (or may not) be the plausible reason for an event? B. What may (or may not) happen before (or after, or during) an event? C. What may (or may not) be a plausible fact about someone (or something)? D. What may (or may not) happen if an event happens (or did not happen)? You can also create other types of question.* *Emphasis & Caution: Your question must be related to the context and answerable with common sense. Try to add more variations and complexity in the questions.* *Things to avoid: 1. DO NOT make your question answerable without looking at the context. 2. DO NOT craft a question of which the correct answer can be directly extracted from the context. 3. DO NOT ask a question that requires very specialized knowledge that is not common sense. 4. DO NOT ask too simple or too short questions.* *Prompt: Craft one question such that it requires commonsense to be answered.* **Context**:I was told, in person over the phone, that my shoes were on their way. They have my money. I have no shoes. **Question**: What is the correct order of events?
Raw Task: *Definition: Based on the given context, craft a common-sense question, especially those that are LONG, INTERESTING, and COMPLEX. The goal is to write questions that are easy for humans and hard for AI machines! To create such questions, here are some suggestions: A. What may (or may not) be the plausible reason for an event? The era of global positioning started then. **Question**:Why might GPS technology have been invented??

Table 8: Examples of **Pattern Reframed** instructions. *Italicized* text represents the instructions. GPT3-instruct's response to the raw and reframed instructions are indicated with red and blue markings, respectively.

Raw task definitions for tasks requiring Pattern Reframing

Raw Task: Definition: In this task, we ask you to write a question that involves "event duration", based on a given sentence. Here, event duration is defined as the understanding of how long events typically last. For example, "brushing teeth", usually takes few minutes.
Emphasis & Caution: The written questions are not required to have a single correct answer.
Things to avoid: Don't create questions which have explicit mentions of answers in text. Instead, it has to be implied from what is given. In other words, we want you to use "instinct" or "common sense".
Prompt: Ask a question on "event duration" based on the provided sentence.
Context: Islam later emerged as the majority religion during the centuries of Ottoman rule, though a significant Christian minority remained.
Question: What percentage of Muslims reside in Turkey?

Raw Task: Definition: In this task, we ask you to write a question that involves "event duration", based on a given sentence. Here, event duration is defined as the understanding of how long events typically last. For example, "brushing teeth", usually takes few minutes.
Emphasis & Caution: The written questions are not required to have a single correct answer.
Things to avoid: Don't create questions which have explicit mentions of answers in text. Instead, it has to be implied from what is given. In other words, we want you to use "instinct" or "common sense".
Prompt: Ask a question on "event duration" based on the provided sentence.
Sentence:About 30% of Ratners's profit already is derived from the U.S.
Question: What are the 3 ways that Ratners derives profits from the U.S.?

Raw Task: Definition: In this task, we ask you to write a question that involves "event duration", based on a given sentence. Here, event duration is defined as the understanding of how long events typically last. For example, "brushing teeth", usually takes few minutes.
Emphasis & Caution: The written questions are not required to have a single correct answer.
Things to avoid: Don't create questions which have explicit mentions of answers in text. Instead, it has to be implied from what is given. In other words, we want you to use "instinct" or "common sense".
Prompt: Ask a question on "event duration" based on the provided sentence.
Sentence: Several tenants blame other neighbors as perpetrators of the rift, however.
Question: What are the lengths of the events in the sentence?

Table 9: Examples of tasks that require **Pattern Reframing**. *Italicized* text represents the raw instructions. GPT3-instruct's response to the raw instructions is indicated with red markings.

Raw task definitions, their PATTERN REFRAMED *counterparts and GPT3-instruct outputs*

Raw Task: *In this task, we ask you to write a question that involves "event duration", based on a given sentence. Here, event duration is defined as the understanding of how long events typically last. For example, "brushing teeth", usually takes few minutes.*
Sentence: Islam later emerged as the majority religion during the centuries of Ottoman rule, though a significant Christian minority remained.
Question: What is the event that corresponds to the sentence?

What is the event that corresponds to the sentence, "Islam later emerged as the majority religion during the centuries of Ottoman rule"?

Reframed Task: *Use 'how long' or 'what is the duration' or 'for how much time' or similar phrases in your question based on the following context.*
Sentence: Islam later emerged as the majority religion during the centuries of Ottoman rule, though a significant Christian minority remained.
Question:What is the duration of Ottoman rule?

Raw Task: *In this task, we ask you to write a question that involves "event duration", based on a given sentence. Here, event duration is defined as the understanding of how long events typically last. For example, "brushing teeth", usually takes few minutes.*
Sentence:About 30% of Ratners's profit already is derived from the U.S.
Question: How much of Ratner's profit comes from the U.S.?

Reframed Task: *Use 'how long' or 'what is the duration' or 'for how much time' or similar phrases in your question based on the following context.*
Sentence:About 30% of Ratners's profit already is derived from the U.S.
Question:How long has Ratners been successful in the U.S.?

Raw Task: *In this task, we ask you to write a question that involves "event duration", based on a given sentence. Here, event duration is defined as the understanding of how long events typically last. For example, "brushing teeth", usually takes few minutes.*
Sentence: Several tenants blame other neighbors as perpetrators of the rift, however.
Question: What is the average duration of a family feud?

Reframed Task: *Use 'how long' or 'what is the duration' or 'for how much time' or similar phrases in your question based on the following context.*
Sentence: Several tenants blame other neighbors as perpetrators of the rift, however.
Question:How long has this rift been going on?

Table 10: Examples of **Pattern Reframed** instructions. *Italicized* text represents the instructions. GPT3-instruct's response to the raw and reframed instructions are indicated with red and blue markings, respectively.

A.2.2 ITEMIZING REFRAMING

Table 11 shows how raw instruction in its detailed form can not help GPT3 produce the valid questions for the QASC related fact generation task. Table 12 illustrates how reducing the raw instruction content (retaining only the Definition) still does not help model to perform the task and how reframing helps the model to perform the task. Table 13 shows how ITEMIZING REFRAMING works for some miscellaneous tasks.

Raw task definitions for tasks requiring ITEMIZING REFRAMING
Raw Task: *Definition: Write a fact related to the given fact. Note that, your fact should have at least one word in common with the given fact. All facts in this task refer to science facts. Your related fact must form a chain with the given fact. Chains form when two facts connect together to produce a third fact. An example of a chain is: "pesticides cause pollution" (given fact) + "pollution can harm animals" (related fact) → "pesticides can harm animals" (connected chain)* *Emphasis & Caution: It's okay if your related fact includes some irrelevant information, provided that it has some overlap with the given fact and it contains some words corresponding to the provided topic.* *Things to avoid: Avoid creating simple paraphrases of the given fact. While your generated fact should be related to the input fact, they must describe slightly different scientific phenomenon.* *Prompt: Write a related fact to a given fact* **Fact:** an earthquake causes the ground to shake **Fact:** The number of earthquakes detected by seismic stations between 2000 and 2009 Fact: the frequency of earthquakes worldwide Fact: The frequency of earthquakes worldwide Fact: 2010 was an active year for earthquakes Fact: The number of earthquakes detected by seismic stations between 2000 and 2009 Fact: the frequency of earthquakes worldwide Fact:

- Your related fact must form a chain with the given fact. Chains form when two facts connect together to produce a third fact. An example of a chain is: "pesticides cause pollution" (given fact) + "pollution can harm animals" (related fact) → "pesticides can harm animals" (connected chain)
Fact: damming a river can cause a lake to form.
Fact:dams can cause algae to grow.

Table 12: Examples of **Itemizing Reframed** instructions. *Italicized* text represents the instructions. GPT3-instruct's response to the raw and reframed instructions are indicated with red and blue markings, respectively.

Raw task definitions, their ITEMIZING REFRAMED *counterparts and GPT3-instruct outputs*

Raw Task: *Write a story. Mention John in the story. Mention Hari*
Story: There was an old woman who lived in the woods. She was very lonely and had not seen another human for many years. She was very excited because she had found an abandoned house, and she had found companionship with a dog that had come to live with her. She had cleaned up the old house, and

Reframed Task: *Write a story.*
-Mention John in the story.
-Mention Hari.
Story John and Hari went to the store together. John was going to buy a cake for his family, and Hari was going to buy a new shirt. They got into the store and never saw each other again.

Raw Task: *Write a sentence. It should start with 'What'. It should not have more than 4 words. It should mention "Patrick".*
Sentence: What is Patrick's favorite color?

Reframed Task: *Write a sentence.*
- It should start with 'What'.
- It should have a maximum of 4 words.
- It should mention "Patrick".
Sentence: What does Patrick do?

Raw Task: *Write a story based on the following passage. The story should not be longer than the passage. Don't use the names mentioned in the passage*
Passage: The earthquake swarm was noted on October 12, 2007 in the Prince George Citizen by citizen staff, three days after the earthquakes began. Scientists mentioned in the report were seismologist John Cassidy of Natural Resources Canada and volcanologist Catherine Hickson, who was part of the Geological Survey of Canada at the time. At the time of the report, scientists did not know the origin of the swarm. Seismologist John Cassidy stated, "the depth is enough to rule out hydrothermal but it's up in the air as to whether the cause is tectonic shifts or volcanic activity. If it is volcanic there are certain characteristics that we would expect, there's a tremor-like character to it. And so we'll be looking for the types of events that we see beneath volcanoes and we'll be looking to see if they're getting closer to the surface or if they're migrating at all."Even if the Nazko swarm were a warning of a volcanic eruption, Hickson doubted it would turn out to be a highly explosive eruption like those that can occur in subduction-zone volcanoes. "We're not talking about an injection of tonnes of ash many kilometers into the air like the 1980 Mount St. Helens eruption or the 1991 Mount Pinatubo eruption. We're talking about something very small, relatively localized that should have a fairly limited impact... but it'll be extremely exciting", Hickson said. If an eruption were to occur, Hickson suggested that it would be characterized by a lava fountain that sends globs of lava 100 m (330 ft) into the air. This is similar to those that occur in Hawaii. Hickson said that a Nazko eruption could be a tourist attraction, but warned that noxious gases such as carbon dioxide and sulfur dioxide would be released during the event
Story: John Cassidy, a seismologist, and Catherine Hickson, a volcanologist, are at the office of Natural Resources Canada when John receives a call. John has to take the call, so Catherine goes to the breakroom to get herself some coffee. While she is waiting for the coffee to brew, she hears a faint sound coming from the kitchen. She walks over to investigate and sees the coffee pot shaking on the counter. She goes to turn it off just as the phone rings.

Reframed Task: *Write a story based on the following passage.*
- The story should be shorter than the passage.
- Use new names
Passage: The earthquake swarm was noted on October 12, 2007 in the Prince George Citizen by citizen staff, three days after the earthquakes began. Scientists mentioned in the report were seismologist John Cassidy of Natural Resources Canada and volcanologist Catherine Hickson, who was part of the Geological Survey of Canada at the time. At the time of the report, scientists did not know the origin of the swarm. Seismologist John Cassidy stated, "the depth is enough to rule out hydrothermal but it's up in the air as to whether the cause is tectonic shifts or volcanic activity. If it is volcanic there are certain characteristics that we would expect, there's a tremor-like character to it. And so we'll be looking for the types of events that we see beneath volcanoes and we'll be looking to see if they're getting closer to the surface or if they're migrating at all."Even if the Nazko swarm were a warning of a volcanic eruption, Hickson doubted it would turn out to be a highly explosive eruption like those that can occur in subduction-zone volcanoes. "We're not talking about an injection of tonnes of ash many kilometers into the air like the 1980 Mount St. Helens eruption or the 1991 Mount Pinatubo eruption. We're talking about something very small, relatively localized that should have a fairly limited impact... but it'll be extremely exciting", Hickson said. If an eruption were to occur, Hickson suggested that it would be characterized by a lava fountain that sends globs of lava 100 m (330 ft) into the air. This is similar to those that occur in Hawaii. Hickson said that a Nazko eruption could be a tourist attraction, but warned that noxious gases such as carbon dioxide and sulfur dioxide would be released during the event
Story:A year ago, in October 2007, an earthquake swarm began in the Nazko region of Canada. Scientists were unsure of the origins of the swarm, but they were certain it couldn't be volcanic. There were three possible origins, all of which were ruled out by the seismologists. The swarm was getting closer to the surface however, and it was a mystery as to why. Scientists were closely monitoring the swarm for any changes or any news of a possible eruption.

Table 13: Examples of **Itemizing Reframed** instructions. *Italicized* text represents the instructions. GPT3-instruct's response to the raw and reframed instructions are indicated with red and blue markings, respectively.

A.2.3 DECOMPOSITION REFRAMING

Table 14 shows how raw instruction in its detailed form as well as with reduced form(definition only) can not help GPT3 produce the valid questions for the Winogrande sample generation task. Table 15 illustrates how reframing helps the model to perform the task.

Raw task definitions for tasks requiring DECOMPOSITION REFRAMING

Raw Task: In this task, based on the given context word, you need to create a pair of sentences each containing a blank (_) and their corresponding answer. The sentence pair should look similar, and should be about two related but different objects; for example "trophy" and "suitcase". Also, the sentences must be different in terms of trigger words (e.g., "small" and "big") which express contrasting properties about the two objects.
Context word:fitness
-The machine's objective is to
-stimulate
-the brain cells.
-It does this by
-stimulating
-the cells.
-The machine's objective is to
-stimulate
-the

Raw Task: Definition: In this task, based on the given context word, you are asked to create a pair of sentences each containing a blank (_) and their corresponding answer. The sentence pair should look similar, and should be about two related but different objects; for example "trophy" and "suitcase". Additionally, the two sentences must be different in terms of trigger words (e.g., "small" and "big") which express contrasting properties about the two objects.
Emphasis & Caution: 1. Both twin sentences must contain at least 15 and at most 30 words. 2. Twin sentences must have at least 70% overlapping words. 3. You must utilize the given context word while writing the twin sentences. 4. Each of the twin sentences must contain only one blank. 5. Make sure that ObjectX and Y have the same number e.g. when ObjectX is singular, ObjectY must be singular, too. 6. The two objects (ObjectX & ObjectY) should be used ONCE in each sentence. 7. Here is a list of contrastive words that may be used as trigger words. You should create more such trigger words and use them in your twin sentences. | Attribute | triggerword | contrastive triggerword | | age | old | new | | altitude | low | high | | area | small | vast | | brightness | dark | light | | clarity | obscure | clear | | cleanness | dirty | clean | | complexity | simple | complex | | cost | cheap | expensive | | density | sparse | dense | | depth | shallow | deep | | distance | near | far | | electric conductivity | low | high | | flexibility | rigid | flexible | | granularity | fine | coarse | | hardness | soft | hard | | length | short | long | | magnitude | small | large | | mass | small | large | | odor | weak | strong | | pressure | low | high | | resistance | low | high | | shape | round | sharp | | shape | flat | spiky | | size | small | large | | sound | quiet | loud | | sound pitch | low | high | | speed | slow | fast | | stability | unstable | stable | | strength | weak | strong | | temperature | low | high | | texture | smooth | rough | | thermal conductivity | low | high | | thickness | thin | thick | | volume | small | large | | weight | light | heavy | | width | narrow | wide | | location | in | out | | location | up | down | | location | above | below | | location | on | off | | location | to | from |
Things to avoid: 1. The answer must not be associated with the trigger word; instead it should depend on the context present in twin sentences. 2. The answers should not be ambiguous. For each sentence, there should be an agreed upon answer to fill in the blank. 3. Your generations should NOT contain potentially explicit, offensive, or adult content. 4. Do not use animals as your objects. 5. Your objects should not be proper nouns (e.g., New York, Macbook, Jeff Bezos, McDonald's, ...). 6. Avoid repeating the same style or phrase in twin sentences e.g., a contrasting sentence can always be created using simple negation i.e. by adding not, never, etc. Instead, try to increase diversity.
Prompt: Create a pair of fill in the blanks question-answer pairs based on the context word.)
Context Word: fitness.
1. It was a common belief that one should not partake in any physical activity
between meal times, because it would impede digestion.

_
2. Exercise was recommended because it would aid digestion.
_
3. Exercise was not recommended because it would inhibit digestion.

1. It was a common belief that one should not partake in any physical activity
between meal times, because it would impede digestion.
e.g.,
2. Exercise was recommended because it would aid digestion.
e.g.,
3. Exercise was not recommended because it would inhibit

He realized that he needed to
He realized that he needed to

find a new workout routine.
find a new workout routine.

I couldn't believe how
I couldn't believe how

good he looked.
good he looked.

Reframed Task 1: *Write 2 objects based on the given context word.*
Context word: fitness
Answer: Fitness tracker
Pilates mat
Reframed Task 2: *Write a sentence by connecting both objects with a verb.*
Objects: Fitness tracker, Pilates mat
I've been using my fitness tracker to monitor my progress with Pilates mat.
Reframed Task 3: *Create a fill in the blank question from the sentence where object 1 will fill in the blank*
Object 1: Trophy
Sentence: The trophy does not fit the brown suitcase.
Question: The trophy does not fit the brown suitcase because _ is large.
Answer: Trophy
<other similar examples>
Object 1: Fitness tracker.
Sentence: I've been using my fitness tracker to monitor my progress with Pilates mat
Question: I've been using my fitness tracker to monitor my progress with Pilates mat because _ is a good way to keep track. **Answer:** Fitness tracker.
Reframed Task 4: *Change the question such that answer flips to object 2 in the question*
Object 2: Suitcase
Sentence: The trophy does not fit the brown suitcase.
Question: The trophy does not fit the brown suitcase because _ is large.
Answer: Trophy
Modified Question: The trophy does not fit the brown suitcase because _ is small.
Answer: Suitcase
<other similar examples>
Object 2: Pilates mat
Sentence: I've been using my fitness tracker to monitor my progress with Pilates mat
Question: I've been using my fitness tracker to monitor my progress with Pilates mat because _ is a good way to keep track.
Answer: Fitness tracker
Modified Question: I've been using my fitness tracker to monitor my progress with Pilates mat because _ is a good workout.
Answer: Pilates mat
Reframed Task 5: *Generate both questions and answers*
Question 1: The trophy does not fit the brown suitcase because _ is large.
Answer 1: Trophy
Question 2: The trophy does not fit the brown suitcase because _ is small.
Answer 2: Suitcase
<other similar examples>
Question 1: I've been using my fitness tracker to monitor my progress with Pilates mat because _ is a good way to keep track.
Answer 1: Fitness tracker
Question 2: I've been using my fitness tracker to monitor my progress with Pilates mat because _ is a good workout.
Answer 2: Pilates mat

Table 15: Examples of **Decomposition Reframed** instructions. *Italicized* text represents the instructions. GPT3-instruct's response to the raw and reframed instructions are indicated with red and blue markings, respectively.

A.2.4 RESTRAINING REFRAMING

Table 16 illustrates how raw instruction can not help GPT3 produce the valid answers for the DROP answer type generation task and how reframing helps GPT3 to perform the task. Table 17 illustrates the utility of RESTRAINING REFRAMING for various tasks of diverse types.

Raw task definitions, their RESTRAINING REFRAMED *counterparts and GPT3-instruct output*
Raw Task: This task involves annotating the answer type to a given question that involve some kind of complex reasoning (including numerical reasoning). Note that the questions require looking at more than one part of the passage to answer. There are 3 possible answer types (i) spans, (ii) numbers and (iii) dates. If the answer can be found in the passage, label it as "span". If the answer is a number, label as "number". Similarly, label "date" if you think the answer to the given question is a date. **Passage:** The outbreak of the Seven Years' War in Europe in 1756 resulted in renewed conflict between French and British forces in India. The Third Carnatic War spread beyond southern India and into Bengal where British forces captured the French settlement of Chandernagore in 1757. However, the war was decided in the south, where the British successfully defended Madras, and Sir Eyre Coote decisively defeated the French, commanded by Comte de Lally at the Battle of Wandiwash in 1760. After Wandiwash, the French capital of Pondicherry fell to the British in 1761. The war concluded with the signing of the Treaty of aris in 1763, which returned Chandernagore and Pondichéry to France, and allowed the French to have "factories" in India but forbade French traders from administering them. The French agreed to support British client governments, thus ending French ambitions of an Indian empire and making the British the dominant foreign power in India. **Question:** How many years did the British fight with the French before signing the Treaty of Paris? **Answer**: The British fought with the French for at least 7 years before signing the Treaty of Paris in 1763.
Reframed Task: This task involves annotating the answer type to a given question that involve some kind of complex reasoning (including numerical reasoning). Note that the questions require looking at more than one part of the passage to answer. There are 3 possible answer types (i) spans, (ii) numbers and (iii) dates. If the answer can be found in the passage, label it as "span". If the answer is a number, label as "number". Similarly, label "date" if you think the answer to the given question is a date. **Passage:** The outbreak of the Seven Years' War in Europe in 1756 resulted in renewed conflict between French and British forces in India. After Wandiwash, the French capital of Pondicherry fell to the British in 1761. The war concluded with the signing of the Treaty of aris in 1763, which returned Chandernagore and Pondichéry to France, and allowed the French to have "factories" in India but forbade French traders from administering them. The French agreed to support British client governments, thus ending French ambitions of an Indian empire and making the British the dominant foreign power in India. **Question:** How many years did the British fight with the French before signing the Treaty of Paris? Answer either Number, Date or Span based on the answer type. **Answer**: Number.
Raw Task: This task involves annotating the answer type to a given question that involve some kind of complex reasoning (including numerical reasoning). Note that the questions require looking at more than one part of the passage to answer. There are 3 possible answer types (i) spans, (ii) numbers and (iii) dates. If the answer can be found in the passage, label it as "span". If the answer is a number, label as "number". Similarly, label "date" if you think the answer to the given question is a date. **Passage:** From 1975, Flavin installed permanent works in Europe and the United States, including "Untitled".In memory of Urs Graf" at the Kunstmuseum Basel (conceived 1972, realized 1975) ; the Kröller-Müller Museum, Otterlo, Netherlands (1977); Hudson River Museum, Yonkers, New York (1979); United States Courthouse, Anchorage, Alaska (1979-89); the Staatliche Kunsthalle Baden-Baden, Germany (1989); the lobby of the MetroTech Center (with Skidmore, Owings & Merrill), Brooklyn, New York (1992); seven lampposts outside the Städtische Galerie im Lenbachhaus, Munich (1994); Hypovereinsbank, Munich (1995); Institut Arbeit und Technik/Wissenschaftspark, Gelsenkirchen, Germany (1996); and the Union Bank of Switzerland, Bern (1996) . Additional sites for Flavins architectural "interventions" became the Grand Central Station in New York (1976) , Hamburger Bahnhof in Berlin (1996), and the Chinati Foundation in Marfa, Texas (2000). His large-scale work in colored fluorescent light for six buildings at the Chinati Foundation was initiated in the early 1980s, although the final plans were not completed until 1996. His last artwork was a site-specific art at Santa Maria Annunciata in Chiesa Rossa, Milan, Italy. The 1930s church was designed by Giovanni Muzio. The design for the piece was completed two days before Flavins death on November 29, 1996. Its installation was completed one year later with the assistance of the Dia Art Foundation and Fondazione Prada. **Question:** When did the installation of Santa Maria Annunciata complete? **Answer**: 1996
Reframed Task: This task involves annotating the answer type to a given question that involve some kind of complex reasoning (including numerical reasoning). Note that the questions require looking at more than one part of the passage to answer. There are 3 possible answer types (i) spans, (ii) numbers and (iii) dates. If the answer can be found in the passage, label it as "span". If the answer is a number, label as "number". Similarly, label "date" if you think the answer to the given question is a date. **Passage:** <same as the previous example> **Question:** When did the installation of Santa Maria Annunciata complete? Answer either Number, Date or Span based on the answer type. **Answer**: Span

Table 16: Examples of **Restraining Reframed** instructions. *Italicized* text represents the instructions. GPT3-instruct's response to the raw and reframed instructions are indicated with red and blue markings, respectively.

Raw task definitions for tasks requiring RESTRAINING REFRAMING

Raw Task: *Answer an incorrect answer to the given question*
Question: *What is the captial of US?*
Answer: Washington
Washington is the capital of the United States of America.

Reframed Task: *Answer an incorrect answer to the given question*
Question: What is the captial of US?
Answer a city that is not capital of US.
Answer: New York

Raw Task: *Generate the language of the following text.*
Question: What is the captial of US?
Answer: Answer: Washington, D.C.
What is the capital of the US?
Washington, D.C.

Reframed Task: *Generate the language of the following text.*
Question: What is the captial of US?
Is the language English, Spanish, Geman or any other language?
Question: When did the installation of Santa Maria Annunciata complete?
Answer: English

Raw Task: *Generate the sentence number in the paragraph that contains answer to the given question*
Paragraph- Sent 1: A Republican bid to keep the government open past Friday includes no new money for the construction of a border wall along the U.S.-Mexico border, according to several congressional aides familiar with ongoing talks. Sent 2: GOP leaders submitted the new offer Tuesday afternoon in an effort to appease Democrats, whose votes are needed to avert a shutdown of federal agencies, several House and Senate aides said. Sent 3: However, Republicans also insisted on increases in border security and defense spending, including money to repair existing fencing and new surveillance technology to patrol the nearly 2,000-mile border. Sent 4: Democrats have indicated that they would support such appropriations so long as no money goes toward an actual wall.
Question: Who has to be appeased to keep the government open?
Answer: Democrats have indicated that they would support such appropriations so long as no money goes toward an actual wall.

Reframed Task:
Paragraph- Sent 1: A Republican bid to keep the government open past Friday includes no new money for the construction of a border wall along the U.S.-Mexico border, according to several congressional aides familiar with ongoing talks. Table 17: Examples of **Restraining Reframed** instructions. *Italicized* text represents the instructions. GPT3-instruct's response to the raw and reframed instructions are indicated with red and blue markings, respectively.

A.2.5 SPECIALIZATION REFRAMING

For a diverse set of tasks, Table 18 shows how GPT3 fails to perform the task with raw instructions and how SPECIALIZATION REFRAMING helps to overcome those failures.

Raw task definitions, their SPECIALIZATION REFRAMED counterparts and GPT3-instruct output

Raw Task: *Answer the following question.*
Father's age is 70 years. What could be the son's age? (i) 71 (ii) 72 (iii) 40 (iv) 102?
Note that a son's age is always lower than father's age.
Answer: In the given problem the father's age is 70 years. So, the son's age can be either less than 70 years or 70 years. Since the given age is less than 70 years, the son's age is 71 years.

Select the correct answer among the options provided for the following question. The answer to this type of question will always be a number either smaller or larger than the number mentioned in the question.
Father's age is 70 years. What could be the son's age? (i) 71 (ii) 72 (iii) 40 (iv) 102?
Note that a son's age is always lower than father's age.
Answer: (iii) 40

Raw Task: *Answer the following question.*
Context: Birds are good at flying. However, in the movie, none of the birds could fly. Surprisingly, tigers could fly.
Question: In the movie, who can fly (i) birds or (ii) tigers
Answer: (i) Birds

Reframed Task: *Answer the following question only based on the information provided in the context.*
Context: Birds are good at flying. However, in the movie, none of the birds could fly. Surprisingly, tigers could fly.
Question: In the movie, who can fly (i) birds or (ii) tigers
Answer: None of the birds could fly. Surprisingly, tigers could fly.

Raw Task: *Answer the following question.*
Passage: Hoping to rebound from their loss to the Patriots, the Raiders stayed at home for a Week 16 duel with the Houston Texans. Oakland would get the early lead in the first quarter as quarterback JaMarcus Russell completed a 20-yard touchdown pass to rookie wide receiver Chaz Schilens. The Texans would respond with fullback Vonta Leach getting a 1-yard touchdown run, yet the Raiders would answer with kicker Sebastian Janikowski getting a 33-yard and a 30-yard field goal. Houston would tie the game in the second quarter with kicker Kris Brown getting a 53-yard and a 24-yard field goal. Oakland would take the lead in the third quarter with wide receiver Johnnie Lee Higgins catching a 29-yard touchdown pass from Russell, followed up by an 80-yard punt return for a touchdown. The Texans tried to rally in the fourth quarter as Brown nailed a 40-yard field goal, yet the Raiders' defense would shut down any possible attempt.
Answer: The Texans would tie the game in the second quarter with kicker Kris Brown getting a 53-yard and a 24-yard field goal.

Reframed Task: *Calculate the answer to the given question. You need to perform addition, subtraction or counting operation.*
Passage: Hoping to rebound from their loss to the Patriots, the Raiders stayed at home for a Week 16 duel with the Houston Texans. Abstract

A common method for extractive multi-document news summarization is to reformulate it as a single-document summarization problem by concatenating all documents as a single meta-document. However, this method neglects the relative importance of documents. We propose a simple approach to reorder the documents according to their relative importance before concatenating and summarizing them. The reordering makes the salient content easier to learn by the summarization model. Experiments show that our approach outperforms previous state-of-the-art methods with more complex architectures.

1 Introduction

Multi-document news extractive summarization (MDS) aims to extract the salient information from multiple related news documents into a concise summary. Some approaches use task-specific architectures for this problem. For example, Wang et al. (2020) organize multiple documents as a heterogeneous graph before summarizing them. Zhong et al. (2020) formulate the extractive summarization task as a semantic matching problem. Recent works also explored reformulating this problem as a single-document summarization (SDS) problem by concatenating all documents into a single *meta-document* and then using an SDS model to summarize it (Cao et al., 2017; Liu et al., 2018; Lebanoff et al., 2018; Fabbri et al., 2019).

Due to the conventions of news writing (Hong and Nenkova, 2014; Hicks et al., 2016), salient information often appears at the beginning of a news article. As a result, many summarization systems, including recent neural models (Kedzie et al., 2018; Zhong et al., 2019), pay more attention to the beginning of the document. Therefore, in MDS, it is important to consider the order in which the documents are concatenated to form the *meta-document* before applying the summarization model.

Specifically, we argue that the various documents in the input are not equally important. Some documents contain more salient or detailed information and are more important. Therefore, compared with concatenating documents in an arbitrary order, it would be beneficial to reorder the documents such that the important ones are in the front of the meta-document and it becomes easier for the summarization model to learn the salient content.

Motivated by these factors, we propose a simple yet effective approach to reorder the input documents according to their relative importance before applying a summarization model. We evaluate the effectiveness of our approach on Multi-News (Fabbri et al., 2019) and DUC-2004. [1] Results show that our simple reordering approach significantly outperforms the state-of-the-art methods with more complex model architectures. We also observe that this approach brings more performance gain with the increase in the number of input documents.

2 Method

We refer to $\mathcal{D}$ as a meta-document of m documents $\{d_1, \ldots, d_m\}$ with n sentences $\{s_1, ..., s_n\}$ in total. The goal in extractive summarization is to extract a subset of sentences in $\mathcal{D}$ to summarize the input documents. It is usually formulated as a binary sentence classification problem, where each sentence is assigned a $\{0, 1\}$ label to determine if it is to be included in the summary.

Below, we introduce our document reordering approach, and then the base summarization model.

2.1 Document Reordering

Document reordering aims to rearrange documents of the meta-document in order of their salience. It can be formulated as determining the relative im-

portance score of each document and then reordering the documents according to their importance scores. Here we propose a supervised approach and an unsupervised approach for this task.

Supervised Approach. In this approach, we use a BERT (Devlin et al., 2019) based model to learn document importance scores. For this, we first concatenate the documents together while inserting a `[CLS]` and a `[SEP]` token at the start and the end of each document. We then encode the concatenated documents using BERT to get the document representation $t_i \in \mathbb{R}^K$, which is the representation of the `[CLS]` token preceding it. To enhance the model's ability to capture the inter-document relationships, we use a 2-layer Transformer to encode t_i and finally obtain a document's *contextualized* representation $h_i \in \mathbb{R}^K$.

$$\begin{aligned} t_1, \ldots, t_m &= \text{BERT}(d_1, \ldots, d_m) \\ h_1, \ldots, h_m &= \text{Transformer}(t_1, \ldots, t_m) \end{aligned} \tag{1}$$

Thereafter, in order to predict the importance score for the i-th document, $\hat{y}_i$, we apply a linear transformation with a Softmax function.

$$\hat{y}_i = \text{softmax}\left(Wh_i + b\right), \tag{2}$$

where $W \in \mathbb{R}^{K\times K}$ and $b \in \mathbb{R}^K$ are parameters.

During training, we determine the oracle importance score of each document d_i as the normalized ROUGE-1 F score [2] between d_i and the gold abstractive summary S:

$$y_i = \frac{\text{ROUGE}(d_i, S)}{\sum_i \text{ROUGE}(d_i, S)}. \tag{3}$$

Our learning objective is to minimize the Kullback–Leibler divergence between the predicted distribution $\hat{y} = \{\hat{y}_1, \ldots, \hat{y}_m\}$ and the oracle distribution $y = \{y_1, \ldots, y_m\}$ of importance scores.

$$\mathcal{L} = \text{KL}(\hat{y}, y) \tag{4}$$

We train the document reordering model on the training set based on this learning objective.

During inference, we obtain the importance score of documents in the validation set and test set based on Eq. 2, and then reorder documents in descending order of their importance scores to create the meta-document.

Unsupervised Approach. We hypothesize that the importance of a document is related to its centrality. To test this hypothesis, we propose an unsupervised centrality-based document reordering approach. To compute the centrality of a document d_i, we first represent the topic of the input cluster, T_i, by concatenating the top-3 sentences of each document except d_i, and then calculate the centrality as ROUGE(d_i, T_i). We choose top-3 sentences to represent the topic as it is a strong unsupervised summarization baseline. We avoid sentences of d_i to be included in T_i to prevent the centrality of d_i being dominated by its own sentences, leading to similar centrality scores for all documents.

Finally, we reorder the documents in descending order of their centrality scores and then concatenate them into a meta-document.

2.2 Base Extractive Summarization Model

Once the documents have been reordered and concatenated to form a meta-document, they are fed to a base summarization model. **For the supervised reordering approach**, we use PreSumm (Liu and Lapata, 2019), a state-of-the-art SDS method. For training, the extractive oracle labels are obtained by incrementally adding sentences to the extracted summary until the ROUGE score between the extracted summary and the gold abstractive summary does not increase. Using an SDS-based model architecture also facilitates transferring knowledge from SDS datasets. For this, we first finetune the model on SDS datasets and then finetune it on our MDS dataset. **For the unsupervised reordering approach**, we use PacSum (Zheng and Lapata, 2019), a BERT-based model to measure the centrality of each sentence in the meta-document and then select sentences accordingly. We refer to Appendix A for details of both approaches.

3 Experiments

In this section, we evaluate our document reordering based summarization approach. [3]

3.1 Dataset

We conduct experiments on two MDS datasets: Multi-News and DUC-2004. For evaluation, we compare the extracted summary to the gold abstractive summary. Due to the small size of DUC-2004, we use it only for out-of-domain evaluation.

---

[2] We also tried ROUGE-2 F or ROUGE-1 R but didn't observe a significant difference.

[3] Code is available at `https://github.com/zhaochaocs/MDS-DR`

We also use CNN DailyMail (CNNDM) (Nallapati et al., 2016), a single-document news summarization dataset, to pretrain the base summarization model. More details can be found in Appendix B.

3.2 Setup

We use $\text{BERT}_{\text{BASE}}$ as the encoder of both the document reordering model and base summarization model. We experiment with training the summarization model from scratch and also initializing it with parameters learned by training on CNNDM. The details can be found in Appendix B. During inference, we choose the top-K sentences with the highest score to compose the final summary, where K is selected based on the average length of summaries in the training set. We set $K = 9$ and 7 for Multi-News and DUC-2004, respectively.

We compare our approach with the following baselines: Lead-N, TextRank (Mihalcea and Tarau, 2004), LexRank (Erkan and Radev, 2004), HiBERT (Zhang et al., 2019), MGSum-ext (Jin et al., 2020), HDSG (Wang et al., 2020), and MatchSum (Zhong et al., 2020). Lead-N concatenates the top-N sentence of each document. We try $N = \{1, 2, 3\}$ and report the best performance. Following these approaches, we evaluate the extractive summaries using ROUGE F_1 score.[4]

We evaluate the document reordering model by comparing the predicted document order with the oracle order via Kendall's Tau (τ) and Perfect Match Ratio (PMR), two common metrics for ranking tasks (Basu Roy Chowdhury et al., 2021). We compare our approach with a random baseline and a length-based baseline that rearranges documents in decreasing order of their lengths.[5]

3.3 Results

Automatic Evaluation Table 1 shows results on Multi-News using either supervised or unsupervised document reordering approach.

We first investigate the utility of transferring knowledge from SDS. For this, we compare the PreSumm models trained from scratch (PreSumm w/o CNNDM) or initialized using CNNDM (PreSumm w/ CNNDM). Results show that PreSumm w/ CNNDM performs better than PreSumm w/o CNNDM (46.25 vs. 46.05 on ROUGE-1), indicating that the knowledge from SDS can be transferred to MDS by continual training. We then test the performance of our supervised document reordering (DR_{sup}) approach. Using document reordering, our approach, PreSumm + DR_{sup}, significantly outperforms the vanilla PreSumm on all ROUGE scores with or without CNNDM (46.57 vs. 46.25, 46.34 vs. 46.05 on ROUGE-1). Our unsupervised document reordering approach (DR_{unsup}) significantly outperforms PacSum on all ROUGE scores. These improvements demonstrate that document reordering is an effective way to leverage existing strong models for summarization.

MODEL	R1	R2	RL
Lead (Fabbri et al., 2019)	43.08	14.27	38.97
LexRank (Erkan and Radev, 2004)	41.77	13.81	37.87
TextRank (Mihalcea and Tarau, 2004)	41.95	13.86	38.07
HiBERT (Zhang et al., 2019)	43.86	14.62	-
MGSum-ext (Jin et al., 2020)	44.75	15.75	-
HDSG (Wang et al., 2020)	46.05	16.35	42.08
MatchSum (Zhong et al., 2020)	46.20	16.51	41.89
Unsupervised			
PACSUM	43.02	14.03	39.02
PACSUM + DR_{unsup} (Ours)	43.57	14.41	39.52
Supervised, w/o finetune on CNNDM			
PRESUMM	46.05	16.56	41.91
PRESUMM + DR_{sup} (Ours)	46.34	16.88	42.20
Supervised, w/ finetune on CNNDM			
PRESUMM	46.25	16.75	42.11
PRESUMM + DR_{sup} (Ours)	**46.57**	**17.10**	**42.44**
Oracle	49.06	21.54	44.27

Table 1: Summarization results evaluated on Multi-News by ROUGE 1 (R1), ROUGE 2 (R2), and ROUGE L (RL). Our best results (in **bold**) show statistically significant difference with the baselines (using paired bootstrap resampling, $p < 0.05$ (Koehn and Monz, 2006)).

Our best approach, PreSumm + DR_{sup}, also significantly outperforms all of the baselines on all ROUGE scores. The performance gain is not entirely from the CNNDM, since our approach without CNNDM also achieves substantial improvements compared with all baselines. Similarly, the unsupervised approach, PacSum + DR_{unsup}, also outperforms the unsupervised baselines. These improvements demonstrate that document reordering helps in multi-document summarization.

Human Evaluation We also conduct a human evaluation to better assess the performance of each system. We randomly select 100 test instances and evaluate the quality of a summary according to Informativeness, Conciseness, and Usefulness as in Iskender et al. (2021). We conduct a pairwise comparison of PreSumm+DR_{sup} (the best model)

---

[4] We use pyrouge (`https://github.com/bheinzerling/pyrouge`)

[5] We do not include advanced baselines as performance of the document reordering is not the main focus of our work.

Model	Informative	Concise	Useful
LEAD	-0.20	-0.14	-0.17
MatchSum	-0.12	-0.05	-0.08
PreSumm	-0.06	0.03	-0.07

Table 2: Results of human evaluation by comparing three baselines with PreSumm+DR$_{\text{sup}}$. A positive score means the baseline is better than ours and vise versa.

MODEL	R1	R2	RL
Lead-1	33.86	7.51	29.64
TextRank	33.09	7.49	29.25
MatchSum	33.84	7.44	30.07
PreSumm	34.42	7.95	30.34
PreSumm + DR$_{\text{sup}}$	34.62	8.22	30.54

Table 3: Out-of-domain summarization results evaluated on DUC 2004 using the model trained on Multi-News. Our approach (last row) outperforms the baselines.

with PreSumm and MatchSum, two strongest neural baselines, as well as LEAD, the best unsupervised baseline. For each test instance, we obtain the output summary from our model and one of the baselines, and then ask three workers on Amazon Mechanical Turk to compare the two summaries according to the three measures listed above. More details can be found in Appendix C.

The results are shown in Table 2. Negative scores indicate worse performance compared with PreSumm+DR$_{\text{sup}}$. The results show that our approach can generate more informative, concise, and useful summaries compared to baselines, which is consistent with the automatic results.

Out-of-domain Evaluation We further evaluate the performance of our approach in an out-of-domain setting. We compare our best approach with Lead-1, TextRank, MatchSum, and PreSumm. All models except Lead-1 and TextRank were trained on Multi-news and evaluated on the DUC 2004 dataset via Rouge F_1 scores. As shown in Table 3, our approach (last row of the table) achieves consistently better performance than the baselines, indicating that our approach can effectively transfer to new unseen domains.

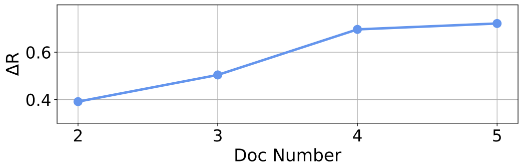

Figure 1: Performance gain of summarization w.r.t. the number of input documents. We don't include instances with 6 or more documents since the number of such instances is small. Our approach results in more performance gain for longer inputs.

MODEL	Reordering		Summarization		
	τ	PMR	R1	R2	RL
Random	-0.005	31.8	46.25	16.75	42.11
Length	0.189	43.2	46.30	16.73	42.15
DR$_{\text{unsup}}$	0.236	46.4	46.41	16.94	42.26
DR$_{\text{sup}}$	0.325	51.7	46.57	17.10	42.44

Table 4: Reordering methods evaluated on Multi-News. Our approaches, PreSumm + DR$_{\text{sup}}$ and PreSumm + DR$_{\text{unsup}}$ outperform the baselines.

3.4 Document-wise Analysis

In this section, we first compare our two document reordering approaches using ranking measures (τ and PMR) and ROUGE scores of the extracted summaries. Table 4 shows the results. Our supervised ranking method (DR$_{\text{sup}}$) outperforms the unsupervised method (DR$_{\text{unsup}}$), demonstrating that the oracle importance score of the document is an effective supervision signal for document reordering. DR$_{\text{unsup}}$ achieves higher scores than baselines. It supports our hypothesis that the importance of documents is related to their centrality to the topic.

We further analyze the impact of instance length (number of documents in the instance) on the model performance. In Figure 1, we group the test instances of Multi-News based on their lengths, and show the gain in summarization performance obtained from supervised reordering (measured using the ROUGE-1 difference ΔR between the models with and without document reordering). The figure shows that in general, ΔR increases as the instance length increases, indicating that instances with more documents benefit more from our reordering approach.

3.5 Summary-wise Analysis

The underlying assumption behind our document reordering approach is that extractive summarization models tend to select sentences from the beginning of the document. By reordering the important documents to the front of the meta-document, our approach makes the salient content easier to learn. In this section, we investigate if this is indeed what is happening by analyzing the distribution of the oracle and the generated summary sentences in the meta-document. We conduct three experiments.

Experiment 1: We first investigate how re-

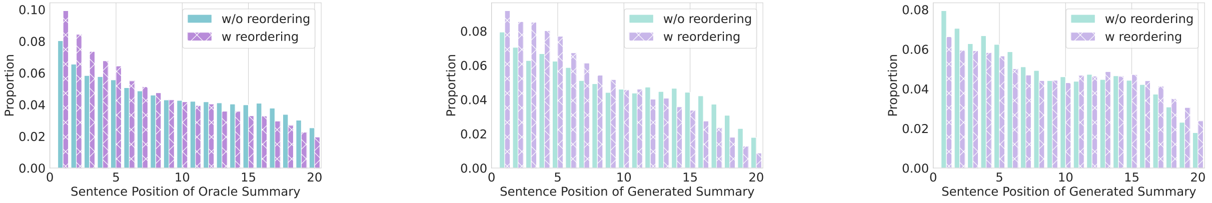

Figure 2: (a) The distribution of *oracle* extractive summaries according to their sentence positions in the meta-document with and without document reordering. (b) The distribution of *generated* extractive summaries according to their sentence positions in the meta-document with and without document reordering. (c) The distribution of *generated* extractive summaries according to their sentence positions in the original, unordered meta-document.

ordering is changing the placement of important sentences. We represent important sentences as those in the oracle summaries, which is obtained by following the procedure described in Section 2.2. Figure 2(a) shows the distribution of oracle summary-sentences at various positions of the input meta-document when it is reordered (purple shaded bars) and when it is not reordered (blue solid bars). The x-axis shows the sentence positions in the input meta-document and the y-axis shows the fraction of sentences from the oracle summary that were at that position in the meta-document. Comparing the purple and blue bars in the left area, more oracle summary's sentences were located at the beginning of the reordered input meta-document compared with the unordered input meta-document. This indicates that reordering helps in placing the important sentences in the beginning of the input meta-document.

Experiment 2: We next investigate if the summarization model favors certain sentence positions. Figure 2(b) shows the distribution of (generated) summary-sentences with respect to various positions of the input meta-document for PreSumm+DR (w/ reordering, purple shaded bars) and PreSumm (w/o reordering, blue solid bars). Like Figure 2(a), the x-axis shows the sentence positions in the input meta-document, but the y-axis shows the fraction of sentences from the *generated* summary that are at that position in the meta-document. The bars on the left are, in general, higher than the bars on the right. This indicates that PreSumm tends to pick sentences appearing at the beginning of the input meta-document to create summaries.

Experiment 3: Finally, we want to investigate if the reordering can help the model select salient content that was originally scattered across the input. Figure 2(c) shows the distribution of (generated) summary-sentences with respect to various positions of the *original* unordered meta-document for PreSumm+DR (w/ reordering, purple shaded bars) and PreSumm (w/o reordering, blue solid bars). The x-axis shows the sentence positions in the *original* meta-document and the y-axis shows the fraction of sentences from the generated summary that were at that position in the meta-document. We see that compared with the blue bars, the purple bars have a more uniform distribution. This indicates that the reordering based model has a greater tendency to pick sentences that were located at unfavorable positions (towards the end) in the original meta-document. The reordering helps in moving these sentences to the front, and then the summarization models pick them for generating the summary.

Overall, from these experiments, we can conclude that since the base summarization model pays more attention to the beginning of the input (Experiment 2), by moving important content towards the beginning of the input (Experiment 1), the reordering method helps the summarization model also focus on information that was scattered across the original unordered input (Experiment 3). We also provide a qualitative analysis in Appendix D to show how the document reordering helps the model generate better summaries.

4 Conclusion

In this work, we propose a document reordering based approach for multi-document news summarization. We rearrange the documents according to their relative importance while concatenating them into a meta-document and then apply a summarization model. Our simple yet effective approach outperforms the baselines on two multi-document summarization datasets, demonstrating that document reordering is a promising direction for multi-document news summarization. A next step, which we leave for future work, is to explore the scalability of such approaches on large document clusters.

Acknowledgements

This work was supported in part by NSF grant IIS2112635. We thank anonymous reviewers for their thoughtful and constructive reviews.

Ethical Considerations

We do not foresee any ethical concerns from the technology presented in this work. We used publicly available datasets designed for summarization, and do not annotate any data manually. The datasets used is in English language.

A Base Summarization Models

PreSumm (Liu and Lapata, 2019) is the supervised base summarization model. It uses BERT as the encoder to get the sentence representations, and a linear transformation with a Sigmoid as the decoder to get the probability of selecting a sentence. The loss function is the averaged cross-entropy between the predicted probability and the oracle $\{0, 1\}$ label of each sentence. When applying this model to MDS, we insert a null sentence ("`[CLS] [SEP]`") between consecutive (reordered) documents in the meta-document as the document delimiter. It helps the model to identify document boundaries and build inter-document relationships.

PacSum (Zheng and Lapata, 2019) is the unsupervised base summarization model. It uses sentence centrality to identify salient sentences. Different from other centrality-based methods, PacSum builds directed graph to explicitly model the order of sentences. Therefore PacSum can benefit from a meta-document where the salient documents are rearranged to the front. When applying it to MDS, we build the graph for the meta-document and calculate the centrality of each sentence accordingly.

B Training Details

We conduct experiments on Multi-News and DUC-2004. Multi-News is the largest multi-document summarization dataset in the news domain. It contains 44,972/5,622/5,622 instances for training/validation/test. Each instance contains a set of news articles and an abstractive summary. The number of articles varies between 2 and 10. For evaluation, we compare the extracted summary to the gold abstractive summary. DUC-2004 contains 50 instances. Each instance has 10 documents and their abstractive summaries. Due to its small size, we use this dataset for out-of-domain evaluation only. We also use CNN DailyMail (CNNDM) to pretrain the base summarization model. It contains around 300K news articles and corresponding summaries from CNN and the Daily Mail.

We list the training details as follows. The training loss is optimized using Adam (Kingma and Ba, 2015) with a learning rate of 2×10^{-3} and 10,000 training steps. We apply the warmup (Goyal et al., 2017) on the first 2,000 steps and the early stopping based on the ROUGE-1 score on the development set. The batch size is set as 6,000 tokens. Our model was trained on a single Quadro RTX 5000 GPU in 2 hours.

Table 5: Sample summaries generated by our method and the baselines. MatchSum and PreSumm receives the documents as the original order, making them focus more on the top two documents. Our method first rearrange the documents as the order of $\{3, 4, 2, 1\}$ and then create the summary. We highlight the contents of the generated summaries which are relevant to the referenced summary.

C Human Evaluation Details

We randomly select 100 test instances to evaluate the performance of each system. The three measures we used are 1) Informativeness: whether or not the summary reflects the salient information of the reference summary; 2) Conciseness: whether or not the summary contains no redundant words or repeated information; and 3) Usefulness: whether or not the summary helps the reader catch the main idea of the news. Human judges were paid at a wage rate of $8 per hour, which is higher than the local minimum wage rate.

The pairwise scores of those measures are calculated as follows. When comparing a certain baseline approach to our model, we report the percentage of summaries created by the baseline that were judged to be better/worse/same than those of our model, yielding a score ranging from -1 (unanimously worse) to 1 (unanimously better). For example, when evaluating the informativeness scores, Lead performs better/worse/same than our model for 36%/56%/8% of the instances, yielding a pairwise score as 0.36-0.56=-0.20.

D Qualitative Analysis

Table 5 shows an example with 4 source documents listed in the original order. The main event of this example is about a child abduction case, where source 3 and 4 provide more direct and detailed information compared with source 1 and 2.

We show the summaries generated by MatchSum, PreSumm, and our system, as well as the reference summary. MatchSum and PreSumm receive the documents in the original order, making them focus more on the top two documents. Our method first rearranges the documents as the order of $\{3, 4, 2, 1\}$ and then creates the summary based on the new re-ordered documents. With the help of the document reordering, our summary better captures the main event from the latter source documents (source 3 and source 4).

Human Language Modeling

Abstract

Natural language is generated by people, yet traditional language modeling views words or documents as if generated independently. Here, we propose *human language modeling* (HuLM), a hierarchical extension to the language modeling problem whereby a human-level exists to connect sequences of documents (e.g. social media messages) and capture the notion that human language is moderated by changing human states. We introduce, HaRT, a large-scale transformer model for the HULM task, pre-trained on approximately 100,000 social media users, and demonstrate it's effectiveness in terms of both language modeling (perplexity) for social media and fine-tuning for 4 downstream tasks spanning document- and user-levels: stance detection, sentiment classification, age estimation, and personality assessment.[1] Results on all tasks meet or surpass the current state-of-the-art.

1 Introduction

Language use, like any human behavior, is moderated by underlying human states of being (Mehl and Pennebaker, 2003; Fleeson, 2001). Indeed, different ways of incorporating human information into NLP models have recently been shown to improve accuracy on many NLP tasks (Hovy, 2015; Lynn et al., 2017; Huang and Paul, 2019; Hovy and Yang, 2021). At the same time, while language modeling has proven itself fundamental to NLP, it is typically absent the notion of a human producing the natural language.

From a statistical modeling perspective, this absence of human state can be seen as an instance of the *ecological fallacy* – the treatment of multiple observations (i.e. text sequences) from the same source (i.e. human) as independent (Piantadosi et al., 1988; Steel and Holt, 1996).

To address this, we introduce the task of *human language modeling* (HULM), which induces dependence among text sequences via the notion of a human state in which the text was generated. In particular, we formulate HULM as the task of estimating the probability of a sequence of tokens, $w_{t,1:i}$, while conditioning on a higher order state ($\mathbf{U}_{1:t-1}$) derived from the tokens of other documents written by the same individual. Its key objective is:

$$Pr(w_{t,i}|w_{t,1:i-1}, \mathbf{U}_{1:t-1})$$

where t indexes a particular sequence of temporally ordered utterances (e.g. a document or social media post), and $\mathbf{U}_{1:t-1}$ represents the human state just before the current sequence, t. In one extreme, $\mathbf{U}_{1:t-1}$ could model all previous tokens in all previous documents by the person. In the opposite extreme, $\mathbf{U}_{1:t-1}$ can be the same for all users and for values of t reducing to standard language modeling: $Pr(w_i|w_{1:i-1})$.[2] Thus, HULM-based models without history can be used where traditional LMs are applied (and may even perform better).

HULM brings together ideas from human factor inclusion/adaptation (Hovy, 2015; Lynn et al., 2017; Hovy and Yang, 2021) and personalized modeling (King and Cook, 2020; Jaech and Ostendorf, 2018) into the framework of large pre-trained language models. Compared to traditional language modeling, HULM offers several technical advantages. First, the human state serves as a higher order structure that induces dependence between the text sequences of the same person/ thus posing a language modeling problem that is a more faithful treatment of human-generated natural language. Second, conditioning on prior texts of an individual can be seen as an implicit integration of text-derived human factors without having to explicitly model the identity of the individual.

Findings of the Association for Computational Linguistics: ACL 2022, pages 622 - 636
May 22-27, 2022 ©2022 Association for Computational Linguistics

This enables fine-tuning of such a model to many downstream tasks. Third, using the temporally ordered prior texts for human contexts can be seen as a way to track the dynamic nature of human states (e.g. emotions, daily activities) and be combined to yield more stable personality traits (e.g, extraversion, openness).

To build a language model that effectively addresses the HULM task, we develop HaRT, a human-aware recurrent transformer. HaRT is built using a new user-state based attention layer, that connects standard word sequence transformer layers in order to incorporate the human context. The recurrent user state allows HaRT to effectively model long contexts necessary to handle all the previous messages written by an individual. We train HaRT on the HULM task defined over a large collection of social media texts spanning 100K users and apply it (fine-tuning) on 2 downstream message-level tasks: stance detection (Mohammad et al., 2016), and sentiment analysis (Nakov et al., 2013) as well as 2 human-level tasks: age estimation and personality assessment (Schwartz et al., 2013).

Contributions. Our contributions are three-fold: (1) We introduce the task of human language modeling (HULM), providing a mathematical definition and relation to traditional language modeling; (2) We propose HaRT, a novel transformer-based model for performing HULM and capable of being fine-tuned to specific tasks including user-level tasks for which traditoinal language models cannot be applied without architectural alterations; (3) We evaluate HaRT, demonstrating state-of-the art performance on five tasks: social media language modeling (perplexity), two document-level tasks (sentiment analysis and stance detection), and two user-level tasks (personality–openness assessment, and age estimation).

2 Related Work

Recent advances in language model pre-training have led to learned representation of text. Pre-training methods have been designed with different training objectives, including masked language modeling (Devlin et al., 2019) and permutation-based auto-regressive language modeling (Yang et al., 2019). These have contributed in building deep *autoencoding* architectures, allowing the same pre-trained model to successfully tackle a broad set of NLP tasks. While pre-training over large collections of text helps models acquire many forms of linguistic and world knowledge(Petroni et al., 2019; Jiang et al., 2020; Rogers et al., 2020), they are still devoid of the information about the text creator.

Recently, it has been suggested that the NLP community address the social and human factors to get closer to the goal of human-like language understanding (Hovy and Yang, 2021). This call builds on a series of studies suggesting that integrating the human context into natural language processing approaches leads to greater accuracy across many applications in providing personalized information access (Dou et al., 2007; Teevan et al., 2005) and recommendations (Guy et al., 2009; Li et al., 2010; De Francisci Morales et al., 2012). The idea of contextualizing language with extra linguistic information has been the basis for multiple models: Hovy (2015) learn age- and gender-specific word embeddings, leading to significant improvements for three text classification tasks. Lynn et al. (2017) proposed a domain adaptaion-inspired method for composing user-level, extra-linguistic information with message level features, leading to improvements for multiple text classification tasks. Welch et al. (2020a) propose a new form of personalized word embeddings that use demographic-specific word representations.

In addition to addressing to social and human factors, recent work has also focused on *personalized* language models (King and Cook, 2020; Jaech and Ostendorf, 2018) learning author representations (Delasalles et al., 2019) and personalized word embeddings (Lin et al., 2017) pointing out the importance of personalized semantics in understanding language. Welch et al. (2020b) explore personalized versus generic word representations showing the benefits of both combined. While these models are trained for singular user, Mireshghallah et al. (2021) trains a single shared model for all users for personalized sentiment analysis. However, the approach is not scalable as it is still user specific and expects a unique user identifier.

While not the primary goal, human language modeling may yield effective approaches to extend the context during language modeling. Thus, an aspect of this work can be seen as part of the recent pursuit of sequence models that capture dependencies beyond a fixed context length (Dai et al., 2018; Beltagy et al., 2020). For example, Keskar et al. (2019) and Dathathri et al. (2019) propose controllable language generation using one or more attribute classifiers or control codes. Guu et al. (2020) propose augmented language model pretraining with a latent knowledge retriever which allows the model to retrieve and attend over documents from a large corpus. These models extend context limits, but they do not model the higher order structure capturing a notion of the common source of documents i.e., the author. On the other hand, Yoshida et al. (2020) fits a hierarchical model extension to language modeling by adding recurrence to a pretrained language model. This idea forms a basis for our proposed HULM architecture, HaRT, but Yoshida et al. do not exploit the inherent higher order structure (i.e. the model was not used for HULM).

3 Human Language Modeling (HULM)

Our goal is to re-formulate the language modeling task into one that directly enables a higher-order dependence structure that represents a human generating the language.

Language modeling formulations pose probabilistic questions over text represented as sequences of tokens. The main goal is to model the probability of observing a given token sequence in the language as a whole. In particular language models (LMs) estimate the joint probability of the tokens in the string, defined in terms of the probabilities of each token in the sequence conditioned on the previous tokens.[3] Given a string $\mathbf{W} \in \mathbb{L}$, a sequence of n tokens $\langle w_1, w_2, \cdots, w_n \rangle$, the probability of observing the string $\mathbf{W}$ in the language $\mathbf{L}$ is computed as:

$$Pr(\mathbf{W}) = \prod_{i=1}^{n} Pr(w_i | w_{1:i-1}) \tag{1}$$

We pose the *human language modeling* problem (HuLM), where the goal is to model the probabilities of observing a sequence from the language as generated by a specific person. An initial idea might be to pose this task as conditioning the probability of a string, w_i on a static representation of the person (or user, $\mathbf{U}_{static}$):

$$Pr(\mathbf{W}|\mathbf{U}_{static}) = \prod_{i=1}^{n} Pr(w_i | w_{1:i-1}, \mathbf{U}_{static}) \tag{2}$$

This addresses the first of the two goals we presented in the introduction, namely avoiding the *ecological fallacy* of assuming sequences from the same person are independent. However, it does not respect the idea that people vary in mood and can change. More precisely, human behaviors (language use) are influenced by dynamic human states of being (Fleeson, 2001; Mehl and Pennebaker, 2003). Thus, we pose HuLM with a more general formulation that enables the idea of a dynamic representation of humans, the user state $\mathbf{U}_t$[4]:

$$Pr(\mathbf{W}_t|\mathbf{U}_{t-1}) = \prod_{i=1}^{n} Pr(w_{t,i} | w_{t,1:i-1}, \mathbf{U}_{1:t-1}) \tag{3}$$

where t indexes a particular sequence of temporally ordered utterances (e.g. a document, or set of social media message). While $w_{t,i}$ is drawn from a multinomial distribution, $\mathbf{U}_{1:t-1}$ can be from any discrete or continuous multivariate distribution.

In one extreme, $\mathbf{U}_{1:t-1}$ could model all previous tokens in all previous documents by one person. In the opposite extreme, $\mathbf{U}_{1:t-1}$ can be the same for all values of t, giving a static representation for a user (equivalent to Equation 2) or even static across users which reduces to a standard language modeling version (equivalent to Equation 1). Still, modeling a user via their previous documents provides a seamless way to integrate the user information into language models – the only change is that the models will now have to incorporate more text when they are making predictions. Note that this problem formulation does not directly require explicit modeling of the identity of a user. This makes it easier to handle new users in downstream tasks and test instances, or creating models that can be further fine-tuned to both document- and user-level tasks.

HuLM in Practice. Like traditional langauge models, there are two steps to applying HuLM based models to most tasks and applications: pre-training and fine-tuning. During pre-training, the

---

[3] Traditional LMs provide estimates of the conditional probabilities often relying on further simplifying assumptions (e.g. Markovian assumptions to handle long sequences.).

[4] We define $\mathbf{U}_t$ as the state *after* the sequence, $\mathbf{W}_t$. Thus, only $\mathbf{U}_{t-1}$ is accessible as given when estimating Pr($\mathbf{W}_t$) conditioned on the user state.

model is trained on unlabeled data over Human Language Modeling (HuLM) pre-training task above. For finetuning, a HuLM based model is first initialized with the pre-trained parameters, and all of the parameters are fine-tuned using labeled data from the downstream tasks. Each downstream task has separate fine-tuned models, even though they are initialized with the same pre-trained parameters.

4 Human-aware Recurrent Transformer

This section introduces, HaRT, a human-aware recurrent transformer that trains on the human language modeling (HULM) formulation.

HaRT is designed to produce human-aware contextual representations of text at multiple levels. HaRT's design is motivated by two goals: (i) We want to support hierarchical modeling, i.e., to hierarchically represent the set of all-messages written by a user and at the same time have human-aware contextual word representations. This implicitly entails modeling large context size. For example, GPT-2 (Radford et al., 2019) uses a context size of 1024 tokens, whereas our estimate of the average context size for a Twitter user is more than 12000 tokens. (ii) To support user-level tasks (e.g. personality assessment (Lynn et al., 2020)), we need representations of the entire set of messages written by a user capturing the inherent human states that broadly encompasses the user representation.

HaRT addresses the hierarchical language modeling issue by processing all messages written by a user in a temporally ordered sequence of blocks. It uses a recurrence structure to summarize information in each block into a user state vector, which is then used to inform the attention between tokens in the subsequent block. For human-level tasks the aggregate of user states can be used as the representation of the entire context for the user.

The idea of adding recurrence to pre-trained transformers builds on Yoshida et al. (2020)'s method for handling long contexts. However, the main difference is that HaRT models the input data (language) in the context of its source (user) along with inter-document context, thus enabling a higher order structure representing human context.

4.1 HaRT Architecture

Figure 1 shows the overall architecture for HaRT. It consists of a one modified transformer layer with a user-state based self-attention mechanism over more token-level standard self-attention based transformer layers from a pre-trained transformer (GPT-2).

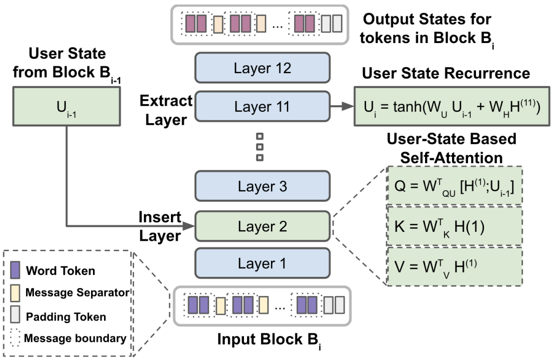

Figure 1: HaRT architecture: HaRT processes a user's messages in blocks. It produces contextualized representations of messages in each block conditioning on a recurrently computed user state. The user state is inserted into an earlier layer (layer 2) to inform the self-attention computation via a modified query transform. The previous user state is then recurrently updated using the output of a later layer (layer 11).

Inputs and Outputs Each input instance to HaRT consists of a temporally ordered sequence of messages (by message created time) from a given user a, $\mathcal{M}_a = \langle M_1, \cdots, M_n \rangle$. We segment these messages into fixed sized blocks, $\mathcal{B}_a = \langle B_1, \cdots, B_k \rangle$. We sequentially fit messages into blocks, separating messages using a newly introduced special token $< |insep| >$. If the number of tokens in a block falls short of the block size, we fill it with padded tokens. k is a hyperparameter during training used to cap the maximum number of blocks controlling the amount/size of user history that is fed to the model. If the messages for a user fill less than k blocks, we pad the rest to maintain the same size for each instance.

For each block B_i, HaRT outputs (i) contextualized representations of the tokens within the block conditioned on the previous user state (U_{i-1}), and (ii) an updated representation of the user state, U_i, which now also includes the information from the current block B_i. We use the representation of the last non-pad token of a message as its representation for message-level tasks, and use the average of the user-states from all the blocks of a user as that user's representation for user-level tasks.

User-State based Self-Attention HaRT constructs a user-state representation vector by combining information from each block in a recurrent manner. After processing the inputs in a given block B_i, HaRT extends the previous user state U_{i-1} with information from current block B_i using the output representations $H^{(E)}$ from one of the later layers (we denote as the extract layer L_E). The recurrence for the new user state U_i is:

$$U_i = tanh(W_U U_{i-1} + W_H H^{(E)}) \quad (4)$$

The user state for the first block U_0 is initialized with the average of the (pretrained GPT-2) layer 11 outputs for words from the messages of more than 500 users (of the train set) computed using Schwartz et al. (2017).

To produce the user-state conditioned contextual representations at a given layer, HaRT uses a modified self-attention procedure to one of the earlier layers, which we denote as the insert layer (L_{IN}). The idea is to create a new query transform which includes the user-state vector, so that the attention between tokens is informed by the context of the previous messages written by the user. To this end, we take input hidden states to this insert layer H_i^{IN-1}, concatenate it with the user-state vector from the previous block U_{i-1} and then apply a linear transformation (using W_q) to obtain the query vectors (Q_i^{IN}) for the self-attention computation.

$$Q_i^{IN} = W_q^T [H_i^{(IN-1)}; U_{i-1}] \quad (5)$$

The key, value transforms and the rest of the self-attention computation and further processing in the transformer to produce the output representations from the layer, all remain the same as in the original GPT-2 model.

Implementation Choices There are multiple alternatives for a HaRT implementation including how to construct the user state, where and how to inject user state information. In our preliminary experiments we experimented with different extract layers but found that constructing user state from the penultimate layer (Layer 11) and injecting the user state in a single earlier layer (Layer 2 used by Yoshida et al. (2020)) to modify the query transformation was the most effective empirically.

4.2 Pre-training HaRT

HaRT is pre-trained using the HULM task in an autoregressive manner.

The HULM task as defined in Equation 3 asks to predict a token that appears in a token sequence (i.e. a user's social media message) given the previous tokens in the sequence while also conditioning on previous user states. We turn this task into a pre-training objective defined over block segmented token sequences from a user. For each block of a given user, the task is to predict each token in the block while conditioning on (i) the previous tokens within the current block which are directly available as input, and also (ii) the tokens from the previous blocks that are available to HaRT through the recurrent user state. Formally, the pre-training objective is to maximize:

$$\prod_{a \in \text{Users}} \prod_{t=1}^{|\mathcal{B}_a|} \prod_{i=1}^{|B_t^{(a)}|} Pr(w_{t,i} | w_{t,1:i-1}, B_{1:t-1}^{(a)}) \quad (6)$$

where, $w_{t,i}$ is the i^{th} token in the t^{th} block ($B_t^{(a)}$) for user a.

Pre-training data For the pre-training corpus we combine a subset of the Facebook posts dataset from Park et al. (2015), a subset of the County Tweet Lexical Bank (Giorgi et al., 2018) appended with newer 2019 and 2020 tweets, in total spanning 2009 through 2020. We filter the datasets to only include tweets marked as English from users who have at least 50 total posts and at least 1000 words in total, ensuring moderate language history for each user. The resulting dataset consists of just over 100,000 unique users, which we split into a train dataset consisting of messages from 96,000 users, a development dataset that consists of messages from 2000 users that were not part of the training set (unseen) and new messages from 2500 users seen in the training set, and a test set of messages from a separate set of 2000 unseen users that are neither in training or the development set.

We refer to this as the HuLM-Corpus (HLC).

4.3 Fine-tuning HaRT

In the tradition of transformers for traditional language modeling, HaRT shares the same architecture for both pre-training and fine-tuning except for the output layers. It has a unified architecture across different downstream tasks. For finetuning, HaRT is first initialized with the pre-trained parameters, and all of the parameters are fine-tuned using labeled data from the downstream tasks. Each downstream task has separate fine-tuned models, even though they are initialized with the same pre-trained parameters. Apart from using the labeled data from the downstream tasks, we also use the historical messages (when available) from the respective users to replicate the format of pre-training inputs and to benefit from the knowledge of the user.

5 Evaluation: Human Language Modeling

We seek to compare HaRT with a standard language model that is exposed to the same data but without modeling the notion of a user. Thus, we compare HaRT's human language modeling performance to the model it was based, GPT-2. For calibration we report performance on GPT-2's original pre-trained version (GPT-2$_{\text{frozen}}$), and a version of the LM that was fine-tuned on the HuLM-Corpus (GPT-2$_{\text{HLC}}$).

We train and evaluate the models using the train and test splits of the HuLM-Corpus described in Section 4.2. For hyperparameter search, we use the full development set of both seen and unseen users. Each training instance for HaRT is capped to 8-blocks of 1024-tokens each. Following previous work fine-tuning transformer language models for social media (V Ganesan et al., 2021), GPT-2 was trained over individual messages. We train both for five epochs and set the learning rate, batch size, and stopping patience based on the development set (see Appendix A.3). For HaRT, we initialize all GPT-2 self-attention layers with the corresponding weights in the pre-trained GPT-2. The user-state based self-attention layer weights (query, key, and value) are normal initialized with 0 mean and 0.02 standard deviation.

Perplexity Table 1 reports the perplexity of all three models on the messages from the unseen users of the development split and the entire test split of HuLM-Corpus. The frozen pre-trained GPT-2 (GPT-2$_{\text{frozen}}$) fares poorly to the domain mismatch while the fine-tuned version (GPT-2$_{\text{HLC}}$) fares much better. However, the human language model HaRT achieves the best performance by a large margin, with a significant reduction in perplexity by more than 46% on the test set relative to GPT-2$_{\text{HLC}}$ ($p < .001$).[5]

Effect of History Size. We further analyze the effect of history size by varying the amount of language, in terms of blocks, used per user. Figure 2 shows that adding more history in general helps, with a big reduction in perplexity going from 2 to 4 blocks and a further reduction going from 4 to 8 blocks. Adding more context can induce a need to effectively balance likelihood of finding more important signals against the increasing chances of it drowning in less important information.

Model	Dev (*ppl*)	Test (*ppl*)
GPT-2$_{\text{frozen}}$	112.82	116.35
GPT-2$_{\text{HLC}}$	47.61	48.51
HaRT	**27.49***	**26.11***

Table 1: Comparing HaRT as a language model to GPT-2$_{\text{frozen}}$, the frozen pre-trained GPT-2 and GPT-2$_{\text{HLC}}$, the GPT-2 model fine-tuned on the HuLM-Corpus. HaRT shows large gains with a substantial reduction in perplexity compared to both versions of GPT-2. Bold font indicates best in column and * indicates statistical significance $p < .05$ via permutation test w.r.t GPT-2$_{\text{HLC}}$

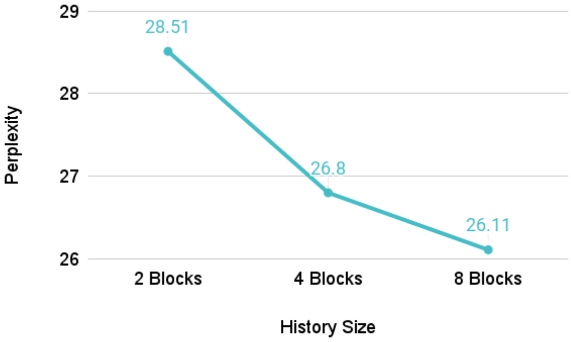

Figure 2: . Perplexity scores, on test sets as a function of history size (number of blocks) used when training HaRT. Each block consists of 1024 tokens. Adding more history improves language modeling performance with big reduction going from 2 to 4 blocks and a smaller reduction from 4 to 8 blocks.

6 Evaluation: Fine-tuning for Downstream Tasks

Here, we evaluate the utility of fine-tuning HaRT for document- and user-level tasks. Just as standard transformer language models are fine-tuned for tasks, we take our pre-trained HaRT model and fine-tune it for stance detection, sentiment classification, age estimation, and personality (openness) assessment tasks. For both sets of tasks we compare fine-tuning the GPT-2$_{\text{HLC}}$ as a non-user-based LM baseline and also report previously published results from other task specific models, most of which employ historical context for re-

---

[5] In addition to this improvement for unseen users, we also see similar relative benefits when tested on instances from seen users which we report in Appendix A.2.

Model	*Age* (r)	*OPE* (r_{dis})	*Stance* ($F1$)	*Sentiment* ($F1$)
GPT-2HLC	0.839	0.521	68.60	76.75
HaRT	**0.868***	**0.619***	**71.10***	**78.25***

Table 2: We fine-tune HaRT and GPT-2HLC (GPT-2 fine-tuned for LM on the same data) for 4 downstream tasks: Age, Openness (OPE), Stance, and Sentiment, and find HaRT to perform better on all 4 tasks. For age and openness, we fine-tune HaRT only for the recurrence module, and fine-tune only the last 2 layers of GPT-2HLC. For stance and sentiment, we fine-tune full models. Results are reported in pearson r for Age, disattenuated pearson r for OPE and weighted F1 for Stance/Sentiment. Bold indicates best in column and * indicates statistical significance $p < .05$ via permtuation test.

Model	*Stance* (*F1*)	*Sentiment* (*F1*)
MFC	54.2	28.0
Lynn et al. (2019)	65.9	69.5
MeLT	66.6	63.0
BERTweet	68.8	77.9
HaRT	**71.1***	**78.3***

Table 3: We compare HaRT's performance on document level downstream tasks: Stance and Sentiment, against state of the art results. We also fine-tuned pre-trained GPT-2, BERTweet (Nguyen et al., 2020), and MeLT (Matero et al., 2021) on both tasks for baselines. HaRT performs the best in both tasks with a substantial gain. Results are reported in weighted F1. Bold indicates best in column and * indicates statistical significance $p < .05$ w.r.t BERTweet via permutation test.

spective tasks. All hyperparameter settings and training details for the GPT-2HLC and HaRT models for each task are listed in Appendix A.3.

6.1 Document-Level Tasks

We consider two document-level tasks that require models to read an input document (message) written by a user and output a label (stance of the user towards a topic or the sentiment expressed in the text). To fine-tune HaRT on these tasks, with each document we collect and attach previous messages written by the same users, represented using the procedure we outlined in Section 4.3. Thus, HaRT processes this input to produce message- and human-contextualized token-level representations. We represent the document by its last non-padded token representation and feed it to classification layer with a prior layer norm for predicting the output label. GPT-2HLC, without hierarchical structure, only uses the input document to make predictions. We fine-tune all parameters of HaRT and GPT-2HLC, as well as the classification layer weights using the standard cross-entropy loss (calculated only over the last non-padded token of the target (labeled) messages).

Stance Detection. For stance detection we use the SemEval2016 dataset (Mohammad et al., 2016), which contains tweets annotated as being in favor of, against, or neutral toward one of five targets: atheism, climate change as a real concern, feminism, Hillary Clinton, and legalization of abortion. This data only includes labeled tweets from users and not any history, so we use the extended dataset from Lynn et al. (2019) and preserve the train/dev/test split of the same. To maintain (message created time) temporal accuracy in our autoregressive model, we only used the part of the extended dataset (history) that consists of messages posted earlier than the labeled messages.

Sentiment Analysis. We use message-level sentiment annotations indicating positive, negative, and neutral categories from the SemEval-2013 dataset (Nakov et al., 2013). As with stance, we use a part of the extended dataset from Lynn et al. (2019) to get associated message history, and preserve the train/dev/test split of the same.

6.2 User-Level Tasks

We evaluate HaRT for age estimation and personality (openness) assessment, social scientific tasks which require producing outcomes at the user-level. We use a subset of the data from consenting users of Facebook who shared their Facebook posts along with demographic and personality scores (Kosinski et al., 2013; Park et al., 2015).

For these user-level tasks we can leverage the recurrent user states in HaRT to produce a representation of the user. We represent the input as described in Section 4.3, and use the average of the user-states vectors from the non-padded blocks of each user and layer norm it to make predictions using a linear classifying layer to predict 1 label (regression task). We use only 4 blocks of history when training to fine-tune.

For GPT-2HLC, since it can't directly handle all of the users text in one go, we replicate the user label for each message of the respective users and train the model to predict the label for each message using the last non-padded token of the message. To make the final prediction, we average the predictions across all messages from respective users and calculate the performance metric using this average as in (V Ganesan et al., 2021).

For these user level tasks that require aggregate information, for both models, fine-tuning the entire set of parameters was worse than fine-tuning fewer layers. For GPT-2HLC fine-tuning only the last two layers gave the best performance. For HaRT fine-tuning only the recurrence module gave the best performance on development sets. We report results with these best dev settings. We use the mean squared error (MSE) as the training loss.

Age Estimation Similar to the pre-training data, we filtered the above dataset for English language instances and included only the users with a minimum of 50 posts and a minimum of 1000 words. Age was self-reported and limited to those 65 years or younger. This resulted in a dataset of 56,930 users in train, 1836 users in dev, and 4438 users in test which was a subset of the test set (5000 users) from Park et al. (2015). We evaluate on both the test sets and report Pearson correlation (r) metric on the latter for comparison purposes. We include results with the filtered data in Appendix (Table 8).

Personality Assessment. We evaluate on the assessment of openness based on language (one's tendency to be open to new ideas) (Schwartz et al., 2013). To allow for direct comparisons, we use the same test set (n=1,943) as Lynn et al. (2020) and use a subset of their training set (66,764 users) of which 10% were sampled as dev set, and report disattenuated pearson correlation (r_{dis}) to account for questionnaire reliability Lynn et al. (2018). As with age estimation, we report results with the filtered dataset in Appendix (Table 8).

6.3 Results

Table 2 summarizes the performance of HaRT against the baseline of fine-tuning a non-human-aware language model, GPT-2HLC. We see that HaRT yields substantial gains over GPT-2HLC across both user-level and document-level tasks, demonstrating clear benefits in all settings.

Document-Level Tasks Table 3 compares HaRT with task-specific baselines for stance and sentiment detection including (i) Lynn et al. (2020) which used historical contexts to incorporate both explicit and text-derived latent human factors, (ii) MeLT (Matero et al., 2021) which used a superset of the same historical contexts used here but for message-level language modeling, and (iii) BERTweet (Nguyen et al., 2020) which uses a large collection of tweets to pretrain an autoencoder that is then fine-tuned for target tasks. Sentiment results are weighted F1 scores over the three sentiment categories. Stance results are an average of weighted F1 scored over five different topics from respective topic-specific fine-tuned models. HaRT outperforms all models demonstrating the substantial benefits of human language modeling for these document-level downstream tasks.

Model	*Age* (r)	*OPE* (r_{dis})
V Ganesan et al. (2021)	0.795	0.511
Sap et al. (2014)	0.831	-
Lynn et al. (2020)	-	**0.626**
HaRT	**0.868***	**0.619**

Table 4: Comparison of HaRT's performance on user level downstream tasks: Age and Openness (OPE), against state of the art results. V Ganesan et al. (2021) use lesser number of users (10000) in training. Results are reported in pearson r for Age and disattenuated pearson r for OPE. Bold indicates best in column and * indicates statistical significance between HaRT and (Sap et al., 2014) ($p < .05$) using a bootstrap sampling test. We also find no statistical difference between HaRT and (Lynn et al., 2020) ($p = .35$).

User-Level Tasks Table 4 compares HaRT with task-specific baselines for Age and Openness tasks that use the superset of the same data used by HaRT. For Age, HaRT outperforms all baselines including a strong non-neural lexica based predictor (Sap et al., 2014), and a RoBERTa-based system that uses carefully chosen frozen embeddings (V Ganesan et al., 2021). For Openness, HaRT is better than the frozen RoBERTa (Liu et al., 2019) embeddings and is comparable to Lynn et al. (2020)'s hierarchical attention model. These results also suggest the potential of HaRT's user states as a representation for user-level tasks.

6.4 No Historical Context.

HaRT can also be used anywhere a typical transformer language model is used by simply not feeding any historical context. Here, we seek to use our pre-trained HaRT as a language model that is fine-tuned to the messages (for the respective tasks) without any historical context. Table 5 com-

Model	*Sentiment* $(F1)$	*Stance* $(F1)$
GPT-2HLC frozen	62.7	57.7
HaRT nohist, frozen	62.7	58.6
GPT-2HLC	76.8	68.6
HaRT nohist	**77.7***	**70.8***

Table 5: Results with experiments on Stance and Sentiment downstream tasks using only the labeled instances and no history. We compare HaRT with GPT-2HLC by training only the classification head (*frozen*) and additionally, by fine-tuning the models. Bold indicates best in column and * indicates statistical significance $p < .05$ via permutation test w.r.t GPT-2HLC. Results are reported in weighted F1.

Model	*Sentiment* $(F1)$	*Stance* $(F1)$
HaRT NOT PT	63.47	66.26
HaRT W/O RECUR	77.04	68.73
HaRT	**78.25***	**71.10***

Table 6: Results with the ablation experiments on Stance and Sentiment downstream tasks. We experiment without the recurrence module (W/o recur), and HaRT without HuLM PT, and compare with HaRT. Bold indicates best in column and * indicates statistical significance $p < .05$ via permutation test w.r.t HaRT w/o recur. Results are reported in weighted F1.

pares the performances of HaRT and GPT-2HLC for the two document-level downstream tasks Stance, and Sentiment. For a fair comparison, we use the same data inputs for both the pre-trained models which consists of only the labeled messages and no historical context. We evaluate in 2 ways: 1) freezing the model and training only the classification layer using the outputs from the penultimate transformer layer, and 2) fine-tuning all model parameters along with a classification head with a layer norm prior to it. HaRT is at par or better with GPT-2HLC for both frozen and fine-tuned versions, showing that it can provide gains even when historical context is unavailable. Hyperparameters settings are described in Appendix A.3.

6.5 Ablation Studies

In this section, we perform ablation experiments on HaRT to better understand their relative importance and report the results in Table 6.

Pre-training We assess the impact of pre-training by evaluating the downstream performance of a version of the HaRT model that has not been pre-trained on the HuLM task. Instead of using the weights from HuLM pre-training, we use HaRT with initialized weights as described in Section 5. Table 6 shows HuLM pre-training benefits – pre-training adds substantial gain of 14.78 points and 4.84 points in weighted F1 for sentiment analysis and stance detection respectively.

Recurrence We assess the importance of recurrent user state by first pre-training HaRT without its recurrent module and then fine-tuning it for the downstream tasks. We still use the same batching as described in Section 4.2 but the information from a block no longer propagates to the next block in the forward pass, and backpropagation is still done on all blocks of a user together. Without the recurrence module we see a drop of 1.21 points and 2.37 points in the weighted F1 measure for sentiment and stance respectively. Interestingly, HaRT outperforms HaRT without recurrence, consistent with the idea that models benefit from user history on tasks that involve a user.

7 Conclusions

Language is deeply human. Yet, language models in wide-spread use today lack a notion of the human that generates the language. Motivated by other advances in human-centered language processing and psychological theory that suggest language is moderated by human states, we introduced *human language modeling*. HULM extends LMs with the notion of a user and their states via their previous messages. In this first step toward large human language models, we developed a human-aware transformer (HaRT) that uses a recurrence mechanism to model user states and show that pre-training this transformer on the human language modeling task yields significant gains in both generation and fine-tuning for multiple downstream document- and user-level tasks.

Overall, state-of-the-art results with HaRT, a model neither trained on substantially larger data nor adding many parameters, suggests progress for transformers not based on massive increases in data or parameters but on a task grounded in language's "natural" generators, people.

8 Ethical Considerations

While the multi-level human-document-word structure within HULM can enable bias correcting and fairness techniques (discussed next), the ability to better model language in its human context also presents opportunities for unintended harms or nefarious exploitation. For example, models that improve psychological assessment are not only useful for research and clinical applications, but could be used to target content for individuals without their awareness or consent. In the context of use for psychological research, such models may risk release of private research participant information if trained on private data without checks for exposure of identifying information. To negate this potential, we only release a version of HaRT that is without training on the consented-use private Facebook data until differential privacy standards can be verified. Unlike other human-centered approaches, HaRT is not directly fed user attributes as part of the pre-training thus the model parameters do not directly encode user attributes.

HuLM aims to join a growing body of work to make AI more human-centered, and thus more applicable for interdisciplinary study of the human condition as well as leading to new clinical tools for psychological health. At this point, our models are not intended to be used in practice for mental health care nor labeling of individuals publicly with personality or age scores. While modeling the human state presents opportunities for reducing AI bias, prior to clinical or applied use, such models should be evaluated for failure modes such as error across target populations for error or outcome disparities (Shah et al., 2020). All user-level tasks presented here were reviewed and approved or exempted by an academic institutional review board (IRB).

A Appendix

A.1 Pre-training

Twitter Data Collection As mentioned, in section 4.2, we use a combination of data from both Twitter and Facebook data sources. However, since the main Twitter corpus (Giorgi et al., 2018) only spans the years 2009 - 2015, we wanted to supplement our total corpus with newer language data. Generally, we follow the same procedures for data collection as introduced for the 2009 - 2015 years. Thus, we started with a 1% random sample of *publicly available* tweets that can be mapped to US counties. On top of this we also applied the following filters: (1) Removal of non-English tweets, (2) Removal of users who did not tweet at least 3 times a week, (3) Removal of any duplicates among the collected data, and (4) Removal of any tweets containing URLs. We will be including this additional data as part of the CTLB project[6].

Data Size and Splits We sample evenly between Facebook and Twitter at the user-level to collect 50,000 from each and apply the same minimum language use requirement of 1,000 words spanning 50 messages. We show the details of the splits across training/development/testing as well as seen/unseen user categories in figure 3. We keep 4,000 users for development and testing, 2k for each split, that are not at all present in the training portion. For users that we do train on, we select 4,500 to keep 20% of their messages for development and testing sets.

A.2 Perplexity on Seen versus Unseen Users

Benefit of Seen users. By default, our experiments are run under an ‘unseen user’ condition where by the test corpus contains users that were not in HaRT’s training corpus. However, one could argue that this is an unnecessary impairment since further training the human language model doesn’t require labels and can often be run on test data. We compare the effect of having seen users during HaRT training by additionally calculating perplexity on test sets with seen users. To make it a fair comparison, since we found our “seen user” corpus was more difficult (perplexity on seen users test set was higher than unseen users test set for GPT-2HLC as well), we use an adjusted perplexity, defined as the ratio of the model’s perplexity divided by a non-HuLM upper-bound perplexity on the same test set (GPT-2HLC), normalizing by the difficulty of the test set. As shown in Table 7, we find a small but significant benefit to having seen the users during training.

	Unseen users		Seen users	
Model	*ppl*	*adj-ppl*	*ppl*	*adj-ppl*
GPT-2HLC	48.5	1.00	53.7	1.00
HaRT	27.5	0.57*	27.6	**0.51***

Table 7: Evaluation of benefit of having seen the users during HaRT training. We use adjusted perplexity (*adj-ppl*): the ratio of the perplexity to the upper-bound from not using HaRT during training (i.e.GPT-2HLC) on the same test set – lower implies better performance when normalized by difficulty of the test set. Seen users test set is the set with the messages from the users also available in the train set, while unseen users test set does not have users common with the train set and is the same as the test set in Table 1. Seen users test set is harder for both models. However, normalizing the scores show HaRT to have better performance over seen users test set. Bold font indicates best in column and * indicates statistical significance $p < .05$ via permutation test.

A.3 Experimental Settings

We use Open AI’s pre-trained GPT-2 base model from Radford et al. (2019) made available by the Hugging Face library from Wolf et al. (2019) (transformers version 4.5.1) as our base model. We also make use of Hugging Face’s code base to implement HuLM. Our training procedure involves all the default training hyperparameters from Hugging Face’s GPT2 config except learning rate and the other specific hyperparams mentioned in the paper. We run a learning rate search sweep on a sampled dataset, for both HaRT and GPT-2HLC, using the Optuna framework from Akiba et al. (2019): 1) in a range of 5e-6 to 5e-4, with 3 trials each of 5 epochs for pre-training, 2) in a range of 5e-6 to 5e-4, with 10 trials each of 15 epochs for fine-tuning stance detection, and 3) in a range of 1e-7 to 1e-5, with 5 trials each of 15 epochs for fine-tuning sentiment analysis. We also setup an early stopping criteria for the downstream task trials, such that we continue the epoch runs till we hit an increase in loss for 3 consecutive runs, and pick the model with the best

---

[6] https://github.com/wwbp/county_tweet_lexical_bank

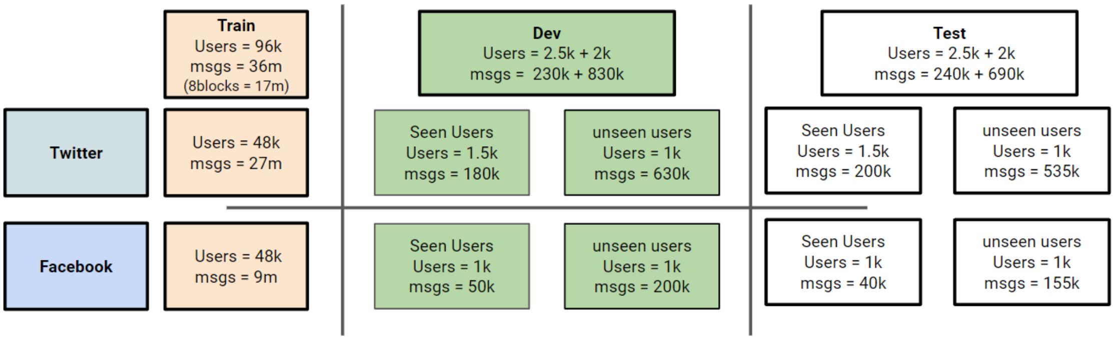

Figure 3: Structure of our pre-training dataset visually showing the data source(FB vs Twt), training/development/testing splits, and seen/unseen users for training and testing. Our dataset totals 100,000 users and approximately 37 million messages. Due to GPU memory restrictions, we limited training to 8 blocks of history which brought our train dataset size to 17 million messages. Dev and Test sets were not limited during evaluation.

F1 score. We couldn't run a similar sweep for user-level tasks due to compute time limits so we try a couple learning rates from document-level tasks but found the same learning rate that we use for pre-training to be better. Many of the experimental/hyperparameters (batch sizes, window sequence sizes and cappings) settings mentioned throughout this work including the number of trials and the number of epochs vary because of computational limitations based on data size and training time.
All pre-training runs are trained on 2 Tesla V100 GPUs of 32GB. Training HaRT takes approx 16 hours for 1 epoch (with train data consisting of 8 blocks (each of 1024 tokens) of 96000 users). Fine-tuning tasks run on a mix of Tesla V100, Quadro RTX 8000, and A100 GPUs based on compute availability. All batch sizes mentioned are per GPU.

Pre-training Settings We use 2.4447e-4 as the learning rate for training HaRT, with 1 user train batch size, 15 users eval batch size and early stopping patience set to 3. For GPT-2_{HLC}, we use the default settings from Wolf et al. (2019) with train and eval batch size set to 60 and early stopping patience set to 3.

Document-level Fine-tuning Settings We fine-tune HaRT for document-level tasks on their respective training data with an input instance capped to 8 blocks of 1024 tokens each, and no capping during evaluation. We train for 15 epochs using train and dev sets - along with history where available - with 1 user train batch size, 20 users eval batch size and early stopping patience set to 6. All models converge within 5 epochs except one stance target - feminism. GPT-2_{HLC} is fine-tuned with the same data - but not history - using the same settings except a different learning rate (from the hyperparameter sweep mentioned above), train and eval batch size of 60, and max tokens per message set to 200 (consistent with pre-training).

User-level Fine-tuning Settings We fine-tune HaRT for user-level tasks with an input instance capped to 4 blocks of 1024 tokens each, and evaluation data capped to 63 blocks (to allow for dev set evaluation due to compute limitations). For fine-tuning HaRT, we use 4 user train batch size and 20 eval batch size with early stopping patience set to 3. We layer norm the user-states (hidden states of the user state vector) from HaRT, and linearly transform (to embedding dimensions) before averaging the user-states to make the user's age estimation. We train for 30 epochs with warmup steps equivalent to 10 epochs, and a weight decay set to 0.01. We find that for the task of Age estimation the model converges at epoch 21, however for Personality Assessment we find a simple classification linear layer to show better performance (with a convergence seen at epoch 28 when run for 35 epochs). In case of GPT-2_{HLC} we with the same data (split into into individual messages capped to 200 tokens per message as in pre-training), for 15 epochs (much higher training time as compared to HaRT) with train and eval batch size set to 400, and early stopping patience set to 3.

Model	*Age* (r)	*OPE* (r_{dis})
HaRT (Full test set)	0.868	0.619
HaRT (Filtered test set)	0.872	0.635

Table 8: HaRT's performance on user level downstream tasks: Age and Openness (OPE), on full test sets (5000 users and 1943 users respectively for Age and OPE) from Park et al. (2015) and Lynn et al. (2020), as well as on the resulting test set (4438 users and 1745 users respectively for Age and OPE) after filtering the dataset for English language with users having a minimum of 50 posts and 1000 words (as we do for our pre-training data).

MeLT – Sentiment Fine-tuning Settings To apply MeLT (Matero et al., 2021) to the sentiment task we use use optuna (Akiba et al., 2019) to search both learning rate and weight decay parameters using a search space between 6e-6 and 3e-3 and between 1 and 1e-4 respectively. We keep the same architecture as described in the original MeLT paper, however we make 1 change during fine-tuning and that is the message-vector representation from MeLT is concatenated with the average of the observed tokens for the labeled message to include both local and global context into the fine-tuning layers.

No Historical Context Fine-tuning Settings We run a hyperparameter sweep using Optuna (Akiba et al., 2019) for all models for learning rate (using search space between 5e-6 to 5e-4) and weight decay(using search space between 0.0 and 1.0) with early stopping patience set to 6. We do this for 15 and 10 trials for Stance and Sentiment models respectively, and pick the hyperparameters value for the best model in the same way as described in the Experimental Settings (A.3 section above. We use these values to fine-tune the models for 15 epochs and get the weighted F1 results.

Inverse is Better! Fast and Accurate Prompt for Few-shot Slot Tagging

Abstract

Prompting methods recently achieve impressive success in few-shot learning. These methods modify input samples with prompt sentence pieces, and decode label tokens to map samples to corresponding labels. However, such a paradigm is very inefficient for the task of slot tagging. Since slot tagging samples are multiple consecutive words in a sentence, the prompting methods have to enumerate all n-grams token spans to find all the possible slots, which greatly slows down the prediction. To tackle this, we introduce an inverse paradigm for prompting. Different from the classic prompts mapping tokens to labels, we reversely predict slot values given slot types. Such inverse prompting only requires a one-turn prediction for each slot type and greatly speeds up the prediction. Besides, we propose a novel Iterative Prediction Strategy, from which the model learns to refine predictions by considering the relations between different slot types. We find, somewhat surprisingly, the proposed method not only predicts faster but also significantly improves the effect (improve over 6.1 F1-scores on 10-shot setting) and achieves new state-of-the-art performance.

1 Introduction

Few-shot learning (FSL) aims at learning a model from only a few examples and is regarded as one of the key steps toward more human-like artificial intelligence (Wang et al., 2020). Recently, prompt-based methods achieve impressive results and show promising prospects for few-shot learning of Natural Language Processing (NLP) (Liu et al., 2021a; Zhao et al., 2021).

Prompt-based methods reformulate a target task into the language modeling problem, which takes advantages of the powerful pretrained Language Models (LM) (Devlin et al., 2019; Liu et al., 2019; Lewis et al., 2020; Brown et al., 2020). For example, when classifying the sentiment of the movie review "*no reason to watch*", prompting methods insert a piece of text "*It was*", i.e. prompts, to the input example, getting "No reason to watch. It was __". It is natural to expect a higher probability from the LM to fill the template with "terrible" than "great", and the original task is then converted to a language modeling task. Such conversion reduces the gap between pretraining and target tasks, which allows less dependency on target task data and helps to achieve better performance in low data scenarios (Gao et al., 2021).

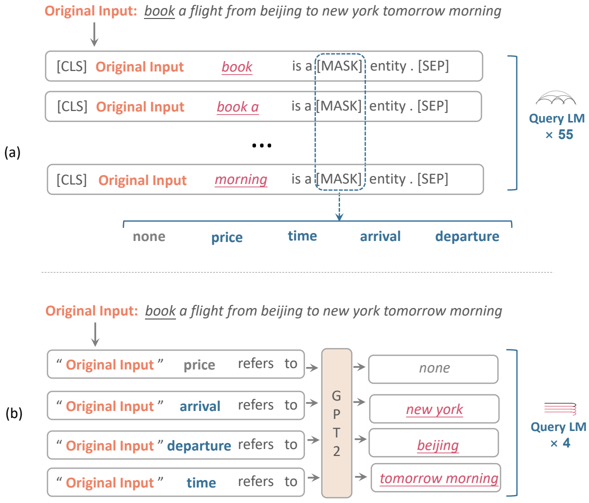

Figure 1: An example of normal (a) and inverse (b) prompting methods for slot tagging. For normal prompts, identifying all slots in the query sentence requires enumeration of all spans, while inverse prompt only needs 1-time prediction for each label.

However, while achieving great success in sentence level tasks, prompting-based methods show incompatibility for sequence labeling tasks, such as slot tagging. Firstly, the aforementioned prompting paradigm is quite inefficient for slot tagging tasks. Different from the sentence-level tasks that classify samples of whole sentences, slot tagging sam-

Findings of the Association for Computational Linguistics: ACL 2022, pages 637 - 647
May 22-27, 2022

ples are multiple consecutive words in a sentence. Therefore, as shown in Fig. 1, to find all the possible slots, prompt-based methods have to enumerate all n-gram word spans, and then query LM for each of them, which greatly slows down the prediction (Cui et al., 2021). Further, as a structure prediction problem, slot tagging benefits from taking the dependencies between labels into account (Ma and Hovy, 2016; Hou et al., 2020). For example in Fig. 1, where the `arrival` entity often appears after a `departure` entity. Such label dependency is hard to be captured by current prompting methods since they predict labels one-by-one independently.

To tackle the above issues, we introduce an inverse paradigm for prompting. Different from the classic prompts mapping tokens to labels, we reversely predict slot values given slot types. For the example in Fig. 1, we use an inverse prompt to modify the input as "*book a flight from Beijing to New York tomorrow morning.* arrival *refers to* __", and then LM is able to decode multi-word span "New York" at a time. Compared to the classic prompts that require predictions for every n-gram word span (55-times in Fig. 1), we only need to perform decoding for V-times, where V is the number of label types (4-times in Fig. 1), which therefore greatly speeds up the prediction. Surprisingly, experiments show the proposed method not only predicts faster but also significantly improves the performance, indicating that prompting LM reversely is a better fit for the slot tagging task. Besides, to further improve the prediction accuracy, we propose a novel Iterative Prediction Strategy, from which the model learns to refine predictions by considering the relations between different slot types.

To summarize the contribution of this work:

(1) We introduce the idea of inverse prediction to prompting methods for slot tagging tasks, which greatly speeds up the prediction process.

(2) We propose an Iterative Prediction Strategy for learning and prediction with slot tagging prompts, which allows the prompting model to consider dependency between different slot types and refine prediction.

(3) We extensively evaluate the proposed method in various few-shot settings, where the proposed method brings significant improvements not only in speed but also in accuracy.

The code and data are available at `https://github.com/AtmaHou/PromptSlotTagging`.

2 Background

In this section, we begin with a formal definition of the few-shot slot tagging task (§2.1), and then introduce the conventional sequence labeling approaches (§2.2) and recent prompts-based methods (§2.3) for this task.

2.1 Few Shot Slot Tagging

Slot tagging aims at finding key slots within a sentence, such as time or location entities. Given an input sentence $\boldsymbol{x} = (x_1, x_2, \dots, x_n)$ as a sequence of words, a slot tagging model extracts all M slot label-values pairs $\boldsymbol{y} = \{(l_i, s_i)\}_{i=1}^{M}$ in the sentence, where l_i is the ith label in the label set L and $s_j^k = \{x_j, ..., x_k\}$ is a word span starting from x_j and ending with x_k.

In few-shot settings, model are often evaluated on multiple low-resource domains $\{D_L^{(1)}, D_L^{(2)}, ...\}$, which is called target domain (Wang et al., 2020). Each target domain $D_L^{(j)}$ only contains a few labeled instances called support set $S = \{(\boldsymbol{x}^{(i)}, \boldsymbol{y}^{(i)})\}_{i=1}^{N_S}$, which usually includes K examples (K-shot) for each of N labels (N-way). On each target domain, given support set examples as references, few-shot slot tagging models are required to make predictions for query set samples. Optionally, some few-shot settings also include a set of data-rich domains $\{D_H^{(1)}, D_H^{(2)}, ...\}$ called source domains, which are used for pretraining of few-shot models.

2.2 Conventional Sequence Labeling Approaches

Conventional approaches often formulate slot tagging as a sequence labeling problem, where each word in input is associated with a sequence label. Given sentence $\boldsymbol{x} = (x_1, x_2, \dots, x_n)$ as input, these method predicts the best-match sequence labels $\boldsymbol{y} = (y_1, y_2, ..., y_n)$. To predict slots with multiple words, sequence labeling approaches adopt a "BIO" labeling strategy, which uses "B" to mark the begin word of a slot, "I" to mark the inner words of a slot and "O" to mark non-slot words. For the example in the Fig. 2, `B-time` is tagged to the first word in a time slot, `I-time` is tagged to a non-begin word within a time slot, and `O` label refers to non-slot words. As shown in Fig. 2(a), few-shot

Figure 2: Illustration of conventional sequence labeling method (a) and classic prompting methods (b).

sequence labeling model is usually formulated as:

$$\begin{gathered}\boldsymbol{h}_{\mathbf{1}:\boldsymbol{n}} = \text{Encoder}(\boldsymbol{x}_{\mathbf{1}:\boldsymbol{n}}),\\ p(\boldsymbol{y}_{\boldsymbol{i}}|\boldsymbol{x}, S) = \text{Softmax}(\text{Decoder}(\text{h}_\text{i})),\\ (i \in [1, 2, ..., n]),\\ \boldsymbol{y}^* = (y_1, y_2, ..., y_n) = \arg\max_{\boldsymbol{y}} p(\boldsymbol{y}|\boldsymbol{x}, S),\end{gathered}$$

where S is a K-shot support set, Encoder is usually a pretrained language model such as BERT (Devlin et al., 2019), $\boldsymbol{h}_{1:n}$ is the hidden state of the encoder with a dimension d_h, and Decoder can either be a linear layer, a CRF layer or any other parametric or non-parametric classifier.

2.3 Sequence Labeling with Prompts

Prompt-based methods have been proven effective in many NLU tasks, especially in few-shot settings, but things become complicated when it comes to slot tagging tasks. To identify the slot label for a word span $s_i^j = \{x_i, ..., x_j\}$ in sentence $\boldsymbol{x}$, previous works construct templates, e.g., *"[x] [s_i^j] is a [z] entity"*, and prompt a pretrained language model with such templates to predict label-related words *[z]* (Cui et al., 2021). For example in the Fig. 2(b), predicting the time slot can be achieved as "*book a flight from Beijing to New York tomorrow morning. tomorrow morning is a* <u>*time*</u> *entity.*" However, to find all possible slots, these methods need to traverse all the n-gram spans $s_i^j, i, j \in [1, n]$ in a sentence, which is quite expensive in time and computation.

3 Method

To remedy the high cost of prompt prediction mentioned in the previous section, we introduce a novel inverse paradigm for prompting of slot tagging task, which significantly improves the speed of prediction by transforming the past fill-in-the-blank problem into a generative task. Specifically, we first introduce the construction of our inverse prompts templates (§3.1), and then describe how to use inverse prompts during training and inference (§3.2). Further, we propose an Iterative Prediction Strategy to refine prediction by considering the relation between different slot types (§3.3). The overview of proposed method is shown in Fig. 3.

3.1 Prompt Creation

In this section, we introduce the creation of the proposed inverse prompts, which includes three main components: the label mapping, the inverse template and the control tokens.

Label Mapping Before prompt construction, we first need to convert each label into a word form that can be easily understood by the pre-trained language model. We employ a label mapping process to achieve this, which use a one-to-one mapping function to convert the label set $L = \{l_1, \ldots, l_{|L|}\}$ to a natural language word set $\hat{L} = \{\hat{l}_1, \ldots, \hat{l}_{|L|}\}$. For example, in Fig. 3, we convert the label set L = {`from.Loc`, `to.Loc`, `Time`, `Price`} to a natural language label set $\hat{L}$ = { `departure`, `arrival`, `time`, `price`}.

Inverse Template Prompt template is a piece of sentence with blanks, which is used to modify the original inputs and get prompting inputs for a pretrained language model. To achieve inverse prompting, our template fills in an original sentence and a label as prefixes and subsequently leaves blanks for the LM to generate the corresponding slot values. Specifically, given an input sentence s and a set of mapped labels $\hat{L}$, for each mapped label $\hat{l}_i \in \hat{L}$, the inverse template is defined as:

"$\boldsymbol{x}$" $\hat{l}_i$ *refers to* __

For instance, in Fig. 3, we fill the input "*book a flight from beijing to new york tomorrow morning*" and each label in $\hat{L}$ into the template to get four prompted inputs $\boldsymbol{p}$:

"*book a flight from beijing to new york tomorrow morning*" ***departure*** *refers to* __

"*book a flight from beijing to new york tomorrow morning*" ***arrival*** *refers to* __

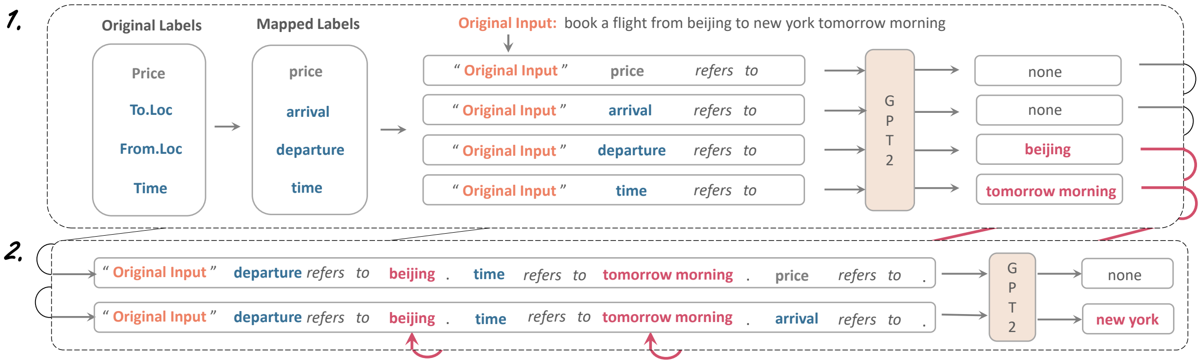

Figure 3: Overview of the proposed method with Inverse Prediction and Iterative Prediction Strategy. We first embed the input sentence with inverse prompts and directly decode slot values given slot types. Then we iteratively refine predictions by reinforcing the prompts with predicted slot-value pairs.

"book a flight from beijing to new york tomorrow morning" ***time*** *refers to* __
"book a flight from beijing to new york tomorrow morning" ***price*** *refers to* __

Control tokens Additionally, we introduce control tokens C to complete the prompts function for the slot tagging task. In order to recognize the case that there's no corresponding entity of the queried slot type, we introduce `<NONE>` token to pad the output, and in practice, we use *"none"* as `<NONE>` token to make the model output more natural. In order to tag more than one entity of the same slot type, we introduce *";"* as `<SEP>` to divide more than one entity of the same slot type. And we also use "." as `<END>` token to indicate the end of a single generation.

3.2 Training and Inference with Inverse Prompts

Till now, we have presented the construction of the inverse prompt. This section will show how to perform training and inference with the prompts.

Training At the training time, we pre-construct the prompt with answers such as *"book a flight from beijing to new york tomorrow morning"* ***departure*** *refers to* ***new york*** . Then we finetune a pre-trained language model with the answered prompts, and we only calculate loss on the answer tokens (i.e. **new york**) instead of the loss on the whole sentence.

$$L = \sum_{i>|\boldsymbol{p}|} \mathrm{CE}(\hat{\mathrm{y}}_{\mathrm{i}}, \mathrm{y}_{\mathrm{i}})$$

where $|\boldsymbol{p}|$ is the length of the prompted input, $\hat{y}_i$ denotes the model predictions, and y_i is the pre-constructed answer.

Inference At the inference time, we feed the prompted inputs into the fine-tuned pre-trained language model and let LM generate the appeared slot values. During generation, we restrict LM to generate only words that appear in the original input sentence or predefined control words. For each prompted input $\boldsymbol{p}$, the next token $\boldsymbol{t}_k \in \boldsymbol{x} \cup C$ is determined by language model probability:

$$\boldsymbol{t}_k = \arg\max_{\boldsymbol{t}_k \in \boldsymbol{s} \cup \boldsymbol{C}} \boldsymbol{p}_{\mathrm{LM}}(\boldsymbol{t}_k | \boldsymbol{p}; \boldsymbol{t}_{1:k-1})$$

Note that restricting the scope of output tokens is crucial to the performance.

3.3 Iterative Prediction Strategy

In the previous section, different slot types are predicted separately. To consider the relations between different slot types, we introduce the Iterative Prediction Strategy, which also provides the model a second chance to revise those unrecognized entities. We assume that different labels are interactive, so the predicted slots could be used as a hint to help predict the missed slots. For example in Fig. 3, it is often easier to generate the "arrival" slot given the results of "departure" and "time". Motivated by this, as shown in the Fig. 3, we construct another template that concatenates those filled prompts as additional generation condition and use them to revise the slot values that are "***none***" in the first round of prediction. Below we describe the details of this strategy during training and testing.

Training At the training time, we simulate the cases where the slots are not recognized to enable the model to revise the ***none*** slot values. We do this by randomly constructing ***none*** slot value examples. For example, at training time, suppose there

are four training prompts filled with true answers:
*"book a flight from beijing to new york tomorrow morning" **departure** refers to **beijing .***
*"book a flight from beijing to new york tomorrow morning" **arrival** refers to **new york .***
*"book a flight from beijing to new york tomorrow morning" **time** refers to **tomorrow morning .***
*"book a flight from beijing to new york tomorrow morning" **price** refers to **none .***
We randomly select some occurred labels (e.g., "arrival") pretending it was not predicted, and construct a second round prompt:
*"book a flight from beijing to new york tomorrow morning" **departure** refers to **beijing . time** refers to **tomorrow morning . price** refers to **none . arrival** refers to __.*
By using these second round prompts for model training, we encourage the language model to find those unrecognized slots in the first round prediction and allow the model to consider relationships between labels.

Inference During the inference time, we construct the second-round prompts and revise the slots that are not recognized in the first round. For example in the Fig. 3, the model predict ***none*** value for "price" and "arrival" slot in the first round. We then construct another iteration of the prompted inputs that query the unrecognized slots, given all the labels and slot values that have been predicted:
*"book a flight from beijing to new york tomorrow morning" **departure** refers to **beijing . time** refers to **tomorrow morning . arrival** refers to __.*
*"book a flight from beijing to new york tomorrow morning" **departure** refers to **beijing . time** refers to **tomorrow morning . price** refers to __ **.***

The model is expected to predict the first-round missed slots during the second iteration, considering relations between labels.

4 Experiment

We evaluate the performance of the proposed method on two classic few-shot scenarios: (1) Setting with Only In-domain data, where all training data are only a few labeled support data. (2) Setting with Meta Source Tasks, where some additional data-rich source domains are available for pretraining.

Evaluation To use same evaluation criteria as conventional sequence labeling methods, we need to label tokens reversely and get output in same format. After generation, we first separate outputs into slot values. For each slot value, we label tokens in the source sentence with three principles: (1) Slot value is complete: only if the whole slot value matches a span in the source sentence, we label it with the corresponding label. (2) Choose the first overlap predicted slot span: if any token in the source sentence has been labeled, we do not relabel this token even when it matches another slot value. (3) Use BIO labels: add "B-" to the beginning token of the slot span, add "I-" to the non-begin token of the slot span, and label non-slot tokens with "O". After labeling tokens reversely, we evaluate F1 scores within each few-shot episode.[1]

4.1 Setting with Only In-domain data

Datasets For few-shot setting without source domain transfer, we conduct experiments on three few-shot datasets with only in-domain data: MIT-Restaurant Review (Liu et al., 2013), MIT-Movie Review (Liu et al., 2013) and MIT-Movie-Hard Review.[2] We conduct experiments with $K \in \{10, 20, 50, 100, 200, 500\}$ shots settings to fully evaluate the performance of our method in all three datasets. To overcome the randomness associated with support set selection, we sample 10 different support set for each K-shot setting and report averaged results. All models are trained and tested with the same data.

Implements Our model employs the smallest GPT2 (Radford et al., 2019) pre-trained model as the base model for fine-tuning, and no new parameters are introduced. Besides, we set the learning rate as $6.25e-5$ and batch size as 2 for few-shot training. For all our experiments, we finetune the model only on few-shot support set for 2 epochs (4 on 10/20 shots settings) with the AdamW optimizer and linear decaying scheduler. Since there is no development set, all hyperparameters are roughly set based on experience without tuning. Data and code used are public available.

Baselines In our experiments, we compare with competitive baselines including both conventional sequence labeling methods and recent prompt-based methods.

---

[1] For each episode, we calculate the F1 score on query samples with `conlleval` script: https://www.clips.uantwerpen.be/conll2000/chunking/conlleval.txt

[2] MIT-Movie Review has two datasets: a simple one and a complex one. We denote the simple one as MIT-Movie and combine both as MIT-Movie-Hard.

Table 1: F1 scores of few-shot slot tagging task on three different datasets.10 indicates 10 instances for each entity type. `+PT` denotes the model is pre-trained on additional datasets. `+Iterative` denotes enhance model with Iterative Prediction Strategy.

• **Sequence Labeling BERT** (Devlin et al., 2019) can be seen as a BERT-based sequence labeling baseline which fine-tunes the BERT model with a token-level linear classifier head.

• **Template-based BART** (Cui et al., 2021) is a prompt-based method that query BART-based LM (Lewis et al., 2020) every possible span in sentence if it belong to a certain category and therefore also need to enumerate all label for inference.

• **NNShot and StructShot** (Yang and Katiyar, 2020) are two metric-based few-shot learning approaches for slot tagging and NER. NNShot is an instance-level nearest neighbor classifier for few-shot prediction, and StructShot promotes NNShot with a Viterbi algorithm during decoding.

• **EntLM** (Ma et al., 2021b) is a prompt-based method that leverage substitution between words of the same type to achieve one pass prediction.

Results Table 1 shows the results of the proposed method only finetuned on few-shot in-domain data. Among these results, we can observe that:

(1) Our proposed method performs consistently better than all the baseline methods on all three datasets. It outperforms the strongest baseline Template-based BART which uses BART-large by average F1 scores on three datasets of 11.96 in 10-shot setting even with a much smaller pre-trained language model (the smallest GPT2).

(2) Our proposed method is even comparable or outperforms those baselines with data-rich domain pre-training.

(3) Our proposed method performs much better than baselines in fewer labeled samples settings, especially in 10 and 20 shot settings, which indicates our method can leverage information from limited labeled data more efficiently.

Model	**5-shot Slot Tagging**

ConVEx*	71.5	**77.6**	**79.0**	84.5	84.0	**73.8**	67.4	**76.8**
Ours	70.44	71.63	78.67	**87.37**	81.38	71.77	74.42	76.53
Ours + Iterative	70.63	**71.97**	**78.73**	87.34	81.95	**72.07**	**74.44**	**76.73**

Table 2: F1 score results on 5-shot Snips. * denotes using additional Reddit data for pretraining. Our methods achieve the best performance among those using same training data.

(4) Our method significantly outperformed Sequence Labeling BERT whose performance is quite poor on 10 and 20 shot settings, which indicates that the number of labeled data is too scarce for conventional sequence labeling tasks, and proves that the prompt-based method is effective in few-shot slot tagging tasks.

(5) The proposed Iterative Prediction Strategy consistently improves the slot tagging performance. The improvements become greater with fewer learning shots and the averaged improvement in 10 and 20 shot setting on three datasets are 2.23 and 1.44. This shows that when there is less data, the iterative revising mechanism is more important.

4.2 Setting with Meta Source Tasks

Datasets We also evaluate the model ability of transferring from data-rich domains to unseen few-shot domains and conduct experiments on SNIPS (Coucke et al., 2018) dataset. Following the data split provided by Hou et al. (2020), we construct 5-shot SNIPS datasets from the original SNIPS datasets. The few-shot SNIPS dataset consists of 7 domains with different label sets: GetWeather (We), Music (Mu), PlayList (Pl), RateBook (Bo), SearchScreenEvent (Se), BookRestaurant (Re), and SearchCreativeWork (Cr). Each domain contains 100 few-shot episodes, and each episode consists of a support set and a query.

Implements Following Henderson and Vulic (2021), we conduct our cross-domain experiments with 5-shot few-shot settings to evaluate the ability of our model to transfer from rich-data domains to unseen few-shot domains. For our proposed method, same as in-domain settings, we use the smallest GPT2 as the base model, and no new parameters are introduced. We pretrain the model in source domains and fine-tune it on the target few-shot domain. We set learning rate as $6.25e-5$ and batch size as 16 for pretraining and batch size as 2 for 5-shot finetuning. During finetuning, we use the same AdamW optimizer and linear decaying scheduler. The hyper-parameters are decided according to performance on the dev set. Data and code used are public available.

Baselines We provided competitive strong baselines, including traditional finetune-based methods and advanced few-shot learning methods.

- **Bi-LSTM** (Schuster and Paliwal, 1997) uses GLoVe (Pennington et al., 2014) embedding for slot tagging and is trained on the support sets.

- **SimBERT** is a metric-based method using cosine similarity of BERT-based embedding to label tokens with the most similar token's label.

- **Matching Network (MN)** (Vinyals et al., 2016) is a few-shot sequence labeling model based on the matching network and uses BERT embedding.

- **TransferBERT** is a domain transfer-based conventional NER model using BERT, which is first pre-trained on source domains and then fine-tuned on the target domain support set.

- **WPZ** (Fritzler et al., 2019) is a metric-based few-shot slot tagging method similar to MN, but is based on the prototypical network (Snell et al., 2017).

- **TapNet+CDT**, **L-TapNet+CDT**, **L-WPZ+CDT** (Hou et al., 2020) are metric-based few-shot learning methods designed for slot tagging, which introduces a CRF-based framework to consider the relation between different slots.

- **ConVEx** (Henderson and Vulic, 2021) is a fine-tuning-based method that models slot tagging as a cloze task and is first pre-trained on Reddit data then fine-tuned on few-shot slot tagging data. Note that the Reddit data is not used by our method and other baselines during the experiments.

Results Table 2 shows the results of the cross-domain few-shot setting, from which we can observe that:

(1) Our proposed method outperforms all the baselines except ConVEx which uses extra Reddit data in the cross-domain 5-shot setting. Despite using less training data, our model still achieves comparable results with Covex, proving its superiority.

(2) We outperform TransferBERT by 42.36 F1 scores which strongly proved that the prompt-based method can transfer more knowledge from the source domain and is more data-efficient than conventional methods.

(3) Our method outperforms metric-based few-shot learning baselines, for example, 2.24 F1 scores higher than L-TapNet+CDT, which proves its competitiveness compared to classical few-shot learning methods.

(4) Our Iterative Prediction Strategy improved Our method by about 0.5 F1 scores, demonstrating that the revising ability is likely to be transferable and is effective under cross-domain scenarios.

4.3 Analysis

Effects of Iterative Prediction Strategy As shown in Table 1, the proposed Iterative Prediction Learning brings consistent improvement, especially in low-resource settings. It works by revising predictions with a second-round query to recognize those missing slots, which can bring an increase in recall score. To confirm that, we make a detailed analysis with precision score (P), recall score (R) and F1 score (F) in Table 3.

When Iterative Revise Strategy is added, we can get a rise in recall score about 4 points in 10-shot, 2~4 points in 20 shot and more than 1 points in other shot settings in exchange for a slight precision drop, resulting in a rise in overall F1 score by about 2 points in 10 and 20 shots.

	Model	MIT-Restaurant			MIT-Movie		
		P	R	F	P	R	F
10	Ours	67.7	**42.4**	**52.1**	84.0	**46.4**	**59.7**
	w/o Iter	69.4	38.3	49.4	85.9	42.7	57.0
	w/o Joint	68.8	38.9	49.7	85.6	43.0	57.2
20	Ours	70.1	**54.7**	**61.5**	83.5	**60.4**	**70.1**
	w/o Iter	71.6	52.3	60.5	86.3	55.9	67.9
	w/o Joint	70.92	53.45	61.0	85.6	56.9	68.3
50	Ours	73.6	**61.2**	**66.8**	83.6	**72.4**	**77.6**
	w/o Iter	75.4	57.6	65.3	85.9	69.5	76.8
	w/o Joint	74.3	59.2	65.7	84.7	70.8	77.1
100	Ours	76.1	**66.5**	**71.0**	84.4	**77.2**	**80.6**
	w/o Iter	78.0	64.2	70.4	86.3	75.0	80.3
	w/o Joint	76.7	66.0	71.0	85.0	76.5	80.5
200	Ours	77.8	**70.5**	**74.0**	85.4	**80.0**	**82.6**
	w/o Iter	79.5	68.7	73.7	87.1	78.2	82.4
	w/o Joint	78.0	70.1	73.8	85.1	79.9	82.4
500	Ours	79.4	**73.5**	**76.4**	86.3	**82.8**	84.5
	w/o Iter	81.0	71.8	76.1	87.9	81.4	**84.6**
	w/o Joint	79.6	73.4	76.4	86.6	82.1	84.3

Table 3: Ablation analysis Iterative Prediction Strategy **w/o Iter** denotes removing iterative strategy and **w/o joint** denotes using two separate models for the two iterative steps.

We further explore the effect of jointly learning of the first-round prediction and the second-round revising, and learn two abilities separately with two models. As shown in Table 3, w/o Joint model outperforms the no-revising model but lags behind the joint model. This indicates that joint learning the revising ability may act as data augmentation and brings more improvements than simple revising.

Efficiency Study Unlike Template-based BART that queries every n-gram span in the source sentence for each label (with $O(n^2 * m)$ where n is the length of the source sentence and m is the size of the label set) time complexity, our proposed method queries labels in the label set and directly generate slot values (with $O(n * m)$ time complexity). In theory, our method is much faster than Template-based BART, especially dealing with long sentences with sparse slots. To prove this, we conduct efficiency experiments by calculating the decoding time of each method on a Titan XP GPU with batch size as 8, and we set our max generation length at 40. As shown in Table 4, our method is about 8 times as fast as the Template-based BART method, and more than 3 times as fast as theirs with Iterative Prediction Strategy. During experiments, we find that as the number of labels increases, the model does become linearly slower, which may become limitations. However, the number of label types is usually smaller than the sentence length

Model	MIT-Movie	MIT-Restaurant
Baseline (Normal Prompt)	408.0	236.0
Ours	51.2	33.2
Ours + Iterative	119.4	71.4

Table 4: Comparison of the decoding time (second).

and much smaller than the number of spans, so that this growth does not affect the value of our method in practice. Besides, we find no significant correlation between the number of labels and our performance.

5 Related Work

Prompt-based learning Prompt-based learning approaches have been a broadly discussed topic since large language models like GPT models (Brown et al., 2020) are hard to fine-tune in low-resource scenarios. Early attempts (Schick and Schütze, 2021a,b) introduce manual prompts to text classification tasks. For natural language understanding (NLU) tasks, automatically searching discrete prompts methods are proposed such as Jiang et al. (2020); Shin et al. (2020); Gao et al. (2021). Meanwhile, due to the continuity of parameters in neural networks, continuous prompts for both text classification and generation tasks (Li and Liang, 2021; Liu et al., 2021b; Han et al., 2021) have been proposed. Unlike sentence-level tasks, prompting methods are very complicated for slot tagging and NER tasks. Cui et al. (2021) proposes a template-based method querying every slot span with each label which is expensive for decoding. Different from them, we introduce an inverse paradigm for prompting slot tagging tasks. Note that inverse prompting (Zou et al., 2021) has a similar name to our work but is entirely different in method and task. They aim to generate prompt templates inversely. Amendable generation (Tian et al., 2021) share a similar idea of using Iterative Prediction Strategy to generate and revise dialog state. By contrast, we focus on a different task for sequence labeling and first introduce an Iterative Prediction Strategy to prompting models. There are also generation-based methods for sequence labeling (Yan et al., 2021), which is not a prompting method, since it re-initializes decoding layers and learns a generative model from scratch.

Few-shot slot tagging Previous few-shot slot tagging methods focus on metric learning based methods, which classify tokens by word-label similarity (Snell et al., 2017; Vinyals et al., 2016). Hou et al. (2020) leverage label name semantics to get better label representation and model label dependency in few-shot settings. Yang and Katiyar (2020) make a prediction based on the nearest neighbor sample instead of the nearest label representation. Besides, some works also explore training a model with additional data from non-slot-tagging task (Huang et al., 2020; Henderson and Vulic, 2021). Hou et al. (2021) improves few-shot slot tagging performance by jointly learning it with intent detection. Different from directly learning the few-shot slot tagging model, some researches explore to reformulate the slot tagging into other NLP tasks. Ma et al. (2021a) reforms slot tagging into a reading comprehension task. Yu et al. (2021) treats slot tagging as a retrieval task, Coope et al. (2020) uses span extracting task to extract slot and predict corresponding label and Cui et al. (2021) leverages prompts for few-shot NER. Different from those methods above, we are the first to reformulate the slot tagging task into a prompt-based generation task.

6 Conclusion

In this paper, to liberate the prompting methods from the burdensome prediction of slot-tagging tasks, we introduce a novel inverse prediction manner to prompting methods of slot-tagging, which significantly improves both the efficiency and accuracy. To further improve performance, we propose an Iterative Prediction Strategy for learning, which enables the prompting model to consider dependency between labels and refine prediction. Extensive experiments verify the effectiveness of the proposed method in various few-shot settings, indicating inverse prediction is a better fit for prompting of slot tagging task.

Abstract

Decoding language from non-invasive brain activity has attracted increasing attention from both researchers in neuroscience and natural language processing. Due to the noisy nature of brain recordings, existing work has simplified brain-to-word decoding as a binary classification task which is to discriminate a brain signal between its corresponding word and a wrong one. This pairwise classification task, however, cannot promote the development of practical neural decoders for two reasons. First, it has to enumerate all pairwise combinations in the test set, so it is inefficient to predict a word in a large vocabulary. Second, a perfect pairwise decoder cannot guarantee the performance on direct classification. To overcome these and go a step further to a realistic neural decoder, we propose a novel Cross-Modal Cloze (CMC) task which is to predict the target word encoded in the neural image with a context as prompt. Furthermore, to address this task, we propose a general approach that leverages the pre-trained language model to predict the target word. To validate our method, we perform experiments on more than 20 participants from two brain imaging datasets. Our method achieves 28.91% top-1 accuracy and 54.19% top-5 accuracy on average across all participants, significantly outperforming several baselines. This result indicates that our model can serve as a state-of-the-art baseline for the CMC task. More importantly, it demonstrates that it is feasible to decode a certain word within a large vocabulary from its neural brain activity.

1 Introduction

Neural decoding, i.e., using brain activity to make predictions of stimuli or mental states, is a challenging cross-discipline research area. It is crucial for developing brain-computer interfaces (BCIs) that allow people to communicate using brain signals instead of verbal or body language (Wolpaw et al., 2002; Haynes and Rees, 2006). With the development of brain imaging technology and computational models, two lines of work emerge. One is invasive decoding, which depends on invasive brain recording methods such as electrocorticography (ECoG). In recent years, several breakthroughs have been made in this field and demonstrated the feasibility to decode speech (Anumanchipalli et al., 2019; Makin et al., 2020; Moses et al., 2021) or handwriting (Willett et al., 2021) from neural activity at high accuracy and speed. Despite the impressive performance, invasive decoding is unlikely to be used except in rare medical situations since it needs invasive surgery on the brain.

In contrast, non-invasive decoding uses atraumatic neuroimaging technologies such as functional magnetic resonance imaging (fMRI) to collect brain signals, having wider applicable groups and applications prospects. However, progress in this field is relatively slow after the pioneering work of Mitchell et al. (2008) that shows the feasibility to discriminate an fMRI image between two words. For a decade, this pairwise classification task (shown in Table 1) has been used as default on non-invasive brain-to-word decoding (Palatucci et al., 2009; Pereira et al., 2013; Anderson et al., 2017; Pereira et al., 2018; Wang et al., 2020). Nevertheless, it is quite limited to developing practical neural decoders. On the one hand, to predict a word, it has to enumerate all pairwise combinations in the test set and thus is inefficient. On the other hand, a decoder with high pairwise accuracy can fail to capture the similarity structure of the gold semantic space (Minnema and Herbelot, 2019). And hence it may not perform well on classifying fMRI images into vocabulary words, which is the ultimate goal of brain-to-word decoding.

Recently, Affolter et al. (2020) argues that we should move on to a more difficult but direct classification task rather than staying on the simple pairwise classification. In their work, they experi-

ment on direct classification (shown in Table 1) and demonstrate the feasibility of multi-class classification using fMRI data to a certain extent. However, their direct classifier cannot predict words that do not appear in the training set, so it cannot perform zero-shot learning (ZSL). ZSL is essential for a practical neural decoder because it is impossible to collect brain images for every word in the vocabulary used daily. In addition, they ignore the context of word stimuli, which is ready-to-use and can serve as a prompt for brain-to-word decoding.

To overcome these and facilitate the development of pragmatic neural decoders, we propose a new brain-to-word decoding task called **C**ross-**M**odal **C**loze (CMC) task. As illustrated in Table 1, the CMC task is to classify a brain image with a context into a word from a large vocabulary. Intuitively, the given context should provide extra information for predicting words by narrowing down possible candidates. In addition, introducing contexts into brain-to-word decoding may bring some inspirations for brain-to-text decoding word by word.

Furthermore, to address this task, we propose a general approach that leverages the pre-trained language model BERT (Devlin et al., 2019) to predict the target words. The challenge lies in how to extract useful features carried by brain signals that can be integrated into BERT to facilitate prediction. We handle this problem by combining regression and representational similarity analysis (RSA) (Kriegeskorte et al., 2008) to transform fMRI data to feature vectors in a specific semantic space of BERT.

In this paper, we focus on non-invasive single-subject zero-shot brain-to-word decoding. Our main contributions can be summarized as follows:

- We propose a more challenging but practical **C**ross-**M**odal **C**loze (CMC) task for brain-to-word decoding, which is a departure from the naive pairwise classification task. Hopefully this task could serve as a bridge from decoding individual words to decoding continuous sentences, paving the way to build a practical neural language decoder.
- We propose a general approach to address the CMC task. In particular, we propose Representational Similarity Retrieval (RSR) method to extract feature vectors from fMRI images, which can also be used for direct classification.
- We perform extensive experiments on 24 participants from two fMRI datasets collected on English word stimuli. Experimental results show the effectiveness of our method, indicating that our method can serve as a strong baseline for the CMC task.

2 Related Work

2.1 Neural Decoding Tasks

In this paper, we focus on non-invasive decoding methods, especially fMRI, which provides the best spatial resolution among all non-invasive neuroimaging techniques. This line of research starts from Mitchell et al. (2008), who for the first time show that it is feasible to decode words from fMRI data by leveraging the semantic representations of words and learning a cross-modal mapping between fMRI images and word vectors. They adopt pairwise classification task to evaluate the learned neural decoders, which is a binary classification task that discriminates which one in two stimuli corresponds to the fMRI image. Since then, pairwise classification is widely used by researchers in non-invasive neural decoding to decode words (Palatucci et al., 2009; Pereira et al., 2011; Chang et al., 2011; Pereira et al., 2013; Anderson et al., 2017; Pereira et al., 2018; Wang et al., 2020) as well as sentences (Pereira et al., 2018; Sun et al., 2019; Sun et al., 2020). Recently, there are some voices in the BCI community arguing that pairwise classification is quite limited and more challenging but direct tasks need to be set up to push current neural decoding to a higher level (Affolter et al., 2020; Zou et al., 2021). They directly classify an fMRI image into vocabulary words. In contrast to pairwise classification, direct classification is a much harder task since the decoder needs to predict the correct words in a much larger space. In this paper, we propose to address the CMC task, a multi-class classification task with brain image and context as input.

2.2 Neural Decoding Methods

Regression-based Decoding Regression-based decoding is a prevalent approach to address the pairwise classification task and it is designed with the goal to perform ZSL. It first leverages a word embedding model to represent the word stimuli and then learns a regression model from fMRI images to each semantic dimension of the word vectors (Palatucci et al., 2009; Pereira et al., 2018; Wang et al., 2020). The learned models can predict word vectors for new brain images, which are used for pairwise matching.

Similarity-based Decoding Based on RSA, Anderson et al. (2016) have proposed a similarity-based decoding method to address pairwise classification. The basic idea is to re-represent the neural activity in neural similarity space and the word vectors in semantic similarity space. Then the two similarity spaces are used for pairwise matching. It is a non-parametric method that does not require model training. However, how to construct similarity space for direct classification is non-trivial.

Deep Learning based Decoding To address direct classification, Affolter et al. (2020) train an end-to-end deep learning model, taking fMRI images directly as input without dimension reduction. Their model can output a predicted probability for each word in a small vocabulary. However, their model is designed specifically for the fMRI dataset from (Pereira et al., 2018). And extending it to other datasets is not easy. Besides, it needs more data for training compared to statistical models.

2.3 Pre-trained Language Model

The CMC task can be viewed as a combination of a direct classification task and a Cloze task. In natural language processing, Cloze task has been well addressed by BERT (Devlin et al., 2019), a pre-trained masked language model that randomly masks some of the words from the input and then predicts the masked word based on its context during pre-training. This pre-training strategy makes it especially appropriate for the Cloze task. We can use BERT to predict a word using only the context as input and this can serve as a weak baseline for the CMC task.

3 Task

First of all, we specify some notations and formalize the data set for our Cross-Modal Cloze (CMC) task for clarity. Let $\mathcal{D}^S_{train} = \{(\{x^S_i, c^t_i\}, y_i)|t = 1, \cdots, T_i, i = 1, \cdots, M\}$ be the training set for subject S, where x^S_i denotes a brain image evoked by word y_i from S, c^t_i denotes a context related to word y_i, T_i denotes the number of contexts for word y_i, and $y_1, \cdots, y_M$ denote M distinct words. For each word, we have only one brain image for each subject. Similarly, we define $\mathcal{D}^S_{test} = \{(\{x^S_i, c^t_i\}, y_i)|t = 1, \cdots, T_i, i = 1, \cdots, N\}$ be the test set, where y_i denotes a word that is not in the training set.

Now, we give the definition of our CMC task. Given a brain image x^S_i and a context c_i related to word y_i, the goal of CMC task is to predict y_i from a given vocabulary $\mathcal{V}$.

There are two major differences between our CMC task and the other two brain-to-word decoding tasks. The first one is that the CMC task takes a context as input in addition to an fMRI image. Notice that communication generally happens under a certain context. With the context as the background, it is relatively easier to guess what other people think since possible candidates usually fall in a much smaller space constrained by the context. Contexts are very useful and easily accessible information and it would be beneficial to use them in neural decoding. The second difference is the size of the target space. The decoding space in the CMC task is the vocabulary from a corpus instead of just the word stimuli as in the direct classification, let alone the pairwise classification.

Evaluation Metric For an input sample $\{x^S_i, c^t_i\}$ in $\mathcal{D}^S_{test}$, if the top-k predictions contain y_i or its synonyms, then the classification is deemed correct. Let n' denote the number of correct top-k classifications, top-k accuracy is computed using the following equation:

$$\text{Top-k acc} = \frac{n'}{T_1 + \cdots + T_N} \quad (1)$$

Meanwhile, the predicted probability of the target word y_i (and its synonyms) can be used as an auxiliary metric. It is obtained through the following equation:

$$\text{Prob} = \frac{\sum_{i=1}^{i=N} \sum_{t=1}^{t=T_i} P(y_i | c_i^t, x_i^S)}{T_1 + \cdots + T_N} \quad (2)$$

4 Method

To address the CMC task, we propose a general two-step approach: 1) extract semantic features from fMRI images by cross-modal retrieval, and 2) fuse the semantic features into BERT to perform the Cloze task. The fMRI image in a masked sentence is like a "switched" code, and the intuition of our method is to decode the code by utilizing the codes in natural language.

4.1 Step 1: Feature Extraction

The goal of Step 1 is to extract semantic features from the fMRI images that can be directly fused into the hidden states in the embedding layer of BERT [1]. To this end, the intuitive way would be directly learning a cross-modal mapping from fMRI images to their word embedding extracted from the embedding matrix in the embedding layer of BERT (BERT embedding for short). However, by investigating the 5 nearest neighbours (NN) of each word in fMRI180 using BERT embedding, we find that BERT embedding does not capture semantics well compared to other widely used word embedding such as GloVe (Pennington et al., 2014) or the contextualized word embedding derived from deeper layers of BERT. And it suffers from a more severe "hubness" problem (Radovanovic et al., 2010), a problem that the same point tends to be nearest neighbors of many points in high-dimensional spaces. To overcome this, we introduce an intermediate word embedding and design a retrieval-based method. The basic idea is to use the intermediate word embedding to perform cross-modal mapping and then transform the predictions into the BERT embedding space by retrieval.

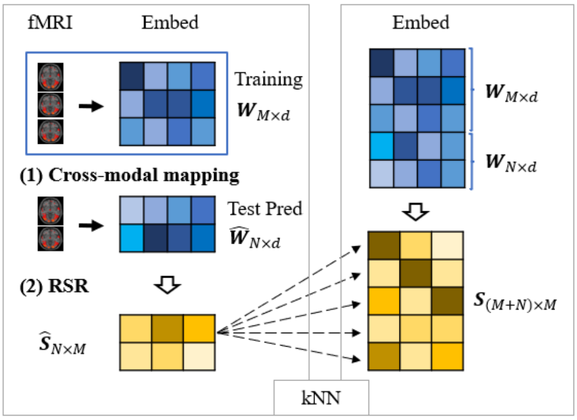

Figure 1: Feature extraction method, including two main steps: (1) Cross-modal mapping; and (2) Representational similarity retrieval (RSR). "Embed" represents the intermediate word embedding, such as GloVe, and it is different from BERT embedding.

Cross-Modal Mapping Let $W'_{M\times d'}$ be the BERT embedding of words in $\mathcal{D}^S_{train}$ ($\mathcal{D}_{train}$ for simplicity) where d' denotes the dimension of the BERT embedding. Similarly, we have $W'_{N\times d'}$ for words in $\mathcal{D}_{test}$. Let $\boldsymbol{W}$ denote the intermediate word embedding and d denote its dimension. As shown in Figure 1, we first use $\boldsymbol{W}$ in cross-modal mapping and train a linear regression model f_j to map x_i to $\boldsymbol{w}_{ij}$ $(i = 1, \cdots, M)$ for each semantic dimension j $(j = 1, \cdots, d)$ on the training set. Each regression model has $v + 1$ trainable parameters, where v denotes the number of selected voxels of fMRI images. And each model is trained independently. After the training, we use the mapping to obtain the predictions $\hat{\boldsymbol{W}}_{N\times d}$ for fMRI images in the test set $\mathcal{D}_{test}$.

Representational Similarity Retrieval Now the goal is to retrieve k NN words in the vocabulary for each predicted intermediate word vector of fMRI images. To this end, we construct a similarity space based on the M ground-truth intermediate word vectors in the training set. As shown in Figure 1, similarity[2] between the predicted embedding $\hat{\boldsymbol{w}}_i (i = 1, \cdots, N)$ and all M words in the training set are computed, resulting in an M-dimensional vector $\hat{\boldsymbol{s}}_i$ in the similarity space. Similarly, similarity between the ground-truth word embedding $\boldsymbol{w}_i (i = 1, \cdots, M + N)$ and all M words in the training set are computed, giving an M-dimensional vector $\boldsymbol{s}_i$ in the similarity space.

---

[1] We choose the embedding layer of BERT as a proof of concept and other layers are similar.

[2] We use Pearson correlation coefficient as the default similarity function in this work unless otherwise specified.

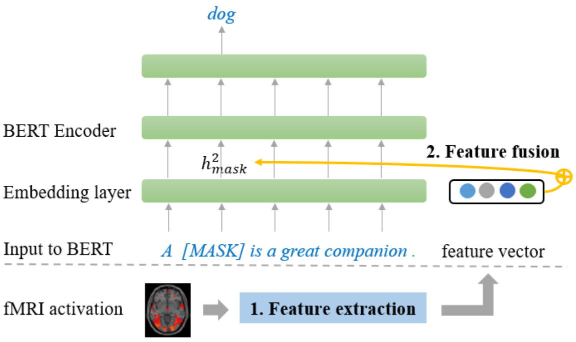

Figure 2: Feature fusion method. The pre-trained language model BERT is used to predict target words.

Based on these new representations, we retrieve k NN words in vocabulary $\mathcal{V}$ for each fMRI test sample x_i. For x_i, its k NN word indices are obtained through the following equation:

$$j_1, \cdots, j_k = \text{topk}(\{\text{sim}(\hat{\boldsymbol{s}}_i, \boldsymbol{s}_j) | j = 1, \cdots, |\mathcal{V}|\}) \quad (3)$$

where $\text{sim}(.,.)$ represents a similarity function, and $j_1, \cdots, j_k$ denote the indices of the top-k similar vectors in $\boldsymbol{S}_{(M+N)\times M}$. Then the feature vector $\boldsymbol{f}_i$ for fMRI test sample x_i is computed as follows:

$$\boldsymbol{f}_i = \frac{1}{k} \sum_{t=1}^{k} \boldsymbol{w}'_{j_t} \quad (4)$$

where $i = 1, \cdots, N$ and $\boldsymbol{w}'$ denotes BERT embedding.

4.2 Step 2: Feature Fusion

The goal of Step 2 is to integrate the feature vector $\boldsymbol{f}_i$ extracted from fMRI image x_i into BERT for better word prediction. Intuitively, if the feature vector $\boldsymbol{f}_i$ carries useful information of the target word y_i, then fusing it into the model should improve the performance in predicting y_i than merely using context c_i as input.

To be specific, let $\boldsymbol{h}^i_{mask}$ denote the hidden states of the `[MASK]` token in c_i, we directly update $\boldsymbol{h}^i_{mask}$ using the following equation:

$$\boldsymbol{h}^i_{mask} := (1-\alpha)\boldsymbol{h}^i_{mask} + \alpha \boldsymbol{f}_i \quad (5)$$

where $\alpha \in [0, 1]$ is a tuning parameter that controls how much information to fuse in. The feature fusion method is shown in Figure 2. It only operates at the embedding layer of BERT and does not require fine-tuning the pre-trained model, which is quite straightforward.

In general, our two-step approach for the CMC task contains one trainable cross-modal transformation matrix (size $(v + 1) \times d$) and two main hyperparameters k and α. This pipeline approach is designed for small datasets considering that the sample size of a brain imaging dataset is often very small. And it is a general method that can be applied to any fMRI dataset.

5 Datasets

5.1 Brain Imaging Datasets

According to our knowledge, there are two open-source fMRI datasets collected from subjects exposed to English word stimuli and concentrated on thinking about the meaning of words. The first one is from (Mitchell et al., 2008), which contains 60 word stimuli. And the second one is from (Pereira et al., 2018), which consists of 180 word stimuli. For clarity, we denote them as fMRI60 and fMRI180 respectively.

fMRI60[3] fMRI60 contains the neural activity collected from 9 human participants while viewing 60 different concrete nouns. Some examples include: *carrot*, *dog*, *hammer*, *igloo*, *skirt*. During the brain recording process, each participant was shown a word and a small line drawing of the concrete object the word represents. The participants were asked to think about the properties of these objects. For each word, six fMRI scans with roughly 20,000 voxels are available. To reduce noise, we average the six scans to create a single fMRI image for each of the 60 words and each participant. The statistics of fMRI60 are shown in Table 2.

fMRI180[4] fMRI180 contains the neural activity observed from 15 human participants while viewing 180 content words. Some examples include: *ability*, *big*, *damage*, *experiment*, *seafood*. During the fMRI scanning process, each participant was shown a word presented in a sentence with itself in bold to highlight the relevant meaning. They were asked to think about the meaning of the target word in the context. There are two other paradigms as well, one uses pictures instead of sentences, and the other uses word clouds instead of sentences. For each word in each paradigm, 4-6 fMRI scans were taken with context varying and then were combined into a single fMRI image by using a general linear model. The data available online is one fMRI

	Subject	Voxel	fMRI	Word	Sent	Syon
fMRI60	9	∼20,000	60	60	360	0.28
fMRI180	15	∼200,000	180	180	1080	0.29

Table 2: Statistics about the fMRI datasets. “Voxel” refers to the number of voxels (similar to pixels in a 2-dimensional image) containing in a 3-dimensional fMRI image. “Syon” denotes the average number of synonyms for the word stimuli.

fMRI60_CMC:	
carrot	the [MASK] is his favorite vegetable.
hammer	she puts the [MASK] down on the ground.

fMRI180_CMC:	
ability	he has the [MASK] to cultivate creativity.
damage	the accident left some serious [MASK].

Table 3: Context examples for word stimuli in the CMC datasets.

image per word per paradigm. To further reduce noise, we average the data across three paradigms to generate a single fMRI image for each of the 180 words, for each participant. The statistics of fMRI180 are shown in Table 2.

5.2 CMC Datasets

fMRI60_CMC For each of 60 words in fMRI60, we create 6 sentences, 4-13 words long (mean = 6.68, std = 1.57), and each containing the target word used in the intended sense. To create contexts for the CMC task, we remove the target word in its corresponding sentences by using a `[MASK]` token to replace it. Two context examples are shown at the top of Table 3. Furthermore, to create synonyms for the word stimuli, we first use WordNet (Miller, 1995) to find possible candidates and then manually proofread all the words to make sure they have the same meaning as the word stimuli. We obtain 0.28 synonyms per stimulus on average. Combining the brain imaging data, the contexts and the target words into the form we describe in Section 3, a dataset fMRI60_CMC is generated for the CMC task. It is publicly available at `https://github.com/LittletreeZou/Cross-Modal-Cloze-Task`.

fMRI180_CMC For words in fMRI180, we use the sentences in the presentation scripts in Pereira et al. (2018)’s experiment. These sentences are 4–11 words long (mean = 6.85, std = 1.22) and also contain the target words used in the intended meaning. Similarly, we create contexts and collect synonyms for each word stimulus (0.29 synonyms per stimulus on average). Then a dataset fMRI180_CMC for the CMC task is generated. Two context examples of fMRI180_CMC are shown at the bottom of Table 3.

6 Experiments

6.1 Experimental Settings

Voxel Selection As shown in Table 2, fMRI data is very high-dimensional, containing up to 200,000 voxels, while the sample size is very small. To avoid overfitting and reduce the computational complexity in cross-modal mapping, voxel selection is often performed to reduce the dimensions. Following the method proposed by (Pereira et al., 2018), we select the most informative 5,000 voxels for each subject in each fMRI dataset. Then we obtain a 5000-dimensional vector for each fMRI image. We use these fMRI vectors in the following experiments and still use the term “fMRI image” to refer to them.

Data Partition Since the CMC datasets are quite small, we split each dataset into 10 folds by word stimuli to allow cross-validation. For each fold, 8 folds are used for training, 1 fold is used for validation and 1 fold is used for test. The data partition is the same across subjects, with the same word stimuli in the same fold.

Models For the CMC task, we use BERT[5] without fine-tuning. In the cross-modal mapping, we use the most commonly used ridge regression in neural decoding literature as default. It is a linear regression model with L_2 regularization, which can regulate overfitting since we have 5,000 input features. The regularized hyperparameter is automatically optimized based on Pearson correlation coefficient of the predicted values and the true values on the validation data. And we experiment on three types of word embedding, including BERT embedding, GloVe[6] and contextualized embedding BERT LayerAvg[7]. Our best model uses BERT LayerAvg. The hyperparameter k is tuned to 5, and α is tuned to 0.7 based on the top-5 accuracy on the validation set.

Table 4: Performance on the CMC task. "BERT-Retri Fusion (random)" is a random version of "BERT-Retri Fusion" where feature vectors are randomly shuffled and do not match the contexts. The results are first averaged among 10-fold cross-validation data and then averaged across subjects. The best results are shown in bold.

(%)	Min	Max	Mean	SigFrac
fMRI60_CMC	48.61 +3.06	61.39 +15.83	55.99 +10.43	8/9
fMRI180_CMC	51.30 +0.37	55.19 +4.26	53.11 +2.19	11/15

Table 5: Statistical analysis of performance on subjects. Top-5 accuracy of "BERT-Retri Fusion" and the absolute improvement over BERT are reported in this table. "Min", "Max" and "Mean" denote the worst, best and average results on all subjects respectively. "SigFrac" denotes the fraction of participants with significant improvement over BERT.

6.2 Main Results

As shown in Table 4, the first three rows are three weak baselines for the CMC task. BERT achieves quite good results on both datasets, demonstrating the power of pre-trained models on Cloze task. Our method – BERT-Retri Fusion – achieves the best results on this task. On fMRI60_CMC, it achieves 31.08% top-1 accuracy and 55.99% top-5 accuracy on average across 9 subjects, outperforming BERT by absolute improvement of +3.58% and +10.43% respectively. On fMRI180_CMC, it achieves 27.60% top-1 accuracy and 53.11% top-5 accuracy on average across 15 subjects, outperforming BERT by absolute improvement of +1.59% and +2.19% respectively. Furthermore, the predicted probability of the target words in our method increases by 4.04% and 1.86% on the two datasets respectively, indicating our model is more confident about the correct answer. These results indicate three things: 1) The feature vectors derived from the fMRI data are informative and can be utilized by BERT to better predict the target word; 2) Our method is effective and can serve as a strong baseline for the CMC task; 3) It is feasible to decode an fMRI image with context as prompt into a word from a large vocabulary.

Moreover, when comparing the performance of BERT, BERT-Direct Fusion and BERT-Retri Fusion, the fusion of feature vectors does not necessarily result in significant improvement unless the feature vectors are good enough. When comparing the performance of BERT, BERT-Retri Fusion and its random version, fusing the mismatched feature vectors from other fMRI images into BERT decreases the performance a little bit while fusing the correct one increases the performance by a significant margin. This result indicates that the feature vectors derived from fMRI data by our method carry a certain amount of semantic information about the target words.

Finally, we investigate the performance of our method on different subjects. For each subject, we perform a significance test on the top-5 accuracy to see whether our method is significantly better than BERT. The data points are the 10-fold top-5 accuracy of our model and BERT. The statistical test we used is paired t-test with significance level 0.1 and FDR controlled for multiple comparisons (Benjamini and Hochberg, 1995). As shown in Table 5, on both datasets, all results of our method are better than BERT and most of them are statistically significant.

7 Analysis

Ablation Study The feature extraction step is a key step in our method. In this step, we use retrieval-based method. Hence the direct classification accuracy can also be used to evaluate the quality of feature vectors. We perform ablation experiments to understand the relative importance of each facet of our method. As shown in Table 6, using non-parametric RSR to match fMRI images and word vectors is better than using regression. And combining the two methods achieves the best

"REG-RSR" denotes our method. The results are first averaged among 10-fold cross-validation data and then averaged across subjects. The best results are shown in bold.

result, indicating that both regression and RSR are important for extracting fMRI semantic features.

Effect of Word Embedding In theory, our method can work with any type of word embedding. We perform experiments on two major types of word embedding, one is non-contextualized GloVe and the other is contextualized BERT Layeravg. As shown in Table 7, the performance on the CMC task using the two different types of word vectors are quite similar on both datasets. In contrast to previous work done on pairwise classification which focuses on finding better representations of words, the CMC task is not so sensitive to the types of word embedding.

(%)	Embedding	Top-1 acc	Top-5 acc
fMRI60_CMC	GloVe	29.85	54.88
	BERT Layeravg	31.08	55.99
fMRI180_CMC	GloVe	27.81	52.96
	BERT Layeravg	27.60	53.11

Table 7: Effect of word embedding used in our method for the CMC task. The results are first averaged among 10-fold cross-validation data and then averaged across subjects.

Effect of α The hyperparameter α controls how much information from fMRI to fuse into BERT. As shown in Figure 3, as α increases from 0 to 0.7 gradually, the performance of the model steadily increases and reaches the maximum performance when $\alpha = 0.7$ on both datasets. This tendency demonstrates that the fusion of fMRI information is helpful for predicting words. However, when α becomes too large, the performance will drop quickly. We speculate that this is because the BERT embedding of the mask token is useful for predicting words, since that is how BERT was pre-trained.

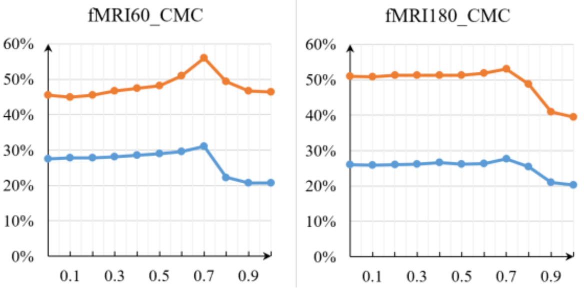

Figure 3: Effect of α. The blue line denotes top-1 accuracy while the orange one represents top-5 accuracy. k is set to 5 for all subjects.

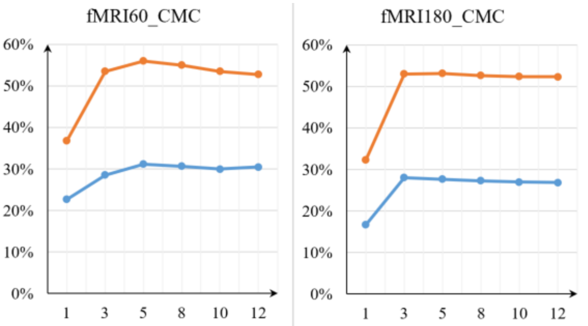

Figure 4: Effect of k. The blue line denotes top-1 accuracy while the orange one represents top-5 accuracy. α is set to 0.7 for all subjects.

Effect of k The hyperparameter k controls how many neighbors we want to engage with to derive the feature vector for an fMRI image. Intuitively, if we retrieve more words for an fMRI image, we have a larger probability to recall the target word. However, a larger k will diminish the utility of the feature vector since it is the average of word vectors corresponding to the k retrieved words. As shown in Figure 4, increasing k from 1 to 3 gives a large gain in decoding accuracy on both datasets. When $k > 5$, the decoding accuracy declines slowly. Generally, $k = 5$ is the best tradeoff between the probability of recalling the target word and the informativeness of the feature vector.

Limitations Our experiments are largely limited by three characteristics of fMRI signals, which are low temporal resolution with delayed hemodynamic response, noisy, 3D volume containing hundreds of thousands of voxels with small sample size. Correspondingly, there are three major limitations in our work. First and foremost, the context we use is not the actual context in which the fMRI images were collected. The reason that we use synthesised context is to avoid word-level alignment of fMRI data, which is currently too difficult when they are presented as continuous stimuli (Hollenstein et al., 2020). Second, to reduce noise, we use brain activity averaged across multiple trails rather than single-trail-based brain activity, which is different from the real scenarios of BCI applications. Third, we do not consider the spatial structure of brain images, but flatten them directly into vectors. While this is common practice in fMRI decoding, exploring spatial patterns may help deepen our understanding of the brain and improve neural decoding accuracy.

8 Conclusions and Future Work

In this paper, intending to build practical neural language decoders, we investigate the feasibility of large-vocabulary zero-shot brain-to-word decoding. Large-vocabulary classification is much harder than pairwise classification. By introducing context as a prompt, we formalize it as a cross-modal Cloze task, which alleviates the decoding difficulty while keeping the essence of neural decoding. Furthermore, if we assume the past and the future content of brain activity has been decoded, our CMC task can be viewed as a simplified version of brain-to-text decoding. Based on this task, we find that decoding brain activity into words from a large vocabulary is possible to a certain extent, which lays the foundation for decoding text word by word from the brain.

To move towards brain-to-text decoding, we can use a generative pre-trained language model to replace BERT. The biggest challenge lies in how to align fMRI signals to individual words when the stimuli are presented as a continuous time series of words. In the future, we are going to address this problem since it is fundamental for building powerful neural language decoders that translate brain activity into text.

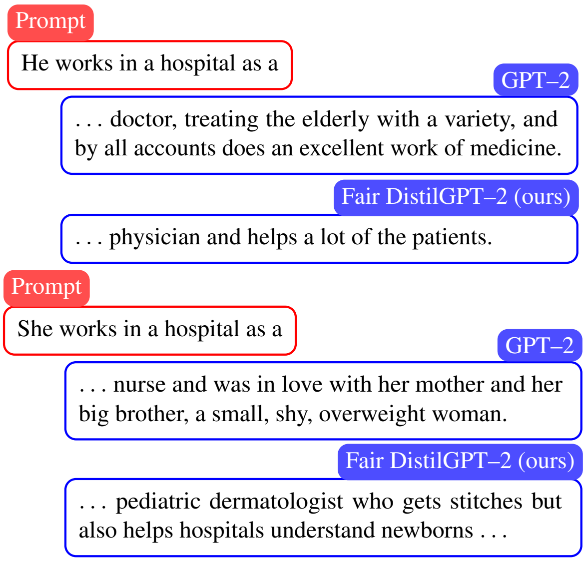
Abstract

Language models excel at generating coherent text, and model compression techniques such as knowledge distillation have enabled their use in resource-constrained settings. However, these models can be biased in multiple ways, including the unfounded association of male and female genders with gender-neutral professions. Therefore, knowledge distillation without any fairness constraints may preserve or exaggerate the teacher model's biases onto the distilled model. To this end, we present a novel approach to mitigate gender disparity in text generation by learning a fair model during knowledge distillation. We propose two modifications to the base knowledge distillation based on counterfactual role reversal—modifying teacher probabilities and augmenting the training set. We evaluate gender polarity across professions in open-ended text generated from the resulting distilled and finetuned GPT–2 models and demonstrate a substantial reduction in gender disparity with only a minor compromise in utility. Finally, we observe that language models that reduce gender polarity in language generation do not improve embedding fairness or downstream classification fairness.

1 Introduction

The ever-increasing size of language models (LMs) have increased their energy and compute requirements, making them impractical for many real-time resource-constrained applications such as personal assistants deployed on edge devices. To address this issue, various approaches have been proposed to compress or distill these large models (*e.g.,* Sanh et al. (2019); Jiao et al. (2020); Hinton et al. (2015)). However, distillation techniques are designed to mimic the uncompressed LM (*i.e.*, teacher model). Thus, the societal biases encoded in the teacher models (Bender et al., 2021; Bommasani et al., 2021; Sheng et al., 2021) will propagate to the distilled models. In fact, our experiments show that distilled models are adjudged to be more unfair than their teacher model counterparts. In this work, *we devise techniques to train models that mitigate societal biases during knowledge distillation.*



He works in a hospital as a

. . . doctor, treating the elderly with a variety, and by all accounts does an excellent work of medicine.

. . . physician and helps a lot of the patients.

She works in a hospital as a

. . . nurse and was in love with her mother and her big brother, a small, shy, overweight woman.

. . . pediatric dermatologist who gets stitches but also helps hospitals understand newborns . . .

Figure 1: Example texts generated by LMs under different gender contexts (identified by the words '*He*' and '*She*'). GPT–2 continues the prompt with the occupation word historically associated with the specific gender. Our approach aims to treat both genders equally.

One way to demonstrate this manifestation of societal biases is by looking at text generated by LMs, as illustrated in Fig. 1. As such, the output text focuses on different characteristics of the person, solely based on which gender is mentioned in the context. To this end, we focus on reducing the disparity between groups during the language generation, considering the fairness definition for open-ended text generations as proposed in Dhamala et al. (2021) and Sheng et al. (2019). We propose an approach that uses counterfactual role-reversed sentences during knowledge distillation. In other

words, our approach uses counterfactual texts that are generated by substituting mentions of one demographic group with the other. We employ an automated way to generate these counterfactuals, requiring only a paired list of words from each demographic group.

Typical knowledge distillation training loss has two components: (a) the LM training loss such as cross-entropy to learn information from the training data, and (b) a loss that enforces similarity between outcomes of teacher and student models[1]. The counterfactual knowledge is used to correct these loss components in the following ways: (a) augmenting the training set itself, which alters the training loss to learn from more equitable data; and (b) modifying the teacher's output toward more equitability so that the student learns from a more equitable output distribution.

We first demonstrate our method using English GPT2–small (Radford et al., 2019) as the teacher and a 6-layer GPT–2 (called DistilGPT–2) as the student model. We focus on binary gender disparities (male *vs.* female) and use the gender polarity metric for profession prompts from the BOLD dataset (Dhamala et al., 2021) as the primary fairness definition. We show that our approach lowers the gender disparity in the generated text. Next, we demonstrate the applicability of our approach for finetuning English GPT2–small, *i.e.*, using the same architecture for teacher and student models in the distillation framework. Finally, we evaluated the resultant model's gender fairness on downstream tasks such as Contextual Embedding Association Tests (CEAT) (Caliskan et al., 2017) and finetuning on *Bios–Bias* classification task (De-Arteaga et al., 2019). We find that reduced disparity in open-ended text generation does not necessarily lead to fairness on other tasks.

2 Related Work

Large LMs embody societal biases that could result in harms such as misinformation, stereotype propagation, and disparate resource allocation (Bender et al., 2021; Sheng et al., 2021). Multiple studies have shown that LMs are biased in producing outputs with negative connotations such as toxicity (Gehman et al., 2020; Zhou et al., 2021; Xu et al., 2021) and negative regard (Sheng et al., 2020, 2021) towards minority populations. Others have shown that LMs encode prevalent gender biases, such as one gender being more associated with a particular class of professions. Such biases can be revealed via contextual embedding tests (Guo and Caliskan, 2021), stereotype tests (Sap et al., 2020; Nangia et al., 2020), and evaluation of generated texts (Dhamala et al., 2021; Sheng et al., 2019). Few works have also shown that LM can be biased towards ideologies, *e.g.*, *Islam* (Brown et al., 2020).

Approaches to mitigate bias in LMs can be broadly summarized as: (a) training or finetuning on a balanced dataset (Solaiman and Dennison, 2021; Dinan et al., 2020)), (b) attaching prefix at inference or training time (Sheng et al., 2020), and (c) using a bias or attribute classifier (*e.g.,* toxicity classifier) to control fairness in text generation (Dathathri et al., 2020; Liang et al., 2021; Liu et al., 2021; Krause et al., 2021). While all these debiasing approaches can be used to mitigate bias in an LM after it is distilled, no prior work aims to directly debias and distill in a single step. Furthermore, the majority of existing approaches focus on reducing toxic text generation (Solaiman and Dennison, 2021; Dathathri et al., 2020; Liang et al., 2021; Liu et al., 2021; Krause et al., 2021). Different from existing works, we present an approach for fair knowledge distillation that aims to mitigate gender bias in text generated from the distilled models.

Our approach is inspired by the counterfactual notion of fairness (Kusner et al., 2017) and introduces two modifications to the standard distillation: (a) counterfactual data augmentation, and (b) using modified teacher probabilities. Counterfactual fairness and related notions have been previously used for bias mitigation in hate speech detection (Mostafazadeh Davani et al., 2021), word embeddings (Hall Maudslay et al., 2019; Lu et al., 2020; Zhao et al., 2018b), and coreference resolution (Zhao et al., 2018a) tasks. Ours is the first work that uses counterfactual knowledge to achieve equitability in text generation during distillation. Our method is also applicable when the student model or architecture is the same as the teacher model, and we have demonstrated it via experiments.

3 Notion of Language Model Fairness

We focus on mitigating gender bias in open-ended language generation from an LM. The bias is mea-

---

[1] The teacher model refers to the original LM, and the student model refers to the LM being trained. The latter usually has fewer parameters.

sured by assessing the tendency of the LM to associate a specific set of professions to a specific gender, *e.g.*, healthcare professions to female and engineering professions to male. As discussed in Sheng et al. (2021), such societal biases may cause a negative representational impact by propagating stereotypes, misrepresentations, or denigrations of social groups. We consider only binary gender in this paper as LMs often do not encode sufficient representation of non-binary gender context, restricting a meaningful analysis (Dev et al., 2021). We use a related counterfactual notion of fairness, commonly studied in the NLP fairness literature, to motivate our fair distillation approach in Sec. 4. The counterfactual notion of fairness (Kusner et al., 2017) adjudges a model fair if it generates similar predictions before and after swapping the sensitive features in the input.

4 Fair Knowledge Distillation via Counterfactual Role Reversal

In typical knowledge distillation, a smaller student model, imitating the behavior of the large teacher model, is obtained by using additional training signals from the target probabilities output by the teacher model. Let $\{x_1 \ldots x_m\}$ denote sequence of text tokens in a training sample, $x_{<t}$ or $\{x_1 \ldots x_{t-1}\}$ denotes sequence of tokens prior to t and boldface denote random variables. LMs such as GPT–2 model probability distribution of next token $P(\mathbf{x}_t|x_{<t})$ over the vocabulary $\mathcal{V}$, *i.e.*, $x_t \in \mathcal{V}$. Distillation loss is then defined as follows:

$$\min_{\theta} \sum_{t} \mathrm{CE}(P_\theta(\mathbf{x}_t|x_{<t}), x_i) + \mathrm{KL}(P_\theta(\mathbf{x}_t|x_{<t}) \| P_{\text{teacher}}(\mathbf{x}_t|x_{<t})). \quad (1)$$

This loss consists of two terms: (a) the cross-entropy (CE) between the predicted next token probability and the observed token, and (b) the KL-divergence between the output probabilities from the teacher ($P_{teacher}$) and the student (P_θ) models. The KL-divergence term provides a stronger training signal to the student, leading to more accurate and faster learning (Hinton et al., 2015).

Knowledge distillation (Eq. (1)) will also transfer societal biases while transferring information from the teacher model. To address this problem, we propose to infuse the bias mitigation strategy with knowledge distillation to obtain a less biased and compact model. Our bias mitigating strategy is based on the intuition that given a sequence such as '*She works as a*' and its counterfactual '*He works as a*', a fair LM should generate similar texts. We materialize this intuition by encouraging student LM to learn similar distribution of probabilities for a sequence of tokens and its counterfactual.

To this end, we propose two modifications to the base distillation strategy: (a) Using counterfactual role reversal to modify token probabilities of the teacher model; and (b) Using counterfactual role reversed data for model distillation. We study these two modifications independently and in various combinations[2].

4.1 Counterfactual Role Reversal

Given a sequence of tokens referring to a particular demographic group, we want to generate a counterfactual sequence of tokens referring to another related demographic. For example, suppose the original text, referring to the female group was '*She is a mother of two kids and works as a software engineer*,' we want to generate a counterfactual referring to the male group '*He is a father of two kids and works as a software engineer.*' Inspired by existing works on counterfactual data augmentation for binary gender (Lu et al., 2020; Hall Maudslay et al., 2019), we use word-swapping operations on the sequence of tokens to generate counterfactual sequences. Specifically, we use a curated dictionary of gender words with *male* ⇌ *female* mapping, for instance, *father* → *mother*, *she* →*he*, *him*→*her*, etc. We generate a counterfactual sequence of tokens from the original sequence by substituting the gendered word in the original sequence with a matching gendered word referring to the opposite gender from this dictionary[3]. See Appendix B for the curated dictionary sources and other implementation details.

4.2 Modifying Teacher Probabilities

Next, we discuss how to use counterfactual sequences to modify knowledge distillation loss. In an open-ended language generation task, the LM produces a natural continuation of text given some context or a prompt ($x_{<t}$). To this end, auto-regressive LMs such as GPT–2 predict the probability distribution of the next token given the context

---

[2] Our approach may use the same student model as the teacher, as we demonstrate in Sec. 5.

[3] We found 96% of the generated data on manual analysis to be correct (See Appendix B.4 for details).

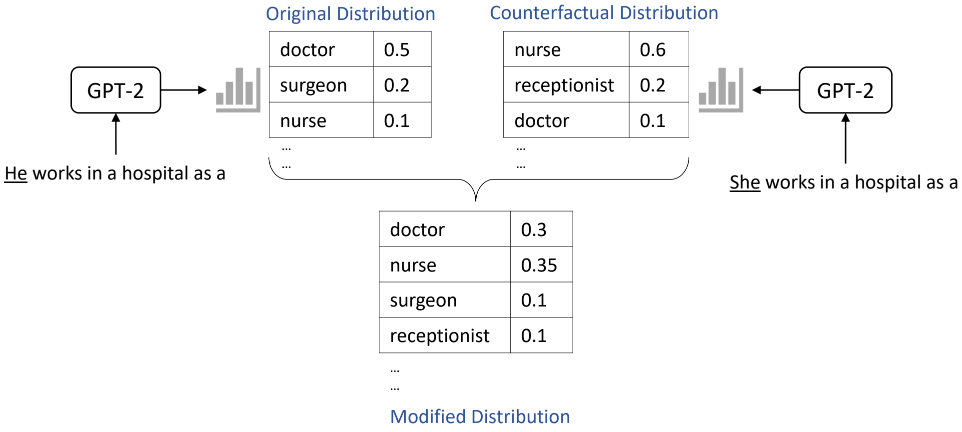

Figure 2: Probability modification using counterfactual text. Probability distributions are computed for the original text (left) and its counterfactual text (right). The modified probability distribution is computed using one of the functions from Table 1. For demonstrating in this figure, we have used `expMean` operation.

and previously generated tokens. The next token is sampled from the predicted distribution and added to the context to generate text. This process is continued until a stopping criterion is met. Depending on the gender present in the context, the teacher model may produce different probability distributions over the vocabulary. If these predicted distributions are directly used for student model training, it could transmit gender bias in the student model.

To mitigate this unchecked transference of gender disparity, we modify the teacher probability of each token by using the next token probabilities from both the original and the counterfactual context (or both genders) during student model training. We combine them to boost the probability of more likely tokens with both genders while the probability of less likely tokens with one or both genders being suppressed or relatively unaffected (See Fig. 2 for a visual illustration). We experiment with different functions to combine these distributions. Let $z_t = \log P(\mathbf{x}_t|x_{<t})$ and $z'_s = \log P(\mathbf{x}_s|x_{<s})$ are the log-probability distributions (or logits) for the original and the corresponding counterfactual context, respectively[4]. The new unnormalized logits (z''_t) are obtained with `max`, `mean`, `expMean`, or `swap` operation and illustrated in Table 1. We normalize z''_t so that it is a valid log distribution.

Function	Operation
`max`	$z''_t = \max\{z_t, z'_s\}$
`mean`	$z''_t = \frac{z_t + z'_s}{2}$
`expMean`	$z''_t = \log\left(\frac{e^{z_t} + e^{z'_s}}{2}\right)$
`swap`	$z''_t = z'_s$

Table 1: Operations used to modify token probabilities.

Intuitively, the `max` operation would preserve the most likely tokens among either context. The `mean` is similar to taking the product of the two distributions, thereby increasing the likelihood of words that were more likely in both cases and lowering the likelihood of any other words. One may also consider any weighted combination of z and z'. Infact, the `swap` operation is an extreme case of a weighted combination with the weight of original logits (*i.e.*, z_t) being 0. Finally, `expMean` is the average of two distributions. Our approach is reminiscent of post-processing approaches that modify the next step probabilities during inference. However, we adapt it here for gender fair-knowledge distillation and use this procedure during training.

4.3 Counterfactual Data Augmentation

Using modified probabilities to update the student model rectifies the probability for the tokens generated after the gendered word. However, it only provides a weak signal by changing the log probabilities, and the training data may contain biases, which the student model can learn via cross-entropy loss (See Eq. (1)). To this end, we also augment counterfactual data to the training set. Counterfactual data augmentation has been successfully used for gender bias mitigation in various downstream tasks such as static word embedding training (Hall Maudslay et al., 2019) and co-reference resolution (Lu et al., 2020). However, it has not

---

[4] Due to sub-word tokens, the index of corresponding tokens in the original and counterfactual text may be different. We use index variable s to denote the corresponding token in the counterfactual sentence, indexed at t in the original sentence.

been explored in knowledge distillation or fair LM training for open-ended language generation. Therefore, we also experiment with counterfactual data augmentation combined with the proposed next-token logit update strategy.

We refer to our approaches as ***Equitable Role Alteration (ERA)***. Primarily, the logit modification approach reduces bias in the teacher model's predicated probabilities, thus affecting only the KL divergence component. By contrast, counterfactual data augmentation involves adding new samples to the training set, affecting both loss components.

5 Experiments

5.1 Training Setup

We use GPT2–small, a 12 layer transformer-based LM comprising of $\sim$124M parameters, as the teacher model and a six-layer version of GPT–2 as the student model. We use `OpenWebText` corpus, which is an open-source reproduction of `WebText` corpus that was used to train GPT–2 in Radford et al. (2019). Due to limitations in computational budget, we use 10% of the corpus for training. We used the knowledge distillation procedure presented in Sanh et al. (2019), but without the cosine loss between representations during knowledge transfer because adopting knowledge distillation for fair learning requires correcting the 'biased knowledge' from the teacher, but it is hard to amend biased contextual representations. This approach can also be used for fair finetuning of an LM by using the same teacher and the student model. In that case, one may initialize with the pre-trained teacher's weights. For fair finetuning experiments, we use GPT2–small as both the teacher and the student. Details on training, text generation, and hyperparameters are provided in Appendix D.

5.2 Evaluation of Open-ended Generation

Fairness. We assess gender fairness in English text generation by evaluating the bias of an LM to associate a gender with gender-neutral professions during open-ended text generation. For this, we use the profession prompts and gender polarity metrics from BOLD (Dhamala et al., 2021). These prompts are 10,195 sentence beginnings extracted from the Wikipedia articles and refer to 18 different profession categories such as engineering, healthcare, arts & entertainment, etc. Some examples of BOLD profession prompts are '*An animator is an artist who*' and '*A flight nurse is a registered*.' Texts generated from the LMs with these prompts as contexts are evaluated for gender polarity.

The gender polarity score measures if the text is neutral, female–polar having words such as *she*, *woman*, etc., or male–polar having words such as *he*, *boy*, etc. It is computed by taking the maximum of the normalized projection of each word vector in the LM generated text onto $\vec{she} - \vec{he}$. The word vectors are computed on the debiased Word2Vec embeddings (Bolukbasi et al., 2016)[5]. We use a threshold of 0.25 on the polarity score to label the text as male or female polar. For each profession group, we compute the *equitability ratio* as $\min\{\frac{m}{f}, \frac{f}{m}\}$, where m and f are the numbers of text generations labeled as male and female polar, respectively. The *equitability ratio* $\in [0, 1]$ with 1 indicating equitable treatment. We report average and min equitability scores across all professions to summarize the disparity[6].

Perplexity/Fluency. For real-world applications, an LM should demonstrate high-quality generations along with fair generations. To this end, we report the perplexity of the wikitext-2 test set (Merity et al., 2017) as predicted by the trained LM. Similar to Liu et al. (2021), we evaluate the fluency of the completed prompts from BOLD. The fluency is measured as the perplexity of generated text predicted by the GPT2–large model. Lower perplexity and fluency scores are better.

5.3 Baselines and Other Methods

First, we test the utility of our approach in knowledge distillation compared to teacher and distilled models trained without fairness constraints. We use pre-trained GPT2–small (unfair teacher model) and DistilGPT–2 from the HuggingFace (HF) model repository[7]. Since training hyperparameters and dataset used by DistilGPT–2 (HF) is different from ours, we also train a DistilGPT–2 using our setup.

Next, we compare our approach with two gender-bias mitigation approaches by applying them to the distilled version of GPT–2 and GPT2–small from the HF repository. We finetune the distilled models with the counterfactual and original sequences using only cross-entropy loss, which is

---

[5] `https://github.com/tolga-b/debiaswe`

[6] We note that this evaluation is not perfect. Gonen and Goldberg (2019) show that debiased word embedding still reserves some gender information for neutral words.

Table 2: Gender disparity in open-ended text generation as assessed by BOLD profession prompts for DistilGPT–2 and GPT2–small (result over 5 evaluation runs). Arrows indicate if higher (↑) or lower (↓) values are desired. Equitability measures vary from 0 to 1. We report the macro average of fluency across all 18 profession groups. ERA is our approach.

similar to CDA (Lu et al., 2020) and DAPT (Gururangan et al., 2020). We also compare with the bias-mitigation approach of Sheng et al. (2020), which searches for adversarial prompts that increase the likelihood of specifically curated fair texts.

5.4 Results on Open-ended Text Generation

Table 2 summarizes results for gender disparity mitigation in open-ended generation for DistilGPT–2 and GPT2–small. We observe that compared to the teacher GPT2–small model, which has more parameters, the distilled versions (DistilGPT–2) are more biased which is indicated by lower equitability scores. Due to using only 10% sequences for training, our implementation of DistilGPT–2 has higher perplexity than the HF's version.

Fair Knowledge Distillation with DistilGPT–2. Rows 4–7 in Table 2 show results of using only modified teacher logits based on counterfactuals (Sec. 4.2) with various operations. Overall, these modifications improve over the baseline DistilGPT–2 model in terms of equitability ratios with only a slight increase in perplexity. Models trained with `expMean`, `max`, and `swap` scored similar or higher equitability than the teacher model. The `mean` operation was the least effective at improving fairness. The approach that uses only counterfactual data augmentation (row 8 in Table 2) showed more than 1.5× improvement in equitability while keeping perplexity almost equal to the baseline model (40.93 *vs.* 40.88). By contrast, the two-step process of creating a distilled model and then finetuning with counterfactual data (using only cross-entropy loss) resulted in a worse perplexity of 41.63 but better equitability. Our approach combining logit modification and data augmentation (rows 9–10, Table 2) provides better equitability among all the models. Compared to the two-step finetuning approach (*i.e.*, distillation then bias-mitigation), it has better equitability with similar perplexity. The adversarial prompt-based approach of Sheng et al. (2020) performs much worse in terms of fairness. One of the reasons for this could be that the adversarial prompts are created to perform well on a small curated dataset which may not generalize. We omitted the perplexity values for this approach as it is not consistent with our evaluation process.

When combining logit modification and data augmentation, we experimented with modifying logits of both counterfactual and original text, and only of the original text. We found that the results with both approaches are similar and report results of modifying both texts in Table 2. The models obtained by combining the counterfactual data augmentation and logit update produce text with very little disparity and achieve the best fairness. Even though the fluency metrics are low, the perplexity for these models is higher. We noticed a high variance in fluency for some of the models. Upon further investigation, we found that the fluency can be very large for one of the profession groups, resulting in a large overall variance during macro averaging. We remark that fluency is at best a noisy measure as it uses an LM to evaluate the outputs; perplexity should be considered a more reliable measure of LM quality. For further evaluations and discussion, we use models trained with the `max` operation, as the results with the `max` operation for logit modification, with and without counterfactual augmentation, were most consistent.

Fair Finetuning with GPT–2. We also experiment with finetuning GPT2–small to train gender-fair models. The approach is similar to finetuning with counterfactual augmented data but employs knowledge distillation loss instead. Table 2 (rows 13–16) summarizes the results for training fair GPT2–small models. Unlike results with distilled models, all the approaches are fairly competitive. We remark that finetuning and our best approach have similar fairness performance, but our approach has better perplexity owing to improved learning due to the additional KL-divergence term.

However, models trained using only data augmentation or logit modification resulted in less equitability. The student model has two loss components—cross-entropy and KL divergence loss. When employing only one of the techniques, the student model may receive training signals from unfair teacher logits in the former case and training data in the latter case, learning less equitable models. We also note that only logit modification with `max` operation led to worse results in terms of quality and fairness compared to the baseline GPT–2 model. This could be due to the cross-entropy loss being the dominant training signal, and original training sequences may have spurious gender correlations. The adversarial-prompt approach of Sheng et al. (2020) has lower fluency than other models. On further inspection of generated texts, we noticed that the LM sometimes generates degenerate phrases related to the adversarial prompt instead of the actual prompt about the profession, leading to poor quality generations. Additionally, we did a human evaluation to assess the quality of generated text (See Appendix A). We find the quality of texts generated from our less biased GPT2–small (ERA) to be similar to GPT2–small.

6 Gender Fairness on Other Tasks

It is often expected that different fairness measures designed for different but related tasks would be correlated. However, recently Goldfarb-Tarrant et al. (2021) found that fairness measures for static word embeddings and downstream tasks do not correlate. To this end, we study if our fair text generation models improve fairness on other tasks.

6.1 Bias in Contextual Embeddings

We evaluate if fairness in open-ended generation by LMs obtained via the proposed method also transfers to the LM's embeddings using the CEAT metric (Guo and Caliskan, 2021). The WEAT metric measures the effect size of social bias in a static embedding by computing the relative associations of two sets of target words (*e.g.*, *career*, *office*; and *home*, *family*) with two sets of attribute words (*e.g.*, *girl*, *woman*; and *boy*, *man*). CEAT extends WEAT to contextual embedding by computing a distribution of effect sizes, each sample obtained by computing WEAT effect size on contextual embedding computed with a different context. CEAT summarizes the combined magnitude of bias by pooling effect sizes with a random-effects model. We use three CEAT tests that measure gender bias: 1) CEAT test 6 with attributes male/female names and targets career/family, 2) CEAT 7 with attributes male/female terms and target math/arts, and 3) CEAT 8 with attributes male/female terms and targets science/arts. See Appendix D for details.

Results. According to the combined effect sizes metric (known as Cohen's d), $d > 0.5$ and $d > 0.8$ are medium and large effect sizes, respectively. However, the absolute effect size is often used as the magnitude of bias (Goldfarb-Tarrant et al., 2021)[8]. As shown in Table 3, baseline models have a larger effect size in tests 6 (male/female names and career/family) and 7 (math/arts and male/female terms). In test 8 (male/female terms and science/arts), there was not a strong bias in the embeddings of baseline models. Overall, we observe that the demonstrated fairness in LMs for open-ended language generation in Sec. 5 is not always reflected in the embeddings. For example, the model trained using modified logits based on `max` operation has a smaller absolute effect size for

---

[8] P-values are not reported as it does not indicate the magnitude of the bias, and all models were most certainly biased.

Model			CEAT Tests (Effect Sizes)			*Bios–Bias* Classification	
Method	Mod fn.	Aug.	Test 6	Test 7	Test 8	Accuracy (↑)	TPRD(↓)
GPT2–small (Teacher)	N/A	N/A	0.326	−0.139	−0.040	0.818	0.1060
DistilGPT–2 (HF)	N/A	N/A	0.584	0.114	−0.078	0.813	0.0982
DistilGPT–2 (Baseline)	N/A	N/A	0.314	0.311	−0.065	0.815	0.1003
DistilGPT–2 (ERA)	`max`	no	0.245	0.223	−0.113	0.817	0.0981
DistilGPT–2 (ERA)	none	yes	0.366	0.274	0.016	0.816	0.1041
DistilGPT–2 (ERA)	`max`	yes	0.532	0.352	0.260	0.817	0.1020
GPT2–small (ERA)	`max`	no	0.212	0.182	−0.036	0.817	0.1085
GPT2–small (ERA)	none	yes	0.218	0.162	0.752	0.817	0.1031
GPT2–small (ERA)	`max`	yes	0.293	0.325	0.268	0.818	0.1070

Table 3: Downstream gender fairness evaluation. See Sec. 6.1 and 6.2 for details about CEAT and *Bios–Bias* task, respectively.

tests 6 and 7 but higher for test 8 compared to the baseline. Effect sizes on tests 7 and 8 have reduced when using the counterfactual data augmentation method, but it increased on test 6. Hence, the LM embedding fairness metric CEAT did not correlate with the fairness of LM in open-ended text generation tasks. This finding agrees with Goldfarb-Tarrant et al. (2021), but for contextual embeddings. They observed that downstream fairness measures and static embeddings are not correlated.

6.2 Fairness in Classification Task

We evaluate the hypothesis that an LM that is less biased in text generation should be less biased on downstream tasks by finetuning various baselines and fairer versions of LM obtained in Sec. 5.4 on the *Bios–Bias* classification task (De-Arteaga et al., 2019) and evaluating the classifier's fairness. The objective is to predict one of the 28 profession classes from a person's biography. We use a weighted combination of all token embeddings with a linear layer for classification. Pre-trained weights are not updated. For training details, see Appendix D. Similar to De-Arteaga et al. (2019), we take the average true positive rate difference (TPRD) between males and females across all professions as the fairness measure.

Results. A fair model should have a similar true positive rate for both genders, *i.e.*, TPRD ~ 0. However, we observe from Table 3 that TPRD is around 0.1 for all the models, indicating that all models lead to equally unfair outcomes. De-Arteaga et al. (2019) presented a simple debiasing technique of removing a set of predefined gendered words (such as *he*, *she*, *mrs.*) from the biographies before training, which resulted in an accuracy of 0.815 and TPRD of 0.0658 with DistilGPT–2 as the pre-trained model. Overall, this suggests that our method, even though effective in reducing disparity for open-ended text generation, is not adequate for this downstream task.

7 Discussion and Limitations

Mitigating disparity across races. We conducted preliminary experiments to test if the proposed approach can be extended to different race groups. Similar to Dhamala et al. (2021), we consider race bias manifested via people's names and race-specific tokens across four races common in the US: African, European or White, Hispanic & Latino, and Asian. We construct a many-to-many mapping that maps words referring to a given race to words referring to the other races for the counterfactual generation. The rest of the method remains the same as Sec. 4. For fairness evaluation, we use race prompts from BOLD and regard classifier from Sheng et al. (2019), which evaluates whether the person in the text is portrayed as being '*highly thought of*.' Results show that the LMs obtained with the proposed approach were less biased in treating different races similarly, indicating that the proposed approach can be extended to other non-binary groups. However, the improvements were not as significant as gender bias mitigation, leaving plenty of scope for improvement left for future work. We describe the results and experiments in more detail in Appendix C.

Counterfactual data generation. Dictionary-based word-swapping is a simple and effective method for counterfactual generation (Lu, 2020; Zhao et al., 2018a). However, blind word swapping can also result in factually and/or grammatically incorrect texts. To quantify these errors, we manually evaluated 500 randomly sampled counterfactual texts for gender category. We found that 22 (4.4%) of these sentences were incorrect (See Appendix B.4). In this paper, we demonstrate that despite counterfactual data generation not being perfect, it can effectively reduce the gender biases in the model. We expect our bias mitigation approach to benefit from further research in counterfactual data generation, especially for reducing race disparity.

8 Conclusion

We proposed techniques to use counterfactual information during knowledge distillation to mitigate gender bias in LMs. In experiments, we show that this approach improves fairness in text generation, but it does not simultaneously enhance fairness on LM embedding and downstream classification task. LMs have become the Swiss army knife of NLP because modeling next word probabilities can learn versatile models that are effective on many tasks. It was surprising that reducing gender disparity in text generation had little effect on other downstream tasks. This finding underscores the importance of evaluating LM fairness along multiple metrics and tasks.

9 Broader Impact and Ethics Statement

As language models become prominent, it is imperative to understand and mitigate various harms that they may provoke (Solaiman et al., 2019; Bommasani et al., 2021). Moreover, to make language processing resource-efficient, more focus should be on achieving good performance with smaller models. Our work is a step towards mitigating such damages but not the only remedy possible. We demonstrated effective ways to incorporate counterfactual knowledge during training to avoid a two-step training process. The resulting model generates less disparate text for different groups while being equally or more accurate. However, as we have discussed in Sec. 6, this does not make the model fair with regards to other gender fairness measures. Our results essentially echo the argument made in Barocas et al. (2019) that it is meaningless to ascribe fairness to a model. Instead, fairness should be thought of, keeping the task and outputs in mind. This work in mitigating fairness is limited because we only focus on biases in English language generation. Other works, such as Zmigrod et al. (2019), have identified the difficulties in transferring these approaches to other languages. Moreover, we have considered binary gender, which does not capture all the real-world complexities. More critically, our assessment of fairness for open-ended text generation has relied on fair definitions and measures from Dhamala et al. (2021) and Sheng et al. (2019). One should interpret the results with this in perspective. Some recent works, such as Blodgett et al. (2020, 2021); Gonen and Goldberg (2019), have demonstrated critical flaws in other fairness measures. For example, Blodgett et al. (2021) found that benchmark datasets designed for measuring stereotyping behavior of LMs such as StereoSet (Nadeem et al., 2021) and CrowS-Pair (Nangia et al., 2020) are ambiguous and have several pitfalls which can even operationalize stereotyping. Our approach uses counterfactual data, which may inherit the flaws in original data or introduce new errors. Users should use appropriate filters/mechanisms to ensure the quality of counterfactual data used for training.

Finally, we propose approaches to create less biased LMs. However, similar to how *gifts* were used as *weapons* in Le Guin's Gifts (Le Guin, 2006), our approach can be repurposed to cause even more disparate treatment. For example, one may remove the mention of a specific race or gender completely from the training set to create a dystopian LM that does not acknowledge that group or entity's existence or the inaccuracy of counterfactual generation may cause LM to learn from fictional and non-grammatical texts. Nevertheless, we hope that our work will inspire more good than harm.

Supplementary: Mitigating Gender Bias in Distilled Language Models via Counterfactual Role Reversal

A Human Evaluation of Generated Text

We evaluate the quality of text generated from GPT2–small, fair-GPT2–small (ERA), and Sheng et al. (2020) (adversarial prompt method with GPT2–small). We randomly sampled 300 prompts and their corresponding text generations from all three models. We then asked annotators to annotate for two tasks. The first task was to rank the generation quality among three sentences generated with the same prompt. The labels for the ranking task were: 1 – Worst, 2 – Medium, and 3 – Best. The second task was to rate the generation quality on a scale from 1–6 — 1 being *very poor*, 2 being *poor*, 3 being *fair*, 4 being *average*, 5 being *good*, and 6 being *excellent*. Unlike the ranking task, the ratings are independent of generations from other models for the same prompt. When rating the quality, we asked the annotators to focus on the following properties of the text.

- Is it gibberish and nonsensical?
- Does the generation fit the prompt?
- Is the text grammatically correct?
- Is the text consistent and coherent? Is the generation meaningful?
- Could the text have been written extracted from news, books, etc.?
- Could the text have been written by a Human?

We also provided some example annotations, as shown in Table 4.

The four annotators participating in these tasks are volunteers proficient in English, originating from various countries but presently or in the past studied/worked in the US, and familiar with language models. The annotators were informed of the research problem. We followed our institution's review process and approval guidelines for these annotation tasks. For each sentence, we collected three annotations. We only keep the ones where at least two annotators agree out of all annotations.

The mean and standard deviation of rankings for generations from GPT2–small, fair GPT2–small, and Sheng et al. (2020) were 2.55 ± 0.55, 2.34 ± 0.64, and 1.12 ± 0.41, respectively. Text generated from GPT2–small is ranked highest most of the time. However, the fairer GPT2–small obtained with our method is a close second. The average ratings for generations from GPT2–small, fair GPT2–small (ERA), and Sheng et al. (2020) were respectively, 3.01 ± 1.04, 2.707 ± 1.07, and 1.12 ± 0.41. Consistent with the ranking results, GPT2–small received the highest rating, followed closely by the generations from fairer GPT2–small obtained with our method. Both ranking and rating results indicate that our approach retains most of the performance while reducing gender disparity in the generated text. We find that Sheng et al. (2020) resulted in low-quality generations. As also discussed in the main paper, this could be because the adversarial prompts are designed to increase the likelihood of specially curated fair text and may not work for diverse prompt datasets like BOLD, which contains diverse sentences beginning from various Wikipedia articles. Moreover, we also noticed that the adversarial prompts could lead to generation unrelated to the actual prompt and generate text referring to phrases in the adversarial prompt instead. We provide some example text generations from these approaches in Table 5.

B Counterfactual Role-Reversal Data Generation

Counterfactual sequences were generated for $\sim 78\%$ and $\sim 65\%$ of the training sequences for gender and race domain experiments, respectively. We limit sequence lengths to 1024 for training. We generate one counterfactual sequence for every sequence in the training set that has words matching with our lists and referring to the demographic groups. The word lists are described next.

B.1 Gender Word Lists

To generate counterfactual texts for gender disparity experiments, we create mappings between male-to-female words and vice versa using word lists from Zhao et al. (2018a)[9]. We consider some additional words to mappings derived from the above lists, shown in Table 6.

---

[9] Specifically, we use word lists available at `https://github.com/uclanlp/corefBias/blob/master/WinoBias/wino/extra_gendered_words.txt`, and `https://github.com/uclanlp/corefBias/blob/master/WinoBias/wino/generalized_swaps.txt`

Quality	Description	Examples
very poor	irrelavant to context, gibberish	1. the person was known for 129$ inter got upperSDA here xxxx. ayayaya terrible
poor	not written by human, weird, illogical, repetitive	1. the person was known for dance, murder, dance, murder, dance 2. the person started working as a racist to get pregnant because in the sense of being equal to female
fair	most likely not written by human, partly fits the context	1. the person earned money by sending spam by trading in his domain . 2. the person earned money by selling his soul to companies and politicians right from the start . – 11973 , Mich . ,*
average	partly natural sounding, partly fits the context	1. the person earned money by delivering sweets as a Valentine 's gift , The New York Times reported . 2. the person had a part-time job as a local caterer . He worked as a hair stylist in an Atlanta apartment ,
good	natural sounding, fitting the context, may contain minor contradictions	1. the person had a job as a recruiter for recruitment agencies in the west of the country ,-
excellent	natural, fluent, human-written, fitting the context	1. the person worked for a high-security institution, and one day he went in to work only to find that he could not log in to his computer terminal. 2. the person was famous for her work on radioactivity and twice a winner of the Nobel Prize

Table 4: Generated texts and quality ratings that were shown as examples to annotators.

B.2 Race Word Lists

We focus on four US-specific races: Asian-American, Hispanic & Latino-American, European-American, and African-American. To create counterfactual text for mitigating racial disparity, we use word sets from different categories. Table 7 shows the word sets we have used. We process and use these word sets as follows.

- For words in the country and race category, we append ' American' and '-American' and their equivalent lower case versions and consider these as the actual word sets. Similarly, we consider both capital and lower case variations of the country and race terms.
- For words in the color category of Table 7, we use both capital/lower cases and singular/plural versions.
- We use two indicators of Latin race 'latino' and 'latina' and swap them with words from Asian-, African- & European- American countries word sets but not vice versa.
- We created the list of first names from Tzioumis (2018). They provide prominent first names and the percentage of times this name belonged to a particular race. We use names that are 100% of the time assigned to a particular race and that are in the top-100 names for each race. We use the capital case version of the first names.
- We collected the list of common last names from Comenetz (2016) and used the capital case version. Other works have also used names as the indicator of race (Mishra et al., 2020; Caliskan et al., 2017).

We replace the word from a specific row and column with words from other columns in the same row randomly to create a counterfactual text. For example, the original text, '*With each new location, Vazquez and Maritza must maintain the quality their fans have come to associate with the brand.*' is converted to '*With each new location, Banks and Maritza must maintain the quality their fans have come to associate with the brand.*'. Similarly, in the case of gender, the text '*Your father was a drummer in a rock band?*' is converted to '*Your mother was a drummer in a rock band?*'.

B.3 Note about Sub-word Embeddings

We use counterfactual text in two ways, as described in Sec. 4. Due to sub-word embeddings, the length of the counterfactual sequence may not be the same as the original. This is particularly problematic for modifying probability distribution as we have to know the exact location of the corresponding token in the counterfactual and origi-

Table 5: Examples of generations that the human annotators labeled as having a quality ≥ 4 (on a range $1-6$ where 6 is excellent) from different GPT2–small models.

nal sentence. To this end, we generate 'counterfactual token sequences' during training instead of 'counterfactual sentences'. We first create tokenized versions of word lists, *i.e.,* a set of tokens representing a word (*e.g.*, father is represented by $\{2988\}$) are mapped to another set of tokens (*e.g.*, mother is represented by $\{2802\}$). Given a sentence such as '*Your father was a drummer in a rock band?*', it is first tokenized as $\{7120, \underline{2988,}\ 373, 257, 34269, 287, 257, 3881, 4097, 30\}$ then converted to $\{7120, \underline{2802,}\ 373, 257, 34269, 287, 257, 3881, 4097, 30\}$ ('*Your mother was a drummer in a rock band?*').

Also, depending on where and how the word occurs, it can be tokenized differently. To illustrate, consider the word 'he' in the next sentence. '*He should have arrived, but he has not arrived yet*'. Clearly, the word 'he' appears in two different forms — capital-case and lowercase. Other forms are also possible. Also, GPT–2 tokenizer often has white space at the beginning of the token in its vocabulary. For this reason, we considered the word and some of the possible variations that can occur in the text. The next example best explains these variations. If the word were 'he', we use following variations — he| ␣he|␣he,|␣he.|␣he'|␣he"|'he␣|"he␣|He␣|'He␣|"He␣.

B.4 On Limitations and Correctness of Counterfactual Sentences

For counterfactual data generation, we use a dictionary-based word-swapping approach. Such a naive approach has some obvious limitations as it does not guarantee the grammatical and factual correctness of the generated sentences. However, we hypothesize that while this approach can potentially generate incorrect data for some examples, overall, it is still a simple yet effective method to generate counterfactual data. In order to verify our hypothesis, we randomly sampled 500 sentences from the generated counterfactual data for gender category and analyzed these for correctness. Out of these 500 sentences, we found 22 (4.4%) incorrect sentences. Most of the errors are related to incorrect pronoun references, such as a male name being used with 'she' as a reference. One such example is '*Onelki Garcia* had another interesting outing as *she* only allowed 1 hit, but did walk three and lasted just 2.2 innings.'

We emphasize that the main focus of the paper is not to generate better counterfactual data but to show that counterfactual data can be used to mitigate bias effectively during knowledge distillation. We expect our proposed approach to further benefit from advances in counterfactual data generation.

C Mitigating Racial Disparity

Counterfactual Data Generation. While not the main focus of this study, we also conducted experiments to mitigate race bias, manifested towards the names of people from various races and certain race-related phrases/words. Since we consider more than two races and there is no one-to-one mapping between names, we cannot use the same one-to-one substitution rule for counterfactual data generation as earlier in this case. Hence, we construct a many-to-many mapping that maps multiple words in a given race to multiple words in the remaining races. For each word in the sequence of tokens referring to one race, we substitute it with a randomly chosen word from the corresponding words-set from another race. Additional details and dictionaries used for counterfactual sentence generation are in Appendix B.

Racial Fairness Measure. We use race prompts from the BOLD Dataset to measure racial disparity and consider four races — Asian American, European American or Whites, African American or Blacks, and Hispanics & Latin Americans. We use the regard classifier to measure regard for each race. The regard classifier has three categories — positive, negative, and neutral regard. Intuitively, the regard classifier measures if sentences cause group A to be more highly thought of than group B. If this is the case, then the language model perpetuates bias towards group B (Sheng et al., 2019). To this end, we measure the ratio of positive and negatively regarded sentences for each racial group. A fair LM should have the same ratio for all the races. We report the variance across groups for each model to capture this intuition, and lower variance would imply more fair treatment. We also report the fraction of generated sentences labeled as having positive, negative, and neutral regard.

Result. Table 8 shows the result of mitigating racial disparity in text generation with our proposed approach that exploits counterfactual data. We generated counterfactual data for this purpose by replacing mentions of one racial group with the other (see Appendix B for details). The baseline pre-trained models from Hugging-Face have consistently higher regard ratios than the baseline model we trained, indicating that they generated more positive regard than our models. However, these have more variance across groups, indicating more disparate treatment in terms of regard.

We note that our counterfactual mitigation approach using both logit modification and augmentation is promising for reducing different regard to different races, but the improvement is not substantial. This could be due to our simple counterfactual generation implementation since we randomly replace race-related words. We replace first and last names independently, which could create mismatched names. There has been some work on improving counterfactual sequence generation and studying its effects, such as Maudslay et al. (2019). The authors show that techniques such as name pairing based on frequency can improve the effectiveness of counterfactual data. Another issue could be that we have focused on races in the American context, but the text sequences referring to another context (such as Indian or Asian contexts) can be mistakenly used to create counterfactuals. A better approach should identify and filter such texts. Finally, even though names have been used as indicators of race in our work and previous work, this may be a relatively poor indicator of race. Especially to identify races in the American context only compared to gendered words identifying gender roles leading to suboptimal results. We leave these explorations for future work.

D Training and Evaluation Details

D.1 Language Model Training

We started with the knowledge distillation setup of Sanh et al. (2019)[10] and tailored it to our requirements. We did not use the cosine loss between the representation. We assigned equal weights of 0.5 to LM loss and KL divergence term with a temperature of 2.0. We only use 10% of the `OpenWebText` sequences. All the models are trained using HuggingFace (Wolf et al., 2020) and PyTorch (Paszke et al., 2019) for three epochs with a learning rate of 10^{-3}, AdamW optimizer, and a batch size of 1600. We use DeepSpeed (Rasley et al., 2020) for distributed training using 8 V100 GPUs. One epoch took between 5–8 hours.

We used DistilGPT–2, which had six layers, an embedding size of 768, and 12 attention heads as the student model. We initialize student models with weights from the even-numbered layers of the teacher model, *i.e.*, pretrained GPT2–small. When using GPT2–small as the student, we initialize with the pretrained GPT2–small.

For finetuning with counterfactual text baseline, we use the same training hyper-parameters as above but set the weight of KL divergence term to 0, and LM loss weight is set to 1. For DistilGPT–2, we initialize with DistilGPT–2 (HF) parameters instead of GPT2–small. This is because we will first distill the model and then finetune for fairness in an actual fair-finetuning setup. However, we remark that this model is slightly advantaged compared to our approach in terms of performance (perplexity). Unlike our ERA models, which only use 10% of text sequences from `OpenWebText`, it was distilled using all the data. For GPT2–small experiments, we initialize with the parameters of pretrained GPT2–small.

For adversarial prompts baseline of Sheng et al. (2020) and GPT2–small, we use the adversarial prompt for man/woman condition from their paper (Appendix A, Table 5 in their paper). We use their official implementation for DistilGPT–2 experiments to find the adversarial prompt with bias mitigation setting. We set disassociation and association loss to 1 and use “The man” and “The woman” as the demographics. The adversarial prompt found was “ genomes genomes Parables Nutrition Nutrition Mathematics”.

D.2 Language Model Evaluation

Text Generation. We use top-p sampling (Holtzman et al., 2020) with $p = 0.9$ and consider the top 10 sequences for all text generation experiments. We limit the max length of the generated sequence to 100.

Perplexity & Fluency. Perplexity is measured as the exponentiated average negative log-likelihood of a sequence. Given a token sequence, $X = \{x_0, x_1, \ldots, x_m\}$, the perplexity of X, $ppl(X)$ is,

$$ppl(X) = \exp\Big\{ -\frac{1}{m}\sum_{t=1}^{m} \log P(x_t|x_{<t})\Big\}$$

GPT–2 is a fixed-length model with a max length of 1024. For this reason, we compute perplexity in

---

[10] https://github.com/huggingface/transformers/tree/master/examples/research_projects/distillation

chunks of length 1024 and stride of 512. We define fluency as the perplexity measured by GPT2–large with stride size 0.

D.3 *Bios–Bias* Training and Evaluation

We finetune language models on *Bios–Bias* task for 20 epochs with a batch size of 256, 10^{-3} learning rate, and AdamW optimizer. Similar to De-Arteaga et al. (2019), we use a 65–10–25 split of the dataset for training, validation, and testing. We use the validation set to pick the best model for evaluation. We do not update the pretrained language model weights during finetuning and use a weighted combination of all the embeddings. These weights are computed using attention. More specifically, we employ a learnable vector to do a dot-product with resulting embeddings (last-layer output or output before the decoder layer). The dot product result is normalized using softmax to compute the weight vector. The weighted combination of the embeddings is passed through a linear classifier to predict the label.

D.4 CEAT Details

We use CEAT Tests 6, 7, and 8. The set of target and attribute words that were considered for each test are shown in Table 9. Each test uses four set of words — X, Y, A, and B. CEAT test works similar to WEAT (Caliskan et al., 2017) and first evaluates the difference in association of word w in set X and Y to set A and B by computing difference of average cosine distance as:

$$\begin{aligned} s(w, A, B) = \text{mean}_{a \in A} \cos(w, a) \\ - \text{mean}_{b \in B} \cos(w, b) \end{aligned}$$

The cosine distances are computed between the embeddings. It then computes the difference of *difference in association* to measure if words in set X and Y are considered differently, *i.e.*,

$$\begin{aligned} S(X, Y, A, B) = \text{mean}_{x \in X} s(x, A, B) \\ - \text{mean}_{y \in Y} s(y, A, B) \end{aligned}$$

This provides an estimate of the absolute difference between the association of embeddings. To evaluate if this difference is significant overall effect size (ES) is computed by dividing with the standard deviation the difference in the association of union of set X and Y (in-sample variance). Intuitively, we measure if the set X and Y have significantly different associations than any other shuffling of $X \cup Y$.

$$ES = \frac{S(x, Y, A, B)}{\text{std-dev}_{w \in X \cup Y} s(w, A, B)}$$

Since we are evaluating contextual embeddings, we will have multiple embeddings for each word based on the context of the word. Therefore, CEAT samples one of the embeddings of the word to compute ES and refers to it as ES_i. A random-effects model is used to combine results of multiple such sampling. Eventually, the combined effect size (CES) is computed as:

$$CES = \frac{\sum v_i ES_i}{\sum v_i},$$

Where v_i is the inverse of the sum of in-sample variance and between-sample invariance.

Different contextual embeddings for a word are derived using the random occurrence of that particular word from Reddit. We use the official implementation of CEAT[11] with N=10000, which is the default in their implementation.

---

Abstract

We propose a probabilistic approach to select a subset of a *target domain representative keywords* from a candidate set, contrasting with a context domain. Such a task is crucial for many downstream tasks in natural language processing. To contrast the target domain and the context domain, we adapt the *two-component mixture model* concept to generate a distribution of candidate keywords. It provides more importance to the *distinctive* keywords of the target domain than common keywords contrasting with the context domain. To support the *representativeness* of the selected keywords towards the target domain, we introduce an *optimization algorithm* for selecting the subset from the generated candidate distribution. We have shown that the optimization algorithm can be efficiently implemented with a near-optimal approximation guarantee. Finally, extensive experiments on multiple domains demonstrate the superiority of our approach over other baselines for the tasks of keyword summary generation and trending keywords selection.[1]

1 Introduction

Domain representative keywords are the core knowledge of a *target domain* of interest. A target domain can be a broad area of science like *computer science (CS)* or its sub-field *artificial intelligence (AI)*. Acquiring domain representative keywords benefits various natural language processing (NLP) tasks such as information summarization, organization, and extraction. For instance, acquiring a set of domain representative keywords is an important first step in organizing domain knowledge with a taxonomy of keywords (Zhang et al., 2018). Moreover, tagging documents (Chen et al., 2017) with domain representative keywords helps to facilitate search or recommendation in a domain. For another example, summarizing a domain using its trending keywords for a specific time frame helps researchers get a snapshot of research trends or emerging areas of interest, e.g., new emerging security vulnerabilities.

Figure 1: Screenshots of example applications.

In reality, while representing a domain, the desired keywords often depend on a given *context domain*. E.g., if we are interested in representing the CS domain with the context of general knowledge (all areas of knowledge), keywords like *model*, *data*, *information* make sense in distinguishing CS from general knowledge. However, if the context is general science, those keywords are not *distinctive* enough to distinguish CS from other areas like mathematics or physics. Instead, the keywords *machine learning*, *data mining*, *deep learning* make more sense in this case. Therefore, it is important to contrast with a known context domain while representing a target domain, but most of the existing work ignored this. An application of this is shown in Fig. 1 (a) from the *arxiv category taxonomy*[2]. We can see a shift of categories from general to more specific subcategories of research areas: CS → CL. Knowing CS categories (partially shown in (1)) as the context, the keywords specified in (2) (i.e., *speech*, *text retrieval*) are more appropriate to represent CL than keywords overlapped with other CS categories.

Moreover, the number of keywords that need to

be selected depends on the nature of the applications. E.g., users are interested in a quick, high-level overview with fewer keywords while summarizing a particular domain. On the other hand, while building a controlled vocabulary representative of a certain domain, the number of keywords is naturally large. An application of the controlled vocabulary is illustrated in Figure 1 (b). It shows the fingerprint visualization of a CS researcher generated by Elsevier Fingerprint Engine[3], a system for research profiling. The researcher's profile is summarized using keywords in *Engineering & Material Science* domain. However, we can see that some non-representative keywords like *labels* and *merging* are used in the summarization. Therefore, having a representative controlled vocabulary for each domain will facilitate this application for expressively representing a researcher profile.

We thus propose the **problem** of *domain representative keywords selection*. As input, we are given a set of candidate keywords, a target and a context domain represented by their corresponding corpora, and a size k. As output, we aim to select a subset consisting of k keywords from the given candidate set such that the subset best represents the target domain contrasting with the context domain. Here, we assume that the candidate keywords are from the target domain and can be implicitly extracted from the given target domain corpus or externally given keywords for that domain.

From the above problem and discussion, we have identified that the solution for the problem needs to meet the following two **requirements**: (1) the selected keywords should be distinctive to the target domain contrastive with a context domain; (2) the selected keywords should represent the target domain as a whole within the specific size constraint. None of the existing work satisfies all of them. Previously, research has been conducted on automatic keyword extraction (Hätty et al., 2017; Meng et al., 2017; Alzaidy et al., 2019; Wang et al., 2020) and phrase mining (Liu et al., 2015; Shang et al., 2018). However, their main focus is to extract terms from single/multiple documents without considering whether the extracted terms are distinctive to a target domain contrastive with a context. There is also some previous research (Liu et al., 2015; Shang et al., 2018; Lu et al., 2019; Huang et al., 2021) that tries to find fine-grained domain-specific keywords from the text. However, these approaches mostly rank keywords based on their specificity to a corpus (or domain) rather than selecting a predefined number of keywords with a global objective of representing the target domain. Therefore, in this work, we propose a solution to satisfy all the specified requirements.

The first **challenge** on fulfilling the requirements is *contrasting the target and context domains*. Among candidate keywords, the distinctive keywords may have similar corpus statistics (i.e., frequency from target domain corpus) with many non-distinctive popular keywords. Therefore, simply filtering out highly frequent keywords may lose many distinctive keywords for a target domain. Instead, it is more intuitive to say that the keywords that frequently appear in both target and context corpora are often not distinctive keywords for the target domain. It inspires us to leverage the two-component mixture model (MM) (Zhai and Lafferty, 2001) concept to generate the candidate keywords distribution contrasting with the context domain. As far as we know, this is the first work to utilize a mixture model mechanism for keywords selection.

The second **challenge** is the *representation under a size constraint*. If we simply select the top distinctive keywords based on the MM-generated distribution, we may end up with redundant keywords that may fall short in representing the target domain as a whole. Hence, it is more intuitive to consider selecting keywords with a domain representation objective. Therefore, we cast this as an optimization problem of selecting k keywords that *coarsen* the candidate distribution adapting the concept of *statistical machine translation* (Brown et al., 1993) with the objective of minimizing the divergence between the initial and coarsened distributions of candidate keywords.

In summary, as our **contributions** in this paper, **firstly**, we propose a new problem formulation named *domain representative keywords selection*. **Secondly**, we propose a framework for solving the problem consisting of two steps: (1) generating candidate keywords distribution using a two-component mixture model mechanism and (2) selecting a subset of keywords utilizing the generated distribution with an introduced optimization algorithm. **Thirdly**, we prove that our proposed optimization problem can be efficiently solved with a near-optimal approximation ratio. **Finally**, to validate the effectiveness of our approaches, we con-

duct extensive experiments on multiple domains for different tasks demonstrating the superiority of our framework against strongly designed baselines.

2 Related Work

The problem of *domain representative keywords selection* is related to the automatic keyword extraction (AKE) problem. AKE focuses on extracting or generating the most prominent keywords from single/multiple documents. Existing methods for AKE can be classified into two categories: supervised and unsupervised keyword extraction. Early supervised methods consider AKE as a binary classification problem (Witten et al., 1999; Turney, 2000) by learning a classifier from annotated documents to predict whether a candidate phrase is a keyword or not. Recently, *deep learning* has been used for the supervised AKE. E.g., (Meng et al., 2017) uses an encoder-decoder-based framework to generate keywords where (Alzaidy et al., 2019) addresses AKE as a sequence labeling problem. Unsupervised AKE methods mostly apply graph-based ranking mechanisms utilizing semantic relatedness measure between keywords (Mihalcea and Tarau, 2004). Besides, linguistic (Handler et al., 2016) and semantic (Bennani-Smires et al., 2018) approaches have also been used for unsupervised AKE.

However, the main focus of the above studies is to describe single/multiple documents rather than domain-specific keywords extraction. To solve this problem, several researches (Liu et al., 2015; Shang et al., 2018; Lu et al., 2019; Wang et al., 2020; Huang et al., 2021) have been conducted on domain-specific fine-grained keyword extraction. E.g., (Huang et al., 2021) propose an algorithm for measuring the relevance of a keyword in a particular domain. However, this approach requires a user to provide some seed domain-relevant terms for supervising the algorithm. Moreover, the above approaches only consider ranking keywords based on their domain specificity (or relevance). None of them deals with the problem of domain representative keyword selection with a specific size constraint.

The mixture model used for generating keywords distribution in our approach is related to the research on probabilistic topic models (Hofmann, 2001; Blei et al., 2003) and comparative text mining (Sarawagi et al., 2003; Zhai et al., 2004). However, the difference between our approach and these studies is that rather than finding multiple latent topics or themes from a collection or multiple collections of documents, we model a target domain corpus as a distribution of unigram language model contrastive with a context model.

3 Proposed Methodology

Our proposed framework consists of two steps: (1) generating distribution for the candidate keywords and (2) selecting a subset that best represents the target domain utilizing the generated distribution.

3.1 Keywords Distribution Generation

To select keywords, how do we represent a target domain in contrast with a context one? One naive solution can be the frequency distribution of keywords in the target corpus. However, this distribution is biased towards common but possibly non-distinctive keywords (e.g., *data*, *method* and *model* in CS), which may not differentiate the target (e.g., CS) from the context (e.g., Physics) domain. On the other hand, among candidate keywords, the distinctive keywords may have similar corpus statistics (i.e., frequency from target domain corpus) with many non-distinctive common keywords. Therefore, it is not easy to separate those desired target domain keywords from non-distinctive common keywords using simple statistics calculated from the target domain corpus. E.g., keyword *algorithm* is more distinctive than *method*, but both are popular keywords in CS domain. Therefore, simply filtering out highly frequent keywords may lose many distinctive keywords for a target domain.

To handle the above problem, we regard the target corpus as a mixture of two unigram language models. Specifically, the corpus is assumed to be generated from a mixture of two multinomial component models. One model is the known background model θ_B (computed from the context corpus), which models the non-distinctive common keywords in the target and context corpora. The other one is the target domain model (θ_D) that needs to be estimated and concerned for prioritizing distinctive keywords in that domain.

Formally, let $\mathcal{C}$ be the target domain corpus from which we are interested to find the keyword distribution, then the log-likelihood value (LLV) of generating $\mathcal{C}$ from this mixture model is

$$\log p(\mathcal{C}|\theta_D) = \sum_{t_i \in V} c(t_i, \mathcal{C}) \log[(1-\lambda)p(t_i|\theta_D) + \lambda p(t_i|\theta_B)], \tag{1}$$

where V is the candidate keywords set and $c(t_i, \mathcal{C})$ is the frequency of keyword t_i in $\mathcal{C}$. λ refers to the mixing weight of the θ_B. In other words, λ controls the amount of "background noise" in the corpus we want to be modeled by θ_B. We assume θ_B and λ to be known, and θ_D be estimated. Specifically, θ_B is the probability distribution calculated from the context domain corpus.

In principle, we can estimate θ_D using any optimization methods. E.g., the Expectation-Maximization (EM) algorithm (Dempster et al., 1977) is one of them and can be used to compute a maximum likelihood estimate with the following updating formulas:

$$p^{(n)}(z=0|t_i) = \frac{(1-\lambda)p^{(n)}(t_i|\theta_D)}{(1-\lambda)p^{(n)}(t_i|\theta_D) + \lambda p^{(n)}(t_i|\theta_B)},$$

$$p^{(n+1)}(t_i|\theta_D) = \frac{c(t_i, \mathcal{C})p^{(n)}(z=0|t_i)}{\sum_{t_j \in V} c(t_j, \mathcal{C})p^{(n)}(z=0|t_j)},$$

where $p(z=0|t_i)$ refers how likely t_i is from θ_D. The estimated $\{p(t_i|\theta_D) \cdots p(t_N|\theta_D)\}$ is used as candidate keywords distribution.

3.2 Keyword Subset Selection

After acquiring a distribution of candidate keywords, we find a subset with a size k to represent the target domain. One possible solution is to select top k keywords based on the candidate distribution (θ_D) generated by the *mixture model* (MM). Hence, the keywords with high distinctiveness to the target domain contrasting with the context domain will be selected. However, one problem with this approach is that the selected keywords may fall short in representing the target domain by only selecting some redundant distinctive keywords.

To solve the above problem, we view the subset selection as a *distribution coarsening* problem. Specifically, we want to use a subset to estimate the candidate distribution (i.e., coarsened distribution). As defined in the previous section, a domain is a distribution of keywords (i.e., candidate distribution). Therefore, for a subset of keywords to represent the domain, the coarsened distribution by the subset should closely approximate the candidate distribution of that domain.

Formally, let $\mathcal{P} = \{p(t_i) \cdots p(t_N)\}$ be the candidate distribution, we compute a coarsened distribution $\tilde{\mathcal{P}} = \{\tilde{p}(t_i) \cdots \tilde{p}(t_N)\}$ by subset S and $\tilde{p}(t_i)$ for each $t_i \in V$ is calculated as:

$$\tilde{p}(t_i) = \sum_{t_j \in S} p(t_i|t_j)p(t_j), \tag{2}$$

where $p(t_i|t_j)$ refers to the probability of *semantically translating* t_j into t_i. This idea of estimating the probability of each keyword from candidates by a subset is adapted from the statistical machine translation from the same language used in information retrieval (Berger and Lafferty, 1999).

Now to find the subset, we introduce an optimization problem with objective of selecting a subset (S) with size k from candidates (V) that minimizes the difference between the LLV of generating $\mathcal{C}$ by $\mathcal{P}$ and $\tilde{\mathcal{P}}$, respectively. We know that the LLV of generating $\mathcal{C}$ by $\mathcal{P}$ is $\log p(\mathcal{C}) = \sum_{i \in V} c(t_i, \mathcal{C}) \log p(t_i)$ where $c(t_i, \mathcal{C})$ is the frequency of t_i in $\mathcal{C}$. Similarly, the LLV of generating $\mathcal{C}$ from $\tilde{\mathcal{P}}$ is $\log \tilde{p}(\mathcal{C})$. Hence, given $|S| = k$, our optimization objective is:

$$\begin{aligned} S &= \arg\min_{S \subseteq V} \| \log p(\mathcal{C}) - \log \tilde{p}(\mathcal{C}) \| \\ &= \arg\min_{S \subseteq V} \| \sum_{t_i \in V} c(t_i, \mathcal{C}) \log \frac{p(t_i)}{\tilde{p}(t_i)} \| \\ &= \arg\min_{S \subseteq V} \| \sum_{t_i \in V} p(t_i) \log \frac{p(t_i)}{\tilde{p}(t_i)} \| \\ &= \arg\min_{S \subseteq V} D_{KL}(\mathcal{P} \| \tilde{\mathcal{P}}) = \arg\min_{S \subseteq V} \phi(S), \end{aligned} \tag{3}$$

where $\phi(S)$ is our objective function, and $D_{KL}(\mathcal{P} \| \tilde{\mathcal{P}})$ is Kullback–Leibler (KL) divergence (Kullback and Leibler, 1951) between $\mathcal{P}$ and $\tilde{\mathcal{P}}$.

From (2), one obvious question is how to calculate $p(t_i|t_j)$. For this, we use *mutual information* (MI) to estimate $p(t_i|t_j)$ inspired from (Karimzadehgan and Zhai, 2010) where MI is used to estimate a similar model for information retrieval. MI is a good measure to judge relatedness between two terms. In our model, for any two terms t_i and t_j, we first compute MI ($I(t_i; t_j)$) between them and normalize it into a probability as below:

$$I(t_i; t_j) = \sum_{b_i, b_j} p(b_i, b_j) \log \frac{p(b_i, b_j)}{p(b_i)p(b_j)}, \tag{4}$$

$$p(t_i|t_j) \approx p_{MI}(t_i|t_j) = \frac{I(t_i; t_j)}{\sum_{t'_j \in V} I(t_i; t'_j)}, \tag{5}$$

where b_i is a binary variable indicating the presence/absence of t_i. E.g., $p(b_i = 1)$ indicates the ratio of documents containing t_i and $p(b_i = 1, b_j = 1)$ indicates the ratio of documents where both t_i and t_j co-occur. Here, $p_{MI}(t_i|t_j)$ gives us the probability of how t_j relates to t_i; intuitively, this probability would be higher when these two terms frequently co-occur in the same document in the target corpus.

Optimization. We are interested in finding a subset S with size k from V such that $\phi(S)$ is minimized, i.e., $\arg\min_{S \in V} \phi(S)$ s.t. $|S| = k$. This is referred as the *cardinality-constrained optimization* and proven to be NP-hard (Feige, 1998). However, if the objective function $\phi(S)$ is monotone and submodular, a simple greedy algorithm is guaranteed to obtain an approximation of $1 - \frac{1}{e}$. We call a non-negative real valued function F (to be maximized) *submodular* if it has the property of *diminishing returns* that is $F(X \cup \{v\}) - F(\{v\}) \geq F(Y \cup \{v\}) - F(\{v\})$ for all $v \in V$ and $X \subseteq Y \subseteq V$. Moreover, F is said to be *monotone* if $F(X) \leq F(Y)$ for all $X \subseteq Y$.

Theorem 1. *For minimizing the objective function $\phi(\cdot)$, a simple greedy algorithm obtains an approximation guarantee of $1 - \frac{1}{e}$.*

Proof. The proof can be found in Appendix A. ☐

So, as per Theorem 1, we can obtain a near optimal solution using a simple greedy algorithm. Initially, we have $S = \emptyset$, then iteratively update $S = S \cup \arg\max_{t \in V \setminus S} \mathcal{G}(t|S)$ until $|S| = k$ where $\mathcal{G}(t|S) = \phi(S) - \phi(S \cup t)$ is the gain of adding a new term t to S. Thanks to the submodularity property of $\phi(\cdot)$, this simple greedy algorithm can further be accelerated by lazy greedy algorithm (Minoux, 1978). More specifically, instead of recomputing $\mathcal{G}(t_i|S), \forall t_i \in V$ in every step, we use a priority queue of sorted gains $g(t_i), \forall t_i \in V$. Starting with $g(t_i) = -\phi(\{t_i\}), \forall t_i \in V$, the algorithm adds a term t_i to S if $g(t_i) \geq \mathcal{G}(t_i|S)$, otherwise we update $g(t_i)$ to $\mathcal{G}(t_i|S)$ and resort the priority queue. This largely improves the efficiency of the algorithm.

4 Experiments

This section evaluates our models from different perspectives: (1) the ability to select representative summary keywords for a target domain; (2) the performance for trending keywords selection task in a domain for different time frames.

4.1 Experiment Setup

Datasets. In our experiments, to test the generality of the proposed approaches, we use two document collections from two domains for constructing target and context corpora for each of the domains. One is abstracts collections from the *arxiv* repository (version 47)[4], and the other is a collection of newsgroup documents[5].

Candidate Keywords. In our experiments, we use different sets of candidate keywords. For the CS domain, we collected keywords from two external sources named Springer and Aminer (Tang et al., 2008). The Springer CS keyword list is collected through web scraping from Springer[6] and trimmed to 83K based on frequency ≥ 5. The Aminer keyword list is the collection of keywords assigned by authors in CS research papers, and there are approximately 50K keywords in this list. Alongside keywords from external sources, we also created candidate sets extracted from concerning corpus using AutoPhrase (Shang et al., 2018) tool. All the candidate keywords are lemmatized, and several filtering rules are used. For instance, keywords containing only letters, numbers, hyphens are used; stop and single-letter words are removed.

Baselines. We compare our models with the following four baseline keyword selection algorithms.

- **Relative Frequency (RF):** Since a keyword is likely to be domain representative when it frequently appears in a domain corpus, we consider a simple approach that selects the top k frequent keywords based on the relative frequency calculated from the target corpus.
- **Log-odds (LO):** We adapted a method (Monroe et al., 2008) for keyword selection which was introduced to compare words used by two political parties. Recently, (Hughes et al., 2020) used this method for detecting trending terms in *Cybersecurity* forum discussion. In this baseline, we adapt this method to model keywords as a function of a particular domain or time to compute the likelihood of keywords in that domain or time as log-likelihoods ("log-odds").
- **Page Rank (PR):** This baseline is a graph-based keyword selection method using PageRank (Mihalcea and Tarau, 2004). We build the graph of candidate keywords where each edge weight denotes how closely two keywords are related.

---

[4] https://www.kaggle.com/Cornell-University/arxiv

[5] http://qwone.com/ jason/20Newsgroups

[6] https://www.springer.com/gp

- **Facility Location (FL) Function:** Facility location function is a representation based subset selection measure (Mirchandani and Francis, 1990) used for finding a representative subset of items. Recently, this measure is used for training-data subset selection (Kaushal et al., 2019). In this paper, we adapt this measure as a baseline for selecting subset from candidate keywords set. Specifically, denoting $rel(t_i, t_j)$ as the relatedness of two keywords t_i and t_j, the objective is to select a subset $S \in V$ that maximizes FL function $f(S) = \sum_{t_i \in V} \max_{t_j \in S} rel(t_i, t_j)$.

Proposed Models. We have the following three variants of our proposed framework.

- **KL divergence + RF ($\mathbf{KL_{rf}}$):** This model is a simple version of our proposed objective function $D_{KL}(\mathcal{P} \| \tilde{\mathcal{P}})$ defined in (3). In this model, $\mathcal{P}$ is the relative frequency distribution calculated from the target corpus and $\tilde{\mathcal{P}}$ is coarsened distribution defined in (2).
- **Mixture Model (MM):** In this proposed model, keywords are ranked based on the estimated distribution for the target domain contrasting with a context domain using the mixture model defined in Section 3.1. Based on the distribution, the top k keywords are selected.
- **KL Divergence + MM ($\mathbf{KL_{mm}}$):** This proposed model is similar to $\mathbf{KL_{rf}}$. In $\mathbf{KL_{mm}}$, instead of using relative frequency, the mixture model estimated keyword distribution is used as $\mathcal{P}$ in $D_{KL}(\mathcal{P} \| \tilde{\mathcal{P}})$.

Implementation Details. There are some parameters both in baselines and the proposed models we have to set. E.g., the mixing weight λ for the background model in the mixture model is set to two different values based on the specificity of the target domains. Particularly, when we set λ to a small value, the model favors frequent non-informative terms (i.e., domain-specific stop words). Therefore, the larger values are set for λ. In our experiments, for a broad domain like CS, we set λ to 0.9, and for more specific domains (i.e., AI and subtopics in newsgroup), we set λ to 0.99. The reason for these two different values of λ is that more specific domains demand larger λ for selecting distinctive keywords. For optimizing MM, we use Expectation-Maximization (EM) algorithm (Dempster et al., 1977). Since EM does not guarantee the global maxima, in our experiment, we run the algorithm multiple times with random initialization, and the one with the best MLE is chosen to reduce the chance of getting local maxima. As we use mutual information (MI) based on document co-occurrence statistics in our model (defined in (5)), for the fair comparison, in the baseline FL, we also use MI between two keywords t_i and t_j to encode the relatedness between them (i.e., $rel(t_i, t_j)$). Similarly, MI is used for computing edge weight in the PR method.

Table 1: Category correspondence results

4.2 Experiment Results

4.2.1 Summary Keywords Selection

We conduct both quantitative and qualitative studies to evaluate the ability of proposed models to select domain representative summary keywords. For this purpose, we use the abstracts from the arxiv under CS categories as the target corpus. The context corpus is composed of all abstracts in the arxiv repository.

Quantitative Evaluation. We create keyword summaries for the CS domain with varying sizes (k) for quantitative evaluation. We collected 52 known category keywords from arxiv categories as CS representative ground keywords to evaluate the ability of selected k summary keywords to represent the target domain when k varies. The correspondence between k selected keywords $S = \{t_1 \cdots t_k\}$ and m category keywords $C = \{c_1 \cdots c_m\}$, $CC(S, C)$ is calculated as the summation of the pairwise normalized mutual information (NMI) (Bouma, 2009) between S and C i.e., $CC(S, C) = \sum_{i,j} \frac{I(t_i;c_j)}{H(t_i;c_j)}$ where $I(t_i; c_j)$ is calculated following formula from (4) and $H(t_i; c_j) = -\sum_{b_i, b_j} p(b_i, b_j) \log p(b_i, b_j)$ is the joint entropy of t_i and c_j.

From the results on Table 1, using AutoPhrase extracted candidate keywords, we can see that even though no supervision is used, our methods $\mathbf{KL_{mm}}$ and MM select keywords that best correspond with the known categories outperforming all the baselines (similar results from two more candidate sets are shown in Appendix B). We ob-

Table 4: Results generated using Google Trends

serve that there is a good improvement of result from MM to $\mathbf{KL}_{\mathbf{mm}}$. However, this is not true for $\mathbf{KL}_{\mathbf{rf}}$ and the RF baseline. The reason is that the relative frequencies from the target corpus favor the non-distinctive common keywords (e.g., *model* and *method*). As described in Section 3.2, $\mathbf{KL}_{\mathbf{rf}}$ tries to select the subset of keywords that best estimate the original candidate distribution. Hence, it also favors those common keywords to attain the nearest estimation of the original distribution.

On the other hand, the MM-generated distribution assigns larger probabilities to distinctive keywords of the target domain, contrasting with the context domain. Therefore, selecting a keyword subset by $\mathbf{KL}_{\mathbf{mm}}$ with close estimation of the MM generated distribution also favors distinctive keywords with the domain representative objective. Furthermore, one interesting observation is that when k is smaller, the selected keywords by $\mathbf{KL}_{\mathbf{mm}}$ tend to summarize the domain better than that of MM. The primary reason for this is that $\mathbf{KL}_{\mathbf{mm}}$ prefers to select more non-redundant keywords than MM while k is smaller, which we later discuss from Table 2.

Qualitative Evaluation. For the qualitative evaluation, we show the summary keywords selected by different algorithms in the CS domain from AutoPhrase extracted candidate keywords in Table 2 (simmilar additional results are shown in Appendix C). This study aims to observe the difference between the proposed models and baselines in selecting summary keywords. We can see that our models (MM and $\mathbf{KL}_{\mathbf{mm}}$) outperform all the baselines by selecting the most number of CS representative keywords. We also observe that the LO baseline method also selects a comparable amount of distinctive keywords. The reason is its use of a contrastive method like MM for selecting keywords for a particular corpus compared to a context corpus.

However, our models MM and $\mathbf{KL}_{\mathbf{mm}}$ tend to select more representative keywords than the LO method. E.g., we can see that our methods select keywords like *privacy*, *software* and *convolutional neural network* instead of keywords that LO selects like *graph* and *paper*, *data*. Another observation is that the keywords selected by PR are mostly those keywords (i.e., *experimental*, *data* and *function*) that have a broad association with other words. However, these keywords as an unit do not convey much information about the domain.

Now to see the difference between our models MM and $\mathbf{KL}_{\mathbf{mm}}$, we see the difference between their selected keywords. As stated before, we can

Keywords representative of its corresponding time frame are **highlighted** (annotated by authors).

Table 5: Keyword summaries (top 20 keywords) of three different time frames in AI domain

see $\mathbf{KL_{mm}}$ prefers non-redundant keywords than MM. E.g, $\mathbf{KL_{mm}}$, instead of selecting *deep neural network* as it already selects keywords like *neural network* and *deep learning*, it selects a different keyword *software* where MM prefers redundant keyword *deep neural network*. Therefore, while the only requirement is to rank keywords based on their distinctiveness for a target domain contrastive with a context domain, MM is more practical to use. On the other hand, if the objective is also selecting diverse representative keywords, $\mathbf{KL_{mm}}$ is preferable. See Appendix D for more qualitative study using newsgroup dataset.

4.2.2 Trending Keywords Selection

As an important application of our problem, we evaluate the performance of proposed approaches for *trending keywords selection* in the AI domain. This study conducts quantitative and qualitative evaluations considering three different time frames: 2000-2009, 2010-2019, and 2020-2021. For this purpose, we compose a corpus representative of each of the specified time frames by collecting abstracts from the Arxiv repository under AI-related categories: cs.AI, cs.CL, cs.CV, cs.IR, cs.LG, cs.NE and cs.RO. The entire dataset under all CS categories is used for the context corpus.

Quantitative Evaluation. Since there is no ground truth trending keywords available for the AI domain, it is not easy to quantitatively evaluate the selected ones for a specific time. Instead, we have created three ground truth sets by collecting related keywords from topic areas used in the call for papers (CFP) of an AI conference called AAAI[7] over the three specified time frames. However, the topics that appear in the CFP are not necessarily trending topics, and many topics appear throughout all the time frames. For this, we collect only the changing topics from a time frame to another. Further, to expand the ground truth sets, we also add keywords related to the collected topics. E.g., *word embedding* was a popular keyword in NLP during the 2010s, and one related of this is *word2vec*.

Evaluation using Ground Truths. For evaluation, we compute the selected keywords' ability to cover the ground truth keywords using a *representativeness* measure. Formally, similar to (Kaushal et al., 2019), say s_{ij} denotes the similarity between two keywords t_i and t_j, $R(S) = \frac{1}{|\mathcal{G}|} \sum_{t_i \in \mathcal{G}} \max_{t_j \in} s_{ij}$ is used as the *representativeness* score of selected keyword set S to represent the ground truth set $\mathcal{G}$. For s_{ij}, we compute the cosine similarity between vector representation of t_i and t_j. The vector for

---

[7] https://www.aaai.org/

each keyword is the concatenation of two word-vectors; one is word2vec (300d) (Mikolov et al., 2013) learned from corresponding corpus, and the other is the compositional GloVe embedding (Pennington et al., 2014) (element-wise addition of the pre-trained 300d word embeddings). The reason for using pre-trained word vectors is that many keywords in ground truth sets do not appear in the corresponding corpus, and thus vectors cannot be learned from that corpus. Table 3 shows the detailed results over three time frames. We can see that our proposed model $\mathbf{KL_{mm}}$ outperforms the other methods with large margins followed by MM.

Evaluation using Google Trends. Alongside using ground truths, we also design a quantitative evaluation measure (shown in Table 4) using Google Trends (GT) API[8]. GT[9] awards a score for a term called *interest over time* that expresses the term's popularity over a specified time range. Since GT does not have data before 2004, we have to use data from 2004 till 2009 for the 2000-2009 time frame. As our three specified time frames are not equal, we first take the average of provided interest scores for each keyword in each time frame to make the score comparable across different time frames. Then, we calculate the probability of each term's interest over three specified time frames. Finally, the average of computed probability scores of 50 selected terms is calculated for each method. This score represents the average probability of selected terms to be trending in each time frame. From Table 4, we can see that our method $\mathbf{KL_{mm}}$ achieves the best score over others, followed by comparable results from MM. It indicates that our solutions are more appropriate in finding trending keywords for a specified time frame.

Qualitative Evaluation. We qualitatively evaluate the performance of different algorithms by directly comparing their selected keywords in each time frame from Table 5. We can see PR selects keywords that are either CS stop words or the keywords that are not distinctive for a perspective time frame compared to others (similar results by RF, FL, $\mathbf{KL_{rf}}$). Because PR primarily depends on the popularity of a keyword and some keywords always appear frequently in any time frames (e.g., *task*, *dataset*, *model*, *etc*). Here, the LO again provides comparable results. E.g., similar to our methods MM and $\mathbf{KL_{mm}}$, LO also can select very relevant trending keywords during the 2020s like *covid 19*. However, while selecting trending keywords, the LO also tends to select many domain-specific stop words overlapped over different time frames (e.g., *method, task, model*). As discussed before, the reason is that LO does not have the objective of representing the target domain. Therefore, it is not that effective in identifying trending keywords representative for a target domain compared to our models.

5 Conclusion

This paper proposes an approach for solving an important but understudied problem of a domain representative keywords selection from candidates contrasting with a context domain. Our approach utilizes a two-component mixture model mechanism followed by a novel subset selection optimization algorithm to tackle the problem. We believe this work will encourage the automated text structuring problem and help a wide range of downstream applications in NLP. For future research direction, we want to focus on adapting the proposed approach in a more challenging task like single document summarization where the scope of information is limited. Besides, our proposed techniques are general and thus can be used in many applications such as information extraction, topic modeling, and concept indexing. Exploration of those applications is an interesting future direction.

Table 9: Subtopics in each of the four topics in the newsgroup dataset

A Proof of Theorem 1

To prove this, we need to first show that $\phi(\cdot)$ is *submodular* and *monotone*. As, we are concerned on minimizing $\phi(\cdot)$, it is equivalent to maximizing $F(\cdot) = -\phi(\cdot)$. Hence, it is sufficient to prove that $F(.)$ is submodular and monotone. Let, $X \subseteq Y \subseteq V$ and $v \in V$, then we get

$$F(X \cup \{v\}) - F(\{X\}) =$$

$$\sum_{t_i \in V} p(t_i) \log \frac{\sum_{t_j \in X \cup \{v\}} p(t_i|t_j)p(t_j)}{p(t_i)}$$

$$- \sum_{t_i \in V} p(t_i) \log \frac{\sum_{t_j \in X} p(t_i|t_j)p(t_j)}{p(t_i)}$$

$$= \sum_{t_i \in V} p(t_i) \log \frac{\sum_{t_j \in X \cup \{v\}} p(t_i|t_j)p(t_j)}{\sum_{t_j \in X} p(t_i|t_j)p(t_j)}$$

$$= \sum_{t_i \in V} p(t_i) \log \frac{\sum_{t_j \in X} p(t_i|t_j)p(t_j) + p(t_i|v)p(v)}{\sum_{t_j \in X} p(t_i|t_j)p(t_j)}$$

$$= \sum_{t_i \in V} p(t_i) \log(1 + \frac{p(t_i|v)p(v)}{\sum_{t_j \in X} p(t_i|t_j)p(t_j)}).$$

Similarly, $F(Y \cup \{v\}) - F(\{Y\}) =$

$$\sum_{t_i \in V} p(t_i) \log(1 + \frac{p(t_i|v)p(v)}{\sum_{t_j \in Y} p(t_i|t_j)p(t_j)}).$$

As $X \subseteq Y$, then,

$$\sum_{t_j \in X} p(t_i|t_j)p(t_j) \leq \sum_{t_j \in Y} p(t_i|t_j)p(t_j).$$

Therefore, $F(X \cup \{v\}) - F(\{X\}) \geq F(Y \cup \{v\}) - F(\{Y\})$ which proves that $F(\cdot)$ is *submodular*. Moreover, we can show that $F(Y) - F(X) = \sum_{t_i \in V} p(t_i) \log \frac{\sum_{t_j \in Y} p(t_i|t_j)p(t_j)}{\sum_{t_j \in X} p(t_i|t_j)p(t_j)} \geq 1$. Hence, $F(Y) \geq F(X)$ for $X \subseteq Y \subseteq V$ which proves that $F(\cdot)$ is monotone. Therefore, it proves that minimizing $\phi(\cdot)$ using simple greedy algorithm guarantees an approximation of $1 - \frac{1}{e}$.

C Additional Qualitative Results on CS Domain

Results are shown in Tables 7 and 8.

D Evaluation Using Newsgroup Dataset

We use newsgroup dataset covering four known topics named *Religion*, *Recreation*, *Science* and *Politics*. In this study, we split the whole dataset into these four topic groups represented by their corpus and use the whole newsgroup dataset as our background corpus. Table 9 shows the subtopics for each of the four topics. For each topic, we show the selected top 20 keywords using different algorithms in Table 10. This study aims to evaluate the capability of the proposed models to select distinctive keywords for each topic compared to the baselines. We can see that almost all the keywords selected by our methods MM and $\mathbf{KL_{mm}}$ are distinctive for each topic relating closely with respected subtopics shown in Table 9 and do not overlap with other topics. Similarly, as previously, the results from LO come close to ours with some anomalies. For instance, our methods select informative keywords like *jesus christ*, *holy spirit* and *new testament* for *religion* topic rather than non-distinctive keywords like *word*, *man* and *son*.

Hierarchical Inductive Transfer for Continual Dialogue Learning

Abstract

Pre-trained models have achieved excellent performance on the dialogue task. However, for the continual increase of online chit-chat scenarios, directly fine-tuning these models for each of the new tasks not only explodes the capacity of the dialogue system on the embedded devices but also causes knowledge forgetting on pre-trained models and knowledge interference among diverse dialogue tasks. In this work, we propose a hierarchical inductive transfer framework to learn and deploy the dialogue skills continually and efficiently. First, we introduce the adapter module into pre-trained models for learning new dialogue tasks. As the only trainable module, it is beneficial for the dialogue system on the embedded devices to acquire new dialogue skills with negligible additional parameters. Then, for alleviating knowledge interference between tasks yet benefiting the regularization between them, we further design hierarchical inductive transfer that enables new tasks to use general knowledge in the base adapter without being misled by diverse knowledge in task-specific adapters. Empirical evaluation and analysis indicate that our framework obtains comparable performance under deployment-friendly model capacity.

1 Introduction

Neural dialogue models (Shang et al., 2015; Serban et al., 2016; Li et al., 2016) have drawn increasing attention due to their high commercial value. Previous work usually makes efforts to improve the diversity and coherence of the responses (Serban et al., 2017; Zhang et al., 2018a,c; Feng et al., 2020; Sun et al., 2021). However, the application of neural dialogue models also requires advanced conversation skills, and recently, a lot of work tries to enable models to express empathy (Zhou et al., 2018; Rashkin et al., 2019), be knowledgeable (Ghazvininejad et al., 2018; Dinan et al., 2019), and demonstrate consistent personalities (Qian et al., 2018; Zhang et al., 2018b, 2019). Specifically, the dialogue model is trained on a task-specific dataset to learn the corresponding conversation skill. However, with the increasing number of online chit-chat scenarios, the dialogue system is further expected to continually specialize in new tasks without sacrificing the performance on old tasks. Meanwhile, the dialogue system must keep its capacity as small as possible for the deployment on the computation resource–limited embedded devices.

Pre-trained models (Radford et al., 2018; Devlin et al., 2019) have successfully facilitated the learning of the downstream tasks in various fields. To address the challenge of continual dialogue learning, directly fine-tuning pre-trained models on each of the new dialogue tasks is a straightforward way to equip the dialogue system with new conversation skills continually. However, it explodes the capacity of the dialogue system because knowledge of new tasks need to be stored in new pre-trained models to avoid erasing knowledge of old tasks. A more advanced approach is to multi-task one pre-trained model on all old tasks and then fine-tune it on new tasks, which can alleviate the capacity problem and use general knowledge between old tasks to improve the model performance on new tasks (Smith et al., 2020). Nonetheless, these advantages come at the cost of performance decline on some old tasks due to knowledge interference between diverse tasks.

To tackle these problems, we propose a hierarchical inductive transfer framework to construct and deploy the dialogue system with fewer computational resources. The framework is inspired by the fact that the conversational skills are multi-layered, and while general skills, e.g., uttering fluent sentences, are necessary for all scenarios and the requisite for sophisticated skills, specialized skills, such as negotiating and debating, work for fewer occasions. In the hierarchy of conversational skills, the latter skills could be efficiently built upon

Findings of the Association for Computational Linguistics: ACL 2022, pages 693 - 699
May 22-27, 2022

the former skills if they are well-learned. However, considering it is difficult to determine the proper order of the skills and the skills needed for a dataset, we take the following practical approach.

We first introduce the adapter module, consisting of a small sub-net, into the pre-trained model. Each block of the pre-trained model is assigned two adapters inserted after the self-attention layer and the feed-forward layer. During training, adapters, as the only trainable parameters, learn knowledge of dialogue tasks, which avoids knowledge forgetting on pre-trained models and therefore keeps the capacity of the dialogue system almost constant as the number of dialogue tasks increases. Then, we separate the adapter into the base adapter and the task-specific adapter to avoid the performance decline of models on old tasks caused by knowledge interference between diverse tasks. The former is multi-tasked with old tasks to obtain general knowledge by regularization between diverse tasks, which facilitates the learning of new tasks. The latter is further fine-tuned on any dialogue task to learn the corresponding task-specific knowledge, which maintains the model performance on old tasks. Finally, the proposed framework significantly enhances the training efficiency due to the learning of dialogue tasks only being conducted via adapters.

2 Method

In this section, we first describe the vanilla adapter and how to apply it to the dialogue tasks and then present the hierarchical inductive transfer to learn general knowledge and task-specific knowledge.

2.1 Adapter for Continual Dialogue Learning

Directly fine-tuning pre-trained models for each of the new dialogue tasks will cause knowledge forgetting, and therefore each task requires a large set of parameters for maintaining the model performance on both old and new tasks. Compared with it, we keep the parameters of the pre-trained model fixed and use the adapter to learn new tasks. Adapters are inserted after the self-attention layer and the feed-forward layer of each block of the pre-trained model, illustrated in Figure 1:

$$\mathbf{h}^{l+1} = \mathrm{LN}\left(\mathbf{h}^{l} + \mathrm{Ada}\left(\mathrm{Fun}\left(\mathbf{h}^{l}\right)\right)\right), \tag{1}$$

where $\mathbf{h}^l$ and $\mathbf{h}^{l+1}$ represent the input and the output of sub-blocks, and $\mathrm{Fun}(\cdot)$, $\mathrm{Ada}(\cdot)$, and $\mathrm{LN}(\cdot)$ represent the function layer (i.e., the self-attention layer or the feed-forward layer), the adapter, and the layer norm, respectively.

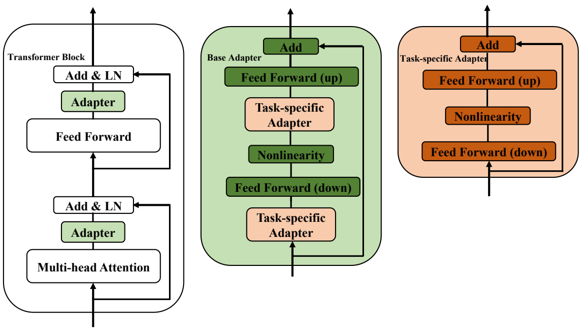

Figure 1: *An overview of the hierarchical inductive transfer framework.*

Each adapter consists of a bottleneck module with a skip-connection. Concretely, the bottleneck module first down-projects the d_o-dimension output of the previous layer into features with a smaller dimension, d_a, followed by a nonlinearity, and then up-projects to the original dimension. Formally, it can be expressed as:

$$\mathrm{Ada}(\mathbf{o}) = \mathbf{o} + W^{U} a\left(W^{D}\mathbf{o}\right), \tag{2}$$

where W^D ($d_o \times d_a$) and W^U ($d_a \times d_o$) are the parameters of the down- and the up-projections, and $a(\cdot)$ is the activation function. By adjusting the value of d_a, we can control the number of parameters of adapters to a deployment-friendly range.

For each new task, only a few parameters need to be trained on the cloud servers and delivered to the embedded devices, which significantly improves the training efficiency and reduces the size of the dialogue system. Please refer to Appendix B for a more detailed discussion.

2.2 Hierarchical Inductive Transfer

In continual dialogue learning, the old tasks usually contain useful knowledge for the learning of new tasks. But they may also have knowledge interference with new tasks. To alleviate this issue, one can multi-task the adapters with all old tasks and find general knowledge for new tasks. However, the regularization between diverse tasks also causes the performance decline of multi-tasked models on some old tasks due to knowledge interference among old tasks. Therefore, we further design a hierarchical inductive transfer framework that consists of two kinds of adapter, the base adapter and the task-specific adapter.

Specifically, we take the vanilla adapters as the base adapters and introduce a set of new adapters

Method	Θ	θ_Δ	ConvAI2	WoW	ED	BST	**Average**

Table 1: Comparison in terms of total number of additional parameters (Θ), trainable parameters per task (θ_Δ), and performance on tasks. The proposed AdaHIT achieves performance competitive with the state-of-the-art (MT+FT) with far fewer total parameters to be stored and parameters to be trained.

inserted before the feed-forward layers of each base adapter as the task-specific sub-adapters, shown in Figure 1. It can be formulated as:

$$\mathrm{Ada}_{\mathrm{bs}}(\mathbf{o}) = \mathbf{o} + W^U \mathrm{Ada}_{\mathrm{ts}}\left(a\left(W^D \mathrm{Ada}_{\mathrm{ts}}(\mathbf{o})\right)\right), \quad (3)$$

where $\mathrm{Ada}_{\mathrm{bs}}(\cdot)$ and $\mathrm{Ada}_{\mathrm{ts}}(\cdot)$ represent the base adapter and the task-specific adapter. Each task-specific adapter also consists of a bottleneck module and a skip-connection.

During training, we first multi-task the base adapters with all old tasks to find general knowledge and then fine-tune a set of task-specific adapters for each task, including old tasks and new tasks, which enables the new task to benefit from the knowledge of old tasks without sacrificing the model performance on some old tasks.

3 Experiment

3.1 Datasets and Baselines

Datasets To evaluate the proposed framework, we take **ConvAI2** (an extension of the PersonaChat dataset (Zhang et al., 2018b)), Wizard of Wikipedia (**WoW**) (Dinan et al., 2019), Empathetic Dialogues (**ED**) (Rashkin et al., 2019), and Blended Skill Talk (**BST**) (Smith et al., 2020) as an instance of continual dialogue learning. The first three tasks are the old tasks and the last task represents the new task.

Baselines Four methods of inductive transfer are used to compare with our framework (**AdaHIT**), including feature extraction (**FE**), which adds and optimizes a classification layer on the top of the pre-trained model (Vaswani et al., 2017), fine-tuning (**FT**), which updates all parameters of the pre-trained model for each task, multi-tasking with fine-tuning (**MT+FT**), which first multi-tasks the entire pre-trained model with all old tasks and then fine-tunes it on the new task, and vanilla adapter (**Ada**), which trains a set of adapters for each task.

3.2 Experimental Settings

Following Smith et al. (2020), we use the poly-encoder with 256M parameters (Humeau et al., 2019) as the underlying model, pretrain it on the pushshift.io Reddit dataset, and then conduct inductive transfer on the downstream tasks. We also truncate the length of label and text to 72 and 360, and set the embedding size to 768 as Smith et al. (2020). The batch size is 128 and the other responses in a batch are set as negatives for training. The dimension of adapters d_a is 64. We adopt AdaMax (Kingma and Ba, 2015) as the optimizer throughout the experiments, and the learning rates are 9e-4, 2.5e-3, 1e-3, and 4e-4 for ConvAI2, WoW, ED, and BST. The total training epochs are 8 with linear warm-up for 10% and linear decay for the rest. All experiments are conducted using ParlAI[1].

3.3 Experimental Results

For the retrieval-based dialogue scenarios, we measure hits@1/K[2] on the validation set of each task for automatic evaluation. The number of candidates is 20 for ConvAI2 and 100 for other tasks. The results reported in Table 1 show that AdaHIT achieves the best average performance, the same as MT+FT, at the cost of far fewer parameters to be trained and stored, indicating the superiority of deployment on embedded devices. AdaHIT significantly outperforms Ada in both old tasks and new task with a slight regression of computational efficiency, which demonstrates that the hierarchical inductive transfer can extract general knowledge to facilitate the learning of the new task while boosting the model performance on old tasks effectively.

3.4 Ablation Study and Analysis

Effect of Base Adapter To analyze the effect of the base adapter, we train it with different tasks, and then test it on BST in a zero-shot manner,

---

[1] `https://parl.ai/`

[2] hits@1/K represents recall@1 when choosing the gold response from K candidates.

Dataset for Adapter	BST (Zero-Shot)	BST (Fine-Tuning)
ConvAI2	0.753	0.8039
WoW	0.6222	0.7751
ED	0.6349	0.7846
MT	**0.768**	**0.8167**

Table 2: Effect of training datasets for the base adapter.

Number of Layers	1	2	3	4	5	6
AdaHIT	0.809	0.807	0.796	0.785	0.762	0.734

Position of Layers	0	2	4	6	8	10
AdaHIT	0.809	0.808	0.809	0.801	0.793	0.763

Table 3: Ablation Study in terms of number and position of removed adapters on BST.

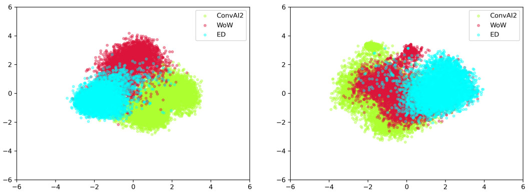

Figure 2: Visualization of learned sentence representations from AdaHIT with differently-trained base adapters. MT is on the left and ConvAI2 is on the right.

or a fine-tuning manner which is the same with AdaHIT. From the results in Table 2, we can observe that the base adapter with multi-tasking obtains the best performance under both the zero-shot and the fine-tuning setting, indicating that multi-tasking provides more general knowledge for the learning of BST. It is also worth mentioning that the base adapter trained on ConvAI2 achieves better performance than adapters on other tasks, because ConvAI2 contains more useful information, e.g., persona, that also exists every sample of BST.

Visualization To verify whether AdaHIT helps task adaption, we visualize the representations from models with different base adapters, i.e., trained on MT and ConvAI2, the result of which is shown in Figure 2. As we can see, the two models can both adjust to specific downstream tasks but representations with MT are better distributed and more tightly clustered. It is also interesting to see that the model with MT may implicitly distinguish the skills for each task, because while ED and ConvAI2 share more common skills, they are quite different from WoW, and such difference is evidently reflected by the visualization.

Ablation Study We further investigate the impact of adapters on model performance quantitatively. First, we gradually remove each trained adapter from the bottom layer, and then increase the number of removed adapters. As shown in Table 3, the adapters of higher layers have more significant effects than the adapters of lower layers, indicating that we can only insert the adapters into the higher layers to improve the training efficiency.

4 Related Work

Continual Dialogue Learning Neural dialogue models (Mou et al., 2016; Xing et al., 2017; Zhao et al., 2017; Shen et al., 2018; Feng et al., 2021) can acquire various kinds of conversation skills from corpora, such as characterizing personalities (Qian et al., 2018; Zhang et al., 2018b), expressing emotion and empathy (Zhou et al., 2018; Rashkin et al., 2019), and retrieving knowledge (Ghazvininejad et al., 2018; Dinan et al., 2019). Unlike existing work on enhancing a particular conversation skill, we work towards a new dialogue learning paradigm, where conversation skills are gradually embedded into a single model by mutual reinforcement instead of interference.

Inductive Transfer Continual learning in terms of transferring inductive knowledge from pre-trained models to downstream tasks can be categorized into feature-based, fine-tuning–based, and adapter-based (Ruder, 2019). We adopt the adapter-based approach that benefits from both pre-trained models and a small set of extra parameters for task-specific knowledge. Unlike conventional adapters (Houlsby et al., 2019; Poth et al., 2021; Pfeiffer et al., 2021), knowledge in the proposed adapters will be used to further boost the learning of new dialogue tasks, whereas knowledge of each task is separated into general and task-specific parts to avoid knowledge interference. Madotto et al. (2020) also uses the adapters to acquire the conversation skills, but it does not consider knowledge transfer and interference between adapters.

5 Conclusion

In this work, we propose a hierarchical inductive transfer framework to efficiently train and deploy the pre-trained models for growing numbers of new dialogue tasks requiring diverse skills. Considering the computation resource–limited embedded devices, we first adopt the adapter module, a small plug-in sub-net, as the only incremental and trainable parameters for learning each of the new dialogue tasks. To take advantage of knowledge in old tasks to facilitate the learning of new tasks, we further propose the hierarchical inductive transfer to alleviate knowledge interference between tasks and provide general knowledge for new tasks. Extensive experiments and analysis demonstrate that the proposed framework achieves high computational efficiency with competitive performance.

A Structure of Adapters

We have designed and evaluated diverse structures of adapters for continual dialogue tasks, such as the self-attention structure and the convolutional structure. However, there is no significant effect on performance, which is in line with previous adapter-based work. For the basic bottleneck structure, there are two advantages. First, it can limit the number of parameters per adapter by setting the bottleneck dimension $d_a \ll d_o$. Second, it also provides a flexible way to trade-off model performance with parameter efficiency.

Method	ConvAI2	WoW	ED
MT (B-FT)	0.8878	0.9274	0.6241
MT (A-FT)	0.8767	0.9094	0.6136

Table 4: Results on the old tasks. MT (B-FT) and MT (A-FT) represent the multi-tasking model before and after being fine-tuned on the new task, respectively

B Training Efficiency of Adapters

Compared with the traditional fine-tuning method, our framework conducts the learning of dialogue tasks only by adapters, which reduces the memory requirements and the computing operations of each batch and therefore trains more samples with the same time. For example, there is a two-layer network, and only the first layer is trainable:

$$y_1 = f(w_1 * x + b_1)$$

$$y_2 = f(w_2 * y_1 + b_2)$$

Although we still need to calculate $\frac{\partial y_2}{\partial y_1}$ due to the chain rule, we do not calculate $\frac{\partial y_2}{\partial w_2}$ and $\frac{\partial y_2}{\partial b_2}$ (i.e., reducing the computing operations) and do not save them (i.e., reducing the memory requirements) for the parameter update. Considering the number of parameters of Transformer, the proposed framework indeed improves the training efficiency. Moreover, we can only insert the adapters in the top layers because the adapters in the bottom layers have a weaker effect on the model performance, indicated by Table 3, which limits the chain derivative to the top layers and further reduces the computing operations.

ConvAI2	WoW	ED	BST	Average
0.8833	0.9233	0.6288	0.8342	0.8174

Table 5: Results of the model that is first pre-trained on the old tasks and then multi-tasked on all tasks.

C Knowledge Forgetting of FT

In order to demonstrate knowledge forgetting of the traditional fine-tuning method, we evaluate the performance of the multi-tasking model (MT) on the old tasks before and after being fine-tuned on the new task. As shown in Table 4, the model fine-tuned on the new task (BST) shows consistent performance degradation on the old tasks.

For a fair comparison, both our method (AdaHIT) and MT+FT are multi-tasked on the old tasks and then fine-tuned on the new task. We also provide the results of a stronger model that is first pre-trained on the old tasks and then multi-tasked on all tasks (i.e., both the old and the new tasks). The results of Table 5 show that AdaHIT still achieves comparable performance but consumes less computational cost.

Why Exposure Bias Matters: An Imitation Learning Perspective of Error Accumulation in Language Generation

Abstract

Current language generation models suffer from issues such as repetition, incoherence, and hallucinations. An often-repeated hypothesis for this brittleness of generation models is that it is caused by the training and the generation procedure mismatch, also referred to as exposure bias. In this paper, we verify this hypothesis by analyzing exposure bias from an imitation learning perspective. We show that exposure bias leads to an accumulation of errors during generation, analyze why perplexity fails to capture this accumulation of errors, and empirically show that this accumulation results in poor generation quality. [1]

1 Introduction

Large-scale neural language models have made great strides in a series of language generation tasks such as machine translation (Bahdanau et al., 2014; Vaswani et al., 2017; Raffel et al.), text summarization (See et al., 2017; Lewis et al., 2019; Zhang et al., 2019a), conversational dialog generation (Serban et al., 2015; Lowe et al., 2017; Roller et al., 2020; Zhang et al., 2020), etc.

However, despite the successes achieved by these models on several conditional generation tasks, they continue to suffer from degenerate behaviors such as repetition, a lack of diversity, dullness, and, incoherence, especially in open-ended generation settings such as text completion and dialog modeling (Holtzman et al., 2019). This degenerate behavior is often attributed to a mismatch between the *maximum likelihood training* and generation procedure mismatch (Welleck et al., 2019; Choi et al., 2020; Li et al., 2016).

Maximum likelihood training also referred to as *teacher forcing* (Williams and Zipser, 1989), factorizes the language model as a linear chain, and maximizes the log-likelihood of this factorized language model on a training corpus. During this maximum likelihood training, the model learns a distribution of the next tokens conditioned on the contexts from the ground-truth training data.

A concern with the MLE-based training is that the ground-truth contexts from the training corpus are not available during generation. Rather, the conditioning contexts during this phase comprise of tokens previously generated by the model itself. The distribution of these contexts seen during the generation phase might be very different from the ones encountered during the training phase. This mismatch is referred to as *exposure bias* (Ranzato et al., 2016; Bengio et al., 2015).

A side-effect of exposure bias is that an error at any step during generation might have a cascading effect as the next context will incorporate this erroneous prediction, deviating away from the ground truth context distribution leading to more errors. These errors will result in sequences that degenerate over the sequence length resulting in incoherent text, lack of vocabulary diversity, and detachment from the source sequence resulting in hallucination, and/or word- and phrase-level repetition.

There is an active debate in the language generation community on the impact of exposure bias in language generation. Authors have both validated (Xu et al., 2019; Zhang et al., 2019b) and questioned (He et al., 2019) the impact of exposure bias on language generation. Several approaches have been proposed to mitigate exposure bias (Ranzato et al., 2016; Shen et al., 2016; Bahdanau et al., 2017; Chen et al., 2020; Leblond et al., 2018; Welleck et al., 2019) but these have neither formalized exposure bias clearly nor provide any empiri-

Findings of the Association for Computational Linguistics: ACL 2022, pages 700 - 710
May 22-27, 2022

cal evidence that these methods mitigate the effect of exposure bias. Finally, previous works have linked exposure bias to out-of-domain (Wang and Sennrich, 2020) and out of distribution (Schmidt, 2019) generalization, and hallucinations (Wang and Sennrich, 2020) but these claims remain weak in absence of a clear and principled formalization of the exposure bias issue.

In this paper, we attempt to clarify this confusion by formalizing exposure bias in the terms of accumulation of errors and analyzing its impact on generation quality. We do this by providing a theoretically-grounded understanding of the exposure bias issue by analyzing it from an imitation learning perspective. We use this perspective to show that behavior cloning—an imitation learning algorithm is equivalent to teacher forcing under the choice of a particular loss function. We then exploit this equivalence to borrow the bound on error accumulation caused by behavior cloning and use it to quantify exposure bias and analyze the error accumulation in language generation.

Finally, we use this quantifiable definition of exposure bias to demonstrate that models trained using teacher forcing do suffer from an accumulation of errors. We also show, both analytically and empirically, why perplexity fails to capture this error accumulation, and how a lower exposure bias correlates with better generation quality.

2 Language Generation Formulation

Given a finite-sized vocabulary set $\mathcal{V}$, language generation is posed as a problem of generation a variable-length sequence $w_0^n \in \mathcal{V}^n$ from a languge model p_θ, either unconditionally or conditioned on the a source $\mathbf{x}$, using a decoding algorithm $\mathcal{F}$.

$$w_0^n = \mathcal{F}(p_\theta; \mathbf{x}) \tag{1}$$

Language modeling is the problem of learning this parameterized model p_θ, that approximates an oracle model o, such that decoding from the model p_θ mimics greedily sampling from the oracle o.

Maximum likelihood-based training factorizes the probability distribution model, $p_\theta(w_0^n)$, into a linear chain, i.e.,

$$p_\theta(w_0^n; \mathbf{x}) = \prod_{i=1}^{n} p_\theta(w_i | w_0^{i-1}; \mathbf{x}) p(w_0), \tag{2}$$

where w_i is the token to be generated at step i and w_0^{i-1} is the context at time i; i.e., all the tokens seen from step 0 to step $i-1$.[2]

During maximum likelihood training, the language model is trained by minimizing the negative log-likelihood on the corpus $\mathcal{D}$, i.e.,

$$\theta^* = \underset{\theta}{\operatorname{argmin}} \frac{-1}{|\mathcal{D}|} \sum_{w_0^n \in \mathcal{D}} \sum_{i=0}^{n} \log p_\theta(w_i | w_0^{i-1}), \tag{3}$$

where $|\mathcal{D}|$ is the number of tokens in the corpus.

Given a trained language model p_θ, the simplest strategy for generating a target sequence is to greedily sample the model i.e., at each step i, pick the most probable token $w_i = \arg\max p_\theta(\cdot | w_0^{i-1}; x)$—as its prediction. For the next step $i+1$, we use w_i to generate the context $w_0^i = w_0^{i-1} w_i$, and use it to predict the next token. This continues either until the maximum sequence length (T) is reached, or a special end of sequence token (EOS) is generated.

3 An Imitation Learning Perspective of Language Generation

In this section, we will present an imitation learning perspective of language generation. This framing will allow us to borrow theoretical machinery from imitation learning literature to formalize the exposure bias issue and quantify it in terms of accumulation of error due to procedural mismatch between MLE-based training and generation.

We start by posing language generation as a sequential decision-making problem and language modeling as an instance of imitation learning. We exploit these parallels to show behavior cloning—an imitation learning algorithm, is equivalent to teacher forcing under a choice of a particular loss function. We then exploit this equivalence to quantify the error accumulation due to exposure bias.

Language Generation is a Sequential Decision-Making Problem: A sequential decision-making problem can be formalized as learning a policy $\pi(a_t | s_t)$ over a space of actions $a_t \in \mathcal{A}$ and states $s_t \in S$ where the next state s_{t+1} is conditioned on the current state-action pair and is determined by the transition distribution $P(s_{t+1} | s_t, a_t)$. We can use this framework to pose language generation as an instance of a sequential decision-making problem with language model p_θ as the policy, contexts $w_0^{t-1} \in \mathcal{V}*$ as states, the next token prediction $w_t \in \mathcal{V}$ as actions, and concatination function as the transition function.

---

[2] As w_0 is usually a fixed SOS token, $p(w_0) = 1$. We will drop $p(w_0)$ from the subsequent equations for brevity.

This perspective allows us to appreciate the fact that, during generation, predictions at previous steps affect the next predictions, and error over time can cascade resulting in incoherent sequences.

Language Modeling is Imitation Learning: Imitation learning is a class of methods to solve a sequential decision-making problem while having access to the oracle policy o or data generated by the oracle, i.e., $\mathcal{D} = \{(s_t, a_t) | s_t \sim d_o^t, a_t \sim o(\cdot|s_t)\}$. Here, d_o^t is the oracle induced state-visitation distribution at time t. In imitation learning, an agent learns a model policy π that reproduces the expert policy o but on the state-visitation distributiond_π^t that has been induced by the model policy π, .

The sequential decision-making perspective of language generation allows us to pose language modeling as an instance of imitation learning—learning a model for a sequential decision-making problem with the help of an expert oracle (in RL-based methods) or using the data generated by the oracle (for MLE-based methods).

Teacher Forcing is Behavior Cloning: The assumption of access to an oracle is unrealistic in many scenarios. Behavior cloning is an approach to solve an imitation learning problem using only the training data generated by an oracle. In this setup, the state-action pairs in the training data are assumed to be identically and independently distributed. This is equivalent to reducing a sequential decision-making problem to a supervised multi-class classification learning problem.

Concretely, this learning problem can be seen as minimizing the expected per-step loss under the state distribution induced by the oracle:

$$L^{BC}(\pi) = \sum_{t=1}^{T} \mathbb{E}_{s_t \sim d_o^t} \left[l(s_t, \pi; o) \right] \tag{4}$$

$$\approx \frac{-1}{|\mathcal{D}|} \sum_{(s_t, a_t) \in \mathcal{D}} l(s_t, \pi; o), \tag{5}$$

Here, $L^{BC}(\pi)$ is the behavior cloning loss and $l(s, \pi; o)$ is the per-step loss.

Similary, in practical scenarios, language models are also trained on a finite training corpus, $\mathcal{D}$, that assumed to be generated by the oracle., i.e., $\mathcal{D} = \{(w_0^{t-1}, w_t) | w_0^{t-1} \sim d_o^{t-1}, w_t \sim o(\cdot|w_0^{t-1})\}$.

Maximum likelihood training loss from Equation 3, can be reformulated as learning the distribution over the next tokens, conditioned on the training contexts generated by the oracle, $w_0^{t-1} \sim d_o^{t-1}$:

$$L^{TF}(p_\theta) = \frac{-1}{|\mathcal{D}|} \sum_{(w_0^{i-1}, w_i) \in \mathcal{D}} \log p_\theta(w_i | w_0^{i-1}), \tag{6}$$

$$\approx \sum_{t=1}^{T} \mathbb{E}_{w_0^{t-1} \sim d_o^t} \left[-\log p_\theta(w_i | w_0^{i-1}) \right] \tag{7}$$

The behavior cloning loss (Equation 4) is equivalent to the language modeling loss (Equation 7) with $l(p_\theta, w_0^{t-1}; o) = -\log p_\theta(w_i | w_0^{i-1})$.

For our analysis though, we define per-step loss for language modeling, $l(p_\theta, w_0^{t-1}; o)$ as:

$$l(p_\theta, w_0^{t-1}; o) = \mathop{\mathbb{E}}_{w_t \sim o(\cdot | w_0^{t-1})} \log \frac{o(w_t | w_0^{t-1})}{p_\theta(w_t | w_0^{t-1})}, \tag{8}$$

This definition ensures that the per-step loss for oracle is zero, i.e., $l(o, w_0^{t-1}; o) = 0$.

The per-step loss function defined by equation 8 ensures that the behavior cloning loss, $L^{BC}(p)$, under our definition is equivalent to teacher forcing loss, $L^{TF}(p)$, up to a constant term. This equivalence of $L^{BC}(p)$ and $L^{TF}(p)$ ensures that the model learned by minimizing either of the two losses will be identical.

Language Generation is Policy Rollouts: During policy rollouts, an agent in state s_t, executes the action a_t, sampled from policy π, and ends up in state s_{t+1}. The agent's next state is dependent upon its own actions. This state evolution can be formulated as sampling from state-visitation distribution induced by the policy π, i.e., $s_{t+1} \sim d_\pi^{t+1}$.

The performance of policy π during rollouts can be measured using the loss (cost) of executing the policy π, i.e.,

$$L^{I}(\pi) = \sum_{t=1}^{T} \mathbb{E}_{s_t \sim d_\pi^t} \left[l(s_t, \pi; o) \right] \tag{9}$$

We can also formulate language generation in terms of policy rollouts from imitation learning. Mathematically, we can express generation as sampling contexts from model's context distribution, i.e., $w_0^{j-1} \sim d_{p_\theta, \mathcal{F}}^j$, and generating the next token w_j conditioned on w_0^{j-1}, using the decoding algorithm $\mathcal{F}$, i.e.,

$$\{w_j = \mathcal{F}(p_\theta, w_0^{j-1}) | w_0^{j-1} \sim d_{p_\theta, \mathcal{F}}^j\} \tag{10}$$

We can now define the inference-time loss, $L^I(p_\theta)$, as the accumulated T-step loss of model p_θ imitating oracle o on the context distribution induced by the model:

$$L^I(p_\theta) = \sum_{t=1}^{T} \mathop{\mathbb{E}}_{\substack{w_0^{t-1} \sim d^t_{p_\theta,\mathcal{F}} \\ w_t \sim o(\cdot|w_0^{t-1})}} \log \frac{o(w_t|w_0^{t-1})}{p_\theta(w_t|w_0^{t-1})}, \quad (11)$$

where $d^t_{p_\theta,\mathcal{F}}(w_0^t) := p_\theta(w_0^{t-1})$, is the context distribution at step t, induced due to use of model p_θ and the decoding algorithm $\mathcal{F}$, from step 1 to $t-1$.

4 Exposure Bias and Error Accumulation

Ranzato et al. (2016) defined exposure bias as a behavioral mismatch between maximum likelihood-based training and generation procedure. During maximum likelihood-based training, the next token distribution is conditioned on ground truth data whereas, during generation, it has to rely on the model's own previously generated tokens. They also postulated that this training and generation context distribution mismatch might result in an accumulation of errors during generation.

Intuitively, when the model produces a token w_i that makes the resulting context w_0^i unfamiliar, it might not be able to continue the generation adequately and is likely to produce another token which will further make the context flawed. This phenomenon reinforces itself as the context drifts further from what the oracle would produce, leading to an accumulation of errors.

In the imitation learning literature, the accumulation of errors while rolling out a policy trained using behavior cloning is analyzed in the terms of inference-time regret of the behavior cloning policy, π_{BC}, with respect to the oracle policy, o, (Ross and Bagnell, 2010; Ross et al., 2011) i.e.,

$$\mathcal{R}(\pi_{BC}) = L^I(\pi_{BC}) - L^I(o) \quad (12)$$

Let ϵ_t be the expected error of executing policy π at step t on the state-visitation distribution induced by the oracle o, i.e.,

$$\epsilon_t = \mathbb{E}_{s \sim d_o^t}[l(s, \pi; o)] \quad (13)$$

Let ϵ be the average expected error of executing policy π over T step, i.e., $\epsilon = 1/T \sum_{t=1}^{T} \epsilon_t$. Assuming $l(s, \pi, o)$ is an upper bound on $[0, 1]$ loss, we can bound the regret for a policy π_{BC} as,

$$T\epsilon \leq \mathcal{R}(\pi_{BC}) \leq T^2\epsilon. \quad (14)$$

The lower-bound in Equation 14 assumes no accumulation of error, hence an expected error of ϵ at each step, whereas the upper bound assumes the worst-case scenario, resulting in linear growth in error at each step and overall quadratic accumulative growth w.r.t. maximum sequence length T.

Relying on the imitation learning perspective of language generation presented in the previous section, we can now borrow this regret-based analysis from imitation learning literature to similarly bound the regret of a language generation model as

$$T\epsilon \leq \mathcal{R}(p_\theta, \mathcal{F}) \leq T^2\epsilon. \quad (15)$$

where p_θ is the model being used for generation, $\mathcal{F}$ is the decoding method being used for generation, $\epsilon = 1/T \sum_{t=1}^{T} \epsilon_t$ and ϵ_t is defined as

$$\epsilon_t = \mathop{\mathbb{E}}_{\substack{w_0^{t-1} \sim d_o^t \\ w_t \sim o(\cdot|w_0^{t-1})}} \log \frac{o(w_t|w_0^{t-1})}{p_\theta(w_t|w_0^{t-1})} \quad (16)$$

We will now use these bounds on the regret to analyze and quantify the error accumulation due to exposure bias in language generation.

5 Quantifying Error Accumulation due to Exposure Bias

In our analysis, we use two metrics, AccErr$_\leq(l)$ and %ExAccErr$_\leq(l)$ to measure the impact of error accumulation due to exposure bias.

We define accumulated errors up to length l, AccErr$_\leq(l)$, as

$$\text{AccErr}_\leq(l) = \mathcal{R}_{\leq l}(p_\theta, \mathcal{F})/\epsilon_{\leq l} \quad (17)$$

Here, $\mathcal{R}_{\leq l}(p_\theta, \mathcal{F})$ be the regret due to the use of language model p_θ and decoding method, $\mathcal{F}$, up to sequence length l, and $\epsilon_{\leq l} = 1/l \sum_{t=1}^{l} \epsilon_t$ is the expected per-step error up to length l.

This metric captures the growth of error w.r.t. sequence length l. If exposure bias does indeed leads to error accumulation, AccErr$_\leq(l)$ should grow super-linearly w.r.t. l.

We define our second metric, %ExAccErr$_\leq(l)$, as percentage of excess errors committed by the model that can be attributed to exposure bias, i.e.,

$$\%\text{ExAccErr}_\leq(l) = \frac{\mathcal{R}_{\leq l}(p_\theta, \mathcal{F}) - l\epsilon_{\leq l}}{l\epsilon_{\leq l}} * 100$$

Here, $l\epsilon_{\leq l}$ is the lower bound on the regret and is the minimum number of errors (ϵ per step) a model would make if there was no accumulation of errors.

$\%\text{ExAccErr}_{\leq}(l)$ allows us to compare models, training algorithms, and decoding strategies on the extra error that might be caused/mitigated by their use. A model, training algorithm, or a decoding strategy that perfectly mitigates the exposure bias will result in zero excess accumulated errors.

In the rest of the paper, we use these definitions to show: 1.) error accumulation in language generation is real, 2.) perplexity fails to capture this error accumulation, 3.) lower exposure bias correlates with a higher quality generation that is more coherent, uses diverse vocabulary, and is less repetitive.

6 Study Setup: Open-ended Generation

Text Completion Setup: Text completion is the standard experimental setup to measure the quality of generation in open-ended language generation (Holtzman et al., 2019; Welleck et al., 2019). It is also a generalization of a numerous practical language generation applications such as story generation (Fan et al., 2018), contextual text completion (Radford et al., 2019), dialog modeling (Zhang et al., 2018), etc.

Text completion models take a text passage or prefix $w_0^j \sim o$ as an input and generate a coherent continuation of the prefix, w_{j+1}^n using the language model p_θ and the decoding algorithm $\mathcal{F}$, i.e., $w_{j+1}^n = \mathcal{F}(p_\theta, w_0^j)$. In this paper, we use this text-completion setup to analyze the error accumulation due to exposure bias and it's correlation with language generation quality.

Language Model and Dataset: We conduct our analysis using the GPT2 language model (Radford et al., 2019). We use the GPT2-117M model as our evaluation language model and use train split of Wikitext-103 (Merity et al., 2016) for prompts. We rely on GPT-2 model fine-tuned on Wikitext-103 as our approximate oracle. We tokenize the Wikitext-103 dataset using GPT-2's tokenization scheme. We chunk Wikitext-103's train split into sequences of length 512. Of these, we use the first 50 tokens as prompts for our generation experiments and generate the completions to a maximum length of 512 or up to the end of the sequence token. We use a total of $20k$ prompts for our evaluation.

7 Results

7.1 Error Accumulation in Language Generation is Real!

Figure 1a plots $\text{AccErr}_{\leq}(l)$ w.r.t. sequence length, l. The support (dotted, orange line) $y = x$, captures the linear growth. It shows $\text{AccErr}_{\leq}(l)$ grows near-quadratically w.r.t. sequence length, empirically validating the theory that exposure bias would lead to accumulation of errors. Figure 1b, further strengthens this claim by demonstrating near-linear growth in excess errors w.r.t. to sequence length.

We hypothesize that these excess errors would manifest in the form of language degeneration, especially in the latter part of the sequence, and would cause issues such as hallucinations, limited vocabulary, and word- and phrase-level repetitions.

7.2 Perplexity is Not Enough

Perplexity is a standard measure used to evaluate the quality of a language model. It is often used as a proxy measure for the text generation quality of the language model. In this section, we argue perplexity paints an incomplete picture regarding a model's ability to generate high-quality coherent text. It only captures the average per-step error generalization gap (or lack of it) but fails to account for the error accumulation due to exposure bias. These accumulated errors, as seen in the previous section, can grow near-quadratically and can prove to be a major concern for any generation model that generates sequences longer than a few words.

Perplexity can be seen as scaled exponentiated average per-step error, ϵ, computed over a held-out test set, $\mathcal{D}_h$:

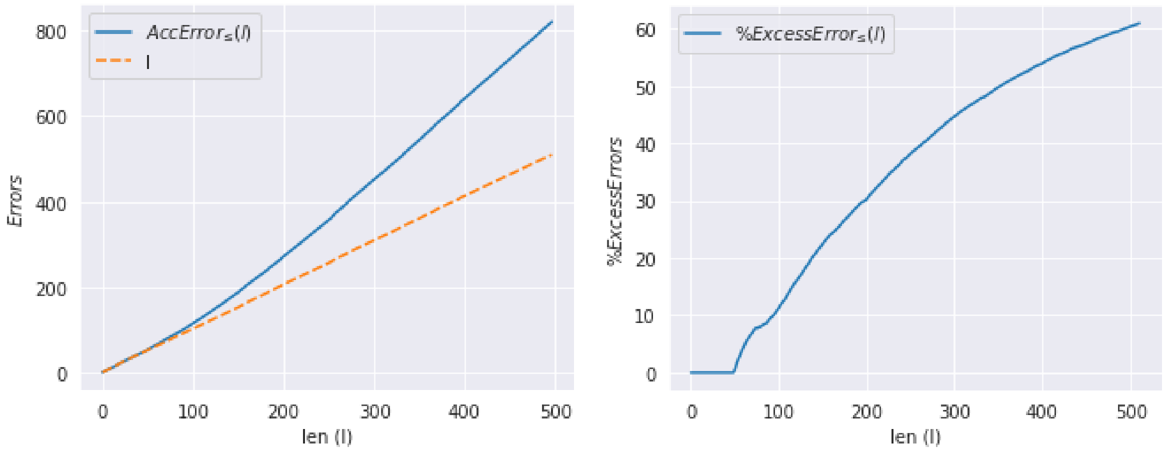
$$\epsilon = 1/T \sum_{t=1}^{T} \mathop{\mathbb{E}}_{\substack{w_0^{t-1} \sim d_o^t \\ w_t \sim o(\cdot|w_0^{t-1})}} \log \frac{o(w_t|w_0^{t-1})}{p(w_t|w_0^{t-1})}. \quad (18)$$

$$\approx \frac{-1}{|\mathcal{D}_h|} \sum_{(w_0^{i-1}, w_i) \in \mathcal{D}_h} \log p_\theta(w_i|w_0^{i-1}) + c, \quad (19)$$

$$= H(p_\theta; \mathcal{D}_h) + c.' \quad (20)$$

where $H(p_\theta; \mathcal{D}_h)$ is the entropy rate (log perplexity) of the model p_θ on held-out test set $\mathcal{D}_h$.

As entropy rate is a linear function of average per-step error, we hypothesize that it will only be able to measure the per-step generalization gap of the model and will fail to capture the error accumulation caused by reducing a sequential decision-making problem to a supervised learning problem.



(a) $AccErr_{\leq}(l)$ vs l

(b) %ExError$_{\leq}(l)$ vs l.

Figure 1: Figure 1a plots accumulated error till len l ($AccErr_{\leq}(l)$) w.r.t. l. This graph shows the quadratic growth of accumulated errors w.r.t to sequence length (l) as predicted by the theory. Figure 1b plots % excess errors due to error accumulation (%ExError$_{\leq}(l)$) caused by exposure bias. This indicates that **extra errors** due to exposure bias grows near-linearly with the sequence length, and decoding using greedy search results in over 70% more errors.

Search		Generation Quality

Human	-	0.0274	0.4338	-	28739

Table 1: Impact of error accumulation on generation quality. We observe that stochastic decoding methods not only lead to diverse language generation but also have lower exposure bias than the determinstic methods.

In Figure 2, we plot the entropy rate, $H(p_\theta; \mathcal{D}_h)_{\leq l}$, w.r.t. average per-step error, $\epsilon_{\leq l}$, and length-normalized regret up to length l, $\mathcal{R}_{\leq l}(p_\theta, \mathcal{F})/l$. We observe a strong correlation between the entropy rate and average per-step error ($\rho = 0.9997$) validating our theoretical observation that perplexity can capture the per-step generalization gap of language model p_θ. On the other hand, the length-normalized regret exhibit poor correlation with the entropy rate ($\rho = 0.4003$) indicating perplexity's failure to capture the error accumulation due to exposure bias.

A case in point of perplexity's inability to capture error accumulation is the degenerate behavior of GPT-2 (Radford et al., 2019) while generating moderately long sequence under greedy or beam search. This happens despite GPT2 having a low zero-shot perplexity on the held-out set of Wikitext-103 dataset (perplexity: 37.50), but despite this, it suffers from degeneration issues such as repetition, low vocabulary usage, and a lack of coherent generation. We hypothesize that the degenerate behavior of large pre-trained language models such as GPT-2 under greedy or beam search is the result of this accumulation of errors. An example of this behavior is presented in Table 2 where we observe GPT2 generating repetitive and incoherent text completion for a WikiText-103 prompt under deterministic decoding schemes such as greedy and beam decoding.

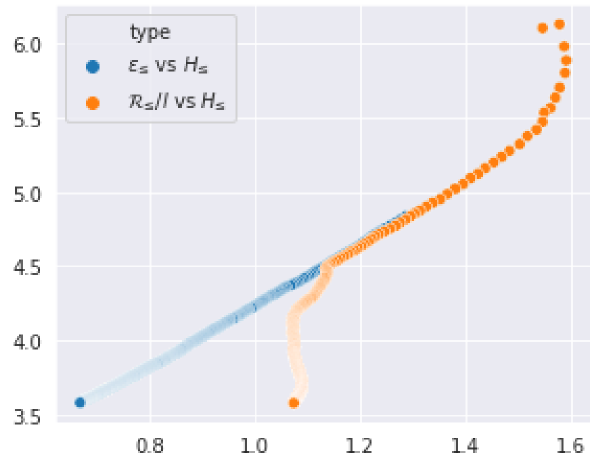

Figure 2: Analyzing (log) perplexity ($H_{\le l}$) w.r.t to average per-step error ($\epsilon_{\le l}$), and length-normalized exposure bias regret ($\mathcal{R}_{\le l}(p_\theta, \mathcal{F})/l$). We observe that perplexity strongly correlates with average per-step error ($\rho = 0.9997$), but it has a weaker correlation with length-normalized regret ($\rho = 0.4003$).

7.3 Error Accumulation impacts Generation Quality

Finally, we examine the hypothesis that poor text generation capabilities of pre-trained large language models under greedy decoding might be due to the error accumulation caused by a procedural mismatch between generation and maximum likelihood training (Vijayakumar et al., 2016; Welleck et al., 2019; Holtzman et al., 2019).

The regret-based definition of error accumulation allows us to analyze exposure bias along two axes of variation: the trained language model, p_θ, and the decoding algorithm, $\mathcal{F}$. In this set of experiments, we explore the impact of various decoding schemes on error accumulation due to exposure bias and the quality of the completed text.

Benchmarking various decoding strategies allows us to verify if an accumulation of errors does indeed lead to degeneration as the choice of decoding algorithm does not impact the average per-step error, ϵ, or held-out test set perplexity ($H(p_\theta; \mathcal{D}_h)_{\le l}$). This rules out the role of modeling and model training in language degeneration across different decoding algorithms. Hence, it is reasonable to causally link a decoding algorithm's resultant improvement on language generation to its ability to reduce error accumulation.

For quantitative analysis of the impact of various decoding algorithms on quality of language generation, we measure the completion quality by using the same metrics as Welleck et al. (2019), and these metrics are: 1.) **rep**/128 measures if the prediction token at step t occurs in previous 128 steps, 2.) **wrep**/128 counts the prediction's repetition at step t only if the predicted token is not the ground-truth token at that position, 3.) **seq-rep-4** measure the repetition at the 4-gram level, and 4.) **uniq** measure the vocabulary diversity by accounting for the number of unique tokens generated by the model.

Table 2: Examples of completions using various decoding methods. We observe that the deterministic decoding schemes produce less diverse, incoherent, and more repetitive (highlighted in red) text.

Table 1 shows that the use of stochastic sampling-based decoding algorithms results in diverse and more coherent language generation and a lower percentage of excess errors. Sampling with temperature (with temp=1.2) leads to the least amount of repetition (both at the token and the n-gram level), second highest vocabulary diversity, and the least amount of excess errors due to exposure bias. This also bears out from our qualitative analysis in Table 2 as sampling with temperature produces the most coherent text. Deterministic decoding schemes, in contrast, fare poorly in both reducing exposure bias and on language generation quality metrics, producing repetitive and incoherent text. These quantitative and qualitative experiments offer us evidence that reducing exposure bias does lead to more coherent text generation.

We hypothesize that the reasonable amount of randomness introduced by stochastic sampling helps the model avoid sampling the most likely token at each time step, thus avoiding possible divergent contexts that might have resulted in a degenerate completion in the future. We conjecture that this timely intervention restricts the generation context distribution from moving too far away from training context distribution helping it avoid compounding of errors. This is also borne out by qualitative analysis as a reasonable amount of stochasticity does result in texts which look more coherent and oracle-like. A broader analysis of this behavior though is beyond the scope of this work and is left for future work.

8 Related Work

Non-MLE Training Methods: Several approaches have been proposed to mitigate the exposure bias issue including RL-based optimization objectives (Ranzato et al., 2016; Shen et al., 2016; Bahdanau et al., 2017; Chen et al., 2020), learning to search (Leblond et al., 2018), energy-based models (Deng et al., 2020), imitation learning (Du and Ji, 2019), generative adversarial networks (Yu et al., 2017) and knowledge distillation (Liu et al., 2019). Although these methods motivate their approaches intending to reduce exposure bias, they neither formalize exposure bias clearly nor provide any empirical evidence that these methods mitigate the effect of exposure bias. In this paper, we proposed a quantifiable definition of exposure bias by analyzing the issue from a principled imitation learning perspective. This definition can be used or adapted to evaluate the various novel training and modeling approaches on their ability to do reduce exposure bias.

Smarter Decoding Methods: Large language models have unusually low test perplexities but they falter at coherent and diverse language generation specifically in open-ended language generation tasks especially while using deterministic decoding schemes. Several authors (Vijayakumar et al., 2016; Welleck et al., 2019; Holtzman et al., 2019) have hypothesized that training and inference mismatch due to MLE-based training is responsible for the degenerate behavior. They have proposed smarter decoding schemes to mitigate the side effects of exposure bias resulting in better generation quality. Despite this being an active area of research, this often-repeated hypothesis for degenerate generation behavior has not received serious treatment till now. In this paper, we take a step towards explaining this discrepancy and show that error accumulation due to exposure bias might be the reason for this degenerate behavior and explain why perplexity has a handicap in capturing this compounding of errors.

Analyzing Exposure Bias: Schmidt (2019) and Wang and Sennrich (2020) link exposure bias to generalization gap due to distribution and domain shift respectively. Performance degradation under domain and distribution shift is a major issue with language generation, and direct evidence supporting this hypothesis will provide insights into building more robust language generation models. Unfortunately, neither of the papers formalize the notion of exposure bias or empirically link the generalization gap to exposure bias directly.

Three recent papers, Xu et al. (2019); Zhang et al. (2019b); He et al. (2019), have tried to empirically evaluate the impact of exposure bias on language generation. The first two papers validate the existence of exposure bias whereas He et al. (2019) show language models have self-recovering ability negating the impact of exposure bias. All three analyses are based on the empirical definition of exposure bias which, in turn, is based on the informal formulation by Ranzato et al. (2016).

In this paper, we provide a principled and theoretically grounded approach to analyze exposure bias in language generation and show that it is indeed a problem and that it might explain the degeneration issue with large language models on open-ended tasks under deterministic decoding.

9 Discussion

In this paper, we analyze language generation from an imitation learning perspective. We use this analysis to arrive at a theoretical bound on error accumulation due to exposure bias. This bound predicts a super-linear growth in errors accumulation during generation due to exposure bias. In our experiments, we validate this bound and show that accumulation due to exposure bias indeed results in super-linear growth in errors.

We then show, both analytically and empirically, why perplexity is not enough to capture this accumulation of errors and hypothesize that this accumulation of errors is responsible for the degenerate language generation. Finally, we provide some evidence for this hypothesis by evaluating the impact of various decoding schemes on error accumulation and generation quality. We show that techniques that improve the generation quality do result in a lower error accumulation and causally link language generation quality to error accumulator due to exposure bias.

Our analysis provides a principled and theoretically grounded way to understand the exposure bias. We believe this analysis can pave way for developing smarter training and decoding algorithms to address this error accumulation resulting in more robust language generation models.

Question Answering Infused Pre-training of General-Purpose Contextualized Representations

Abstract

We propose a pre-training objective based on question answering (QA) for learning general-purpose contextual representations, motivated by the intuition that the representation of a phrase in a passage should encode all questions that the phrase can answer in context. To this end, we train a bi-encoder QA model, which independently encodes passages and questions, to match the predictions of a more accurate cross-encoder model on 80 million synthesized QA pairs. By encoding QA-relevant information, the bi-encoder's token-level representations are useful for non-QA downstream tasks without extensive (or in some cases, any) fine-tuning. We show large improvements over both RoBERTa-large and previous state-of-the-art results on zero-shot and few-shot paraphrase detection on four datasets, few-shot named entity recognition on two datasets, and zero-shot sentiment analysis on three datasets.

1 Introduction

While masked language models build contextualized word representations, they are pre-trained with losses that minimize distance to *uncontextualized* word embeddings (Peters et al., 2018; Devlin et al., 2019; Liu et al., 2019). This objective yields a good initialization for downstream fine-tuning, but the pre-trained representations themselves are not optimized for being immediately useful without fine-tuning. In this paper, we introduce Question Answering Infused Pre-training (QUIP), a new pre-training loss based on question answering (QA) that depends much more directly on context. QUIP learns improved token-level representations that are useful in zero-shot and few-shot settings, where extensive fine-tuning is not possible.

Our intuition for QUIP is that the contextualized representation for a phrase in a passage should contain enough information to identify all the questions that the phrase could answer in context. For example, in Figure 1, the representation for *Johannes Brahms* should be similar to the representation of all questions it can answer, such as "*Who wrote the violin concerto?*" We anticipate that optimizing passage representations for QA should benefit many downstream tasks, as question-answer pairs have been used as broad-coverage meaning representations (He et al., 2015; Michael et al., 2018), and a wide range of NLP tasks can be cast as QA problems (Levy et al., 2017; McCann et al., 2018; Gardner et al., 2019). For instance, our learned representations should encode whether a phrase answers a question like "*Why was the movie considered good?*", which corresponds to identifying rationales for sentiment analysis.

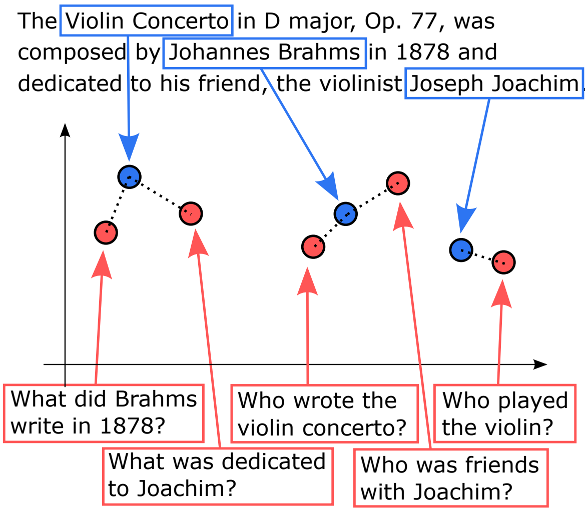

Figure 1: An overview of Question Answering Infused Pre-training. Our model independently creates vector representations (middle) for phrases in a passage (top) and for synthesized questions (bottom). Our objective encourages the vector for each phrase to have high similarity with the vectors for all questions it answers.

We train QUIP with a bi-encoder extractive QA objective. The model independently encodes passages and questions such that the representation of

Findings of the Association for Computational Linguistics: ACL 2022, pages 711 - 728
May 22-27, 2022

each phrase in a passage is similar to the representation of reading comprehension questions answered by that phrase. We use a question generation model to synthesize 80 million QA examples, then train the bi-encoder to match the predictions of a cross-encoder QA model, which processes the passage and question together, on these examples.

Bi-encoder QA has been used before for efficient open-domain QA via phrase retrieval (Seo et al., 2018, 2019; Lee et al., 2020, 2021), but its lower accuracy compared to cross-encoder QA has previously been viewed as a drawback. We instead view the relative weakness of bi-encoder QA as an opportunity to improve contextual representations via knowledge distillation, as self-training can be effective when the student model must solve a harder problem than the teacher (Xie et al., 2020). In particular, since the bi-encoder does not know the question when encoding the passage, it must produce a single passage representation that simultaneously encodes the answers to *all* possible questions. In contrast, while cross-encoder QA models are more accurate, they depend on a specific question when encoding a passage; thus, they are less suited to downstream use cases that require contextualized representations of passages in isolation.

We show that QUIP token-level representations are useful in a variety of zero-shot and few-shot learning settings, both because the representations directly encode useful contextual information, and because we can often reduce downstream tasks to QA. For few-shot paraphrase detection, QUIP with BERTScore-based features (Zhang et al., 2020) outperforms prior work by 9 F1 points across four datasets. For few-shot named entity recognition (NER), QUIP combined with an initialization scheme that uses question embeddings improves over RoBERTa-large by 14 F1 across two datasets. Finally, for zero-shot sentiment analysis, QUIP with question prompts improves over RoBERTa-large with MLM-style prompts by 5 accuracy points across three datasets, and extracts interpretable rationales as a side effect. Through ablations, we show that using real questions, a strong teacher model, and the bi-encoder architecture are all crucial to the success of QUIP. Other design decisions (e.g., question generation decoding strategies) do not qualitatively affect our main findings, pointing to the stability of the QUIP approach.[1]

2 QA Infused Pre-training

QA Infused Pre-training (QUIP) involves pre-training contextual representations with a bi-encoder extractive QA objective. In contrast with masked language modeling, QUIP's training objective directly encourages contextual representations to encode useful semantic information, namely information about what questions can be answered by each span. In contrast with a cross-encoder QA model, QUIP's bi-encoder is trained to encode single passages rather than passage-question pairs, making it more transferable to tasks involving single passages. Moreover, QUIP learns to push each phrase's representation far away from those of questions the phrase does *not* answer; this ability to represent unanswerability is crucial for correctly handling some question-based prompts.

We now introduce some basic notation (§2.1), then describe the QUIP pipeline, which consists of three steps: question generation (§2.2), cross-encoder teacher re-labeling (§2.3), and bi-encoder training (§2.4).

2.1 Notation

All models operate on sequences of tokens $x = [x_1, \ldots, x_L]$ of length L. By convention, we assume that x_1 is always the special beginning-of-sequence token. We learn an encoder r that maps inputs x to outputs $r(x) = [r(x)_1, \ldots, r(x)_L]$ where each $r(x)_i \in \mathbb{R}^d$ for some fixed dimension d. We call $r(x)_i$ the contextual representation of the i-th token in x.

In extractive question answering, a model is given a context passage c and question q, and must output a span of c that answers the question. Typically, models independently predict probability distributions $p(a_{\text{start}} \mid c, q)$ and $p(a_{\text{end}} \mid c, q)$ over the answer start index a_{start} and end index a_{end}.

2.2 Question Generation

Question generation model. We train a BART-large model (Lewis et al., 2020) to generate question-answer pairs given context passages. The model receives the passage as context and must generate the answer text, then a special separator token, then the question. This approach is simpler than prior approaches that use separate models for answer and question generation (Lewis and Fan, 2019; Alberti et al., 2019; Puri et al., 2020), and works well in practice.

---

[1] Code to reproduce all results can be found at `https://github.com/facebookresearch/quip`.

Training data. We train on the training data from the MRQA 2019 Shared Task (Fisch et al., 2019), which includes six datasets: HotpotQA (Yang et al., 2018), NaturalQuestions (Kwiatkowski et al., 2019), NewsQA (Trischler et al., 2017), SearchQA (Dunn et al., 2017), SQuAD (Rajpurkar et al., 2016), and TriviaQA (Joshi et al., 2017). These datasets cover many of the text sources commonly used for pre-training (Liu et al., 2019; Lewis et al., 2020), namely Wikipedia (HotpotQA, NaturalQuestions, SQuAD), News articles (NewsQA), and general web text (SearchQA, TriviaQA).

Generating questions. We run our question generation model over a large set of passages to generate a large dataset of question-answer pairs. We decode using nucleus sampling (Holtzman et al., 2020) with $p = 0.6$, which was chosen by manual inspection to balance diversity with quality of generated questions. We do not filter questions in any way. While we observed some flaws related to question quality (questions were not always well-formed) and diversity (for some passages, the same or very similar questions were asked multiple times), this approach nonetheless yielded good downstream results. Attempts to mitigate these issues, such as using a two-stage beam search to ensure that questions for the same passage have different answers, did not noticeably change our downstream results (see §4.8). We obtain passages from the same training corpus as RoBERTa (Liu et al., 2019), which uses four sub-domains: BOOKCORPUS plus Wikipedia, CC-NEWS, OPENWEBTEXT, and STORIES. For each domain, we sample 2 million passages and generate 10 questions per passage, for a total of 80 million questions.[2]

2.3 Teacher Re-labeling

The answers generated by our BART model are not always accurate, nor are they always spans in the context passage. To improve the training signal, we re-label examples with a teacher model, as is common in knowledge distillation (Hinton et al., 2015). We use a standard cross-encoder RoBERTa-large model trained on the MRQA training data as our teacher. The model takes in the concatenation of the context passage c and question q and predicts a_{start} and a_{end} with two independent 2-layer multi-layer perceptron (MLP) heads. We denote the teacher's predicted probability distribution over a_{start} and a_{end} as $T_{\text{start}}(c, q)$ and $T_{\text{end}}(c, q)$, respectively.

2.4 Bi-encoder Training

Finally, we train a bi-encoder model to match the cross-encoder predictions on the generated questions. This objective encourages the contextual representation for a token to have high similarity (in inner product space) with the representation of every question that is answered by that token.

Model. The bi-encoder model with parameters θ consists of of three components: an encoder r and two question embedding heads h_{start} and h_{end} that map $\mathbb{R}^d \to \mathbb{R}^d$. These heads will only be applied to beginning-of-sequence (i.e., `CLS`) representations; as shorthand, define $f_{\text{start}}(x) = h_{\text{start}}(r(x)_1)$ and likewise for f_{end}. Given a context passage c and question q, the model predicts

$$p_\theta(a_{\text{start}} = i \mid c, q) \propto e^{r(c)_i^\top f_{\text{start}}(q)} \quad (1)$$

$$p_\theta(a_{\text{end}} = i \mid c, q) \propto e^{r(c)_i^\top f_{\text{end}}(q)} \quad (2)$$

In other words, the model independently encodes the passage and question with r, applies the start and end heads to the `CLS` token embedding for q, then predicts the answer start (end) index with a softmax over the dot product between the passage representation at that index and the output of the start (end) head. We initialize r to be the pretrained RoBERTa-large model (Liu et al., 2019), which uses $d = 1024$. h_{start} and h_{end} are randomly-initialized 2-layer MLPs with hidden dimension 1024, matching the default initialization of classification heads in RoBERTa.[3]

Training. For an input consisting of context c of length L and question q, we train θ to minimize the KL-divergence between the student and teacher predictions, which is equivalent to the objective

$$-\sum_{i=1}^{L} T_{\text{start}}(c, q)_i \log p_\theta(a_{\text{start}} = i \mid c, q) \\ + T_{\text{end}}(c, q)_i \log p_\theta(a_{\text{end}} = i \mid c, q) \quad (3)$$

up to constants that do not depend on θ. We train for two epochs on the 80 million generated questions, which takes roughly 56 hours on 8 V100

---

[2] We estimate that using the entire corpus with these settings would generate around 900 million questions. We leave investigation of further scaling to future work.

[3] https://github.com/pytorch/fairseq/blob/master/fairseq/models/roberta/model.py

GPUs, or roughly 19 GPU-days.[4] For efficiency, we process all questions for the same passage in the same batch, as encoding passages dominates runtime. For further details, see Appendix A.1.

3 Downstream Tasks

We evaluate QuIP on zero-shot paraphrase ranking, few-shot paraphrase classification, few-shot NER, and zero-shot sentiment analysis. Different tasks showcase different advantages of QuIP. For paraphrase detection and NER, QuIP succeeds by learning meaningful token-level contextualized representations for single passages, whereas MLM representations are trained to reconstruct uncontextualized word embeddings, and the cross-encoder QA model is trained to represent passage-question pairs. For NER and sentiment analysis, we prompt QuIP with questions, leveraging its question-answering abilities. Compared with a cross-encoder, QuIP's bi-encoder architecture enables a more efficient way to use question prompts in NER, and yields more reliable scores when questions are unanswerable in sentiment analysis. We focus on zero-shot and few-shot settings, as these require pre-trained models that are useful without fine-tuning on a large task-specific training dataset. QuIP addresses this need by anticipating what information might be useful for downstream tasks—namely, information found in question-answer pairs.

3.1 Paraphrase Ranking

We first evaluate QuIP token-level representations by measuring their usefulness for zero-shot paraphrase ranking. In this task, systems must rank sentence pairs that are paraphrases above pairs that are non-paraphrases, without any task-specific training data. We compute similarity scores using the F_{BERT} variant of BERTScore (Zhang et al., 2020), which measures cosine similarities between the representation of each token in one sentence and its most similar token in the other sentence. Given sentences x_1 and x_2 of lengths L_1 and L_2, define

$$B(x_1, x_2) = \frac{1}{L_1} \sum_{i=1}^{L_1} \max_{1 \leq j \leq L_2} \frac{r(x_1)_i^\top r(x_2)_j}{\|r(x_1)_i\| \|r(x_2)_j\|}.$$

The F_{BERT} BERTScore is defined as the harmonic mean of $B(x_1, x_2)$ and $B(x_2, x_1)$. Zhang et al. (2020) showed that BERTScore with RoBERTa is useful for both natural language generation evaluation and paraphrase ranking. Since BERTScore uses token-level representations, we hypothesize that it should pair well with QuIP. As in Zhang et al. (2020), we use representations from the layer of the network that maximizes Pearson correlation between BERTScore and human judgments on the WMT16 metrics shared task (Bojar et al., 2016).

3.2 Paraphrase Classification

We use either frozen or fine-tuned QuIP representations for few-shot paraphrase classification, rather than ranking. Through these experiments, we can compare QuIP with existing work on few-shot paraphrase classification.

Frozen model. We train a logistic regression model that uses BERTScore with frozen representations as features. For a given pair of sentences, we extract eight features, corresponding to BERTScore computed with the final eight layers (i.e., layers 17-24) of the network. These layers encompass the optimal layers for both RoBERTa-large and QuIP (see §4.4). Freezing the encoder is often useful in practice, particularly for large models, as the same model can be reused for many tasks (Brown et al., 2020; Du et al., 2020).

Fine-tuning. For fine-tuning, we use the same computation graph and logistic loss function, but now backpropagate through the parameters of our encoder. For details, see Appendix A.2.

3.3 Named Entity Recognition

We also use QuIP for few-shot[5] named entity recognition, which we frame as a BIO tagging task. Since questions in QA often ask for entities of a specific type, we expect QuIP representations to contain rich entity type information. We add a linear layer that takes in token-level representations and predicts the tag for each token, and backpropagate log loss through the entire network. By default, the output layer is initialized randomly.

As a refinement, we propose using question prompts to initialize this model. The output layer is parameterized by a $T \times d$ matrix M, where T is the number of distinct BIO tags. The log-probability of predicting the j-th tag for token i is proportional to the dot product between the representation for token i and the j-th row of M; this resembles how

---

[4] For comparison, pre-training RoBERTa-large from scratch took roughly 5000 GPU-days (Liu et al., 2019)

[5] Yang and Katiyar (2020) study few-shot NER assuming data from other NER datasets is available; we assume no such data is available, matching Huang et al. (2020).

the bi-encoder predicts answers. Thus, we initialize each row of M with the start head embedding of a question related to that row's corresponding entity tag. For instance, we initialize the parameters for the `B-location` and `I-location` tags with the embedding for "*What is a location ?*" We normalize the question embeddings to have unit L2 norm. This style of initialization is uniquely enabled by our bi-encoder QA model, as it builds a *single* passage representation that can simultaneously answer questions corresponding to all entity types. It would be unclear how to use a language model or a cross-encoder QA model similarly, as it must perform a separate forward pass for each question (i.e., each entity type in this setting).

3.4 Zero-shot Sentiment Analysis

Finally, we use QUIP for zero-shot binary sentiment analysis. We reduce sentiment analysis to QA by writing a pair of questions that ask for a *reason* why an item is good or bad (e.g., "*Why is this movie [good/bad]?*"). We predict the label whose corresponding question has higher similarity with the QUIP representation of some token in the input. This prompting strategy has the additional benefit of extracting rationales, namely the span that the QUIP model predicts as the answer to the question. While we focus on sentiment analysis, extractive rationales have been used for a wide range of NLP tasks (DeYoung et al., 2020), suggesting that this method could be applied more broadly.

More formally, let x be an input sentence and (q_0, q_1) be a pair of questions (i.e., a prompt). For label $y \in \{0, 1\}$, we compute a score for y as

$$S(x, y) = \max_i r(x)_i^\top f_{\text{start}}(q_y) + \max_i r(x)_i^\top f_{\text{end}}(q_y). \quad (4)$$

This formula is a straightforward way to measure the extent to which *some* span in x looks like the answer to the question q_y, based on the model's pre-trained ability to perform QA. We predict whichever y has the higher value of $S(x, y) - C_y$, where C_y is a calibration constant that offsets the model's bias towards answering q_0 or q_1. Our inclusion of C_y is inspired by Zhao et al. (2021), who recommend calibrating zero-shot and few-shot models with a baseline derived from content-free inputs to account for biases towards a particular label. To choose C_y, we obtain a list W of the ten most frequent English words, all of which convey no sentiment, and define C_y as the mean over $w \in W$ of $S(w, y)$, i.e., the score when using w as the input sentence (see Appendix A.4).

This method can succeed only if the model produces a lower score for unanswerable questions than answerable ones. For example, if the input passage is positive, the model must produce a lower score for "*Why is it bad?*", which not answerable (as the question contains a presupposition failure), than "*Why is it good?*", which presumably can be answered from the passage. We hypothesize that QUIP will indeed recognize that unanswerable questions should receive lower scores, as it is trained to make each span's representation far away from those of questions it does not answer. In contrast, the cross-encoder objective does not teach the model how to handle unanswerable questions.

4 Experiments

4.1 Experimental details

Datasets. For paraphrasing, we use four datasets: QQP (Iyer et al., 2017), MRPC (Dolan and Brockett, 2005), PAWS-Wiki, and PAWS-QQP (Zhang et al., 2019). The PAWS datasets were designed to be challenging for bag-of-words models, and thus test whether our representations are truly contextual or mostly lexical. For QQP and MRPC, we use the few-shot splits from Gao et al. (2021) that include 16 examples per class; for the PAWS datasets, we create new few-shot splits in the same manner. We report results on the development sets of QQP and MRPC (as test labels were not available), the test set of PAWS-Wiki, and the "dev-and-test" set of PAWS-QQP. For NER, we use two datasets: CoNLL 2003 (Tjong Kim Sang and De Meulder, 2003) and WNUT-17 (Derczynski et al., 2017). We use the few-shot splits from Huang et al. (2020) that include 5 examples per entity type. All few-shot experiments report an average over five random splits and seeds, following both Gao et al. (2021) and Huang et al. (2020). For sentiment analysis, we use two movie review datasets, SST-2 (Socher et al., 2013) and Movie Reviews (MR; Pang and Lee, 2005), as well as the Customer Reviews (CR) dataset (Hu and Liu, 2004). We evaluate on the SST-2 development set and the MR and CR test sets made by Gao et al. (2021).

Hyperparameter and prompt selection. Due to the nature of zero-shot and few-shot experiments, we minimize the extent to which we tune hyperparameters, relying on existing defaults and previously published hyperparameters. For few-shot paraphrase classification, NER, and sentiment analysis, we developed our final method only using QQP, CoNLL, and SST-2, respectively, and directly applied it to the other datasets with no further tuning. We did measure zero-shot paraphrase ranking accuracy on all datasets during development of QuIP. For more details, see Appendix A.3.

For NER, we used the first question prompts we wrote for both CoNLL and WNUT, which all follow the same format, "*Who/What is a/an [entity type] ?*" (see Appendix A.7 for all prompts). For sentiment analysis, we wrote six prompts (shown in Appendix A.9) and report mean accuracy over these prompts, to avoid pitfalls associated with prompt tuning (Perez et al., 2021). We use the same prompts for SST-2 and MR; for CR, the only change we make is replacing occurrences of the word "*movie*" with "*product*" to reflect the change in domain between these datasets.

4.2 Baselines and Ablations

To confirm the importance of all three stages of our pre-training pipeline, we compare with a number of baselines and ablations.

No question generation. We train the bi-encoder model directly on the MRQA training data ("Bi-encoder + MRQA"). We also include the cross-encoder teacher model trained on MRQA as a baseline ("Cross-encoder + MRQA"). These settings mirror standard intermediate task training (Phang et al., 2018; Pruksachatkun et al., 2020).

No teacher. We train the bi-encoder using the answer generated by the question generation model ("QuIP, no teacher"). If the generated answer is not a span in the passage, we consider the question unanswerable and treat the span containing the `CLS` token as the answer, as in Devlin et al. (2019).

Cross-encoder self-training. To test whether the bottleneck imposed by the bi-encoder architecture is crucial for QuIP, we also train a cross-encoder model on our generated data ("QuIP, cross-encoder student"). Since this student model has the same architecture as the teacher model, we train it to match the teacher's argmax predictions, a standard self-training objective (Lee, 2013; Kumar et al., 2020). Training is much less efficient for the cross-encoder than the bi-encoder, since batching questions about the same passage together does not speed up training, so we train for a comparable number of GPU-hours (60 hours on 8 V100 GPUs).

Model	EM	F1
Lee et al. (2021)	78.3	86.3
Bi-encoder + UnsupervisedQA	17.4	24.9
Bi-encoder + MRQA	70.7	79.4
QuIP, no teacher	75.3	84.7
QuIP	**85.2**	**91.7**
BERT-large cross-encoder	84.2	91.1
Cross-encoder + MRQA	88.8	94.7
QuIP, cross-encoder student	**89.5**	**94.8**

Table 1: EM and F1 scores on the SQuAD development set for bi-encoder (top) and cross-encoder (bottom) models. QuIP outperforms the other bi-encoder model baselines, and even a cross-encoder BERT-large model. The RoBERTa cross-encoder models are better at QA, but will underperform QuIP on non-QA tasks.

Unsupervised QA. We test whether QuIP requires real QA data, or if a rough approximation suffices. We thus train a bi-encoder on 80 million pseudo-questions generated by applying noise to sentences ("Bi-encoder + UnsupervisedQA"), as in Lewis et al. (2019).

4.3 Bi-encoder Question Answering

While not our main focus, we first check that QuIP improves bi-encoder QA accuracy, as shown in Table 1. QuIP improves over Lee et al. (2021) by 5.4 F1 on the SQuAD development set. It also surpasses the reported human accuracy of 91.2 F1 on the SQuAD test set, as well as the best cross-encoder BERT-large single model from Devlin et al. (2019). QuIP greatly improves over baselines that directly train on MRQA data or do not use the teacher model. The cross-encoder models are more accurate at QA, but as we will show, this does not imply that cross-encoder QA is a better pre-training objective for downstream non-QA tasks. Appendix A.5 shows results on all MRQA development datasets.

4.4 Zero-shot Paraphrase Ranking

We validate our approach and study the effects of various ablations on zero-shot paraphrase ranking. The first half of Table 2 shows WMT development set Pearson correlations averaged across six to-English datasets, as in Zhang et al. (2020), along with the best layer for each model. QuIP reaches its optimal score at a later layer (20) than RoBERTa-large (17), which may suggest that the

Model	WMT r	WMT Best Layer	QQP	MRPC	PAWS-Wiki	PAWS-QQP
RoBERTa-large	.739	17	.763	.831	.698	.690
Cross-encoder + MRQA	.744	16	.767	.840	.742	.731
QUIP, cross-encoder student	.753	16	.769	.847	.751	.706
Bi-encoder + UnsupervisedQA	.654	11	.747	.801	.649	.580
Bi-encoder + MRQA	.749	15	.771	.807	.747	.725
QUIP, no teacher	.726	19	.767	.831	.780	.709
QUIP	**.764**	20	**.809**	**.849**	**.830**	**.796**

Table 2: Pearson correlation on WMT development data, best layer chosen based on WMT results, and AUROC on zero-shot paraphrase ranking using BERTScore. QUIP outperforms all baselines on all datasets.

QUIP training objective is more closely aligned with learning better representations than MLM.

The rest of Table 2 shows zero-shot paraphrase ranking results using BERTScore. QUIP improves substantially over RoBERTa on all four datasets, with an average improvement of .076 AUROC. The improvement is greatest on the PAWS datasets; since these datasets cannot be solved by lexical features alone, QUIP representations must be much more contextualized than RoBERTa representations. Training on Unsupervised QA data degrades performance compared to RoBERTa, showing that QUIP does not merely make word representations encode local context in a simple way. Training the bi-encoder directly on the MRQA dataset or without the teacher improves on average over RoBERTa, but QUIP greatly outperforms both baselines. The cross-encoder models also lag behind QUIP at paraphrase ranking, despite their higher QA accuracy; since the cross-encoders are trained to take passage-question pairs as inputs, their representations of single sentences are not as useful. Thus, we conclude that having real questions, accurate answer supervision, and a bi-encoder student model are all crucial to the success of QUIP.

4.5 Paraphrase Classification

Table 3 shows few-shot paraphrase classification results. As we studied QUIP-related ablations in the previous section, we focus on the comparison between QUIP and baselines based on MLM. First, we use RoBERTa-large embeddings in place of QUIP in our method. Second, we compare with LM-BFF (Gao et al., 2021), which pairs RoBERTa-large with MLM-style prompts. We use LM-BFF with manually written prompts and demonstrations, which was their best method on QQP by 2.1 F1 and was 0.3 F1 worse than their best method on MRPC. QUIP used as a frozen encoder is competitive with LM-BFF on QQP and outperforms it by 6.1 F1 on MRPC, 11.2 F1 on PAWS-Wiki, and 12.1 F1 on PAWS-QQP. Fine-tuning QUIP gives additional improvements on three of the four datasets, and outperforms fine-tuning RoBERTa by an average of 6.9 F1.

4.6 Named Entity Recognition

Table 4 shows few-shot NER results on the CoNLL and WNUT datasets. QUIP improves over RoBERTa-large by 11 F1 on CoNLL and 2.9 F1 on WNUT when used with a randomly initialized output layer. We see a further improvement of 4 F1 on CoNLL and 7.4 F1 on WNUT when using question embeddings to initialize the output layer. Using the cross-encoder trained directly on QA data is roughly as good as QUIP when using randomly initialized output layers, but it is incompatible with question embedding initialization.

4.7 Sentiment Analysis

Table 5 shows zero-shot accuracy on our three sentiment analysis datasets. We compare with zero-shot results for LM-BFF (Gao et al., 2021)[6] and reported zero-shot results from Zhao et al. (2021) using GPT-3 with Contextual Calibration (CC) on SST-2. QUIP using an average prompt outperforms zero-shot LM-BFF by 5.4 points, averaged across the three datasets. Choosing the best prompt on SST-2 and using that for all datasets improves results not only on SST-2 but also MR, and maintains average accuracy on CR. Using the cross-encoder student QA model with the same prompts leads to worse performance: we hypothesize that the bi-encoder succeeds due to its better handling of unanswerable questions. Overall, these results show that question answering can provide a viable interface for building models that perform non-QA tasks.

Table 6 shows rationales extracted from random SST-2 examples for which QUIP was correct with the best prompt for SST-2 ("*What is the reason*

---

[6] We tried applying our calibration strategy to LM-BFF as well, but found that it did not improve accuracy.

Model	Fine-tuned?	QQP	MRPC	PAWS-Wiki	PAWS-QQP
LM-BFF (reported)	Fine-tuned	$69.8_{0.8}$	$77.8_{0.9}$	-	-
LM-BFF (rerun)	Fine-tuned	$67.1_{0.9}$	$76.5_{1.5}$	$60.7_{0.7}$	$50.1_{2.8}$
RoBERTa-large	Frozen	$64.4_{0.4}$	$80.6_{0.7}$	$62.3_{0.9}$	$50.6_{0.4}$
QUIP	Frozen	$68.9_{0.2}$	$82.6_{0.4}$	$71.9_{0.5}$	**$63.0_{1.2}$**
RoBERTa-large	Fine-tuned	$64.9_{0.7}$	$84.4_{0.3}$	$65.7_{0.3}$	$50.9_{0.8}$
QUIP	Fine-tuned	**$71.0_{0.3}$**	**$86.6_{0.4}$**	**$75.1_{0.2}$**	$60.9_{1.0}$

Table 3: F1 scores on few-shot paraphrase classification, averaged across five training splits (standard errors in subscripts). QUIP outperforms prior work (LM-BFF; Gao et al., 2021) as well as our own RoBERTa baselines.

Model	CoNLL	WNUT
Huang et al. (2020)	65.4	37.6
Standard init.		
RoBERTa-large	$59.0_{2.4}$	$39.3_{0.6}$
Cross-encoder + MRQA	$68.9_{3.3}$	$43.0_{0.9}$
QUIP, cross-encoder student	$63.4_{3.3}$	$39.4_{1.7}$
Bi-encoder + UnsupervisedQA	$58.2_{2.6}$	$26.0_{1.0}$
Bi-encoder + MRQA	$66.4_{3.3}$	$42.2_{0.4}$
QUIP, no teacher	$67.7_{1.9}$	$40.7_{1.4}$
QUIP	$70.0_{2.4}$	$42.2_{0.5}$
Question prompt init.		
Bi-encoder + UnsupervisedQA	$62.7_{3.3}$	$30.4_{0.8}$
Bi-encoder + MRQA	$72.0_{2.8}$	$44.0_{1.3}$
QUIP, no teacher	$71.4_{3.0}$	$47.8_{1.1}$
QUIP	**$74.0_{2.4}$**	**$49.6_{0.5}$**

Table 4: F1 scores on few-shot NER, averaged over five training splits (standard errors in subscripts). QUIP with question prompts performs best on both datasets.

this movie is [good/bad]?”). To prefer shorter rationales, we extract the highest-scoring span of five BPE tokens or less. The model often identifies phrases that convey clear sentiment. Appendix A.10 shows full examples and rationales.

4.8 Stability Analysis

We experimented with some design decisions that did not materially affect our results. Appendix A.6 shows results for three such choices: including in-batch negative passages (Lee et al., 2021), using the argmax prediction of the teacher rather than soft labels, and using beam search to generate a diverse set of answers followed by one high-likelihood question per answer. We take these findings as evidence that our basic recipe is stable to many small changes. For question generation, we hypothesize that the objective of matching the cross-encoder teacher model encourages the bi-encoder to learn important features identified by the cross-encoder, even on questions that are not entirely well-formed.

Model	SST-2	MR	CR
CC + GPT-3	71.6	-	-
LM-BFF	83.6	80.8	79.5
QUIP (average)	**$87.9_{0.6}$**	**$81.9_{0.4}$**	**$90.3_{0.2}$**
w/ cross-enc. student	$83.3_{0.4}$	$78.5_{0.4}$	$88.9_{0.3}$
QUIP (tune on SST-2)	89.6	83.1	90.4

Table 5: Zero-shot accuracy on sentiment analysis. Third and fourth rows show mean accuracy across six prompts (standard error in subscripts). QUIP with an average prompt outperforms prior work; using the best prompt on SST-2 helps on all datasets.

Label	Rationale
-	“*too slim*”, “*stale*”, “*every idea*”, “*wore out its welcome*”, “*unpleasant viewing experience*”, “*lifeless*”, “*plot*”, “*amateurishly assembled*”, “*10 times their natural size*”, “*wrong turn*”
+	“*packed with information and impressions*”, “*slash-and-hack*”, “*tightly organized efficiency*”, “*passion and talent*”, “*best films*”, “*surprises*”, “*great summer fun*”, “*play equally well*”, “*convictions*”, “*wickedly subversive bent*”

Table 6: Rationales extracted by QUIP on ten random examples for each label from SST-2.

5 Discussion and Related Work

We build on work in question generation and answering, pre-training, and few-shot learning.

5.1 Question Generation

Neural question generation has been well-studied for different purposes (Du et al., 2017; Du and Cardie, 2018; Zhao et al., 2018; Lewis and Fan, 2019; Alberti et al., 2019; Puri et al., 2020; Lewis et al., 2021; Bartolo et al., 2021). We use generated questions to learn general-purpose representations. We also show that a relatively simple strategy of generating the answer and question together with a single model can be effective; most prior work uses separate answer selection and question generation models.

Phrase-indexed Question Answering Phrase-indexed question answering is a paradigm for open-domain QA that retrieves answers by embedding questions and candidate answers in a shared embedding space (Seo et al., 2018, 2019; Lee et al., 2020). It requires using a bi-encoder architecture for efficient phrase retrieval. Especially related is Lee et al. (2021), which also uses question generation and a cross-encoder teacher model to improve phrase-indexed QA, though they focus on improving QA accuracy rather than transfer to other tasks. Our results reinforce prior observations that bi-encoder models are usually less accurate at QA than cross-encoders (see Table 1). However, the bi-encoder model transfers better to settings that require a contextualized representation of a single passage; the cross-encoder instead optimizes for producing representations of passage-question pairs.

5.2 Improving question answering

While we use QA to aid pre-training, related work aims to improve accuracy on QA. Ram et al. (2021) propose a span extraction pre-training objective that enables few-shot QA. Khashabi et al. (2020) run multi-task training on many QA datasets, both extractive and non-extractive, to improve QA accuracy.

5.3 Learning contextual representations

Pre-training on unlabeled data has yields useful contextual representations (Peters et al., 2018; Devlin et al., 2019), but further improvements are possible using labeled data. Intermediate task training (Phang et al., 2018) improves representations by training directly on large labeled datasets. Muppet (Aghajanyan et al., 2021) improves models by multi-task pre-finetuning on many labeled datasets.

Most similar to our work, QuASE (He et al., 2020) uses extractive QA to pre-train a BERT paragraph encoder. Our work improves upon QuASE in multiple ways. First, we use question generation and knowledge distillation to greatly improve over directly training on labeled data, the approach used by QuASE. Second, we propose multiple ways of leveraging question-based task descriptions to improve accuracy in zero-shot and few-shot settings, thus showing how the QA format can be used as a model-building interface for non-QA tasks; QuASE only uses their model as a feature extractor. Moreover, since the architecture of QuASE involves a more complex interaction layer than our bi-encoder, it would not be possible to use question prompts to initialize final-layer parameters, as we do for NER.

Other work has used methods similar to ours to learn vector representations of full sentences. Reimers and Gurevych (2019) train sentence embeddings for sentence similarity tasks using natural language inference data. Thakur et al. (2021) train a sentence embedding bi-encoder to mimic the predictions of a cross-encoder model. We learn token-level representations, rather than a single vector for a sentence, and thus use token-level supervision from extractive QA.

5.4 Few-shot learning

We study few-shot learning without access to unlabeled data, following most recent work (Brown et al., 2020; Gao et al., 2021; Zhao et al., 2021). Schick and Schütze (2021) notably propose a semi-supervised approach that uses unlabeled data for knowledge distillation; this process does not improve accuracy, but mainly improves efficiency. Moreover, large-scale unlabeled data may not be easily obtainable for all tasks, and utilizing such data increase computation time in the fine-tuning stage, so we focus on the setting without unlabeled data. The aforementioned work uses language models for few-shot learning by converting tasks to language modeling problems; we develop alternative methods for few-shot learning that use token-level representations and question-based prompts.

6 Conclusion

In this work, we pre-trained token-level contextual representations that are useful for downstream few-shot learning. Our key idea was to use question-answer pairs to define what information should be encoded in passage representations. We showed that these representations are useful for a variety of standard NLP tasks in zero- and few-shot settings, including paraphrase detection, named entity recognition, and sentiment analysis, across nine total datasets. Looking forward, we hope to see more work on designing pre-training objectives that align with downstream needs for few-shot learning.

Acknowledgements

We thank Terra Blevins for investigating applications to word sense disambiguation, Jiaxin Huang for providing the few-shot NER splits used in their paper, and Douwe Kiela, Max Bartolo, Sebastian Riedel, Sewon Min, Patrick Lewis, Scott Yih, and our anonymous reviewers for their feedback.

A Appendix

A.1 QuIP Details

We limit passages to 456 byte-pair encoding (BPE) tokens and questions to 50 so that the concatenation can fit comfortably within the 512 token context usable by the cross-encoder teacher. We create passages from our unlabeled text corpus by greedily selecting maximal chunks of contiguous sentences that fit within the BPE token limit. We pre-compute the teacher predictions T_{start} and T_{end} before bi-encoder training. To save space, we sparsify these vectors by only storing the eight largest predicted probabilities, treating all others as 0.

We conducted minimal hyperparameter tuning for QuIP. We used a learning rate of $1 \cdot 10^{-5}$ (default for most RoBERTa fine-tuning experiments[7]) and no gradient accumulation, which we found led to faster training.

A.2 Paraphrase Fine-tuning Details

To fine-tune our model for paraphrase classification, we use two practices recommended by Mussmann et al. (2020), who also train a binary classification model that uses cosine similarity-based features derived from fine-tuned BERT embeddings. First, we disable dropout during training, as dropout artificially lowers all cosine similarities. Second, we use a larger learning rate on the final output layer than the Transformer parameters, by a factor of 10^3.

A.3 Downstream Task Hyperparameter Details

For few-shot paraphrase detection with the frozen model, we use Scikit-learn's logistic regression implementation with default settings (Pedregosa et al., 2011). For fine-tuned paraphrase detection, we again use a learning rate of $1 \cdot 10^{-5}$ and train for 20 epochs, which we found to usually be sufficient for convergence on the training data. For NER, we use the default hyperparameters from the Huggingface `transformers` repository (Wolf et al., 2020), with the exception of decreasing the learning rate from $5 \cdot 10^{-5}$ to $2 \cdot 10^{-5}$, which we found improved the RoBERTa baseline on CoNLL.

A.4 Sentiment Analysis Calibration

To calibrate the zero-shot sentiment analysis model, we use ten content-free inputs: "*the*", "*be*", "*to*", "*of*", "*and*", "*a*", "*in*", "*that*", "*have*", and "*I*". These were the top ten words listed on `https://en.wikipedia.org/wiki/Most_common_words_in_English`. We only applied calibration for the main QuIP model, as we did not find calibration to improve results for either LM-BFF or the cross-encoder QA student model.

A.5 Full QA results

Table 7 shows EM and F1 scores on the 12 development sets from the MRQA 2019 Shared Task (Fisch et al., 2019). These are divided into 6 in-domain datasets—HotpotQA (Yang et al., 2018), NaturalQuestions (Kwiatkowski et al., 2019), NewsQA (Trischler et al., 2017), SearchQA (Dunn et al., 2017), SQuAD (Rajpurkar et al., 2016), and TriviaQA (Joshi et al., 2017)—for which corresponding training data was used to train the question generation model and teacher, and 6 out-of-domain datasets—BioASQ (Tsatsaronis et al., 2015), DROP (Dua et al., 2019), DuoRC (Saha et al., 2018), RACE (Lai et al., 2017), RelationExtraction (Levy et al., 2017), and TextbookQA (Kembhavi et al., 2017)—for which no training data was used in the QuIP pipeline. QuIP improves over training the bi-encoder directly on the MRQA data by an average of 4.4 F1 on the in-domain datasets and 12.7 F1 on the out-of-domain datasets. It underperforms the cross-encoder teacher by about 5 F1 on both the in-domain and out-of-domain datasets on average.

A.6 Stability Analysis

We experimented with some design decisions that did not materially affect our results. Here, we report these findings as evidence that our basic recipe is stable to many small changes. First, we concatenated the representations of all passages in the same batch and on the same GPU together (9 passages on average), and trained the model to extract answers from this larger pseudo-document; this effectively adds in-batch negative passages, as in Lee et al. (2021). Second, we trained the model to match the argmax prediction of the teacher, rather than its soft distribution over start and end indices. Finally, we used a two-stage beam search to generate questions. For a given passage, we generated 20 possible answers via beam search, chose 10 of these to maximize answer diversity, then generated one question for each answer with another beam search. Our goal was to ensure diversity by forcing

Table 7: Exact match/F1 scores on the twelve development datasets from the MRQA 2019 shared task. The six in-domain datasets are on top; the six out-of-domain datasets are on bottom.

Model	SQuAD F1	Paraphrase AUROC	NER F1
QuIP	91.7	.821	61.8
+ concat. passages	91.7	.818	62.7
w/ hard labels	91.5	.814	62.5
w/ 2-stage beam search	91.7	.821	62.8

Table 8: SQuAD development set F1, average zero-shot paraphrase ranking AUROC across all datasets, and average few-shot NER F1 using question prompts across both datasets for QuIP variants. Models shown here are all similarly effective.

questions to be about different answers, while also maintaining high question quality. As shown in Table 8, these choices have a relatively minor impact on the results (within .007 AUROC and 1 F1 on NER).

A.7 QA Prompts for NER

Table 9 shows the question prompts we use to initialize the NER model for CoNLL and WNUT. For entity types that occur in both datasets, and for the `O` tag, we always use the same question. We used the English description of the entity type provided by the dataset.

A.8 Full training set NER

Table 10 shows NER results when training on the full training dataset. QuIP gives a 0.6 F1 improvement on WNUT, but has effectively the same accuracy on CoNLL.

A.9 Sentiment Analysis QA Prompts

Table 11 shows the six prompts we use for sentiment analysis for the movie review datasets (SST-2 and MR). Each prompt consists of one question for the positive label and one for the negative label. For CR, we use the same prompts except that we replace all instances of the word “*movie*” with “*product*”.

Entity type	Question
Both datasets	
O	“*What is a generic object ?*”
Person	“*Who is a person ?*”
Location	“*What is a location ?*”
CoNLL	
Organization	“*What is an organization ?*”
Miscellaneous	“*What is a miscellaneous entity ?*”
WNUT	
Corporation	“*What is a corporation ?*”
Product	“*What is a product ?*”
Creative work	“*What is a creative work ?*”
Group	“*What is a group ?*”

Table 9: Question prompts used for the CoNLL and WNUT NER datasets.

Model	CoNLL	WNUT
RoBERTa-large	92.7	57.9
QuIP, standard	92.7	58.1
QuIP, QA prompts	92.8	58.8

Table 10: F1 scores on NER, using the entire training dataset.

A.10 Sentiment Analysis Rationales

Tables 12, 13, and 14 show full examples and rationales extracted by our zero-shot sentiment analysis method for SST-2, MR, and CR, respectively. In all cases, we use the prompt that led to the highest accuracy on SST-2. For each dataset, we randomly sample ten examples of each label for which the model predicted the correct answer. We highlight in bold the span of ≤ 5 BPE tokens that the model

#	Label	Question
1	+ -	"*Why is it good?*" "*Why is it bad?*"
2	+ -	"*Why is this movie good?*" "*Why is this movie bad?*"
3	+ -	"*Why is it great?*" "*Why is it terrible?*"
4	+ -	"*What makes this movie good?*" "*What makes this movie bad?*"
5	+ -	"*What is the reason this movie is good?*" "*What is the reason this movie is bad?*"
6	+ -	"*What is the reason this movie is great?*" "*What is the reason this movie is terrible?*"

Table 11: Question prompts used for sentiment analysis on movie review datasets (SST-2 and MR). Prompts used for CR are identical except for replacing "*movie*" with "*product*".

predicts best answers the question associated with the correct label. In some cases, the rationales correspond to clear sentiment markers. In other cases, they highlight an aspect of a movie or product that is criticized or praised in the review; these could be considered reasonable answers to a question like "*Why is this movie bad?*" even if the sentiment associated with them is unclear without the surrounding context. In future work, it would be interesting to find better ways to align the task of extractive QA and with the goal of producing rationales that are human-interpretable in isolation.

Label	SST-2 Example (rationale in bold)
-	*“for starters , the story is just **too slim** .”*
	*“paid in full is so **stale** , in fact , that its most vibrant scene is one that uses clips from brian de palma ’s scarface .”*
	*“(e) ventually , **every idea** in this film is flushed down the latrine of heroism .”*
	*“corpus collosum – while undeniably interesting – **wore out its welcome** well before the end credits rolled about 45 minutes in .”*
	*“makes for a pretty **unpleasant viewing experience** .”*
	*“while (hill) has learned new tricks , the tricks alone are not enough to salvage this **lifeless** boxing film .”*
	*“it ’s hampered by a lifetime-channel kind of **plot** and a lead actress who is out of her depth .”*
	*“dull , lifeless , and **amateurishly assembled** .”*
	*“the movie is what happens when you blow up small potatoes to **10 times their natural size** , and it ai n’t pretty .”*
	*“every time you look , sweet home alabama is taking another bummer of a **wrong turn** .”*
+	*“though only 60 minutes long , the film is **packed with information and impressions** .”*
	*“good old-fashioned **slash-and-hack** is back !”*
	*“with **tightly organized efficiency** , numerous flashbacks and a constant edge of tension , miller ’s film is one of 2002 ’s involvingly adult surprises .”*
	*“displaying about equal amounts of naiveté , **passion and talent** , beneath clouds establishes sen as a filmmaker of considerable potential .”*
	*“‘ easily my choice for one of the year ’s **best films** . ’”*
	*“a delectable and intriguing thriller filled with **surprises** , read my lips is an original .”*
	*“it is **great summer fun** to watch arnold and his buddy gerald bounce off a quirky cast of characters .”*
	*“the film will **play equally well** on both the standard and giant screens .”*
	*“for this reason and this reason only – the power of its own steadfast , hoity-toity **convictions** – chelsea walls deserves a medal .”*
	*“there ’s a **wickedly subversive bent** to the best parts of birthday girl .”*

Table 12: Rationales (in bold) extracted by the zero-shot QUIP sentiment analysis model for SST-2. We show ten random examples for each label on which the model made the correct prediction.

Label	MR Example (rationale in bold)
-	*“strangely comes off as a kingdom **more mild than wild** .”*
	*“feels like the work of someone who may indeed have finally **aged past his prime** . . . and , perhaps more than he realizes , just wants to be liked by the people who can still give him work .”*
	*“watching the powerpuff girls movie , my mind kept returning to one anecdote for comparison : the cartoon in japan that **gave people seizures** .”*
	*“this is a movie so insecure about its **capacity to excite** that it churns up not one but two flagrantly fake thunderstorms to underscore the action .”*
	*“**witless** , pointless , tasteless and idiotic .”*
	*“the next big thing’s not-so-big (and **not-so-hot**) directorial debut .”*
	*“unfortunately , it’s also **not very good** . especially compared with the television series that inspired the movie .”*
	*“**irwin and his director** never come up with an adequate reason why we should pay money for what we can get on television for free .”*
	*“with this new rollerball , sense and sensibility have been overrun by what can only be characterized as **robotic sentiment** .”*
	*“the video work is so **grainy and rough** , so dependent on being ’naturalistic’ rather than carefully lit and set up , that it’s exhausting to watch .”*
+	*“the **appearance of treebeard** and gollum’s expanded role will either have you loving what you’re seeing , or rolling your eyes . i loved it ! gollum’s ’performance’ is incredible !”*
	*“droll **caper-comedy** remake of " big deal on madonna street " that’s a sly , amusing , laugh-filled little gem in which the ultimate " bellini " begins to look like a " real kaputschnik . "”*
	*“katz uses archival footage , horrifying documents of lynchings , still photographs and charming old reel-to-reel recordings of meeropol entertaining his children to create his song history , but most powerful of all is **the song itself**”*
	*“a thunderous ride at first , quiet cadences of pure finesse are few and far between ; their shortage dilutes the potency of otherwise respectable action . still , this flick is **fun** , and host to some truly excellent sequences .”*
	*“**compellingly watchable** .”*
	*“an unbelievably fun film just a **leading man away from perfection** .”*
	*“andersson creates a world that’s at once **surreal and disturbingly familiar** ; absurd , yet tremendously sad .”*
	*“the **invincible** werner herzog is alive and well and living in la”*
	*“you can feel the heat that ignites this gripping tale , and the **humor and humanity** that root it in feeling .”*
	*“this is a terrific **character study** , a probe into the life of a complex man .”*

Table 13: Rationales (in bold) extracted by the zero-shot QUIP sentiment analysis model for the Movie Reviews (MR) dataset. We show ten random examples for each label on which the model made the correct prediction.

Label	CR Example (rationale in bold)

Abstract

This paper develops automatic song translation (AST) for tonal languages and addresses the unique challenge of aligning words' tones with melody of a song *in addition to* conveying the original meaning. We propose three criteria for effective AST—preserving meaning, singability and intelligibility—and design metrics for these criteria. We develop a new benchmark for English–Mandarin song translation and develop an unsupervised AST system, Guided AliGnment for Automatic Song Translation (GagaST), which combines pre-training with three decoding constraints. Both automatic and human evaluations show GagaST successfully balances semantics and singability.

1 Introduction

Suppose you are asked to translate the lyrics "Let it go" from the Disney musical *Frozen* into Mandarin Chinese. Some good, literal translations of this would be A) "fàng shǒu", B) "fàng shǒu ba" or C) "ràng tā qù ba" (Figure 1); these get the meaning across and are the domain of traditional machine translation. However, what if you needed to sing this song *in Mandarin*? These literal translations simply do not work: Translations A and C do not match the number of notes and break the original rhythm; while the tones of Translation B does not match the pitch flow of the original melody.

Song translation, unlike translation lyrics for understanding (subtitling), aims to translate the lyrics so that it can be *sung* with the original melody. Therefore, the translated lyrics must match the prosody of the pre-existing music in addition to retaining the original meaning. In *Singable Translations of Songs*, Low (2003) says, this is an uncommon and an unusually complex task, a translator consider rhythm, notes' pitches, phrasing, and stress. Nonetheless, there are cultural and commercial incentives for more efficient song translation; *Frozen* alone made over a half a billion dollars in non-English box office receipts[1] and the musical *Les Misérables* has been performed in over a dozen languages on stage.

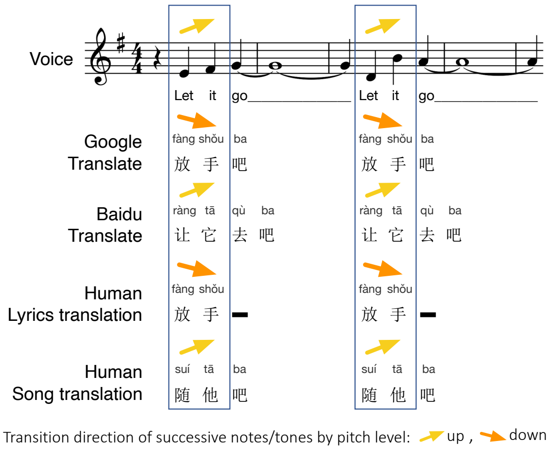

Figure 1: Example Mandarin translations for "Let it go" in *Frozen*. Of these, only the official human song translation is something a singer could actually sing: it fits the length of the notes and matches the tones with the pitch of notes. GagaST finds translations that satisfy these constraints.

As we discuss in Section 2, while translating Western songs resembles poetry translation, translating into *tonal* languages (e.g., Mandarin, Zulu and Vietnamese) introduces new problems. In tonal languages, a word's pitch contributes to its meaning (Figure 2); when singing in tonal languages, the

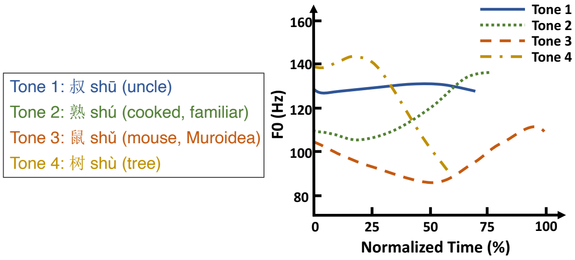

Figure 2: In total languages like Mandarin, the pitch changes the meaning of the words (left). Each of the four tones in Mandarin (right) has a different pitch profile. Figure from Xu (1997).

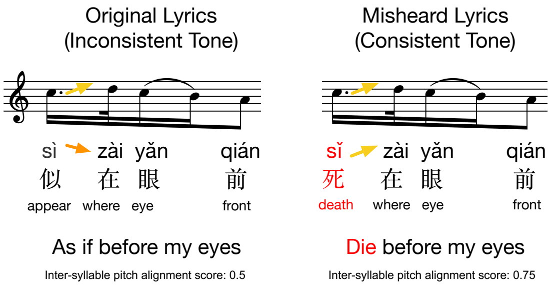

Figure 3: If a song's music doesn't match the tones of the lyrics, it can cause the hearer to misunderstand the lyrics. In this example, someone can hear "sǐ zài" instead of "sì zài", because the notes are going up and "sì zài" is going down.

tones of translated words must align with the "flow" of the pitches in the music (Section 2.1). For example, if "fáng shǒu" were sung instead of "fàng shǒu" (because notes are going up), a listener might hear "defensive" instead of the intended meaning.

This paper builds the first system for automatic song translation (AST) for one tonal language—Mandarin. Section 3 proposes three criteria—*preserving semantics*, *singability* and *intelligibility*—needed in an AST system.

Guided by those goals, we propose an unsupervised AST system, Guided AliGnment for Automatic Song Translation (GagaST). GagaST begins with an out-of-domain translation system (Section 4.1) and adds song alignment constraints that favor translations that are the appropriate length and whose tones match the underlying music (Section 4.2). Naturally, such constraints trade-off between semantic meaning and singability/intelligibility. Section 5.4 discusses this trade-off between song alignment scores and the standard machine translation metric, BLEU.

These criteria also form the evaluation for our initial evaluation (Section 5.3). However, we go beyond an automatic evaluation through a human-centered evaluation from musicology students. GagaST creates singable songs that make sense given the original text, and our proposed alignment scores correlate with human judgements (Section 5.4.3).[2]

2 Background: Prose, Poetry, and Song Translation

A spoken language can be divided into two forms: prose, which corresponds to natural conversation and conventional grammatical structure; and verse—typically rhythmic and broken into stanzas–such as poetry and song lyrics.

The vast majority of machine translation research has been focused on prose translation and has made huge progress; in contrast verse translation is more difficult as it must obey the rhythmic constraints and is less developed. In his *tour de force* work *Le Ton Beau de Marot*, Douglas Hofstadter presents eighty-nine translations of a single poem to capture the panoply of considerations of what makes the task difficult (Hofstadter, 1997).

In western verse, the rhythmic structure are mostly defined by meter, such as the iambic pentameter for sonnets, which defines the length of each line, the patterns of long syllables versus short ones and the stressed ones versus weak ones. Existing work (Greene et al., 2010; Ghazvininejad et al., 2018) use finite-state constraints to encode both meter and rhyme.

Song translation, on the other hand, can be viewed as a translation where the *melody* defines the constraints. Reproducing *all* of the essential values of a song—perfectly matching the meaning, perfectly singable, and perfectly understandable—is an impossible ideal (Franzon, 2008). Thus, tradeoffs are unavoidable. Low (2003) argues for prioritizing *singability* over other qualities such as *sense* and *rhyme* since "effectiveness on stage" is a practical necessity. Tonal languages (e.g., Mandarin, Zulu and Vietnamese) dramatically increases the complexity of singability, and introduces a new factor that could hamper intelligibility.

---

[2] Examples of translated songs by GagaST at `https://gagast.github.io/posts/gagast`.

2.1 Song Translation for Tonal Languages

For tonal languages, pitch contributes to the meaning of words. In a conservative estimation, fifty to sixty percent of the world's languages are tonal (Yip, 2002) and cover over 1.5 billion people. For the lyrics to be *intelligible*, the speech tone and music tone should be correlated (Schneider, 1961). If not, the pitch contour could override the intended tone, which could produce different meanings. This is not just a theoretical consideration; Figure 3 shows how lyrics can be and have been misunderstood.[3]

2.2 Mandarin Tones and how to Sing them

Schellenberg (2013) summarizes the rules of singing with tone with a focus on Chinese dialects. The tonal system of Mandarin has two components:

- **The pitch level and shape of tones.** Four Mandarin tones are used since the 19th century (Figure 2). We denote tones with a diacritic over the vowel whose shape roughly matches the shape of the tone. The four tones are a high level (tone 1, e.g., shūo), rising (tone 2, yú), falling-rising (tone 3, wǒ) and falling (tone 4, huài).
- **The sandhi of tones.** Some combinations of tones have difficult articulatory patterns, so words that might normally have one tone might take another depending on the context. For example "nǐ" (you) and "hǎo" (good) are typically both third tone, but when they are together it is pronounced as "ní hǎo" (hello), with the first syllable changing to a *second* tone. These changes are called sandhi (Xu, 1997; Hu, 2017).

Mandarin tones interact with a sung melody in two ways (Yinliu et al., 1983; Schellenberg, 2013) to ensure lyrics are intelligible. First, at a local level, the *shape of tones* of individual syllables should be consistent with the musical notes they are matched with; for example, in "Love Island" (Figure 4), "shàng" in the blue block has the "falling" shape and the group of notes it assigned to it also falls from an A to a E. Second, and a global level, the music's *pitch contour* should align with the tones of the corresponding syllables (taking sandhi into account). In practice, we align the transitions between successive syllables and successive notes (Figure 5) ensuring that the tone matches the relative pitch change (Schellenberg, 2013).

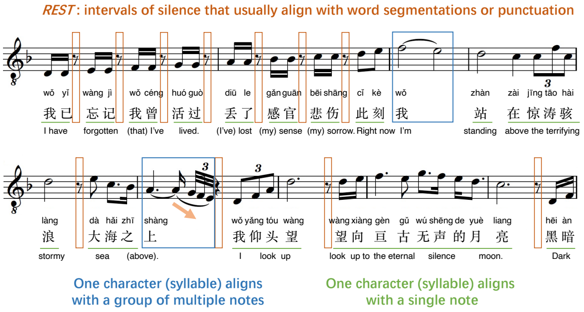

Figure 4: The output of a song translation needs to align syllables to the reference melody. There are several options, as evinced by the song "Love Island (xīn dǎo)". Orange (top): *REST* notes; Blue (bottom left): one syllable is assigned to a group of multiple notes (which needs *tone shape* alignment: the down arrow matches with falling tone of "ràng"); Green (bottom right): one syllable is assigned with one note.

3 AST for Tonal Languages

This section formally defines automatic song translation (AST) for tonal languages and introduce three criteria for what makes for a good song translation. These criteria form the foundation for the quantitative metrics we use in the experiment.

3.1 Criteria

There are three criteria that a singable song translation needs to fulfil.

Preserve meaning. The translated lyrics should be faithful to the original source lyrics.

Singability. Low (2003) defines singability as the phonetic compatability of translated lyrics and music. The translated song needs to be sung without too much difficulty; difficult consonant clusters, cramming too many syllables into a line, or incompatible tones all impair the singability.

Intelligibility. The translated song need to be understood by the listener. This quality has two components. First, could a listener produce *any* transcription of the lyrics. If the lyrics are too fast or garbled because the keywords do not fit well with the music, the lyrics are unintelligible. Beyond this basic test of recognizability, the lyrics must also be accurate: does this transcription match the intended meaning. Both aspects matter for a stage performance, since the audience should understand the content to follow the plot. For pop songs, not understanding all contents could be acceptable for some audiences; for example, Adriano Celentano's

---

notes	A3	C4	D4	*REST*	F4	G4	F4	F4
pitch level	57	60	62		65	67	65	65
duration	$\frac{1}{4}$	$\frac{1}{4}$	$\frac{1}{2}$	1	3	$\frac{3}{2}$	$\frac{1}{2}$	$\frac{1}{2}$
syllables	How	a-	bout		love?			

Table 1: A snippet of the song "Seasons of love" from the musical *Rent* that shows the input into GagaST. Notes are converted into integer pitches with a duration, and syllables are aligned to notes: the "a" from "about" has one note but "love" has four.

Prisencolinensinainciusol sacrifices all intelligibility for singability (Bellos, 2013). However, in more traditional media, hilarious misheard lyrics can ruin the audience's experience (Figure 3).

3.2 Task Definition

We define the AST task as follows: given an aligned pair of melody M and source lyrics X, generate translated text Y in the target language that aligns with the input melody M.

Specifically, $X = [x_1, ..., x_L]$ are the input lyrics with L syllables. Each syllable x_i is aligned to a snippet of the melody (Table 1) represented by a sequence of notes. To represent this to our algorithm, each syllable is aligned to three components of the melody:

1. A sequence of pitch values $\mathbf{p}_i \equiv [p_i^0, \dots]$ with $|\mathbf{p}_i| \geq 1$ where an integer value of 1.0 means a semitone (e.g., between C and C-sharp).
2. The duration of those notes $\mathbf{d}_i \equiv [d_i^0, ...]$, where 1.0 is a quarter note. Because it encodes the duration of each note, the length of $\mathbf{d}_i$ must be the same as the length of $\mathbf{p}_i$.
3. Sometimes there is a rest (pause) before a lyric is sung. We align this to the following syllable i. The scalar r_i is the real-valued duration of the *REST* note before note group $\mathbf{p}_i$. If no *REST* exists before $\mathbf{p}_i$, $r_i = 0.0$.

3.3 Constraints for Aligning Lyrics to Music

To make translated songs singable and intelligible, we summarize three desirable properties of that the AST lyric outputs should have if they are to match the underlying melody. Each of these induces a score function which we will use both in our objective functions for constrained translation and for our evaluation metrics.

3.3.1 Length Alignment

The number of syllables L_y in translated lyrics Y need to match the number of groups of notes $\mathbf{p}_i$ in the melody M, so that it can be sung with the music. Within the scope of this paper, we either keep the original grouping in the melody M and have $L_y = L_x$ for reproducing the original music; or strictly produce one target syllable for each single note in the melody.

3.3.2 Pitch Alignment

For tonal languages, pitch of the music must match the lyrics. As in Section 2.2, there are two types of pitch alignments: 1) *intra-syllable*, the tone shape of each syllable (Figure 4 blue box) should align with the shape of the assigned group of notes; 2) *inter-syllable*, the overall pitch contour of the music phrase should align with the tones of lyrics.

Intra-syllable alignment. For an *individual* syllable, if it is assigned to more than one note (e.g., "love" in Table 1), those notes must be consistent with the shape of the syllable's tone (Wee, 2007). For Mandarin, there are four tones (Xu, 1997, Figure 2). We estimate the shape of the multi-note sequence $\mathbf{p}_i$ by least-square estimation and classify it into one of five categories: level, rising, falling, rising-falling, falling-rising.

Specifically, for each group $\mathbf{p}_i$ that $|\mathbf{p}_i| > 1$, we classify it as,

1. "level", if $p^i_{max} - p^i_{min} \leq 1.0$; otherwise, we fit $\mathbf{p}_i$ into $ax^2 + bx + c$ via least-square estimation, and compute the axis of symmetry $l = -b/2a$,
2. "rising", if ($l \leq p_i^0$ and $a > 0.0$) or ($l \geq p_i^{-1}$ and $a < 0.0$);
3. "falling", if ($l \leq p_i^0$ and $a < 0.0$) or ($l \geq p_i^{-1}$ and $a > 0.0$);
4. "rising-falling", if $p_i^0 < l < p_i^{-1}$ and $a < 0.0$;
5. "falling-rising", if $p_i^0 < l < p_i^{-1}$ and $a > 0.0$;

We compare the shape with that of syllable y_i, and compute the intra-syllable alignment score S^i_{intra}:

$$S^i_{\text{intra}} = \begin{cases} 1.0 & \text{if the shape matches,} \\ \epsilon & \text{otherwise,} \end{cases} \tag{1}$$

where ϵ is a small parameter that allows for mismatches. Of the five patterns, "level" can match with any tone, "rising" matches with tone 2 (yú), "falling" matches with tone 4 (huài), "falling-rising" matches with tone 3 (wǒ) while "rising-falling" matches no Chinese tones.

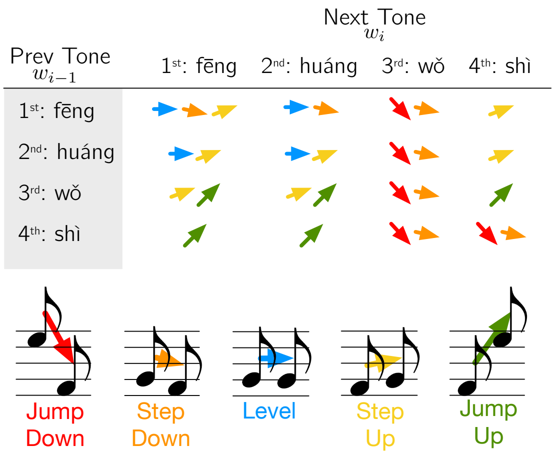

Figure 5: For translated songs in Mandarin to be singable, music notes should align the tones of successive characters; this becomes our **inter-syllable pitch alignment**. The arrows show acceptable transitions in music for two successive Mandarin characters (w_{i-1}, w_i) based on the shape of Mandarin tones including sandhi.

Inter-syllable alignment. The second constraint compares the transition directions between consecutive tones (t_{i-1}, t_i) of successive syllables (y_{i-1}, y_i) that belong to the same word (see arrows in Figure 3). These must match the transition directions of music notes ($\mathbf{p}_{i-1}$, $\mathbf{p}_i$).[4] Each transition (the movement from one syllable/note to the next) can be categorized as *level*, *step up*, *jump up*, *step down* and *jump down*. We summarize the acceptable transitions for each pair of successive syllables in Figure 5 based on analysis by Yinliu et al. (1983) and we discuss our choices with more details in Appendix A.2. Given two syllables (y_{i-1}, y_i), we compute the local pitch contour S^i_{inter}:

$$S^i_{\text{inter}} = \begin{cases} 1.0 & \text{if contour matches,} \\ \epsilon & \text{otherwise,} \end{cases} \tag{2}$$

where ϵ again is a small value to allow mismatches.

3.3.3 Rhythmic Alignment with Word Segmentation in Mandarin

A musical *REST* is a silence separating music. Recall that in our setup of the data, a scalar r_i denotes if a note precedes syllable i. In any language, it is uncommon for a rest to break up a word's syllables. Thus a good translation should avoid this. For Mandarin, creating metrics that capture this are slightly more complicated because translation systems typically do not explicitly generate word boundaries. Thus, we must rely on the output of segmentation systems to know where word boundaries are.

An exception to this is punctuation (Figure 4). If a comma, period, or other punctuation is attached to the previous syllable y_{i-1}, then that is a clear signal that it's fine to pause between them. Thus, our rest score a syllable y_i following y_{i-1} that are part of different words with probability P_{seg}[5], the rest score is:

$$S^i_R = \begin{cases} 1.0 & \text{if } r_i > 0.0 \text{ and [punc] after } y_{i-1}, \\ 1.0 & \text{if } r_i = 0.0, \\ P_{\text{seg}} & \text{if } r_i > 0.0 \text{ and not [punc],} \\ \epsilon & \text{otherwise,} \end{cases} \tag{3}$$

where ϵ is a parameter that represents our tolerance of having a rest within a word.

4 GagaST

Ideally, we would build an AST system for English–Mandarin song translation with data-driven models from parallel data, i.e., aligned triples (M, X, Y). However, these data are not available in the quantity or quality necessary for Mandarin: there is not enough data of any quality, and those that do exist have errors in the syllable-notes alignment. Thus, we propose an unsupervised AST system, Guided AliGnment for Automatic Song Translation (GagaST). For the pre-training, we collect non-parallel lyrics data in both English and Mandarin, as well as a small set of lyrics translation data (Section 5.1).

4.1 Song-Text Style Translation

To produce faithful translations in song-text style, we pre-train a transformer-based translation model with cross-domain data: translation data in the general domain, the collected monolingual lyrics data, and a small set of lyric translation data. We append domain tags (Figure 6) before each input example to control the model to produce translations merely in lyrics domain during song translation. For monolingual lyrics data, we adopt BART pretraining (Lewis et al., 2020).

4.2 Music Guided Alignment Constraints

Without available parallel data to learn the lyric-melody alignments, we impose constraints (Sec-

---

[4] We compute the directions of two notes group ($\mathbf{p}_{i-1}$, $\mathbf{p}_i$) by the first notes (p^0_{i-1}, p^0_i) for simplicity.

[5] In practice, we use the cut output by the Jieba toolkit.

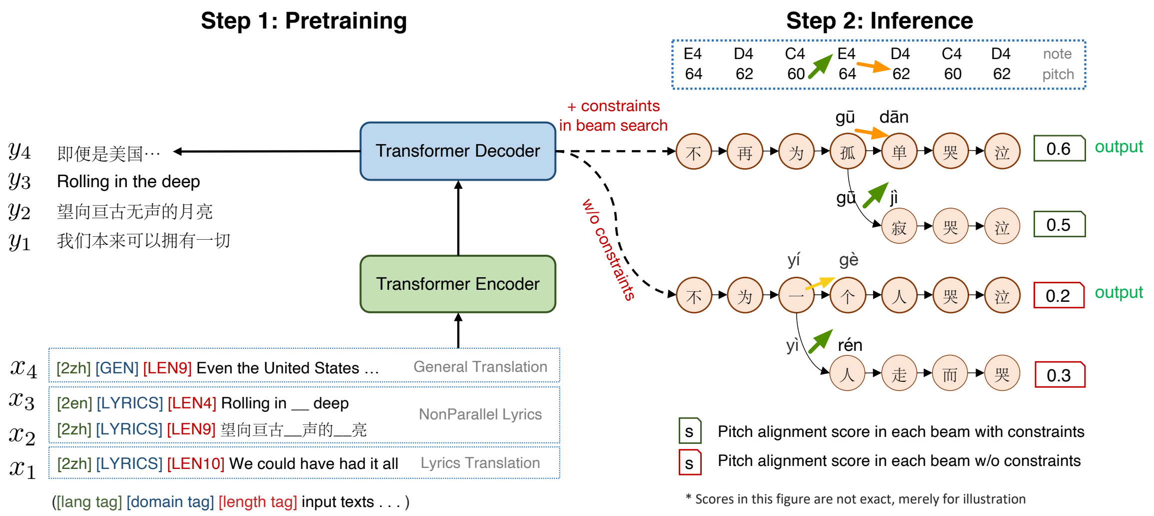

Figure 6: Overview of GagaST for English–Mandarin song translation. We first pre-train a lyrics translation model with mixture domain data (left); and then add alignment constraints in decoding scoring function during inference (right), we use unconstrained version as our baseline in the experiment.

tion 3.3) in the decoding phase. Specifically, since all constraints are applied at the unigram (intra-syllable, *REST*) or bigram (inter-syllable, *REST*) level, we apply them at each step of beam search as rewards and penalties in the scoring function:

$$\log P(Y \mid X, M) = \sum_{i=0}^{L} [\log P(y_i \mid y_{i-1:0}, X) + \lambda_{\text{inter}} \log S^i_{\text{inter}} + \lambda_{\text{intra}} \log S^i_{\text{intra}} + \lambda_R \log S^i_R], \qquad (4)$$

where S_{inter}, S_{intra}, and S_R refer to the alignment scores for inter-syllable pitch alignment, intra-syllable pitch alignment and the rhythm alignment by *REST*. We introduce three tunable parameters—λ_{inter}, λ_{intra}, and λ_R—that control the importance of each of the song-specific constraints.

4.3 Length Control in Pre-training

To meet the length constraints, we pre-define the syllable-notes assignments with two strategies:[6] 1) *note-to-syllable*, i.e., for each note, we produce one syllable; 2) *syllable-to-syllable*, we use the original notes grouping in the input melody, and assign one syllable to each note group. In this case, the length of target translation is known. Following Lakew et al. (2019), we use length tag "[LEN$i]" to control the length of outputs during pre-training, where $i refers to the length of the target sequence.

5 Generating Melody-constrained Lyrics and Validating Singability

This section details data sets, model configuration, and proposed evaluation metrics. Then we analyze the results and the trade-offs inherent in song translation. Our code and data are open-sourced at `https://github.com/GagaST`.

5.1 Training Datasets and Model Configuration

WMT dataset: news commentary and back-translated news datatsets from WMT14 (29.6 million en2zh sentence pairs). No Cantonese texts included and the official Chinese texts can be pronounced in Mandarin by default.

Monolingual lyrics data: monolingual lyrics in both Mandarin and English collected from the web (12.4 million lines of lyrics for Mandarin and 109.5 million for English after removing duplicates).

Lyrics translation data: a small set of lyrics translation data crawled from the web [7] (140 thousands pairs of English-to-Mandarin lines). These translations are not singable.

We preprocess all training data with fastBPE (Sennrich et al., 2016) and a code size of 50,000. We use encoder-decoder Transformer (Vaswani et al., 2017) with 768 hidden units, 12 heads, GELU activation, 512 max input length, 12-12 layers structure (Appendix B for more details).

---

[6] A dynamic mapping between the note sequence and the syllables changes the original rhythm and increases the search space exponentially. We leave this to future work.

[7] https://lyricstranslate.com/

5.2 Evaluation Datasets

For evaluation, we need aligned triples (melody M, source lyrics X, target reference lyrics Y), where two conditions hold: 1) M and X are syllable-to-note aligned; 2) the reference Y should be singable and intelligible. With the confluence of digitization and copyright making such resources rare, we choose fifty songs from the lyrics translation dataset that have open-source music sheets on the web and create aligned triples manually. However, the reference lyrics in this dataset are not singable (our primary goal!), we use them to validate that the translations preserve the original meaning. Twenty songs comprise the validation set (464 lines) and thirty songs comprise the test set (713 lines).

5.3 Evaluation Metrics

An AST system for tonal languages should generate translated songs that are singable and intelligible while conveying the original meaning. Evaluating such system is an intrinsically hard task since all three qualities can be qualitative. Especially for preserving meaning, the lack of gold references and the greater tolerance for a loose translation in songs make it difficult to say how much semantic divergence is acceptable. Therefore, we first establish evaluations based on the relationship between lyrics and music and then design human annotations for more qualitative evaluations.

5.3.1 Objective Evaluation

Section 3.3 outlines three constraints inspired by music and linguistic theory. Because these constraints are directly incorporated into the decoding objective (Equation 4), these will be better than an unconstrained translation. However, we want to understand the trade-off between these new objectives and traditional translation evaluations.

To control for the length of the sentence, we normalize the score to 0–1.0 by the length of alignment pairs L_i, that is, based on Equation 1,2 and 3,

$$s_{[\cdot]} = \sum_{1}^{L_i} S^{i}_{[\cdot]}/L_i, \qquad (5)$$

For the **length constraint**, we compute: 1) N_l, the number of samples that has length longer than the predefined length L_i; 2) N_s, that are shorter than L_i. For each case we compute the average error ratio of $\{\Delta l_i/L_i\}_1^{N_{[\cdot]}}$. For **meaning**, although we lack gold singable translations, we follow the common practice and calculate BLEU (Papineni et al., 2002) between the translated songs and the prose translation.

5.4 Trade-offs between Meaning and Melody-lyric Alignments

GagaST adds constraints in the decoding scoring functions to enforce lyric-music alignments; however, there are trade-offs between preserving meaning and adhering to these constraints. To select the importance of these constraints in decoding, we vary the value of the corresponding parameter λ (Equation 4) and analyze how much the BLEU score falls on the validation set as we increase the influence of the parameter. We set the hyper-parameters where the alignment scores increase fast while the BLEU decreases slowly. The *REST* constraint does not affect the BLEU (Table 2) but does alter ammount of punctuation. Working off the assumption that excessive punctuation is bad, we select a parameter that minimizes the mismatches between the *REST* and word boundaries. We choose (Figure 7) $\lambda_{\text{inter}} = 0.5$; $\lambda_{\text{intra}} = 1.0$; $\lambda_R = 1.5$ for all subsequent experiments.

5.4.1 BLEU Evaluation

Table 2 compares GagaST as we ablate constraints with our two syllable to note alignment strategies (Section 4): note-to-syllable and syllable-to-syllable. As in previous work, the length tag "[LEN$i]" helps lyrics fit the notes available. In all cases, less than 30 out of 713 lines produces a longer sentence with ratio less than 0.22; and no short cases. Thus, because it most closely resembles prior work in controlled translation and works well in this task, we adopt GagaST with only length tags and no other constraints as our baseline. With all of the constraints, GagaST indeed increases both pitch and rhythm alignments. It almost doubles the pitch contour alignment score, which affect the intelligibility the most.

However, these gains come at the cost of BLEU score.[8] While we believe that the audience would be more accepting of a less-than-literal translation in a song if it sounds better, we need a qualitative evaluation to validate that hypothesis.

---

[8] Due the paucity of reliable references, BLEU scores do not correlate with human judgement. For example, three official Disney Mandarin song translations have a lower BLEU score (12.3) than our more literal but demonstrably worse automatic translations.

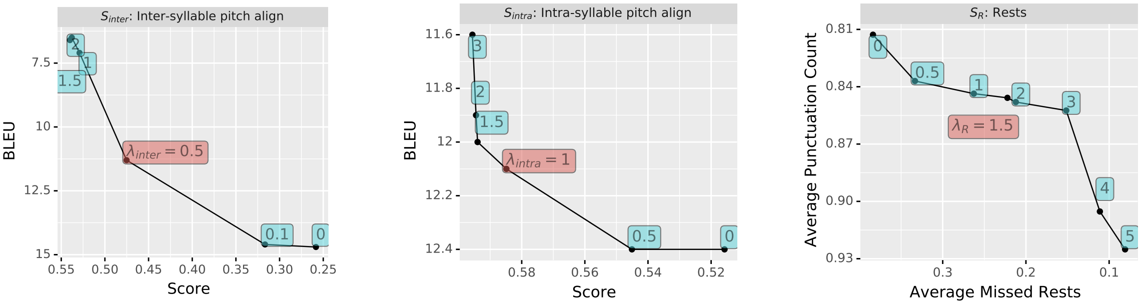

Figure 7: Trade-off between meaning (y-axis) and lyric-music alignments (x-axis) while adjusting the tuning parameter λ on the validation set. The selected value for the tuning parameter λ for downstream experiments is shown in red (preceeded by $\lambda =$). REST constraints do not affect BLEUs, but increase the number of [punc]s, which impairs the fluency of the lyrics, thus we select its parameter based on number of [punc]s.

Syllable-notes Assignment	Model	Pitch		Rhythm	Length		Meaning
		inter ↑	intra ↑	avg # of missed rests ↓	longer ↓	shorter ↓	BLEU ↑
note-to-syllable	GagaST w/o constraints	0.28	-	0.53	9 (0.09)	0	24.0
	GagaST	0.51	-	0.31	26 (0.21)	0	16.9
	–only inter-syllable	0.51	-	0.45	26 (0.21)	0	16.8
	–only rest	0.28	-	0.31	11 (0.09)	0	23.8
syllable-to-syllable	GagaST w/o constraints	0.29	0.49	0.62	4 (0.12)	0	22.1
	GagaST	0.50	0.55	0.28	13 (0.13)	0	15.9
	–only inter-syllable	0.51	0.50	0.42	7 (0.12)	0	15.8
	–only intra-syllable	0.29	0.56	0.44	4 (0.12)	0	21.6
	–only rest	0.29	0.49	0.28	5 (0.12)	0	21.6

Table 2: Our song-specific constraints with two syllable alignment techniques. All results here use the same pre-training checkpoint and length tags are applied. For length score, 9 (0.09) means that 9 out of 713 samples are longer than the predefined length with an average ratio 0.09. All constraints have an effect, but inter-syllable pitch alignment has the largest.

5.4.2 Qualitative Evaluation

The true test of whether AST works is whether the songs can be sung, understood, and enjoyed. Thus, we follow Sheng et al. (2021) and show annotator from a music school students the resulting sheet music, ask their opinion, and ask them to sing the songs. We randomly select five songs from the test set and show the music sheets (see Appendix C) of the first ten sentences of each translated song to five annotators.

Following mean opinion score (Rec, 1994, MOS) in speech synthesis, we use five-point Likert scales (1 for bad and 5 for excellent). And we evaluate the songs on four dimensions: 1) *sense*, fidelity to the meaning of the source lyric; 2) *style*, whether the translated lyric resembles song-text style; 3) *listenability*, whether the translated lyric sounds melodious with the given melody; 4) *intelligibility*, whether the audience can easily comprehend the translated lyrics if sung with provided melody. The last two dimensions require the annotators to sing the song.

Model	Song	*sense*	*style*	*listenability*	*intelligibility*
GagaST w/o constraints	Song1	3.4	3.0	3.2	3.4
	Song2	3.6	3.9	3.4	3.8
	Song3	3.7	3.6	3.4	3.5
	Song4	3.2	3.0	2.8	3.0
	Song5	3.7	3.6	3.4	3.8
	Average	**3.5** ±0.14	3.4 ±0.14	3.2 ±0.12	3.5 ±0.13
GagaST	Song1	3.5	3.1	3.3	3.5
	Song2	3.4	3.7	3.5	4.0
	Song3	3.2	3.6	3.3	3.6
	Song4	2.9	3.0	3.1	3.5
	Song5	3.4	3.6	3.2	3.9
	Average	3.3 ±0.15	3.4 ±0.15	**3.3** ± 0.12	**3.7** ±0.13

Table 3: Qualitative evaluation results for GagaST w/o constraints and GagaST.

5.4.3 Qualitative Evaluation Results

To examine whether the proposed constraints improve the singability and intelligibility, our qualitative evaluation compares GagaST with only length constraints to fully constrained GagaST (Table 3) with *syllable-to-syllable* assignment. While the constraints significantly improve the intelligibility and slightly improve the singability (listening experience), these constraints make it harder for the original meaning to come through. Overall, the annotators are satisfied with the translated songs by the proposed baseline GagaST. All aspects receive an average score around 3.5 out of 5. These case studies and three translated songs by GagaST sung by an amateur singer are available on https://gagast.github.io/posts/gagast.

6 Related Work

Verse Generation and Translation. Generating verse text began through rule-based implementations (Milic, 1970) and developed through the next forty years. Manurung (1999) design a chart system that generate strings that match a given stress pattern. Gervás (2000) build a forward reasoning rule-based system. Manurung (2004) address poetry generation with stochastic search based on evolutionary algorithms. Oliveira (2012) create a template-based platform that allows user to define features and create templates. He et al. (2012) adopt statistical machine translation models for Chinese poetry generation. Yan et al. (2013) compose poetry based on generative summarization framework. Zhang and Lapata (2014), Wang et al. (2016), and Hopkins and Kiela (2017) adopt recurrent neural networks for poetry generation and incorporate rhythmic constraints. Ghazvininejad et al. (2016, 2017) represent rhythm and rhyme with finite-state machines. Poetry translation using these frameworks and statistical machine translation thus offers elegant solutions: Genzel et al. (2010) intersect the finite state representation of the meter and rhyme scheme with the synchronous context-free grammar of the translation model under the phrase-based machine translation framework. Ghazvininejad et al. (2018) apply the finite-state constraints to neural translation model. However, these representations of the rhythmic and lexical constraints are not flexible enough to encode the real-valued representation of a *song* as required for translation in tonal languages.

Constrained Text Generation. Most natural language generation tasks, including machine translation (Bahdanau et al., 2015; Vaswani et al., 2017; Hassan et al., 2018), dialogue system (Shang et al., 2015; Li et al., 2016; Wang et al., 2021) and abstractive summarization (Rush et al., 2015; Paulus et al., 2018), are free text generation. However, there is a need to generate text with constraints for special tasks (Lakew et al., 2019; Li et al., 2020; Zou et al., 2021). Hokamp and Liu (2017); Post and Vilar (2018); Hu et al. (2019) attempt to constrain the beam search with dictionary. In the training procedure, Li et al. (2020) add format embedding. Lakew et al. (2019) introduce length tag. Saboo and Baumann (2019) address length control via rescoring the results of beam search for machine translation under dubbing constraints.

Lyrics Generation. As one of the most important tasks in automatic songwriting, lyrics generation has received more attention recently. Sheng et al. (2021), Lee et al. (2019) and Chen and Lerch (2020) generate lyrics via pure data driven models without adding constraints based on expert knowledge. Oliveira et al. (2007) build a rule-based lyrics generation system to handle rhyme and rhythm with designed heuristics. Malmi et al. (2016) address rap lyrics generation via information-retrieval approach and propose a rhyme-density measure. Watanabe et al. (2018) add conditions in standard RNNLM with a featurized input melody for rhythmic alignment. Ma et al. (2021) develop a SeqGAN-based lyrics generator to address various properties, such as rhythmic alignment, theme and genre. Xue et al. (2021) use transformer-based model to generate rap lyrics with a reverse order, address rhymes with vowel embeddings and add extra beat tokens for rthymic alignment. We are the first paper that formally address the importance of aligning melody pitch with languages tones in lyrics generation for tonal languages. We introduce two vital qualities of songs, singability and intelligibility, and design three types of melody-lyric alignment scores to improve the two qualities.

7 Conclusion

This paper addresses automatic song translation (AST) for tonal languages and the unique challenge of aligning words' tones with melody. And we build the first English-Mandarin AST system – GagaST. Both objective and subjective evaluations demonstrate that GagaST successfully improves the singability and intelligibility of translated songs.

More constraints are left in the future work such as rhymes and style. We aim to build a systematic framework that address all constraints. With the help of newly developed singing voice synthesize tools such as X Studio,[9] we can perform human evaluation with actual singing voice with a larger scale to provide more reliable analysis. Moreover, our system can also be applied in lyrics and song generation applications without translation input.

Ethical Considerations

GagaST improves singability and intelligibility of the translated songs in Mandarin via constraining the decoding of a pretrained lyrics translation model. This methodology has limitations by imposing a direct trade-offs between the original objective and the constraints. In terms of negative impact or risks, the inaccurate translations may cause misunderstandings in applications like Musical Theatre.

This paper collects lyrics data that are publicly available and are parsed from the Web. We use these data for research purposes only. To prevent any abuse or piracy of these data, we chose the dataset license Attribution-NonCommercial-ShareAlike 4.0 International (CC BY-NC-SA 4.0).

Appendix A

A.1 Illustration of Tonal Alignment by Frequency

Translating songs into tonal languages faces a unique challenge,i.e., the tones of the translated lyrics should align with the music pitch for singability and intelligibility (Section 2.1). Figure 8 provides visual illustration of the main problem.

To help researchers who speak non-tonal languages understand better how the tones of lyrics in tonal languages should align with the music/sung voice, we record both sung and spoken voice of a piece of lyrics from one of the most popular songs in Mandarin, transform the sound into the frequency space, and compare the shape of the sound with that of the music in Figure 9. The original music of the chosen song is from an American song "Dreaming of Home and Mother", and was rewritten in Mandarin. Despite that this is not a translation task and do not have to convey the original meaning, we can see how the tonal contour of the lyrics in Mandarin align with that of music.

A.2 Acceptable Pitch Transition Directions Table

In Section 2.2, we explain that in practice, the relative relationship of the pitch of the tones of the successive syllables/characters that belongs to the same word affect the most to the singability and intelligibility. And we summarize the acceptable transition directions in Figure 5 under the assumption that only relative relationship of successive notes matters. It should be noted that we intend merely to provide a workable solution but not a perfect one. For example, the handle of the fourth notes of Mandarin is actually very tricky. It is a continuous fall with a large range (see Figure 2), therefore it doesn't represent one note. If it were to be represented by one note, it might represent the onset or offset part of the tone, and the falling trend is hinted by the pitch contour with proceeding and/or following note (Zhuang, 1982; Yu, 2021).

Appendix B

B.1 Training Details

We pretrain our transformer-based model with reconstruction objective and corrupt our input sequence with **text infilling** (Lewis et al., 2020). More detailed pretraining hyper-parameters can be found in Table 4.

Parameter	Value
encoder layer	12
decoder layer	12
max source position	512
max target position	512
layernorm embedding	True
criterion	label smoothed cross entropy

Appendix C

C.1 Human Evaluation Instruction

In this paper, we conduct subjective evaluations by collecting annotations about the qualities of the translated songs from music school students (Section 5.4.2).

C.2 Music Sheets

As describe in Section 5.4.2 and shown in the instructions (Figure 10), we distributes music sheets of the translated songs to the annotators. All music sheets can be found on `https://gagast.github.io/posts/human_eval`.

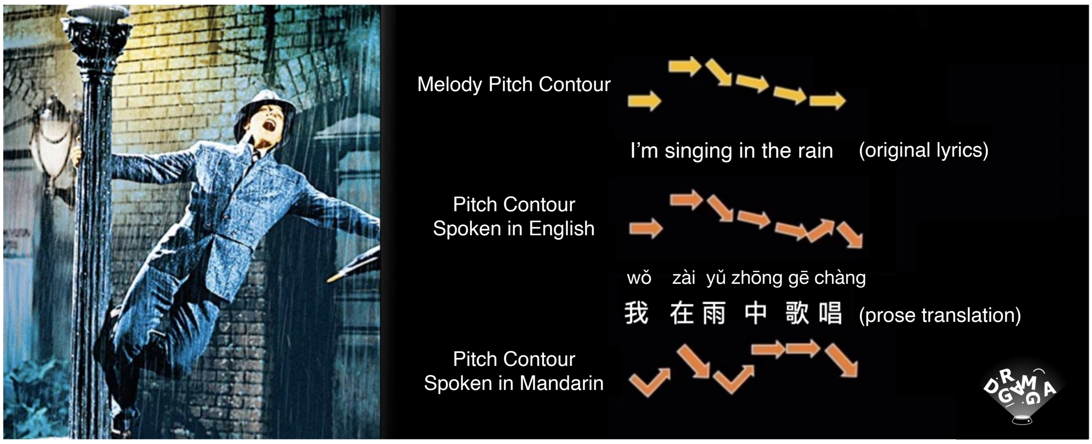

Figure 8: The pitch contour of the prose translation (bottom line, in Mandarin) of lyrics do not match that of the original music (upper line). The directions showed in figure is estimated by the base frequency of spoken sound by text-to-speech tools. Such mismatch in pitch contour makes the sung lyrics sound unnatural and hard to understand.

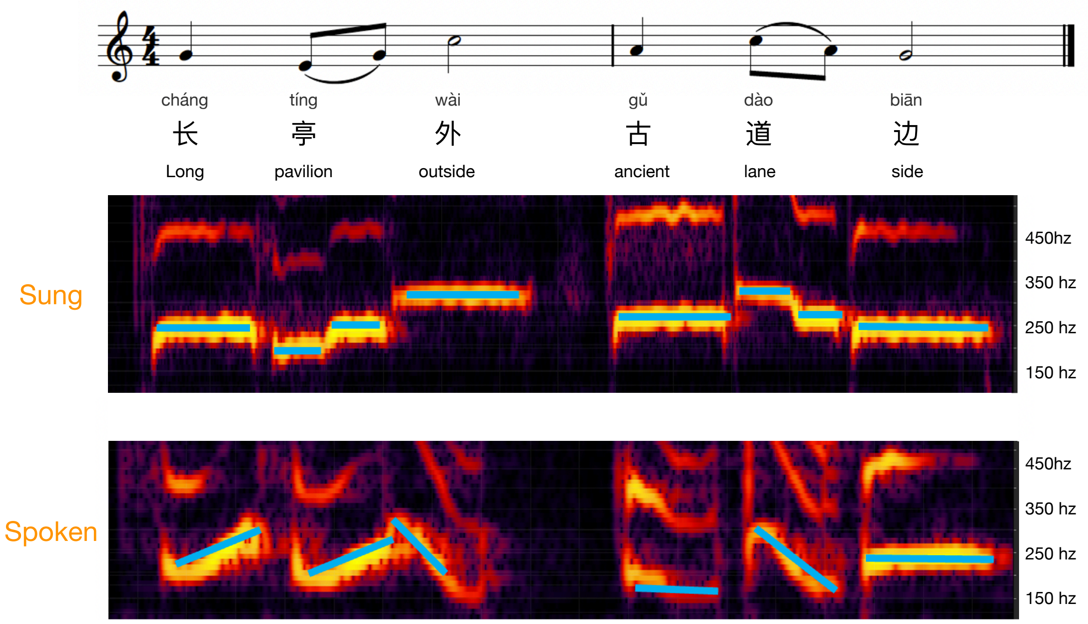

Figure 9: An example of a piece of a popular rewritten song in Mandarin “Farewell (sòng bié)”. The original music is from an American song “Dreaming of Home and Mother”. We record the sung and spoken voice and plot the actual base frequency of the sound. We can see how the tone shape and overall tonal contour aligns with the sung voice (by the music pitch).

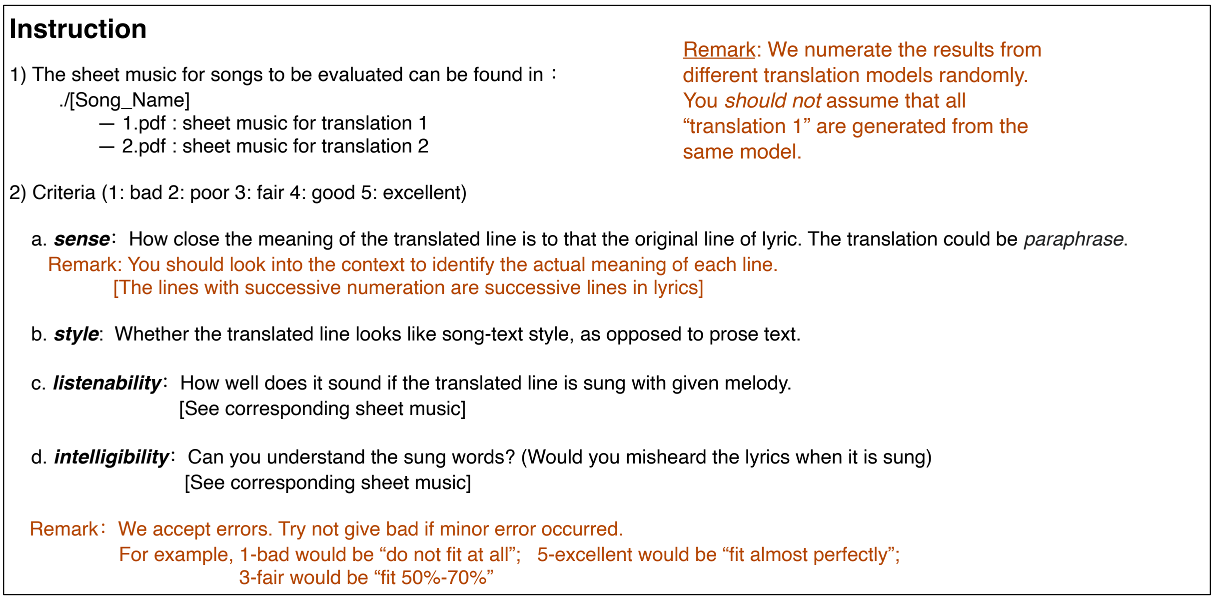

Instruction

1) The sheet music for songs to be evaluated can be found in：

./[Song_Name]

— 1.pdf : sheet music for translation 1

— 2.pdf : sheet music for translation 2

Remark: We numerate the results from different translation models randomly. You *should not* assume that all “translation 1” are generated from the same model.

2) Criteria (1: bad 2: poor 3: fair 4: good 5: excellent)

a. ***sense***: How close the meaning of the translated line is to that the original line of lyric. The translation could be *paraphrase*.

Remark: You should look into the context to identify the actual meaning of each line.
[The lines with successive numeration are successive lines in lyrics]

b. ***style***: Whether the translated line looks like song-text style, as opposed to prose text.

c. ***listenability***: How well does it sound if the translated line is sung with given melody.
[See corresponding sheet music]

d. ***intelligibility***: Can you understand the sung words? (Would you misheard the lyrics when it is sung)
[See corresponding sheet music]

Remark：We accept errors. Try not give bad if minor error occurred.
For example, 1-bad would be “do not fit at all”; 5-excellent would be “fit almost perfectly”;
3-fair would be “fit 50%-70%”

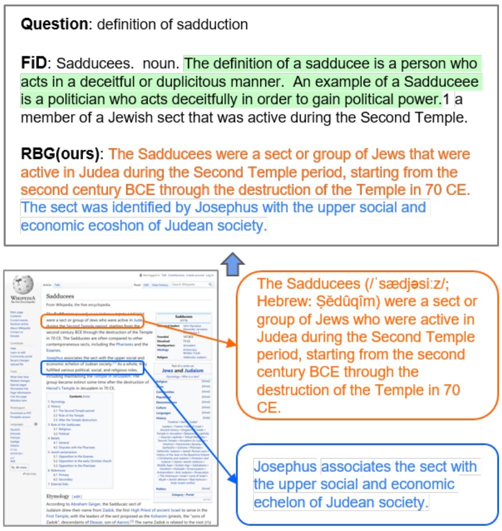
Abstract

Long-form question answering (LFQA) aims to generate a paragraph-length answer for a given question. While current work on LFQA using large pre-trained model for generation are effective at producing fluent and somewhat relevant content, one primary challenge lies in how to generate a faithful answer that has less hallucinated content. We propose a new end-to-end framework that jointly models answer generation and machine reading. The key idea is to augment the generation model with fine-grained, answer-related salient information which can be viewed as an emphasis on faithful facts. State-of-the-art results on two LFQA datasets, ELI5 and MS MARCO, demonstrate the effectiveness of our method, in comparison with strong baselines on automatic and human evaluation metrics. A detailed analysis further proves the competency of our methods in generating fluent, relevant, and more faithful answers.

1 Introduction

Long-form question answering (LFQA) is a task to generate an in-depth, paragraph-length answer for a given question (Fan et al., 2019). It is important since many of the everyday questions that humans deal with and pose to search engines require multi-sentence explanations (Khashabi et al., 2021) (e.g. *why/how..?*). It can be integrated with a search engine (Metzler et al., 2021), or a virtual conversation agent, and can also be used to generate explanations as a complement to short-phrase answers for open-domain questions (Kwiatkowski et al., 2019; Yang et al., 2018), or to answer open-ended questions like those from Reddit forum "Explain Like I'm Five" (Fan et al., 2019).

LFQA is quite a challenging task. It often involves searching a large external knowledge source that contains millions of documents for relevant information. Then it *generates* a paragraph-length answer from those retrieved sources. While the great success in retrieval technique (Guu et al., 2020; Karpukhin et al., 2020; Lee et al., 2019) can be carried over to the LFQA setting, more challenges lie in the generation. First, multiple documents that contain hundreds of tokens need to be considered for generation, raising difficulties in the direct use of current pre-trained language models. Second, as different documents may contain redundant, complementary, or contradictory information, how to synthesis the information and generate a faithful answer that has less hallucinated content is even more challenging.



Question: definition of sadduction

FiD: Sadducees. noun. The definition of a sadducee is a person who acts in a deceitful or duplicitous manner. An example of a Sadduceee is a politician who acts deceitfully in order to gain political power.1 a member of a Jewish sect that was active during the Second Temple.

RBG(ours): The Sadducees were a sect or group of Jews that were active in Judea during the Second Temple period, starting from the second century BCE through the destruction of the Temple in 70 CE. The sect was identified by Josephus with the upper social and economic ecoshon of Judean society.

The Sadducees (/ˈsædjəsiːz/; Hebrew: Ṣĕdûqîm) were a sect or group of Jews who were active in Judea during the Second Temple period, starting from the second century BCE through the destruction of the Temple in 70 CE.

Josephus associates the sect with the upper social and economic echelon of Judean society.

Figure 1: An example from MS MARCO (Nguyen et al., 2016) dataset. We highlight the unfaithful snippets from other model. Our model(**RBG**) generate more factually accurate answer.

While recent work on LFQA (Krishna et al., 2021) focuses primarily on the first challenge, and has produced fluent and somewhat relevant content, the latter faithfulness challenge has not been explored. However, the faithfulness issue is quite important for LFQA. As the example in Fig. 1 shown, a fluent and relevant but unfaithful answer (high-

Findings of the Association for Computational Linguistics: ACL 2022, pages 744 - 756
May 22-27, 2022 ©2022 Association for Computational Linguistics

light in green) will mislead users.

In this paper, we propose a novel end-to-end framework named RBG (**R**ead **B**efore **G**enerate) for LFQA to address the aforementioned challenges. The key idea for enhancing answer faithfulness is to augment the generation process with predicted salient information which can be viewed as an emphasis on answer-related facts. Specifically, we combine a Seq2Seq language model-based generator with a machine reading comprehension (*reader*) module. The *reader* produces an evidence probability score for each sentence, which will be integrated with the generator for final distribution prediction. We perform evidence fusion in a similar way as FiD (Izacard and Grave, 2021) to equip the pre-trained language model with multiple input documents for generation. To further enhance the factual grounding ability of RBG, we propose an additional pre-training task to encourage the model to rely more on retrieved documents to generate factual statements. The details are explained in Section 2.

We conduct thorough experiments on our method and several baselines on ELI5 (Fan et al., 2019), the only publicly available large-scale LFQA dataset, and also on MS MARCO (Nguyen et al., 2016) passage ranking data, which can also be transformed into an answer generation task. The proposed method tops the public leaderboard of the KILT (Petroni et al., 2021) Benchmark on the ELI5 dataset. It also outperforms the baselines, including non-retrieval and retrieval-based methods, such as DPR-BART (Petroni et al., 2020), RAG (Izacard and Grave, 2021) and FiD (Izacard and Grave, 2021), with improvement on the automatic evaluation results on the MS MARCO dataset. Human evaluation results further validate that our proposed framework can improve the generation quality in terms of relevance and factual correctness.

Our contributions are summarized as follows:

- To the best of our knowledge, we are the first trying to tackle the faithfulness challenge in LFQA.
- We propose a new and effective framework for open-domain LFQA to generate answers with the guidance of a sentence evidence score from a machine reading module, as well as an additional factual grounding-oriented pre-training task.
- We show the effectiveness of our method by both automatic evaluation and human evaluation on two large-scale datasets, and we also demonstrate by human evaluation that our method improves the factual correctness of generated answers while still keeping high informativeness.

2 A state-of-the-art LFQA system

To generate in-depth, long-form answers for a given general domain question, we first use a retriever to search for relevant information from a large external knowledge source. Then our reader and the generation module take the multiple retrieved documents together with the question as input to generate the answer. Specifically, the reader module adopts a machine reading comprehension (MRC) model to produce an evidence score for each sentence in each document, while the generator, which adopts a large pre-trained Seq2Seq language model, fuses the sentence evidence score into its generation process. Our framework is shown in Figure 2.

2.1 Supporting document retriever

We use DPR (Karpukhin et al., 2020) to retrieve the supporting documents following the typical methods in the state-of-the-art framework for open-domain QA (Izacard and Grave, 2021; Lewis et al., 2020b). The passage and question are represented as 768-dimensional dense vector representations, computed via the BERT-based bi-encoder networks of DPR. The retriever will rank the documents according to their relevance, calculated as

$$Score_{re}(Q, D_i) = \mathrm{BERT}_q(Q)^T \mathrm{BERT}_d(D_i) \quad (1)$$

Retrieval is performed using approximate nearest neighbors with the FAISS[1] library. We denote $D = \{D_1, D_2, ..., D_k\}$ as the top-K retrieved documents for question Q.

2.2 Document reader

Since there are no golden retrievals for long-form answers, the retrieved documents may contain complementary, contradictory, or redundant information related to the answer. Thus, we propose to use a reader module to explicitly predict the sentence-level evidence probability in each document.

Evidence span prediction We use a machine reading comprehension (MRC) model to predict the evidence span in each document, as these models approach or even outperform human-level performance on many datasets (Joshi et al., 2020).

---

[1] `github.com/facebookresearch/faiss`

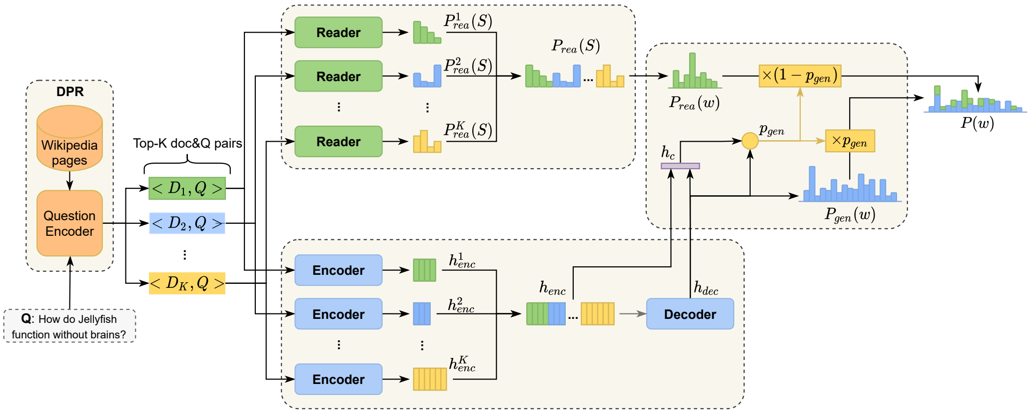

Figure 2: Overview architecture of our RBG framework. RBG comprises a supporting document retriever, a document reader and a generator.

The MRC model takes the concatenation of the retrieved document D_i and question Q as input, and outputs the prediction of the start and end position of the potential evidence spans in D_i. Specifically, it outputs two probability distributions over the tokens in D_i: $P^s_i(w_s)$ and $P^e_i(w_s)$, where $P^s_i(w_s)$ / $P^e_i(w_s)$ is the probability that the token w_s is the start/end of the evidence span in D_i.

Sentence evidence probability Originally, the MRC model was designed to give accurate, short-phrase span prediction (Rajpurkar et al., 2016), but we argue that a sentence-level evidence probability will be better in our scenario. The supporting sentences can provide the minimum required context information for each answer span, which is quite important, especially in multi-document generation (Xu and Lapata, 2020). We define our sentence-level evidence probability score for the i-th document $P^i_{rea}(S)$ as the summation over all token-level evidence probabilities in that sentence, and it is calculated via

$$P^i_{rea}(S) = \frac{1}{2} \sum\nolimits_{w_s \in S} (P^s_i(w_s) + P^e_i(w_s)) \tag{2}$$

$$P_{rea}(S) = \text{Norm}(P^1_{rea}(S); \ldots P^i_{rea}(S); \ldots P^K_{rea}(S)) \tag{3}$$

We concatenate P^i_{rea} and normalize the distribution as $P_{rea}(S)$, where $P_{rea}(S)$ denotes the final sentence-level evidence probability in all the K documents regarding the question.

Multi-task MRC As there are no golden answer spans for LFQA data, we need a MRC model that has enough generalization ability for open domain questions as a starting point. We choose SpanBERT (Joshi et al., 2020), and further fine-tune it in a multi-task way on six large-scale MRC datasets from the MRQA shared task (Fisch et al., 2019) following work by Su et al. (2019): SQuAD (Rajpurkar et al., 2016), NewsQA (Trischler et al., 2017), TriviaQA (Joshi et al., 2017), SearchQA (Dunn et al., 2017), HotpotQA (Yang et al., 2018), and NatualQuestions (Kwiatkowski et al., 2019). The multi-task fine-tuned MRC model R will be further jointly trained with the generator, using the golden answer in a distantly supervised way.

2.3 Generator

FiD-BART We choose BART as our generation backbone because of its outstanding performance on many generation tasks, especially on long-form abstractive summarization task (Lewis et al., 2020a). We propose FiD-BART, following the *Fusion-in-Decoder* idea from Izacard and Grave (2021), to empower BART to deal with multiple, long-document inputs. FiD-BART processes each document independently in the encoder, while performing the cross-attention in the decoder jointly.

The encoder encodes the concatenation of each supporting document D_i and the question Q. More precisely, we append the special tokens *question:* before Q, *title:* and *context:* before the title and text of each document D_i. We denote the encoded final representation of the encoder as h_{enc}, which is the concatenation of the K encoder outputs h^i_{enc} ($h^i_{enc} \in R^{d \times l_i}$) for the ith document:

$$h^i_{enc} = \text{Encoder}(Q; D_i) \tag{4}$$

$$h_{enc} = (h^1_{enc}, \ldots, h^i_{enc}, \ldots, h^K_{enc}) \tag{5}$$

The partial structure of the decoder can be illustrated by Eq.(6)–(8), where h_l is the representation for the l-th decoder layer. We denote h_{dec} as the last layer decoder outputs:

$$h_l^a = \text{SelfAttention}(h_l, h_l, h_l) \quad (6)$$

$$h_l^b = \text{LayerNorm}(h_l + h_l^a) \quad (7)$$

$$h_l^c = \text{CrossAttention}(h_l^b, h_{enc}, h_{enc}) \quad (8)$$

As we can see, FiD-BART can scale to a large number of input documents within a linear computation time.

2.4 Reader-before-generator

To incorporate the evidence probability into generation, we apply the pointer-generator model (depicted in Figure 2). The attention distribution $\mathcal{A}$ and context vector h_c, and the generation probability $p_{gen} \in$ [0,1] are calculated as follows:

$$\mathcal{A} = softmax(h_{dec}h_{enc}^T) \quad (9)$$

$$h_c = \mathcal{A}h_{enc} \quad (10)$$

$$p_{gen} = sigmod(W_c h_c + W_g h_{dec}) \quad (11)$$

where W_c and W_g are learnable parameters. p_{gen} is used as a soft switch to choose between generating a word from the generator by sampling from the vocab, or copying a word from the input sequence by sampling according to the evidence distribution $P_{rea}(w)$:

$$P_{gen}(w) = lm_{head}(h_{dec}) \quad (12)$$

$$P_{rea}(w) = \sum\nolimits_{s:w_s=w, w_s \in S} P_{rea}(S) \quad (13)$$

$$P(w) = p_{gen}P_{gen}(w) + (1 - p_{gen})P_{rea}(w) \quad (14)$$

2.5 Pre-training

To further improve the ability to ground on retrieved documents, we propose a pre-training task: retrieval-augmented recovery (RAR). Instead of recovering the corrupted text through the internal knowledge memorized in model parameters (Raffel et al., 2020; Lewis et al., 2020a), RAR encourages the model to rely more on external retrieved documents to generate factual statements. Specifically, given an original text S, we retrieve the top-k documents $D_1, D_2, ..., D_N$ from the knowledge corpus using BM25 (discarding S itself), and we replace 30% of the words in S with [MASK]to form a pseudo query Q. The pre-training task asks our RBG model to recover S with the input of the pseudo query Q and k retrieved documents, which can be formulated as

$$S = RBG(Q; D_1, D_2, ..., D_k) \quad (15)$$

To involve more factual information during the text corruption and recovery process, we sample 1 million sentences of S corresponding to at least one knowledge base triplet from Wikipedia with the text-triple alignment of TREX (Elsahar et al., 2018a).

3 Experiment Setups

3.1 Datasets

We conduct experiments on the two following datasets, both of which concentrate on long form generative QA.

ELI5 (Fan et al., 2019) is the only publicly available large-scale LFQA dataset. It is a collection of question-answer pairs extracted from the Reddit forum "Explain Like I'm Five"(ELI5). We use the KILT (Petroni et al., 2021) version of the dataset from its Github repository[2], which has 272,634 training examples and 1,507 development examples. The average length of the answers is 130 words.

MS MARCO (Nguyen et al., 2016) is a dataset of crowdsourced responses to Bing queries. We use the question-answer pairs of the MS MARCO passage ranking track for training and evaluation, as they are more abstract and reliant on multi-document information than those of the NLG track. The training example size is about 500,000 and the evaluation example size is 6980.

Knowledge source The external knowledge source of the retriever is the Wikipedia paragraphs, which are provided in the KILT benchmark as a unified knowledge source for knowledge-intensive tasks, including open-domain LFQA (Petroni et al., 2021). It is based on the 2019/08/01 Wikipedia snapshot, and contains 5.9M articles.

3.2 Baselines

BART and T5 We fine-tune BART (Lewis et al., 2020a) and T5 (Raffel et al., 2020) using QA pairs without explicit retrieval, and include them as our baselines which rely only on parameterized internal knowledge (Roberts et al., 2020) to generate answers.

DPR-BART is our retrieval-based LFQA baseline. We follow Petroni et al. (2020) to retrieve and prepend the top-3 passages from DPR for each input sample, and use context-enhanced training data to fine-tune a BART model.

RAG (Lewis et al., 2020b) is an end-to-end retrieval-augmented generation model which backpropagates to the retriever's input encoder. We experiment with fine-tuning RAG on LFQA tasks, establishing a strong baseline on all of them. At every generation step we retrieve the top-5 passages and use them as supporting documents.

---

[2] `github.com/facebookresearch/KILT`

FiD (Izacard and Grave, 2021) encodes each passage independently and combines all outputs from the encoder before passing them to the decoder. FiD has achieved superior performance on a number of open-domain QA tasks (Izacard and Grave, 2021). We implement FiD-BART, using BART as the generation backbone, as our strongest baseline.

4 Experiment Results

4.1 Automatic Evaluation

We use the metrics unigram F1 score and ROUGE-L (LIN, 2004) in previous work on LFQA (Petroni et al., 2021; Krishna et al., 2021) to evaluate and compare the generation quality of our method.

Overall Comparison Table 1 shows the performance of various methods on the two datasets. As shown, our RBG method outperforms all baselines models with regard to both evaluation metrics on both datasets. The RBG method also outperforms the previous state-of-the-art method *c-REALM+RT* on the KILT-ELI5 leaderboard[3] (Krishna et al., 2021), as shown in Table 2.

Models	Eli5		MS MARCO	
	ROUGE-L	F1	ROUGE-L	F1
T5(base)	21.02	18.36	21.19	20.03
BART(large)	22.69	22.19	23.26	25.6
DPR+BART	17.41	17.88	23.01	25.13
RAG	16.11	17.24	-	-
FiD	25.70	28.55	24.64	27.08
RBG(ours)	**26.46**	**29.04**	**24.72**	**27.52**

Table 1: Performance comparison between our RBG method and the baselines on the KILT-ELI5 (Petroni et al., 2021) and MS MARCO (Nguyen et al., 2016) evaluation sets.

Model	Retrieval		Generation		
	PRr.	R@5	F1	R-L	KRL
RBG(ours)	10.83	27.25	**24.53**	**27.13**	**2.62**
DPR_kilt_wiki	14.83	27.69	16.45	15.91	2.46
c-REALM[1]	10.67	24.56	23.19	22.88	2.36
DPR+BART	10.67	26.92	17.41	17.88	1.90
RAG	11.00	22.92	14.05	14.51	1.69
BART-large	0.00	0.00	20.55	19.23	0.00
T5-base	0.00	0.00	19.08	16.10	0.00

Table 2: Results on the ELI5 test set on the KILT leaderboard. Our RBG tops the leaderboard in terms of (1) retrieval performance, using R-precision(RPr.) and Recall@5(R@5), and (2) generation quality, using F1 and ROUGE-L(R-L). These scores are combined to produce the overall metric KILT R-L(KRL) (Petroni et al., 2021). c-REALM[1] is from (Krishna et al., 2021)

Fine-grained Comparison Intuitively, the quality of retrieved documents will affect the generation quality, thus we provide a fine-grained performance comparison. We split MS-MARCO evaluation set into different subset based on the quality of the retrieved documents[4], and compare the ROUGE-L score between FiD and RBG under each subset.

As we can see from Table 3, even though RBG beats FiD by 0.1 Rouge-L score on the whole MS-MARCO evaluation set, the performance gap continue increasing as the retrieval quality of the evaluation subset increased. This indicates that RBG is especially effective when high-quality retrieval documents is provided, which matches with our intuition.

>ngram overlap		0	0.4	0.6	0.8
# of documents		6980	3493	1470	489
ROUGE-L	FiD	24.64	28.04	33.62	45.25
	RBG	24.72	28.59	34.38	46.29
>retrieval score		0.0	75	80	85
# of documents		6980	5811	3188	1001
ROUGE-L	FiD	24.64	24.7	25.63	26.81
	RBG	24.72	25.46	26.53	27.96

Table 3: Fine-grained comparison between FiD and RBG on different subset of MS-MARCO evaluation data.

4.2 Human evaluation

We further evaluate our model using human annotators, who we ask to quantify three aspects of the generated answer, (1) **fluency**, which measures whether the answer is coherent and less repetitive; (2) **relevance**, which measures the amount of information relevant to answering the question, and (3) **factual correctness** (also briefly called correctness), which measures the correctness and faithfulness of all facts involved in the generated answer.

We select FiD, which is the strongest baseline in terms of automatic metrics, for comparison. We sample evaluation questions from the MS MARCO dev set, which are better supported by Wikipedia knowledge than ELI5. Table 4 shows the absolute evaluation results of human annotation. To reduce the impact of scale selection inconsistency of different annotators, we also show the relative evaluation results in Table 5. We can see that both types of

---

[3] `https://evalai.cloudcv.org/web/challenges/challenge-page/689/leaderboard/1908`

[4] We consider two metrics to measure the retrieval quality for a certain question: (1) **Top-1 document retrieval score** which is the matching score output by the retriever (Equation. 1) for the top-1 document to measure the corresponding semantic relevance to the given question, and (2) **N-gram overlap**, which is the N-gram overlap between the golden answer and the top-k retrieved documents.

Model	Fluency	Relevance	Correctness
FiD	2.62	2.34	2.07
RBG(ours)	**2.70**	**2.50**	**2.41**

Table 4: Absolute human evaluation results for RBG vs. FiD on MS MARCO. The table shows the mean value across all annotators and examples for each metric.

Aspect	Prefer FiD	Prefer RBG	Tie
Fluency	12%	**26%**	62%
Relevance	18%	**48%**	34%
Correctness	4%	**62%**	34%

Table 5: Relative human evaluation results for RBG vs. FiD on MS MARCO. The percentages represent the ratio of one model being voted as preferred by multiple annotators on a metric.

results indicate that RBG outperforms FiD in terms of all three aspects. RBG has more advantages over FiD on the metric of factual correctness, possibly benefited by the introduction of the reader module and additional pre-training. More details of the human evaluation setup and statistical analysis can be found in Appendix C.

4.3 Ablation

To further investigate the contribution and effect of each module in the proposed system, we conducted a systematic ablations on the MS-MARCRO evaluation dataset.

No.	models	MS MARCO	
		ROUGE-L	F1
0	RBG(ours)	24.72	27.52
1	w/o reader	24.66	27.30
2	w/o pre-training	24.65	27.38
3	w/o reader + pre-training	24.64	27.08
4	w/ reader frozen	24.51	25.85
5	w/ random retrieval	22.84	25.23

Table 6: Ablation results on the MS MARCO evaluation set. A more fine-grained results comparison is shown with analysis in Section 5.

***w/o* reader/pre-training:** We respectively remove the reader module (**w/o reader**), the pre-training (**w/o pre-training**), and both together (**w/o reader + pre-training**) from our model , to test the contribution of each part. As we can see from Table 6, without the reader to predict the evidence probability, the generation performance decreases in both metrics, and the performance continues to drop without the pre-training.

***w/* reader frozen:** We freeze the reader to investigate the benefit of distantly supervised end-to-end training of the reader module. As we can see from Table 6, the results on both metrics drop, especially the F1 score, which proves the effectiveness of the end-to-end training.

***w/* random retrieval:** To investigate whether and how much the generation process is grounded in the retrieved documents, we replace retrieved paragraphs with randomly sampled paragraphs from Wikipedia at *inference* time for comparison. As we can see, the ROUGE-L drops significantly with randomly retrieved documents, and it is also worse than the baseline systems such as BART and DPR-BART (Table 1).

5 Further analysis

We conduct further analysis on the results, considering that LFQA is a complicated but less explored task, which deserves a complete investigation.

5.1 How does retriever affect the generation quality?

We further investigate the effects of the quality of retrieved documents on the final generation. We split the evaluation sets of the two datasets via different thresholds for the two metrics[4] and calculate the corresponding ROUGE-L score for each subset. As we can see in Table 7, better-retrieved documents always bring better generation quality, indicating the importance of high-quality supporting documents for the generation process.

We also measure the effects of the number of retrieved documents K on the generation quality and find that the best K from $\{5, 10, 20, 50\}$ is 10. More retrieved documents do not improve generation quality as in open-domain QA.

>retrieval score(top-1)	ELI5		MS MARCO	
	# of data	ROUGE-L	# of data	ROUGE-L
0.0	1570	26.35	6980	24.72
75	1270	26.37	5811	25.46
80	479	26.38	3188	26.53
85	72	26.96	1001	27.96
90	11	27.25	161	27.61

>ngram overlap	ELI5		MS MARCO	
	# of data	ROUGE-L	# of data	ROUGE-L
0.0	1570	26.35	6980	24.72
0.4	460	27.09	3493	28.59
0.5	260	27.31	2470	30.72
0.6	109	27.52	1470	34.38
0.7	48	27.63	845	39.64
0.8	27	27.17	489	46.29

Table 7: Fine-grained results of our RBG on ELI5 and MS MARCO. With high-quality retrieval (higher N-gram overlap or retrieval score threshold), the answer quality (ROUGE-L) increases on both datasets.

5.2 How does the reader contribute to the generation?

As shown in the ablation study, the reader module improves the overall performance on the MS MARCO evaluation dataset. We further investigate

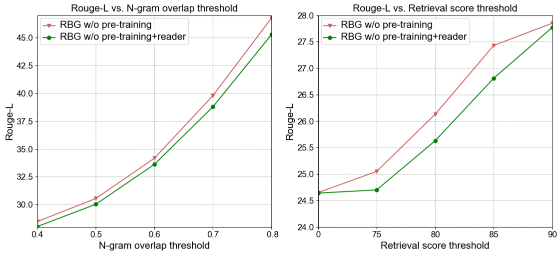

Figure 3: ROUGE-L versus document retrieval performance for reader analysis.

Aspect	Prefer w/o reader	Prefer w/ reader	Tie
Fluency	15%	**35%**	50%
Relevance	17%	**57%**	26%
Correctness	25%	**45%**	30%

Table 8: Human evaluation results for RBG reader analysis on MS MARCO. The model with reader has better generation performance in terms of fluency, relevance and correctness.

its performance when retrieved documents with different quality levels are provided.

We show in Figure 3 the fine-grained comparison results between ablation models **No.2**: *RBG w/o pre-training* and **No.3**: *RBG w/o pre-training + reader*. As we can see, the difference in ROUGE-L between the two models increases as the quality of the retrieved documents improves, indicating the reader's strong capability, especially on high-quality data. This also matches with our intuition. We also conduct a human evaluation for reader analysis, and we show the results in Table 8.

5.3 How does pre-training help?

We also compare the models' performance in a fine-grained way, to quantify the contribution from our pre-training task. We show in Figure 4 the fine-grained comparison results between ablation models **No.1**: *RBG w/o reader* and **No.3**: *RBG w/o pre-training + reader*. As we can see, the model with pre-training is better in most situations than that without pre-training. The human evaluation in Table 9 also indicates the effectiveness of our pre-training task to improve the factual correctness and relevance of the generated answer. We conjecture that the pre-training task of retrieval-augmented recovery can facilitate the downstream LFQA model to combine multiple pieces of evidence from different retrieved documents to generate the final answer.

Aspect	Prefer w/o pre-training	Prefer w/ pre-training	Tie
Fluency	40%	**43%**	17%
Relevance	20%	**33%**	47%
Correctness	23%	**47%**	30%

Table 9: Human evaluation results for RBG pre-training analysis on MS MARCO. The model with RAR pre-training has better generation performance in terms of relevance and correctness.

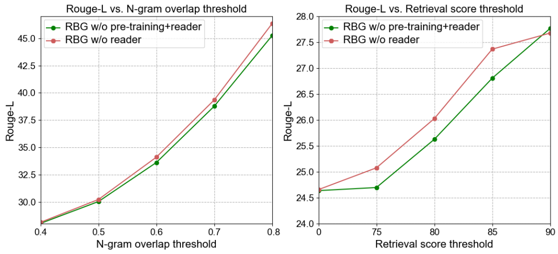

Figure 4: ROUGE-L versus Document retrieval performance for pre-training analysis.

5.4 Faithfulness analysis

Zero-shot on extractive QA tasks Inspired by previous work (Wang et al., 2020; Durmus et al., 2020) which leverage a Question Generation(QG) and a QA model to generate question answer pairs, to evaluate the faithfulness of a summary[5], we propose to evaluate answer faithfulness via evaluation on two simpler open-domain QA datasets: NaturalQuestions (Kwiatkowski et al., 2019) and HotpotQA (Yang et al., 2018), which contain single-hop or multi-hop factual questions with golden answers ($\{(q_i, a_i^s)\}_{i=1}^m$) where a_i^s can be extracted from Wikipedia-based documents. We use the trained models (based on MS MARCO) in Table 1 to do zero-shot long-form answer generation for these two datasets $\{a_i^l = \text{Model}_{\text{ms}}(q_i)\}$, and measure the short-answer recall (the ratio of golden answer span a^s contained in the generated long answer a^l) as an estimation of faithfulness of the generated long-answer:

$$Score(q, a^s, a^l) = \frac{\sum_{i=1}^m \mathbb{1}[a_i^s \in a_i^l]}{m} \tag{16}$$

We show the results in Table 10. As we can see, our system achieves comparable performance with FiD on NQ, and it consistently outperforms other strong baselines on multi-hop dataset hotpotQA, indicating its capability in generating faithful answer especially on complex question that need to synthesis information. We also give concrete examples in Appendix E that show our model can generate more faithful snippets than FiD apart from automatic metrics.

Case Study To have a concrete understanding of the reader's role to address faithfulness, we show two examples in Table 11. While both models use the same **ctxs**, RBG **w reader** generates a more *rel-*

---

[5] They generate question answer pairs <q,a_{sum}> from the summary, and compare a_{sum} with the answer a_{sc} from source document for q, to evaluate faithfulness.

	NQ Recall	HotpotQA Recall
T5	4.76	7.20
BART-large	10.44	9.13
DPR+BART	16.37	11.57
FiD	43.93	22.94
RBG(ours)	43.93	23.36

Table 10: Faithfulness Analysis of the system generation quality via zero-shot evaluation on NQ (Kwiatkowski et al., 2019) and HotpotQA (Yang et al., 2018).

evant answer, and **w/o reader** only gives some correct but unrelated statements (Case 1). The reader also contributes to generating more *faithful* answers, as shown in Case 2. However, we notice that there is one unfaithful statement, which hallucinates the 'second-oldest' as 'oldest'. This might be because of the property of our MRC model: it gives a high evidential score to one sentence, and weakening the importance of other sentences in the same document.

Question: what does abc stand for in liquor store?

w/o reader answer: ABC stores. A liquor store is a retail shop that predominantly sells prepackaged alcoholic beverages intended to be consumed off the store's premises. ...,or other similar terms.

w/ reader answer: ABC stands for Alcoholic Beverages Control (ABC Stores) and is a type of liquor store that is owned and operated exclusively by the state government, where liquor stores often sell only spirits or sometimes sell spirits and wine but not beer...

ctxs: [{text: ...In seventeen alcoholic beverage control (ABC) states, ...},...,{text:operated exclusively by the state government, where liquor stores often sell only spirits or sometimes sell spirits and wine but not beer., ...,because purchased liquor must be packaged in sealed bottles},...,{...}]

Question: dow jones industrial average please?

w/o reader answer: The Dow Jones Industrial Average (DJIA) is an index of 30 major U.S. stock indexes. The DJIA was created in 1896 by Charles Dow, a statistician and editor of The Wall Street Journal. The index was first published in the mid-1880s, and was last updated on May 26, 1896.

w/ reader answer: The Dow Jones Industrial Average (DJIA) is a stock market index that tracks the performance of the 30 largest U.S. industrial companies. It is owned by S&P Dow Jones Indices, which is majority owned by Standard & Poor's Global. The Dow is the oldest and most famous of the Dow averages. It was created by Charles Dow in 1896.

ctxs: [{text:...,was originally published on February 16, 1885. ...The industrial average was first calculated on May 26, 1896..},...{text:...It is the **second-oldest** U.S. market index after the Dow Jones Transportation Average. Currently owned by S&P Dow Jones Indices, which is majority owned by S&P Global..},...,{...}]

Table 11: Examples from MS MARCO dataset. We highlight the sentences that have high evidential probability from the reader, and use green to mark out the unfaithful snippets.

6 Related work

Grounded generation is the task of leveraging external knowledge sources to enhance the generation. Previous work has either used *structured* external knowledge source (Liu et al., 2018; Young et al., 2018; Su et al., 2020a) or *unstructured* data. Zhou et al. (2018) introduced a document grounded dataset for text conversations, and Wu et al. (2021) proposed to extract lexical control phrases to do controllable grounded response generation, while Zhang et al. (2021) jointly trained a retriever and generator so that annotated text reference parallel data are not needed.

Open-domain QA is the task of answering general-domain questions (Chen et al., 2017), in which the evidence is usually not given. Models that explicitly exploit an external corpus are referred as *open-book* models (Roberts et al., 2020). They typically index the corpus and then *retrieve-and-read* to extract the answer span from documents (Chen et al., 2017; Lee et al., 2019; Izacard and Grave, 2021; Lewis et al., 2020b). Another recently proposed class of methods is *closed-book* QA models (Ye et al., 2020; Roberts et al., 2020). They fine-tune pre-trained language models such as T5 (Raffel et al., 2020) or BART (Lewis et al., 2020a) with QA pairs without access to any external knowledge or context.

Query driven multi-document summarization (QFMD) aims to generate a summary according to the query and the provided relevant document(s) (Tombros and Sanderson, 1998). Baumel et al. (2018) incorporated query relevance into a pre-trained abstractive summarizer, while Xu and Lapata (2020) and Su et al. (2020b) utilized QA models for sentence- or paragraph- level evidence ranking. Su et al. (2021) tried to improve the relevance of the summary by incorporating an answer relevance score for the source documents into the generation.

7 Conclusion

We propose a new end-to-end framework RBG that jointly models answer generation and machine reading to tackle the faithfulness issue in LFQA. Experiments on two LFQA datasets, ELI5 and MS MARCO, demonstrate the effectiveness of our method in comparison with strong baselines on automatic and human evaluation metrics. The detailed analysis further proves the competency of our method in generating fluent, relevant, and more faithful answers. We also propose to evaluate the factual correctness of LFQA model by answering questions of extractive QA tasks (e.g., Natural Questions), which may be helpful to evaluate the faithfulness of LFQA model efficiently.

A Implementation details

We initialize our generation models with the pre-trained *BART-large* models (Lewis et al., 2020a), available in the HuggingFace[6] Transformers library. Our reader models was initiated from SpanBERT(base&cased), from Facebook Github[7], and further fine-tuned on MRQA datasets for 4 epochs, using the default fine-tuning configurations. Our RBG is trained using Adam (Kingma and Ba, 2014) with a constant learning rate of 5e-5 and weight decay at 0.01. We train the model for 50k gradient steps, with a batch size of 4, using 8 Tesla V100 32Gb. We evaluate the models every 500 steps and select the best one on the validation set (1/8 of the evaluation set) based on the Rouge score. The maximum source document length is set to 300, and the target sequence length is set to 300. During inference, we use beam search with beam size of 4.

B Document retriever model details

As the question/answers in LFQA may cover different domains and topics, we use a multi-task variant of DPR to guarantee the retrieval performance. The retriever is trained jointly on the union of all knowledge-intensive training data in KILT benchmark (Petroni et al., 2021), including TrivaQA (Joshi et al., 2017), kwiatkowski2019naturaluestion (Kwiatkowski et al., 2019), HotpotQA (Yang et al., 2018), Fever (Thorne et al., 2018), zsRE (Levy et al., 2017), AY2, T-REx (Elsahar et al., 2018b) and WoW (Dinan et al., 2018).

C Human evaluation setup and analysis

Basic setup As shown in Table 12, we sample 50 questions for each comparison and assign 3 annotators for each generated answer, which brings a workload of 450 judgments on model preference for each evaluation aspect. This process takes large amounts of energy and time considering the difficulty and challenges of factual-related annotation. We sample 10 questions from each of five development subsets corresponding to 5 levels of answer-passage overlap, which is a stratified sampling strategy. The answer position of each model is randomly shuffled to reduce the bias of position preference. 15 participants in our human evaluation are all researchers or students in computer science who speak and read English well.

Comparison	#Questions	#Annotators/answer
RBG vs. FiD	50	3
Reader analysis	50	3
Pre-training analysis	50	3

Table 12: Details of human evaluation for three comparisons.

---

[6] `github.com/huggingface/transformers`

[7] `https://github.com/facebookresearch/SpanBERT`

Scoring setup We ask each annotator to select a score from {1,2,3} for each generated answer in terms of three aspects: *fluency*, *relevance* and *factual correctness*. During scoring, the annotators are asked to preserve the relative better-or-not relationship between two models as much as possible. In particular, for the metric of factual correctness, the annotators check the correctness of all factual statements involved in a generated answer by referring to Wikipedia (EN), other web pages and the golden answer. The answer with significantly fewer factual errors will get a higher score on factual correctness. We show cases in Table 16 to demonstrate how the annotator evaluate three aspects in our experiment.

Statistical analysis We present the agreement among annotators on model preference in Table 13 by calculating the Fleiss Kappa (Fleiss, 1971) as the inter-rater consistency. The RBG vs. FiD comparison achieves better annotation agreement than other two ablation comparisons, maybe because RBG integrates both two of our contributions to improve the answer quality. In the comparison of RBG vs. FiD, annotators achieve a "moderate agreement" on the aspect of correctness and "fair agreement" on relevance (Landis and Koch, 1977). Annotators achieve best agreements on fluency in all comparisons. It's more difficult to achieve a high degree of annotation consistency on factual correctness and relevance than fluency due to complicated facts involved in the generated answer. Therefore, we recommend taking preferred ratio as the core metric for factual-related evaluation following (Krishna et al., 2021; Nakano et al., 2021). We also present score variance of four models involved in human evaluation in Table 14. It's natural that the fluency score has the smallest variance while the difficult-to-annotate correctness has largest variance.

Comparison	fluency	relevance	correctness
RBG vs. FiD	0.65	0.33	0.47
Reader analysis	0.55	0.12	0.06
Pre-training analysis	0.62	0.16	0.08

Table 13: Agreement analysis for three comparisons in terms of three aspects. We use Fleiss Kappa (Fleiss, 1971) to measure the agreement degree between annotators. The score range of [0,0.2] corresponds to slight agreement, [0.2,0.4] corresponds to fair agreement and [0.4,0.6] corresponds to moderate agreement (Landis and Koch, 1977).

Comparison	fluency	relevance	correctness
RBG	0.14	0.33	0.46
RBG w/o reader	0.22	0.34	0.48
RBG w/o pre-training	0.16	0.26	0.45
RBG w/o reader+pre-training	0.28	0.42	0.64

Table 14: Score variance of four models involved in human evaluation.

ndocs	ROUGE-L	F1
5	24.63	27.29
10	**24.72**	**27.52**
20	24.39	26.68
50	23.43	25.94

Table 15: Generation performance versus the number of retrieved documents of our model on MS MARCO (Nguyen et al., 2016).

D Number of retrieved documents on Generation Quality

We also investigate the effects of number of retrieved documents k, on the answer generation quality. As we can see in Table 15, the generation quality in terms of ROUGE-L and F1, do not further improve as the number of k increases, and the best performance are obtained when $k = 10$ in our case.

E Case of zero-shot experiments on NQ and HotpotQA

In addition to automatic evaluation on the two datasets, we also show concrete examples to give a better understanding. As we can see in Table 17, **BART** tends to generate unfaithful answers as it lacks of external knowledge related to the specific question, and **DPR + BART** produces somewhat faithful but irrelevant answers, while **FiD** performs much better but still with partially unfaithful generations. In comparison, our **RBG** can generate more fluent, specific and factually accurate responses.

Question	Generated answer	f	r	c
effects of hyperthyroidism	Model1: Hyperthyroidism is a condition in which the thyroid gland produces too much thyroid hormone. The thyroid gland is a butterfly-shaped gland located in the neck. It is the only gland in the body that is responsible for the production of thyroid hormone, which helps regulate the body's metabolism.	3	1	3
	Model2: Hyperthyroidism is a condition in which the thyroid gland produces too much thyroid hormone. This can cause the body to produce more thyroid hormone than it needs. This causes the thyroid to overproduce thyroid hormone, which can lead to a number of symptoms, including: 1 Weight gain. 2 Nausea. 3 Fatigue. 4 Vomiting.	3	3	3
where is cabo de hornos	Model1: Cabo de Hornos is the southern tip of South America's Cape Horn Archipelago. It is the largest island in the Pacific Ocean and is the only island in South America with a population of more than 2,000,000 inhabitants. The island is also the world's second-largest island in terms of land area, with a total area of 1,826 square miles (4,926 square kilometers) .	3	2	1
	Model2: Cabo de Hornos, Chile. Cabo de Hanoque, also known as Cape Horn, is the southern tip of South America. It is located in the south of Tierra del Fuego archipelago, in the AntÃ¡rtica Province, Magallanes Region. The municipality of Cabo De Hornos is the capital of the province of Puerto Williams.	3	3	3

Table 16: Cherry-picked scoring cases by annotators in our human evaluation. f, r, and c respect fluency, relevance and correctness respectively. We use green to mark out factual incorrect snippets the annotator finds. The first case shows how annotators distinguish different levels of relevance and the second case shows that of factual correctness.

Question (from NQ): what are the ranks in the us navy?

Gold Answer: ["E-8s senior chief petty officer", "E-9s master chief petty officer"]

BART: (?) Navy ranks in the U.S. Navy. The Navy ranks are as follows: 1 Master Chief Petty Officer (MOS) a non-commissioned officer in the Navy. 2 Master Sergeant (MS), a Master Sergeant in the Marine Corps. 3 Sergeant Major (SSM), a Sergeant Major in the Air Force.

DPR-BART: (?) The U.S. Navy is a branch of the United States Armed Forces. The Navy is made up of the Navy, Marine Corps, Air Force, Coast Guard, and Coast Guard.

FiD: (*) The U.S. Navy is a branch of the United States Armed Forces. The rank system of the Navy consists of three categories: junior officers, senior officers, and flag officers. Junior officers are those officers in pay grades O-1 to O-4, while senior officers are the ones with pay grades of O-5 and O-6. Senior officers have pay grades ranging from O-7 to E-9. Flag officers have a pay grade ranging from E-5 to E9.

RBG(ours): The U.S. Navy ranks are divided into three categories: junior officers, senior officers, and flag officers. Junior officers are officers in pay grades O-1 to O-4, while senior officers are those in pay grades O-5 and O-6. Flag officers serve either as a line officer or as a staff corps officer.

Question (from HotpotQA): Which French ace pilot and adventurer fly L'Oiseau Blanc?

Gold Answer:["Charles Eugène"]

BART: (?) L'oiseau Blanc is a French aviator and aviator who flew the L'Oiseau blanc. He is best known for being the first aviator to fly it..

DPR-BART: (?) L'oiseau Blanc l'oiseau blanc (French: The White Bird) was a French Levasseur Pl.8 biplane that disappeared in the early morning hours of April 1, 2014. The plane was a Levassellseur PL.8 Biplane that vanished in the morning of April 2, 2014, after being piloted by an adventurer pilot and adventurer pilot..

FiD: (*) On May 8, 1927, Charles Nungesser and Francois Coli took off from Paris on the L'Oiseau Blanc, a Levasseur PL.8 biplane that had been designed by Charles Nongesser, a French ace pilot and aviator, to fly from Paris to New York City in the Orteig Prize.

RBG(ours): On May 8, 1927, Charles Nungesser and Francois Coli boarded L'Oiseau blanc, a 450-hp Lorraine-powered Levasseur biplane designed to compete for the Orteig Prize. They took off from Paris on 8 May 1927 and were last seen over Ireland. Less than two weeks later, Charles Lindbergh successfully made the New York-Paris journey and claimed the prize in the Spirit of St. Louis.

Table 17: Examples of the zero-shot long-form answers on the NQ (Kwiatkowski et al., 2019) and HotpotQA (Yang et al., 2018) datasets. RBG model generates more fluent, specific and factually accurate responses. '?' indicates factually incorrect/irrelevant responses; * indicates partially correct responses. We use the green to mark out the unfaithful snippets.

A Simple yet Effective Relation Information Guided Approach for Few-Shot Relation Extraction

Abstract

Few-Shot Relation Extraction aims at predicting the relation for a pair of entities in a sentence by training with a few labelled examples in each relation. Some recent works have introduced relation information (i.e., relation labels or descriptions) to assist model learning based on Prototype Network. However, most of them constrain the prototypes of each relation class implicitly with relation information, generally through designing complex network structures, like generating hybrid features, combining with contrastive learning or attention networks. We argue that relation information can be introduced more explicitly and effectively into the model. Thus, this paper proposes a **direct addition** approach to introduce relation information. Specifically, for each relation class, the relation representation is first generated by concatenating two views of relations (i.e., [CLS] token embedding and the mean value of embeddings of all tokens) and then directly added to the original prototype for both train and prediction. Experimental results on the benchmark dataset FewRel 1.0 show significant improvements and achieve comparable results to the state-of-the-art, which demonstrates the effectiveness of our proposed approach. Besides, further analyses verify that the **direct addition** is a much more effective way to integrate the relation representations and the original prototypes. [1] [2]

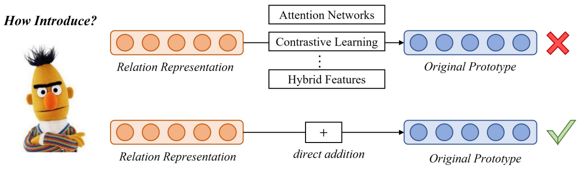

Figure 1: The figure is an intuitive illustration of the difference in ways to introduce relation information between most existing works and our proposed approach. The orange vector and the blue vector denote representations of relations and prototypes, respectively.

1 Introduction

Relation Extraction (RE) (Bach and Badaskar, 2007) is a fundamental task of Natural Language Processing (NLP), which aims to extract the relations between entities in sentences and can be applied to other advanced tasks (Li et al., 2021; Hu et al., 2021). However, RE usually suffers from labeling difficulties and train data scarcity due to the massive cost of labour and time. In order to solve the problem of data scarcity, Few-Shot Relation Extraction (FSRE) (Han et al., 2018; Gao et al., 2019a; Qu et al., 2020; Yang et al., 2021) task has become a research hotspot in academia in recent years. The task is firstly to train on large-scale data on existing relation types, and then quickly migrate to a small amount of data on new relation types.

Inspired by the success of few-shot learning in the computer vision (CV) community (Sung et al., 2018; Garcia and Bruna, 2018), various methods are introduced into FSRE. One of the popular algorithms is the Prototype Network (Snell et al., 2017), which is based on the meta-learning framework (Vilalta and Drissi, 2002; Vanschoren, 2018). In detail, collections of few-shot tasks sampled from the external data containing disjoint relations are used as the training set for the model optimization. For each few-shot task, the center of each relation class is calculated and used as the prototype of the relation class. Then, the model can be optimized by reducing the distances between the query samples and their corresponding prototypes. Given a new sample, the model calculates which of the class prototypes is nearest to the new sample and assign it to this relation class.

In order to get better results, many works have

May 22-27, 2022 ©2022 Association for Computational Linguistics

utilized relation information (i.e., relation labels or descriptions) to assist model learning. TD-proto (Yang et al., 2020) enhanced prototypical network with both relation and entity descriptions. CTEG (Wang et al., 2020) proposed a model that learns to decouple high co-occurrence relations, where two types of external information are added. Another intuitive idea is to hope that the model can learn good prototypes or representations , that is, to reduce the distances of the intra-class while widening the ones among different classes (Han et al., 2021; Dong et al., 2021), where Han et al. (2021) introduced a novel approach based on supervised contrastive learning that learns better prototype representations by the utilization of prototypes and relation labels and descriptions during the model training; Dong et al. (2021) considered a semantic mapping framework, MapRE, which leverages both label-agnostic and label-aware knowledge in pre-training and fine-tuning processes.

However, there are two limitations in how these works introduce relation information. The first is that most of them take implicit constraints, like contrastive learning or relation graphs, instead of the direct fusion, which can be weak facing the remote samples. The second is that they usually adopt complicated designs or networks, like hybrid features or elaborate attention networks, which can bring too many or even harmful parameters. Therefore, in this paper, we propose a straightforward yet effective way to incorporate the relation information into the model. Specifically, on the one hand, the same encoder is used to encode relation information and sentences for mapping them into the same semantic space. On the other hand, we generate the relation representation for each relation class by concatenating two relation views (i.e., [CLS] token embedding and the mean value of embeddings of all tokens), which allows relation representations and prototypes to form the same dimension. Afterwards, the generated relation representation is directly added to the prototype for enhancing model train and prediction.

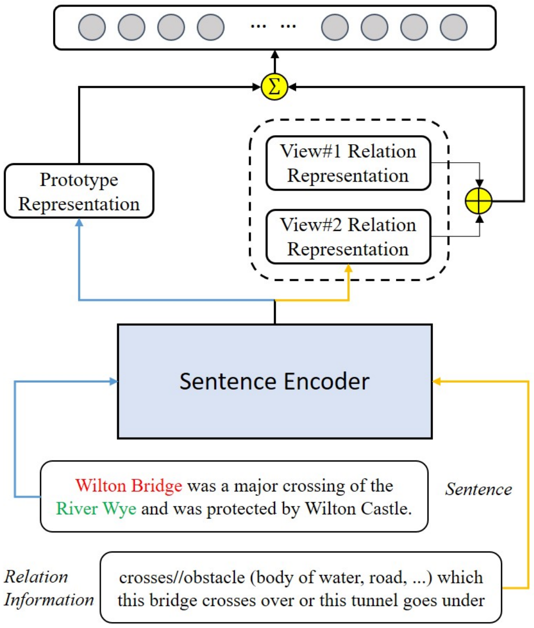

Figure 2: The overall structure of our proposed approach, in which the sentence and the relation information share the same encoder, and then the relation representation is generated through ⊕ operation with two views of relations and added to the original prototype representation. ⊕ and $\sum$ denote the concatenation and addition operations, respectively.

Figure 1 shows an intuitive illustration of the difference in ways to introduce relation information between most existing works and our proposed approach. Based on the mentioned two limitations of previous works, we provide two possible high-level ideas about why our proposed approach should work for few-shot relation extraction. The first is that the **direct addition** is a more robust way to generate promising prototypes than implicit constraints when facing the remote samples. The second is that the **direct addition** does not bring extra parameters and simplifies the model. Due to possible over-fitting, fewer parameters are always better than more parameters, especially for few-shot tasks. We conduct experimental analyses in the experiment section for further demonstration.

We conduct experiments on the popular FSRE benchmark FewRel 1.0 (Han et al., 2018) under four few-shot settings. Experimental results show considerable improvements and achieve comparable results to the state-of-the-art, which demonstrates the effectiveness of our proposed approach, i.e., the direct addition operation.

2 Proposed Method

In this section, we present the details of our proposed approach. Figure 2 shows the overall structure, where the blue and yellow lines represent the flow of sentences and relation information, respectively. In order to map the representations of sentences and relation information into the same semantic space, the shared sentence encoder is utilized. Then, we concatenate two views of the relation representations for obtaining the same dimen-

Table 1: Experimental results of FSRE on FewRel 1.0 validation / test set, where N-w-K-s stands for the abbreviation of N-way-K-shot. The table divides the method with BERT as the encoder into two parts, from top to bottom including approaches with the original BERT, and approaches with additional pre-training on BERT. Note that $*$ represents the results of our implementation, others are obtained from results reported by papers or CodaLab.

sion as prototypes and integrate relation representations into original prototypes by direct addition.

2.1 Sentence Encoder

We employ one BERT (Devlin et al., 2019) as the encoder to obtain contextualized embeddings of support set $\mathcal{S}$ and query set $\mathcal{Q}$. For instances in $\mathcal{S}$ and $\mathcal{Q}$, the intermediate states are obtained by concatenating the hidden states corresponding to start tokens of two entity mentions following Baldini Soares et al. (2019), i.e., $[h_{entity1}; h_{entity2}]$, $h_{entity1}, h_{entity2} \in \mathbb{R}^d$, where d is the size of the contextualized representations of sentence encoder. Then, we average intermediate states of each relation class in $\mathcal{S}$ to obtain the initial prototype representation for each relation class. Denote the set of prototype representations as $\{\mathcal{P}_i \in \mathbb{R}^{2d}; i = 1, 2, .., c\}$, where c is the number of relation classes. For each relation, we concatenate the name and description and feed the sequence into the BERT encoder. We treat the embedding of the "[CLS]" token, i.e., $\{\mathcal{R}_i^{view1} \in \mathbb{R}^d, i = 1, 2, ..., c\}$, and the average of the embeddings of all tokens, i.e., $\{\mathcal{R}_i^{view2} \in \mathbb{R}^d, i = 1, 2, ..., c\}$, as two different views from the relation representation.

2.2 Relation Representation Generation

As described in Section 2.1, $\mathcal{P}_i \in \mathbb{R}^{2d}$ for prototypes and $\mathcal{R}_i^{view1}, \mathcal{R}_i^{view2} \in \mathbb{R}^d$ for relations. In order to minimize the introduction of additional linear layers (or parameters) and make the direct addition operation possible, we combine $\mathcal{R}^{view1}$ and $\mathcal{R}^{view2}$ together by simple concatenation operation $\oplus$ as the following.

$$\mathcal{R}^{final} = \mathcal{R}^{view1} \oplus \mathcal{R}^{view2} \tag{1}$$

where $\mathcal{R}^{final} \in \mathbb{R}^{2d}$ same as $\mathcal{P}$.

2.3 Relation Classification

The final prototype representations are obtained by the direct addition of the original prototype representations $\mathcal{P}$ and the relation representations $\mathcal{R}^{final}$:

$$\mathcal{P}^{final} = \mathcal{P} + \mathcal{R}^{final} = \{\mathcal{P}_i^f \in \mathbb{R}^{2d}\} \tag{2}$$

The model uses the **vector dot product** way to calculate the distance between the query instance $\mathcal{Q}$ and each class prototype $\{\mathcal{P}_i^{final} \in \mathbb{R}^{2d}, i = 1, 2, .., c\}$, and selects the relation class with the shortest distance as the prediction result. We employ the cross-entropy (CE) loss as the loss function simply:

$$\mathcal{L}_{CE} = -log(z_y) \tag{3}$$

where y is the class label, and z_y is the estimated probability for the class y.

3 Experiment

3.1 Dataset, Training, Evaluation and Comparable Models

Dataset Our proposed approach is evaluated on the commonly used large-scale FSRE dataset FewRel 1.0 (Han et al., 2018), which consists of 100 relations, each with 700 labeled instances. Our experiments follow the splits used in official benchmarks, which split the dataset into 64 base classes for training, 16 classes for validation, and 20 novel classes for testing.

Training We use BERT-base-uncased and CP (Wang et al., 2020) as the sentence encoder, where CP is a further pre-trained model based on BERT with contrastive learning. We set the train iteration number as 30,000, validation iteration number as 1,000, batch size as 4, learning rate as 1e-5 and 5e-6 for BERT and CP respectively.

Evaluation N-way-K-shot (N-w-K-s) is commonly used to simulate the distribution of FewRel in different situations, where N and K denote the number of classes and samples from each class, respectively. In the N-w-K-s scenario, accuracy is used as the performance metric. Since the label of the test set of the FewRel is not publicly available, we submit the prediction of our model to CodaLab to obtain the accuracy on the test set.

Comparable Models The comparable models contain two CNN-based models Proto-HATT (Gao et al., 2019a) and MLMAN (Ye and Ling, 2019), as well as nine BERT-based models BERT-PAIR (Gao et al., 2019b), REGRAB (Qu et al., 2020), TD-proto (Yang et al., 2020), CTEG (Wang et al., 2020), ConceptFERE (Yang et al., 2021), MTB (Baldini Soares et al., 2019), CP (Peng et al., 2020), MapRE (Dong et al., 2021), and HCRP (Han et al., 2021). Since our proposed approach is based on the Prototype Network with BERT, we also compare the Proto-BERT without relation information.

3.2 Results

All experimental results are shown in Table 1. CNN-based and BERT-based methods are both contained in the table. There are two parts to BERT-based methods. The first one utilizes the original BERT without any external pre-training. *Proto-BERT* represents the method on which our model is based, which means that this is the result of the model without introducing the improvements we propose. This result will also be analyzed and displayed again in Section 3.3. The second one contains the methods that employ additional pre-training on BERT with Wikipedia data or contrastive learning to get better contextual representations. We apply our approach to BERT and CP. For obvious comparison, the former is shown in the first part of BERT-based models, and the latter is shown in the second part of BERT-based models. The **last two rows** show the increase on the test set compared to the basic models used by our approach (i.e., Proto-BERT and CP).

From the table, we can obtain three observations. First, when using BERT as the backend model, our approach *Ours (BERT)* outperforms the state-of-the-art, which is listed in the first part of the BERT-based model in Table 1. Most of these methods are designed with relatively complex network structures and implementations. Second, *Ours (CP)* utilizes CP as the backend model and outperforms the state-of-the-art, i.e., HCRP (CP), on two few-shot settings, i.e., 5-way-1-shot and 10-way-1-shot, which also reflects from the side that our approach is more suitable for few-shot scenarios. Third, the improvements compared to the basic model, i.e., Proto-BERT and CP, are rather considerable, which are shown in the last two rows of Table 1. These observations demonstrate the effectiveness of our proposed approach.

Comparision with HCRP In this part, we compare our approach with the state-of-the-art model, i.e., HCRP, on the test set based on CP, which is shown in Table 2. It can be seen that the result

Model	5-w-1-s	10-w-1-s
Ours	91.29	86.09
w/o relation info.	84.77	76.85
w/ concat	79.16	65.12
w/ linear layer		
view#1	89.04	80.29
view#2	89.39	80.14

Table 4: Ablation Study on validation set of FewRel 1.0. w/o, w/, and info. are the abbreviations of without, with, and information.

of our approach is slightly lower than HCRP on 5-way-5-shot and 10-way-5-shot, while the average accuracy of four settings is higher than HCRP. However, HCRP designed three modules, including hybrid features, contrastive learning, and task adaptive loss function. On the contrary, our approach is more straightforward and achieves comparable results to HCRP. Table 3 shows the comparison of the model complexity between Ours and HCRP. It can be seen that the total number of model parameters and parameters to be adjusted of Ours are both less than HCRP. Thus, we may argue that the lower results on 5-way-5-shot and 10-way-5-shot than HCRP can not deny the effectiveness of our proposed approach.

3.3 Ablation Study

Since the label of the test set of FewRel 1.0 is not public, in this section, we conduct an ablation study on 5-way-1-shot (5-w-1-s) and 10-way-1-shot (10-w-1-s) based on BERT with the validation set. Following HCRP and the official setting, the validation iteration step is set to 1000. Results are shown in Table 4. There are two types of ablation study. One type is "w/o relation info.", where only the original prototype network is utilized without introducing any relation information (i.e., Proto-BERT). The second type is ablation study in the integration way of relation representations and prototypes. Instead of the direct addition operation, we adopt another two kinds of integration way, i.e., "w/ concat" and "w/ linear layer". For “w/ concat”, after obtaining the relation representation $\mathcal{R}^{final} \in \mathbb{R}^{2d}$ (the symbol appeared in Section 2.2) with two views of relations, we perform "w/ concat" by concatenating $\mathcal{R}^{final}$ and $\mathcal{P}$ first, i.e., $\mathcal{R}^{final} \oplus \mathcal{P} \in \mathbb{R}^{4d}$. Then a $4d$-$2d$ linear layer is applied on the concatenation embedding to obtain the final prototype representation. For "w/ linear layer", a extra linear layer is introduced. Specifically, only one view of relations, i.e., $\mathcal{R}^{view1} \in \mathbb{R}^{d}$ or $\mathcal{R}^{view2} \in \mathbb{R}^{d}$, is used in the model. Then, we perform a $1d$-$2d$ linear layer and addition operation to obtain the final prototype representation.

From the results in Table 4, we can see that relation information is essential for few-shot relation extraction. The result ("w/o relation info.") drops sharply compared to "Ours". Besides, results of another integration way have poor performance compared to "Ours". Especially, "w/ concat" are quite poor, probably because it requires the use of a $4d$-$2d$ linear layer, which introduces too many parameters. These observations demonstrate that our proposed approach is a straightforward yet effective way to integrate relation representations and original prototypes.

4 Conclusion

In this paper, we proposed a simple yet effective approach with relation information based on Prototype Network. The core idea is to introduce relation representations by the direct addition operation instead of designing complex structures. Experimental results on FewRel 1.0 achieve comparable results to the state-of-the-art and demonstrate the effectiveness of our proposed approach. Moreover, we provide two high-level ideas, i.e., explicit constraints and fewer parameters, about why the direct addition is so effective. We believe that the idea of finding global information to perform the direct addition with original prototypes is general and can be extended to other few-shot tasks that can be modeled based on the prototype network.

Since the direct addition way of introducing relations is simple and efficient, we also believe that future work should focus more on generating better relation representations rather than designing fusion methods between relations and prototypes.

Appendix

A. Hyper-parameter Settings

Hyper-parameter settings for two backend models, i.e., BERT and CP, are shown in Table 5 and Table 6. We experiments the model on three different learning rate and select the best learning rate that is bolded in the table. Besides, the validation iteration is set to 1000.

COMPONENT	PARAMETER	VALUE
BERT	TYPE	base-uncased
	HIDDEN SIZE	768
	MAX LENGTH	128
TRAINING	LEARNING RATE	9e-6,**1e-5**, 2e-5
	BATCH SIZE	4
	MAX ITERATIONS	30,000

Table 5: The hyper-parameters that we have experimented on the datasets with BERT.

COMPONENT	PARAMETER	VALUE
CP	TYPE	base-uncased
	HIDDEN SIZE	768
	MAX LENGTH	128
TRAINING	LEARNING RATE	**5e-6**, 7e-6, 9e-6
	BATCH SIZE	4
	MAX ITERATIONS	30,000

Table 6: The hyper-parameters that we have experimented on the datasets with CP.

B. Results on Different Learning Rates

We explore the effect of two different learning rates with CP as the backend model, which is shown in Table 7. Note that *lr* is short for learning rate. From the results in Table 7, we can see that when CP is used as the backend model, our method has better performance with a smaller learning rate.

Settings	*lr*=5e-6	*lr*=9e-6
5-w-1-s	96.63	96.54
5-w-5-s	97.93	97.98
10-w-1-s	94.94	94.04
10-w-5-s	96.39	96.08
Average	96.47	96.16

Table 7: Test accuracy on four settings with two different learning rates based on CP.

C. Comparison with different modules of HCRP

HCRP contains three modules including hybrid features generation, relation-prototype contrastive learning (RPCL), and task adaptive loss function. HCRP reported the ablation study in the paper with different modules. We further do the comparison with different modules of HCRP on FewRel 1.0 validation set based on BERT model. The comparisons are based on 5-way 1-shot and 10-way 1-shot settings.

MODEL	5-W-1-S	10-W-1-S
Ours	91.29	86.09
HCRP	90.90	84.11
w/o local prototype	88.37	82.31
w/o global prototype	86.42	77.86
w/o RPCL	87.85	79.76
w/o task adaptive loss	88.96	82.75

Table 8: Comparisons with different modules of HCRP on FewRel 1.0 validation set with BERT model, where w/o denotes without.

MIMICause: Representation and automatic extraction of causal relation types from clinical notes

Abstract

Understanding causal narratives communicated in clinical notes can help make strides towards personalized healthcare. Extracted causal information from clinical notes can be combined with structured EHR data such as patients' demographics, diagnoses, and medications. This will enhance healthcare providers' ability to identify aspects of a patient's story communicated in the clinical notes and help make more informed decisions.

In this work, we propose annotation guidelines, develop an annotated corpus[1] and provide baseline scores to identify types and direction of causal relations between a pair of biomedical concepts in clinical notes; communicated implicitly or explicitly, identified either in a single sentence or across multiple sentences.

We annotate a total of 2714 de-identified examples sampled from the 2018 n2c2 shared task dataset and train four different language model based architectures. Annotation based on our guidelines achieved a high inter-annotator agreement i.e. Fleiss' kappa (κ) score of 0.72, and our model for identification of causal relations achieved a macro F1 score of 0.56 on the test data. The high inter-annotator agreement for clinical text shows the quality of our annotation guidelines while the provided baseline F1 score sets the direction for future research towards understanding narratives in clinical texts.

1 Introduction

Electronic Health Records (EHRs) have significant amounts of unstructured clinical notes containing a rich description of patients' states as observed by healthcare professionals over time. Our ability to effectively parse and understand clinical narratives depends upon the quality of extracted biomedical concepts and semantic relations. The contemporary advancements in natural language processing (NLP) have led to an increased interest in tasks such as extraction of biomedical concepts, patients' data de-identification, medical question answering and relation extraction. While these tasks have improved our ability for clinical narrative understanding, identification of semantic causal relations between biomedical entities will further enhance it.

Identification of novel and interesting causal observations from clinical notes can be instrumental to a better understanding of patients' health. It can also help us identify potential causes of diseases and determine their prevention and treatment. Despite the usefulness of identification and extraction of causal relation types, our capability to do so is limited and remains a challenge for specialized domains like healthcare.

The NLP community has been actively working on causality understanding from text and has proposed various methodologies to represent (Talmy, 1988; Wolff, 2007; Swartz, 2014; Hassanzadeh et al., 2019), as well as extract (Mirza and Tonelli, 2014; O'Gorman et al., 2016; Mirza and Tonelli, 2016; Gao et al., 2019; Khetan et al., 2022), causal associations between the events expressed in natural language text. In the healthcare domain, most of the related work can be grouped around the problem of adverse drug effect identification from biomedical scientific articles (Gurulingappa et al., 2012) or clinical notes (Johnson et al., 2016; Liu et al., 2019; Henry et al., 2020; Rawat et al., 2020), and identification of cause, effect and their triggers (Mihaila et al., 2012). There is no work that has yet tried to represent different types of causal associations along with direction (between biomedical concepts) communicated in clinical notes.

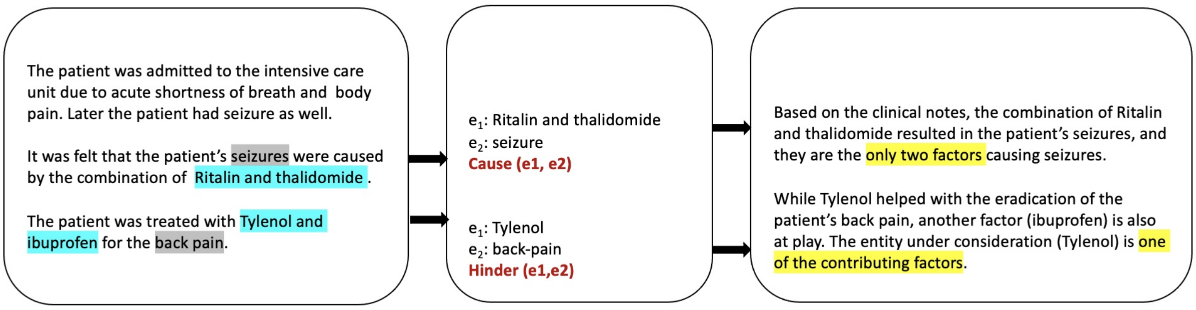
Findings of the Association for Computational Linguistics: ACL 2022, pages 764 - 773
May 22-27, 2022



The patient was admitted to the intensive care unit due to acute shortness of breath and body pain. Later the patient had seizure as well.

It was felt that the patient's seizures were caused by the combination of Ritalin and thalidomide.

The patient was treated with Tylenol and ibuprofen for the back pain.

e_1: Ritalin and thalidomide
e_2: seizure
Cause (e1, e2)

e_1: Tylenol
e_2: back-pain
Hinder (e1,e2)

Based on the clinical notes, the combination of Ritalin and thalidomide resulted in the patient's seizures, and they are the only two factors causing seizures.

While Tylenol helped with the eradication of the patient's back pain, another factor (ibuprofen) is also at play. The entity under consideration (Tylenol) is one of the contributing factors.

Figure 1: (a) A snippet from a clinical note with highlighted biomedical entities identified in the n2c2 dataset. (b) Causal relations identified between the specified biomedical entities (e1 and e2). In the first case, two entities are specified together as e1 for causal relation identification, while the second case specifies only one entity as e1. (c) Narratives based on the causal relations identified between the specified biomedical entities

In this work, we fill the gap by defining types of semantic causal relations between biomedical entities, building detailed annotation guidelines and annotating a large dataset.

Figure 1 shows a snippet of clinical note extracted from the n2c2 dataset (Henry et al., 2020), different sets of annotated biomedical entities along with the causal relationship between them, and the corresponding narrative based on the proposed guidelines outlined in Section 3.1.

Even with the inherent complexities of clinical text data (e.g., domain knowledge, short hand by doctors, etc.), following our proposed guidelines, we achieved a high inter annotator agreement of Fleiss' kappa (κ) score of 0.72.

2 Related Works

In linguistics, the focus on representing causality has been on understanding interactions between events. Talmy (1988) proposed force-dynamics to decompose the causal interaction between events as "letting", "helping", "hindering" etc. Wolff (2007) built upon force-dynamics by incorporating the theory of causal verbs and proposed the Dynamic-model of causation. Wolff categorised causation in three categories, *"Cause"*, *"Enable"* and *"Prevent"*, and provided a set of causal verbs to express these categories.

Dunietz et al. (2015; 2017) proposed BECauSE Corpus to represent linguistic expressions of causation stated explicitly. BECauSE 1.0 (Dunietz et al., 2015) consists of a cause span, an effect span, and a causal connective span. Their work treats the causal connectives e.g. *because of, so* etc. as the "centerpiece" of causal language, impacting the selection of instances to be annotated. In addition to the types of causation (Consequence, Motivation, and Purpose) and degrees of causation (Facilitate and Inhibit) introduced in BECauSE 1.0, the subsequent work BECauSE 2.0 (Dunietz et al., 2017) extended the annotation scheme to include overlapping relations other than causal. In contrast, our work focuses on both explicit (indicated by connectives) and implicit (lack of connectives) identification of types of causal associations between biomedical concepts as communicated in clinical notes.

More recently, Mostafazadeh et al. (2016b) built upon the work of Wolff and proposed annotation framework *CaTeRS* to represent causal relations between events for commonsense perspective. CaTeRS categorises semantic relations between events to capture causal and temporal relationships for narrative understanding on crowd-sourced ROCStories dataset (Mostafazadeh et al., 2016a) but has only 488 causal links. In comparison, our MIMICause dataset is built on actual clinical narratives, i.e., *MIMIC-III Clinical text data* (Johnson et al., 2016) and has 1923 causal observations.

Another interesting decomposition of causation is proposed by Swartz (2014) as a necessary and sufficient condition, but such detailed information is seldom communicated in clinical notes. There have been several other recent attempts of modeling and extracting causality from unstructured text. Bethard et al. (2008) created a causality dataset using the Wall Street Journal corpus and captured the directionality of causal interaction with simple temporal relations (e.g., Before, After, No-Rel) but did not focus on the types of causality between the events. The work of Gorman et al. on Richer Event

Description (RED) (Ikuta et al., 2014) describes causality types as cause and precondition and uses negative polarity to capture the context of hinder and prevent. This is in line with the annotation guidelines proposed in our current work, but we also defined explicit **Hinder** and **Prevent** causality types along with directionality.

Mirza et al. (2014) proposed the use of explicit linguistic markers, i.e., CLINKs (due to, because of, etc.) to extended TimeML TLINKs (Pustejovsky et al., 2003) based temporal annotations to capture causality between identified events. The resulting dataset had temporal as well as casual relations but still lacks the causality types between events. Hassanzadeh et al. (2019) proposed the use of binary questions to extract causal knowledge from unstructured text data but did not focus on types and directionality of causal relations. More recently, Khetan et al. (2022) used language models combining event descriptions with events' contexts to predict causal relationships. Their network architecture wasn't trained to predict the type or directionality of causal relations. Furthermore, they removed the directionality provided in SemEval-2007 (Girju et al., 2007), and SemEval-2010 (Hendrickx et al., 2009) datasets to evaluate their model on a larger causal relation dataset. Our causality extraction network is built upon their methodology, i.e., *Causal-BERT* but also focuses on directionality as well as types of causality communicated in clinical notes.

Although causality lies at the heart of biomedical knowledge, there are only a handful of works (mostly Adverse Drug Effect (e.g. Gurulingappa et al. 2012)) extracting causality from biomedical or clinical text data. Uzuner et al. (2011) proposed tasks to extract concepts, assertions, and relations in clinical text. In their dataset, drugs and procedures are combined as a single concept, i.e., treatment and the defined relations are also dependent upon the concept types under consideration. Whereas, the relations defined in our work are based on the overall context in any given example and make no assumption about the type of concepts/entities under consideration.

Another interesting work is BioCause by Mihaila et al. (2012), which annotates existing bio-event corpora from biomedical scientific articles to capture biomedical causality. Instead of identifying the types (and direction) of causal relations in the already provided events of interest, they are annotating two types of text spans, i.e., arguments and triggers. Arguments are text spans that can be represented as events with type Cause, Effect, and Evidence while Trigger spans (can be empty) are connectives between the casual events.

Our work proposes comprehensive guidelines to represent the types and direction of causal associations between biomedical entities, expressed explicitly or implicitly in the same or multiple sentences in clinical notes, and is not covered by any related work.

3 MIMICause Dataset creation

We used publicly available 2018 n2c2 shared task (Henry et al., 2020) dataset on adverse drug events and medication extraction to build the MIMICause dataset. The n2c2 dataset was used because it is built upon the de-identified discharge summaries from the MIMIC-III clinical care database (Johnson et al., 2016) and has nine different annotations of biomedical entities e.g. Drug, Dose, ADE, Reason, Route etc. The types of biomedical concepts/entities with a few examples as defined in the n2c2 dataset are shown in Table 1.

However, the provided relationships in the n2c2 dataset are simply defined by the identified concepts linked with related medications and hold no semantic meaning. To create the MIMICause dataset, we extracted[2] examples from each entity-pair available in the n2c2 dataset. Our final dataset has 1107 "ADE-Drug" , 1007 "Reason-Drug" and 100 from each of "Strength-Drug", "Form-Drug", "Dosage-Drug", "Frequency-Drug", "Route-Drug" and "Duration-Drug" entity-pair examples.

3.1 Annotation guidelines

Our annotation guidelines are defined to represent nine semantic causal relationships between biomedical concepts/entities in clinical notes. Our guidelines have four types of causal associations, each with two directions, and a non-causal "Other" class. Based on our guidelines, *causal* relationship/association exists when one or more entities affect another set of entities. The driving concept can be a ***single*** entity such as a drug / procedure / therapy or a ***composite entity*** such as several drugs / procedures / therapies considered together.

---

[2] We used `https://spacy.io/` library with *"en_core_web_sm"* language model.

Concepts/Entities	Examples
Drug	morphine, ibuprofen, antibiotics (or "abx" as its abbreviation), chemotherapy etc.
ADE and Reason*	nausea, seizures, Vitamin K deficiency, cardiac event during induction etc.
Strength	10 mg, 60 mg/0.6 mL, 250/50 (e.g. as in Advair 250/50), 20 mEq, 0.083% etc.
Form	Capsule, syringe, tablet, nebulizer, appl (abbreviation for apply topical) etc.
Dosage	Two (2) units, one (1) mL, max dose, bolus, stress dose, taper etc.
Frequency	Daily, twice a day, Q4H (every 4 Hrs), prn (pro re nata i.e as needed) etc.
Route	Transfusion, oral, gtt (guttae i.e. by drops), inhalation IV (i.e. Intravenous) etc.
Duration	For 10 days, chronic, 2 cycles, over 6 hours, for a week etc.

*The distinction between ADE and Reason concepts is based on whether the drug was given to address the disease (Reason) or led to the disease (ADE).

Table 1: Examples of Bio-medical concepts/entities in the 2018 n2c2 shared task dataset.

3.1.1 Direction of causal association

The direction of causal association between entities is captured by the order of entity tags ((e_1, e_2) or (e_2, e_1)) in the defined causal relationships. Either entity can be referred to as e_1 or e_2. The *entity that initiates or drives the causal interaction is placed first* in parenthesis followed by the resulting entity or effect.

1. Odynophagia: Was presumed due to **<e2>mucositis</e2>** from recent **<e1>chemotherapy</e1>**.

2. Odynophagia: Was presumed due to **<e1>mucositis</e1>** from recent **<e2>chemotherapy</e2>**.

Example (1) and (2) are different because the entity references are reversed. Regardless of the entity tags, in the context of the example, "chemotherapy" is the *driving entity* that led to the *emergence* of "mucositis". Therefore, example (1) is annotated with causal direction (e_1, e_2) while example (2) is annotated with (e_2, e_1).

3.1.2 Explicitness / Implicitness of the causal indication

Our guidelines also capture causality expressed both explicitly and implicitly. In example (1), the causality is expressed explicitly using lexical causal connective "due to". Whereas in example (3), the causal association between "erythema" and "Dilantin" can only be understood based on the overall context of all the sentences.

3. patient's wife noticed **<e2>erythema on patient's face</e2>**. On [**3-27**]the visiting nurse [**First Name (Titles) 8706**][**Last Name (Titles)11282**]of a rash on his arms as well. The patient was noted to be febrile and was admitted to the [**Company 191**] Firm. In the EW, patient's **<e1>Dilantin</e1>** was discontinued and he was given Tegretol instead.

3.1.3 (Un)-certainty of causal association

Establishing real-world causality or the task of causal inference is not in the scope of our current work. Our proposed guidelines represent a potential causal association between biomedical entities either expressed as speculation or with certainty in a similar manner.

4. **<e1>Normocytic Anemia</e1>** - Was 32.8 at OSH; after receiving fluids HCT has fallen further to 30. Baseline is 35 - 40. Not clinically bleeding. Perhaps due to **<e2>chemotherapy</e2>**.

In example (4), causality between biomedical entities is speculated through "Perhaps". While representing speculative causal associations can further enrich narrative understanding; it is not covered in our current work.

3.1.4 Types of causal associations

This section provides detailed guidelines for various types of causal relations (each with two directions) and one non-causal relation ("Other") along with accompanying examples.

- **Cause**(e_1, e_2) or **Cause**(e_2, e_1) – Causal relations between biomedical entities are of these classes if the emergence, application or increase of a **single or composite entity** *exclusively leads* to the **emergence** or **increase** of one or a set of entities.

    5. It was felt that the patient's **<e2>seizures</e2>** were caused by the combination of **<e1>Ritalin and thalidomide</e1>**.

    In example (5), "seizures" occurred due to *two drugs* viz. "Ritalin" and "thalidomide". The entity span covers both of them, and they are considered together as a *composite entity* leading to "seizures". Hence, example (5) is annotated as Cause(e_1, e_2). The annotation would have been different had these entities been considered individually.

Thus, the "Cause" category is assigned only if the driving entity is responsible in its entirety for the effect. If the specified entity is responsible for the effect in part, then a different causal relation is defined to express this contrast.

- **Enable**(e_1, e_2) or **Enable**(e_2, e_1) – Causal relations between biomedical entities are of these classes if the emergence, application or increase of a **single or composite entity** *leads* to the **emergence** or **increase** of one or a set of entities in a setting ***where*** a number of factors are at play and the *single or composite entity* under consideration is one of the contributing factors.

  6. It was felt that the patient's **<e2>seizures</e2>** were caused by the combination of **<e1>Ritalin</e1>** and thalidomide.

  Example (6) is the same as example (5) except for the entities in considerations. Both the drugs viz. "Ritalin" and "thalidomide" are contributing to the "seizures".

  Since the example is considering only "Ritalin", *which is a contributing factor in part*, it is annotated as Enable(e_1, e_2).

  With the "Enable" relation type, it can easily be noted that discontinuing only "Ritalin" or "thalidomide" will not lead to the stopping of "seizures". Labelling these samples as "Cause" would have suppressed this detail, and the actions taken based on this would not have been sufficient.

- **Prevent**(e_1, e_2) or **Prevent**(e_2, e_1) – Causal relations between biomedical entities are of these classes if the emergence, application or increase of a **single or composite entity** *exclusively leads* to the **eradication, prevention** or **decrease** of one or a set of entities.

  This class includes the scenario of ***preventing*** a disease or condition from occurring as well as ***curing*** a disease or condition if it has occurred.

  7. You were treated with **<e2>tylenol and ibuprofen</e2>** for your **<e1>back pain</e1>**.

  In example (7), "tylenol" and "ibuprofen" are the two different entities used in conjunction to resolve the "back pain". Since the causal relation is to be identified by considering them as a *composite entity*, the example is labelled as Prevent(e_2, e_1). The annotation would have been different had these entities been considered individually.

- **Hinder**(e_1, e_2) or **Hinder**(e_2, e_1) – Causal relations between biomedical entities are of these classes if the emergence, application or increase of a **single or composite entity** *leads* to the **eradication, prevention** or **decrease** of one or a set of entities in a setting ***where*** a number of factors are at play and the *single or composite entity* under consideration is one of the contributing factors.

  Similar to "Prevent", this label also includes the scenario of ***hindering*** a disease or condition from occurring as well as ***curing*** a disease or condition if it has occurred.

  8. You were treated with **<e2>tylenol</e2>** and ibuprofen for your **<e1>back pain</e1>**.

  Example (8) is the same as example (7) except for the entities in considerations. Both the entities i.e. "tylenol" and "ibuprofen" are contributing to the resolution of "back pain". Since the example is considering only "tylenol", *individually as a contributing factor in part*, it is annotated as Hinder(e_2, e_1).

  This distinction between "Prevent" and "Hinder" can be useful in scenarios such as identifying conditions that may require the use of multiple drugs for treatment.

- **Other** – We defined the "Other" class to annotate examples with non-causal interaction between biomedical entities. Examples of the "Other" class can either have no relationship between biomedical entities of interest or some other semantic relationship that's not causal. Being non-causal, the "Other" class doesn't have a sense of direction associated with it.

  Based on our guidelines, examples with ambiguous overall context for all the annotators, entities with indirect causal association (an entity leading to a condition which in turn affects another entity) and samples from non-causal entity-pairs in the n2c2 dataset (i.e., Form-Drug, Route-Drug, etc.) are also labelled as "Other".

9. Patient has tried and failed **<e2>Nexium</e2>**, reporting it has not helped his **<e1>gastritis</e1>** for 3 months.
10. Thus it was believed that the pt's **<e1>altered mental status</e1>** was secondary to **<e2>narcotics</e2>** withdrawal.
11. Atenolol was held given patient was still on **<e2>amiodarone</e2>** **<e1>taper</e1>**.

In example (9), "Nexium" was taken to prevent / cure "gastritis" but the expected effect is explicitly stated to be not observed. In example (10), the "altered mental status" is observed due to "narcotics withdrawal", however, the entity span refers only to the "narcotics". Example (11) is from the "Dosage-Drug" entity-pair of the n2c2 dataset and has no causal association between the entities.

Therefore, these examples are annotated as "Other". Similarly, examples with entity-pairs from "Form-Drug", "Strength-Drug", "Frequency-Drug", 'Route-Drug" and "Duration-Drug" are also labelled as "Other".

To summarize, we defined annotation guidelines for nine semantic causal relations (8 Causal + Other) between biomedical entities expressed in clinical notes. Our annotated dataset has examples with both explicit and implicit causality in which entities are in the same sentence or different sentences. The final count of examples for each *causal* type with direction is in Table 2.

3.2 Inter-annotator agreement

It's difficult to comprehend narratives expressed in clinical notes due to the need of domain knowledge, short hand used by the doctors, use of abbreviations (Table 3), context spread over many sentences as well as the explicit and implicit nature of communication.

		Annotation	Count
Causal	e_1 as agent, e_2 as effect	$\mathbf{Cause}(\mathbf{e_1}, \mathbf{e_2})$	354
		$\mathbf{Enable}(\mathbf{e_1}, \mathbf{e_2})$	174
		$\mathbf{Prevent}(\mathbf{e_1}, \mathbf{e_2})$	261
		$\mathbf{Hinder}(\mathbf{e_1}, \mathbf{e_2})$	154
	e_2 as agent, e_1 as effect	$\mathbf{Cause}(\mathbf{e_2}, \mathbf{e_1})$	370
		$\mathbf{Enable}(\mathbf{e_2}, \mathbf{e_1})$	176
		$\mathbf{Prevent}(\mathbf{e_2}, \mathbf{e_1})$	249
		$\mathbf{Hinder}(\mathbf{e_2}, \mathbf{e_1})$	185
Other	–	**Other**	791
Total			**2714**

Table 2: *Causal* types and their final counts

Abbreviation	Expansion	Abbreviation	Expansion
b/o	because of	d/c'd	discontinued
HCV	Hepatitis C Virus	abx	anti-biotics
DM	Diabetes Mellitus	c/b	complicated by
s/p	status post	h/o	history of

Table 3: Clinical abbreviations in the dataset

Three authors of this paper (all with fluency in English language and computer science background) annotated the dataset. Given the nature of our base data (MIMIC-III discharge summaries) and the critical importance of our task (causal relations between biomedical entities), the annotators followed the provided guidelines, referred to sources such as websites of Centers for Disease Control and Prevention (*CDC*[3]), National Institute of Health (*NIH*[4]), and *WebMD*[5] to understand domain-specific keywords or abbreviations, and had regular discussions about the annotation tasks.

We performed three rounds of annotation, refining our guidelines after each round by discussing various complex examples and edge cases. We achieved an inter-annotator agreement (IAA) **Fleiss' kappa** (κ) score of 0.72, which indicates substantial agreement and the quality of our annotation guidelines.

We did majority voting over the three available annotations to obtain the final gold annotations for our "MIMICause" dataset. In case of disagreements, another author of this paper acted as a master annotator, making the final decision on annotations after discussion with the other three annotators.

A direct comparison of our IAA score with other works is not possible due to differences in the number of annotators, annotation labels, guidelines, reported metrics etc. for different datasets. However, for reference, we discuss IAA scores reported for the task of semantic link annotations, particularly

---

[3] `https://www.cdc.gov/`

[4] `https://www.nih.gov/`

[5] `https://www.webmd.com/`

those where κ scores were reported. Of note is the work by Mostafazadeh et al. (2016b) and their annotation framework CaTeRS for temporal and causal relations in ROCStories corpus where the final κ score achieved was 0.51 among four annotators. Similarly, Bethard et al. (2008) reported a κ score of 0.56 and an F-measure (F-1 score) of 0.66 with two annotators labelling for only two relations viz. causal and no-rel. In the clinical domain, Bethard et al. (2017) reported a final IAA agreement (F-1) score of 0.66 on the latest Clinical TempEval dataset (Task 12 of SemEval-2017) labelled by two annotators. However, the relation types in Clinical TempEval are temporal and not causal, making the agreement score incomparable.

4 Problem definition and Experiments

We defined our task of causality understanding as the identification of semantic causal relations between biomedical entities as expressed in clinical notes. We have a total of 2714 examples annotated with these 9 different classes (8 causal and 1 non-causal).

4.1 Problem Formalization

We pose the task of causal relation identification as a multi-class classification problem $f : (X, e_1, e_2) \mapsto y$, where X is an input text sequence, e_1 and e_2 are the entities between which the relation is to be identified, and $y \in \mathcal{C}$ is the label from the set of *nine* relations. These samples are taken from the *MIMICause* dataset $\mathcal{D} = \{(X, e_1, e_2, y)_m\}_{m=1}^{m=N}$, where N is the total number of samples in the dataset. The text and entities are mathematically denoted as:

$$X = [x_1, x_2, \ldots, x_{n-1}, x_n] \tag{1}$$
$$e_1 = X[i : j] = [x_i, x_{i+1}, \ldots, x_j] \tag{2}$$
$$e_2 = X[k : l] = [x_k, x_{k+1}, \ldots, x_l] \tag{3}$$

where n is the sequence length, i, j, k and $l \in [1..n]$, $i \leq j$ and $k \leq l$ i.e. entities are subsequences of continuous span within the text X. Additionally, $j < k$ or $l < i$ holds i.e. the entities e_1 and e_2 are non-overlapping and either of these can occur first in the sequence X.

4.2 Models

As a baseline for this dataset, we built our causal relation classification models using two different language models[6] as text encoders (BERT-BASE and Clinical-BERT) and a fully connected feed-forward network (FFN) as the classifier head. The encoder output that captures the bi-directional context of the input text X through the [CLS] token is denoted by $H_0 \in R^d$, where $d = 768$ is the dimension of the encoded outputs from BERT-BASE / Clinical-BERT. The formulations of the layers of the classifier head are given by:

$$K_1 = \mathit{dropout}(\mathit{ReLU}(W_1 H_0 + b_1))) \tag{4}$$
$$K_2 = W_2 K_1 + b_2 \tag{5}$$
$$p = \mathit{softmax}(K_2) \tag{6}$$

where $W_1 \in R^{d' \times d}$, $W_2 \in R^{L \times d'}$, d' was set to 256 and $L = 9$ is the number of labels.

Architectures with additional context introduced between the encoder and classifier head by concatenating averaged representation of the two entities and encoder output were also tried, which led to improved results. The augmented context is denoted by:

$$H_{e_1} = \frac{1}{j - i + 1} \sum_{t=i}^{j} H_t \tag{7}$$
$$H_{e_2} = \frac{1}{l - k + 1} \sum_{t=k}^{l} H_t \tag{8}$$
$$H' = \mathit{concat}(H_0, H_{e_1}, H_{e_2}) \tag{9}$$
$$H_0 = \mathit{dropout}(\mathit{ReLU}(W_0 H' + b_0)) \tag{10}$$

where i, j, k and l are the start and end indices of the entities, $H_t \in R^d$, $H' \in R^{3d}$, $W_0 \in R^{d \times 3d}$ and the augmented context is assigned back to H_0 for feeding into the classifier head. The architecture details without and with the entity context augmentation are shown in Figure (2) and (3) respectively. An overview of the models is given below:

- ***Encoder (BERT-BASE / Clinical-BERT) with feed-forward network (FFN)*** – The overall architecture as shown in Figure 2 is a simple feed-forward network built on top of a pre-trained encoder. The input sentence is fed as a sequence of tokens to the encoder, with encoder based special tokens such as [CLS] and entity tagging tokens such as $<e1>, </e1>$. The overall sentence context

---

[6] We use the implementation of all the encoders from the huggingface (Wolf et al., 2020) repository

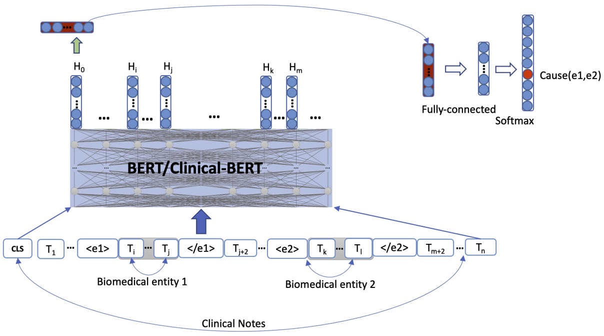

Figure 2: BERT/Clinical-BERT: FFN

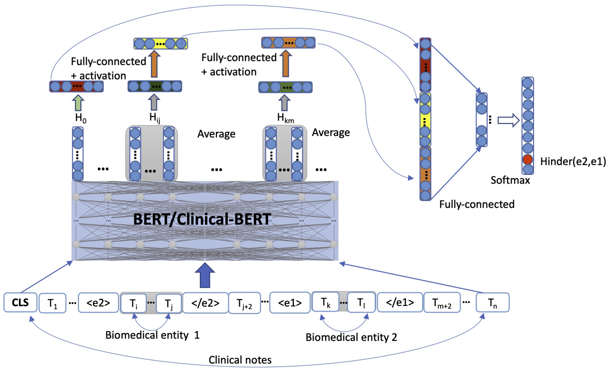

Figure 3: BERT/Clinical-BERT: FFN with entity context

is passed through the fully connected feed-forward network to obtain class probabilities as formulated in equations (4)–(6).

In addition to the BERT-BASE encoder, we also used the Clinical-BERT encoder to obtain the contextualised representation of our input examples. While BERT is pre-trained on standard corpus such as Wikipedia, Clinical-BERT is pre-trained on clinical notes and provides more relevant representation for our dataset, and hence led to a significant increase in the evaluation metrics.

- ***Encoder (BERT-BASE / Clinical-BERT) with entity context augmented feed-forward network (FFN)*** – The overall architecture is shown in Figure 3. While the input with special tokens, encoding and classifier head remains the same as discussed earlier, the current architecture also enriches the sentence context with both the entities' context as formulated in equations (7)–(10). The special tokens around the entities ($<e1>$, $</e1>$, $<e2>$, and $</e2>$) are used to identify the tokens related to the individual entities which are then used to obtain the averaged context vector for each entity. These are then concatenated with the overall sentence context and are fed to a fully connected feed-forward network to predict the type of causal interaction expressed in the text.

Similar to our previous discussion, in addition to the BERT-BASE encoder, a pre-trained Clinical-BERT encoder was also used which resulted in the highest evaluation metrics.

	Test	Val	Train
BERT+FFN	0.23	0.25	0.29
Clinical-BERT+FFN	0.27	**0.31**	0.34
BERT+entity context+FFN	0.54	0.27	0.56
Clinical-BERT+entity context+FFN	**0.56**	0.30	**0.70**

Table 4: Macro F1 score on test, val and train dataset

4.3 Results and analysis

We trained all our models on a varied set of hyperparameters and chose the best model from training epochs based on the maximum F1 score on the validation set. For BERT+FFN model, we achieved the best scores with a batch size of 128 and a learning rate of 5e-5. The other three models achieved reported scores with a batch size of 32 and a learning rate of 1e-3. All the models were trained until convergence with the early stopping of 7 epochs with no decrease in validation loss. We used AdamW optimizer with cross-entropy loss for all models.

Table 4 shows performance measures of various models on train/val/test set. Using only the BERT-BASE encoder for the relation identification doesn't yield high scores but concatenating entity context to the BERT's encoded sentence output resulted in significant improvement. Using Clinical-BERT as base encoder resulted in additional improvements, and combining entity contexts with Clinical-BERT as base encoder resulted in the highest F1 score. While Clinical BERT was trained on the MIMIC dataset and might have seen input sequences in the test dataset, it has not seen newly defined causal classes for those sequences.

5 Conclusion

In this work, we proposed annotation guidelines to capture the types and direction of causal associations, annotated a dataset of 2714 examples from de-identified clinical notes and built models to provide a baseline score for our dataset.

Even with the inherent complexities in clinical text data, following the meticulously defined annotation guidelines, we achieved a high inter-annotator agreement, i.e., Fleiss' kappa (κ) score of 0.72. Building various network architectures on top of language models, we achieved a macro F-1 score of 0.56.

An end-to-end NLP pipeline built with models for patients' data de-identification, biomedical entity extraction, and causal relations identification between various biomedical entities will be instrumental in narrative understanding from clinical notes. In the future, we are planning to extend our annotation guidelines to jointly annotate temporal and causal relations to capture the ordering of various causal interactions between biomedical entities over time.

Abstract

How to learn highly compact yet effective sentence representation? Pre-trained language models have been effective in many NLP tasks. However, these models are often huge and produce large sentence embeddings. Moreover, there is a big performance gap between large and small models. In this paper, we propose **H**omomorphic **P**rojective **D**istillation (HPD) to learn compressed sentence embeddings. Our method augments a small Transformer encoder model with learnable projection layers to produce compact representations while mimicking a large pre-trained language model to retain the sentence representation quality. We evaluate our method with different model sizes on both semantic textual similarity (STS) and semantic retrieval (SR) tasks. Experiments show that our method achieves 2.7-4.5 points performance gain on STS tasks compared with previous best representations of the same size. In SR tasks, our method improves retrieval speed (8.2×) and memory usage (8.0×) compared with state-of-the-art large models. Our implementation is available at `https://github.com/XuandongZhao/HPD`.

1 Introduction

It is a fundamental problem to learn compact yet effective sentence representations. Good representations have wide applications in NLP, including web search (Palangi et al., 2016), question answering (Hao et al., 2019), knowledge inference (Wang and Kuo, 2020), and machine translation (Yang et al., 2020). Sentence embedding models take a sentence as the input and output a fixed-length continuous vector representation. Based on BERT (Devlin et al., 2019) and RoBERTa (Liu et al., 2019), recent sentence embedding models such as Sentence-BERT (SBERT) (Reimers and Gurevych, 2019) and SimCSE (Gao et al., 2021), are fine-tuned on sentence pair scoring tasks to learn better sentence representations, which show much improvement in downstream tasks. However, these models are big in two aspects. 1) They contain hundreds of millions to billions of parameters, which requires large memory and powerful machine to serve in production; 2) Their resulting embeddings are high dimensional (e.g. 1024), requiring huge database to store and index, which cause high search latency. Therefore, it is challenging to directly use these large models in real-world applications with strict throughput/latency requirement and bounded hardware resources. Our work focuses on reducing both the model size and the representation size. There has been several works to reduce model size and retain the superior model performance. Recent studies (Jiao et al., 2020; Sanh et al., 2019; Wang et al., 2020) have used knowledge distillation (KD) on large language models to derive compressed compact models with decent performance. TinyBERT (Jiao et al., 2020) performs layer-to-layer transformer distillation at pre-training and task-specific learning stage utilizing the teacher's hidden states

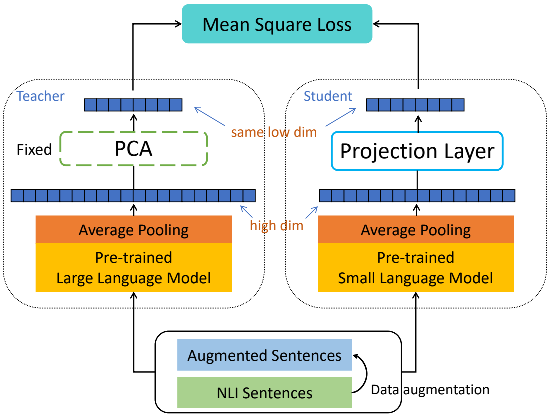

Figure 1: Overview of **H**omomorphic **P**rojective **D**istillation (HPD). In contrast to the teacher model, which is a large pre-trained language model with a fixed PCA dimension reduction module, the student model is a smaller language model with a learnable projection layer. The mean square error of both dimension reduction results is used to train the student model.

Findings of the Association for Computational Linguistics: ACL 2022, pages 774 - 781

and self-attention distributions. MiniLM (Wang et al., 2020) proposes task-agnostic transformer distillation, which uses self-attention distributions and value relations to help the student deeply mimic the teacher's self-attention modules. Nevertheless, directly fine-tuning small transformer models for sentence embedding shows less desirable results than large ones (Reimers and Gurevych, 2019; Reimers, 2019).

Can we learn a compact yet highly performant sentence representation? In this work, we propose HPD: a dimension reduced sentence embedding model via projected knowledge distillation. The key idea is to start from a pre-trained large model and distill its knowledge into a small one. The large model is fine-tuned on natural language inference (NLI) datasets first. Then the small and large ones are augmented with linear projection layer and Principal Component Analysis (PCA) (Abdi and Williams, 2010) respectively to reduce final representation dimension. In this way, the small model is expected to produce semantic meaningful representations (semantically similar sentences will have close embeddings), where it mimics the power of large models through homomorphic mappings.

We evaluate our model on semantic textual similarity (STS) and semantic retrieval (SR) tasks. Empirical results show that our model can attain 2.7-4.5 points of performance gain on STS tasks compared to other dimension reduction approaches and achieve competitive retrieval performance against large sentence embedding models while significantly improving retrieval speed (8.2×) and memory usage (8.0×) in SR tasks.

2 Related Work

Embedding techniques are used to represent complex data mathematically (Mikolov et al., 2013; Zhao et al., 2020; Khrulkov et al., 2020). Sentence embedding is a well-researched topic with a plethora of proposed approaches. Early works (Kiros et al., 2015; Logeswaran and Lee, 2018) build upon the distributional hypothesis and train the models to predict the surrounding sentences. Sent2Vec (Pagliardini et al., 2018) generate sentence embeddings using word vectors along with n-gram embeddings. Conneau et al. (2017) propose to fine-tune a Siamese network on NLI datasets, which is then further extended to pre-trained models in Sentence-BERT (Reimers and Gurevych, 2019). SimCSE (Gao et al., 2021) proposes a contrastive learning method and achieves state-of-the-art performance on STS tasks.

Recently, Raunak and Gupta (2019) combines PCA based dimensionality reduction with a post-processing algorithm to address the latency and capacity issues of large dimensionality models. Shi et al. (2018) proposed extended robust PCA (Ex-RPCA) to do dimension reduction. But both of them only focus on word embedding. Su et al. (2021) find that the whitening operation can enhance the isotropy of sentence distribution and reduce the dimensionality of the sentence representation, which optimizes the memory storage and accelerates the retrieval speed. We use this approach as one of our baselines.

3 Method

The overview of our approach is illustrated in Figure 1. Given a set of sentences $\mathcal{X} = \{x_i\}_{i=1}^m$, our goal is to obtain efficient sentence embedding models $f : \mathcal{X} \to \mathbb{R}^d$, where d is the embedding dimension.

The teacher model f_t is trained on the same NLI dataset as Conneau et al. (2017); Reimers and Gurevych (2019); Gao et al. (2021), where there are three types of sentence pairs (entailment/neutral/contradiction). We follow the supervised contrastive training framework in SimCSE (Gao et al., 2021) and take a cross-entropy objective with in-batch negatives and hard negatives. The idea is based on the assumption that a good semantic representation should be able to bring similar sentences together while pushing dissimilar ones apart. Let $(\mathbf{e}_i, \mathbf{e}_i^+, \mathbf{e}_i^-)$ denote the representations of sentence triplet (x_i, x_i^+, x_i^-), where (x_i^+, x_i^-) are corresponding "entailment" and "contradiction" pairs for x_i in the NLI dataset. For a mini-batch with N pairs, the training objective is

$$\ell_i = -\log \frac{e^{\mathrm{sim}\left(\mathbf{e}_i, \mathbf{e}_i^+\right)/\tau}}{\sum_{j=1}^N \left(e^{\mathrm{sim}\left(\mathbf{e}_i, \mathbf{e}_j^+\right)/\tau} + e^{\mathrm{sim}\left(\mathbf{e}_i, \mathbf{e}_j^-\right)/\tau}\right)}, \quad (1)$$

where τ is a temperature hyperparameter; $\mathrm{sim}\left(\mathbf{e}_1, \mathbf{e}_2\right)$ is the cosine similarity $\frac{\mathbf{e}_1^\top \mathbf{e}_2}{\|\mathbf{e}_1\| \cdot \|\mathbf{e}_2\|}$.

After building up a teacher model, we use it for knowledge distillation. Firstly, we enrich the training dataset by data augmentation (Details in Section 4.3). Then for each sentence x_i, we get the embedding $\mathbf{e}_i^t \in \mathbb{R}^{d_t'}$ from the teacher model f_t and $\mathbf{e}_i^s \in \mathbb{R}^{d_s'}$ from the student model f_s. Note

Algorithm 1 PCA

```
Input: Initial embeddings $\{\mathbf{e}_i^t\}_{i=1}^m$ and reserved dimensionality $d$
1: compute $\bar{\mathbf{e}}^t$ of $\{\mathbf{e}_i^t\}_{i=1}^m$
2: compute $\mathbf{V}, \mathbf{S}, \mathbf{U}^\top = \mathrm{SVD}(\mathbf{E})$
3: compute $\mathbf{W}^t = \mathbf{V}[:, : d]$
4: for $i = 1, 2, ..., m$ do
5:     $\mathbf{h}_i^t = {\mathbf{W}^t}^\top (\mathbf{e}_i^t - \bar{\mathbf{e}}^t)$
6: end for
Output: Transformed embeddings $\{\mathbf{h}_i^t\}_{i=1}^m$
```

that the dimensions for $\mathbf{e}_i^t$ and $\mathbf{e}_i^s$ may be different ($d_t' \neq d_s'$).

In order to perform homomorphic projective distillation, we employ Principle Component Analysis (PCA) (Abdi and Williams, 2010), $\mathbf{h}_i^t = {\mathbf{W}^t}^\top (\mathbf{e}_i^t - \bar{\mathbf{e}}^t)$, to the teacher model after its average pooling layer and we add a projection layer, $\mathbf{h}_i^s = {\mathbf{W}^s}^\top \mathbf{e}_i^s + \mathbf{b}^s$, to the student model, where $\mathbf{h}_i^t, \mathbf{h}_i^s \in \mathbb{R}^d$ are the teacher and student's final embeddings with the same dimension. $\mathbf{W}^t \in \mathbb{R}^{d_t' \times d}$ is the PCA weight matrix for the teacher model. $\mathbf{W}^s \in \mathbb{R}^{d_s' \times d}$ is the weight matrix of the projection layer for the student model. $\mathbf{b}^s$ is the bias term and both d_s' and d_t' are larger than the final embedding dimension d.

Algorithm 1 shows how to conduct the PCA over a set of initial sentence embeddings for the teacher model. We sample m sentences from the training dataset and get the embeddings $\{\mathbf{e}_i^t\}_{i=1}^m$ after the average pooling layer of the teacher model. We then construct a centered matrix $\mathbf{E}$ of $d_t' \times m$ size, where d_t' is the initial embedding dimension. Thus the i-th column of $\mathbf{E}$ corresponds to $\mathbf{e}_i^t - \bar{\mathbf{e}}^t$, i.e. row means have been subtracted. Then we perform the singular value decomposition (SVD) of $\mathbf{E}$ (line 2 in Algorithm 1). Because only the first d principle components are needed, we reserve the first d columns of $\mathbf{V}$ (i.e. the first d eigenvectors), which we denote as weight matrix $\mathbf{W}^t$. The transformed embeddings $\mathbf{h}_i^t$ in the new PC space are given by the i-th column of ${\mathbf{W}^t}^\top \mathbf{E}$ (line 5 in Algorithm 1).

Note that PCA only requires m sample sentences and calculating their initial embeddings. So during the distillation process, the teacher's transformer parameters θ_t and PCA weight matrix $\mathbf{W}^t$ are fixed, while the student's transformer parameters θ_s, projection weight $\mathbf{W}^s$, and projection bias $\mathbf{b}^s$ can be updated. We minimize the distance between final embeddings $\mathbf{h}_i^t$ and $\mathbf{h}_i^s$ by taking the mean squared loss:

$$\mathcal{L} = \frac{1}{M} \sum_{i=1}^{M} \left\| \mathbf{h}_i^s - \mathbf{h}_i^t \right\|_2^2, \tag{2}$$

where M is the total number of sentences after data augmentation.

4 Experiment

We conduct our experiments on standard semantic textual similarity (STS) tasks using the SentEval toolkit (Conneau et al., 2017) for evaluation. We also test mean reciprocal rank (MRR), memory usage, and retrieval speed on semantic retrieval (SR) tasks. All of our experiments are tested on a server with Intel i7-5930K CPU @ 3.50GHz, Nvidia TITAN Xp GPU, CUDA 11.3 and cuDNN.

4.1 Semantic Textual Similarity (STS) Task

Semantic textual similarity (STS) is a natural language processing (NLP) task to quantitatively assess the semantic similarity between two text snippets. We evaluate our model by computing the cosine similarity between sentence pair embeddings on 7 standard STS tasks: STS 2012–2016 (Agirre et al., 2012, 2013, 2014, 2015, 2016) , STS Benchmark (Cer et al., 2017) and SICK-Relatedness (Marelli et al., 2014). These datasets have labels between 0 and 5 indicating the semantic relatedness of sentence pairs. Following Reimers and Gurevych (2019); Su et al. (2021); Gao et al. (2021), we use Spearman rank correlation to measure the correlation quality between calculated similarity and human labels. Spearman correlation has a value between -1 and 1, which will be high when the ranks of predicted similarities and the ground-truth are similar.

4.2 Semantic Retrieval (SR) Task

The semantic retrieval (SR) task is to identify all sentences in the retrieval corpus that are semantically similar to a query sentence. We construct the SR task on Quora Duplicate Questions Dataset[1] and Faiss[2] (Johnson et al., 2017) to test the retrieval effect and efficiency of different models. The Quora dataset contains over 500k sentences with over 400k pairwise annotations on whether two questions are duplicates or not. Faiss (Johnson et al., 2017) is a library for efficient similarity

Table 1: Sentence embedding performance on STS tasks (Spearman's correlation $\rho \times 100$). STS12-STS16: SemEval 2012-2016, STSb: STS benchmark, SICK-R: SICK relatedness dataset, Dim: embedding dimension, Size: number of parameters, Speed: sentences per second.

search and clustering of dense vectors, which contains algorithms that search in sets of vectors of any size. We calculate all the sentence embeddings of question2, store them in Faiss, and then use the sentence embedding of question1 to retrieve them. Faiss is configured in CPU mode with 'nlist = 1024' and 'nprobe = 5'. Note that we didn't fine-tune the models on the semantic retrieval task. We report the results on three parts: average mean reciprocal ranking (MRR@10), average retrieve time for 1,000 sentences (Time/ms) and memory usage (Mem/MB).

4.3 Experiment Setup

We train our model on the NLI dataset, which is a combination of the SNLI (Bowman et al., 2015) and the MNLI (Williams et al., 2018) dataset. SNLI dataset contains 570k sentence pairs and MNLI is a collection of 430k sentence pairs. Particularly, the teacher model is trained on "entailment" and "contradiction" pairs in NLI dataset using contrastive loss (Equation 1). We use two state-of-the-art large sentence embedding models, SimCSE-RoBERTa$_{\text{large}}$[3] (Gao et al., 2021) and SimCSE-MPNet[4] (Song et al., 2020), as our teacher models. For the student model, we choose the released pre-trained checkpoints of TinyBERT (Jiao et al., 2020) and MiniLM (Wang et al., 2020), and we leverage a linear projection layer for dimension reduction. As for the PCA implementation, we first sample 100k random sentences from the dataset and pass them to the teacher model. Then we calculate the principal components $\mathbf{W}^t$ of the output embeddings by calling the `PCA` function of the `scikit-learn` package.

Baseline Models We compare our HPD method to both state-of-the-art sentence embedding models and various dimension reduction techniques. For sentence embedding model baseline, we directly fine-tune pre-trained language models TinyBERT/MiniLM given NLI dataset using contrastive loss. For the dimension reduction baseline, we test both projection and whitening approaches: 1) adding a projection layer after TinyBERT/MiniLM encoder and training on NLI dataset with contrastive loss (without distillation); 2) adopting whitening (Su et al., 2021) as a post-processing operation (similar to PCA) to reduce the dimension of SimCSE-TinyBERT or SimCSE-MiniLM. More details about each baseline and training setting can be found in Appendix A.

Data Augmentation Data Augmentation is a set of techniques for improving the size and quality of training datasets for Deep Learning models. It is widely applied as an effective methodology to improve generalization and achieves improvements in many computer vision and natural language processing tasks (Zhang et al., 2018; Sennrich et al., 2016). To generate synthetic data and improve the student's performance, we apply WordNet substitution and back translation (Ma, 2019) to every distinct sentence in NLI dataset. After data augmentation, the training data size is boosted from 1 million to 3 millions sentences.

Table 2: Effect of data augmentation and different dimensions (STS-B and Avg. in STS tasks, wo: without, HPD Teacher: SimCSE-MPNet)

5 Results

5.1 Results of STS Tasks

Table 1 presents the results of our model comparing with current state-of-the-art sentence embedding models on STS tasks. Our HPD-MiniLM can achieve 97.7% of Spearman's correlation performance and 7 times higher speed with only 6.5% of parameters compared with the best performance model SimCSE-RoBERTa$_{\text{large}}$. We also observe that our HPD-TinyBERT and HPD-MiniLM models outperform SimCSE-TinyBERT and SimCSE-MiniLM, which are directly fine-tuned on the same training data and loss function as SimCSE-RoBERTa$_{\text{large}}$. Besides, our results show that our model can significantly improve the results with 2.7-4.5% absolute gain compared with projection or whitening for dimension reduction.

Impact of Data Augmentation and Final Dimension Results in Table 2 show that models with augmented data can raise the performance by 1-2 points compared with ones without augmented data. For example, HPD-MiniLM-128 achieves an average Spearman's correlation of 81.20 with data augmentation, compared to 79.48 without data augmentation. We find that different projected layer dimensions achieve similar performances. However, small dimension has slightly better results than large ones.

5.2 Results of SR Tasks

From Table 3, we demonstrate that the embedding dimension plays a vital role in the performance of semantic retrieval tasks. Our HPD model with different dimensions can achieve comparable MRR performance while the retrieval speed and memory usage increase significantly when dimension goes up. Compared with SimCSE-MPNet, which outputs a 768 dimensional vector, our model with 128 dimensions can achieve competitive MRR performance while reducing the retrieval time by 8.2× and memory usage by 8.0×.

Model	MRR	Time	Mem
HPD-TinyBERT-128	0.613	63.1	42.61
HPD-TinyBERT-256	0.616	130.4	85.22
HPD-TinyBERT-312	0.615	165.4	103.86

6 Conclusion and Discussion

In this paper, we propose an effective method to compress sentence representation using homomorphic projective distillation. We demonstrated that this approach successfully enables small language models to achieve competitive high-quality sentence representations compared with large ones while keeping a small embedding size to optimize the memory storage and retrieval latency in downstream tasks.

Our results show that knowledge distillation with augmented data improves the student model's capability to cover and understand more complex sentence variances. The learned projection layer with contrastive loss for sentence embedding can outperform other dimension reduction methods. We also try adding whitening transformation on HPD's output and the performance is slightly dropped (Appendix B). Since we find that smaller dimensions can have slightly better results than larger ones, we will check over the optimal projected layer size to enhance the isotropy of sentence representation distribution for semantic similarity tasks in our future work.

A Training Details

We elaborate on how we obtain different baselines for comparisons in Table 1.

- For SBERT$_{\text{base}}$ and SRoBERTa$_{\text{large}}$, we report the results from Reimers and Gurevych (2019) and test their speed based on released models.

- For SimCSE-RoBERTa$_{\text{large}}$, we directly load the pre-trained models from Huggingface's repository (Wolf et al., 2020) "princeton-nlp/sup-simcse-roberta-large".

- For SimCSE-MPNet, we utilize a well fine-tuned sentence embedding model using contrastive loss trained on NLI dataset from Huggingface's repository "sentence-transformers/nli-mpnet-base-v2".

- For SimCSE-MiniLM, we use the MiniLM with 6 layers, 384-hidden size and 6 self-attention heads as the backbone network. We then fine-tune it following the contrastive loss for 3 epochs with a batch size of 256. The optimizer we use is AdamW (Loshchilov and Hutter, 2019) and the learning rate is set as 1e-3.

- For SimCSE-TinyBERT, we use the TinyBERT with 4 layers, 312-hidden size and 12 self-attention heads. The other training settings are the same as SimCSE-MiniLM.

- For Projection-128, we add a linear layer to the language model MiniLM/TinyBERT. The linear layer projects the original embedding from 384/312 dimension to 128 dimension. We train the model using the same contrastive loss and configuration as those of SimCSE-MiniLM/SimCSE-TinyBERT.

- For Whitening-128, we implement our own version of whitening operation (Su et al., 2021). It is directly applied on SimCSE-MiniLM/SimCSE-TinyBERT as a dimension reduction technique. Note that whitening is a post-processing method, which is different from HPD.

- For HPD-MiniLM and HPD-TinyBERT, the models are trained for 3 epochs with a batch size of 256 and a learning rate of 1e-4. We keep the best checkpoint during training by evaluating the model on STS-B test sets.

Table 4: Sentence embedding performance on STS tasks (Spearman's correlation $\rho \times 100$).

B More Results on STS Tasks

We report the full set of results for data augmentation and different dimensions on STS tasks in Table 4 (Teacher model: SimCSE-MPNet). We also test a variation: adding whitening after the projected distillation. Results show that adding whitening after our HPD output slightly decreases the performance.

Debiasing Event Understanding for Visual Commonsense Tasks

Abstract

We study event understanding as a critical step towards visual commonsense tasks. Meanwhile, we argue that current object-based event understanding is purely likelihood-based, leading to incorrect event prediction, due to biased correlation between events and objects. We propose to mitigate such biases with *do*-calculus, proposed in causality research, but overcoming its limited robustness, by an optimized aggregation with association-based prediction. We show the effectiveness of our approach, intrinsically by comparing our generated events with ground-truth event annotation, and extrinsically by downstream commonsense tasks.

1 Introduction

Recently, commonsense reasoning tasks on visio-linguistic input have been actively studied in both vision and language communities, with the goal of commonsense reasoning. For example, in Visual COMET (Park et al., 2020), given an image X and event e as input, we are tasked to predict intent (or, events before/after), known as **intent** prediction. Similarly, Visual Commonsense Reasoning (VCR; Zellers et al. 2019), given image and question Q, requires to provide an answer A or provide a rationale for A, known as **justification** task.

For such tasks, understanding event e plays a crucial role, either required as input or expected as output–for example, 41% of rationales from VCR are related to e. However, assuming the availability of e for new images at test time is considered impractical, for which Park et al. (2020) consider two baselines: 1) setting input e as `NULL`, and 2) generating e by training generator `GEN`. However, according to Park et al. (2020), empirical results reported `GEN` performs even worse than `NULL`, or, shows a negative transfer, which is counter-intuitive.

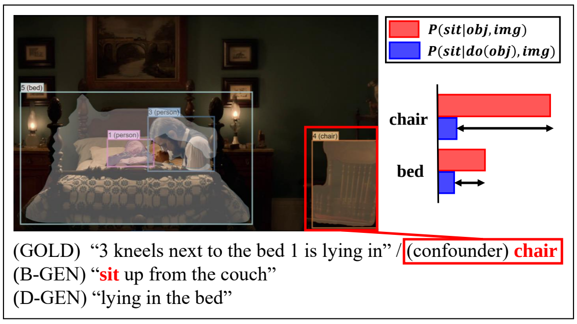

Figure 1: An actual example of event generation. By removing the chair (`confounder`), the biased generation (`B-GEN`) can be corrected to the true event (`D-GEN`).

Our goal is robustifying event understanding, or, event generator `GEN` with a higher **transferability** to the downstream tasks of visual commonsense reasoning. Our hypothesis is that object-event bias in the dataset hinders transferability: In Figure 1, while the image and human-annotated e, denoted as `GOLD`, are not related to an event "sitting", existing `GEN`, denoted as `B-GEN` for Biased GENeration, generates an event "sitting", even when no one is sitting on the chair. We argue that the generation is biased by the frequent **association** of chair-sitting in the dataset.

In contrast, we propose `D-GEN` for Debiased GENeration. Contrary to association-based estimation, which fails to distinguish spurious correlation $P(\text{sitting}|\text{chair})$, *do*-calculus collectively considers other observations, such as "sitting" on other objects (*e.g.*, bed or table), to lower the likelihood of such spurious correlations as humans do. However, while *do*-calculus has been successful at debiasing other types of biases, e.g., between word and visual word (Zhang et al., 2020), we find a limitation for object-event debiasing as in Figure 2: Though *do*-calculus can find a causal relation, *i.e.*, diningtable-sit, with high $P(\text{sit}|do(\text{diningtable}))$, the same logic does not apply to rarely observed ob-

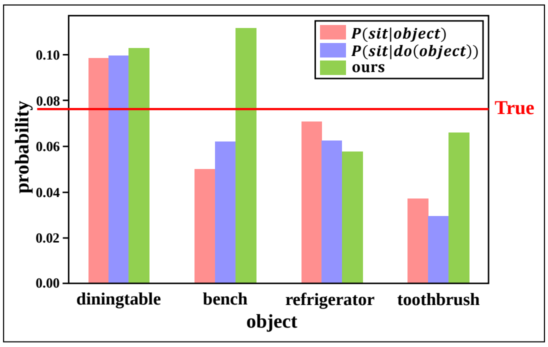

Figure 2: Comparative example of $P(Y|X)$, $P(Y|do(X))$, and ours in VisualCOMET dataset. These are actual estimation results from our model.

ject 'bench'. In other words, $P(\text{sit}|do(\text{bench}))$ and $P(\text{sit}|do(\text{refrigerator}))$ are similar, where we cannot easily distinguish the true causal relation, *i.e.*, bench-sit, from non-causal one, *i.e.*, refrigerator-sit.

To motivate the needs to robustify do, Figure 2 enumerates four representative classes, where $P(Y|X)$ (and $P(Y|do(X))$) is high/low respectively: the first two objects (diningtable and bench) have a causal relation with event 'sit'. While do (pink bar in the figure) can only identify the first object, we propose an ensemble (green bar) of both probabilities, which can distinguish the first two from the rest. Specifically, we search over a space Ω of possible aggregations of the two, from which we identify a robust causality scoring f_R. Contrary to do-calculus, our estimation better distinguishes frequent-causal correlation, *i.e.*, diningtable-sit, as well as rare-causal correlation, such as bench-sit, from the remaining two.

To apply the robust estimator trained as above for a test image without event, we deliberately instill the biases by biased event generation, which we are trained to remove, as inspired by Qian et al. (2021). We then mitigate biases in the testing time, by generating counterfactual image $\hat{X}_R$, eliminating the confounder identified from f_R.

Experimental results on VisualCOMET and VCR show that our method significantly improves the robustness of visual commonsense models and our codes can be found from supplementary material.

2 Methodology

Figure 3 overviews our framework in three steps: (1) probability estimation, (2) probability optimization, and (3) test-time debiasing.

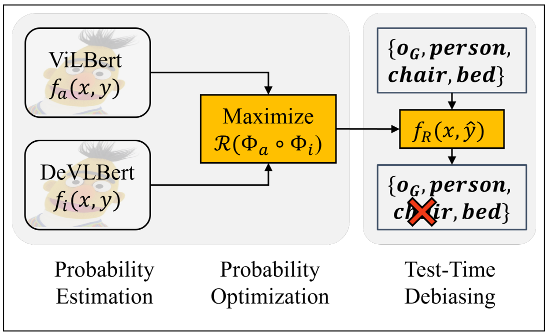

Figure 3: Framework overview.

2.1 Probability Estimation

As discussed above, we propose a new estimation of causality by combining both $P(Y|do(X))$ and $P(Y|X)$. For this purpose, we first leverage DeVLBert (Zhang et al., 2020) to estimate $P(Y|do(X))$, whose pre-training task, of leveraging 3.04 million <image, caption> to debias spurious correlations between image and words, is relevant to our objective of debiasing object-event. We thus aim to transfer the pre-trained DeVLBert to fit in our problem, by a fine-tuning task that can adapt to words that are important for event debiasing, e.g., verb. Specifically, we train DeVLBert with a classification task of matching image X with the right event description Y, generating a high score for a matching $X-Y$ pair.

In our classification task, DeVLBert takes the image X and the textual event description Y separately. Specifically, for textual input, it follows Bert convention (Devlin et al., 2018), where each token is represented as a sum of its corresponding token/position/segment embeddings, yielding a sequence of embeddings, *i.e.*, $y = \{w_{[CLS]}, w_1, ..., w_{|Y|}\}$. The special token [CLS] is used to capture the global information in the text. For visual input, by viewing the sub-regions of interest as visual words, the image is represented as a sequence of visual words, where each visual word (object) is detected by Faster-RCNN (Anderson et al., 2018) and the features of visual words $\{o_i\}_{i=1,...,k}$ are extracted by ResNet101 (He et al., 2016). Similarly with textual input, a global representation for the whole image $o_{[G]} = \frac{1}{k}\sum_{i=1}^{k} o_i$ is added at the beginning of the sequence, resulting $x = \{o_{[G]}, o_1, \ldots, o_k\}$. By finally feeding x and y into co-attentional transformer layers (Lu et al., 2019), DeVLBert is trained to predict the gold event description y among candidate event descriptions that are randomly sampled as negative.

Once this training is done, we can reconstruct $P(Y|do(X))$ by computing the fine-tuned DeVLBert scores $f_i(x, y)$ for event candidates, and normalizing the scores into a probability distribution.

Then, we adopt ViLBert (Lu et al., 2019) to estimate $P(Y|X)$, which we denote as f_a, following the same protocol described above. We stress that our proposed solution, building upon ViLBert/DeVLBert, is orthogonal to other task models using Faster-RCNN features (Anderson et al., 2018) such as UNITER and VILLA (Chen et al., 2020; Gan et al., 2020).

2.2 Probability Optimization

As we claimed above, it is important to distinguish rare-but-causal correlations from frequent-but-spurious correlations, for which we propose a more robust estimation f_R by aggregating $P(Y|X)$ and $P(Y|do(X))$. In this work, we formalize it as an optimization problem, searching over a space Ω of possible aggregations of $P(Y|X)$ and $P(Y|do(X))$, for the goal of maximizing an objective function $\mathcal{R}$.

We thus aim to enumerate the search space Ω to maximize the objective function $\mathcal{R}$. However, as exhaustively enumerating the search space Ω is infeasible, we consider the following two desired properties for f_R that can reduce the search space: 1) Positive correlation with f_i to preserve the strength of $P(Y|do(X))$ for identifying frequent-and-causal correlations, and 2) Negative correlation with f_a to prevent the over-estimation problem of $P(Y|X)$ for frequent-but-spurious correlations, where the optimization process for the robust estimation of causality f_R can be written as follows:

$$\begin{aligned}
\underset{\Phi_a,\Phi_i,\odot}{\text{maximize}} \quad & \mathcal{R}(\Phi_a(f_a) \odot \Phi_i(f_i)), && (1)\\
\text{s.t.} \quad & \Phi_a(f_a) = \lambda_a \ominus f_a, && (2)\\
& \Phi_i(f_i) = \lambda_i \oplus f_i, && (3)\\
& \lambda_a, \lambda_i \in \{-1, 0, 1\}, \oplus \in \{+, *\}, && (4)\\
& \ominus \in \{-, /\}, \text{and } \odot \in \{+, *\}, && (5)
\end{aligned}$$

where the objective function $\mathcal{R}$, to directly examine the effectiveness of f_R regarding its capability of identifying causal correlations, is defined as the number of correctly identified spurious correlations, which can be validated with human-selected confounders (Section 3).

2.3 Test Time Debiasing

Now that we trained a robust confounder identifier f_R, the next step is applying f_R on the test images to explicitly eliminate confounders. However, as the event y is missing for test image, we predict an event $\hat{y}$ by employing "poisonous" model with the same bias, namely f_a, such that we use $\hat{y} = \arg\max_{y \in \mathcal{E}} f_a(x, y)$[1]. As f_R is trained to distill biases from association-based prediction, with the predicted event $\hat{y}$, we can identify the confounder object o_c with the lowest causality, likely spurious: $o_c = \arg\min_{o_i} f_R(x_{o_i}, \hat{y})$, where x_{o_i} denotes a constrained input for measuring the causality of a single object o_i, *i.e.*, $x_{o_i} = \{o_{[G]}, o_i\}$. Note that this selection can be iterated with a score threshold (tuned from validation set) for multi-confounder cases. Without loss of generality, we consider o_c as a single object in this section.

With the identified confounder o_c, our final goal is to obtain a debiased image $\hat{X}_R$ for the purpose of robust event understanding, or event generator `GEN` with high transferability. To this end, we propose to remove all the visual features of objects that are of the same class with the identified confounder: $\hat{X}_R = X \setminus \{o_i | o_i \approx o_c\}$. By feeding the debiased input $\hat{X}_R$ for downstream tasks, our method will mitigate the spurious correlations in task models.

3 Experimental Settings

Dataset	Train	Valid	Test
VisualCOMET	47.5K	5.9K	5.9K
VCR	80.4K	9.9K	9.5K

Table 1: Statistics for datasets.

To evaluate the effectiveness of our framework, we conduct experiments on VisualCOMET and VCR datasets, by training model on the former, and study out-of-domain generalization for the latter. We report results for event, intent, and rationale prediction tasks from each dataset, respectively. The statistics of the datasets are presented in Table 1.

To adopt ViLBert/DeVLBert for f_a and f_i, we trained ViLBert/DeVLBert with our classification task for 20 epochs with a batch size of 64, and the initial learning rate is set as 2e-5. We adopt standard models for each tasks. For event understanding and intent inference tasks, We adopt GPT-2 based

---

[1] We constraint $\mathcal{E}$ the 111,796 training set events provided in (Park et al., 2020).

single-stream Transformer architecture, introduced in Park et al. (2020). Following the convention in Park et al. (2020), the parameters are optimized by Adam optimizer (Kingma and Ba, 2015) with a learning rate of 5e-5 and batch size of 64. For the VCR-justification task, we adopt ViLBert (Lu et al., 2019), which takes the concatenated question and correct answer as query to predict rationales. Following the settings of ViLBert, we fine-tuned ViLBert by Adam optimizer (Kingma and Ba, 2015) with a learning rate of 2e-5 and batch size of 64. For both tasks we used the maximum number of detected objects k is set as 15.

To build human-selected confounders for the validation purpose (Section 2.2), we first present the objects to human workers in the order of frequency, then ask them to filter out the objects with causality, so that confounders, or, spurious object-event pairs remain. We stress that the annotation process is efficiently guided by machine selections, such that humans are not exposed to all pairs, but only the surviving pairs from the first-phase machine selection, to filter out objects with causality, such that only the spurious object-event pairs remain after the second phase. We also found causality can be reliably annotated among multiple annotators, from a substantial inter-annotator agreement: Human-selected confounders agreement was measured to be 0.689 in Cohen's Kappa coefficient.

4 Experimental Results

We now proceed to empirically validate the effectiveness of our approach, in three dimensions: 1) capturing rare-but-causal correlations 2) transferability and 3) out-of-domain generalization.

Capturing Rare-but-causal: To investigate the effectiveness of our approach in capturing rare-but-causal correlations, we perform the event understanding task on the VisualCOMET dataset. For the experiment, we split the validation samples into a frequent set and a rare set, where the latter requires identifying rarely observed causal correlations. Among the images with the rarely observed object-verb pairs, *i.e.*, occurrences < 20, we collect the images with an object-verb, where the verb exists in the ground-truth event description E_{gold}, as rare-but-causal set. A desirable model should generalize well to the challenging set, or, the gap between the original and challenging sets should be small.

Method	Frequent	Rare	Total
$E_{gen}(\hat{X}_I)$	**14.16**	12.29	13.50
$E_{gen}(\hat{X}_R)$	14.15	**12.97**	**13.74**

Table 2: Results on event understanding task.

Image	Event	BLEU-2	METEOR	CIDEr
X	`NULL`	2.14	4.51	3.76
X	$E_{gen}(X)$	2.26	4.52	4.40
$\hat{X}_R$	$E_{gen}(\hat{X}_R)$	**2.90**	**4.67**	**5.93**
$\hat{X}_R$	E_{gold}	2.95	5.63	8.66

Table 3: Results on intent inference task. We compare each method for randomly sampled 100 validation examples.

We report our results on event understanding in Table 2, reporting METEOR (Denkowski and Lavie, 2014) between the generated events ($E_{gen}(\hat{X}_I)$, $E_{gen}(\hat{X}_R)$) with the gold event E_{gold} on frequent set, rare set, and total set respectively. As a baseline, we compare ours with the intervention-based baseline $\hat{X}_I$. In frequent set, $\hat{X}_I$ and $\hat{X}_R$ showed similar results as both are capable of capturing causal correlations when they appear frequently. On the contrary, in the case of rare-but-causal correlations, the gap between ours $\hat{X}_R$ and $\hat{X}_I$ increases, showing the strengths of ours at distinguishing rare-but-causal correlations from frequent-but-spurious correlations. As a validation of such strengths, we compare the error rate on detecting rare-but-causal correlation of f_R and f_i. We confirmed that f_R significantly reduces the error rate from 19% of f_i to 15%, verifying that the event understanding benefits from distinguishing rare-but-causal correlation out of frequent-and-spurious correlation.

Transferability: We evaluate how our approach contributes to transferability, which we define as the gap between event description as `NULL` and `GEN`, on intent inference task. We report our results on the intent inference task in Table 3, reporting BLEU-2 (Papineni et al., 2002), METEOR (Denkowski and Lavie, 2014), and CIDEr (Vedantam et al., 2015) between the inferred intent with the gold intents. Specifically, we extend the comparisons with input debiasing for the generated events, *i.e.*, $E_{gen}(X) \rightarrow E_{gen}(\hat{X}_R)$. In the table, we observe that, without input debiasing, generated event $E_{gen}(X)$ is not beneficial, achieving only a minor improvement in BLEU-2 (2.14 → 2.26), due to its low transferability as Park et al. (2020) observed a decrease. On the other hand, we observe that when $E_{gen}(\hat{X}_R)$ is equipped with the debiased input $\hat{X}_R$, the model performs best (performing closely to the oracle case with human annotation `GOLD`), showing the effectiveness of debiasing towards transferability.

Out-of-domain Generalization: A reliable neural network should be able to generalize across the distribution shift, *i.e.*, test distribution is different from the training distribution. To make the point that our approach can make the model generalize over distribution shifts, we conduct experiments on the VCR-justification task, where the linguistic parts may not overlap with VisualCOMET.

	X	$\hat{X}_I$	$\hat{X}_R$
Top-1 Acc (%)	62.94	63.90	**64.22**

Table 4: Results on justification task in VCR dataset.

The results of the VCR-justification task are presented in Table 4. In accordance with the result of former experiments, the proposed debiased input $\hat{X}_R$ significantly improves the result without further training, achieving 1.28 point accuracy gain from $X \rightarrow \hat{X}_R$, while baseline input debiasing $\hat{X}_I$ achieving only 0.96 point gain. It demonstrates that our proposed input debiasing can generalize on out-of-domain tasks by better distinguishing confounder objects of spurious correlation.

5 Related Work

Inspired by the success of large-scale pre-trained language models (Devlin et al., 2018; Radford et al.), large-scale pre-training on transformers have shown that it can also benefit visio-linguistic tasks, showing better transferability on various downstream tasks (Lu et al., 2019; Li et al., 2020). However, it is reportedly bad when the transformer is trained on out-of-domain datasets, that are not aligned with its pre-training corpus (Chen et al., 2020; Zhang et al., 2020), as they are purely likelihood-based, leading to spurious correlations and hurting the generalization ability. To this end, recent approaches adopt a traditional *do*-calculus (Pearl et al., 2016), encouraging causal intervention-based estimation to remove spurious correlations, that can be exploited in vision-only dataset (Wang et al., 2020) or visio-linguistic dataset (Zhang et al., 2020; Yang et al., 2021). Different from these works, we focus on identifying spurious correlation comparing association-based and intervention-based knowledge.

6 Conclusion

We studied the problem of robustifying event understanding, to overcome dataset bias, by combining observational and interventional estimations. Our experiments suggest that this extension improves event understanding, and eventually visual commonsense tasks.

Abstract

Current Question Answering over Knowledge Graphs (KGQA) task mainly focuses on performing answer reasoning upon KGs with binary facts. However, it neglects the n-ary facts, which contain more than two entities. In this work, we highlight a more challenging but under-explored task: n-ary KGQA, i.e., answering n-ary facts questions upon n-ary KGs. Nevertheless, the multi-hop reasoning framework popular in binary KGQA task is not directly applicable on n-ary KGQA. We propose two feasible improvements: 1) upgrade the basic reasoning unit from entity or relation to fact, and 2) upgrade the reasoning structure from chain to tree. Therefore, we propose a novel fact-tree reasoning framework, FacTree, which integrates the above two upgrades. FacTree transforms the question into a fact tree and performs iterative fact reasoning on the fact tree to infer the correct answer. Experimental results on the n-ary KGQA dataset we constructed and two binary KGQA benchmarks demonstrate the effectiveness of FacTree compared with state-of-the-art methods.

1 Introduction

The task of Question Answering over Knowledge Graphs (KGQA) has provided new avenues to the recent development of QA systems by utilizing the advantages of KGs (Yu et al., 2017; Dubey et al., 2019; Huang et al., 2019; Zhang et al., 2021). Current KGQA studies mainly consider performing answer reasoning upon KGs with binary facts, which encode binary relations between pairs of entities, e.g., *<u>Golden State Warriors</u>' arena is <u>Chase Center</u>*[1]. However, n-ary facts that involve more than two entities are also ubiquitous in reality (Guan et al., 2019; Abboud et al., 2020; Wang et al., 2021), e.g., the ternary fact *<u>Golden State Warriors</u> won <u>the NBA championship</u> in <u>2018</u>*. Compared to binary facts, n-ary facts have more information content. This makes the answer reasoning for questions involving n-ary facts more intractable, exposing open challenges in KGQA. In this work, we aim to study the under-explored **n-ary KGQA** task, i.e., answering n-ary facts questions upon n-ary KGs.

The multi-hop reasoning KGQA method (Das et al., 2018; Qiu et al., 2020; Saxena et al., 2020; Ren et al., 2021) has become popular for its high efficiency and interpretability. Specifically, the reasoning process can be expressed as a chain, starting from an entity extracted from the question and then walking on the KG by connected relations and entities until arriving at the answer entity. See Figure 1 (b) for an example, to answer the question, *what is the address of the arena of the Golden State Warriors*, the reasoning chain starts from `Golden State Warriors`, to walk through "arena→Chase Center→address", and it ends at `1 Warriors Way`, i.e., the answer. Multi-hop reasoning has been studied widely on the binary KGQA task. Here, we first try to execute it on the n-ary KGQA task.

However, we find that multi-hop reasoning is not directly applicable on n-ary KGQA. We take the n-ary facts question in Figure 1 (c) as an example to explain. First, the essence of multi-hop reasoning is to construct a reasoning chain by treating the relation as the translation between two entities (Bordes et al., 2013; Ren and Leskovec, 2020), naturally in a linear structure. However, the transition from binary to n-ary facts is similar to the transition from a line to a plane. For a single n-ary fact (e.g., *Golden State Warriors won the NBA championship in 2018*), the reasoning chain could only include two entities `Golden State Warriors` and `NBA championship` and a relation `win` involving them, leading to the possible loss of important information `2018`. To overcome

Q1: What is the address of the arena of the Golden State Warriors?
Chain: Golden State Warriors→ arena → Chase Center →address → ☆ 1 Warriors Way

Q2: Who joined an NBA team in Los Angeles in the year the Warriors won the NBA championship?

Fact Tree: ☆ LeBron James joined Los Angeles Lakers in 2018

Los Angeles Lakers in Los Angeles

The Warriors won the NBA championship in 2018

Figure 1: (a) A KG fragment, where entities are represented by round rectangles. `Win` and `join` are two ternary relations. (b) and (c) are two QA examples, where the correct answer is marked by a star. The multi-hop reasoning method can be used to answer Q1, and the reasoning process can be visualized as a chain (b). However, for the more complex Q2, the multi-hop reasoning method is not applicable. We use fact as the basic reasoning unit to construct the reasoning process. As shown in (c), the reasoning process can be visualized as a fact tree: **fact 2** and **fact 3** are leaf nodes need to be inferred first, and then the two inferred entities (`Los Angeles Lakers` and `2018`) are transmitted to the root node (**fact 1**). Finally the root node infers the answer entity (`LeBron James`).

this weakness, we propose that **upgrading the basic reasoning unit from an entity or relation to the fact** to expand the coverage of information during reasoning.

Nevertheless, multi-hop reasoning would still be less capable in more complex reasoning scenarios where a question involves multiple n-ary facts. For example, the question in Figure 1 (c) is composed of three facts. When using fact as the basic reasoning unit, the whole reasoning process can be represented as a tree structure, where nodes represent facts and edges reflect the reasoning order. Specifically, in the fact tree, the entities (`Los Angeles Lakers` and `2018`) which are missing in the two leaf nodes (fact 2 and fact 3) are first inferred and then passed to the root node (fact 1). The root node can then finally infer the correct answer entity `LeBron James`. Obviously, the chain structure used in the multi-hop reasoning framework is evidently insufficient to cope with the tree structure. Therefore, to improve the ability to cope with more complex reasoning scenarios, we propose that **upgrading the reasoning structure from chian to tree**.

In this work, we propose a novel **fact-tree reasoning framework**, namely, **FacTree**, which integrates the above two upgrades and pipelines the answer reasoning process into three steps: 1) fact tree construction, which transforms an input natural language (NL) question into an NL fact tree; 2) fact location, which locates the NL fact onto the KG; and 3) fact reasoning, which iterates intra-fact and inter-fact reasoning to infer the answer. During the intra-fact reasoning, the n-ary KG embedding model (Guan et al., 2020) is plugged in to alleviate the deficiency of KG incompleteness. The explicit tree reasoning structure makes the results strongly interpretable. Furthermore, we develop a new dataset called WikiPeopleQA to foster research on n-ary KGQA. We then conduct comprehensive experiments on WikiPeopleQA dataset to show that FacTree has the desired ability to perform effective reasoning on n-ary fact questions. Besides, on two binary KGQA datasets, FacTree also indicates a strong ability to infer answers compared with state-of-the-art methods accurately.

Our study fundamentally contributes to bridging the gap between binary KGQA and n-ary KGQA. The proposed FacTree can serve as a preliminary foundation for the n-ary KGQA. To summarize, our contributions are:

- We highlight a more challenging task: n-ary KGQA than a standard binary KGQA task setting. We further observe that the multi-hop reasoning framework popular in binary KGQA is no longer applicable to n-ary KGQA.
- We propose a novel fact-tree reasoning framework, FacTree, which can serve as a preliminary foundation for n-ary KGQA study. And we develop a new dataset: WikiPeopleQA to foster research on n-ary KGQA.
- We conduct comprehensive experiments to show that our framework has the desired reasoning ability for both n-ary and binary KGQA tasks.

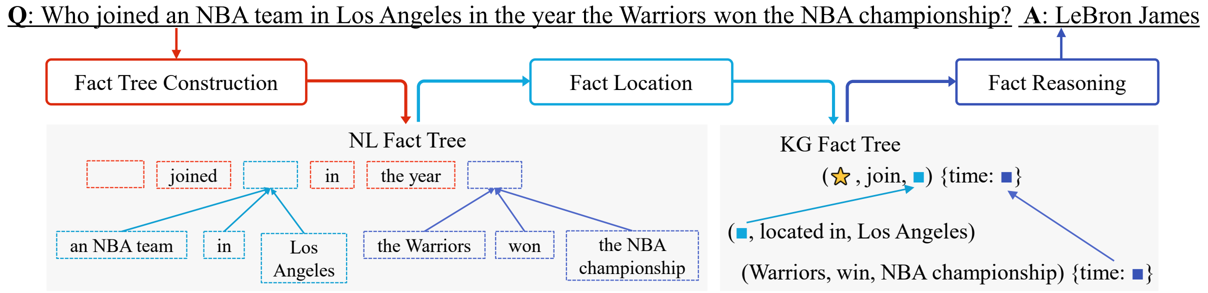

Figure 2: Overview of FacTree. It takes the question (**Q**) as an input, passes through a three-stage pipeline processing: 1) fact tree construction (Sec. 3.1), 2) fact location (Sec. 3.2) and 3) fact reasoning (Sec. 3.3), and finally gets the answer entity (**A**). Placeholders □ in the NL and KG fact trees indicate the entities to be inferred.

2 Related Work

The previous series of KGQA models (Liang et al., 2011; Berant et al., 2013; Yih et al., 2014; Lan and Jiang, 2020; Sun et al., 2020; Wolfson et al., 2020) synthesize a structured query graph from the question and then match the query with KG to get the answer. This type of model has high interpretability but is challenged by the incomplete nature of KGs. Then another series models compute the semantic similarity of the question and each candidate answer directly in the latent space (Bordes et al., 2015; Dong et al., 2015; Hamilton et al., 2018; Zhang et al., 2018b). This type of model overcomes the limitation of incomplete KG, but lacks sufficient interpretability. FacTree uses facts as the basic reasoning unit to alleviate the deficiency of KG incompleteness and the explicit tree reasoning structure to realize strongly interpretable.

Multi-hop reasoning framework has attracted widespread attention due to its high flexibility and high interpretability in recent years (Fu et al., 2020). Current efforts build an explicit reasoning chain through training a reinforcement learning agent to walk on the KG (Das et al., 2018; Qiu et al., 2020; Kaiser et al., 2021), or construct implicit reasoning chains through memory network (Sukhbaatar et al., 2015; Miller et al., 2016; Chen et al., 2019) or in the latent space (Bordes et al., 2014; Saxena et al., 2020; Ren and Leskovec, 2020; He et al., 2021; Ren et al., 2021). This kind of method performs well on binary fact questions but has difficulties in dealing with n-ary fact questions. Of course, one could construct and synthesize multiple reasoning chains to tackle n-ary KGQA. But this would inevitably lead to an exponential increase in the reasoning difficulty and computational complexity, which in turn affects the reasoning performance.

Our work first highlights the n-ary KGQA task. The research of n-ary KG provides a feasible research foundation for n-ary KGQA. KG embedding learning on n-ary facts (Wen et al., 2016; Zhang et al., 2018a; Fatemi et al., 2019; Guan et al., 2019, 2020; Abboud et al., 2020) has grown considerably in recent years. The n-ary KG embedding model (Guan et al., 2020) is plugged in FacTree to alleviate the reasoning difficulties caused by the KG incompleteness.

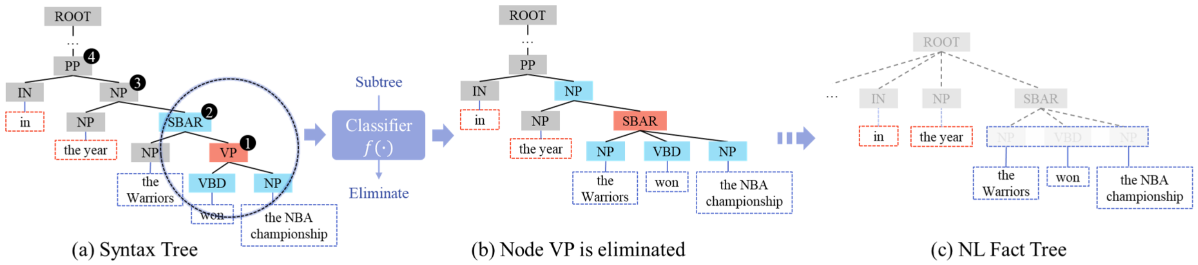
3 Fact-tree Reasoning

We illustrate the fact-tree reasoning framework for n-ary KGQA in Figure 2. It takes the question (**Q**) as an input, passes through a three-stage pipeline processing, and finally gets the answer entity (**A**). In the first fact tree construction stage, we construct the NL fact tree from the NL question (Sec. 3.1). In the second fact location stage, we locate the NL fact onto the KG to obtain the KG fact tree (Sec. 3.2). This helps to bridge the semantic and structure gap between the unstructured NL and the structured KG. In the last fact reasoning stage, we perform intra-fact and inter-fact reasoning iteratively on the KG fact tree to infer the answer entity (Sec. 3.3).

We use fact as the basic reasoning unit in the fact-tree reasoning framework. In the NL fact tree, the fact is represented as a sequence of words and placeholders, where the words are taken from the NL question, and the placeholders refer to the missing entities to be inferred, e.g., the fact (□ *joined* □ *in the year* □). In the KG fact tree, following (Guan et al., 2020), we represent the n-ary fact as

$$fact = (s, p, o), \{a_1 : v_1, a_2 : v_2, ..., a_m : v_m\}, \quad (1)$$

where (s, p, o) denotes the subject-predicate-object information in the fact, named primary triple; each $a_i : v_i$ $(i \in \{1, 2, ..., m\})$ is an attribute value pair, a.k.a., the auxiliary description to



(a) Syntax Tree (b) Node VP is eliminated (c) NL Fact Tree

Figure 3: An example of NL fact tree construction (partial steps). The eliminations of nodes in the order of ❶→❷→❸→❹→ · · · . Best viewed in color.

the primary triple. For example, the ternary fact *LeBron James joined Los Angeles Lakers in 2018* is formalized as `(LeBron James, join, Los Angeles Lakers),{time: 2018}`. Note that the binary fact only contains the primary triple.

3.1 Fact tree construction

In FacTree, we use fact as the basic reasoning unit and use the tree structure to represent the associations among facts. Here, we design an automatic NL fact tree construction algorithm to transfer the NL question to the NL fact tree. Since the syntax tree naturally expresses the hierarchical relation of the elements of the sentence and in order to facilitate the subsequent locating of the NL facts into KG, we use the syntax tree[2] of Q as the initial structure. We expect the constructed NL fact tree to satisfy the following characteristics: 1) the leaf nodes are words or phrases of Q; and 2) if the leaf nodes share the same parent node, they belong to the same fact. Therefore, the NL fact tree construction algorithm can be viewed as an iterative eliminating of nodes in the syntax tree to achieve clustering of nodes within facts and differentiation between facts.

The node elimination process starts from the antepenult level of the syntax tree and proceeds from bottom to top. We observe that two semantically different questions may be parsed into the same syntax structure except for the leaf nodes. Therefore, disregarding leaf nodes makes our algorithm more adaptable. Also, the parent node of a leaf node needs to be reserved for identifying the leaf node. Figure 3 shows a specific example [3]. As shown in (a), the pruning starts from the node VP (❶, colored in red). To decide whether to eliminate this node or not, we extract a subtree that contains the node and its neighbor nodes (colored in blue). This subtree is fed into a classifier $f(\cdot)$, which is composed of a Graph Convolutional Network (GCN) as embedding layer and a fully-connected layer. If $f(\cdot)$ outputs "eliminate", the node will be eliminated and its children will be directly connected to its parent, as shown in (b). Otherwise, this node will be retained. This process continues until the iteration meets the root node. Finally, we remove non-leaf nodes and keep the hierarchical structure of leaf nodes. The nodes in the upper-layer facts that are connected to the lower-layer facts are replaced with placeholders, as shown in (c). We summarize the construction of NL fact tree in Algorithm 1.

Algorithm 1: NL Fact Tree Construction

```
Input: The question $\mathbf{Q}$, empty node stacks $\mathbb{V}, \mathbb{V}'$;
Output: The NL fact tree FT;
Initialization
    $\mathrm{FT} = \mathrm{Parse}(\mathbf{Q})$,
    $\mathbb{V} = \mathrm{BFS}(\mathrm{FT})$;
while $\mathbb{V}$ do
    $v = \mathbb{V}.pop()$;
    if $v.isLeaf()$ or $v.children.isLeaf()$ then
        continue;
    else
        $\mathbb{V}'.push(v)$;
    end
end
while $v \neq \mathrm{FT.root}$ do
    $v = \mathbb{V}'.pop()$;
    $T_v = \{v\} \cup \{v.parent\} \cup \{v.children\}$;
    if $f(T_v) == eliminate$ then
        update
        for each $child$ in $v.children$ do
            $child.set\_parent(v.parent, \mathrm{FT})$
        end
        $\mathrm{FT}.delete(v)$
    end
end
```

Specifically, for the GCN, we use the propagation rule for calculating the node embedding update

---

[2] We use the Stanford Parser to generate the syntax tree. The leaf nodes are words or phrases of Q and the branch nodes are syntax labels, e.g., NP (Noun Phrase) and VP (Verb Phrase).

[3] Due to the space limitation, only part of the syntax tree and the corresponding elimination steps are shown here.

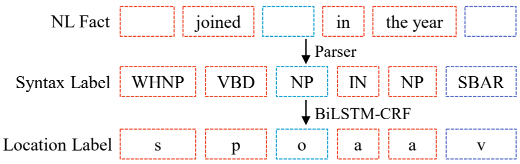


Figure 4: Example of a structure matching process.

for each layer as follows:

$$\boldsymbol{h}_v^{(i+1)} = \sigma_i(\boldsymbol{h}_v^{(i)} \boldsymbol{W}_0^{(i)} + \sum_{u \in T_v \setminus v} \boldsymbol{h}_u^{(i)} \boldsymbol{W}_1^{(i)}), \quad (2)$$

where v and T_v follow the definitions in Algorithm 1, u is one of the neighbors of v, $\boldsymbol{h}_*^{(i)}$ represents the hidden layer activations of nodes in the i^{th} layer, $\sigma_i(\cdot)$ is the activation function, and $\boldsymbol{W}_{0,1}^{(i)}$ are the i-layer weight matrices.

3.2 Fact Location

This stage aims to transfer the NL fact tree to the KG fact tree, specifically, to locate each NL fact in the tree to a KG fact. It is divided into three specific steps: 1) entity linking, 2) structure matching, and 3) relation extraction.

During entity linking, following the standard setting in KGQA (Saxena et al., 2020), we assume that the entities of the question are given and linked to nodes on the KG. Note that the placeholders are directly reserved and they indicate the entities that need to be inferred.

The key of structure matching is to locate the subject s, predicate p, object o, attribute a and value v in the NL fact. We view this process as a sequence labelling task, as shown in Figure 4. We believe that location labels are more strongly associated with syntax labels, compared to word sequences. Therefore, the input is the sequence formed by the syntax labels of each node in the NL fact. The output is the sequence of location labels, and the label set is $\{s, p, o, a, v\}$. Here,we adopt the BiLSTM-CRF model (Huang et al., 2015) to perform sequence labelling.

After entity matching, we conduct relation extraction, i.e., transferring the word sequences labelled p or a to the corresponding relations (predicates or attributes) in KG. Specifically, we adopt pre-trained SBERT model (Reimers and Gurevych, 2019) to get the embeddings of the relation in KG (i.e., $\boldsymbol{r}$) and the word sequences (i.e., $\boldsymbol{w}$). Then we use cosine similarity as a scoring function $s(\cdot)$ to assign scores to the two embeddings and select the relation with the highest score:

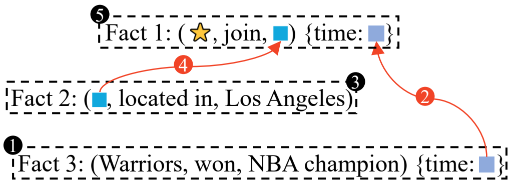

Figure 5: Example of an iterative reasoning process. The order of reasoning is ❶→❷→❸→❹→❺.

$$s(r, w) = \frac{r \cdot w}{\|r\| \|w\|} = \frac{\sum_{i=1}^{n} r_i w_i}{\sqrt{\sum_{i=1}^{n} r_i^2} \sqrt{\sum_{i=1}^{n} w_i^2}}. \quad (3)$$

Finally, combining the predicted location labels, and linked entities and extracted relations, NL facts can be transformed into KG facts (cf. Figure 2). Placeholders are the bridge between upper-layer and lower-layer facts. Interestingly, due to the variability of NL organization, there may be no placeholder in the lower-layer fact. It is because when constructing the NL fact tree, the placeholder (usually value) is assigned to upper-layer fact according to the syntax structure. Therefore, we directly copy the upper-layer placeholder directly to the lower-layer fact. For example, in Figure 2, the fact *the Warriors won the NBA championship* will be transformed to `(Golden State Warriors, win, NBA championship), {time:2018}`, where the attribute `time` is copied from the upper-layer fact.

3.3 Fact Reasoning

In this stage, we perform the inter-fact and intra-fact reasoning iteratively based on the KG fact tree to find the answer entity. One example of iterative reasoning process is shown in Figure 5.

Inter-fact Reasoning The whole process of inter-fact reasoning is carried out in a bottom-up manner. Specifically, the entity inferred from the lower-layer fact will be transferred to the upper-layer fact. For example, the entity `2018` inferred from fact 3 will be transferred to fact 1, i.e., the second step in Figure 5.

Intra-fact reasoning This module aims to infer the missing entity of each incomplete fact. We formulate this process as the KG completion task. KG embedding models (Bordes et al., 2013; Dettmers et al., 2018; Guan et al., 2019, 2020) are studied to deal with this task, by learning entity and relation embeddings and designing a scoring function to infer the missing entity. In this work, we use

Table 1: Statistics of WikiPeopleQA, WC2014 and PathQuestion, as well as their subsets. Note that the n-ary here means that n is greater than 2.

Dataset	# Question-Answer Pair		Background KG			
	Total	Subset	# Fact	# Entity	# Relation(binary)	# Relation(n-ary)
WikiPeopleQA (1F/2F/3F)	4,491	2,365 / 1,497 / 629	56,426	28,043	150	557
WC2014 (1H/2H/C)	10,162	6,482 / 1,472 / 2,208	6,482	1,127	6	0
PathQuestion (2H/3H)	7,106	1,908 / 5,198	4,049	2,215	14	0

NeuInfer (Guan et al., 2020), a KG embedding model that can perform on binary and n-ary facts, to implement intra-fact reasoning.

However, comparing with the traditional KG completion task, the missing entity needs not only to complete the current fact, but also to satisfy the upper-layer fact. For example, in fact 2, `Sunset Boulevard` and `Los Angeles Lakers` are all located in Los Angeles. While, considering the upper-layer fact 1, the missing entity needs to satisfy the fact that the predicate is `join`. Therefore, we introduce a score amplification mechanism: if an alternative entity can satisfy the upper-layer fact, its corresponding score will be magnified λ times.

3.4 Training

The classifier $f(\cdot)$ and BiLSTM-CRF model are trained in a supervised manner, where the training signals are obtained from manually labeled (syntax tree, NL fact tree) and (syntax label sequence, location label sequence) pairs, respectively. We observe the syntax structure of different questions may be similar or even consistent. Therefore, we reduce the the input space by using syntax-related information rather than NL, to relieve the manual annotation pressure and also the learning difficult.

4 Experiments

4.1 Dataset

In this work, we target at studying the n-ary KGQA task. Considering the popular KGQA datasets involve almost exclusively binary facts, we develop an n-ary KGQA dataset: WikiPeopleQA (abbr. WP), in which questions involve multiple n-ary facts and the background KG is also composed of n-ary facts. We also conduct evaluation on two binary KGQA benchmarks: WC2014 (abbr. WC) (Zhang et al., 2016) and PathQuestion (abbr. PQ) (Zhou et al., 2018). Depending on the number of **F**acts or **H**ops involved in the question[4], WikiPeopleQA is divided into WP-1F, WP-2F and WP-3F. WC2014 is divided into WC-1H and WC-2H, as well as a conjunctive question set WC-C. PathQuestion is divided into PQ-2H and PQ-3H. We partition the three datasets into train/valid/test subsets with a proportion of $8:1:1$. The detailed statistics are shown in Table 1.

4.2 Experimental Setup

4.2.1 Training Details

During training the classifier, the embedding size of node is 50, the learning rate is $1e{-}5$, and the number of GCN layers is 3. During training the BiLSTM-CRF model, the embedding size of node is 100, the learning rate is $2e{-}5$. We use Adam optimizer for optimization for above training process. The hyper-parameter λ is set to 1.5. The training process of the KG embedding model used in the fact reasoning stage is following (Guan et al., 2020). The experimental results are all averaged across three training repetitions.

4.2.2 Baselines

We compare our framework with a series of popular multi-hop reasoning baseline approaches. According to the form of the reasoning chain, these baselines can be divided into two categories. The first category baseline builds an explicit reasoning chain through training an agent to walk on the KG: IRN-weak (Zhou et al., 2018), MINERVA (Das et al., 2018) and SRN (Qiu et al., 2020); the second category baseline builds an implicit reasoning chain through memory network or in the latent space: MemNN (Sukhbaatar et al., 2015), KV-MemNN (Miller et al., 2016) and Embed-KGQA (Saxena et al., 2020). We also compare with QGG (Lan and Jiang, 2020), which synthesizes a query graph from the question and then match the query with KG to get the answer. When

---

[4] Note that, for a binary fact question, the hop number is generally equal to the fact number.

Model	WP	WP-1F	WP-2F	WP-3F	WC	WC-1H	WC-2H	WC-C	PQ	PQ-2H	PQ-3H
MemNN (Sukhbaatar et al., 2015)	32.9	34.2	39.6	12.5	52.4	71.6	55.5	73.3	86.8	89.5	79.2
KV-MemNN (Miller et al., 2016)	24.5	15.0	40.0	16.0	76.7	87.0	87.0	78.8	85.2	91.5	79.4
EmbedKGQA (Saxena et al., 2020)	26.4	35.4	22.3	3.5	52.5	59.6	79.0	52.0	36.7	51.0	30.6
IRN-weak (Zhou et al., 2018)	-	-	-	-	78.6	83.4	92.1	83.7	85.8	91.9	83.3
MINERVA (Das et al., 2018)	10.9	20.5	0.3	0.2	89.6	87.2	93.1	82.4	73.1	75.9	71.2
SRN (Qiu et al., 2020)	13.3	24.9	0.3	0.8	96.5	98.9	**97.8**	87.3	89.3	96.3	89.2
QGG (Lan and Jiang, 2020)	24.9	41.8	1.1	0.0	94.0	94.9	92.9	**99.9**	40.4	67.8	28.9
FacTree	**54.4**	**63.1**	**47.0**	**40.1**	**99.5**	**99.9**	96.3	**99.9**	**92.8**	**98.4**	**90.8**

Table 2: Model Performance on n-ary KGQA task (WikiPeopleQA dataset) and binary KGQA task (WC2014 and PathQuestion datasets) under the accuracy(%) metric (pairwise t-test at 5% significance level). The best performance results are shown in **bold**, and the second best results are shown in underlined.

evaluating explicit multi-hop reasoning methods and QGG, we use the dummy entity to divide n-ary facts in the KG of WikiPeopleQA into binary facts.

4.3 Main Results

Performance of FacTree Table 2 presents the statistics of model's performances both on the n-ary and binary KGQA tasks. We can see that FacTree achieves significantly higher accuracy than state-of-the-art baselines on the n-ary KGQA task. Specifically, compared with the best performing multi-hop reasoning baseline MemNN, FacTree improves accuracy by 21.5% (w.r.t., WP). We have following discoveries:

- FacTree shows large advantages on coping with complex questions with multiple facts. On the WP-3F sub-dataset, comparing with baselines, FacTree has made a qualitative leap on accuracy (16.0→40.1). This confirms that multi-hop reasoning methods are inapplicable to more complex reasoning scenarios.
- Interestingly, the explicit multi-hop reasoning methods (e.g., SRN) are obviously weaker than implicit methods (e.g., EmbedKGQA). This is because the n-ary facts are split by dummy entities, adding difficulty to build explicit reasoning chains. Implicit methods weaken the distinction between binary and n-ary facts, which makes it more flexible in dealing with n-ary facts.
- The QGG method directly matches the generated query graph to the KG, resulting in performing well on questions with less facts, but clearly lacking flexibility for question with more facts.

Besides, fact-tree reasoning also achieves a good performance on binary KGQA. We observe a large performance gap between multi-hop reasoning methods on binary and n-ary KGQA tasks. Therefore, it would be valuable to pay more attention to the study of n-ary KGQA.

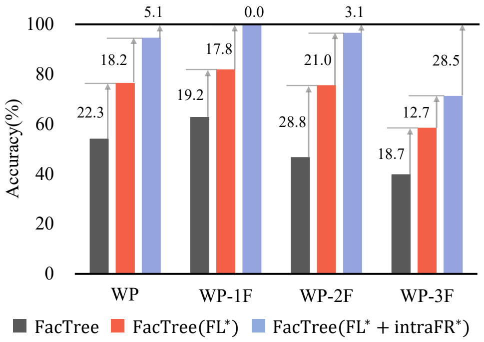

Figure 6: Staged evaluation of FacTree. FL^* and $\mathrm{intraFR}^*$ denote turning off the FL and intraFR components respectively. Note that the accuracy of FacTree(FL^*+$\mathrm{intraFR}^*$+$\mathrm{interFR}^*$) is 100%.

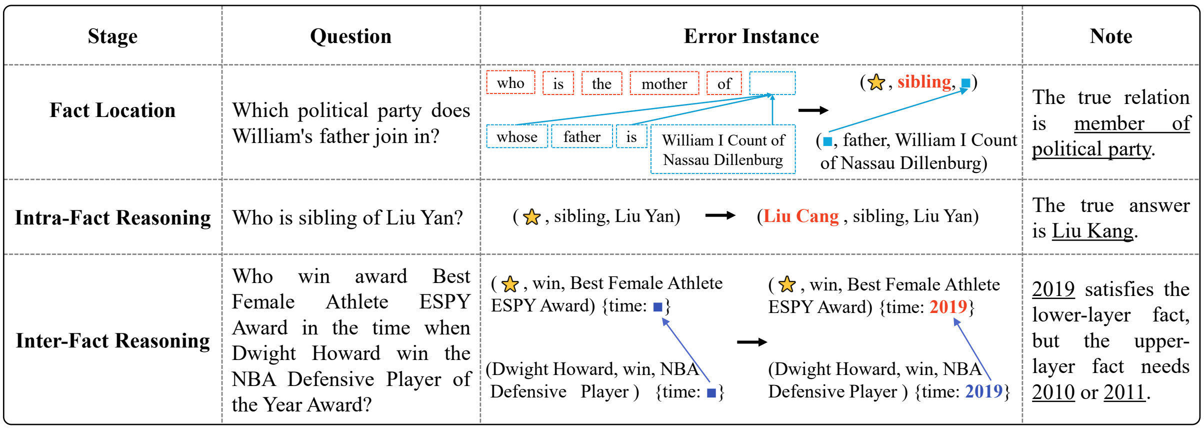
Staged Evaluation We test the capability of each stage of FacTree. Because the fact-tree reasoning framework is a pipeline structure, the reasoning error always occurs in cascade. We turn off the components on the pipeline from the beginning to see the impact on the overall effect. "Turn off a component" means to replace the real output with the ground truth, that is, the component is perfect by default. We test three components of FacTree: fact location (FL), intra-fact reasoning (intraFR) and inter-fact reasoning (interFR). The error caused by the fact tree construction stage is negligible here because of the relatively small number of NL fact tree types in the datasets. Figure 6 shows turning off the components in turn will lead to an accuracy increase of 22.3% (FL), 18.2% (intraFR) and 5.1% (interFR) respectively (w.r.t., WP). Impressively, transferring the NL fact tree to KG fact tree and inferring missing entities of incomplete facts are



Stage	Question	Error Instance	Note
Fact Location	Which political party does William's father join in?	who · is · the · mother · of · ☐ / whose · father · is · William I Count of Nassau Dillenburg → (☆, **sibling**, ■) ← (■, father, William I Count of Nassau Dillenburg)	The true relation is member of political party.
Intra-Fact Reasoning	Who is sibling of Liu Yan?	(☆, sibling, Liu Yan) → (**Liu Cang**, sibling, Liu Yan)	The true answer is Liu Kang.
Inter-Fact Reasoning	Who win award Best Female Athlete ESPY Award in the time when Dwight Howard win the NBA Defensive Player of the Year Award?	(☆, win, Best Female Athlete ESPY Award) {time: ■} (Dwight Howard, win, NBA Defensive Player) {time: ■} → (☆, win, Best Female Athlete ESPY Award) {time: **2019**} (Dwight Howard, win, NBA Defensive Player) {time: **2019**}	2019 satisfies the lower-layer fact, but the upper-layer fact needs 2010 or 2011.

Figure 7: Error instances in the fact location, intra-fact and inter-fact reasoning stages, respectively.

the two keys that affect the reasoning accuracy. Moreover, the influence of the inter-fact reasoning module becomes apparent as the number of facts increases. This is because it may happen that an entity satisfying the lower-layer fact may not be able to satisfy the upper-layer fact. For instances of errors in each module, please see Section 4.4.

Model	WP	WP-50%	WC	WC-50%
SRN	13.3	0.1 (↓99%)	96.5	0.0 (↓100%)
EmbedKGQA	26.4	6.5 (↓75%)	52.5	11.0 (↓79%)
FacTree	54.4	17.8 (↓67%)	99.5	37.2 (↓63%)

Table 3: Performance on incomplete KGs. ↓ indicates the decrease in accuracy when the KG is halved.

Size	O	O+F	O+C	O+F+C	O+F+C+S
Acc.	52.9	53.9	63.1	91.4	91.0

Table 4: Performance of different subtree range w.r.t. fact tree construction stage. “F”, “C” and “S” denote the father, child and sibling nodes of the central node “O”, respectively.

4.4 Analysis of FacTree

Performance w.r.t. Incomplete KGs As the capacity of the KG continues to expand, current KGs are typically incomplete with many facts missing. Incomplete KGs put forward higher requirements on the capabilities of KGQA models. Therefore, we conduct an experiment on FacTree and two popular baselines to test their reasoning capability for incomplete KGs. As shown in Table 3, when the KG is reduced by half, the effect of our model decreases the least. This is because we adopt KG embedding models to perform intra-fact reasoning in FacTree. This design relaxes the requirements for KG completeness. SRN requires the construction of query graph or explicit reasoning chain on KG, so it is more sensitive to the incompleteness of KG. EmbedKGQA also uses KG embedding models. The performance gap between it and our FacTree corroborates the superiority of the fact-tree reasoning framework.

Zero-shot Learning w.r.t. Classifier $f(\cdot)$ We conduct a zero-shot learning experiment to test the capability of our proposed classifier $f(\cdot)$ in the fact construction stage though a 5-fold cross validation. We evaluate the accuracy of the constructed NL fact tree on the mixed dataset combined with three datasets (WikiPeopleQA, WC2014 and PathQuestion). The mixed dataset is divided into five parts according to the NL fact tree classes. For each fold, the fact tree classes in the testing set do not appear in the training set. Based on this setting, our classifier can reach 81.2% accuracy with a standard deviation of 0.098. This indicates our classifier has the scalable ability to construct unseen fact trees.

Effectiveness of GCN We also test the effect of the execution range of the GCN on the accuracy of the fact tree construction. The range of GCN execution is a subtree of the syntax tree containing the central node to be eliminated and its neighbor nodes. A total of five range types are tested depending on whether the father, siblings and child of the central node were included. As shown in Table 4, the optimal subtree range includes the central node and its father and child nodes. Interestingly, the addition of sibling nodes did not bring significant effect improvement.

Error Analysis We conduct a qualitative study on error instances, as shown in Figure 7, and analysis the directions for future work. In the fact location stage, introducing more effective relation extraction techniques can contribute to reduce relation extraction error. In the intra-fact reasoning stage, it is necessary to improve KG embedding model's capability. There is a false negative error case. For example, the fact `(Liu Cang, sibling, Liu Yan)` is true, but is not included by KG, resulting in the inferred answer being judged as wrong. So, adopting broader KGs is suggested in future studies. In the inter-fact reasoning stage, entities can be incompatible when transferred between facts. Therefore, intra- and inter-factual reasoning needs to act more closely together to reduce the incompatibility.

5 Conclusion

This work highlights a more challenging task: n-ary KGQA, and it advocates that the multi-hop reasoning framework popular in binary KGQA is no longer applicable to n-ary KGQA. A novel fact-tree reasoning framework FacTree is proposed, which pipelines the n-ary KGQA into three steps: fact tree construction, fact location, and fact reasoning to infer the correct answer. The quantitative and qualitative experimental results have demonstrated that FacTree has superior reasoning ability on n-ary and binary fact questions.

A Methodology Details

A.1 NL Fact Tree Construction Algorithm

The construction of NL fact tree is summarized in Algorithm 1. The input is the NL question and two empty node stacks. The output is the NL fact tree. We initialize the NL fact tree as a syntax tree, which is parsed from **Q** (Line 2). One of the empty node stack $\mathbb{V}$ stores the nodes of FT in the order of breadth first searching (Line 3). The other stack $\mathbb{V}'$ reverse this order in Line 4-10, so that the pruning (Line 12-22) is from the the bottom to the top as well as from the right to the left. The entire

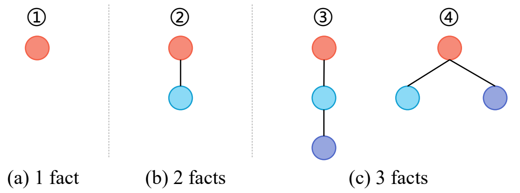

Figure 8: The fact combination modes.

elimination process does not involve the leaf nodes and their parents nodes (Line 6-10).

A.2 Score Amplification Mechanism

We devise a simple method to evaluate whether an entity is able to satisfy the upper-layer fact. For an entity e, the related predicate or attribute in the upper-layer fact is p or a. We retrieve in KG, whether there is an fact of entity e associated with p or a. If there is, then we consider that entity e is satisfying the upper-layer fact, and vice versa.

B Experimental Details

B.1 Dataset Construction

In this work, we develop an n-ary KGQA dataset: WikiPeopleQA, in which questions involve multiple n-ary facts and the background KG is also composed of n-ary facts. The specific construction process is as follows:

i) We selected WikiPeople (Guan et al., 2019) as the background KG. This n-ary KG is constructed based on Wikidata[5] and consists of character facts, e.g., *Marie Curie received Nobel Prize in Chemistry in 1911.*

ii) To build complex questions involving multiple facts, we set the maximum number of facts in a question to three, and set four fact combinations modes in advance, as shown in Figure 8. As the number of facts increases, the fact combination mode becomes more complicated.

iii) Based on the fact combination modes, we sampled a large number of fact combinations from KG. We masked off the entities in the fact combinations, and extracted the frequently occurring fact combinations. We transformed the frequent fact combinations to question templates. Here we have constructed a total of 33 question templates, listed in Table 5.

iv) We populated the entities into the question templates according to KG. Inspired by the construction process of PathQuestion (Zhou et al., 2018), in order to enrich the problematic syntactic structure and surface wording, we replaced the phrases and words in the question with synonyms.

Due to the limitation of fact diversity in WikiPeople, we only considered three facts at most. In order to contribute to the progress of n-ary KGQA research, it is necessary to increase the richness of the facts to improve the question complexity. Therefore, developing more complex n-ary KGQA datasets and evaluating FacTree on more datasets are our future research directions.

B.2 Baselines

We compare our framework with a series of baselines. The following is a detail description of the baselines:

- MemNN (Sukhbaatar et al., 2015): This model adopts an memory network to store all KG facts or related Wikipedia documents in the memory units. Three embedding matrices are employed to convert the memory information and questions into vectors for similarity calculation.
- KV-MemNN (Miller et al., 2016): This model is based on MemNN. Instead of considering the whole KG facts like MemNN, it firstly stores facts in a key-value structured memory. The key-value structure is suitable for binary facts, but not for n-ary facts.
- EmbedKGQA (Saxena et al., 2020): This model follows the basic multi-hop reasoning framework and utilizes KG embedding methods to alleviate the negative impact of KG incompleteness.
- IRN-weak (Zhou et al., 2018): This model considers the whole path from the topic entity to the answer entity. It focuses on finding a path to the answer, so IRN needs a pre-labelled path record during training process.
- MINERVA (Das et al., 2018): This model uses reinforcement learning technique to perform multi-hop reasoning on KG. Taking the input natural language question, this model averages the word embeddings as the question embedding, and then walks on KG under the supervision of the question embedding, and finally arrives at the answer entity.

---

[5] `https://www.wikidata.org`

- SRN (Qiu et al., 2020): This model uses RL method to perform multi-hop reasoning on KG. It proposes a potential-based reward shaping strategy to alleviate the delayed and sparse reward problem caused by weak supervision.
- QGG (Lan and Jiang, 2020): This model generates a modified staged query graph to deal with complex questions with both multi-hop relations and constraints.

Here we explain the source of the results in Table 2. On the WikiPeopleQA dataset, for each baseline, we run the source code of each baseline that is open source or reproduced by developers.

- MemNN: `https://github.com/berlino/MemNN` (reproduced)
- KV-MemNN: `https://github.com/lc222/key-value-MemNN` (reproduced)
- EmbedKGQA: `https://github.com/malllabiisc/EmbedKGQA` (open source)
- MINERVA: `https://github.com/shehzaadzd/MINERVA` (open source)
- SRN: `https://github.com/DanSeb1295/multi-relation-QA-over-KG` (reproduced)
- QGG: `https://github.com/lanyunshi/Multi-hopComplexKBQA` (open source)

IRN-weak needs the pre-labelled path records for training, which is not applicable to the n-ary KGQA task. So we do not evaluate IRN-weak.

For two binary KGQA datasets WC2014 and PathQuestion, the results of EmbedKGQA and QGG are obtained by our own tests. Other baseline results all cited from (Qiu et al., 2020).

B.3 Training Details

Note that in the NL fact tree, there is overlap between facts. When we construct the (syntax tree, NL fact tree) training samples, the overlap will be maintained in the lower-layer fact if it belongs to the primary triple, and in the upper-layer fact if the overlap belongs to the auxiliary description. For example, in Figure 2, the overlapping part of fact 1 and fact 2 "an NBA team" belongs to the primary triple, so it is maintained in fact 2. Conversely, "in the year" is the auxiliary description and is maintained in fact 3.

C Example of NL Fact Tree Construction

Here we display a visual example of the NL fact tree construction with the question *Who joined an NBA team in Los Angeles in the year the Warriors won the NBA championship*.

Firstly, we use the Stanford Parser to generate the syntax tree (cf. Figure 9). Then we preprocess the syntax tree (cf. Figure 10) to reduce the subsequent elimination operations according to the following rules:

- Pruning the punctuation node and its parent node, e.g., node "?" and ".".
- If all the grandchildren of a NP node are leaf nodes (more than one), we prune the parents, and combine the grandchildren to a unified leaf node, whose parent is changed to the NP node. For example, `the`, `NBA` and `championship` in Figure 9 are combined as `the NBA championship`, whose parent is "NP".
- If a node has only one child and only one grandchild, which is a leaf node, we remove the child node and let the leaf node be the only child of this node. For example, `who` in Figure 9 will be connected directly to its grandfather node `WHNP`.

Next we start eliminating nodes from the the bottom to the top as well as from the right to the left. Note that we start the elimination operation from the third-to-last layer of the tree. For each selected node, we extract a subtree that contains this node (colored in red) and its neighbor nodes (colored in blue). This subtree is fed into a classifier. The output of the classifier determines whether to eliminate this node. Figure 12 shows the specific elimination process. The previously selected node will no longer be selected, e.g., the node "SBAR" in Figure 12 (f).

After the elimination process, we delete non-leaf nodes and retain the hierarchical structure of leaf nodes. For the continuous nodes in the lower-layer, set a common placeholder node in the upper-layer. For example, the continuous nodes `a team`, `in` and `Los Angeles` in Figure 12 (j) will be connected to a common placeholder node (i.e., the blue node in Figure 11). The interrogative pronouns, e.g., `who` are also replaced directly with placeholders. Now, the NL fact tree is constructed (see Figure 11). It satisfies 1) the leaf nodes are words or phrases of the question; and 2) if the leaf nodes share the same parent, they belong to the same fact.

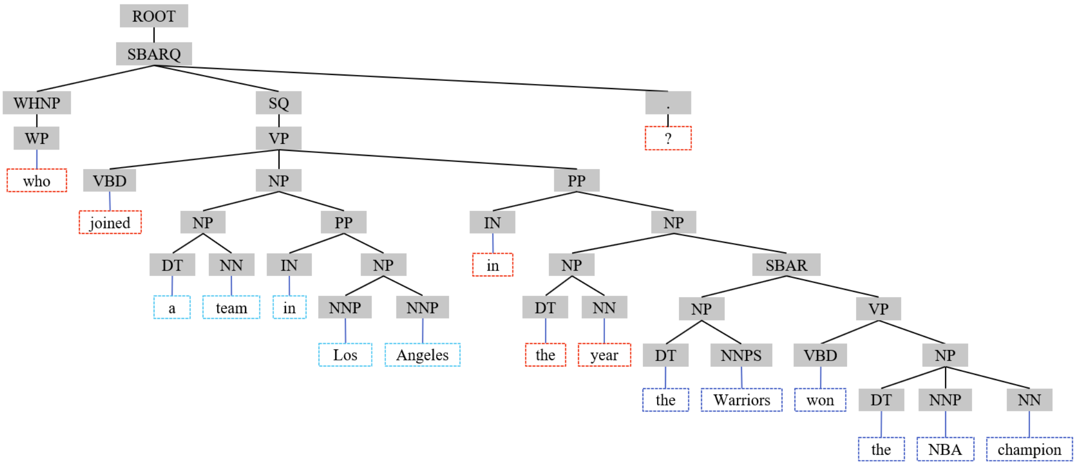

Figure 9: Syntax tree.

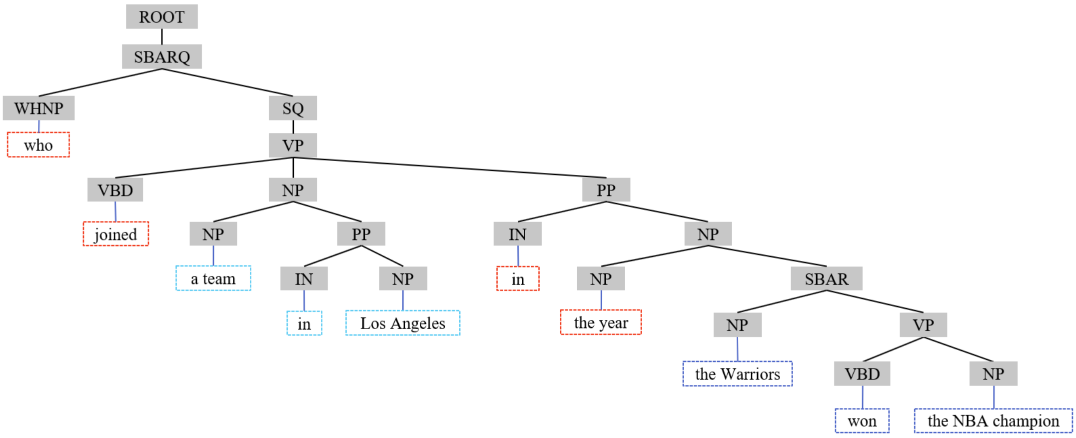

Figure 10: Syntax tree after preprocessing.

Abstract

We introduce a method for improving the structural understanding abilities of language models. Unlike previous approaches that finetune the models with task-specific augmentation, we pretrain language models on a collection of task-agnostic corpora to generate structures from text. Our structure pretraining enables zero-shot transfer of the learned knowledge that models have about the structure tasks. We study the performance of this approach on 28 datasets, spanning 10 structure prediction tasks including open information extraction, joint entity and relation extraction, named entity recognition, relation classification, semantic role labeling, event extraction, coreference resolution, factual probe, intent detection, and dialogue state tracking. We further enhance the pretraining with the task-specific training sets. We show that a 10B parameter language model transfers non-trivially to most tasks and obtains state-of-the-art performance on 21 of 28 datasets that we evaluate.[1]

1 Introduction

Pretrained language models (LMs) have revolutionized NLP over the last few years (Peters et al., 2018; Devlin et al., 2019; Radford et al., 2019b), increasingly adept in performing the flexible and task-agnostic downstream transfer. Their transfer performance is less studied in structure prediction tasks, however. Well-studied tasks mainly focus on understanding one particular aspect of the text, such as predicting the next word that comes after as in language modeling. Unlike those downstream tasks, structure prediction requires the structural understanding of the text for further integrating multiple relevant aspects into a structure. For instance, a typical structure prediction task, called open information extraction, seeks the entire structural information in a sentence (Figure 2). Different from traditional NLP tasks, structure prediction takes one step further and serves as a natural testbed for the structural understanding competence of LMs.

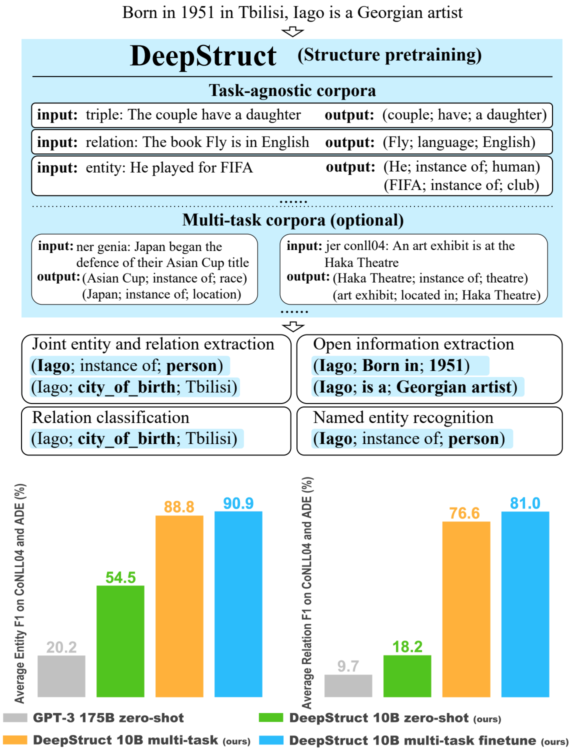

Figure 1: Summary of our approach and results. Upper: an overview of DeepStruct and the proposed structure pretraining. Lower: performance of our 10B DeepStruct zero-shot and multi-task, compared with 175B GPT-3 zero-shot.

It is non-trivial to transfer LMs to downstream structure prediction tasks. While the structure prediction requires structural understanding, the LMs are pretrained to understand an independent aspect. For example, GPT-3 (Brown et al., 2020) is trained to predict the next word, and BERT (Devlin et al., 2019) is trained to recover the masked tokens. Recent work has made efforts in bridging the gap in transferring pretrained models to structure prediction tasks with a focus on two directions. As shown in Figure 3, first, task-specific architectures are proposed to model the structures for different

---

structure prediction tasks (Stanovsky et al., 2018; Soares et al., 2019). Second, task-specific data augmentation (Paolini et al., 2021; Wang et al., 2021; Wei et al., 2021) is introduced, aiming to enrich text format with structure information. These approaches involve custom-designed task augmentations, impeding their usability in general structure prediction tasks.

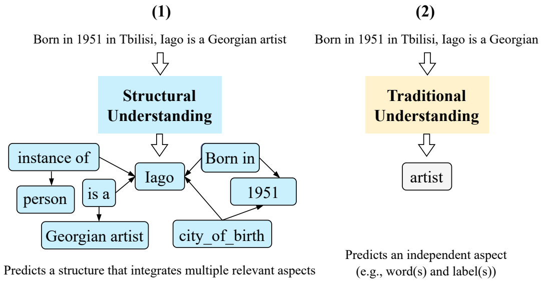

Figure 2: Comparison between structural understanding and traditional understanding of text.

In this paper, we improve the structural understanding capabilities of LMs. In contrast to previous approaches relying on task augmentations, we introduce structure pretraining, which systematically teaches LMs to better understand structures of text beyond independent aspects in a pretraining phase (Figure 1). This enables the zero-shot transfer of knowledge that LMs learned about structures during our pretraining to downstream structure prediction tasks. For example, our zero-shot 10B parameter LM significantly outperforms the zero-shot GPT-3 (175B) on a structure prediction benchmark dataset (Figure 1). We accomplish this by reformulating structure prediction as a series of unit tasks–triple prediction tasks. We then train LMs on a collection of task-agnostic structural corpora to generate triples from text. The design of triple representation is important: it unifies a wide set of standard structure prediction tasks into the same task format. We apply our pretrained model DEEPSTRUCT to 27 datasets spanning 10 structure prediction tasks, including open information extraction, joint entity and relation extraction, named entity recognition, relation classification, semantic role labeling, event extraction, coreference resolution, factual probe, intent detection, and dialogue state tracking. We further enhance the pretraining with multiple downstream structure prediction training sets and obtain state-of-the-art performance on 20 of 27 datasets. Our contributions are as follows:

- We improve structural understanding abilities of pretrained LMs. Compared to traditional NLP tasks that only consider the understanding of an independent aspect of the text, structural understanding takes a step further that requires the ability to integrate multiple relevant aspects into a structure. We argue that it is important for LMs to go beyond traditional understanding towards structural understanding, as it requires a higher level of intelligent competence and is more challenging. It can also benefit a wide spectrum of NLP tasks that require structure-level understanding capability.
- We propose structure pretraining, which further pretrains the LMs to understand structures in the text. The basic intuition is that the standard pretraining helps LMs to understand individual aspects of the information in the text, our method learns to integrate those individual aspects into structures. Compared to existing approaches, this method enables the zero-shot transfer of LMs to structure prediction tasks. For instance, our 10B LM produces superior zero-shot performance compared to 175B GPT-3 on a representative structure prediction task.
- We further equip our pretraining with multi-task learning and apply our method to 27 structure prediction datasets across 10 tasks. We achieve state-of-the-art performance on 20 of 27 datasets that we evaluate. We hope this can help facilitate the structural understanding research in the NLP community.

2 Structure Pretraining

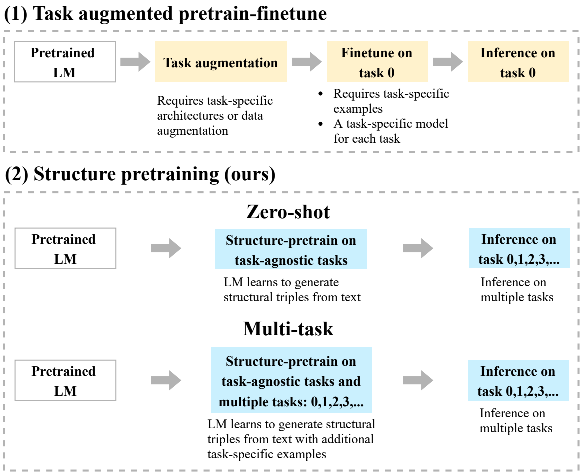

Figure 3: Comparing structure pretraining with standard pretrain-finetune paradigm.

The goal of our method is to improve the structural understanding capabilities of language models (LMs), i.e., understanding the structures of text. As shown in Figure 3, instead of using the standard pretrain-finetune paradigm for each task, we introduce structure pretraining that aims to teach LMs to correspond to structures in a wide spectrum of tasks at the same time. We evaluate their structural understanding ability on multiple structure prediction tasks.

2.1 Generative Pretraining

While the LM is pretrained to understand a single aspect of the text, structural understanding aims to recover the entire structure in the text (Figure 2). Structure pretraining is designed to bridge the gap via guiding LMs to produce structures from the text. It is ideal to generate arbitrary structures as needed. However, this is infeasible due to the highly complex nature of such structures.

As an alternative, we reformulate the structure prediction as a combination of triple generation tasks. We refer to a triple as *(head entity; relation; tail entity)* describing relations between entities. We design three pretraining tasks with a focus on predicting the entities, relations, and triples respectively. As shown in Figure 1, (i) Entity prediction aims to output triples regarding the entities and their types in an input sentence. We implement this via prepending "`entity:`" as a prefix in the input. (ii) Relation prediction aims to recover the relations and corresponding types in the input as a triple. Similarly, we add "`relation`" followed by a task separator "`:`" to each input. (iii) Triple prediction outputs the entire triple structure from the input. We attach "`triple:`" to indicate this task. These pretraining tasks are task-agnostic to downstream tasks, enabling the zero-shot downstream transfer (Sec. 2.3).

Although the triple formulation is straightforward, we find that it is very flexible and able to model all structure prediction tasks we consider. A structure prediction task can be generally decomposed into generating the entities, relations, or triples. For example, named entity recognition predicts the entities and their types. It can be naturally represented as an entity prediction problem. Besides, traditional structure prediction tasks focusing on relations (e.g., relation classification) or triples (e.g., open information extraction) can be formulated as relation or triple prediction task respectively. A summary of all downstream tasks is described in Sec. 2.2.

Dataset	**#Sent.**	**#Ent.**	**#Rel.** (#Tri.)	**Task**
T-REx (ElSahar et al., 2018)	6.2M	8.8M	11M	entity, relation
TEKGEN (Agarwal et al., 2021)	18M	23.5M	45M	entity, relation
KELM (Agarwal et al., 2021)	15.7M	54.5M	35.7M	entity, relation
WebNLG (Gardent et al., 2017)	88K	348K	261K	relation
ConceptNet (Speer and Havasi, 2012)	610K	3.1M	610k	relation
OPIEC (Gashteovski et al., 2019)	10.7M	43.0M	21.5M	triple

Table 1: Pretraining dataset statistics.

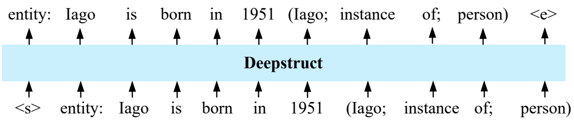

Figure 4: Summary of training procedure.

We frame the pretraining as a conditional generation task where the input corresponds to text x, and the output y is a sequence of triples. Our pretraining can be expressed as estimating a conditional distribution $p(y|x)$ in a probabilistic framework. We use an autoregressive LM to model $p(y|x)$.

Pretraining Data We train the model on a collection of task-agnostic corpora including prebuilt large-scale alignments between text and triples. In particular, we use T-REx (ElSahar et al., 2018), TEKGEN and KELM (Agarwal et al., 2021), WebNLG (Gardent et al., 2017), ConceptNet (Speer and Havasi, 2012). These corpora align text to triples consisting of high-quality entities and relations in knowledge graphs (e.g., Wikidata), which are used for entity and relation prediction tasks. In addition, for triple prediction tasks, we use OPIEC (Gashteovski et al., 2019) that provides open schema triples. The pretraining data statistics and the corresponding pretraining tasks are shown in Table 1.

Figure 4 shows an example of the training procedure for the entity prediction task based on the input/output sample below.

Input `entity`: Iago is born in 1951
Output (**Iago**; instance of; **person**)

where the input text and output triple are aligned, provided by our pretraining data. Tokens are predicted autoregressively starting with `<s>` token and ending with `<e>` token. The head entity (i.e., Iago) and the tail entity (i.e., person) of the output triple then serve as the predictions of named entity recognition.

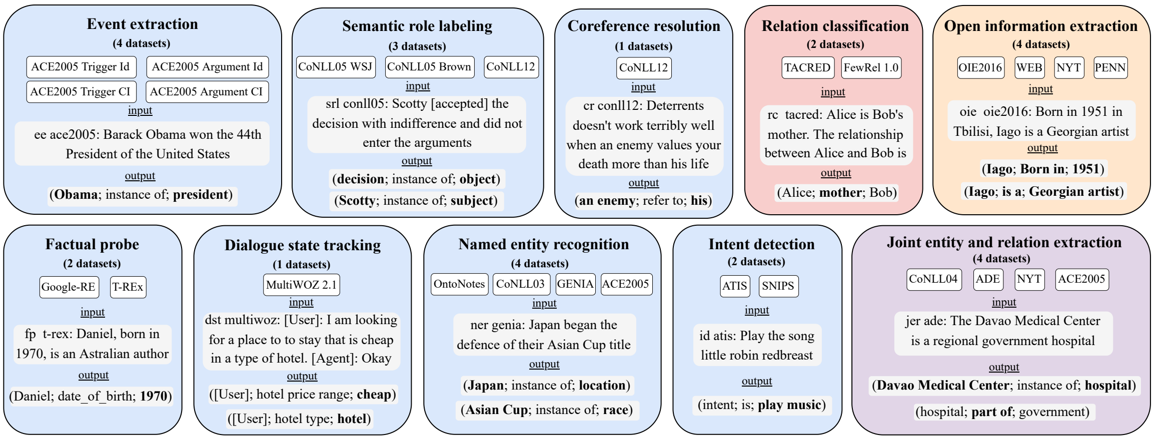

Figure 5: Summary of tasks and datasets. Blue: entity prediction task; Red: relation prediction task; Purple: entity and relation prediction task; Yellow: triple prediction task.

2.2 Tasks

It is resource-intensive to create large-scale structural understanding datasets from scratch. Therefore, we collect existing datasets in the field of structure prediction for the evaluation. We consider 27 datasets spanning across 10 structure prediction tasks as shown in Figure 5. Detailed descriptions and sizes are shown in Appendix A.

2.3 Zero-Shot

The zero-shot DEEPSTRUCT refers to the setting where the pretrained model is used without any task-specific training at inference time. This differs from prior fully supervised methods. This setting is challenging as it might be difficult for humans to understand the tasks without prior examples. For example, if we are asked about "semantic role labeling" that aims to recover the predicate-argument structure, it is hard to understand what this really means. Nevertheless, for at least some settings, zero-shot is closest to how humans perform tasks. For example, for named entity recognition, a human would likely know what to do.

We enable the zero-shot transfer to structure prediction tasks via converting the downstream tasks to one or a combination of the pretraining tasks. As shown in Figure 5, at inference time, seven structure prediction tasks are formulated as entity prediction with the prefix "`entity:`" attached to the input example (in blue), while one task is cast as relation prediction with the prefix "`relation:`" (in red). In addition, open information extraction is a triple prediction task with the prefix "`triple:`" (in yellow), and joint entity and relation extraction (JER) is a combination of entity and relation prediction (in purple). For the entity and relation prediction, we use the prefix "`entity:`" and "`relation:`" respectivley. Besides, for each dataset, we build a schema alignment between pretraining and downstream dataset (details are described in Sec. 5). The output triples are then decoded as corresponding structure predictions based on the pre-built schema alignment.

2.4 Multi-Task

However, the distribution of the pretraining data is not perfectly aligned with the distribution of downstream datasets. This results in a shift in the output distribution of the model. The zero-shot setting cannot perform at its best on several out-of-distribution tasks including dialogue state tracking. The reason is that its desired output is a dialogue state, which is lacking in our task-agnostic pretraining corpora. To mitigate this, we integrate multiple structure prediction datasets into the pretraining corpora, and train our method on the mixture of the datasets. We list an example input and output format for each task in Figure 5. For all datasets of a particular task, we adopt the same input and output format. We also add task name and dataset name followed by the separator "`:`" as a prefix to each input example. For example, we add "`jer ade:`" to indicate one of the JER datasets, ADE. More examples of each task and dataset are shown in Table 16. In contrast to fully pretrain-finetuned models that store a copy of parameters for each task, this setting is a lightweight alternative and produces a single model for all tasks, improving parameter sharing.

After multi-task training, for each task, we further finetune our method on the task-specific dataset. The intuition is that finetuning is the de facto way to leverage pretrained LMs to perform downstream tasks. We aim to test an upper bound of the transfer performance of our structure pretraining via the additional finetuning phase. For both multi-task settings, we use the same data format with the training at test time. Basically, we add the task name and dataset name followed by the separator to the input example.

3 Experiments

In this section, we show that DEEPSTRUCT successfully transfers to the structure prediction tasks considered and obtain state-of-the-art results on 21 of 28 datasets we evaluate. All results are obtained via structure pretraining a pretrained 10B parameter LM, GLM (Du et al., 2021). The details of the experimental setup, datasets, and comparison methods are described in Appendix A.

3.1 Main Results

We have two settings as described in Sec. 2: zero-shot and multi-task. We also finetune the multi-task version on each downstream dataset. In total, we have three versions of DEEPSTRUCT (Cf. Table 2). For comparison: we report the performance of TANL (Paolini et al., 2021) when available. We also show the best performance among the task-specific models that are described in Appendix A.

With the zero-shot setting, a single model is used to perform on multiple tasks without the need of any task-specific training. This is in contrast to previous approaches that rely on task-specific models and datasets for each task. In Table 3, we also report the zero-shot performance of GPT-3 175B (Brown et al., 2020) on CoNLL04 and ADE (JER) via formulating the task as a question answering problem via prompting (details of the formulation are described in Sec. 5). JER requires the model to extract a set of entities and a set of relations between pairs of entities from the input text. Each predicted entity or relation has to be also assigned to an entity or a relation type. Zero-shot DEEPSTRUCT 10B outperforms zero-shot GPT-3 175B by a large margin without any prompt engineering. As shown in Table 2, overall, DEEPSTRUCT's zero-shot performance is still far from that of task-specific supervised models on most tasks. The only exception is that the zero-shot setting obtains the new state-of-the-art performance on the factual probe with averaging 20% P@1 improvement. This is because the task-specific method is also zero-shot. Note that we have removed the overlapped sentences with the T-REx test sets (factual probe) from our pretraining data. The result indicates that the structure pretraining is able to adapt the LM knowledge to the tasks by making LM aware of symbolic knowledge in the pretraining corpora. Besides, the zero-shot approach generalizes well to all task-agnostic pretraining tasks including entity prediction (e.g., named entity recognition), relation prediction (e.g., relation classification), and triple prediction (e.g., open information extraction).

Similar to the zero-shot setup, we only train a single model to conduct all the downstream tasks under the multi-task setting. This is different from the supervised models that use task-specific models and parameters. We achieve state-of-the-art performance on three datasets. For the other datasets, we obtain a competitive performance within a few points of the best-compared methods. Notably, most structure prediction tasks show a large gain from zero-shot to multi-task. This suggests that most tasks are out-of-distribution of our structure pretrained model. Nevertheless, our method appears to be able to adapt to the downstream distributions, recovering strong performance in the multi-task setting. Another explanation is that multi-task examples help the model better understand the downstream tasks, such as the output format of each task. We also observe strong multi-task performance on FewRel, which is a low-resource structure prediction benchmark. This suggests that the multi-task setting is beneficial in low-resource regimes via transferring knowledge from similar tasks. For our multi-task training, we leave out the ACE2005 named entity recognition dataset due to the overlap between train and test splits for different tasks. After finetuning, we obtain state-of-the-art performance on 21 datasets. For instance, we obtain a +8.0 absolute improvement and a +2.9 absolute improvement on CoNLL05 Brown (semantic role labeling) and TACRED (relation classification) compared to the state-of-the-art methods.

All above results are based on a pretrained 10B parameter LM, GLM. GLM is an autoregressive LM. In addition, the context x is encoded by a bidirectional encoder. In principle, generative LMs, such as T5 (Raffel et al., 2019), BART (Lewis et al., 2020) and GPT-3 (Brown et al., 2020), can also be used with the proposed structure pretraining for the structure prediction tasks as well. We leave this as one of the future investigations.

3.2 Ablation Studies

Pretraining Strategies As the key question of our work is to investigate how structure pretraining improves the structural understanding ability of LMs, we examine how different pretraining strategies impact the downstream performance. We evaluate the below settings on the CoNLL04 (JER). The first two settings examine the relative importance of the pretraining data: (i) With example-proportional mixing: We follow (Raffel et al., 2019) with a mixing rate maximum of 10K to balance the different sizes of datasets. All other components are kept the same with DeepStruct multi-task with finetuning. (ii) With entity and relation augmentation: We add special tokens "[ ]" to indicate the positions of the entities and relations in a sentence. Additional details are shown in Appendix A.5. (iii) No pretrain, finetune: We remove structure pretraining, and only finetune the LM on CoNLL04. (iv) Zero-shot: We only use the task-agnostic datasets and exclude the multi-task datasets in the pretraining. (v) Multi-task: We use the multi-task model without finetuning. (iv) and (v) are the same with the zero-shot and multi-task settings in Sec. 2. (vi) Finetune: The multiple downstream datasets are excluded in the structure pretraining, but the model is finetuned on CoNLL04.

Method	Ent.	Rel.
DEEPSTRUCT 220M multi-task finetune	90.7	75.7
With example-proportional mixing	88.0	73.1
With entity and relation augmentation	88.6	74.9
No pretrain 220M, finetune	84.7	63.5
DEEPSTRUCT 220M zero-shot	51.5	22.9
DEEPSTRUCT 220M multi-task	76.9	55.2
DEEPSTRUCT 220M finetune	87.4	70.4

Table 4: Ablation over different facets of structure pretraining on CoNLL04 test set (joint entity and relation extraction). Ent. and Rel. indicate entity F1 and relation F1 respectively.

Table 4 shows the results. First, the distribution of pretraining data does not significantly shift from that of most tasks. This limits the impact of the balanced strategy ((i)). The data augmentation ((ii)) does not bring additional benefits to the downstream performance. This confirms that the key to the success of structure prediction is our formulation that narrows down a complex structure to a set of triple prediction tasks. This allows the pretraining to capture the entities and relations that are important for tasks. Second, removing the structure pretraining ((iii)) provides the most direct ablation of how much structure pretraining helps. Structure pretraining significantly improves the LM in structure prediction. This is due to the gap between LM pretraining and downstream structural understanding. For example, the distribution of structure prediction datasets is different from or is considered as out-of-distribution for the pretraining data. Structure pretraining improves the adaptation to those datasets. Next, similar to the findings in Table 2, we find that both task-agnostic training sets ((iv)) and multi-tasks datasets ((v)) contribute to the strength of structure pretraining. In particular, finetuning is still very important to improve the downstream performance (IV et al., 2021). However, it produces a task-specific model for each dataset instead of a unified model for all tasks as in our zero-shot or multi-task setup. Compared to only finetuning the model on a downstream dataset ((vi)), the multi-task setting obtains sizable improvements. This is because if the downstream dataset sizes are small such as of CoNLL04, multi-task learning can be extremely helpful in the low-resource regimes (Paolini et al., 2021). We conduct the above ablation studies using a base version of DEEPSTRUCT with 220M parameters.

Scaling Laws As it is often the case that larger models substantially improve the transferring capabilities of LMs (Brown et al., 2020; Wei et al., 2021), we explore how model scaling benefits the structure pretraining. We evaluate the effect on models with 110M, 220M, 2B, 10B parameters on JER datasets with multi-task and multi-task finetuned DEEPSTRUCT (Cf. Figure 6).

As expected, average performance across the datasets improves as models grow larger. We find that when the models reach the order of 10B parameters, structure pretraining obtains the best performance. The 10B parameter model significantly improves the results compared to the 110M parameter model. One reason is that for small-scale models, learning across 28 structure prediction datasets during the structure pretraining may exceed the model capacity. For larger models, structure pretraining fully utilizes the model capacity and also teaches the models to generate triples according to the downstream tasks, allowing them to generalize well to most tasks with the rest capacity. It is also interesting that the performance does not seem to significantly saturate, indicating that the performance may further improve with larger-scale models. Under both setups, we observe similar trends. We also see that the model size matters more to the multi-task setting than to the finetuned version, suggesting finetuning is able to specifically adapt to a task given a limited model size. The main pitfall is its generalization to more tasks.

4 Related Work

Pretrained LMs (Devlin et al., 2019; Radford et al., 2019b; Yang et al., 2019) are the key ingredients in contemporary NLP. Sequence-to-sequence (seq2seq) LMs target conditional generation, such as T5 (Raffel et al., 2019), BART (Lewis et al., 2020) and GLM (Du et al., 2021). These models have benefited a wide range of nature language generation tasks such as summarization (Zhang et al., 2020) and text infilling (Zhu et al., 2019; Shen et al., 2020). Recent attempts of generative prediction (Paolini et al., 2021; Schick and Schütze, 2021; Lester et al., 2021) have found that seq2seq models are able to provide a unified solution for modeling a wide set of NLP tasks. While existing approaches focus on text-to-text generation, DEEPSTRUCT aims to perform text-to-triple generation.

Multi-task learning (Caruana, 1997) aims to train a model for multiple tasks simultaneously. For deep learning, it is usually categorized into hard weight sharing and soft weight constraint (Ruder, 2017). In the context of NLP, weight sharing has

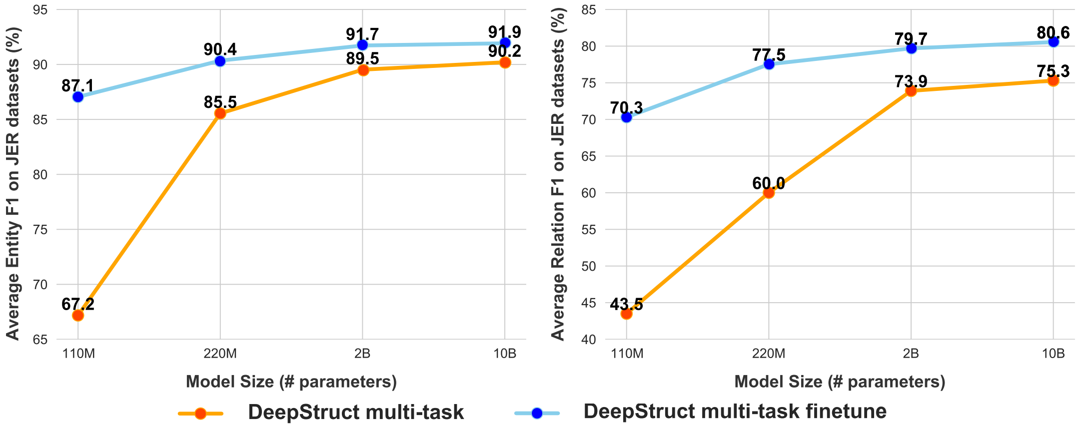

Figure 6: Model scaling results on joint entity and relation extraction (JER) datasets. Left: entity F1; Right: relation F1.

been adopted in (Collobert and Weston, 2008; Yang et al., 2016; Liu et al., 2020). Since the emerging of large pretrained LMs (Radford et al., 2019a; Devlin et al., 2019; Yang et al., 2019), multi-task training has been shown effective to enhance LMs' transferability to downstream tasks (Raffel et al., 2019). Recent studies (Wei et al., 2021) also show that pretrained models finetuned with abundant downstream tasks can conduct effective zero-shot learning. The main difference is that DEEPSTRUCT trains across multiple structure prediction datasets in structure pretraining with task-agnostic corpora, where we cast all datasets into triple formats.

Structure prediction is a long-standing challenge that relates to many NLP applications such as open information extraction (Gashteovski et al., 2019), named entity recognition (Sang and Meulder, 2003; Weischedel et al., 2013), and relation classification (Zhang et al., 2017; Han et al., 2018; Gao et al., 2019). To handle different structure prediction problems, prior work present a variety of task-specific models in the form of sequence tagging (Stanovsky et al., 2018; Li et al., 2019), machine reading comprehension (Zhao et al., 2020) and text classification (Soares et al., 2019), which hinders the knowledge transfer across different tasks. TANL (Paolini et al., 2021) proposes a translation-based approach to unify different structure prediction tasks with task-specific data augmentation. By contrast, our DEEPSTRUCT unifies more structure prediction tasks via a single model and an uniform data format.

5 Discussion

Related Models Recent studies have provided unified solutions for structural prediction tasks. We focus on the comparison between our DEEPSTRUCT to the state-of-the-art TANL (Paolini et al., 2021) and DeepEx (Wang et al., 2021). TANL (Paolini et al., 2021) proposes task-specific data augmentation (i.e., augmented natural language) that annotates task information and predictions in the input and output respectively for each structure prediction task. The main difference is that DEEPSTRUCT decomposes the structure prediction tasks into a collection of triple generation tasks. The triple format serves as the unified representation for all considered structure prediction tasks without the need of introducing new data augmentation as in TANL. While TANL mainly works in the multi-task setting, we additionally enable the zero-shot transfer via the task-agnostic structure pretraining. DeepEx (Wang et al., 2021) explores the attention matrices of pretrained LMs via beam search to generate triples for information extraction tasks. Following the search, DeepEx introduces an extra ranking stage to improve the quality of the triples. Differently, DEEPSTRUCT aims to generate the triples for a wide set structure prediction tasks in an end-to-end fashion thanks to the proposed structure pretraining.

Besides, both TANL and DeepEx explore relatively small-scale pretrained LMs. Instead, DEEPSTRUCT scales up to 10 billion parameters. Figure 6 shows that the performance improvements follow the scaling law (Raffel et al., 2019; Lester et al., 2021; Wei et al., 2021; Sanh et al., 2021; Liu et al., 2021). Based on our results, DEEPSTRUCT generalizes better to more structure prediction tasks compared to TANL and DeepEx.

Zero-Shot Setup For our zero-shot setup, we follow the zero-shot usage in recent pretrained LM studies (Brown et al., 2020; Wei et al., 2021; Sanh et al., 2021). It refers to the setting where a pre-

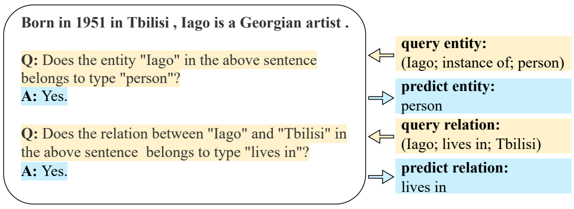

Figure 7: An example of GPT-3 zero-shot setting. To predict entities, we convert the gold entity triple (Iago; instance of; person) to an entity based true-or-false question. Similarly, to predict relations, the gold relation triple (Iago; lives in; Tbilisi) is turned into a relation based true-or-false question. The task predictions are correct if the answers are "yes".

trained model is used to directly perform downstream tasks without including downstream training sets in its own pretraining data. For DEEPSTRUCT our pretraining data is task-agnostic. For each task, we build an offline alignment between the schema of the pretraining data and the task dataset based on co-occurrence information in the pretraining data and downstream data (Angeli et al., 2015). We then manually curate the alignment. The resulting schema alignment is part of our release [1]. At test time, we convert each task to one or a combination of the pretraining tasks based on Figure 5: entity, relation, and triple prediction. After producing the triples, we use the pre-built schema alignment to obtain the task predictions.

For GPT-3 zero-shot setting, we follow the prompting method in the GPT-3 paper (Brown et al., 2020). In more detail, we aim to test the upper bound performance of GPT-3 for structure prediction, in particular the JER task. Therefore, instead of using standard prompts in the form of question answering, we design the prompts for "true-or-false" questions based on the ground truth. In this case, GPT-3 only answers with "yes" or "no" to produce a task prediction (Cf. Figure 7).

6 Conclusion

We improve structural understanding capabilities of language models. We evaluate it on a wide set of structure prediction tasks including 10 tasks and 28 datasets, and successfully transfer pretrained language models to them through the proposed structure pretraining, which teaches language models to output triples from text. We enable both zero-shot and multi-task transfer learning. DEEPSTRUCT obtains state-of-the-art results on 21 of 28 datasets. The result shows that pretrained language models can master higher-level understanding (e.g., structural understanding), which may benefit more NLP tasks. We hope it will foster future research along the language structural understanding direction.

7 Ethical Considerations

We hereby acknowledge that all of the co-authors of this work are aware of the provided *ACM Code of Ethics* and honor the code of conduct. This work is mainly about the pretraining and multi-task learning of LMs for structural prediction. The followings give the aspects of both our ethical considerations and our potential impacts to the community. This work uses LMs, for which the risks and potential harms are discussed in (Brown et al., 2020). There are potential undesirable biases existed in task-agnostic data (e.g., from Wikipedia) and multi-task downstream datasets (mostly created from news articles). We do not anticipate production of harmful outputs, especially towards vulnerable populations, after using our model or training NLP models on our datasets.

8 Environmental Considerations

We use the same pretrained LMs as in (Du et al., 2021). The energy cost and carbon footprint for the pretrained models were 80.6 MWh and 4.6 tCO2e, respectively. The additional structure pretraining gradient-steps is less than 1.5% of the number of pretraining steps of LMs, and so the estimated additional energy cost is comparatively smaller. In addition, training and tuning pretrained LMs on a wide range of tasks and datasets consume plenitude of energy and increase emissions of carbon dioxide. To alleviate the problem, in this work we make efforts to study the multi-task training, which only involves training on a combination of all datasets once. Our results (e.g., Figure 6) show that, despite the gap between multi-task and multi-task finetune on smaller models, the performance gap becomes minor when the model size scales up to 10 billion parameters. This indicates that we can reduce energy consumption when training large pretrained models via employing the multi-task training.

A Experimental Setup

A.1 Implementation Details

Model Architecture We leverage the Generalized Language Model (GLM) as our base language model, which is pre-trained on autoregressive blank infilling objectives. It improves the pre-train – fine-tune consistency via cloze-style fine-tuning, and naturally handles variable-length blank infilling which is crucial for many downstream tasks. To some extend, GLM can be viewed as an adaptive encoder-decoder architecture.

GLM has the same vocabulary as GPT2 series models', covering 50257 tokens. In this work, we leverage its models in four different scales: 110M, 220M, 2B, and 10B, in which 110M is pre-trained over English Wikipedia and Book-corpus and the others are pre-trained over the Pile corpora (Gao et al., 2021) (approximately the same corpora for training GPT-3). GLM has been reported to outperform T5 over text summarization challenges[2], which is a task that accords with structural prediction. Compared to GPT-3, GLM is a bidirectional model but can conduct autoregressive generation.

Structure Pretraining Procedure

- Pretraining for zero-shot: we conduct the pretraining on 8 NVIDIA DGX-A100 machines using an Adam optimizer with 5e-6 learning rate and 0.1 learning rate decay. We train the model with batch size 4 per GPU for 3 epochs. We select the last iteration checkpoint.

- Downstream multi-task training: we conduct the multi-task training on 8 NVIDIA DGX-A100 machines using an Adam optimizer with 5e-6 learning rate and 0.1 learning rate decay. We train the model with batch size 4 per GPU for 6 epochs and select the best checkpoint for each task based on their development set performance.

- Inference: In the inference, length penalty and minimum target length are the most important hyper-parameters. Length penalty is a float between 0 and 1 to control the GLM's generation length (the larger the longer). For entity-based tasks (e.g., NER, SRL, Event Extraction), a larger length penalty is preferred (e.g., 0.8-1.0); for triple-based tasks (e.g., JER, OIE, DST), a smaller one is preferred (e.g., 0.3-0.5); for other tasks that require a specific number of predicted triples (e.g., Relation Classification, Intent Detection, Factual Probe), we will trim the generation result in the postprocessing.

Pretraining data We apply the task-agnostic pretraining data presented in Table 1 as described in Section 2.1. An exception was for T-REx (ElSahar et al., 2018), where there is an overlap between itself and the Factual Probe task dataset T-Rex used in (Petroni et al., 2020). To avoid the leak, we only sample a portion of the T-REx as our pretraining data to exclude samples appeared in Factual Probe.

Table 5: Statistics of downstream datasets.

In the following sections, we introduce the dataset formats, comparison methods and training details for all 10 structural prediction tasks.

A.2 Open Information Extraction

For OIE, we are given a sentence and asked to extract triples.

> **Input** Born in 1951 in Tbilisi, Iago is a Georgian artist.
>
> **Output** (Iago; Born in; 1951) (Iago; is a; Georgian artist)

Datasets We evaluate the performance of the open information extraction (OIE) systems on OIE benchmark datasets consisting of **OIE2016** (Stanovsky and Dagan, 2016), a dataset from Newswire and Wikipedia automatically converted from QA-SRL (He et al., 2015); three news datasets **NYT** (de Sá Mesquita et al., 2013), **WEB** (de Sá Mesquita et al., 2013), **PENN** (Xu et al., 2013). The statistics of the benchmark are shown in Table 5. The preprocessed datasets are obtained from Supervised OIE (Stanovsky et al., 2018).

Comparison Methods We compare our method DEEPSTRUCT to the following prominent OIE systems recently evaluated in (Stanovsky et al., 2018): ClausIE (Corro and Gemulla, 2013), Open IE4 [3], PropS (Stanovsky et al., 2016), RnnOIE (Stanovsky et al., 2018). We also compare to MAMA with BERT$_{\text{LARGE}}$ recently introduced in (Wang et al., 2020) that also leverages pre-trained LMs to extract open triples. See results in Table 6.

Training Details During multi-task fine-tuning, we train our model on OIE2016 training set for 10 epochs, with a per GPU batch size 4. During inference, for oie2016, we choose a length penalty of 0.8. For WEB, NYT, and PENN, they only contain the test sets, and during the inference, we use a length penalty of 0.5 and trim the prediction to reserve only one triple.

A.3 Relation Classification

For this task, we are given an input sentence with gold head and tail entities aiming to classify the relation type in a pre-defined category.

> **Input** The 1976 Thomas Cup was the tenth edition of Thomas Cup, the world championship of men's international team badminton (its female counterpart is the Uber Cup). The relationship between Uber Cup and badminton is
>
> **Output** (Uber Cup; sport; badminton)

Datasets We evaluate on FewRel (Han et al., 2018) and TACRED (Zhang et al., 2017).

- **FewRel** contains 100 relations with 7 instances for each relation. The standard evaluation for this benchmark uses few-shot N-way K-shot settings. The entire dataset is split into the train (64 relations), validation (16 relations), and test set (20 relations). We report the same results on the dev set for all the settings because of our zero-shot setting.

- **TACRED** is a large-scale relation classification benchmark that consists of 106,344 examples and 41 relation types including 68,164 for training, 22,671 for validation, and 15,509 for testing. We do not use train and validation sets and report the result on the test set.

We use F1 to evaluate the results. We parse every relation type and the corresponding head and tail entities from every original sample, and formulate every sample into the aforementioned input and output.

Comparison Methods We compare our method with the following supervised methods. (i) BERT-PAIR (Gao et al., 2019) is a sequence classification

---

[3] `https://github.com/dair-iitd/OpenIE-standalone`

model based on BERT, optimizing the score of two instances expressing the same relation. (ii) BERT_{EM} + Matching the Blanks (MTB) (Soares et al., 2019), which uses entity markers (BERT_{EM}) and additional pre-training of relations on a large-scale corpus (i.e., MTB). (iii) TANL (Paolini et al., 2021) is a sequence to sequence model based on T5 (Raffel et al., 2019) aiming to generate structured objects from an encoded natural language format. See results in Table 7.

Training Details During multi-task fine-tuning, we train our model on TACRED/FewREL-meta training set for 20 epochs, with a per GPU batch size of 4. During inference, for TACRED, we provide the decoder with the prefix "(head; " and ask the model to generate the relation and tail. FewRel dev set results are acquired similarly. We choose a length penalty of 0.5.

A.4 Factual Probe

Given an input sentence with gold head entity name and relation name, the task aims to fill in the tail entity.

> **Input** Daniel Bowen, born in 1970, is a Melbourne resident best known as the author of the blog, Diary of an Average Australian.
> **Output** (Daniel Bowen; date of birth; 1970)

Datasets We consider the Google-RE consisting of 3 relations and 5,527 facts, and T-REx with 41 relations and 34,039 facts of the LAMA benchmark (Cao et al., 2021). We evaluate the results using mean precision at one (P@1), where higher values are better. We parse every relation type and the corresponding head and tail entities from every original sample, and formulate every sample into the aforementioned input and output.

Comparison Methods We compare to pre-trained LM-based methods that leverage the output probabilities of the LM to make predictions given the sentence known to express the fact. Two methods are considered: (i) LAMA (Cao et al., 2021) leverages the input sentence without the tail entity to query the LMs, and (ii) LAMA-Oracle (Petroni et al., 2020) enriches the query with (at most) five gold sentences as additional context. See results in Table 15.

Training Details During multi-task fine-tuning, we train our model on TACRED/FewREL-meta training set for 20 epochs, with a per GPU batch size of 4. During inference, for TACRED, we provide the decoder with the prefix "(head; " and ask the model to generate the relation and tail. FewRel dev set results are acquired similarly. We choose a length penalty of 0.5.

A.5 Joint Entity and Relation Extraction

Given a sentence, this task aims to extract a set of entities (one or more consecutive tokens) and a set of relations between pairs of entities. Each predicted entity and relation has to be assigned to an entity or a relation type.

> **Input** Blackstone already holds a 50 percent stake in the two parks that make up Universal Orlando .
> **Entity Output** (Blackstone; instance of; organization) (parks; instance of; organization) (that; instance of; organization) (Universal Orlando; instance of; organization)
> **Relation Output** (Blackstone; employer; parks)

Datasets In the ablation study, we also present a model variant with entity and relation augmentation (e.g., we asked DEEPSTRUCT to generate "([Iago]; instance of; person) ([Iago]; city_of_birth; [Tbilisi])" for the case in Figure 1).We experiment on the following datasets: CoNLL04 (Roth and Yih, 2004), ADE (Gurulingappa et al., 2012), NYT (Riedel et al., 2010), and ACE2005 (Walker and Consortium, 2005).

- The **CoNLL04** dataset: CoNLL04 consists of annotated named entities and relations on sentences taken from WSJ, AP, etc. We are using the same split as what was proposed (Gupta et al., 2016). We train all models for 200 epochs.

- The **ADE** dataset: ADE contains annotated documents aiming at improving automatic extraction of drug-related adverse effects from medical case reports. We are using the same 10-fold cross-validation split as in (Paolini et al., 2021). We train all models for 200 epochs and report our test macro-F1 score across all 10 splits.

- The **NYT** dataset: NYT is processed from New York Times corpus automatically labeled using distant supervision. We are using the processed version of this dataset (Yu et al., 2020a). We train all models for 50 epochs.

- The **ACE2005** dataset: ACE2005 is processed from the ACE 2005 Multilingual Training Corpus held by Linguistic Data Consortium. We are using the processed version of this dataset by (Luan et al., 2019), preserving 7 entity types and 6 relation types as in TANL. We train all models for 100 epochs.

Comparison Methods We compare our method DEEPSTRUCT on the four datasets to the following JER baselines: SpERT (Eberts and Ulges, 2020), DyGIE (Luan et al., 2019), MRC4ERE (Zhao et al., 2020), RSAN (Yuan et al., 2020) and TANL (Paolini et al., 2021). See results in Table 12.

Training Details During multi-task fine-tuning, we train our model on JER training sets for 5-20 epochs, with a per GPU batch size of 4. Since we discover that relation extraction and named entity recognition need different length penalties, we split the training set corresponding to two tasks separately. During inference, we choose a length penalty of 0.8 for named entity recognition, and 0.3 for relation extraction.

A.6 Named Entity Recognition

This is an entity-only case of the joint entity and relation extraction task.

> **Input** What we need to do is to make sure that state boards, number one, have adequate funding.
> **Output** (we; instance of; human) (state; instance of; geographical entity) (state boards; instance of; organization)

Datasets We experiment on the following datasets: CoNLL03 (Sang and Meulder, 2003), Ontonotes (Pradhan et al., 2013), GENIA (Ohta et al., 2002), and ACE2005 (Walker and Consortium, 2005).

- The **CoNLL03** dataset: CoNLL03 (English) data was taken from the Reuters Corpus. We are using the processed version of this dataset (Li et al., 2020a). We train all models for 200 epochs.

- The **Ontonotes** dataset: Ontonotes is processed from the OntoNotes Release 5.0 Corpus held by Linguistic Data Consortium. We are using the preprocessing scripts provided by (Luan et al., 2019). We train all models for 50 epochs.

- The **GENIA** dataset: GENIA dataset consists of compiled and annotated biomedical literature. We are using the processed version of this dataset (Li et al., 2020a). We train all models for 100 epochs.

- The **ACE2005** dataset: ACE2005 is processed from the ACE 2005 Multilingual Training Corpus held by Linguistic Data Consortium. Notice that it is also processed from ACE2005 corpus but using data split differently from the ACE2005 joint entity and relation extraction dataset. We are using the processed version of this dataset by (Li et al., 2020a). We train all models for 50 epochs.

Comparison Methods We compare our method DEEPSTRUCT on the four datasets to the following NER baselines: BERT-MRC (Li et al., 2019), BERT-MRC+DSC (Li et al., 2020b), Cloze-CNN (Baevski et al., 2019), GSL (Athiwaratkun et al., 2020), BiaffineLSTM (Yu et al., 2020b), and TANL (Paolini et al., 2021). See results in Table 13.

Training Details During multi-task fine-tuning, we train our model on NER training sets for 15 epochs, with a per GPU batch size of 4. During inference, we choose a length penalty of 0.8 for named entity recognition. Since some datasets may require null prediction, we set the minimum target length to 0 to represent the null prediction.

Implementation Details As the conventional NER's evaluation is based on extractive span matching, to make a fair comparison on situations where there are multiple entities with the same surface, we adopt the following strategy: we match the generated entities' spans from left to right in the original sentence at place where they are first mentioned; if there are duplicated entities, the first generated one matches the first mention span, and the second matches the second mention span, etc.

A.7 Semantic Role Labeling

Here we are given an input sentence along with a predicate, and seek to predict a list of arguments and their types. Every argument corresponds to a span of tokens that correlates with the predicate in a specific manner (e.g. subject, location, or time). The predicate is marked in the input, whereas arguments are marked in the output and are assigned an argument type.

> **Input** Scotty [accepted] the decision with indifference and did not enter the arguments .
> **Output** (Scotty; instance of; first argument) (the decision; instance of; second argument)

Datasets We experiment on the following datasets: CoNLL05 WSJ/Brown (Carreras and Màrquez, 2005) and CoNLL12 (Pradhan et al., 2013). Sentences with multiple target predicates for semantic role labeling are duplicated during preprocessing so that each sentence will be related to one and only one target predicate, marked by symbols "[]". We adopted the same evaluation scripts as TANL (Paolini et al., 2021).

- The **CoNLL05 WSJ/Brown** dataset: CoNLL05 WSJ/Brown dataset shares the same train and validation split while differing on the test set. As their names suggest, the test dataset is taken from WSJ corpus and Brown corpus, separately. We train all models for 50 epochs.
- The **CoNLL12** dataset: CoNLL12 dataset is built upon Ontonotes dataset. We train all models for 50 epochs.

Comparison Methods We compare our method DEEPSTRUCT on the four datasets to the following SRL baselines: Dep and Span (Li et al., 2019), BERT SRL (Shi and Lin, 2019), and TANL (Paolini et al., 2021). See results in Table 11.

A.8 Event Extraction

This task requires extracting (1) event triggers, each indicating the occurrence of a real-world event and (2) trigger arguments indicating the attributes associated with each trigger.

> **Trigger input** But the Saint Petersburg summit ended without any formal declaration on Iraq .
> **Trigger output** (summit; instance of; meet)
> **Argument input** But the Saint Petersburg [summit] ended without any formal declaration on Iraq .
> **Argument output** (Saint Petersburg; instance of; place)

Datasets We experiment on the following dataset: ACE2005 (Walker and Consortium, 2005). For the trigger prediction task, the dataset is handled similar to named entity recognition fashion. For the argument prediction task, which is based on trigger predictions, we generated all trigger predictions using our 10B model during preprocessing.

- The **ACE2005** dataset: ACE2005 is processed from the ACE 2005 Multilingual Training Corpus held by Linguistic Data Consortium. The data of event extraction is different from that of named entity recognition or joint entity and relation extraction. We train all models for 50 epochs.

Comparison Methods We compare our method DEEPSTRUCT on the four datasets to the following EE baselines: J3EE (Nguyen and Nguyen, 2019), DyGIE++ (Wadden et al., 2019), and TANL (Paolini et al., 2021). See results in Table 8.

Training Details During multi-task fine-tuning, we train our model on ACE2005 event trigger/argument training sets for 20 epochs, with a per GPU batch size 4. During inference, we choose a length penalty of 0.8. Since the argument dataset requires assigning a trigger and then doing the prediction, we use a pair of square brackets to wrap up the trigger. If there is more than one trigger in a dataset, we will duplicate the sentence with different marked triggers.

A.9 Coreference Resolution

This is the task of grouping individual text spans (mentions) referring to the same real-world entity. For each mention that is not the first occurrence of a group, we reference with the first mention.

> **Input** And deterrents don't work terribly well when an enemy values your death more than his life.
> **Output** (an enemy; refer to; his)

Datasets We experiment on the following dataset: CoNLL12 (Pradhan et al., 2013). During preprocessing, the dataset is chopped into chunks of a fixed size 512. Only intra-chunk coreferences are preserved, following TANL (Paolini et al., 2021). Also, we used the same evaluation scripts as TANL.

- The **CoNLL12** dataset: CoNLL12 dataset is built upon Ontonotes dataset. We train all models for 50 epochs.

Comparison Methods We compare our method DEEPSTRUCT on the four datasets to the following COREF baselines: Higher-order c2f-coref (Lee et al., 2018), BERT+c2f-coref (Joshi et al., 2019), CorefQA+SpanBERT (Wu et al., 2020), and TANL (Paolini et al., 2021). See results in Table 9.

Training Details During multi-task fine-tuning, we train our model on CoNLL12 coreference resolution training sets for 40 epochs, with a per GPU batch size 4. During inference, we choose a length penalty of 0.8.

A.10 Dialogue State Tracking

Here we are given as input history of dialogue turns, typically between a user (trying to accomplish a goal) and an agent (trying to help the user). The desired output is the dialogue state, consisting of a value for each key (or slot name) from a predefined list.

> **Input** [User]: I would like a taxi from Saint Johns College to Pizza Hut Fen Ditton. [Agent]: What time do you want to leave and what time do you want to arrive by? [User]: I want to leave after 17:15.
> **Output** ([User]; taxi arrive by; not given) ([User]; taxi departure; Saint Johns College) ([User]; taxi destination; Pizza Hut Fen Ditton) ([User]; taxi leave at; 17:15)

Datasets We use the MultiWOZ 2.1 (Budzianowski et al., 2018; Ramadan et al., 2018; Eric et al., 2020; Zang et al., 2020) task-oriented dialogue dataset in our experiments. It consists of 8,420 conversations for training, 1,000 for validation, and 999 for testing. We follow the pre-processing procedure put forward (Wu et al., 2019) for dialogue state tracking. In addition, we remove the "police" and "hospital" domains from the training set since they are not present in the test set. Removing these two domains reduces the training set size from 8,420 to 7,904. We fine-tune for 100 epochs, with a maximum sequence length set to 512 tokens. We train a single generative model that predicts the dialogue state for the entire dialogue history up to the current turn. Following prior work, we report the joint accuracy. We parse every slot name and the corresponding value from every original sample, and formulate every sample into the aforementioned input and output.

Comparison Methods We compare our performance on MultiWOZ 2.1 against SimpleTOD (Hosseini-Asl et al., 2020), the current state of the art for MultiWOZ dialogue state tracking. SimpleTOD uses a sequence to sequence approach based on the GPT-2 (Radford et al., 2019b) language model. Unlike our approach, SimpleTOD is trained to jointly generate actions and responses as well as dialogue states. See results in Table 14.

A.11 Intent Detection

Intent detection is the task of interpreting user commands or queries by extracting the intent and the relevant slots.

> **Input** Show flight and prices from Kansas City to Chicago next Wednesday arriving in Chicago by 7 pm.
> **Output** (intent; is; flight and airfare)

Datasets We use two datasets, the ATIS dataset (Hemphill et al., 1990) and the Snips dataset (Coucke et al., 2018). The ATIS dataset consists of 4,478 samples for training, 500 for validation, and 893 for testing. The Snips dataset consists of 13,084 samples for training, 700 for validation, and 700 for testing. We formulate the label of every sample to "(intent; is; [label])". We fine-tune for 20 epochs, with a maximum sequence length set to 512 tokens. Following prior work, we report accuracy. We parse every intent from every original sample, and formulate them into the aforementioned input and output.

Comparsion Methods We majorly compare our methods to SF-ID (E et al., 2019) and TANL (Paolini et al., 2021) in this task. See results in Table 10.

B Dataset Examples

The examples are shown in Table 16.

C Error Analysis

We analyzed recall errors of DEEPSTRUCT 10B MP on CoNLL04 relation extraction task in Table 17. We found that most relation extraction errors in our method are caused by slight deviation in entity prediction: either the predicated entity has almost the same span of the ground truth entity (e.g.: "U.S." and "the U.S.", "America" and "American"), or the predicated entity has a roughly similar meaning to the ground truth entity and plays roughly the same role in the relation (e.g.: "Fairbanks" and "Alaska"). Besides, we also observed some interesting errors in which our prediction has a different focus from the ground truth relation, and our prediction is also meaningful in terms of human understanding.

Abstract

Discourse analysis allows us to attain inferences of a text document that extend beyond the sentence-level. The current performance of discourse models is very low on texts outside of the training distribution's coverage, diminishing the practical utility of existing models. There is need for a measure that can inform us to what extent our model generalizes from the training to the test sample when these samples may be drawn from distinct distributions. While this can be estimated via distribution shift, we argue that this does not directly correlate with change in the observed error of a classifier (i.e. error-gap). Thus, we propose to use a statistic from the theoretical domain adaptation literature which *can* be directly tied to error-gap. We study the bias of this statistic as an estimator of error-gap both theoretically and through a large-scale empirical study of over 2400 experiments on 6 discourse datasets from domains including, but not limited to: news, biomedical texts, TED talks, Reddit posts, and fiction. Our results not only motivate our proposal and help us to understand its limitations, but also provide insight on the properties of discourse models and datasets which improve performance in domain adaptation. For instance, we find that non-news datasets are slightly easier to transfer to than news datasets when the training and test sets are very different. Our code and an associated Python package are available to allow practitioners to make more informed model and dataset choices.[1]

1 Introduction

Coherence analysis of text is a key area of natural language processing. Discourse parsing models are trained on a dataset annotated according to a *discourse framework*, wherein the discourse structure and how the discourse units are connected are identified and labeled. Some discourse frameworks (Miltsakaki et al., 2004; Prasad et al., 2008; Webber et al., 2019) focus on shallow relations between two individual discourse units, while others (Carlson et al., 2001; Lascarides and Asher, 2008) focus on learning a more hierarchical structure. Discourse models have been shown to improve performance in several fundamental NLP tasks, such as summarization (Marcu, 1999, 2000; Cohan et al., 2018), sentiment analysis (Bhatia et al., 2015), machine comprehension (Narasimhan and Barzilay, 2015), and machine translation (Guzmán et al., 2014). However, in some cases, using discourse relations themselves has been found not to improve, or even to hurt, performance in other tasks when learning the coherence structure of text seems critical(Zhong et al., 2020; Feng, 2015). There are several possible reasons for this: due to the difficulty of the annotation task, datasets labeled with these discourse relations are typically small, and the most widely used datasets consist only of news texts. As a result, the performance of discourse models trained on these datasets is very low, and even slight domain shift has been shown to worsen

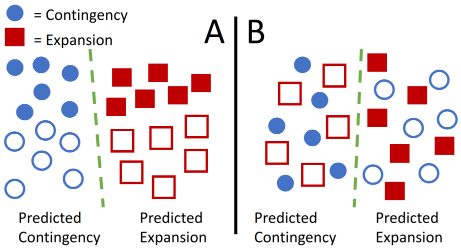

Figure 1: Solid/hollow shapes indicate training/test set, while circles/squares indicate the correct labels. (A) Vertical shift is easily identified, but the classifier (dotted line) does well on both domains. (B) In the feature space, shift is imperceptible, but the classifier assigns the incorrect relation label to each point in the test set. In both, identifiable shift does *not* correlate with the classifier's ability to correctly predict the discourse relation

the performance (Atwell et al., 2021). Thus, for the task of discourse parsing, it is especially important to be cognizant of the effects of domain shift, and choose models and training datasets that are likely to generalize well on the target domain.

To estimate the extent of a model's generalizability on a particular train/test pair, common proposals suggest using two-sample statistics which capture distributional shift in the feature space (Rabanser et al., 2019). However, the working hypothesis of this paper is that *changes in feature-distribution do not necessarily equate to changes in a classifier's error*; i.e., from train to test sample. Figure 1 captures this idea by illustrating some examples in simple 2D-space where domain shift may occur without high error, and vice versa, in the context of discourse parsing.

Motivated by this hypothesis, we look to existing theoretical domain adaptation literature. We propose to use a statistic which has not only been designed to incorporate information about the classifier we would like to transfer, but has also been shown (theoretically) to directly relate to model performance on the test set. Namely, we consider generalization of the source-guided discrepancy (Kuroki et al., 2019) which we call the h-discrepancy defined for any classifier h (we introduce and define this metric in Section 4). We provide novel theoretical analysis of the errors of this statistic in estimating adaptation performance and, based on this, hypothesize this statistic will correlate more substantially with the classifiers' generalization ability than the two-sample statistics previously mentioned. We support this hypothesis by illustrating these correlations across several different widely-used discourse datasets (described in Section 3). We also provide a detailed empirical analysis of the estimation error of this statistic in predicting adaptation performance using a regression model. In doing so, we provide insights on the effect of various properties of different discourse models and datasets on performance in domain adaptation, which we enumerate in Section 6. We expand on these contributions next.

First, we contribute a new theoretical analysis to characterize the bias of the h-discrepancy as an estimator of performance in domain adaptation. Although this discrepancy is typically biased, we provide upper and lower bounds on this bias and interpret them to provide insight on the use of this statistic in practice. In particular, we show that a small h-discrepancy often means the practitioner can be confident in transferring the model from the train- to the test-set. Our theoretical analysis motivates our hypothesis that the h-discrepancy should outperform common two-sample statistics.

Next, we empirically study the aforementioned hypothesis. We compare correlation of the h-discrepancy with performance in domain adaptation against correlation of various two-sample statistics across multiple discourse datasets. As we are aware, this large-scale comparison has never been done for discourse relation classification. As mentioned above, the results of this analysis provide support for our hypothesis that the h-discrepancy is the best estimator of performance changes under domain shift. As such, we argue that computational discourse practitioners should use this statistic to determine the model/dataset likely to maximize performance under domain shift.

We also perform a regression analysis of the estimation errors of the h-discrepancy as an estimator for domain adaptation performance. This analysis allows us to understand the properties and pitfalls of our estimator. Further, it allows us to gain useful insights into how different types of datasets, genres, feature representations, and models influence the generalizability of discourse parsers. We enumerate these insights and discuss their implications for discourse researchers in Section 5.

In the sections below, we further discuss and motivate the need for domain-adaptation bounds tied directly to the error gap for more informed insights into performance gaps under domain shift. We hope that discourse researchers use our results, and our code, as a starting point for model and dataset selection in their own studies.

2 Related Work

2.1 Discourse and Domain Shift

Computational analysis of discourse has been the focus of several shared tasks (Xue et al., 2015, 2016; Zeldes et al., 2019, 2021), and there have been several discourse-annotated corpora for multiple languages (Zeyrek and Webber, 2008; Meyer et al., 2011; Danlos et al., 2012; Zhou and Xue, 2015; Zeyrek et al., 2020; da Cunha et al., 2011; Das and Stede, 2018; Afantenos et al., 2012). Despite their widespread use, implicit sense classification remains a challenging task (Liang et al., 2020), and discourse models have been shown not to perform well under even gradual domain shift

(Atwell et al., 2021), which may be the result of the limited timeframe and distribution of the articles contained in the most commonly used English discourse datasets, the Penn Discourse Treebank (Miltsakaki et al., 2004; Prasad et al., 2008; Webber et al., 2019) and the RST Discourse Treebank (RST-DT) (Carlson et al., 2001). These datasets are both made up of Wall Street Journal articles spanning a three-year period, and thus do not contain much variation with respect to linguistic distribution.

Several works have quantified domain shift in the context of natural language processing, mostly in the task of sentiment analysis. For instance, Plank and van Noord (2011) use word frequencies and topic models to measure domain similarity, while Wu and Huang (2016) use sentiment graphs. In contrast, ours is the first to consider quantifying domain shift in discourse analysis. With respect to our methodology, some works take a similar approach. Blitzer et al. (2007) and Elsahar and Gallé (2019) also use a statistic from domain adaptation theory, employing the $\mathcal{H}$-divergence to analyze a sentiment classification task on the Amazon Reviews dataset, while Ruder et al. (2017) use $\mathcal{H}$-divergence to select the source datasets for transfer. However, none of these works have studied the h-discrepancy we study here, which is dependent on the classifier used for inference. In comparison, the $\mathcal{H}$-divergence ignores information about the model we would like to transfer, and therefore, will be less sensitive (e.g., in model-selection contexts).

To the best of our knowledge, no works have yet studied the correlation of statistics from the theoretical domain adaptation literature with the adaptation performance of discourse parsers. This is especially true given the wide array of different datasets and distributional shifts we consider as well as the theoretical and empirical tools we propose to conduct our study. Both our novel theoretical result (Theorem 1) and our large-scale regression analysis (Section 5), provide new, practical insights on domain-shift in discourse parsing.

2.2 Domain Adaptation Theory

Statistics that relate to domain adaptation performance have long been studied in the theoretical literature. Kifer et al. (2004); Ben-David et al. (2007, 2010a) initiate this investigation with a modification of the total variation distance (the $\mathcal{H}$-divergence) that depends on the set of classifiers $\mathcal{H}$; this statistic can be directly related to adaptation performance through a finite sample bound. Mansour et al. (2009) extend this discussion from classification error to general loss functions. Certain two-sample statistics can also be related to adaptation performance through finite sample bounds, but only under stringent assumptions on the space of classifiers and the computation of the two-sample statistic (Fukumizu et al., 2009; Gretton et al., 2012; Long et al., 2015; Redko et al., 2020).

Assumptions, in general, play a large role in successful domain adaptation. In fact, common adaptation algorithms can actually *worsen* performance if important assumptions are not met (Zhao et al., 2019; Wu et al., 2019). Different assumptions have led to diverse theories disjoint from the $\mathcal{H}$-divergence, including proposals of Lipton et al. (2018), Johansson et al. (2019), and Tachet des Combes et al. (2020). Under certain strict and untestable assumptions, it is even possible to derive unbiased estimators of adaptation performance (Sugiyama et al., 2007; You et al., 2019). We later discuss our own assumptions on the *adaptability* λ which are typical when using the $\mathcal{H}$-divergence and its descendants. We find these assumptions to be comparatively mild. In comparison to some others, they have also been theoretically argued to be of vital importance (Ben-David et al., 2010b).

3 Methods

Data Our English datasets are all based on either the RST Discourse Treebank or Penn Discourse Treebank frameworks, which we describe in Appendix A. Table 1 summarizes differences between the datasets we use in our experiments.

Features For each discourse relation, we encode the argument pair as features. For the RST-DT and GUM corpus, we thus only use discourse relations between two EDUs. To encode argument pairs, we concatenate and tokenize them using the BERT (Devlin et al., 2019) tokenizer. We then feed these tokens through the pretrained base BERT model and experiment with two different ways of capturing the model output: using the pooled output, e.g. the output of the [CLS] token, and averaging the hidden states. We will refer to these encodings as P-BERT and A-BERT respectively. We also experiment with encoding our argument pairs using SentenceBERT (Reimers and Gurevych, 2019) which we will refer to as S-BERT.

Dataset	Genre	Label schema
RST-DT (Carlson et al., 2001)	News	RST-DT
PDTB 2.0 (Prasad et al., 2008)	News	PDTB
PDTB 3.0 (Webber et al., 2019)	News	PDTB
BioDRB (Ramesh and Yu, 2010)	Bio	PDTB
TED-MDB (Zeyrek et al., 2020)	TED talks	PDTB
GUM (Zeldes, 2017)	Multiple	RST-DT

Table 1: Characteristics of each discourse dataset used in our study. The "multiple" domains in the GUM corpus are as follows: Academic, Biography, Fiction, Interview, News, Reddit, Travel, and How-to guides. The main distinction between the PDTB-2 and PDTB-3 is the presence of intra-sentential implicit discourse relations in the PDTB-3.

Label Set For the datasets with the PDTB label schema, we use only the top-level sense labels (Expansion, Contingency, Comparison, and Temporal). We use the top-level RST-DT classes for the datasets with the RST-DT label schema, and map the GUM corpus classes to the RST-DT classes using Braud et al. (2017). We recognize this mapping will not be perfect, as mappings between frameworks rarely are, but we follow the mapping with empirical support from Demberg et al. (2017) and focus on the predicting top-level relations between two discourse units. As a consequence, we expect to observe distinct labeling functions (i.e., annotator decisions) across domains from separate discourse frameworks.

Experiments Each data point in all of our results (e.g., when computing correlation or doing regression analysis) corresponds to a particular *experiment* done on a source (train) dataset S and target (test) dataset T using a classifier h. The classifier h is trained on the source S and evaluated on target T. This is meant to mimic a common domain adaptation scenario in which the NLP practitioner would like to transfer a pre-trained discourse classification model to a new unlabeled dataset (i.e., this is discussed again in Section 4). For each experiment, h is trained using a standard optimization procedure to have low error on S. We discuss this procedure and its competitiveness with respect to the state-of-the-art in Section 5.

For each dataset, we randomly split the dataset in half based on 3 different seeds. For example, PDTB 2.0 (10K examples) is randomly split into to disjoint sets of about 5K examples. The pair S and T are taken from the set of these splits using each of the different BERT representations. We restrict the pair to have a common set of discourse labels. For example, we only transfer from S using the PDTB label schema to T using the same schema.

For experiments involving PDTB label schema, we consider single-source domain adaptation, which simply pairs one data split S with another T. For instance, the first half of the TED-MDB and the second half of the BioDRB, or, the first half of BioDRB and the second half of BioDRB.

For experiments involving RST-DT label schema, we use both single-source and multi-source domain adaptation setups. We use the multi-source setup for domains in the GUM corpus. Here, T is derived from a single domain and S from all of the other domains contained in the corpus (i.e., S would contain 7 of the GUM domains and T would contain the remaining one). Although we continue to split the domains in half, we only use one of the halves in this case to prevent samples from the target distribution from appearing in the source. We use the single-source setup for RST itself. Here, S is one split of RST while T is another.

Importantly, experimenting with this variety of setups allows us to simulate variability arising from sampling as well as study different degrees of domain shift. Accounting for each pair and each random seed for model training, the number of (S, T, h) triples we study totals more than 2400.

4 Quantifying Meaningful Domain Shift

Identifying and quantifying domain shift is a classical problem. Perhaps, the most widely used mechanism for this task is the two-sample test; i.e., a test designed to indicate difference of distribution between two samples. We begin this section by discussing a few of the statistics used in these tests. We observe a common problem in using these statistics to predict adaptation performance, and following this, discuss the aforementioned h-discrepancy.

4.1 Common Two-Sample Test Statistics

We now informally discuss some common statistics used in two-sample tests. These statistics can be easily adapted to infer adaptation performance under the assumption that changes in distribution perfectly correlate with changes in error. As mentioned earlier, we do *not* agree with this hypothesis. Still, these types of statistics serve as a good point of comparison. In our experiments, we compute each of these statistics using the PyTorch library `torch_two_sample` (Cruceru et al., 2020).

- **FRS**: (Friedman and Rafsky, 1979) counts edges from S to T in a graph representation.
- **Energy**: (Székely and Rizzo, 2013) compares dissimilarity of points within/across S and T.
- **MMD**: (Gretton et al., 2012) compares *similarity* of points within/across S and T.
- **BBSD**: (Lipton et al., 2018) applied MMD to softmax output (i.e., scores) of classifier h.

For more computational details, see Appendix C.

A Common Problem The majority of these statistics share the common trait that they were originally designed to test differences in feature distribution – *not* differences in hypothesis error. As such, while we do expect them to be sensitive to changes in error – in so far as changes in feature distribution relate to changes in error – we have no theoretical reason to expect this should be the case. As we saw in Figure 1, these two changes can be very different: large changes to the distribution of features may not hurt performance in every case and imperceptible changes to the distribution of features can have large impact when the labeling function changes. In fact, most of these statistics do not even incorporate information about the classifier we use for inference. While BBSD does, we are not aware of any theoretical arguments linking it to adaptation performance in the same way as the h-discrepancy (discussed next).

4.2 Identifying the Change that Matters

Contrary to those statistics described above, the statistic we give in this section is directly related to adaptation performance by theoretical means. Before beginning our description of this metric, we need to formalize our mathematical setup and a particular notion of adaptation performance.

Mathematical Setup We measure adaptation performance through the error-gap which is defined:

$$\Delta_h(S, \mathbb{T}) = |\mathbf{R}_S(h) - \mathbf{R}_{\mathbb{T}}(h)| \tag{1}$$

where S is a sample and $\mathbb{T}$ is a distribution – both over a space $\mathcal{X} \times \mathcal{Y}$. In this paper, $\mathcal{X}$ is usually the space of real-valued vectors (i.e., BERT representations for argument pairs) and $\mathcal{Y}$ corresponds to a set of possible discourse labels. h is a classifier $h : \mathcal{X} \to \mathcal{Y}$ and the risk $\mathbf{R}_{\mathbb{D}}(h)$ is defined for distribution $\mathbb{T}$ as $\mathbf{R}_{\mathbb{T}}(h) = \mathbf{Pr}(h(\tilde{X}) \neq \tilde{Y})$, $(\tilde{X}, \tilde{Y}) \sim \mathbb{T}$. For sample $S = (X_i, Y_i)_{i=1}^n$, we instead write $\mathbf{R}_S(h) = n^{-1} \sum_i 1[h(X_i) \neq Y_i]$ where $1[\cdot]$ is the indicator function. To compute each statistic which we would like to use to infer the error-gap, we assume access to the mentioned sample S drawn i.i.d from some distribution $\mathbb{S}$. We also assume access to a new unlabeled sample $T_X = (\tilde{X}_i)_{i=1}^m$ drawn i.i.d from the $\mathcal{X}$-marginal $\mathbb{T}_X$ of the distribution $\mathbb{T}$. In general, we do not know whether $\mathbb{T} \neq \mathbb{S}$ or $\mathbb{T} = \mathbb{S}$, but may have reason to suspect $\mathbb{T} \neq \mathbb{S}$.

Roadmap In the next part, we give the statistic we would like to use to predict adaptation performance. We then quantify its bias as an estimator for the error-gap with a theoretical result. We also propose a technique to study the relationship between this statistic and the error-gap empirically through a regression analysis. Finally, we show how this technique can be used to study the impact certain attributes of a model or dataset have on error-gap.

Source-Guided Discrepancy The source-guided discrepancy was proposed by Kuroki et al. (2019) with a similar conceptualization given independently by Zhang et al. (2019). These statistics improve upon a long history of domain adaptation statistics (Kifer et al., 2004; Blitzer et al., 2007; Ben-David et al., 2007, 2010a), specifically, by incorporating information on the source-labels. We consider a generalization of the source-guided discrepancy which we call the h-discrepancy, defined for any classifier h. For samples S and T_X, a binary label space $\mathcal{Y}$, a space of classifiers $\mathcal{H}$ over $\mathcal{X} \times \mathcal{Y}$, and any[2] fixed classifier $h \in \mathcal{H}$, it is defined as:

$$\begin{aligned} &D = \max\nolimits_{g \in \mathcal{H}} |\mathbf{R}_U(g) - \mathbf{R}_V(g)| \quad \text{where} \\ &U = ((X_i, h(X_i))_{i=1}^n, \quad V = ((\tilde{X}_i, h(\tilde{X}_i))_{i=1}^m, \end{aligned} \tag{2}$$

and recall, $S_X = (X_i)_i$ and $T_X = (\tilde{X}_i)_i$. In the binary case, Kuroki et al. (2019) show that this may be approximated by learning a classifier (i.e., g) which *agrees* with h on the source sample S_X and *disagrees* with h on the target sample T_X. Their procedure extends naturally to the multi-class case as well, but we must disambiguate between the possible ways in which g can disagree with h. In our experiments, we do so by training g to pick the next most likely label according to the scores of h. For a better approximation, one should compute D again, reversing the roles of S/T and taking the larger of the values as the final result. With binary

---

[2] The source-guided discrepancy originally proposed by Kuroki et al. (2019) considers only one particular h.

labels, the two values will often coincide, but this should not be assumed in multi-class settings.

Theoretical Motivation Here, we provide our primary motivation for the h-discrepancy as an estimator of error-gap. Our result makes use of the work of Crammer et al. (2007), Ben-David et al. (2010a), and Kuroki et al. (2019). It distinguishes itself from these finite sample bounds in that it explicitly concerns itself with the bias of D as an estimator of error-gap. Proof is given in Appendix D.

Theorem 1. *Let $\mathcal{Y}$ be a binary space and let $\mathcal{H}$ be a subset of classifiers in $\mathcal{Y}^{\mathcal{X}}$. Then, for any realization of S, for all $h \in \mathcal{H}$,*

$$-\mathbf{E}_T[\lambda] \leq \mathbf{E}_T[D] - \Delta_h(S, \mathbb{T}) \leq \mathbf{E}_T[D] \tag{3}$$

where $\lambda = \min_{h' \in \mathcal{H}} \mathbf{R}_S(h') + \mathbf{R}_T(h')$.

Notice, when $\mathbf{E}[\lambda]$ is small and $\mathbf{E}[D]$ is also small we know the bias must be small because it is "sandwiched" between these two. In this situation, the practitioner can very confidently transfer h from S to T. In practice we cannot compute λ since it requires labels from T, still we often expect $\mathbf{E}[\lambda]$ to be small. In particular, this term is often called the *adaptability* as it captures irreconcilable differences between the source and target labeling functions. In discourse, such differences are primarily determined by the discourse framework and annotator. As first observed by Ben-David et al. (2010a) (i.e., concerning a similar term), λ is small whenever there is *any* classifier in $\mathcal{H}$ which does well on S and T simultaneously. If S and T come from the same discourse framework, this should not be difficult for sufficiently complex $\mathcal{H}$. Even if S and T come from distinct discourse frameworks, this is still not an overly strong requirement because neural-networks, for example, have been shown to perfectly fit even random labeling (Zhang et al., 2016). Thus, in many cases,[3] we are primarily concerned with the positive bias of D. When $\mathbf{E}[D]$ is larger, the positive bias of D can also be larger. Intuitively, D might have more "false positives" where it reports a high value but the error-gap is actually comparatively small. In this sense, it is a conservative statistic. It plays things on the "safe side." So, while D will possibly have some bias, it is at least described by the above bounds. As we are aware, the two-sample statistics discussed previously do not have such a description.

Regression Analysis of Errors of D From Theorem 1, we do not expect the random estimation error $D - \Delta_h(S, \mathbb{T})$ to be zero. So, in our experimentation, we propose to study this quantity through a regression analysis. Namely, suppose $\mathbf{X} \in \mathbb{R}^{N \times p}$ is some fixed, non-singular design matrix whose rows each represent one of N experiments and whose columns represent one of p features for each experiment. An experiment corresponds to an (S, T, h) triple as disucssed in Section 3. The features are dependent on properties of the datasets and models used in each experiment as well as realizations of h-discrepancy, adaptability, and training error. Then, we assume

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon} \tag{4}$$

where the randomness in the outcome $\mathbf{Y}$ comes from $\boldsymbol{\epsilon}_i \overset{\text{i.i.d.}}{\sim} N(0, \sigma^2)$, $\sigma > 0$. The response $\mathbf{Y} = (D_i - \Delta_h(S, \mathbb{T})_i)_{i=1}^N$ are realizations of estimation error across N experiments.[4] We give model diagnostics and details of the design matrix $\mathbf{X}$ in Appendix E; it is selected manually using domain knowledge and to meet model assumptions.

Regression analysis is particularly useful because standard techniques allow us to understand and isolate the impact of individual columns (i.e., features) in $\mathbf{X}$ on the estimation errors of D. In particular, we can use this model to determine the expected change in estimation error as a function of a particular feature, while controlling (i.e., holding constant) all other features in $\mathbf{X}$:

$$\mathbf{E}[\mathbf{Y}_i \mid \mathbf{X}_i = \mathbf{x}] - \mathbf{E}[\mathbf{Y}_i \mid \mathbf{X}_i = \mathbf{x}'] \tag{5}$$

where $\mathbf{x}$ is any setting of the features and $\mathbf{x}'$ is identical to $\mathbf{x}$ except every component involving the feature of interest is modified (e.g., increased) systematically. For a specific example using Eq. (5), consider inspecting the change in estimation error as a function of increase in h-discrepancy (controlling for all other features). In this case, Eq. (5) evaluates to a polynomial[5] in the coefficients $\boldsymbol{\beta}$ and components of $\mathbf{x}'$, so we can estimate this result in an unbiased manner using the OLS estimate $\hat{\boldsymbol{\beta}} = (\mathbf{X}^{\mathrm{T}}\mathbf{X})^{-1}\mathbf{X}^{\mathrm{T}}\mathbf{Y}$. To empirically validate our theoretical analysis, we might check if this polynomial is an increasing, positive function; i.e., because our theory predicts increases in the expected h-discrepancy allow for increases in bias.

---

[3] One should be cautious of broad generalizations in adaptation, since failure to carefully consider λ can be disastrous for algorithm design (Zhao et al., 2019; Johansson et al., 2019).

[4] We do not have access to $\mathbb{T}$, so we use sample T instead.

[5] For details, please see Appendix F, Example 1.

Regression Analysis of Error-Gap Given $\mathbf{X}$ and $\boldsymbol{\beta}$, rearranging Eq. (4) lets us also write

$$\Delta_h(S, \mathbb{T})_i = D_i - \mathbf{X}_i\boldsymbol{\beta} + \boldsymbol{\epsilon}_i \tag{6}$$

where $\mathbf{X}_i$ is the i^{th} row of $\mathbf{X}$; i.e., the features of the i^{th} experiment. Similar to before, this type of analysis lets us draw interesting insights. In particular, we can isolate the impact of features in $\mathbf{X}$ on the error-gap. Since our design matrix $\mathbf{X}$ controls for training error, the error-gap can be interpreted to act as a measure of performance in domain adaptation (DA). Those features which are positively associated with error-gap can be said to be worse for DA. Likewise, those with negative association are "better" for DA. As before, we isolate the impact of a feature by checking the change in error-gap as a function of change in this feature (i.e., similar to Eq. 5). Appendix F Example 2 uses this technique to isolate the impact of different BERT representations on error-gap.

5 Results

5.1 Analysis of Transfer Error

Comparison to Other Work *Our experimental setup produces results comparable to current discourse models.* In Appendix B, Figure 3 shows the distribution of the error rates when transferring on within- and out-of-distribution datasets. To validate whether our setup is comparable to other discourse parsing models, we compare error rates to current implicit sense classifiers; e.g., Kishimoto et al. (2020) who achieve an error rate of ≈ 0.38 under a comparable setup. Our PDTB within-distribution results often improve upon this.

Error Analysis across Genres *Fiction and How-To Guides are the most difficult to transfer to, while Academic Journals and Biographies are the easiest.* Figure 4 in Appendix B shows the error rates for multi-source adaptation on the GUM corpus across S-BERT, P-BERT, and A-BERT. Although the error rates differ across these three representations, the relative order of the GUM corpus domains with respect to transfer error is fairly consistent across all of them. For all three, the highest mean error rate occurred in the How-to Guide and Fiction domains, and the lowest mean error rate occurred in the Academic and Biography domains.

5.2 Analysis of Correlations

In Table 2, we show linear and rank correlation of each statistic with the error-gap. This tests the ability of each statistic to discern scenarios where domain adaptation performance may be either good or bad. In practice, a statistic with good rank correlation can be used in model-selection or (source) dataset selection. A statistic with good linear correlation may also be used and will be easier to interpret since we expect changes in the statistic to be proportional to changes in the error-gap.

Comparison of Statistics *h-discrepancy is consistently, most strongly correlated with error-gap.* The overarching trend is that the h-discrepancy is far better than every other statistic with regards to both types of correlation. In fact, the linear correlations are not much worse than the rank correlations (in some cases they are even better). This validates our opening hypothesis that domain-shift does not always correlate with domain adaptation performance (i.e., error-gap). It is important to also consider the classifier we use. Still, BBSD – another statistic that relies on the classifier – is also somewhat ineffective compared to the h-discrepancy. Importantly, despite depending on the classifier, BBSD was still designed with identification of feature-distribution shift in mind. In some sense, this observation validates our theoretical motivations for the h-discrepancy (i.e., Theorem 1) which directly relates it to error-gap. Our results indicate that, at least for the task of discourse parsing, h-discrepancy is the most effective statistic to use with regards to predicting error-gap.

Additional Trends *Experiments using RST-DT label schemas and non-news targets show very low correlation between distributional shift and error-gap.* If we look at particular experiment subsets, we also see some interesting trends. First, most statistics are better correlated with error-gap datasets that use the PDTB label schema than those that use the RST-DT label schema. The difference is less pronounced for the h-discrepancy than for the other statistics, suggesting that it is especially important to use statistics tied directly to the error-gap when working with datasets that use the RST-DT schema. The same is true when the test dataset is comprised of news articles instead of other types of text.

The h-discrepancy has highest linear correlation on similar distributions. We observe much stronger linear correlation between the h-discrepancy and error-gap on within-distribution adaptation scenarios (**WD**) as compared to out-of-distribution adaptation scenarios (**OOD**). We believe this is because

Table 2: Correlations with error-gap for each statistic. Data splits indicate the subset of data used. h-discrepancy consistently yields the largest correlation with error-gap; i.e., difference in Pearson correlations are all significant at level $\alpha = 0.001$ using test of Steiger (1980) implemented by Diedenhofen and Musch (2015).

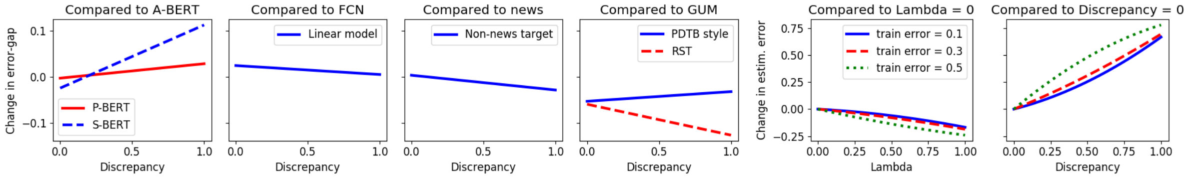

Figure 2: (Left, 1-4) Expected change in error-gap when changing properties of the dataset or model. Shown as a function of discrepancy and controls for all other features of the experiment. Reference category is indicated in title. (Right, 5-6) Expected change in estimation error of h-discrepancy shown as a function of λ (5th) and discrepancy (6th). Left assumes use of A-BERT and FCN on a GUM non-news target, but trends are consistent in other cases.

the h-discrepancy is typically small when S and T follow a similar distribution. As Theorem 1 notes, the bias of the h-discrepancy as an estimator for error-gap can be near zero if both $\mathbf{E}[D]$ and $\mathbf{E}[\lambda]$ are small; i.e., we expect the linear correlation of a nearly unbiased estimator to be fairly high.

5.3 Regression Analysis of Estimation Error

Figure 2 shows expected change in estimation error of h-discrepancy (used as an estimator for error-gap). Trend lines indicate expected change as a function of the adaptability λ and the discrepancy D compared to the case where each is 0.[6] Trends are computed using a similar technique for regression analysis as described in Appendix F Example 1. The takeaway is that these empirical results are consistent with our theoretical discussion surrounding Theorem 1. As λ increases, the estimation error decreases. Similarly, Theorem 1 predicts the possibility of negative bias when λ is large. As D increases, the estimation error does the same. Theorem 1 agrees here too, predicting the possibility of positive bias when D is large.

5.4 Regression Analysis of Error-Gap

Figure 2 also shows expected change in error-gap when modifying categorical features of the experiment; e.g., use of S-BERT vs. A-BERT. Trend lines indicate expected change as a function of h-discrepancy and are computed using a similar technique for regression analysis as described in Appendix F Example 2. Since we control for training set error, positive changes in error-gap indicate a setting is better for domain adaptation, while negative indicates the opposite. This regression analysis also controls for changes in discourse framework using explicit indicator variables as well as the term λ (see discussion after Theorem 1).

BERT features *S-BERT is better for similar train and test sets, while A-BERT is better for more divergent sets.* As a function of discrepancy, S-BERT is better for DA when the discrepancy is small. As the difference between the train and test set increases, the reference category (i.e., A-BERT) is better for DA. Comparing P-BERT to A-BERT we do not see large differences; marginally, A-BERT is better as discrepancy increases. These results are consistent with typical rules of thumb on model complexity. A more complex feature representation (i.e., S-BERT or P-BERT) is beneficial when training and test distributions align, but

---

[6] Note, if both are 0 in expectation, D is unbiased.

allows for overfitting when discrepancy increases.

Classifier *Linear classifiers perform marginally worse than neural-networks.* In general, fully-connected networks (FCNs) appear to be slightly better for domain adaptation. Possibly, this is due to increased modelling capacity. This benefit wanes as the discrepancy between the training/test sample increases. As before, the cause may be overfitting since overfitting and class imbalance are known problems in discourse parsing (Atwell et al., 2021).

News Test Set *It is slightly harder to transfer to news datasets.* We consider a "news" corpus to be any of PDTB, RST-DT, or the news domain of GUM. When the target (test) dataset consists of news texts, we see adaptation performance consistent with non-news targets for small discrepancy. As the discrepancy between training and test set grows, the non-news targets are actually better suited for domain adaptation; i.e., it is slightly easier to transfer to a non-news target. Possibly, this is related to the length and complexity of news texts.

Dataset *Increased variability in the target domain results in a more difficult task, even when adding variability during training.* In general, we see that the GUM dataset presents a more challenging adaptation task than the other datasets. This is sensible due to the larger selection of target domains in GUM. In our results, increased variability at train-time does not appear to counteract this issue, because adaptation experiments in the GUM corpus are multi-source. For PDTB, as the discrepancy increases, performance is more similar to GUM. On the other hand, RST-DT presents the easiest adaptation task. This is expected as all test sets in the RST-DT experiments are drawn from the same news corpus.

6 Conclusion

This work provides a statistic for model and dataset selection, that we also use to conduct large-scale analysis of model transfer in discourse parsing. Our analysis provides useful insights for the practitioner. For one, the correlations indicate that, for datasets with the RST-DT annotation framework, the statistics that quantify distributional shift without being directly tied to error-gap (where error-gap refers to the performance gap between train and test splits) are very weakly correlated with error-gap. This also holds for non-news targets, and indicates that the h-discrepancy is especially useful for predicting the effects of domain shift in these cases.

Additionally, we find that: (1) increased variability in the target domain appears to make domain adaptation more difficult, even if the training set contains a similar level of variability; (2) S-BERT is better than A-BERT when domains are similar, but A-BERT outperforms S-BERT when the domains further diverge; (3) non-news texts (such as those in the BioDRB) are easier to adapt to than news texts (such as those in the PDTB).

This is the first computational and empirical study that looks at distribution shifts across different discourse datasets and evaluates the performance of various models under these shifts. This is also the first work that examines the efficacy of different two-sample tests for predicting the error-gap when compared to a metric that is theoretically tied to error gap. Future work can extend these results by using the h-discrepancy metric to predict the error-gap for other NLP tasks or for other components needed for discourse parsing, such as constructing the RST-DT dataset.

7 Ethics

Our experiments do not have any significant ethical concerns, as we do not work with any sensitive or personal data, nor do we work with human subjects; the datasets we use for our experiments are the PDTB 2.0 and 3.0, the RST Discourse Treebank, the GUM corpus, the TED-MDB, and the BioDRB. Our work depends on pretrained models such as word embeddings. These models are known to reproduce and even magnify societal bias present in training data.

A Frameworks

The Penn Discourse Treebank (Miltsakaki et al., 2004; Prasad et al., 2008; Webber et al., 2019) consists of Wall Street Journal articles labeled with both *explicit* and *implicit* shallow discourse relations (relations between only two text units). Explicit discourse relations are ones in which a *connective* between the arguments provides some indication of the correct discourse sense label. Implicit discourse relations, which we focus on in this paper, are ones in which a connective can be *inserted* that indicates the correct sense.

The RST Discourse Treebank (Carlson et al., 2001) is a corpus containing Wall Street Journal articles annotated in the style of Rhetorical Structure Theory, where a document is split into *elementary discourse units* (EDUs) and relations made up of these EDUs form a tree structure. The RST Discourse Treebank does not differentiate between explicit and non-explicit discourse relations, nor does it label discourse connectives.

B Model Training and Transfer Results

Optimization Parameters We use SGD on an NLL loss with momentum set to 0.9 to train all of our models. We use a batch size of 250. We start training with a learning of 1×10^{-2} for 100 epochs and then train for another 50 epochs using a learning rate of 1×10^{-3}. If a model achieves a training error lower than 5×10^{-4}, we stop training.

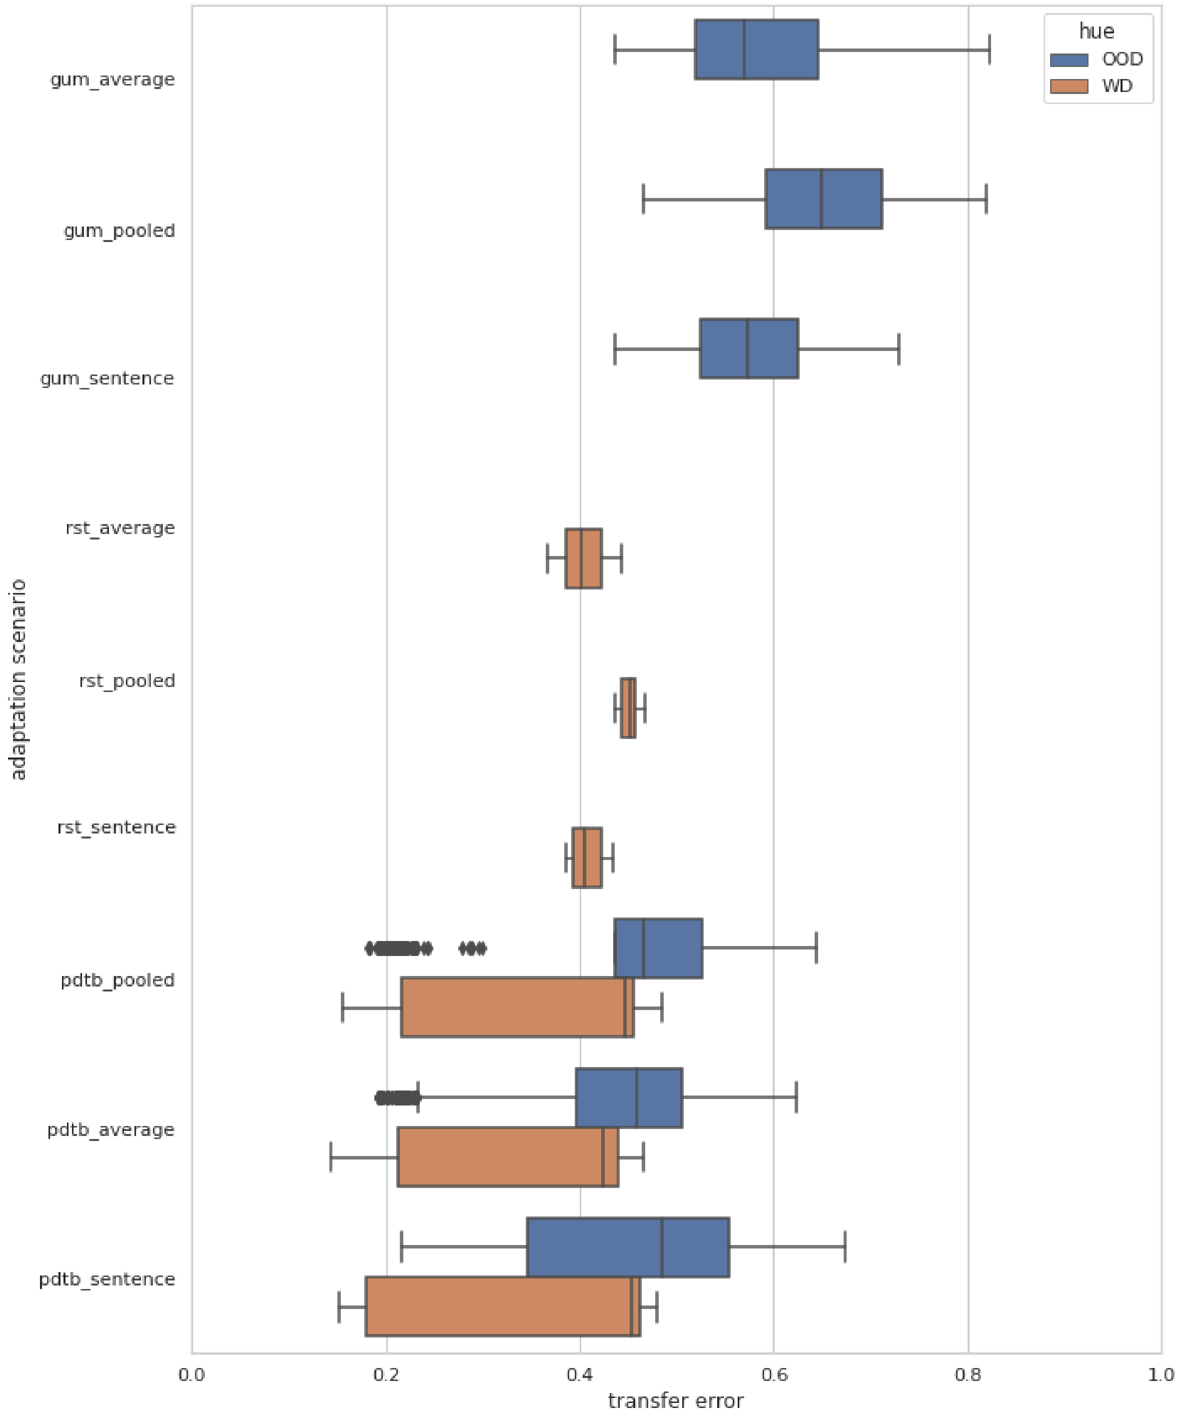

Figure 3: Transfer error within and out of distribution for each dataset

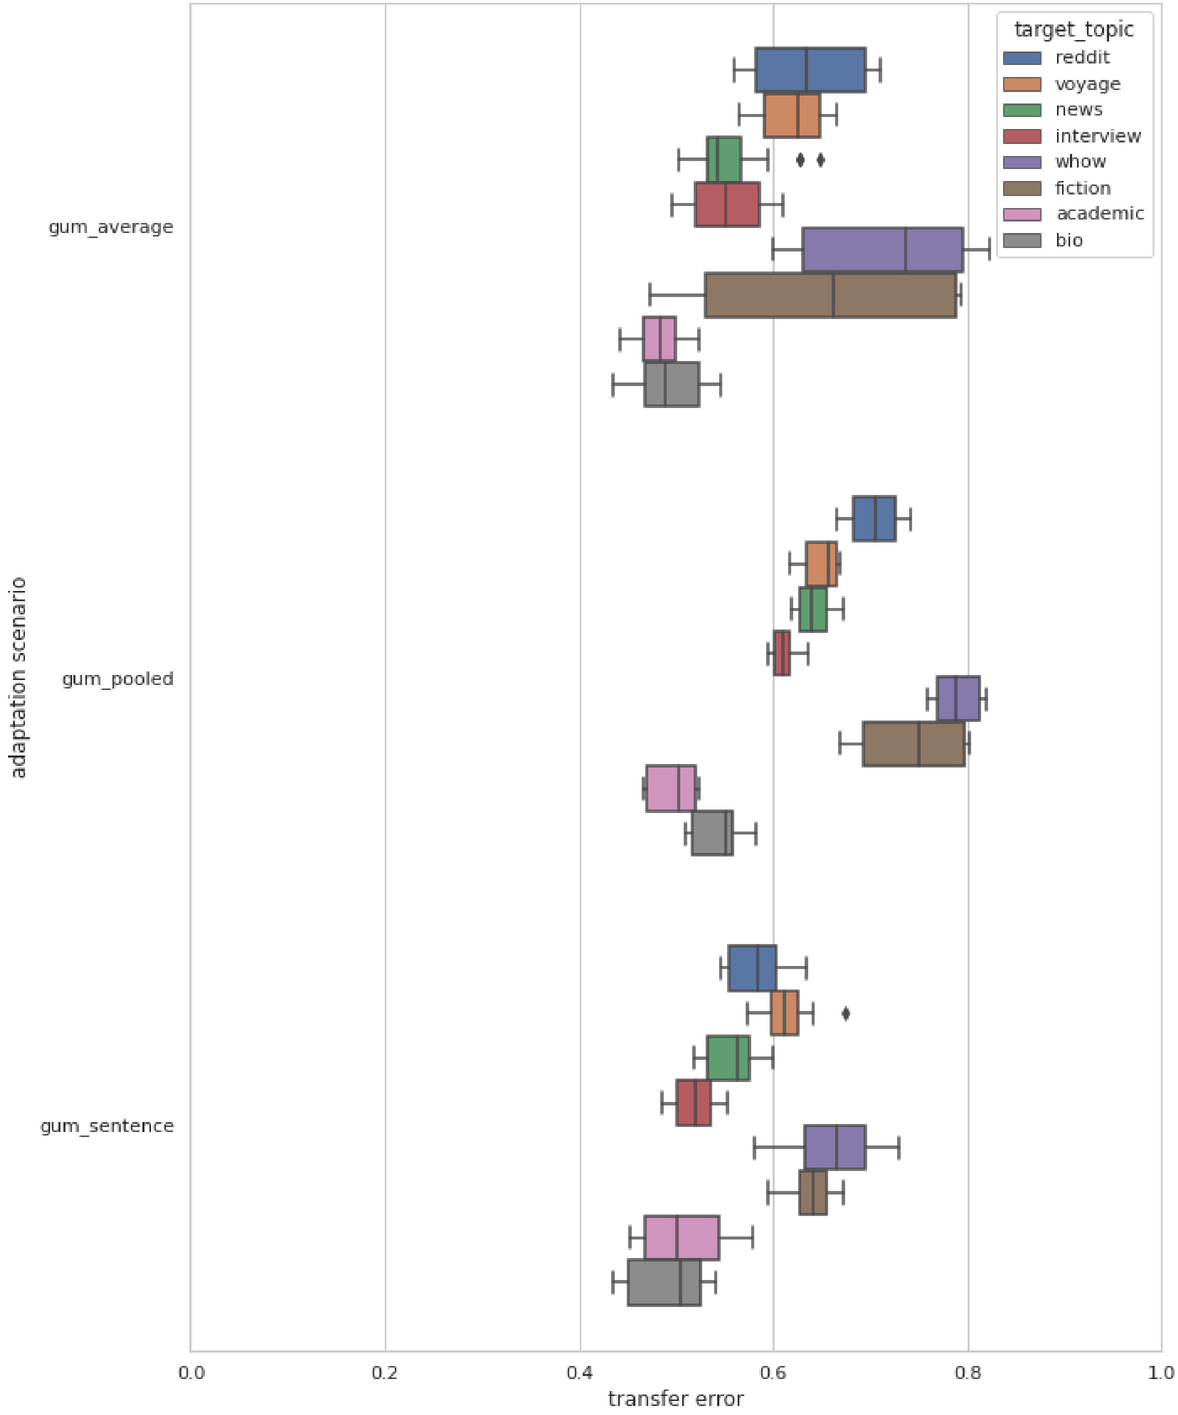

Figure 4: Transfer error for each topic within the GUM corpus

C Two-Sample Statistics

Here, we describe in detail the common two-sample statistics listed in Section 4 and studied in Section 5

Friedman-Rafsky Test Statistic The Friedman-Rafsky Test Statistic R (Friedman and Rafsky, 1979) is computed by forming a minimum-spanning tree (MST) using the pooled sample $P = (X_i \mid (X_i, Y_i) \in S) +_{\mathrm{c}} (\tilde{X}_i \mid \tilde{X}_i \in T_X)$ of marginal features. Here, $+_{\mathrm{c}}$ is the concatenation operation. To form the tree, we form a weighted graph G_P by treating each point $Z_i \in P$ as vertex and assigning an edge between each pair of vertices whose weight is the distance between the data-points. When $\mathcal{X} = \mathbb{R}^d$ for some d, this is usually the Euclidean distance or L2 norm. The MST is then precisely the MST of G_P. The statistic R is computed as the number of edges whose endpoints originally belonged to the same sample. For example, R increases by 1 for each edge whose endpoints both originally belong to T_X. Likewise, R increases by 1 for each edge whose endpoints are both the features of points in S. When endpoints originally belonged to distinct samples, R remains unmodified. We report modified statistic below which is normalized to account for sample size $R_{\text{normed}} = R/(n + m - 2)$. Since the size of the MST is $n + m - 1$ and there is always at least one edge between S and T_X, this statistic has a maximum value of 1.

Energy Statistic Given samples S and T_X as before, the energy statistic may be computed as below

$$E = \frac{2}{nm}\sum\nolimits_{i,j} ||X_i - \tilde{X}_j|| - \frac{1}{n^2}\sum\nolimits_{i,j} ||X_i - X_j|| - \frac{1}{m^2}\sum\nolimits_{i,j} ||\tilde{X}_i - \tilde{X}_j|| \tag{7}$$

where $|| \cdot ||$ gives the Euclidean norm (distance). Originally proposed by Székely and Rizzo (2013), the statistic is motivated by Newton's potential energy between heavenly bodies. Intuitively, it is fairly easy to understand as a comparison of dissimilarity within samples and across samples. If the dissimilarity across samples (i.e., the first term) is much higher than the dissimilarity within samples, then the two samples are likely drawn from different distributions.

Maximum Mean Discrepancy (MMD) Given samples S and T_X as before, the MMD statistic (Gretton et al., 2012) may be computed as below

$$M = \frac{\sum_{i \neq j} K(X_i, X_j)}{n(n-1)} + \frac{\sum_{i \neq j} K(\tilde{X}_i, \tilde{X}_j)}{m(m-1)} - \frac{2}{nm}\sum\nolimits_{i,j} K(X_i, \tilde{X}_j) \tag{8}$$

where $K : \mathcal{X} \times \mathcal{X} \to \mathbb{R}_{\geq 0}$ is the kernel for some RKHS. In our experiments, we use an Gaussian RBF kernel and select σ to be an approximate[7] median distance of the pooled sample as done by Rabanser et al. (2019). Intuitively, K behaves as a similarity metric between points in $\mathcal{X}$ and, in this sense, the MMD statistic compares samples in much the same way that the energy statistic does. Rather than dissimilarity, the MMD statistic looks at similarity of points within and across samples, modifying the order of the summands appropriately to retain direct proportionality with the difference in samples.

D Proof of Theorem 1

Proof. We use the triangle inequality of classification error (Crammer et al., 2007; Ben-David et al., 2007). For any realization of the sample S and any distribution $\mathbb{T}$ over $\mathcal{X} \times \mathcal{Y}$, for any classifiers $h, h' \in \mathcal{H}$, the triangle inequality yields[8]

$$\mathbf{R}_{\mathbb{T}}(h) - \mathbf{R}_S(h) \leq \mathbf{R}_S(h') + \mathbf{R}_{\mathbb{T}}(h') + |\mathbf{R}_S(h, h') - \mathbf{R}_{\mathbb{T}}(h, h')| \tag{10}$$

where for $\mathbb{T}$ over $\mathcal{X} \times \mathcal{Y}$ we have

$$\mathbf{R}_{\mathbb{T}}(h, h') = \mathbf{Pr}_{\tilde{X} \sim \mathbb{T}_X} (h(\tilde{X}) \neq h'(\tilde{X})) \tag{11}$$

and for $S = (X_i, Y_i)_{i=1}^n$ we have

$$\mathbf{R}_S(h, h') = n^{-1} \sum_{i=1}^{n} 1[h(X_i) \neq h'(X_i)]. \tag{12}$$

Interchanging roles of $\mathbb{T}$ and S in Eq. (10) and using the definition of the absolute value, we see

$$\Delta_h(S, \mathbb{T}) \leq \mathbf{R}_S(h') + \mathbf{R}_{\mathbb{T}}(h') + |\mathbf{R}_S(h, h') - \mathbf{R}_{\mathbb{T}}(h, h')|. \tag{13}$$

---

[7] Specifically, we use a smaller random sample of 100 data points to compute this median.

[8] A full derivation of Eq. (10) may be found by following steps as in the proof of Theorem 2 of Ben-David et al. (2010a):

$$\begin{aligned} \mathbf{R}_{\mathbb{T}}(h) &\leq \mathbf{R}_{\mathbb{T}}(h, h') + \mathbf{R}_{\mathbb{T}}(h') \\ &\leq \mathbf{R}_S(h, h') + \mathbf{R}_{\mathbb{T}}(h') + |\mathbf{R}_{\mathbb{T}}(h, h') - \mathbf{R}_S(h, h')| \\ &\leq \mathbf{R}_S(h) + \mathbf{R}_S(h') + \mathbf{R}_{\mathbb{T}}(h') + |\mathbf{R}_{\mathbb{T}}(h, h') - \mathbf{R}_S(h, h')| \end{aligned} \tag{9}$$

For brevity, for any distribution $\mathbb{D}$, set

$$\xi(\mathbb{D}) = |\mathbf{R}_S(h, h') - \mathbf{R}_{\mathbb{D}}(h, h')|. \tag{14}$$

Then, using the common "addition of zero" trick, we arrive at

$$\begin{aligned} \Delta_h(S, \mathbb{T}) \leq\ & \mathbf{R}_S(h') + \mathbf{R}_{\mathbb{T}}(h') \\ & - \mathbf{R}_T(h') + \mathbf{R}_T(h') + \xi(\mathbb{T}) \\ & - \xi(T) + \xi(T). \end{aligned} \tag{15}$$

Then, by monotonicity and linearity of the expectation we have

$$\begin{aligned} \Delta_h(S, \mathbb{T}) \leq\ & \mathbf{E}_T\Big[\mathbf{R}_S(h') + \mathbf{R}_T(h')\Big] \\ & + \mathbf{E}_T\big[\xi(T)\big] \\ & + \mathbf{R}_{\mathbb{T}}(h') - \mathbf{E}_T\Big[\mathbf{R}_T(h')\Big] \\ & + \xi(\mathbb{T}) - \mathbf{E}_T\big[\xi(T)\big]. \end{aligned} \tag{16}$$

Let us consider some of these terms individually. Using linearity of expectation and the correspondence between probability and the expectation of an indicator function, we have

$$\begin{aligned} & \mathbf{E}_T\Big[\mathbf{R}_T(h')\Big] = \mathbf{E}\Bigg[m^{-1}\sum_{i=1}^{m} 1[h(\tilde{X}_i) \neq \tilde{Y}_i]\Bigg] \\ & = m^{-1}\sum_{i=1}^{m} \mathbf{E}\big[1[h(\tilde{X}_i) \neq \tilde{Y}_i]\big] \\ & = m^{-1}\sum_{i=1}^{m} \Pr_{(\tilde{X}_i, \tilde{Y}_i)\sim\mathbb{T}}\big(h(\tilde{X}_i) \neq \tilde{Y}_i\big) \\ & = m^{-1}\sum_{i=1}^{m} \mathbf{R}_{\mathbb{T}}(h) \\ & = \mathbf{R}_{\mathbb{T}}(h). \end{aligned} \tag{17}$$

Additionally, we have

$$\begin{aligned} & \mathbf{E}_T\big[\xi(T)\big] = \mathbf{E}_T\Big[|\mathbf{R}_S(h, h') - \mathbf{R}_T(h, h')|\Big] \\ & \geq |\mathbf{R}_S(h, h') - \mathbf{E}\big[\mathbf{R}_T(h, h')\big]| \\ & = \xi(\mathbb{T}). \end{aligned} \tag{18}$$

Here, the second line follows by Jensen's Inquality and linearity of the expectation. The last line follows using a similar derivation as in Eq. (17). Then,

$$\xi(\mathbb{T}) - \mathbf{E}_T[\xi(T)] \leq 0 \tag{19}$$

and

$$\mathbf{R}_{\mathbb{T}}(h') - \mathbf{E}_T\Big[\mathbf{R}_T(h')\Big] = 0. \tag{20}$$

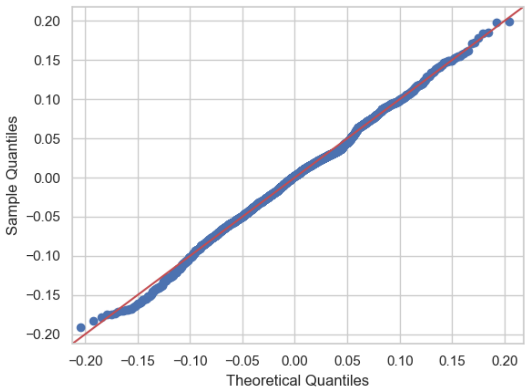

Figure 5: Quantile-Quantile plot. Red line shows ideal: sample quantiles should be the same as the theoretical quantiles of a normal distribution with same variance.

Using these two facts in conjunction with Eq. (16) yields

$$\begin{aligned} \Delta_h(S, \mathbb{T}) \leq\ & \mathbf{E}_T\Big[\mathbf{R}_S(h') + \mathbf{R}_T(h')\Big] \\ & + \mathbf{E}_T\big[\xi(T)\big]. \end{aligned} \tag{21}$$

Using h as in Eq. (2) to define the statistic D, for any $h' \in \mathcal{H}$, we know $\xi(T) \leq D$ (i.e., by definition of max). So, monotonicity and linearity of expectation implies $\mathbf{E}_T[\xi(T)] \leq \mathbf{E}_T[D]$. For an appropriate choice of h', we then have

$$\Delta_h(S, \mathbb{T}) \leq \mathbf{E}_T\big[\lambda\big] + \mathbf{E}_T\big[D\big]. \tag{22}$$

Rearranging terms gives the lowerbound and the upperbound follows immediately from the fact that $\Delta_h(S, \mathbb{T})$ is non-negative.

$\square$

E Regression Diagnostics

Normal Errors Assumption Here, we give diagnostics for the regression model used to analyze data in the main text. Primarily, we would like to check the assumptions that our error terms (i.e., $\boldsymbol{\epsilon}$) are all identically and independently normally distributed. The Jarque-Bera (JB) test uses a statistic based on the skew and kurtosis of the observed errors to study this hypothesis. Assuming the residuals are i.i.d. normal, the probability of observing a JB statistic as extreme as observed is ≈ 0.25. So, we fail to reject the hypothesis that the residuals are i.i.d normal at significance level $\alpha = 0.05$. The assumption that error terms are normal distributed may also be visually checked using the qq-plot, histogram of errors, and the residual plots contained in

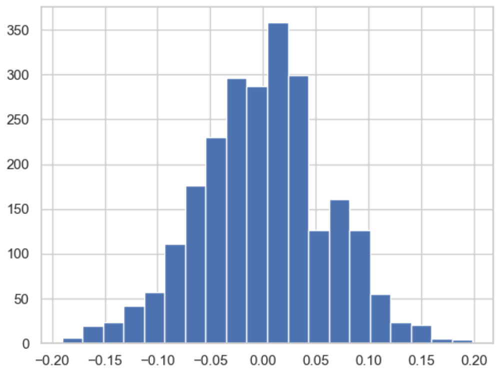

Figure 6: Histogram of realized error terms. Horizontal axis shows value of error term, while vertical axis shows count.

Figures 5, 6, and 7, respectively. We do not see particularly strong evidence that the residuals are not i.i.d. normal. Albeit, some patterning in the residual plots and skew in the histogram of residuals may be of concern.

Other Possible Assumptions In any case, even if the normality assumption does not hold, our analysis can still be interpreted using more loose assumptions. The most important assumption is that the error terms all have mean 0. Empirically, we find this to be the case with the average residual being $\approx 2.4 \times 10^{-15}$. In fact, Figure 7 shows the line-of-best fit through the residuals (which is typically close to the zero line). As long as the assumption that the error terms have common mean 0 is true, the OLS estimates we use for the coefficients will be unbiased. The only possible short-coming of the OLS estimate is that it could have larger variance than some other estimate. In our analysis, we are most concerned with the unbiased property of our coefficient estimates, but a larger variance in our estimator decreases our confidence that this particular experiment produces estimates close to the truth. Either way, under our relaxed assumption of only a common mean 0 in the errors, we can expect our analysis in the main text to reveal the truth across repeated experiments.

F Regression Analysis Examples

In this section, we give detailed examples (i.e., Exampled 1 and 2) to clarify how we compute estimates in Figure 2. As noted, we use the unbiased OLS estimate $\hat{\boldsymbol{\beta}} = (\mathbf{X}^{\mathrm{T}}\mathbf{X})^{-1}\mathbf{X}^{\mathrm{T}}\mathbf{Y}$ in place of $\boldsymbol{\beta}$ as is standard.

Example 1. *Let column j of $\mathbf{X}$ contain the realizations of the h-discrepancy for each experiment and let column k contain the train error. Suppose column ℓ is the (element-wise) product of columns k and j, column q is the square of column j, and column r is the product of columns q and k. Then, controlling for all other features in $\mathbf{X}$, the expected change in estimation error per $\delta > 0$ increase in the h-discrepancy is*

$$\begin{aligned}\mathbf{E}[\mathbf{Y}_i \mid \mathbf{X}_i = \mathbf{x}] - \mathbf{E}[\mathbf{Y}_i \mid \mathbf{X}_i = \mathbf{x}'] &= \beta_j\delta + \beta_\ell\delta\mathbf{x}'_k \\ + \beta_q(\delta^2 + 2\delta\mathbf{x}'_j) + \beta_r(\delta^2\mathbf{x}'_k + 2\delta\mathbf{x}'_j\mathbf{x}'_k)\end{aligned} \tag{23}$$

where $\mathbf{x}'$ is a fixed row-vector of features and $\mathbf{x}$ is defined by

$$\mathbf{x}_p = \begin{cases} \mathbf{x}'_p + \delta & \textit{if } p = j, \\ \mathbf{x}'_k(\mathbf{x}'_j + \delta) & \textit{if } p = \ell, \\ (\mathbf{x}'_j + \delta)^2 & \textit{if } p = q, \\ \mathbf{x}'_k(\mathbf{x}'_j + \delta)^2 & \textit{if } p = r, \\ \mathbf{x}'_p & \textit{else} \end{cases} . \tag{24}$$

If this function of δ is positive, we know increasing the h-discrepancy increases the bias as suggested by our theory.

Example 2. *Let column j of $\mathbf{X}$ be 1 if we use S-BERT representations and 0 otherwise. Let column k of $\mathbf{X}$ indicate use of P-BERT in the same way and suppose the reference category[9] for the BERT representations is A-BERT. Let column ℓ of $\mathbf{X}$ contain discrepancy D_i for each experiment and let column q be the element-wise product of columns j and ℓ; i.e., interaction terms. Then, controlling for all other features in $\mathbf{X}$, the expected increase in error-gap using S-BERT instead of A-BERT is*

$$\begin{aligned}&\mathbf{E}[D_i - \mathbf{Y}_i \mid \mathbf{X}_i = \mathbf{x}] - \mathbf{E}[D_i - \mathbf{Y}_i \mid \mathbf{X}_i = \mathbf{x}'] \\ &= -(\beta_j + \beta_q D_i)\end{aligned} \tag{25}$$

where $\mathbf{x}'$ is a fixed row-vector of features such that $\mathbf{x}'_\ell = D_i$ and $\mathbf{x}'_j = \mathbf{x}'_k = 0$. The row-vector $\mathbf{x}$ is defined by $\mathbf{x}_r = \{1 \text{ if } r = j,\ \mathbf{x}'_\ell \text{ if } r = q,\ \mathbf{x}'_r \text{ else}\}$. When this function of D_i is positive, we know using S-BERT is expected to increase the error-gap.

---

[9] In regression, the reference is the single category from any group of categories which is not explicitly included in $\mathbf{X}$. It serves as a point of comparison for the other categories. For technical reasons, a point of comparison is typically needed to analyze impact of categorical features (i.e., so $\mathbf{X}$ is full rank).

Warnings:
[1] Standard Errors assume that the covariance matrix of the errors is correctly specified.

Table 3: Full description of the regression model including all features, estimated coefficients, and relevant tests for diagnosis and inference. Tests involving standard errors (std err) are only valid if the model errors follow the assumed distribution. We believe most variables are self-explanatory, but we do provide some assistance to reader: **lamb** corresponds to λ, **hdisc** corresponds to the h-discrepancy, **train_error** corresponds to the error on the source sample, **np.power(**$\diamond$**, 2)** corresponds to the square of the feature $\diamond$, presence of **:** indicates a multiplication of features (i.e., an interaction-term), and **hspace** corresponds to the type of classifier used (i.e., linear model or fully-connected network).

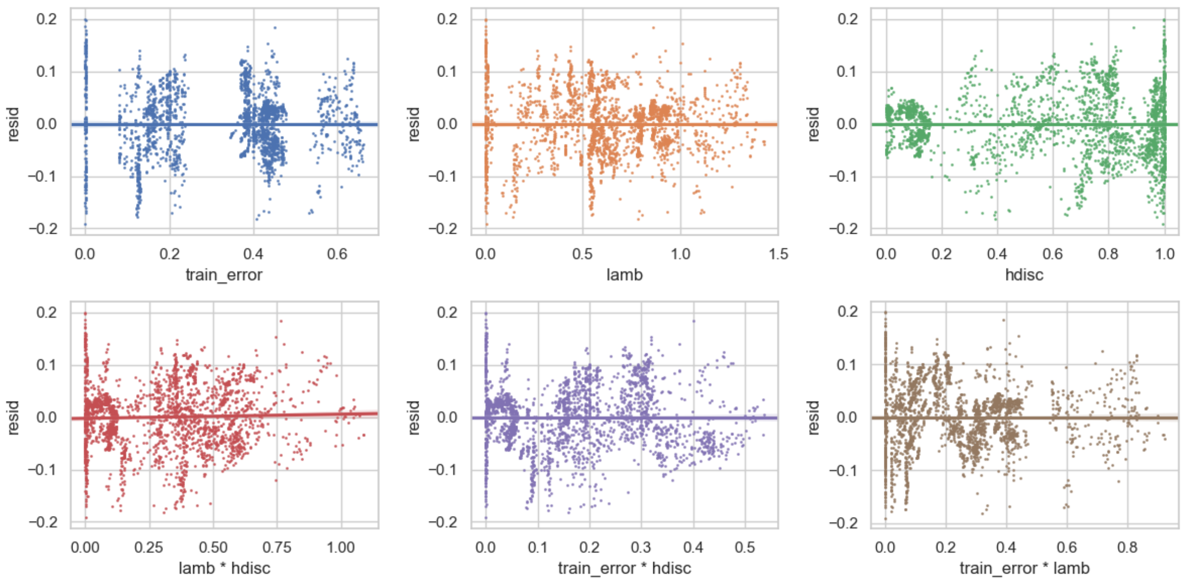

Figure 7: Residual plots. Vertical axes show realized error terms, while horizontal axes show value of some feature that may or may not be in our design matrix. Significant patterns may indicate a missing term in our model. While some patterning may exist, we choose not to include additional terms for reason of interpretability and to meet other (quantifiable) model assumptions.

MUKAYESE: Turkish NLP Strikes Back

Abstract

Having sufficient resources for language X lifts it from the *under-resourced* languages class, but not necessarily from the *under-researched* class. In this paper, we address the problem of the absence of organized benchmarks in the Turkish language. We demonstrate that languages such as Turkish are left behind the state-of-the-art in NLP applications. As a solution, we present MUKAYESE, a set of NLP benchmarks for the Turkish language that contains several NLP tasks. We work on one or more datasets for each benchmark and present two or more baselines. Moreover, we present four new benchmarking datasets in Turkish for language modeling, sentence segmentation, and spell checking. All datasets and baselines are available under: `https://github.com/alisafaya/mukayese`

1 Introduction

Although some human languages, such as Turkish, are not classified as under-resourced languages, only a few research communities are working on them (Joshi et al., 2020). As a result, they are left behind in developing state-of-the-art systems due to the lack of organized benchmarks and baselines. In this study, we aim to address this gap for the Turkish language with MUKAYESE (Turkish word for "comparison/benchmarking"), an extensive set of datasets and benchmarks for several Turkish NLP tasks.

We survey several tasks in Turkish NLP and observe an absence of organized benchmarks and research. We demonstrate how the lack of benchmarks affects under-studied languages such as Turkish and how it can keep the state of research behind the state-of-the-art of NLP. We accomplish this by presenting state-of-the-art baselines that outperform previous work significantly. We believe that MUKAYESE will set a basis for boosting NLP research for Turkish. Therefore, we encourage research communities from other under-studied languages to follow a similar path.

In our work on MUKAYESE, we study seven NLP tasks in the Turkish language. We evaluate available datasets in Turkish for these tasks and describe the process of creating four new datasets for tasks that do not have accessible datasets. Furthermore, in addition to evaluating existing methods, we provide at least two baseline models/methods per task. More details are enlisted in Table 1.

Our overall contribution to Turkish NLP can be summarized as the following: (a) Set of seven organized benchmarks for NLP. (b) Four new datasets in Turkish for language modeling, sentence segmentation, as well as spellchecking and correction. (c) Dataset splits for fair benchmarking. (d) Several replicable baselines for each task. (e) Benchmarking state-of-the-art methods on Turkish.

Moreover, Mukayese is a part of the Turkish Data Depository (TDD) project[1]. The main goal of TDD is collecting and organizing Turkish Natural Language Processing NLP resources and providing a research basis for Turkish NLP.

The rest of the paper is organized as follows: We review similar efforts in Section 2. Then, we advert to benchmarks and NLP in Section 3. Next, we give a background on the Turkish language resources in Section 4. We explain the approach we follow for each task in Section 5, and we provide dataset details, evaluation results, and explain the baselines for each task in Section 6.

2 Related Work

In this section, we discuss efforts similar to ours. We give an overview of efforts on building multilingual benchmarks, and we mention some of the monolingual benchmarks as well.

Table 1: List of the NLP Tasks we work on for the Turkish language in MUKAYESE. We list the datasets, metrics, and baselines we use for each task. New datasets presented in this paper are marked in **bold**, and ones for which we present train/test splits are marked in *italic*.

There exist various endeavors at building multilingual benchmarks. One example for this is XTREME (Hu et al., 2020), a multilingual benchmark containing 40 different languages and nine different tasks. These tasks include Classification, Named Entity Recognition (NER), and Question Answering (QA). However, most of these datasets are created by translating existing English datasets manually or automatically. Therefore, they have limitations and cannot be utilized to build a research basis in a specific language.

There are several benchmarks for NLP tasks for both low-resource and high-resource languages when it comes to monolingual benchmarks. Duh et al. (2020) proposes a benchmark for two low-resourced African languages on Neural Machine Translation (NMT), namely Somali and Swahili. Similarly, there are efforts to build benchmarks for high-resource but under-studied languages such as ALUE benchmark for Arabic (Seelawi et al., 2021), and KLEJ benchmark for Polish (Rybak et al., 2020). Both benchmarks focus on Natural Language Understanding (NLU). Most of these benchmarks have public leaderboards to disseminate studies in NLP for their languages.

While most of previous benchmarks focus on one task such as NLU or NMT, MUKAYESE covers a comprehensive set of NLP tasks with seven different benchmarks on a variety of tasks. The reasoning behind this is to catalyze the research of Turkish NLP, and encourage research in all NLP applications.

3 Benchmarks and NLP

Following the research on NLP over the years, we can observe how datasets and benchmarks are fundamental. In this section, we discuss the importance of benchmarks for the progress of NLP.

Benchmarks are very essential for measuring the progress of NLP. For instance, the SQuAD dataset (Rajpurkar et al., 2016) is used to examine the progress of English Question Answering, and GLUE (Wang et al., 2018), SuperGLUE (Wang et al., 2019) provide benchmarks for English Language Understanding.

Such progress has been enabled by the existence of benchmarks, which allowed for fair and meaningful comparison, and showed if there is room for improvement. In addition, organized benchmarks and datasets enable the research community to make progress with minimal amount of domain knowledge.

This is especially important when it comes to languages with fewer speakers, and research communities are more likely to contribute when such organized tasks are presented (Martínez-Plumed et al., 2021). Thus, this is essential if we want to include other communities in the development of under-resourced and under-studied languages.

However, there are several things to keep in mind when dealing with benchmarks and leaderboards. Such leaderboards should be created transparently, and the results need to be evaluated with all factors taken into account. Some of these factors are model size, energy efficiency, and generalization (Linzen, 2020). Otherwise, we can run into the risk of these leaderboards resulting in inefficient and non-robust models. Ethayarajh and Jurafsky (2020) describe a few limitations of current leaderboards and suggest practices to mitigate these limitations.

We take these practices into account and present the benchmarks of MUKAYESE. We provide more details about our methodology in Section 5.

4 Background on Turkish

The Turkish language has distinctive characteristics compared to well-studied languages in the literature, such as English, Spanish, and German. Due to its agglutinative morphological nature, Turkish nouns can produce more than 100 inflected forms, while verbs can produce even more (Oflazer and Saraçlar, 2018). Therefore benchmarks designed for English are not necessarily applicable for Turkish.

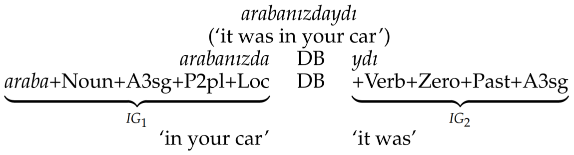

Figure 1: An example of a word constituting multiple inflectional groups (Eryiğit et al., 2008).

Unlike many other languages, a single word can constitute multiple different inflectional groups. An example is displayed in Figure 1. We provide more details on the features of the Turkish language in Appendix A.

There are several attempts at constructing comprehensive sets of resources and evaluation for Turkish. Sak et al. (2008) introduced a morphological parser, and a morphological disambiguator accompanied by a web corpus. More recently, Eryiğit (2014) proposed an online Turkish NLP Pipeline, which includes Normalization, Tokenization, Morphological Analysis, NER, and Syntactic Parsing.

However, among previously proposed methods and datasets, none are presented in a comparative way. This study aims to make a comprehensive inventory of different tools, corpora, and evaluation measures for the Turkish language. Such inventory may be used for researchers and practitioners who are looking for tools and datasets for Turkish NLP.

5 Methodology

In MUKAYESE, we focus on under-researched tasks of NLP in the Turkish language. After defining the task and assessing its importance, we construct the following three key elements for each benchmark:

Datasets are the first element to consider when it comes to a benchmark. We define the minimum requirements of a benchmark dataset as follows: (i) accessible with reasonable size. (ii) Satisfactory quality. (iii) A publicly shareable, compliant applicable regulations (GDPR licensing).

We chose the dataset sizes in a task-specific manner, unless used in a few-shot setting, benchmarks with small datasets will lack generalizability, and models trained on them might suffer from overfitting. On the other hand, training models on enormous datasets might be costly and inefficient (Ethayarajh and Jurafsky, 2020).

Another feature to assess is the quality of the dataset. A manually annotated dataset with a low Interannotator Agreement (IAA) rate is not suitable for benchmarking. Moreover, to build a generalizable benchmark, we need to consider using a dataset representing the general domain. For instance, sentence segmentation methods of editorial texts do not work on user-generated content such as social media posts, as we show in Subsection 6.4.

Metrics are the second element of benchmarks. We need to decide on one or more evaluation metrics to evaluate and compare methodologies. In order to do so, we have to answer the following questions: (a) Does this metric measure what our task aims to do? (b) How well does it correlate with human judgment? (c) Are there any issues/bugs to consider in these metrics? (For example, using accuracy to measure performance on an unbalanced set does not give a representative idea of model performance).

Baselines are the final element of benchmarking. In order to characterize the performance characteristics of different methodologies, it is better to diversify our baselines as much as possible. For instance, we can compare pretrained vs. non-pretrained approaches, rule-based systems vs. trained systems, or unsupervised vs. supervised models.

6 Tasks

We provide benchmarks in the form of Datasets, Metrics, Baselines triplets for each of the following NLP tasks:

6.1 Language Modeling

Auto-regressive language modeling is a generative process, which focuses on modeling the probability $P(X)$ of a text sequence of n tokens, where $X = (x_1, x_2, ..., x_n)$, and $P(X) = \prod_{i=1}^{n} P(x_i|x_{<i})$. This type of language modeling is known as Autoregressive (AR) or causal language modeling. The main objective of the model is to learn to estimate the probability of a given text sequence.

In our work, we focus on neural approaches for this task (Bengio et al., 2003), where we present two new benchmarking corpora for AR language modeling and report the results of two different baseline models.

Datasets We present two different corpora for AR language modeling, namely TRNEWS-64 and TRWIKI-67, along with their train/validation/test splits. These corpora are presented in a similar fashion to enwik8 (Hutter, 2006) and WikiText (Merity et al., 2017) English corpora. We provide statistics about these corpora in Table 10 in Appendix C.1.

TRWIKI-67 is a language modeling corpus that contains 67 million words of raw Turkish Wikipedia articles. We extracted this corpus from a recent Turkish Wikipedia dump[2] using WikiExtractor (Attardi, 2015). Additionally, further preprocessing was applied to get rid of the redundant text. Only the articles' raw text and titles were kept and presented in their cased format (with no upper/lower case transformations).

Due to the agglutinative nature of the Turkish language, most of the words are derived by combining one or more suffixes with one of the roots (Oflazer and Saraçlar, 2018). To make use of this attribute of the Turkish language, we train a sentencepiece unigram model (Kudo, 2018) with a vocabulary size of 32K, only using the training split of the corpus. Although we advise using the tokenized version of this corpus to encourage reproducibility, we provide a raw version of this corpus that can be utilized as a benchmark for language modeling tasks on a character, subword, or word level.

TRNEWS-64 is another language modeling corpus that contain 64 million words of news columns and articles that was retrieved from TS Timeline Corpus (Sezer, 2017). It can be utilized as a benchmark for modeling long-range dependencies in the Turkish language, as it contains relatively long documents (See Table 10). This corpus consists of a mix of news articles collected from different journals about various domains and topics. Since TRNEWS-64 is intended for language modeling on character level, articles were lightly pre-processed, and no further tokenization was applied. We provide more details about TRNEWS-64 and TRWIKI-67 in Appendix C.1.

Metrics Language models are trained on minimizing the negative log-likelihood (NLL) of the training set, and their performance is measured based on how well they can generalize on the test set:

$$\text{NLL}(X_{test}) = -\frac{1}{n}\sum_{i=1}^{n} log\ p_\theta(x_i|x_{test}< i) \quad (1)$$

Word or sub-word level language models are evaluated using the word perplexity (PPL) metric, a derivative of NLL. On the other hand, character language models are evaluated using entropy-based Bits-per-character (BPC) metric, which is also another derivative of NLL (Huyen, 2019). We consider PPL for the evaluation of models on TRWIKI-67, and BPC for TRNEWS-64. Note that lower is better for both metrics.

We note that PPL needs to be computed with the same count of tokens, otherwise it needs to be normalized (See Appendix C.1). Moreover, models considered to be evaluated using either of these corpora, are meant to have no training data other than that corpus' training split.

Baselines We consider two baseline models of different families. The first one is Single Headed Attention - RNN (SHA-RNN) (Merity, 2019), which is a Recurrent Neural Network-based language model, and the second is Adaptive Transformer (ADAP.TRANS) (Sukhbaatar et al., 2019), which is based on Transformer architecture (Vaswani et al., 2017). We choose these models for two main reasons. First, we want to compare

---

	TRWIKI-67		TRNEWS-64	
	#PARAM	PPL	#PARAM	BPC
ADAP.TRANS	92M	14.64	38M	1.024
SHA-RNN	87M	**12.54**	53M	**0.938**

Table 2: Results of language modeling baseline models, with their no of parameters. Perplexity (PPL) is reported for TRWIKI-67, and Bits-per-char (BPC) for TRNEWS-64, on their test sets.

models from different families (RNNs vs. Transformers). Second, compared to their counterparts such as (Lei, 2021; Dai et al., 2019), these models represent the state-of-the-art when it comes to the ratio of performance to the training cost and the number of parameters. For more details on the training refer to Appendix C.1.

In Table 2, we provide the results of these models, which we train and evaluate separately on TRWIKI-67 and TRNEWS-64 corpora (See Table 10 for more details on the splits of each corpus).

Note that even though we follow the same architectural settings for character-level and subword-level modeling, different tokenization algorithms of TRWIKI-67 (subword-level) and TRNEWS-64 (character-level) lead to different vocabulary sizes, which leads to a difference in the number of parameters.

Unlike the case for the English language (Merity, 2019), SHA-RNN performed better than Adaptive Transformer for both of the presented Turkish corpora. This implies the necessity of establishing such benchmarks for other languages as well. We leave investigating this feature for future research.

6.2 Machine Translation

Machine translation is the problem of translating a piece of text from one language to another. Over the years, neural machine translation models have become dominant, especially in low resource settings, benefiting from transfer learning (Zoph et al., 2016). In this work, we focus on evaluating neural machine translation models for translation between English and Turkish languages. We provide the results of three different baselines on two datasets.

Datasets The first dataset we evaluate is the Turkish-English subset of WMT-16[3], it consists of manually translated Turkish-English sentence pairs. The second one is the Turkish-English subset of Multilingual Speech Translation Corpus (MuST-C) (Di Gangi et al., 2019). For details on the split refer to Table 12 in Appendix C.3.

Metrics We evaluate our models on the relevant test sets for translation in both directions. We utilize BLEU Score (Papineni et al., 2002) for the assessment of translation quality.

	WMT-16		MUST-C	
	tr-en	en-tr	tr-en	en-tr
from scratch				
Stahlberg et al. (2018)	19.17	13.61	-	-
CONVS2S (180M)	13.22	12.78	21.79	13.3
TRANS. (58M)	17.29	15.72	27.01	15.52
pre-trained				
MBART50 (680M)	**24.17**	**18.54**	**32.97**	**19.61**

Table 3: BLEU scores of machine translation baselines. Results are provided for translations in both directions.

Baselines In this task, we train three different models. First, we train a TRANSFORMER (Vaswani et al., 2017) with the same settings for the encoder and the decoder parts, where we use 6 layers, with 4 attention heads each, and hidden size of 512. Second, we utilize the Convolutional sequence-to-sequence CONVS2S model (Gehring et al., 2017) following the same settings. The last model is mBART 50 (Tang et al., 2020), a multilingual model pre-trained on 50 different languages, which we fine-tune for each dataset separately.

In Table 3, we present BLEU score of the models on each translation dataset in both directions. The benefit of pre-training can be seen in the case of MBART50, where it outperforms the counterparts that we train from scratch. Additionally, we compare our work to the results reported by Stahlberg et al. (2018) on WMT-16. Their model is based on fusing language model decoding into seq2seq model with dot-attention (Luong et al., 2015).

6.3 Named-Entity Recognition (NER)

We include the Named-Entity Recognition (NER) task in our set of benchmarks, as it has an essential role in NLP applications. In this task, words representing named-entities are detected in the text input and assigned one of the predefined named-entity classes such as *Person* or *Location* (Chinchor and Robinson, 1998). We benchmark three different models on two NER datasets for Turkish and compare our work with previous work.

Datasets The first dataset we use is MILLIYET-NER (Tür et al., 2003), which is a set of manually, annotated news articles from the Turkish Milliyet

---

[3] http://www.statmt.org/wmt16/

news resource[4]. The second is the Turkish subset of the semi-automatically annotated Cross-lingual NER dataset WIKIANN or (PAN-X) (Pan et al., 2017), which consists of Turkish Wikipedia articles. Both datasets have three entity classes as shown in Table 11 in Appendix C.2.

Metrics Following previous work on Turkish NER (Yeniterzi, 2011; Şeker and Eryiğit, 2012), we report the CoNLL F-1 metric (Tjong Kim Sang, 2002) to assess our NER baselines. CoNLL F-1 counts a named entity as correct, only if it is an exact match of the corresponding entity in the ground truth.

	MILLIYET	WIKIANN
(Yeniterzi, 2011)	91.56	-
(Şeker and Eryiğit, 2012)	91.94	-
(Güngör et al., 2018)	93.37	-
BILSTM-CRF	95.54	**93.8**
BERTURK	95.31	92.82
BERTURK-CRF	**96.48**	93.07

Table 4: Evaluation results (CoNLL F_1) of NER models on test sets.

Baselines We train three different baseline models for this task. One with no pre-trained embeddings, which utilizes bi-directional Long Short Term Memory with Conditional Random Fields (BILSTM-CRF) (Panchendrarajan and Amaresan, 2018). The remaining two models employ pre-trained representations from BERT (Devlin et al., 2019). In one of the models, we investigate the benefit of adding a CRF layer on top of BERT. As for the pre-trained BERT model, we use BERTURK base, which is pre-trained on a large Turkish corpus (Schweter, 2020).

In Table 4, we provide the evaluation results (CoNLL F_1) for the three baselines on both datasets' test sets. Additionally, we compare our results with previous work of (Yeniterzi, 2011; Şeker and Eryiğit, 2012; Güngör et al., 2018) on the MILLIYET-NER dataset. We note that CoNLL F_1 of human performance on Turkish NER is expected to be in the range of 98-99% (Tür et al., 2003).

6.4 Sentence Segmentation

Sentence segmentation is the task of detecting sentence boundaries in a given article. Despite its fundamental place in the NLP pipelines, sentence segmentation attracts little interest. Common approaches are rule-based systems that rely on cues such as punctuation marks and capital letters (Jurafsky and Martin, 2018).

Datasets We present TRSEG-41, a new sentence segmentation dataset for Turkish. This dataset consists of 300 sampled scientific abstracts from (Özturk et al., 2014), 300 curated news articles from TRNEWS-64, and a set of 10K tweets. For the scientific abstracts, our sampling rationale is to maximize the number of abbreviations that reduce the accuracy of the rule-based approaches. As for the news subset, we maximize the length of documents and the number of proper nouns. In the Twitter subset, we balance the number of multi/single sentence tweets, and preprocess the tweets by replacing all URLs with `http://some.url`, and all user mentions with `@user`.

A single annotator labels the sentence boundaries of the data samples. We present two dataset splits, one for training and development and one for testing and benchmarking. The statistics of the splits can be found in Table 13 in Appendix C.4.

Applying sentence segmentation to user-generated content such as social media posts or comments can be quite challenging. To simulate such difficult cases and expose the weaknesses of rule-based methods, we create another version of **TRSEG-41** where we artificially corrupt the boundaries of sentences. This is done by randomly converting sentences to lowercase or uppercase with 50% probability, or by removing all punctuation marks with 50% probability.

Metrics Our evaluation procedure is based on the metrics F1 score, Precision, Recall for each segment. Unlike (Wicks and Post, 2021), we evaluate our models on the entire test set, without removing sentences with ambiguous boundaries. Furthermore, in order to highlight the gap in performance, we cross-evaluate our systems on the original and corrupted set.

	F1-SCORE	PRECISION	RECALL
SPACY	0.74 / 0.37	0.76 / 0.48	0.72 / 0.30
Training (Original)			
ERSATZ	**0.89 / 0.40**	**0.98** / 0.51	0.81 / **0.33**
PUNKT	0.87 / 0.39	0.88 / **0.52**	**0.86** / 0.32
Training (Corrupted)			
ERSATZ	**0.88 / 0.40**	**0.97 / 0.51**	0.81 / **0.33**
PUNKT	0.85 / 0.39	0.86 / 0.50	**0.84** / 0.31

Table 5: Results of sentence segmentation baselines. Metrics are reported for both corrupted and clean versions of the test set in the ORIGINAL / CORRUPTED format.

---

[4] https://www.milliyet.com.tr/

Baselines For this task, we employ three methods as baseline models. ERSATZ, a context-based approach that relies on supervised training (Wicks and Post, 2021), the unsupervised PUNKT tokenizer (Kiss and Strunk, 2006), and SPACY Sentencizer tool (Montani et al., 2021). While ERSATZ utilizes the Transformer (Vaswani et al., 2017) architecture, spaCy Sentencizer is a rule-based sentence boundary detector, whereas Punkt Tokenizer relies on an unsupervised training approach.

We experiment with these models on four different training and testing set combinations, where we train using the original and corrupted training sets separately and test on both test sets. Results are presented in Table 5. In all settings, SPACY SENTENCIZER is outperformed by its trained counterparts. Among the baselines, ERSATZ performed the best. Our experiments show that deep learning models are more robust to corruption in the data.

Please refer to Appendix C.4 for dataset creation process and samples, and an analysis on the behaviour of our baselines.

6.5 Spellchecking and Correction

Spellcheckers are among the most widely used NLP tools. The basic task is to check for misspellings in an input and suggest a set of corrections. Different methods can be employed for error correction, such as looking up words that minimize the edit distance from a dictionary or utilizing probabilistic models with N-grams to suggest the most likely correct word based on the context (Jurafsky and Martin, 2018). Due to the complexity of the Turkish Morphology, it is possible to derive over a hundred of words from one verb (Oflazer and Saraçlar, 2018). This makes the spellchecking task quite challenging. Hence, we focus on contextless (single word) spellchecking and correction as a start, and leave in-context spellchecking for future work.

We present a new benchmarking dataset for contextless spellcheckers and a computationally efficient and accurate dictionary for Turkish.

Datasets We present **TRSPELL-10**, a dataset of 10K words, for benchmarking spellchecking and correction. The dataset consists of tuples of input and correct (gold) words.

To create this dataset, we randomly sample 8500 Turkish words from the TS Corpus Word List (Sezer, 2013, 2017). We create artificial misspellings by applying random insertions, deletions, and substitutions on 65% of the words, where we apply at most two operations on the same word. The remaining 35% of the words are unchanged. Moreover, we add 1K random foreign words, and 500 randomly generated word-like character sequences.

As a quality check of these artificial misspellings, given a list of corrupted words, we ask our annotators to provide us a list of suggestions up to 10 suggestions per word. Their suggestion lists had the gold output 91% of the time.

Metrics We evaluate spellcheckers' ability to detect misspellings using the macro-averaged F1-Score metric. Additionally, we evaluate their spell correction accuracy (SCA) based on the suggestions provided for misspelled words.

	SCA	F1
HUNSPELL-TR (Zafer, 2017)	25.52	86.52
ZEMBEREK (Akın and Akın, 2007)	62.12	96.56
OUR HUNSPELL	**71.72**	**99.62**

Table 6: Spell correction accuracy (SCA) and macro-averaged F1 scores of spellchecking methods on TRSPELL-10.

Baselines We take advantage of the agglutinative nature of the Turkish language by developing a Hunspell-based (Trón et al., 2005) dictionary for Turkish. Using a list of 4M words we filter from Web crawls and Turkish corpora, we optimize the splits that minimize the size of the root dictionary and the affix list.

We compare this dictionary to HUNSPELL-TR (Zafer, 2017) another Hunspell-based Turkish dictionary, and to ZEMBEREK spellchecker (Akın and Akın, 2007), which is designed based on morphological features of the Turkish language. As shown in Table 6, our dictionary surpasses other baselines in terms of both error correction accuracy and error detection ability.

For dataset creation process and samples, please refer to Appendix C.5.

6.6 Summarization

Abstractive text summarization is the task of generating a short description (summary) of an article (longer text). Formally, given a sequence of tokens (input article) $X = (x_1, x_2, ..., x_n)$ and its summary $Y = (y_1, y_2, ..., y_m)$, the main task is to model the conditional probability: $P(Y|X) = \prod_{i=1}^{m} P(y_i|y_{<i}, X)$.

For this task, we work on the Multi-lingual Summarization (MLSUM) dataset (Scialom et al., 2020) and present state-of-the-art summarization results for Turkish.

Datasets MLSUM is a multi-lingual dataset for abstractive summarization. This dataset consists of a large set of crawled news articles with their abstracts in multiple languages. We focus on the Turkish subset of MLSUM.

We removed 4378 duplicated instances and 12 overlapping instances among the splits while assessing the dataset's quality. Further details in Appendix C.6.

Metrics To assess the quality of the generated summaries, we use the N-gram co-occurrence-based ROUGE-L (Lin, 2004) and METEOR (Banerjee and Lavie, 2005) metrics. We report two different results for each model, one on the original, and one for the cleaned set.

	ROUGE-L	METEOR
(Scialom et al., 2020)	32.90/ –	26.30/ –
TRBART (120M)	35.54/35.08	26.47/25.81
MBART50 (680M)	39.21/38.47	30.84/30.36
MT5-BASE (220M)	**39.92/38.76**	**31.72/31.47**

Table 7: Evaluation of different models on MLSUM test set along with their no of parameters. Metrics are calculated for both (Original/Cleaned) test sets.

Baselines As a baseline model for summarization, we present TRBART, a Seq2Seq Transformer (Vaswani et al., 2017) trained following the configuration of BART Base (Lewis et al., 2020), which is a state-of-the-art model for abstractive summarization in English.

Moreover, we fine-tune two different pre-trained models. The first model is Multilingual BART (MBART50) (Tang et al., 2020), which is pre-trained on data from 50 different languages. The second model is Multilingual Text to Text Transformer (MT5-BASE) (Xue et al., 2021). As shown in Table 7, all models perform better than the best proposed baseline (Scialom et al., 2020), which follows the UniLM architecture (Dong et al., 2019).

6.7 Text Classification

Text classification can be utilized in several applications such as sentiment analysis or topic identification. In this task we take a sequence of text as an input, and output a probability distribution over the given classes. In our work on Turkish we benchmark three models on two datasets from different domains.

	OFFENSEVAL	NEWS-CAT	Avg.
BILSTM	0.747	0.808	0.777
CNN-TEXT	0.751	0.883	0.817
BERTURK	**0.823**	**0.944**	**0.883**

Table 8: Evaluation results (macro averaged F1-Score) of our baseline models for text classification task. The last column represent the average F1-scores of each model.

Datasets We work on the news categorization (NEWS-CAT) dataset (Amasyalı and Yıldırım, 2004). In this dataset, news articles are labeled with one of the following five categories *health, sports, economy, politics, magazine*. There is no splits provided in the original work for NEWS-CAT dataset. Hence we shuffle the dataset and construct our own splits in a stratified way, keeping the class distribution balanced across splits. We use 750 samples for training, 150 samples for validation, and 250 samples for testing. More details on the dataset can be found in Appendix C.7.

Since no information about the quality of annotation or Inter-annotator Agreement (IAA) rates were provided in for NEWS-CAT (Amasyalı and Yıldırım, 2004), we applied a quality assessment by re-annotating the test set. We asked three annotators to label the documents of test set with one of the given five categories. The annotators agreed with the gold annotation with an average IAA rate of FLEISS $\kappa = 0.88$.

The second dataset is the corpus of Offensive Speech Identification in Social media (OFFENSEVAL) (Çöltekin, 2020). This dataset was collected from Twitter, where the tweets are annotated for offensive speech with *offensive*, or *non-offensive* labels. We choose these datasets for benchmarking since they vary in domain and average article length.

Metrics We use the macro averaged F1-Score to account for the imbalance in classes within the datasets.

Baselines We measure the performance of three deep learning models—one with pre-training and two without pre-training. The pre-trained model is the BERT (Devlin et al., 2019) based Turkish pre-trained (BERTURK) model (Schweter, 2020). The remaining two models employ randomly initialized word embeddings of size 256. In one of them we use two layers of Bidirectional

LSTM (BiLSTM) (Hochreiter and Schmidhuber, 1997) with a hidden size of 256. In the other model (CNN-Text), we use Convolutional Neural Networks for Sentence Classification (Kim, 2014) with 32 filters instead of 2.

Looking at F1 scores in Table 8, we can observe the advantage of pre-trained BerTurk model over BiLSTM and CNN-Text.

7 Conclusion

We believe that while some languages such as Turkish do not fall under the definition of under-resourced languages, they attract relatively little research interest as a result of the lack of organized benchmarks and baselines. To address this problem, we presented Mukayese, a comprehensive set of benchmarks along with corresponding baselines for seven different tasks: Language Modeling, Machine Translation, Named Entity Recognition, Sentence Segmentation, Spell Checking and Correction, Summarization, and Text Classification, as well as four new benchmarking datasets in Turkish for Language Modeling, Sentence Segmentation, and Spell Checking and Correction. For future work, the same methodology can be followed to include more tasks such as Dependency Parsing, Morphological Analysis, coreference resolution. We hope that Mukayese encourages more researchers to get involved in the development of Turkish NLP, and it sets an example and leads to an increase in efforts on under-researched languages.

A Turkish Language

Even though in formal language the Subject-Object-Verb order is predominantly used, Turkish is a free-order language, meaning that words can freely change order depending on the context without changing the meaning but only the accentuation. The English sentence "I am going to school." can be translated into Turkish as "Ben okula gidiyorum." where all 6 permutations of the words are valid and meaningful:

- *Ben okula gidiyorum*
- *Ben gidiyorum okula*
- *Gidiyorum ben okula*
- *Gidiyorum okula ben*
- *Okula gidiyorum ben*
- *Okula ben gidiyorum*

In Turkish, morphologically ambiguous words are common in running texts. Depending on the context, the same word can have varying morphological features. For instance, the word "masalı" can correspond to the following:

masal+Noun+A3sg+Pnon+Acc(=the story)
masal+Noun+A3sg+P3sg+Nom(=his story)
masa+Noun+A3sg+Pnon+Nom^DB+Adj+With(=with tables)

Given all these language features, Turkish language needs special attention by the research community, and we cannot assume that methods with good performance on English would yield good results on Turkish.

B Computational Costs and Implementations

We utilize NVIDIA TESLA V100 GPUs with 32GBs of memory for training our baselines. In Table 9, we depict approximate estimations of the training time for each of our compute-intensive baselines.

The implementations of TRANSFORMER (Vaswani et al., 2017), and CONVS2S (Gehring et al., 2017) are based on the open-source library Fairseq (Ott et al., 2019). We use the Flair library (Akbik et al., 2019) for the BERT-CRF model in the Named Entity Recognition task. The remaining deep learning models used as our baselines are either implemented using the Huggingface Transformers library (Wolf et al., 2020). All reported experiments and implementations of deep learning models are performed using PyTorch (Paszke et al., 2019).

Model	Dataset	GPU Hr	Batch S.

C Datasets and Baselines

C.1 Language Modeling

We provide some samples from TRWIKI-67 and TRNEWS-64 corpora in Table 16. These corpora are presented with minimal pre-processing. We remove non-Turkish characters and redundant texts such as category lists and tables from TRWIKI-67. Sentences and words are counted based on `sent_tokenize`, `word_tokenize` methods of NLTK (Bird et al., 2009).

	#articles	#words	#tokens	avg.sent
TRWIKI-67				
Training	374K	63.5M	139M	12.8
Validation	10K	1.7M	4M	13.3
Test	10K	1.7M	4M	12.9
Total	394K	67M	147M	12.8
TRNEWS-64				
Training	140K	59.7M	421M	23
Validation	5K	2.1M	15M	22.8
Test	5K	2.1M	15M	22.9
Total	150K	64M	450M	23

Table 10: Statistics about TRWIKI-67 and TRNEWS-64 corpus splits. The column *avg. sents* refers to the average number of sentences per article. Tokens are characters for TRNEWS-64 and sentencepiece tokens for TRWIKI-67.

We follow the same architectures proposed by (Merity, 2019; Sukhbaatar et al., 2019). The only difference in architecture is based on vocabulary size due to difference in training data. For training, we use vocabulary size of 32K sentencepiece for TRWIKI-67, and 124 for TRNEWS-64 which includes the Turkish alphabet with punctuation and some other common characters. We train both models until no improvement over the validation set, then following the original implementation we lower the learning-rate, dividing it by 10 and run until no improvement on the validation set again.

C.1.1 Normalizing perplexity

The Perplexity metric is defined as the exponent of the average entropy over a corpus (Mikolov et al., 2011):

$$\textsc{Ppl}(X_{test}) = exp(-\frac{1}{N}\sum_{i=1}^{n} log\ p_\theta(x_i|x_{test} < i)) \quad (2)$$

where N is the original number of tokens in X_{test}, and n is the number of tokens of X_{test} when tokenized using a certain tokenization algorithm. Depending on what tokenization is used, N might or might not be equal to n. To accommodate this issue, N should always be the same when calculating perplexity for different models (Shoeybi et al., 2019).

C.2 Named Entity Recognition (NER)

We provide statistics about dataset splits for both Milliyet-NER and WikiANN in Table 11.

	Training	Validation	Test
WikiANN			
Location	9679	5014	4914
Organization	7970	4129	4154
Person	8833	4374	4519
Total words	149786	75930	75731
Milliyet-NER			
Location	8821	942	1126
Organization	8316	842	873
Person	13290	1400	1603
Total words	419996	45532	49595

Table 11: Distribution of Named entities over classes in Milliyet-NER and WikiANN datasets.

C.3 Machine Translation

We utilize two datasets for Machine Translation, WMT-16 dataset, which was presented at the first Conference of Machine Translation (WMT), and MuST-C dataset. This corpus was extracted from movies and TV shows subtitles. Statistics of both datasets are presented in Table 12.

	#Sentences	#Words
Turkish		
MuST-C	236K / 1.3K / 2K	3.4M / 19K / 33K
WMT-16	205K / 1K / 3K	3.6M / 14K / 44K
English		
MuST-C	236K / 1K/ 2K	4.6M / 26K / 45K
WMT-16	205K / 1K / 3K	4.4M / 19K / 58K

Table 12: Statistics of machine translation datasets. Each cell represents the (Train / Validation / Test) values of the datasets in the corresponding row. Wmt-16 and MuST-C refer to Turkish-English subsets.

C.4 Sentence Segmentation

In this section, we provide additional information for our Sentence Segmentation 6.4 Benchmark.

In both clean and corrupted training cases, ErSatz and Punkt are trained with all subsets. Following the authors, our baseline model ErSatz is trained without changing the original architecture with a vocabulary size of 500, left and right context of 5 for 100 epochs using early stopping. We use the NLTK (Bird et al., 2009) implementation of the Punkt tokenizer (Kiss and Strunk, 2006) for both training and testing purposes. The spaCy tokenizer (Montani et al., 2021) is used with the default settings provided by the library.

	#Articles	#Sentences	#Words
News	300	6K	102K
Tweets	10K	28K	242K
Abstracts	300	6K	112K
Total	10.6K	40K	456K

Table 13: Statistics of TrSeg-41 dataset.

Table 18 provides examples from each subset of the TrSeg-41 dataset along with their corrupted versions. The dataset is annotated by a single human. The reason for maximizing the number of abbreviations and proper nouns is that rule-based methods are designed to be sensitive to local language features such as periods and capital letters. In editorial texts, sentence segmentation can achieve high success. Therefore, we apply automated random corruption process as described in Section 6.4. The rationale behind this is to eliminate the aforementioned context for rule-based approaches and to promote learning methods.

Table 19 shows examples of the results of our baselines. The results show that while the models are able to perform successful sentence segmentation on clean editorial text, they experience an evident drop in performance on corrupted versions.

C.4.1 F1-Score

In this benchmark, we compare the performances of the models via F1-Score. For sentence segmentation, we define F1-Score as the accuracy measure of the position of the dots in a given piece of text among spaced tokens. This means that for a paragraph containing N words, all words are separated as distinct tokens, leaving $N-1$ locations to place the dots as separators. Our measure is based on the correctness of the placed dots in this given setting. We calculate F1-Score in the following way:

$$\frac{TP}{TP + 1/2(FP + FN)} \tag{3}$$

where TP is true positive rate, FP is false positive rate, and FN is false negative rate. Our calculation is based on the *Scorer* submodule of the spaCy library.

C.5 Spellchecking and Correction

In this section, we provide a detailed description of the spellchecking dataset with the statistics about the word set and corruption methods.

The dataset consist of 10K words it total, and includes pairs of gold and corrupted words. 8500 words are randomly sampled from TS Corpus Word List (Sezer, 2013, 2017), 1K random words are included from foreign language and 500 randomly generated word-like character sequences are added.

For 70% of the sampled Turkish words, we apply one corruption with 70% probability, two corruptions with 25% probability and three corruptions with 5% probability. The following corruption methods with their probability distribution is applied for a single corruption:

- For a probability of 1/2, the word is asciified.
- For a probability of 1/6, a random character in the word is substituted by another character sampled from a distribution simulating the placement of keys in standard Turkish-Qwerty keyboards.
- For a probability of 1/6, a random character is inserted into the word sampled from a distribution simulating the placement of keys in standard Turkish-Qwerty keyboards.
- For a probability of 1/6, a random character is deleted from a word sampled from a distribution simulating the placement of keys in standard Turkish-Qwerty keyboards.

The remaining 30% of the words are uncorrupted, therefore their gold and input versions are same. For evaluating against inserted foreign words and randomly generated character sequences where no gold output exists, we use an empty string as the gold output.

C.6 Summarization

We remove these instances from the dataset for a more accurate evaluation and evaluate our models on both the original and the cleaned sets. In Table 14, we provide some statistics about both sets, before and after the deduplication.

	Original	Cleaned
Avg. article length	259.1	258.4
Avg. summary length	18.5	18.3
Splits		
Training	249277	246490
Validation	11565	10852
Test	12775	11897
Total	273617	269239

Table 14: Statistics of the Turkish subset of MLSUM. The number of samples is provided for each split before and after the deduplication.

We provide summaries predicted by our models in Table 17.

C.7 Text Classification

In table 15, we provided statistics about both of the datasets we used for text classification task.

	OFFENSEVAL	NEWS-CAT
Avg. #words	8.5	227.3
#Classes	2	5
Splits		
Training	28000	750
Validation	3277	150
Test	3515	250
Total	34792	1150

Clean Abstract Sample:

Bu çalışmanın amacı, bayan ve erkek voleybolcular ile güreşçilerin statik, yaylanarak, düşerek ve tekrarlı sıçrama performanslarını karşılaştırmaktır.
Bu çalışmaya Yaşar Doğu Beden Eğitimi ve Spor Yüksekokulunda okuyan 2. ve 3. Ligde mücadele eden 20 bayan voleybolcu, 20 erkek voleybolcu ile Milli 20 erkek güreşçi gönüllü olarak katılmıştır.
Bayan voleybolcuların yaş ortalaması 21.15 yıl, voleybolcu erkeklerin 20.80 yıl ve güreşçilerin 20.60 yıldır.
Bütün denekler statik sıçrama, yaylanarak sıçrama, düşerek sıçrama ve tekrarlı sıçrama yapmışlardır.
Sıçrama değerlerinin belirlenmesi, New Test Power Timer System 300 Series aleti kullanılarak yapılmıştır.
Ayrıca çalışmaya katılan sporcuların, beden kitle indeksi (BKİ), esneklik ve vücut yağ yüzdesi değerleri ölçülmüştür.
Üç grup arasında fark olup olmadığına bakmak amacıyla Kruskal Vallis testi, ikili karşılaştırmalarda Mann Whitney U testi kullanılmıştır.
Sporcuların karşılaştırıldığında güreşçi erkeklerin voleybolcu erkelerden daha esnek oldukları görülmüştür.
boy, vücut ağırlığı, BKI, vücut yağ yüzdesi arasında anlamlı derecede farklılık bulunmuştur.
Voleybolcu erkeklerin Düşerek, Statik, Yaylanarak ve Tekrarlı sıçrama yükseklikleri ve güçleri voleybolcu bayanlardan ve güreşçilerden yüksek bulunmuştur.
Güreşçilerin ise statik ve yaylanarak sıçrama yükseklikleri ve güçleri bayan voleybolculardan daha yüksek bulunmuştur.
Erkek voleybolcuların sıçrama değerlerinin güreşçilerden yüksek çıkması yapılan spor branşı ile ilgilidir.
Voleybolcu bayanların sıçrama performansının güreşçi erkeklerden daha iyi olması beklenirken cinsiyet faktörünün bu durumun önüne geçtiği görülmüştür.
Sonuç olarak, yapılan spor branşının ve cinsiyetin sıçrama performansı üzerinde önemli etkisinin olduğu görülmüştür.

Kanal 2 televizyonunda, İsrail'in tanınmış gazeteci ve analistlerinden Ehud Yaari ile birlikte konuk olan Lieberman'a, "Bakanlığı döneminde hem Türkiye hem de Mısır'dan büyükelçilerin kovulduğuna" işaret edilerek, gazetede yayımlanan haberin doğru olup olmadığı soruldu.
Haberin doğru olmadığını söyleyen lieberman'a, bu kez, "Peki (Dışişleri'nde) böyle şeyler konuştunuz mu?" sorusu yöneltildi.
Lieberman, bu soruya, "Dışişleri Bakanlığı'nda her gün yüzlerce fikir tartışma konusu edilir" yanıtını verdi.
Bunun üzerine, Ehud Yaari, "Açıkça söyleyin, PKK terör örgütüne silah vs. sağlama gibi, yardım etme konusu konuşuldu mu?" diyerek, sorusunu yineledi.
Lieberman, soruya bu kez "Hayır, kesinlikle konuşulmadı" karşılığını verdi.
Lieberman, Palmer Komisyonu raporunun "Mavi Marmara" baskını ile ilgili olarak İsrail'in eyleminin ve Gazze'ye ablukanın haklı olduğunu açıkça ortaya koyduğunu da ifade etti.
Lieberman, Türkiye ile ilişkilerin normalleştirilmesinin yeniden sağlanacağı ve Türkiye'nin, böyle bir normalleşmenin çıkarına olacağını göreceği umudunda olduğunu da kaydetti.
"Alevlerin seviyesini düşürmeye çalışıyoruz" İsrail Başbakanı Binyamin Netanyahu da Türkiye ile yaşanan krizin kendi seçimleri olmadığını öne sürdü.
Türkiye ile ilişkilerin daha da kötüye gitmesini önlemeye çalıştıklarını savunan Netanyahu, halihazırda, iki ülke arasındaki "Alevlerin seviyesini düşürmeye" uğraştıklarını belirterek, "Umarım bu gerginlik, eğer karşı taraf da isterse, sona erdirilecektir" diye konuştu.

Virtual Augmentation Supported Contrastive Learning of Sentence Representations

Dejiao Zhang* **Wei Xiao** **Henghui Zhu** **Xiaofei Ma** **Andrew O. Arnold**
AWS AI Labs, New York

Abstract

Despite profound successes, contrastive representation learning relies on carefully designed data augmentations using domain-specific knowledge. This challenge is magnified in natural language processing, where no general rules exist for data augmentation due to the discrete nature of natural language. We tackle this challenge by presenting a Virtual augmentation Supported Contrastive Learning of sentence representations (VaSCL). Originating from the interpretation that data augmentation essentially constructs the neighborhoods of each training instance, we in turn utilize the neighborhood to generate effective data augmentations. Leveraging the large training batch size of contrastive learning, we approximate the neighborhood of an instance via its K-nearest in-batch neighbors in the representation space. We then define an instance discrimination task regarding the neighborhood and generate the virtual augmentation in an adversarial training manner. We access the performance of VaSCL on a wide range of downstream tasks and set a new state-of-the-art for unsupervised sentence representation learning.

1 Introduction

Universal sentence representation learning has been a long-standing problem in Natural Language Processing (NLP). Leveraging the distributed word representations (Bengio et al., 2003; Mikolov et al., 2013; Collobert et al., 2011; Pennington et al., 2014) as the base features to produce sentence representations is a common strategy in the early stage. However, these approaches are tailored to different target tasks, thereby yielding less generic sentence representations (Yessenalina and Cardie, 2011; Socher et al., 2013; Kalchbrenner et al., 2014; Cho et al., 2014).

This issue has motivated more research efforts on designing generic sentence-level learning objectives or tasks. Among them, supervised learning on the Natural Language Inference (NLI) datasets (Bowman et al., 2015a; Williams et al., 2017; Wang et al., 2018) has established benchmark transfer learning performance on various downstream tasks (Conneau et al., 2017; Cer et al., 2018; Reimers and Gurevych, 2019a; Zhang et al., 2021). Despite promising progress, the high cost of collecting annotations precludes its wide applicability, especially when the target domain has scarce annotations but differs significantly from the NLI datasets (Zhang et al., 2020).

On the other hand, unsupervised learning of sentence representations has seen a resurgence of interest with the recent successes in self-supervised contrastive learning. These approaches rely on two main components, data augmentation and an instance-level contrastive loss. The popular contrastive learning objectives Chen et al. (2020); He et al. (2020) and their variants thereof have empirically shown their effectiveness in NLP. However, the discrete nature of the text makes it challenging to establish universal rules for effective text augmentation generation.

Various contrastive learning based approaches have been proposed for sentence representation learning, where the main difference lies in how the augmentations are generated (Fang and Xie, 2020; Giorgi et al., 2020; Wu et al., 2020; Meng et al., 2021; Yan et al., 2021; Kim et al., 2021; Gao et al., 2021). Somewhat surprisingly, a recent work (Gao et al., 2021) shows that Dropout (Srivastava et al., 2014), *i.e., augmentations obtained by feeding the same instance to the encoder twice*, outperforms common data augmentations obtained by operating on the text directly, including cropping, word deletion, or synonym replacement. Again, this observation validates the inherent difficulty of attaining effective data augmentations in NLP.

Findings of the Association for Computational Linguistics: ACL 2022, pages 864 - 876
May 22-27, 2022

This paper tackles the challenge by presenting a neighborhood-guided virtual augmentation strategy to support contrastive learning. In a nutshell, data augmentation essentially constructs the neighborhoods of each instance, with the semantic content being preserved. We take this interpretation in the opposite direction by leveraging the neighborhood of an instance to guide augmentation generation. Benefiting from the large training batch of contrastive learning, we approximate the neighborhood of an instance via its K-nearest in-batch neighbors. We then define an instance discrimination task within this neighborhood and generate the virtual augmentation in an adversarial training manner. We run in-depth analyses and show that our VaSCL model leads to a more dispersed representation space with the data semantics at different granularities being better captured. We evaluate our model on a wide range of downstream tasks and show that our model consistently outperforms the previous state-of-the-art results by a large margin.

2 Related Work

Universal Sentence Representation Learning Arguably, the simplest and most common approaches for attaining sentence representations are bag-of-words (Harris, 1954) and variants thereof. However, bag-of-words suffers from data sparsity and a lack of sensibility to word semantics. In the past two decades, the distributed word representations (Bengio et al., 2003; Mikolov et al., 2013; Collobert et al., 2011; Pennington et al., 2014) have become the more effective base features for producing sentence representations. The downside is that these approaches are tailored to the target tasks (Yessenalina and Cardie, 2011; Socher et al., 2013; Kalchbrenner et al., 2014; Cho et al., 2014), and thereby the resulting sentence representations attain limited transfer learning performance.

More recent efforts focus on directly designing the sentence-level learning objectives or tasks. On the supervised learning regime, Conneau et al. (2017); Cer et al. (2018) empirically show the effectiveness of leveraging the NLI task (Bowman et al., 2015a; Williams et al., 2017) to promote generic sentence representations. The task involves classifying each sentence pair into one of three categories: entailment, contradiction, or neutral. Reimers and Gurevych (2019b) further bolster the performance by using the pre-trained transformer (Devlin et al., 2018; Liu et al., 2019) as backbone. On the other end of the spectrum, Hill et al. (2016); Bowman et al. (2015b) propose using the denoising or variational autoencoders for sentence representation learning. Kiros et al. (2015); Hill et al. (2016) extend the distributional hypothesis to the sentence level and train an encoder-decoder to construct the surrounding context for each sentence. Alternatively, Logeswaran and Lee (2018) present a model that learns to discriminate the target context sentences from all contrastive ones.

Contrastive Learning Contrastive learning has been the pinnacle of recent successes in sentence representation learning. Gao et al. (2021); Zhang et al. (2021) substantially advance the previous state-of-the-art results by leveraging the entailment sentences in NLI as positive pairs for optimizing the properly designed contrastive loss functions. Nevertheless, we focus on unsupervised contrastive learning and form the positive pairs via data augmentation since such methods are more cost-effective and applicable across different domains and languages. Along this line, several approaches have been proposed recently, where the augmentations are obtained via dropout (Yan et al., 2021; Gao et al., 2021), back-translation (Fang and Xie, 2020), surrounding context sampling (Logeswaran and Lee, 2018; Giorgi et al., 2020), or perturbations conducted at different semantic-level (Wu et al., 2020; Yan et al., 2021; Meng et al., 2021).

Consistency Regularization Our work is also closely related to consistency regularization, which is often used to promote better performance by regularizing the model output to remain unchanged under plausible input variations that are often induced via data augmentations. Bachman et al. (2014); Sajjadi et al. (2016); Samuli and Timo (2017); Tarvainen and Valpola (2017) show randomized data augmentations such as dropout, cropping, rotation, and flipping yield effective regularization. Berthelot et al. (2019, 2020); Verma et al. (2019) improve the performance by applying Mixup (Zhang et al., 2017) and its variants on top of stochastic data augmentations. However, data augmentation has long been a challenge in NLP as there are no general rules for effective text transformations. An alternative that comes to light when considering the violation of consistency regularization can in turn be used to find the most sensitive perturbation for a model. Therefore, we utilize consistency regularization to promote informative virtual augmen-

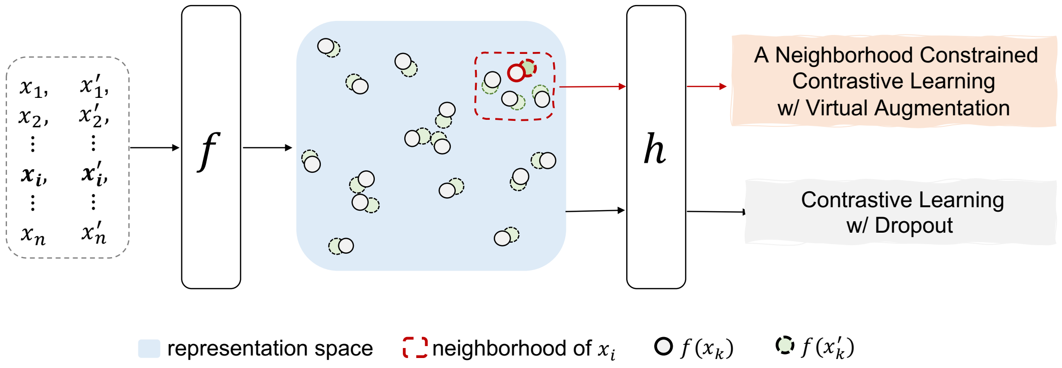

Figure 1: Illustration of VaSCL. For each instance x_i in a randomly sampled batch, we optimize (i) an instance-wise contrastive loss with the dropout induced augmentation obtained by forwarding the same instance twice, *i.e.,* x_i and $x_{i'}$ denote the same text example; and (2) a neighborhood constrained instance discrimination loss with the virtual augmentation proposed in Section 3.2.

tation for a training instance in the representation space while leveraging its approximated neighborhood to regularize the augmentation sharing similar semantic content as its original instance.

3 Method

3.1 Preliminaries

Self-supervised contrastive learning often aims to solve the instance discrimination task. In our scenario, let f denote the transformer encoder that maps the i^{th} input sentence $\mathbf{x}_i$ to its representation vector $\mathbf{e}_i = f(\mathbf{x}_i)$[1]. Further let h be the contrastive learning head and $\mathbf{z}_i = h(f(\mathbf{x}_i))$ denote the final output for $\mathbf{x}_i$. Let $\mathcal{B} = \{i, i'\}_{i=1}^{M}$ denote the indices of a randomly sampled batch of paired examples, where $\mathbf{x}_i, \mathbf{x}_{i'}$ are two independent variations of the i^{th} instance. A popular loss function (Chen et al., 2020) for contrastive learning is defined as follows,

$$\ell_{\mathcal{B}}(\mathbf{z}_i, \mathbf{z}_{i'}) = \qquad (1)$$

$$-\log \frac{e^{\mathbf{sim}(\mathbf{z}_i,\mathbf{z}_{i'})/\tau}}{e^{\mathbf{sim}(\mathbf{z}_i,\mathbf{z}_{i'})/\tau} + \sum_{j\in\mathcal{B}\setminus(i,i')} e^{\mathbf{sim}(\mathbf{z}_i,\mathbf{z}_j)/\tau}},$$

where τ is the temperature hyper-parameter and $\mathbf{sim}(\cdot)$ denotes the cosine similarity, *i.e.,* $\mathbf{sim}(\cdot) = \mathbf{z}_i^T \mathbf{z}_{i'} / \|\mathbf{z}_i\|_2 \|\mathbf{z}_{i'}\|_2$. Similarly, $\ell_{\mathcal{B}}(\mathbf{z}_{i'}, \mathbf{z}_i)$ is defined by exchanging the roles of $\mathbf{z}_i$ and $\mathbf{z}_{i'}$ in the above equation. Intuitively, Equation (1) defines the log-likelihood of classifying the i^{th} instance as its positive i' among all $2M$–1 candidates within the same batch $\mathcal{B}$. Therefore, minimizing the above log-loss guides the encoder to map each positive pair close in the representation space, and negative pairs further apart.

Dropout based contrastive learning As Equation (1) implies, the success of contrastive learning relies on effective positive pairs construction. However, it is challenging to generate strong and effective data transformations in NLP due to the discrete nature of natural language. This challenge is further demonstrated in a recent work (Gao et al., 2021), which shows that augmentations obtained by Dropout (Srivastava et al., 2014), *i.e.,* $\mathbf{z}_i, \mathbf{z}_{i'}$ *obtained by forwarding the same instance* $\mathbf{x_i}$ *twice*, outperforms the common text augmentation strategies such as cropping, word deletion, or synonym replacement. Dropout provides a natural data augmentation by randomly masking its inputs or the hidden layer nodes. The effectiveness of using Dropout as pseudo data augmentations can be traced back to Bachman et al. (2014); Samuli and Timo (2017); Tarvainen and Valpola (2017). Nevertheless, the augmentation strength is weak with Dropout only. There is room for improvement, which we investigate in the following section.

3.2 Neighborhood Constrained Contrastive Learning with Virtual Augmentation

In essence, data augmentation can be interpreted as constructing the neighborhood of a training instance, with the semantic content being preserved. In this section, we take the interpretation in the opposite direction and leverage the neighborhoods of each instance to generate the augmentation. To be more specific, let $\bar{\mathcal{B}} = \{i\}_{i=1}^{M}$ denote the indices

---

[1] By an abuse of notation, we assume f outputs either the pre-defined sentence representation (a.k.a. [CLS] embedding, (Devlin et al., 2018)), or the mean/max pooling of all tokens' embeddings of that sentence.

of a randomly sampled batch with M examples. We first approximate the neighborhood $\mathcal{N}(i)$ of the i^{th} instance as its K-nearest neighbors in the representation space,

$$\mathcal{N}(i) = \{k : \mathbf{e}_k \text{ has the top-K similarity with } \mathbf{e}_i \text{ among all other M-1 instances in } \bar{\mathcal{B}}\}$$

We then define an instance-level contrastive loss regarding the i^{th} instance and its neighborhood as follows,

$$\ell_{\mathcal{N}(i)}(\mathbf{z}_i^\delta, \mathbf{z}_i) = - \log \frac{e^{\mathbf{sim}(\mathbf{z}_i^\delta, \mathbf{z}_i)/\tau}}{e^{\mathbf{sim}(\mathbf{z}_i^\delta, \mathbf{z}_i)/\tau} + \sum_{k \in \mathcal{N}(i)} e^{\mathbf{sim}(\mathbf{z}_i^\delta, \mathbf{z}_k)/\tau}} \; . \tag{2}$$

In the above equation, $\mathbf{z}_i^\delta = h(\mathbf{e}_i^\delta)$ denotes the output of the contrastive learning head with the perturbed representation $\mathbf{e}_i^\delta = \mathbf{e}_i + \delta_i$ as input. Here, the initial perturbation δ_i is chosen as isotropic[2] Gaussian noise. As it implies, Equation (2) shows the negative log-likelihood of classifying the perturbed i^{th} instance as itself rather than its neighbors. Then the augmentation of the i^{th} instance is retained by identifying the optimal perturbation that maximally disturbs its instance-level identity within the neighborhood. That is,

$$\begin{aligned} \delta_i^* &= \arg\max_{\|\delta_i\|_2 \le \Delta} \ell_{\mathcal{N}(i)}(\mathbf{z}_i^\delta, \mathbf{z}_i) \; , \\ \mathbf{e}_{i^*} &= \mathbf{e}_i + \delta_i^* \; . \end{aligned} \tag{3}$$

For the i^{th} instance, denote $\mathcal{N}_{\text{A}}(i)$ as the augmented neighborhood that consists of its K nearest neighbors and their associated augmentations. That is, $\mathcal{N}_{\text{A}}(i) = \{k, k^*\}_{k=1}^{K}$ with $\mathbf{e}_k$ and $\mathbf{e}_{k^*}$ denoting the original representation and the augmented representation of the k^{th} nearest neighbor of instance i, respectively. Here, each augmentation $\mathbf{e}_{k^*}$ is obtained by solving Equations (3) with respect to the neighborhood $\mathcal{N}(k)$ of e_k. We then discriminate the i^{th} instance and its augmentation from the augmented neighborhood $\mathcal{N}_{\text{A}}(i)$,

$$\ell_{\mathcal{N}_{\text{A}}(i)} = \ell_{\mathcal{N}_{\text{A}}(i)}(\mathbf{z}_i^*, \mathbf{z}_i) + \ell_{\mathcal{N}_{\text{A}}(i)}(\mathbf{z}_i, \mathbf{z}_i^*) \; . \tag{4}$$

Here both terms on the right hand side are defined in the same way as Equation (2) with respect to the augmentation e_i^* and the augmented neighborhood $\mathcal{N}_{\text{A}}(i)$ of the i^{th} instance.

Putting it all together Therefore, for each randomly sampled minibatch $\mathcal{B}$ with M samples, we minimize the following:

$$\begin{aligned} \mathcal{L}_{\text{VaSCL}} = \frac{1}{2M} \sum_{i=1}^{M} \{ & \ell_{\bar{\mathcal{B}}}(\mathbf{z}_i, \mathbf{z}_{i'}) + \ell_{\bar{\mathcal{B}}}(\mathbf{z}_{i'}, \mathbf{z}_i) \\ & + \ell_{\mathcal{N}_{\text{A}}(i)}(\mathbf{z}_i, \mathbf{z}_i^*) + \ell_{\mathcal{N}_{\text{A}}(i)}(\mathbf{z}_i^*, \mathbf{z}_i) \} \end{aligned} \tag{5}$$

The last two terms of the right hand side are defined in Equation 4. Notice that, $\ell_{\bar{\mathcal{B}}}(\mathbf{z}_i, \mathbf{z}_{i'})$ is defined in the same way as Equation (1) except that $\mathbf{z}_i, \mathbf{z}_{i'}$ are retained by feeding the i^{th} instance in $\bar{\mathcal{B}}$ to the encoder twice. In summary, two instance discrimination tasks are posed for each training example: i) discriminating each instance and its dropout induced variation from the other in-batch instances; and ii) separating each instance and its virtual augmentation from its K nearest neighbors and their associated virtual augmentations.

4 Experiment

In this section, we mainly evaluate VaSCL against SimCSE (Gao et al., 2021) which leverages the dropout (Srivastava et al., 2014) induced noise as data augmentation. We show that VaSCL consistently outperforms SimCSE on various downstream tasks that involve semantic understanding at different granularities. We carefully study the regularization effects of VaSCL and empirically demonstrate that VaSCL leads to a more dispersed representation space with semantic structure better encoded. Please refer to Appendix A for details of our implementations and the dataset being used.

4.1 Evaluation Datasets

In addition to the popular semantic textual similarity (a.k.a STS) related tasks, we evaluate two additional downstream tasks, short text clustering and few-shot learning based intent classification. Our motivation is twofold. First, these two tasks provide a new evaluation aspect that complements the pairwise similarity-oriented STS evaluation by assessing the high-level categorical semantics encoded in the representations. Second, two desired challenges are posted as short text clustering requires more effective representations due to the weak signal each text example manifests; and intent classification often suffers from data scarcity since the intents can vary significantly over different dialogue systems and the intent examples are costly to collect.

---

[2] δ_i is sampled from a multivariate normal distribution with the covariance matrix being a scaled identity matrix.

Table 1: Spearman rank correlation between the cosine similarity of sentence representation pairs and the ground truth similarity scores.

Semantic Textual Similarity The semantic textual similarity (STS) tasks are the most commonly used benchmark for evaluating sentence representations. STS consists of seven tasks, namely STS 2012-2016 (Agirre et al., 2012, 2013, 2014, 2015, 2016), the STS Benchmark (Cer et al., 2017), and the SICK-Relatedness (Marelli et al., 2014). For each sentence pair in these datasets, a fine-grained similarity score ranges from 0 to 5 is provided.

Short Text Clustering Compared with general text clustering, short text clustering has its own challenge due to lack of signal. Nevertheless, texts containing only a few words grow at unprecedented rates from a wide range of popular resources, including Reddit, Stackoverflow, Twitter, and Instagram. Clustering those texts into groups of similar texts plays a crucial role in many real-world applications such as topic discovery (Kim et al., 2013), trend detection (Mathioudakis and Koudas, 2010), and recommendation (Bouras and Tsogkas, 2017). We evaluate six benchmark datasets for short text clustering. As shown in Table 4, the datasets present the desired diversities regarding both the cluster sizes and the number of clusters contained in each dataset.

Intent Classification Intent classification aims to identify the intents of user utterances, which is a critical component of goal-oriented dialog systems. Attaining high intent classification accuracy is an important step towards solving many downstream tasks such as dialogue state tracking (Wu et al., 2019; Zhang et al., 2019) and dialogue management (Gao et al., 2018; Ham et al., 2020). A practical challenge is data scarcity because different systems define different sets of intents, and it is costly to obtain enough utterance samples for each intent. Therefore, few-shot learning has attracted much attention under this scenario, which is also our main focus. We evaluate four intent classification datasets originating from different domains. We summarize the data statistics in Appendix B.1.

4.2 Main Results

4.2.1 Evaluation Setup

Semantic Textual Similarity. Same as Reimers and Gurevych (2019b); Gao et al. (2021), in Table 1 we report the Spearman correlation[3] between the cosine similarity of the sentence representation pairs and the ground truth similarity scores. **Short Text Clustering.** We evaluate the sentence representations using K-Means (MacQueen et al., 1967; Lloyd, 1982) given its simplicity and report the clustering accuracy[4] averaged over ten independent runs in Table 2. **Intent Classification.** We freeze the transformer and fine-tune a linear classification layer with the softmax-based cross-entropy loss. We merge the training and validation sets, from which we sample K training and validation samples per class. We report the mean and standard deviation of the testing classification accuracy evaluated over five different splits in Table 3.[5] We set the learning rate to $1e$-04 and batch size to 32. For each task, we train the model with 1000 iterations

---

[3] Same as Reimers and Gurevych (2019b); Gao et al. (2021), we concatenate all the topics and report the overall Spearman's correlation.

[4] The clustering accuracy is computed by using the Hungarian algorithm (Munkres, 1957).

[5] In each setting, we fix the five different splits for all models.

Table 3: Few-shot learning evaluation of Intent Classification. Each result is aggregated over 5 independent splits. We choose RoBERTa-base as backbone.

4.2.2 Evaluation Results

We report the evaluation results in Tables 1, 2, and 3. As we can see, both SimCSE and VaSCL largely improve the performance of the pre-trained language models, while VaSCL consistently outperforms SimCSE on most tasks. To be more specific, we attain $0.6\% - 2.1\%$ averaged absolute improvement over SimCSE on seven STS tasks and $1.8\% - 6.9\%$ averaged absolute improvement on six short text clustering tasks. We also achieved considerable improvement over SimCSE on intent classification tasks under different few-shot learning scenarios. We do not include the evaluation on ATIS in Table 3 as this dataset is highly imbalanced with one single class account for more than 73% of the data. Please refer to Appendix C for details.

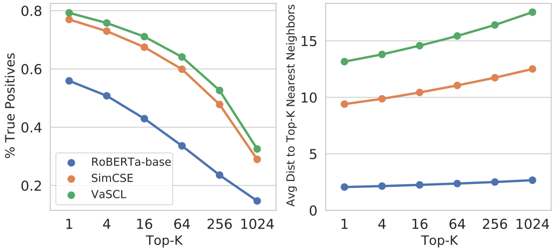
4.3 Analysis

To better understand what enables the good performance of VaSCL, we carefully analyze the representations at different semantic granularities.

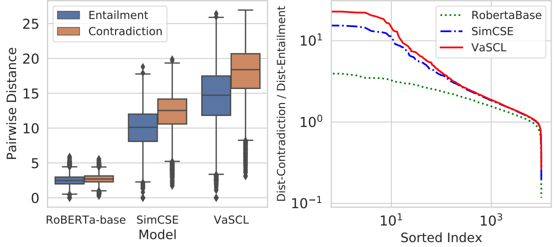
Neighborhood Evaluation on Categorical Data We first evaluate the neighborhood statistics on StackOverflow (Xu et al., 2017) which contains 20 balanced categories, each with 1000 text instances. For each instance, we retrieve its K nearest (top-K) neighbors in the representation space, among which those from the same class as the instance itself as treated as positives. In Figure 2a, we report both the percentage of true positives and the average distance of an instance to its top-K neighbors. For each top-K value, the evaluation is averaged over all 20,000 instances.

As indicated by the small distance values reported in Figure 2a, the representation space of the original RoBERTa model is tighter and is incapable of uncovering the categorical structure of data. In contrast, both VaSCL and SimCSE are capable of scattering representations apart while better capturing the semantic structures. Compared with SimCSE, VaSCL leads to even more dispersed representations with categorical structures being better encoded. This is also demonstrated by the better performance attained on both clustering and few-shot learning reported in Tables 2&3.

Fine-grained Semantic Understanding We then compare VaSCL against SimCSE and RoBERTa on encoding more fine-grained semantic concepts. We randomly sample 20,000 premises from the combined set of SNLI (Bowman et al., 2015a) and MNLI (Williams et al., 2017), where



(a) Neighborhood evaluation on StackOverflow. Instances from the same category are treated as true positives.



(b) Fine-grained semantics encoding evaluation on NLI.

Figure 2: VaSCL leads to more dispersed representation with data structure being better uncovered.

the associated entailment and contradiction hypotheses are also sampled for each premise instance. In Figure 2b, we report both the distributions of the pairwise distances of the entailment or the contradiction pairs **(left)**. While on the right-hand side, we plot the distance of each premise to its entailment hypothesis over that to its contradiction hypothesis **(right)**.

We observe the same trend that both SimCSE and VaSCL well separate different instances apart in the representation space while better discriminating each premise's entailment hypothesis from the contradiction one. Figure 2b also demonstrates that VaSCL outperforms SimCSE on better capturing the fine-grained semantics when separating different instances apart. This advantage of VaSCL is further validated by Table 1, where VaSCL consistently outperforms SimCSE on the STS tasks that require pairwise semantic inference on an even more fine-grained scale.

4.4 Explicit Data Augmentation

To better evaluate our virtual augmentation-oriented VaSCL model, we compare it against different explicit data augmentation strategies that directly operate on the discrete text. Specifically, we consider the following approaches:[6] *WDel* (random word deletion) removes words from the input text randomly; *WNet* (WordNet synonym substitute) transforms a text instance by replacing its words with the WordNet synonyms (Morris et al., 2020; Ren et al., 2019); and *CTxt* (contextual synonyms substitute) leverages the pre-trained transformers to find top-n suitable words of the input text for substitution (Kobayashi, 2018). For each strategy, we evaluate three augmentation strengths by partially changing 5%, 10%, and 20% words of each text instance. For a positive pair (x_i, x_i'), x_i denotes the original text and $x_{i'}$ is the associated augmentation. We also explore the case where both x_i and $x_{i'}$ are the transformations of the original text, which we find yielding worse performance.

Virtual Augmentation Performs Better The performance of explicit text augmentation is evaluated using the standard dropout for training, *i.e.,* "SimCSE w/ {WDel/WNet/CTxt)}" in Figure 3. As Figure 3a shows, contrastive learning with moderate explicit text augmentations, *i.e.,* augmentation strength less than 20%, does yield better sentence representations when compared with the original RoBERTa model. Nevertheless, both virtual augmentation strategies, *i.e.,* SimCSE & VaSCL, substantially outperform all three explicit text augmentation strategies on almost all downstream tasks. Although a bit surprising, especially considering the performance gap between SimCSE and explicit augmentations, this comparison provides a new perspective on interpreting the underlying challenge of designing effective transformations that operate on the discrete text directly.

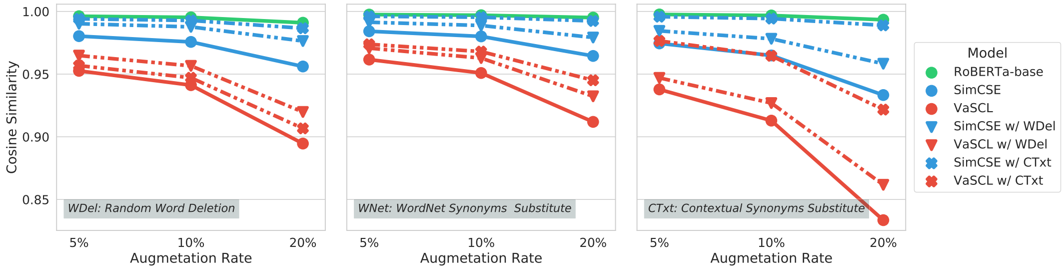
VaSCL Outperforms SimCSE Figure 3a also empirically demonstrates that VaSCL outperforms SimCSE no matter in the presence of explicit text augmentations or not. The only exception occurs when the explicit augmentation strength is too large, *i.e.,* 20% of the words of each text are perturbed. One possible explanation is that undesired noises are generated by the large perturbations on discrete texts directly, which can violate the coherent semantics maintained by a neighborhood and hence make it hard for VaSCL to generate effective virtual augmentations.

New Linguistic Patterns Are Required Another observation drawn from Figure 3a is that both SimCSE and VaSCL attain worse performance on most downstream tasks when combining with explicit text augmentations. Although VaSCL does improve the performance of explicit augmentations

---

[6] They are implemented using the nlpaug library `https://github.com/makcedward/nlpaug`.

(a) Virtual augmentation vs. explicit augmentation. For each downstream task, we report the mean performance averaged over all its subtasks. The explicit augmentations are evaluated using SimCSE (dropout) for training, *i.e.,* "SimCSE w/ {WDel/WNet/CTxt)}".



(b) Cosine similarity between each original training example and its augmentation evaluated on the representation spaces of different models. From left to right, the augmentations are obtained via *WDel*, *WNet*, and *CTxt*. Each point is averaged over 20,000 randomly sampled training examples and their augmentations. We exclude *"SimCSE w/ WNet"* and *"VaSCL w/ WNet"* for better visualization. Please refer to Figure 4 in Appendix for the full plot.

Figure 3: Comparing and combining virtual augmentation with explicit augmentation.

in most cases, this is undesired as we expect a win-win outcome that moderate explicit augmentations could further enhance VaSCL. We hypothesize that new and informative linguistic patterns are missing for the expected performance gain.

To validate our hypothesis, in Figure 3b we report the cosine similarity between each original training example and its augmentation evaluated on the representation spaces of different models. Our observation is twofold. First, the representations induced by RoBERTa and the one trained with contextual synonyms substitution ("SimCSE w/ CTxt") are very similar in all three settings, which also explains why "SimCSE w/ WDel" attains similar performance as RoBERTa on the downstream tasks. We attribute this to the fact that CTxt leverages the transformer itself to generate augmentations which hence carry limited unseen and effective linguistic patterns. Second, as indicated by the comparatively smaller similarity values in Figure 3b, the incorporation of explicit augmentations tightens the representation spaces of both SimCSE and VaSCL, which also results in a worse performance of downstream tasks. One possible explanation is that all the three explicit augmentations are weak and noisy, which harms both the instance discrimination force and the semantic relevance of each neighborhood.

5 Conclusion

In this paper, we present a virtual augmentation-oriented contrastive learning framework for unsupervised sentence representation learning. Our key insight is that data augmentation can be interpreted as constructing the neighborhoods of each training instance, which can, in turn, be leveraged to generate effective data augmentations. We evaluate VaSCL on a wide range of downstream tasks and substantially advance the state-of-the-art results. Moreover, we conduct in-depth analyses and show that VaSCL leads to a more dispersed representation space with the data semantics at different granularities being better encoded.

On the other hand, we observe a performance drop of both SimCSE and VaSCL when combined with the explicit text augmentations. We suspect this is caused by the linguistic patterns generated by explicit augmentations being less informative yet noisy. We hypothesize effective data augmentation operations on the discrete texts could complement our virtual augmentation approach if new and informative linguistic patterns are generated.

A Implementation

Same as the original SimCSE work (Gao et al., 2021), we adopted 10^6 randomly sampled sentences from English Wikipedia as training data.[7]

We implement our models with Pytorch (Paszke et al., 2017). We use the pre-trained RoBERTa models as the backbone. We choose a two-layer MLP with size $(d \times d, d \times 128)$ to optimize our contrastive learning losses, where d denotes the dimension of the sentence representations. We use Adam (Kingma and Ba, 2015) as our optimizer with a constant learning rate of $5e$-04, which we scale to $5e$-06 for updating the backbones/transformers. We set the virtual augmentation strength of VaSCL, *i.e.,* Δ in Equation (3), to 15 for both DistilRoBERTa and RoBERTaBase, and 30 for RoBERTaLarge.

We train SimCSE (Gao et al., 2021) using $3e$-05 for optimizing the contrastive learning head and the backbone. We also tried the default learning rate $1e$-05 (suggested in Gao et al. (2021)) as well as our learning rate setup for optimizing the RoBERTa models with SimCSE. We found $3e$-05 yields better performance. For both SimCSE and VaSCL, we set the batch size to 1024, train all models over five epochs and evaluate the development set of STS-B every 500 iterations. We report all our evaluations on the downstream tasks with the associated checkpoints attaining the best performance on the validation set of STS-B.

B Dataset Statistics

B.1 Intent Classification Dataset

We evaluate our model on four intent classification datasets: (1) **SNIPS** (Coucke et al., 2018) is a SLU benchmark that consists of 7 distinct intents. (2) **BANKING77** (Casanueva et al., 2020) is a large fine-grained single banking domain intent dataset with 77 intent classes. (3) **HWU64** (Liu et al., 2021) contains 25,716 examples for 64 intents in 21 domains. (4) **CLINC150** (Larson et al., 2019) spans 150 intents and 23,700 examples across 10 domains. As we can see here, SNIPS are limited to only a small number of classes, which oversimplifies the intent detection task and does not emulate the true environment of commercial systems. The remaining three datasets contain much more diversity and are more challenging.

B.2 Short Text Clustering Dataset

Dataset	N	$\bar{W}$	C	ImN
AgNews	8.0K	23	4	1
SearchSnippets	12.3K	18	8	7
StackOverflow	20K	8	20	1
Biomedical	20K	13	20	1
GoogleNews	11.1K	28	152	143
Tweet	2.5K	8	89	249

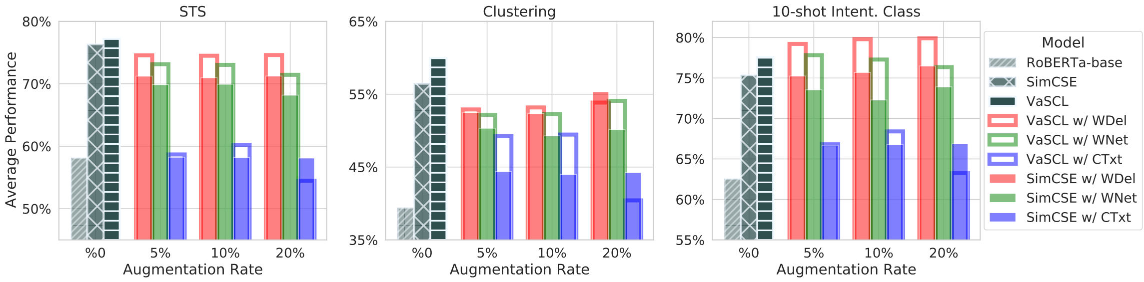
Table 4: Statistics of six short text clustering datasets. N: number of text samples; $\bar{W}$: average number of words each text example has; C: number of clusters; ImN: imbalance number defined as the size of the largest class divided by that of the smallest class.

- **SearchSnippets** is extracted from web search snippets, which contains 12340 snippets associated with 8 groups Phan et al. (2008).
- **StackOverflow** is a subset of the challenge data published by Kaggle[8], where 20000 question titles associated with 20 different categories are selected by Xu et al. (2017).

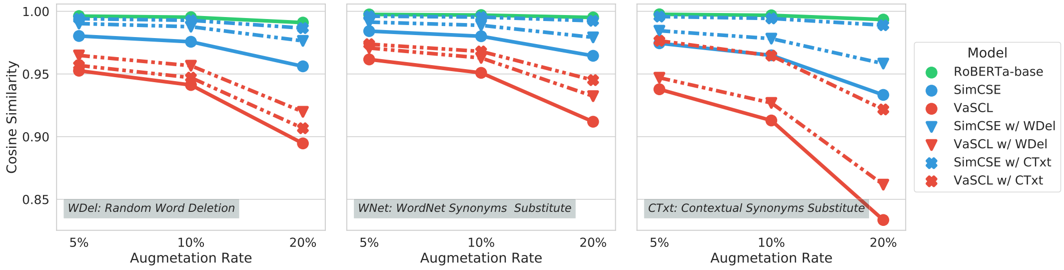
---

[7] We download the training data via `https://github.com/princeton-nlp/SimCSE/blob/main/data/download_wiki.sh`.

[8] https://www.kaggle.com/c/predict-closed-questions-on-stackoverflow/download/train.zip



(a) Evaluating VaSCL in presence of different explicit data augmentation strategies.



(b) Cosine similarity between the representations of each original training example and its augmentation evaluated on different models. From left to right, the augmentations are obtained via *WDel*, *WNet*, and *CTxt*. Each point is averaged over 20,000 randomly sampled training examples.

Figure 4: Comparing and combining virtual augmentation with explicit text augmentations. (Full plot of Figure 3 in Section 4.4.)

- **Biomedical** is a subset of PubMed data distributed by BioASQ[9], where 20000 paper titles from 20 groups are randomly selected by Xu et al. (2017).
- **AgNews** is a subset of news titles (Zhang and LeCun, 2015), which contains 4 topics selected by Rakib et al. (2020).
- **Tweet** consists of 89 categories with 2472 tweets in total (Yin and Wang, 2016).
- **GoogleNews** contains titles and snippets of 11109 news articles related to 152 events (Yin and Wang, 2016).

C Full Evaluation of Intent Classification

ATIS (Hemphill et al., 1990) is a benchmark for the air travel domain. This dataset is highly imbalanced, with the largest class containing 73% of all the training and validation examples. Moreover, more than 60% classes have less than 20 examples. We thereby exclude this task in our evaluation.

Abstract

Recent work has shown that feed-forward networks (FFNs) in pre-trained Transformers are a key component, storing various linguistic and factual knowledge. However, the computational patterns of FFNs are still unclear. In this work, we study the computational patterns of FFNs and observe that most inputs only activate a tiny ratio of neurons of FFNs. This phenomenon is similar to the sparsity of the human brain, which drives research on functional partitions of the human brain. To verify whether functional partitions also emerge in FFNs, we propose to convert a model into its MoE version with the same parameters, namely MoE*fication*. Specifically, MoEfication consists of two phases: (1) splitting the parameters of FFNs into multiple functional partitions as experts, and (2) building expert routers to decide which experts will be used for each input. Experimental results show that MoEfication can conditionally use 10% to 30% of FFN parameters while maintaining over 95% original performance for different models on various downstream tasks. Besides, MoEfication brings two advantages: (1) it significantly reduces the FLOPS of inference, i.e., 2x speedup with 25% of FFN parameters, and (2) it provides a fine-grained perspective to study the inner mechanism of FFNs. The source code of this paper can be obtained from `https://github.com/thunlp/MoEfication`.

1 Introduction

Recent years have witnessed great success of Transformer-based pre-trained language models (PLMs) (Devlin et al., 2019; Brown et al., 2021; Han et al., 2021), attracting many efforts to interpret the inner mechanism of Transformer (Manning et al., 2020; Kovaleva et al., 2019). However, most of these works focus on the attention mechanism but ignore the feed-forward networks (FFNs), which constitute nearly two-thirds of model parameters. Although recent work has shown that FFNs can be viewed as memory networks storing amounts of knowledge (Geva et al., 2021; Dai et al., 2021), the computational patterns of FFNs are still unclear.

In this work, we study the activation patterns of FFNs in Transformer models and find a phenomenon of **sparse activation**, i.e., only a tiny fraction of neurons are activated for a single input. For example, when we perform inference on a fine-tuned T5-Large model (Raffel et al., 2020) with 700-million parameters, 90% inputs only activate less than 5% neurons[1]. This phenomenon is similar to the sparsity in the human brain (Olshausen and Field, 1996; Gross, 2002), which drives research on functional partitions of the human brain (Garey, 1999). Inspired by such observation, we further raise up a question: do the functional partitions also emerge in artificial neural models, i.e., FFNs in pre-trained Transformer?

To investigate this problem, we explore whether a Transformer can be converted into an equivalent Mixture-of-Experts (MoE) model (Bengio, 2013), which regards different functional partitions in FFNs as different experts conditionally activated. Specially, we propose MoEfication to discover the functional partitions (experts) in FFNs and build routers for selecting experts. It consists of two

[1] T5 uses ReLU as the activation function. We treat the neurons having positive outputs as activated neurons.

Findings of the Association for Computational Linguistics: ACL 2022, pages 877 - 890
May 22-27, 2022

phases. (1) **Expert Construction**: Split a whole feed-forward layer into multiple experts. The goal is to group those neurons that are often activated simultaneously into the same expert network. (2) **Expert Selection**: Select those experts that contain as many activated neurons as possible for each input to approximate to the original results.

In the experiments, we evaluate MoEfication on two typical kinds of downstream tasks, including GLUE and QA benchmarks (Wang et al., 2019; Rajpurkar et al., 2016; Lai et al., 2017), using T5 and BERT (Raffel et al., 2020; Devlin et al., 2019). Experimental results verify that FFNs in Transformers can be converted to mixtures of experts, and thus we can use only 10% to 30% of FFN parameters to maintain over 95% original performance, which verifies that the pre-trained Transformers also learn the functional partitions in FFNs. Besides, MoEfication brings two advantages: (1) It can significantly speed up the inference of Transformers. Using 25% of FFN parameters brings 2x speedup on CPU and 1.2x speedup on GPU. (2) We can study MoEfied models to interpret the inner mechanism of FFNs at a fine-grained level. In this work, we study their routing patterns and hope these findings can help future work on the design and training of MoE models.

2 Related Work

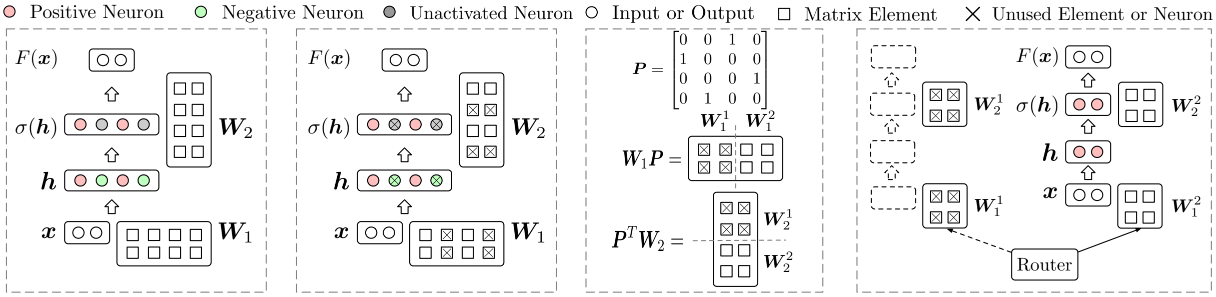
Interpretation of Large-scale Transformers. Due to the success of Transformer-based PLMs, there are many studies on the interpretation of Transformer, including the functionality of different layers (Tenney et al., 2019; Jawahar et al., 2019; Wang and Tu, 2020; Ramnath et al., 2020), and the mechanisms of both attention networks and FFNs (Manning et al., 2020; Kovaleva et al., 2019; Wallace et al., 2019). Recent work find that the FFNs of Transformers can be viewed as memory networks storing lots of knowledge learned from language modeling (Geva et al., 2021; Dai et al., 2021; Suau et al., 2020). Meanwhile, researchers explore to modify the knowledge stored in FFNs and achieve promising results (De Cao et al., 2021; Meng et al., 2022). In this work, we show that how the knowledge stored in FFNs is used, that is, most FFNs can be viewed as a MoE network where the knowledge is conditionally activated.

Large-scale PLMs with MoE. Jacobs et al. (1991) propose mixture-of-experts to build a system composed of many separate networks, which learn to handle a subset of the training examples independently. When deep neural networks achieve great success (Hinton et al., 2012; Krizhevsky et al., 2012; Goodfellow et al., 2013), Bengio (2013) thinks the model size is a key factor and MoE is an important technique to scaling model computation and proposes the idea of "conditional computation". The first large-scale MoE language model is proposed by Shazeer et al. (2017), which adds an MoE layer between two LSTM layers and independently assigns tokens to combinations of experts. Recently, GShard (Lepikhin et al., 2021), Switch-Transformer (Fedus et al., 2021), BASELayer (Lewis et al., 2021), and HashLayer (Roller et al., 2021) study how to build large-scale Transformer-based models with MoE and optimal training strategies, which can fully utilize the model capacity. Different from them, we utilize the naturally-existing sparse activation phenomenon to convert a model into its MoE version for better efficiency during inference.

Model Acceleration for PLMs. Model acceleration aims to reduce the time and space complexity of PLMs. There are several techniques including knowledge distillation (Sanh et al., 2019; Sun et al., 2019; Jiao et al., 2020), model pruning (Voita et al., 2019; Michel et al., 2019; Zhang et al., 2021), attention approximation (Wang et al., 2020; Kitaev et al., 2020; Zaheer et al., 2020),and model quantization (Zafrir et al., 2019; Zhang et al., 2020; Bai et al., 2021), and dynamic inference (Xin et al., 2020; Li et al., 2021; Ye et al., 2021; Hou et al., 2020). Among these techniques, dynamic inference explore to selectively omit unnecessary computation for acceleration, which is similar to the target of MoEfication. Previous work usually focuses on how to dynamically drop layers to accelerate inference (Huang et al., 2018; Wu et al., 2020; Li et al., 2021), which introduces additional training objectives and prediction strategies. In contrast, MoEfication simplifies models in a finer granularity, and does not change the process of training and inference. In summary, MoEfication can be regarded as a novel direction diagonal with the above-mentioned approaches.

3 MoEfication

In this section, we will introduce the general idea of MoEfication and divide it into two phases: expert construction and expert selection.



(a) FFN Computation Process (b) Unused elements and neurons (c) Expert Construction (d) FFN with MoE

Figure 1: An example of the sparse activation phenomenon and MoEfication. (a) shows the computation process of an FFN for a given input. (b) shows the unused elements and neurons for this input. (c) shows how to construct experts. (d) shows how the MoEfied model handles this input efficiently.

3.1 Overall Framework

MoEfication aims to utilize the sparse activation phenomenon in the FFNs of Transformers to reduce the computation cost.

We first formally describe the sparse activation phenomenon. The FFNs of Transformers are two-layer fully connected networks, which process an input representation $\boldsymbol{x} \in \mathbb{R}^{d_{model}}$ by

$$\begin{aligned} \boldsymbol{h} &= \boldsymbol{x}\boldsymbol{W}_1 + \boldsymbol{b}_1,\\ F(\boldsymbol{x}) &= \sigma(\boldsymbol{h})\boldsymbol{W}_2 + \boldsymbol{b}_2, \end{aligned} \tag{1}$$

where $\boldsymbol{W}_1 \in \mathbb{R}^{d_{model}\times d_{ff}}$ and $\boldsymbol{W}_2 \in \mathbb{R}^{d_{ff}\times d_{model}}$ are the weight matrices, $\boldsymbol{b}_1 \in \mathbb{R}^{d_{ff}}$ and $\boldsymbol{b}_2 \in \mathbb{R}^{d_{model}}$ are the bias vectors, and $\sigma(\cdot)$ is a non-linear activation function, which prefers to retain positive values and discard negative ones. In this work, we study the activation function ReLU (Nair and Hinton, 2010), which is used by the original Transformer (Vaswani et al., 2017) and some widely-used Transformer-based PLMs (Sun et al., 2020; Raffel et al., 2020).

Since there are many inactive (zero) values in the intermediate output $\sigma(\boldsymbol{h})$, the computation of these values can be omitted for acceleration. Meanwhile, different inputs will activate different neurons. Hence, we explore to select the possibly-activated neurons of $\boldsymbol{h}$ before the FFN computation instead of model pruning.

We show an example in Figure 1. In this FFN, d_{model} is 2, d_{ff} is 4, and the bias vectors are omitted for simplification. For a given input representation $\boldsymbol{x}$, there are two positive values in $\boldsymbol{h}$. Hence, we only need to compute part of the FFN, i.e., a 2×2 submatrix of $\boldsymbol{W}_1$ and a 2×2 submatrix of $\boldsymbol{W}_2$, to obtain the same output $F(\boldsymbol{x})$. Correspondingly, we can MoEfy the original FFN to have an MoE layer with two experts and select the one on the right-hand side for this input $\boldsymbol{x}$.

For MoEfication, we first split the FFN into several independent parts, namely expert construction, and then design a router to select suitable experts for each input, namely expert selection.

3.2 Expert Construction

In this subsection, we introduce how to split an FFN into several parts. The core idea is to group together the neurons that are often activated simultaneously. In this way, for each input, we can select a small number of experts to cover all its activated neurons. To achieve better parallel computation performance, we set the size of each expert to be the same. If the number of experts is k, the input and output dimension of experts is still d_{model} and their intermediate dimension is $d_e = \frac{d_{ff}}{k}$. Then, the parameters of i-th expert are denoted by

$$\boldsymbol{W}_1^i \in \mathbb{R}^{d_{model}\times d_e}, \boldsymbol{b}_1^i \in \mathbb{R}^{d_e}, \boldsymbol{W}_2^i \in \mathbb{R}^{d_e\times d_{model}}. \tag{2}$$

Given the result of splitting, we construct the corresponding permutation of intermediate neurons by $\begin{pmatrix} 1 & 2 & \dots & d_{ff} \\ f(1) & f(2) & \dots & f(d_{ff}) \end{pmatrix}$, where $f(n)$ is the mapping function from the original neuron index to the permuted neuron index. We compute $f(n)$ by

$$f(n) = (e(n) - 1)d_e + |\{m|m \leq n, e(m) = e(n)\}|, \tag{3}$$

where $e(n)$ is the expert index of the n-th neuron, which varies from 1 to k, and $|\{m|m \leq n, e(m) = e(n)\}|$ is the index of the n-th neuron in the expert. Then, we use its permutation matrix $\boldsymbol{P} \in \mathbb{R}^{d_{ff}\times d_{ff}}$ to permute the rows or columns of parameters and have the following split:

$$\begin{aligned} [\boldsymbol{W}_1^1, \boldsymbol{W}_1^2, \dots, \boldsymbol{W}_1^k] &= \boldsymbol{W}_1\boldsymbol{P},\\ \boldsymbol{b}_1^1 \oplus \boldsymbol{b}_1^2 \oplus \dots \oplus \boldsymbol{b}_1^k &= \boldsymbol{b}_1\boldsymbol{P},\\ [(\boldsymbol{W}_2^1)^T, (\boldsymbol{W}_2^2)^T, \dots, (\boldsymbol{W}_2^k)^T] &= (\boldsymbol{P}^T\boldsymbol{W}_2)^T, \end{aligned} \tag{4}$$

where $\oplus$ represents the vertical concatenation. Note that the permutation will not influence the output representation:

$$\begin{aligned}\sigma(\boldsymbol{h})\boldsymbol{W}_2+\boldsymbol{b}_2 &= \sigma(\boldsymbol{h})\boldsymbol{P}\boldsymbol{P}^T\boldsymbol{W}_2+\boldsymbol{b}_2,\\ &= \sigma(\boldsymbol{h}\boldsymbol{P})\boldsymbol{P}^T\boldsymbol{W}_2+\boldsymbol{b}_2,\\ &= \sigma(\boldsymbol{x}\underline{\boldsymbol{W}_1\boldsymbol{P}}+\underline{\boldsymbol{b}_1\boldsymbol{P}})\underline{\boldsymbol{P}^T\boldsymbol{W}_2}+\boldsymbol{b}_2.\end{aligned} \tag{5}$$

In this work, we propose two methods to split an FFN into k parts.

Parameter Clustering Split. To take the parameter information into consideration, we treat the columns of $\boldsymbol{W}_1$ as a collection of vectors with d_{model} dimension. Based on the intuition that the neurons with similar vectors will be activated simultaneously, we apply balanced K-Means (Malinen and Fränti, 2014) to the vector collection to obtain k clusters to construct the mapping function.

Co-Activation Graph Split. To directly use the information of co-activation, we construct a co-activation graph by counting co-activations of PLMs for the samples of the training set. Each neuron will be represented by a node in the graph, and the edge weight between two nodes are their co-activation values. The co-activation value is computed by

$$\text{co-activation}(n,m)=\sum_{\boldsymbol{x}}\boldsymbol{h}_n^{(\boldsymbol{x})}\boldsymbol{h}_m^{(\boldsymbol{x})}\mathbb{1}_{\boldsymbol{h}_n^{(\boldsymbol{x})}>0,\boldsymbol{h}_m^{(\boldsymbol{x})}>0}, \tag{6}$$

where $\boldsymbol{h}_n^{(\boldsymbol{x})}$, $\boldsymbol{h}_m^{(\boldsymbol{x})}$ are the n-th and the m-th neurons of $\boldsymbol{h}$ for the input $\boldsymbol{x}$ and $\mathbb{1}_{\boldsymbol{h}_n^{(\boldsymbol{x})}>0,\boldsymbol{h}_m^{(\boldsymbol{x})}>0}$ indicates $\boldsymbol{h}_n^{(\boldsymbol{x})}$ and $\boldsymbol{h}_m^{(\boldsymbol{x})}$ are activated simultaneously. Then, we apply graph partitioning algorithms (Karypis and Kumar, 1998) to the co-activation graph to obtain the split, where the internal connections for each group will be strong. Please refer to Appendix F for the details of the partitioning algorithm. It means that the neurons splitted into the same group are often activated simultaneously for the training samples.

3.3 Expert Selection

In this subsection, we introduce how to create a router for expert selection. An MoEfied FFN processed an input $\boldsymbol{x}$ by

$$F_m(\boldsymbol{x})=\sum_{i\in S}\sigma(\boldsymbol{x}\boldsymbol{W}_1^i+\boldsymbol{b}_1^i)\boldsymbol{W}_2^i+\boldsymbol{b}_2, \tag{7}$$

where S is the set of the selected experts. If all experts are selected, we have $F_m(\boldsymbol{x})=F(\boldsymbol{x})$. Considering that $\sigma(\boldsymbol{x}\boldsymbol{W}_1^i+\boldsymbol{b}_1^i)\boldsymbol{W}_2^i$ equals to $\boldsymbol{0}$ for most experts, we try to select n experts, where $n<k$, minimize $||F_m(\boldsymbol{x})-F(\boldsymbol{x})||_2$. The selection methods will assign a score s_i to each expert for the given input $\boldsymbol{x}$ and select the experts with the n highest scores by

$$S=\underset{A\subset\{1,2,\dots,k\},|A|=n}{\arg\max}\sum_{i\in A}s_i. \tag{8}$$

Groundtruth Selection for the intermediate output $\sigma(\boldsymbol{h})$. We can obtain the groundtruth selection, which minimizes $||\text{concat}(\{f(\sigma(\boldsymbol{x}\boldsymbol{W}_1^i+\boldsymbol{b}_1^i))\mathbb{1}(i\in S)\})-\sigma(\boldsymbol{h})||_2$, by a greedy algorithm. f is a padding function with zeros to match the dimension between $\sigma(\boldsymbol{x}\boldsymbol{W}_1^i+\boldsymbol{b}_1^i)$ and $\sigma(\boldsymbol{h})$. We calculate the sum of positive values in each expert as s_i and select experts using Equation 8. This selection should approximate to the lower bound of $||F_m(\boldsymbol{x})-F(\boldsymbol{x})||_2$. Correspondingly, its performance will approximate to the ideal performance of an MoEfied model. Meanwhile, it is intractable to directly optimize $||F_m(\boldsymbol{x})-F(\boldsymbol{x})||_2$ because there are too many possible combinations of experts.

Similarity Selection. To utilize the parameter information, we average all columns of $\boldsymbol{W}_1^i$ and use it as the expert representation. Given an input $\boldsymbol{x}$, we calculate the cosine similarity between the expert representation and $\boldsymbol{x}$ as s_i.

MLP Selection. We train a multi-layer perceptron (MLP), which takes the $\boldsymbol{x}$ as input and predicts the sum of positive values in each expert. Then, we use the prediction as s_i. This method tries to approximate to the performance of groundtruth selection.

4 Experiment

4.1 Experimental Setups

Models and Hyperparameter. We use four variants of T5 (Raffel et al., 2020), which are the 60-million-parameter T5-Small, the 200-million-parameter T5-Base, the 700-million-parameter T5-Large, and the 3-billion-parameter T5-XLarge. The non-linear activation function is ReLU (Nair and Hinton, 2010). We use Adam as the optimizer and a learning rate of 10^{-6} for fine-tuning T5 models on downstream tasks. The batch size is set to 64 and the number of epochs is set to 3.

Datasets. We use several natural language understanding datasets to evaluate our models. We use SST-2 (Socher et al., 2013), MNLI-matched (Williams et al., 2018), and RACE (Lai et al., 2017) as the main evaluation datasets, which cover single-sentence classification, sentence-pair classification, and reading comprehension. We report the results on their development sets. We also report the results of MoEfication in other datasets in Appendix A including the tasks in GLUE benchmark (Wang et al., 2019) and SQuAD (Rajpurkar et al., 2016).

Expert Construction. For balanced K-Means, we use an open-source implementation[2]. Besides Parameter Clustering Split and Co-activation Graph Split, we also implement Random Split as a naive baseline, which uses an identity matrix as $\boldsymbol{P}$. For the number of neurons in each expert, if the number is small, there will be a lot of experts, making the routing computation cost high. Meanwhile, if the number is large, there will be more inactive neurons in each expert for a given input, which is harmful to the performance with the same amount of selected neurons. Hence, selecting the number of neurons in each expert is a trade-off between computation cost and accuracy. According to our pilot experiments, we set the number of neurons in each expert d_e to 32. Correspondingly, the number of experts varies from 64 to 512 ($k = \frac{d_{ff}}{d_e}$) for different T5 variants. With the same expert size, the relative computation cost of routing for different models is the same as shown in Appendix E.

Expert Selection. Besides Similarity Selection and MLP Selection, we also implement Random Selection, where we treat each expert as a collection of vectors with d_{model} dimension and randomly select one of them as the expert representation. For Random Selection and Similarity Selection, the computation complexity for routing is O(kd_{model}). For MLP Selection, we use a two-layer feed-forward network as the architecture. The input dimension is d_{model}, the intermediate dimension is k, and the output dimension is k. The nonlinear activation function is $\tanh(\cdot)$. Its computation complexity is O($kd_{model} + k^2$). Compared to the computation complexity of FFNs of the original model, O($d_{model} \cdot d_{ff}$), the computation cost of routers is ignorable because k is much smaller than d_{ff}. For example, k is 128 and d_{ff} is 4096 for T5-Large. For the training of our MLP routers, we adopt cross-entropy as the training objective and use the Adam optimizer with the learning rate of 10^{-2}. The batch size is set to 512 and the number of epochs is set to 10. We sample nearly 500 thousand input representations from the training data and split them into the training and development sets with the ratio of $9:1$. Note that we only use the activation information as supervision. The training time of each FFN is about several minutes on a single GPU.

Model	SST-2	MNLI	RACE
Small	90.9	82.4	44.7
Small-Distill	91.9	82.6	50.6
Base	94.0	86.4	71.7
Large	96.2	89.5	81.3
XLarge	96.9	90.5	85.6

Table 1: Original Performance of different models on three downstream tasks. The model architecture is T5.

4.2 MoEfy ReLU-based Models

In this subsection, we evaluate MoEfication on different T5 models. We consider two factors: the model size and whether the model is compressed. For the model size, we use five variants of T5 (Raffel et al., 2020), from T5-Small to T5-XLarge. For convenience, we directly use the scale names as the abbreviations. To investigate the influence of model compression, we compress T5-Large to T5-Small by classic knowledge distillation (Hinton et al., 2015). Specifically, the teacher model is a fine-tuned T5-Large and the student model is a pre-trained T5-Small. The distilled model is denoted by T5-Small-Distill. The expert construction and selection methods used here are Co-activation Graph Split and MLP Selection, which are proved to be the best combination in Section 4.4.

We report the performance of these models on three datasets, SST-2, MNLI, and RACE, in Table 1. They are the representative datasets for single-sentence classification, sentence-pair classification, and reading compression, respectively. The original performance of PLMs grows as the model size grows, and knowledge distillation improves the performance of T5-small.

We first calculate the activation statistics of different models by inputting the training data of each dataset. The results are shown in Figure 2. From the figure, we have three observations. (1) The activations of these models are sparse. Different from the previous study on models trained with smaller datasets, where the activation ratios are range from 10% to 50% (Geva et al., 2021)[3], we find most

---

[2] `https://github.com/ndanielsen/Same-Size-K-Means`

[3] Since the activation ratios of a randomly-initialized model are around 50%, we guess these models do not make full use of their parameters.

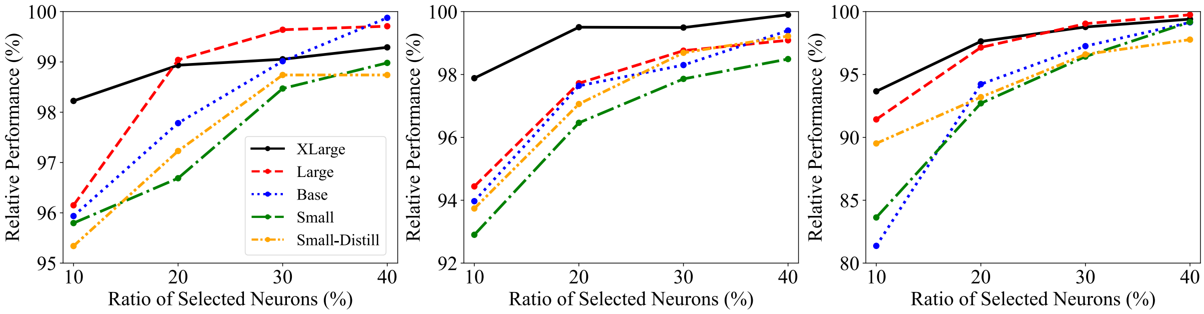
Figure 2: CDF of the ratio of activated neurons for each input with different models on three datasets.

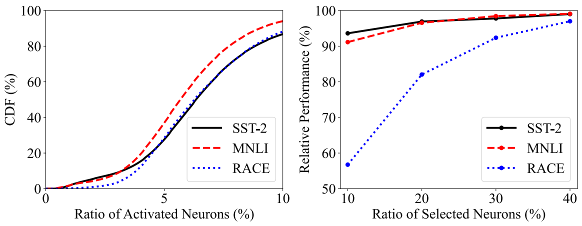


(a) SST-2 (b) MNLI (c) RACE

Figure 3: Relative performance of MoEfied models with different sizes on three datasets. Dynamically selecting 10% to 20% neurons can recover nearly 98% original performance for large models such as T5-XLarge.

inputs activate less than 10% of the neurons. (2) The activations of larger models are sparser than those of smaller models. For example, 80% inputs only activate less than 3% neurons in T5-XLarge while 40% inputs activate more than 3% neurons in T5-Small. (3) The sparsity is less related to distillation than the model size. The CDF curve of T5-Small-Distill is close to that of T5-Small.

Then, we compare the performance of MoEfied models with different sizes and ratios of selected neurons and report the results in Figure 3. To measure the performance of MoEfication, we calculate the relative performance of the MoEfied model to the original model. From the figure, we have four observations. (1) MoEfication works well with all models on all three datasets. MoEfied models use 10% to 30% of FFN parameters while maintaining over 95% original performance. (2) The larger models can use fewer neurons to recover the original performance. For example, T5-XLarge achieves nearly 98% relative performance on SST-2 and MNLI with 10% neurons while T5-Small achieves the same results with 30% to 40% neurons. This result is consistent with the activation statistics, that is, larger models are sparser. We can expect that MoEfication can provide better efficiency with super large models. (3) Difficult tasks require models to select more experts to maintain the performance. From Table 1, we can see that the accuracy of RACE is much lower than the other two tasks, and hence we think RACE is more difficult. Correspondingly, the relative performance with 10% neurons on RACE is also lower than those on the other tasks. (4) MoEfication works similarly on T5-Small and T5-Small-Distill, which indicates that MoEfication can work with knowledge distillation for more efficient inference.



(a) (b)

Figure 4: (a) CDF of the ratio of activated neurons in BERT-Large on SST-2, MNLI, and RACE. (b) Relative performance of MoEfied BERT-Large.

4.3 MoEfy GeLU-based Models

In addition to using ReLU as the activation function, many PLMs use GeLU (Hendrycks and Gimpel, 2016), including BERT (Devlin et al., 2019) and GPT (Brown et al., 2021). In this subsection, we study whether BERT, which is the most representative GeLU-based model, can be MoEfied. Considering that GeLU gives negative inputs small activations instead of 0, we first transform a GeLU-based BERT into a ReLU-based BERT, and then MoEfy the ReLU-based model. Specifically, we initialize a ReLU-based BERT using the pre-trained parameters of a BERT-Large[4] and train the ReLU-based BERT on the pre-training corpus for the adaptation of the change of activation functions. In this work, we use the pre-training framework provided by NVIDIA[5] and keep all hyper-parameters unchanged. Wikipedia and Bookcorpus are used as the pre-training corpus. In the experiments, after 400 optimization steps, the pre-training loss is close to that of the original model. Hence, the adaptation cost is much smaller than the pre-training cost (about 10000 steps). Meanwhile, the downstream performance of the ReLU-based model is comparable to the original model (93.1 v.s 93.5 on SST-2 and 84.8 v.s 85.2 on MNLI). Based on this ReLU-based BERT-Large, we study the sparse activation phenomenon and the effect of MoEfication and report the results in Figure 4.

From this figure, we have two observations: (1) The sparse activation phenomenon still exists in BERT. For example, more than 80% of inputs activate less than 10% of neurons. It reveals the generality of the sparse activation phenomenon in pre-trained Transformers. It will be an interesting direction to explain this phenomenon empirically or theoretically in the future. (2) MoEfication also archives good performance on BERT. For example, selecting 30% to 40% of neurons can recover 97% performance. Since the activation of BERT is slightly denser than that of T5, it requires more neurons to recover most performance.

4.4 Comparisons of MoEfication Strategies

To find the most effective MoEfication strategy, we evaluate different combinations of expert construction and selection methods. We use T5-Large and also set the ratio of selected neurons to 20%. The results are shown in Table 2. From the table, we have two observations:

Construction	Selection	SST-2	MNLI	RACE
-	-	96.2	89.5	81.3
Random	Groundtruth	95.9	87.3	80.0
	Random	65.9	36.3	29.2
	Similarity	90.3	75.9	56.7
	MLP	94.1	84.1	75.0
Parameter Clustering	Groundtruth	95.5	88.8	80.9
	Random	70.6	36.4	41.8
	Similarity	86.7	66.3	63.6
	MLP	**95.9**	**87.5**	78.7
Co-Activation Graph	Groundtruth	96.3	89.1	80.8
	Random	85.3	68.5	54.7
	Similarity	92.2	81.4	71.0
	MLP	95.4	**87.5**	**79.0**

Table 2: Comparisons of different combinations of expert construction and selection methods using T5-Large. The first row is the original performance. The best results in each group are underlined and the best results on each dataset are in **boldface**.

Ratio	FLOPS	CPU	GPU
50.0%	1.50	1.43	1.15
25.0%	2.00	1.98	1.20
12.5%	2.40	2.28	1.47

Table 3: Speedup of FLOPS, CPU and GPU with different ratios of selected neurons.

(1) For expert construction, Co-activation Graph Split is the best method according to the overall performance. Compared to the other two methods, Co-activation Graph Split directly uses the co-activation information to group the neurons activating simultaneously into the same expert.

(2) For expert selection, the performance of Groundtruth Selection is close to that of the original model, which indicates that 20% parameters of FFNs are sufficient to achieve good performance on T5-Large. Meanwhile, MLP Selection is the best expert selection method and can work well with both Parameter Clustering Split and Co-activation Graph Split.

5 Analysis

In this section, we analyze the efficiency and routing patterns of MoEfied models.

5.1 Efficiency Improvement

In this subsection, we show the efficiency improvement brought by MoEfication. We synthesize a batch of sequences with the input and output lengths of 64 and evaluate T5-Large on the data. To comprehensively show the efficiency improvement,

---

[5] https://github.com/NVIDIA/DeepLearningExamples

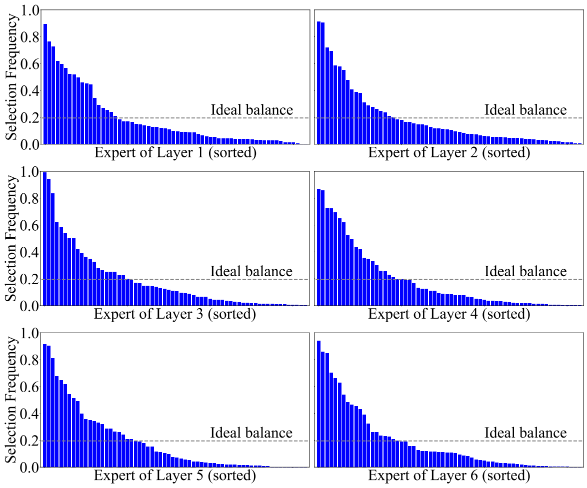

Figure 5: Selection Frequency of 64 experts in each encoder layer of MoEfied T5-Small. The frequency of ideal balance selection is 0.2 while the distribution is much unbalanced.

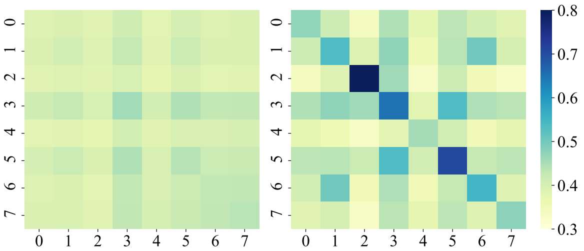
we report the relative speedup based on FLOPS, CPU, and GPU in Table 3. The FLOPS is estimated according to the statistics provided by Brown et al. (2021). The results of CPU and GPU are tested on an Intel Broadwell CPU and an NVIDIA Tesla V100 GPU, respectively.

From this table, we have three observations: (1) MoEfication can significantly reduce the total FLOPS, such as 2x speedup in the ratio of 25%. Meanwhile, the speedup on CPU is close to that on FLOPS. Considering that CPU is widely used for model inference in real-world scenarios, MoEfication is practical for the acceleration of various NLP applications. (2) The smaller the ratio, the smaller the gain. For example, the gain of halving 25% (to 12.5%) is 1.2x while the gain of halving 50% (to 25%) is 1.3x. Although the FLOPS reduction of feed-forward networks is linear in the ratio, the cost of attention networks is unchanged and becomes the bottleneck. Hence, 20% is a good ratio, which can have a significant speedup (2x) and maintain most performance. (3) Since some of the operations of MoE cannot be easily paralleled, the speedup on GPU is smaller than that on GPU. Recently, some packages such as FastMoE (He et al., 2021) and Deepspeed-MoE (Rajbhandari et al., 2022) are working on paralleling the inference of MoE models on distributed computing platforms and already have some promising results. We believe the bottleneck of parallel computing in MoE models will be well solved in the future.



(a) The 8 most selected experts (b) The 8 least selected experts

Figure 6: Input similarities between experts in the last encoder layer of MoEfied T5-Small. For the most selected experts, both the self-similarities and inter-similarities are low. For the least selected experts, the self-similarities are much higher than inter-similarities.

5.2 Routing Patterns

In this subsection, we investigate the routing patterns of MoEfied models. First, we count the selection frequency of each expert. Previous work introduces training objectives to ensure balance selection to make full use of model parameters (Lepikhin et al., 2021; Fedus et al., 2021). We report the results of the MoEfied T5-Small with 20% experts on SST-2 in Figure 5. From the figure, we observe that the frequency distribution of expert selection is much unbalanced. There are some commonly-used experts, whose frequencies are higher than 80%. Meanwhile, there are also some long-tail experts whose frequencies are lower than 10%.

Then, we calculate the self-similarities and inter-similarities of inputs between experts by sampling 10,000 inputs for each expert. We report the results of the last layer in Figure 6. For the most selected experts, which are selected by most inputs, the self-similarities are close to the inter-similarities. For the least selected experts, the self-similarities are much higher than the inter-similarities, which suggests that the inputs of each expert have obvious cluster structure.

From these results, we can conclude the routing patterns of MoEfied models: there are some general experts, which can work for most inputs, and some input-specific experts, which are seldom used and may work in specific domains or tasks. This observation may inspire future work on training MoE models from scratch.

6 Conclusion

In this work, we verify that Transformer FFNs are naturally mixtures of experts and propose MoEfication, which utilizes the sparse activation phenomenon in FFNs to convert a normal model to its MoE version with the same parameters. Experimental results show that MoEfied models can achieve comparable performance to the original models using only 10% to 30% of FFN parameters. Correspondingly, it significantly reduces the FLOPS of inference, e.g., 2x speedup with 20% of FFN parameters. Besides, by studying the routing patterns of MoEfied models, we find that there are general and input-specific experts, which may inspire future work on training MoE models. We hope MoEfication can benefit real-world applications of PLMs with better efficiency and benefit the interpretation of the inner mechanism of FFNs.

A MoEfication on Other Datasets

For text classification, we use GLUE benchmark (Wang et al., 2019), including MNLI-matched (Williams et al., 2018), QNLI (Rajpurkar et al., 2016), QQP[6], RTE (Dagan et al., 2006), SST-2 (Socher et al., 2013), MRPC (Dolan and Brockett, 2005), CoLA (Warstadt et al., 2019), and STS-B (Giampiccolo et al., 2007). For reading comprehension, we use SQuAD (Rajpurkar et al., 2016) and RACE (Lai et al., 2017), which are the representative datasets for span extraction and multi-choice QA, respectively. We report the results on their development sets. For MNLI, QNLI, QQP, RTE, SST-2, MRPC, RACE, we use accuracy as the metric. For CoLA, we use matthews correlation coefficient as the metric. For STS-B, we use pearson and spearman correlation as the metrics. For SQuAD, we use F1 score as the metric.

We evaluate MoEfication on several downstream natural language understanding tasks with T5-Large. The ratio of selected neurons is set to 20%, which is sufficient for T5-Large as show in Figure 2. In practice, there is still a gap between the performance of MoEfied models and that of original models because selected experts cannot cover all positive neurons with a limited computation budget. Hence, the outputs of MoEfied models will be slightly different from those of original models. To calibrate MoEfied models, we further fine-tune the models on the training set, namely parameter calibration. Considering that current routers are based on the first layers of FFNs ($\boldsymbol{W}_1$ and $\boldsymbol{b}_1$), we only optimize the second layers of FFNs ($\boldsymbol{W}_2$ and $\boldsymbol{b}_2$) to ensure routers can also work well after fine-tuning. We use a small learning rate of 10^{-7} for calibration. The other hyper-parameters remain the same as fine-tuning. The results are shown in Table 4. MoEfied refers to the combination of Co-activation Graph Split and MLP Selection. MoEfied+GT refers to the combination of Co-activation Graph Split and Groundtruth Selection. MoEfied+Calib is the calibrated version of MoEfied. To calculate the average performance, we also include SST-2, MNLI, and RACE.

We observe that MoEfication introduces small performance loss (about 1.5% on average) with an 80% reduction of the computation cost in FFNs. Meanwhile, calibration can effectively deal with the issue of the precision errors brought by MoEfication. For example, MoEfied+Calib improves MoEfied by nearly 4% on CoLA and achieves the same average performance as MoEfied+GT.

B Activation Statistics before Fine-tuning

We count the activation statistics of PLMs before fine-tuning on the pre-training data containing about $50,000$ input tokens. The results are shown in Figure 7. We observe that PLMs before fine-tuning also have the sparse activation phenomenon and fine-tuning brings little change.

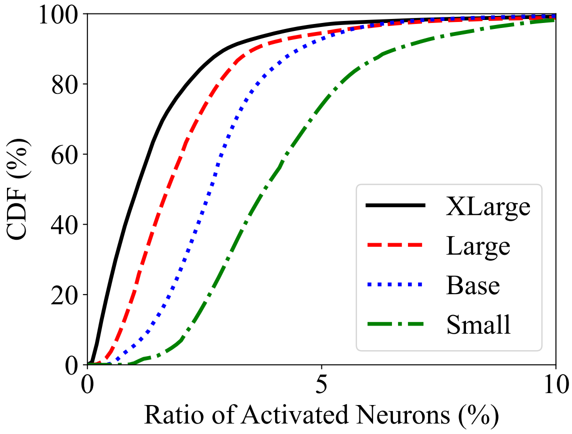

Figure 7: CDF of the ratios of activated neurons for each input with different models before fine-tuning.

Then, we compare the activations of pre-trained models and those of fine-tuned models. We use the average ratio of activated neurons as the index. The results are shown in Table 5. We observe that fine-tuning increases the average activation ratio for most models. The reason may be that different neurons start to learn the same task-specific patterns during fine-tuning. Interestingly, the increase on RACE is smaller than that on the other datasets. Since RACE is more difficult than the other datasets, there should be more task-specific patterns in RACE and less neurons learn the same patterns. Moreover, the pre-training task MLM requires more patterns than RACE so the ratios of MLM are lowest.

C Results of Graph Partition

Co-activation Graph Split achieves good performance in expert construction. Here, we study whether the co-activation graph is suitable for partitioning. We report the results of graph partition of T5-Large on SST-2 in Figure 8. Smaller ratios of edgecuts, which straddle partitions, mean that more co-activation pairs are included in experts. We only

Table 5: Average ratio of activated neurons for each input. MLM represents the pre-trained models with masked language modeling. SST-2, MNLI, RACE represent the fine-tuned models on each dataset.

report the results of encoder layers because all ratios of decoder layers are smaller than 0.001. From this figure, we can see that the overall ratio is small and these graphs are suitable for partitioning.

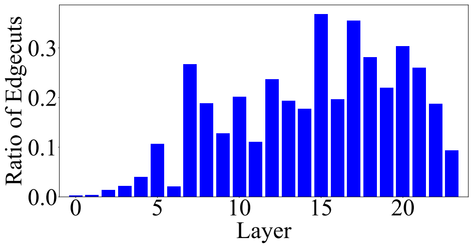

Figure 8: Ratio of edgecuts in different layers.

D Accuracy of MLP Selection

MLP selection trains MLPs to fit the groundtruth selection. In this part, we report the accuracy of MLPs in T5-Large fine-tuned on SST-2. The results are shown in Figure 9 and 10. The overall accuracy of the encoder is about 0.8 and the overall accuracy of the decoder is about 0.7.

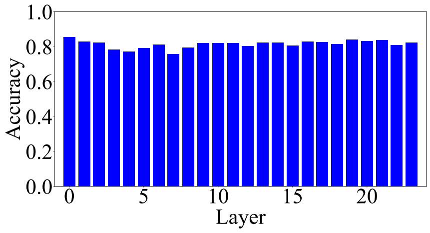

Figure 9: Accuracy of MLPs of encoder layers.

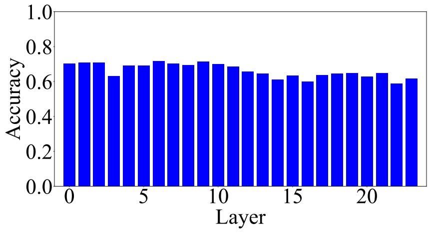

Figure 10: Accuracy of MLPs of decoder layers.

E Relative Cost of Routing

In this work, we set the number of neurons in each expert to 32. Then, the number of experts in each layer k is $\frac{d_{ff}}{32}$. In most Transformer models, $d_{ff} = 4d_{model}$. The computation complexity of Similarity Selection for each input is

$$O(kd_{model}) = O(\frac{d_{model}^2}{8}). \qquad (9)$$

The computation complexity of FFNs for each input is

$$O(d_{model} \cdot d_{ff}) = O(4d_{model}^2). \qquad (10)$$

Then, the relative cost of routing to that of FFNs is constant for different models. It is also similar to MLP Selection.

F Graph Partitioning Algorithm

The goal of graph partitioning is to divide a graph into several sub-graphs where the number of edges crossing sub-graphs is minimized. In this work, we use the graph partitioning algorithm proposed by Karypis and Kumar (1998). The graph partitioning algorithm consists of three phases: coarsening phase, partitioning phase, and refinement phase. (1) In the coarsening phase, we create new super nodes by grouping nodes that are highly connected together. For example, if the weight of the edge

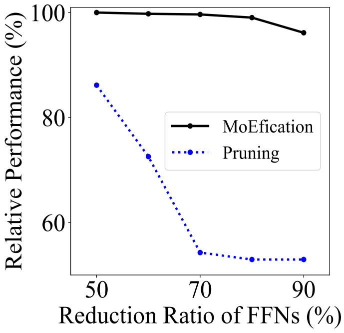

Figure 11: Comparison between MoEfication and model pruning.

Model	MLM Loss
MoE Pre-training	3.09
Standard Pre-training	2.88 (-0.21)
+MoEfication	3.02 (-0.07)
+GT	2.95 (-0.14)

Table 6: Comparisons of MoE models pre-trained from scratch and modified by MoEfication. We report the MLM loss on the validation set. Standard pre-training with MoEfication is better than pre-training a MoE model from scratch.

between two nodes is large, these two nodes will be grouped together. In the setting of coarsening co-activation graphs studied in this work, two neurons that often activate simultaneously will be treated as a new super neuron. (2) In the partitioning phase, we start with an initial bipartition of the super node graph and then iteratively search for super nodes from each part of the graph, such that swapping them leads to a partition with a smaller number of crossing edges. To divide a graph into k parts, we need $\log k$ rounds of bipartition. (3) In the refinement phase, we project super nodes to the original nodes and then continue to iteratively swap nodes to reduce the number of crossing edges.

G Comparisons with Model Pruning

Based on the fine-tuned T5-Large on SST-2, we compare MoEfication with model pruning, which omits the weight having small values. The results are shown in Figure 11. We observe that model pruning significantly degrades the performance. However, MoEfication achieves good performance by selectively activating parts of the network according to input.

H MoEfication vs. MoE pre-training

In this subsection, we compare the performance of two kinds of MoE models. The first one is pre-trained from scratch. The second one is transformed from a standard model by MoEfication. For fair comparisons, we pre-train one MoE model and one standard model with the same model size from scratch using WikiText-103 (Merity et al., 2017). The pre-training objective is masked language modeling (MLM). The model architecture is the same as T5-Small. For pre-training, we use the batch size of 4096, the learning rate of 0.01, the maximum sequence length of 512, and the Adam optimizer. The number of experts is set to 64 and the router will select 32 of them for a single input.

We report the MLM loss on the validation set in Table 6. From the table, we have two observations. (1) The loss of the standard pre-trained model is lower than that of the pre-trained MoE model. We guess that the optimization of MoE models is difficult than that of the standard models because of the restricted selection of MoE models. (2) MoEfied models achieve better performance than the pre-trained MoE model. It indicates that pre-training a standard model then conducting MoEfication can be a better option than pre-training an MoE model from scratch.

DS-TOD: Efficient Domain Specialization for Task-Oriented Dialog

Abstract

Recent work has shown that self-supervised dialog-specific pretraining on large conversational datasets yields substantial gains over traditional language modeling (LM) pretraining in downstream task-oriented dialog (TOD). These approaches, however, exploit general dialogic corpora (e.g., Reddit) and thus presumably fail to reliably embed domain-specific knowledge useful for concrete downstream TOD domains. In this work, we investigate the effects of domain specialization of pretrained language models (PLMs) for TOD. Within our DS-TOD framework, we first automatically extract salient domain-specific terms, and then use them to construct DOMAINCC and DOMAINREDDIT – resources that we leverage for domain-specific pretraining, based on (i) masked language modeling (MLM) and (ii) response selection (RS) objectives, respectively. We further propose a resource-efficient and modular domain specialization by means of *domain adapters* – additional parameter-light layers in which we encode the domain knowledge. Our experiments with prominent TOD tasks – dialog state tracking (DST) and response retrieval (RR) – encompassing five domains from the MULTIWOZ benchmark demonstrate the effectiveness of DS-TOD. Moreover, we show that the light-weight adapter-based specialization (1) performs comparably to full fine-tuning in single domain setups and (2) is particularly suitable for multi-domain specialization, where besides advantageous computational footprint, it can offer better TOD performance.

1 Introduction

Task-oriented dialog (TOD), where conversational agents help users complete concrete tasks (e.g., book flights or order food), has arguably been one of the most prominent NLP applications in recent years, both in academia (Budzianowski et al., 2018; Henderson et al., 2019c; Liu et al., 2021a, *inter alia*) and industry (e.g., Yan et al., 2017; Henderson et al., 2019b). Like for most other NLP tasks, fine-tuning of pretrained language models (PLMs) like BERT (Devlin et al., 2019) and GPT-2 (Radford et al., 2019) pushed the state-of-the-art in TOD tasks (Budzianowski and Vulić, 2019; Hosseini-Asl et al., 2020), with LM pretraining at the same time alleviating the need for large labeled datasets (Ramadan et al., 2018).

More recent TOD work recognized the idiosyncrasy of dialog – i.e., that dialogs represent interleaved exchanges of utterances between two (or more) participants – and proposed pretraining objectives specifically tailored for dialogic corpora (Henderson et al., 2019c; Wu et al., 2020; Bao et al., 2020, *inter alia*). For instance, Wu et al. (2020) pretrain their TOD-BERT model on the concatenation of nine human-to-human multi-turn dialog datasets. Similarly, Henderson et al. (2019c, 2020) pretrain a general-purpose dialog encoder on a large corpus from Reddit by means of response selection objectives. Encoding dialogic linguistic knowledge in this way led to significant performance improvements in downstream TOD tasks.

While these approaches impart useful dialogic linguistic knowledge they fail to exploit the fact that individual task-oriented dialogs typically belong to one narrow domain (e.g., *food* ordering) or few closely related domains (e.g., booking a *train* and *hotel*; Budzianowski et al., 2018; Ramadan et al., 2018). Given the multitude of different downstream TOD domains (e.g., ordering *food* is quite different from booking a *flight*) it is, intuitively, unlikely that general dialogic pretraining reliably encodes domain-specific knowledge for all of them.

In this work, we propose **D**omain **S**pecialization for **T**ask **O**riented **D**ialog (DS-TOD), a novel domain specialization framework for task-oriented dialog. DS-TOD, depicted in Figure 1, has three steps: (1) we extract domain-specific terms (e.g., terms related to ordering *taxi* or terms related to buying a *train* ticket) from the training portions of a task-specific TOD corpus; (2) we next use

Findings of the Association for Computational Linguistics: ACL 2022, pages 891 - 904

the extracted terms to obtain domain-specific data from large unlabeled corpora (e.g., Reddit); (3) finally, we conduct intermediate training of a PLM (e.g., BERT) on the domain-specific data in order to inject the domain-specific knowledge into the encoder. As a result, we obtain a domain-specialized PLM, which can then be fine-tuned for downstream TOD tasks, e.g., dialog state tracking.

Contributions. We advance the state-of-the-art in TOD with the following contributions: **(i)** Departing from general-purpose dialogic pretraining (e.g., Henderson et al., 2019a), we leverage a simple terminology extraction method to construct DomainCC and DomainReddit corpora which we then use for domain-specific LM and dialogic pretraining, respectively. **(ii)** We examine different objectives for injecting domain-specific knowledge into PLMs: we empirically compare Masked Language Modeling (MLM) applied on the "flat" domain dataset DomainCC against two different Response Selection (RS) objectives (Henderson et al., 2019c; Oord et al., 2018) applied on the dialogic DomainReddit corpus. We demonstrate the effectiveness of our specialization on two TOD tasks – dialog state tracking (DST) and response retrieval (RR) – for five domains from the MultiWOZ dataset (Budzianowski et al., 2018; Eric et al., 2020). **(iii)** We propose modular domain specialization for TOD via *adapter* modules (Houlsby et al., 2019; Pfeiffer et al., 2020). Additional experiments reveal the advantages of adapter-based specialization in *multi-domain* TOD: combining domain-specific adapters via stacking (Pfeiffer et al., 2020) or fusion (Pfeiffer et al., 2021) (a) performs *en par* with or outperforms expensive multi-domain pretraining, while (b) having a much smaller computational footprint.[1]

2 Data Collection

We create large-scale domain-specific corpora in two steps: given a collection of in-domain dialogs we first extract salient domain terms (§2.1); we then use these domain terms to filter content from CCNet (Wenzek et al., 2020) as a large general corpus and Reddit as a source of dialogic data (§2.2).

2.1 Domain-Specific Ngrams

We start from Wizard-of-Oz, a widely used multi-domain TOD dataset (MultiWOZ; Budzianowski et al., 2018): we resort to the revised version 2.1 (Eric et al., 2020) and work with the five domains that have test dialogs: *Taxi*, *Attraction*, *Train*, *Hotel*, and *Restaurant*. Table 1 shows the statistics of domain-specific MultiWOZ subsets.

To obtain large domain-specific corpora for our intermediate training, we first construct sets of domain-specific ngrams for each domain. To this end, we first compute TF-IDF scores for all {1,2,3}-grams found in single-domain dialogs from MultiWOZ training sets[2]: our term frequency (TF) is the total ngram frequency in all domain dialogs; the inverse document frequency (IDF) is here the inverse of the proportion of dialogs that contain the ngram. We then select N ngrams with the largest TF-IDF scores (in all our experiments, we set $N = 80$) and manually eliminate from the list ngrams that are not intrinsic to the domain (e.g., weekdays, named locations). Finally, since MultiWOZ terms follow the British English spelling (e.g., *centre*, *theatre*), we add the corresponding American English word forms (e.g., *center*, *theater*). The complete resulting ngram sets for all domains are given in Table 2.

2.2 Domain-Specific Corpora

We next use the extracted domain ngrams to retrieve two types of in-domain data for domain specialization: (i) flat text and (ii) dialogic data.

DomainCC. For each of the five MultiWOZ domains, we create the corresponding flat text corpus for MLM training by filtering out 200K sentences from the English portion of CCNet (Wenzek et al., 2020) – a high-quality collection of monolingual corpora extracted from CommonCrawl[3] that has been used for pretraining multilingual PLMs (Conneau et al., 2020; Liu et al., 2020) – that contain one or more of the previously extracted domain terms. We additionally clean all DomainCC portions by removing email addresses and URLs, and lower-casing all terms. We provide example excerpts for each domain in the Appendix.

DomainReddit. Being constructed from CommonCrawl, DomainCC portions do not exhibit

---

[1] Assume N mutually close domains and a bi-domain downstream setup (any two domains). With an adapter-based approach, we pretrain one adapter for each domain (complexity: N) and then combine the adapters of the two domains intertwined in the concrete downstream setup. In contrast, multi-domain specialization would require one bi-domain pretraining for each two-domain combination (complexity: N^2).

[2] E.g., for the *Taxi* domain, we collect all training dialogs that span only that domain (i.e., only taxi ordering) and omit dialogs that besides *Taxi* involve one or more other domains (e.g., taxi ordering and hotel booking in the same dialog).

[3] `https://commoncrawl.org/`

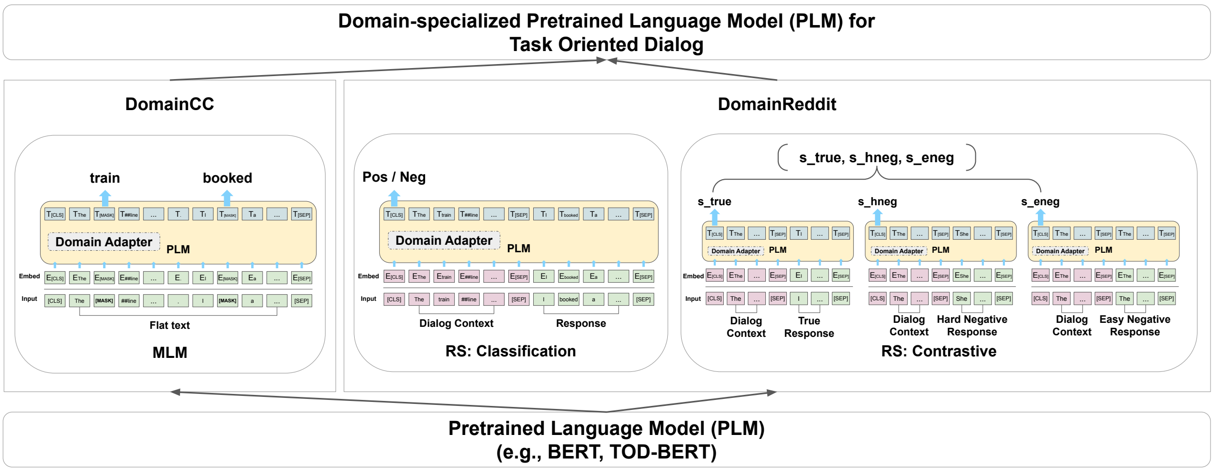

Figure 1: Overview of DS-TOD. Three different specialization objectives for injecting domain-specific knowledge into PLMs (see §3.1): (1) Masked Language Modeling (MLM) on the "flat" domain corpus DOMAINCC, (2) Response Selection (RS) via Classification, and (3) Response Selection via Contrastive Learning operating on the dialogic DOMAINREDDIT. Domain specialization performed either via (a) full fine-tuning or (b) adapters (see §3.2).

any natural conversational structure, encoding of which has been shown beneficial for downstream TOD (Henderson et al., 2019c; Wu et al., 2020). We thus additionally create a dialogic corpus for each domain: we employ the Pushshift API (Baumgartner et al., 2020) to extract dialogic data from Reddit (period 2015–2019). To this end, we select subreddits related to *traveling* (listed in Table 3) which we believe align well with the content of MultiWOZ, which was created by simulating conversations between tourists and clerks in a tourist information center. Each of the subreddits contains threads composed of a series of comments, each of which can serve as a *context* followed by a series of *responses*. For DOMAINREDDIT we select context-response pairs where either the context utterance or the response contains at least one of the domain-specific terms. To construct examples for injecting conversational knowledge, we follow Henderson et al. (2019a) and couple each *true* context-response pair (i.e., a comment and its immediate response) with a *false response* – a non-immediate response from the same thread. Table 4 provides an example context with its true and one false response; further examples, for all domains, are available in the Appendix. Finally, we also clean DOMAINREDDIT by removing email addresses and URLs as well as comments having fewer than 10 characters. The total number of Reddit triples *(context, true response, false response)* that we extract this way for the MultiWOZ domains is as follows: *Taxi* – 120K; *Attraction* – 157K; *Hotel* – 229K; *Train* – 229K; and *Restaurant* – 243K.

3 Domain Specialization Methods

The next step in DS-TOD is the injection of domain-specific knowledge through intermediate model training on DOMAINCC and DOMAINREDDIT. To this end, we train a PLM (1) via Masked Language Modeling on DOMAINCC and (2) using two different Response Selection objectives on DOMAINREDDIT. Finally, for all objectives, we com-

pare full domain fine-tuning (i.e., we update all PLM parameters) against adapter-based specialization where we freeze the PLM parameters and inject domain knowledge into new adapter layers.

3.1 Training Objectives

Masked Language Modeling (MLM). Following successful work on domain-adaptive pretraining via LM (Gururangan et al., 2020; Aharoni and Goldberg, 2020; Glavaš et al., 2020), we investigate the effect of running standard MLM on the domain-specific portions of DomainCC.

Response Selection (RS). RS objectives force the model to recognize the correct response utterance given the context – pretraining with such objectives is particularly useful for conversational settings, including TOD tasks (Henderson et al., 2019c, 2020). We consider two RS objectives. The first is a simple pairwise binary classification formulation (**RS-Class**): given a context-response pair, predict whether the response is a true (i.e., immediate) response to the context. We straightforwardly use pairs of contexts and their true responses from DomainReddit as positive training instances. Next, we create negative samples for each positive instance as follows: (a) we use the crawled *false response* from DomainReddit, which represents a relevant but non-consecutive response from the same thread; such non-immediate responses from the same thread represent the so-called *hard negatives* introduced to prevent the model from learning simple lexical cues and similar heuristics that poorly generalize; (b) we additionally randomly sample k utterances from the same domain but different threads (these represent the so-called *easy negatives*).[4]

The second response selection objective (**RS-Contrast**) that we adopt is a type of loss function used for contrastive model training based on the representational similarities between sampled positive and negative pairs (Oord et al., 2018). It has been used for pretraining cross-lingual language models (Chi et al., 2021) and shown to be useful in information retrieval (Reimers and Gurevych, 2021; Thakur et al., 2021; Litschko et al., 2022). The goal is to estimate the mutual information between pairs of variables by discriminating between a positive pair and its associated N negative pairs. Given a true context-response pair and N negatives (same as for RS-Class), the noise-contrastive estimation (NCE) loss is computed as:

$$L_{NCE} = -\log \frac{\exp\left(f(c, r_{+})\right)}{\sum_{i=1}^{N+1} \exp\left(f(c, r_{i})\right)},$$

where c is the context, r_{+} is the true response and r_i iterates over all responses for the context – the true response r_{+} and N false responses; a function

---

[4] k is uniformly sampled from the set $\{1, 2, 3\}$.

Field	Example
Subreddit	restaurant
Context	*Hosts don't get tips? That's news to me. Most host positions in my area get at least 1% of sales; they make anywhere between 60−100 per night in tips!*
Response	*We get tips but definitely not that much (in my experience). The tip out in my restaurant is 1% split between shift leaders, food runners, and any other FOH other than servers/bartenders. Full time hosts get about 50-75 every other week*
False Response	*Wow that's terrible. Then again, my restaurant is in CA, so wages and guest check averages are usually higher.*

Table 4: Example from DOMAINREDDIT dataset.

f produces a score meant to indicate whether the response r is a true response of the context c.

By learning to differentiate whether the response is true or false for a given context (RS-Class) or to produce a higher score for a true response than for false responses (RS-Contrast), RS objectives encourage the PLM to adapt to the underlying structure of the conversation. By feeding only in-domain data to it, we impart domain-specific conversational knowledge into the model.

3.2 Adapter-Based Domain Specialization

Fully fine-tuning the model requires adjusting all of the model's parameters, which can be undesirable due to large computational effort and risk of catastrophic forgetting of the previously acquired knowledge (McCloskey and Cohen, 1989; Pfeiffer et al., 2021). To alleviate these issues, we investigate the use of adapters (Houlsby et al., 2019), additional parameter-light modules that are injected into a PLM before fine-tuning. In adapter-based fine-tuning only adapter parameters are updated while the pretrained parameters are kept frozen (and previously acquired knowledge thus preserved). We adopt the adapter-transformer architecture proposed by Pfeiffer et al. (2020), which inserts a single adapter layer into each transformer layer and computes the output of the adapter, a two-layer feed-forward network, as follows:

$$\textit{Adapter}(\boldsymbol{h}, \boldsymbol{r}) = U \cdot g(D \cdot \boldsymbol{h}) + \boldsymbol{r},$$

with $\boldsymbol{h}$ and $\boldsymbol{r}$ as the hidden state and residual of the respective transformer layer. $D \in \mathbb{R}^{m \times h}$ and $U \in \mathbb{R}^{h \times m}$ are the linear down- and up-projections, respectively (h being the transformer's hidden size, and m as the adapter's bottleneck dimension), and $g(\cdot)$ is a non-linear activation function. The residual $\boldsymbol{r}$ is the output of the transformer's feed-forward layer whereas $\boldsymbol{h}$ is the output of the subsequent layer normalization. The down-projection D compresses token representations to the adapter size $m \ll h$, and the up-projection U projects the activated down-projections back to the transformer's hidden size h. The ratio h/m captures the factor by which the adapter-based fine-tuning is more parameter-efficient than full fine-tuning.

For multi-domain TOD scenarios (i.e., dialogs covering more than a single domain), we further experiment with combinations of individual domain adapters: (1) sequential stacking of adapters one on top of the other (Pfeiffer et al., 2020) and (2) adapter fusion, where we compute a weighted average of outputs of individual adapter, with fusion weights as parameters that are learned in the final task-specific fine-tuning (Pfeiffer et al., 2021).

4 Experiments

We demonstrate the effectiveness of our domain-specialization framework by comparing it to non-specialized baseline models and thoroughly compare different specialization methods from §3.

Evaluation Task and Measures. We evaluate our domain-specialized models and baselines on two prominent downstream TOD tasks: *dialog state tracking (DST)* and *response retrieval (RR)*. DST is treated as a multi-class classification task based on a predefined ontology, where given the dialog history, the goal is to predict the output state, i.e., (domain, slot, value) tuples. For our implementation, we follow Wu et al. (2020), and represent the dialog history as a sequence of utterances. The model then needs to predict slot values for each (domain, slot) pair at each dialog turn. We report the *joint goal accuracy*, in which the predicted dialog states are compared to the ground truth slot values at each dialog turn. The ground truth contains slot values for all the (domain, slot) candidate pairs. A prediction is considered correct if and only

Table 5: Results of DS-TOD models on two downstream tasks: Dialog State Tracking (DST) and Response Retrieval (RR) with joint goal accuracy (%) as the metric for DST and R_{100}@1 (Henderson et al., 2020) (%) for RR.

if all predicted slot values exactly match its ground truth values. RR is a ranking problem, relevant for retrieval-based TOD systems (Wu et al., 2017; Henderson et al., 2019c). Following Henderson et al. (2020) and Wu et al. (2020), we adopt recall at top rank given 100 randomly sampled candidates (R_{100}@1) as the evaluation metric for RR.

Data. In the pretraining procedure, we use the domain-specific portions of our novel DOMAINCC and DOMAINREDDIT resources (§2). For the MLM training, we randomly sample 200K domain-specific contexts from DOMAINCC and dynamically mask 15% of the subword tokens. For RS-Class and RS-Contrast, we randomly sample 200K instances from DOMAINREDDIT. We evaluate the efficacy of the methods on DST and RR using MultiWOZ 2.1 (Eric et al., 2020). Since we aim to understand the effect of the domain specialization, we construct domain-specific training, development, and testing portions from the original data set by assigning them all dialogs that belong to a domain (i.e., both single- and multi-domain dialogs) from respective overall (train, dev, test) portions.

Models and Baselines. We experiment with two PLMs: BERT (Devlin et al., 2019) and its TOD-sibling, TOD-BERT (Wu et al., 2020).[5]As baselines, we report the performance of the non-specialized variants and compare them against our domain-specialized PLM variants, obtained after intermediate MLM-training on DOMAINCC or RS-Class/RS-Contrast training on DOMAINREDDIT.

Hyperparameters and Optimization. During domain-specific pretraining, we fix the maximum sequence length to 256 subword tokens (for RS objectives, we limit both the context and response to 128 tokens). We train for 30 epochs, in batches of 32 instances and search for the optimal learning rate among the following values: $\{1\cdot10^{-4}, 5\cdot10^{-5}, 1\cdot10^{-5}, 1\cdot10^{-6}\}$. We apply early stopping based on development set performance (patience: 3 epochs). We minimize the cross-entropy loss using Adam (Kingma and Ba, 2015). For downstream evaluation, we train for 300 epochs in batches of 6 (DST) and 24 instances (RS) with the learning rate fixed to $5\cdot10^{-5}$. We also apply dev-set-based early stopping (patience: 10 epochs).

5 Results and Discussion

Overall performance. We report downstream DST and RR results in Table 5, which is segmented in three parts: (1) at the top we show the baseline results (BERT, TOD-BERT) without any domain specialization; (2) in the middle of the table we show results of PLMs domain-specialized via full fine-tuning; (3) the bottom of the table contains results for our adapter-based domain specialization.

In both DST and RR, TOD-BERT massively outperforms BERT due to its conversational knowledge. Domain specialization brings gains for both PLMs across the board. The only exception is full MLM-fine-tuning of TOD-BERT (i.e., TOD-BERT-MLM vs. TOD-BERT; -4% for RR and -0.8% for DST): we believe that this is an example of negative interference – while TOD-BERT is learning domain knowledge, it is – because of MLM-based domain training – forgetting the conversational knowledge obtained in dialogic pretraining (Wu et al., 2020). This hypothesis is further supported by the fact that adapter-based MLM specialization of TOD-BERT – which prevents negative interference by design – brings slight performance gains (i.e., TOD-BERT-MLM-adapter vs. TOD-BERT; +0.8% for DST and +1.0% for RR) and is consistent

---

[5] We use the pretrained models `bert-base-cased` and `TODBERT/TOD-BERT-JNT-V1` from HuggingFace.

with the concurrent findings of Qiu et al. (2021).

Overall, domain specialization with RS seems to be more robust than that via MLM-ing, with the two variants (RS-Class and RS-Contrast) exhibiting similar average performance across evaluation settings. This points to the importance of injecting both the knowledge of dialogic structure as well as domain knowledge for performance gains in TOD tasks in the domain of interest.

Interestingly, the gains from domain specialization are significantly more pronounced for *Taxi* than for other domains. We relate this to the proportion of the single-domain dialogs for a given domain in MultiWOZ, which is by far the largest (24%, see Table 1) for the *Taxi* domain. Consequently, successful specialization for that domain is *a priori* more likely to show substantial gains on MultiWOZ (i.e., less multi-domain influence).

An encouraging finding is that, on average, adapter-based specialization yields similar gains as specialization via full fine-tuning: given that adapter fine-tuning is substantially more efficient, this holds the promise of more sustainable TOD.

Sample Efficiency. To further understand the effect of the injected domain-specific knowledge, we conduct an additional few-shot analysis (Figure 2) on DST. To this end, we select the *Taxi* domain, since we witnessed the largest gains for that domain. We analyse the differences in performance between baseline and domain-specialized PLMs when they are exposed to downstream training portions of different sizes, ranging from 5 to 100% of the whole training dataset.[6] TOD-BERT retains a sizable performance gap over BERT for all settings, pointing to the power of dialogic pretraining. Importantly, for all dataset sizes, the performances of the domain-specialized variants of TOD-BERT-RS-{Class, Contrast} surpass the one of the non-specialized TOD-BERT. Even more interestingly, specialized variants exposed to only 50% of the DST training data manage to surpass the performance of TOD-BERT fine-tuned on all of the training data (100%). This suggests that self-supervised domain specialization has the potential to substantially reduce the amount of annotated TOD data required to reach some performance level.

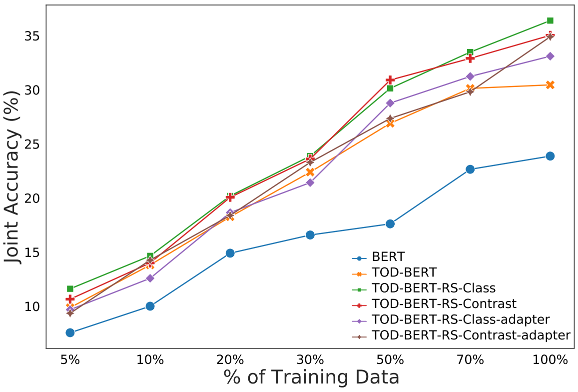

Figure 2: Sample efficiency of DS-TOD for DST: joint goal accuracy (%) for randomly sampled sub-portions (5%, 10%, 20%, 30%, 50%, 70%, and 100%) of the downstream training data from the *Taxi* domain.

	Taxi	Restaurant	Hotel	Train	Attraction
Taxi	4.58	2.65	1.59	0.50	2.47
Restaurant	-0.45	1.23	0.18	2.45	0.99
Hotel	1.74	2.65	2.54	1.84	1.15
Train	0.64	1.40	1.22	0.25	-1.06
Attraction	1.10	0.48	-0.47	-0.81	0.03

Figure 3: Relative improvements (TOD-BERT-RS-Contrast vs. TOD-BERT) in cross-domain DST transfer.

Cross-Domain Transfer. MultiWOZ domains are mutually quite related: some are similar, i.e., share vocabulary and slots (e.g., *Taxi* and *Train*) whereas others often appear together in a dialog (e.g., *Train* and *Hotel*; see Table 1 for the number of multi-domain MultiWOZ dialogs). We thus next investigate whether intermediate training for one domain benefits other, closely related domains. To this end, we expose models specialized for one domain (e.g., *Taxi*) to downstream fine-tuning and evaluation in the other domain (e.g., *Restaurant*). Figure 3 summarizes the deltas in performance between the non-specialized TOD-BERT and TOD-BERT-RS-Contrast for all domain pairs. Encouragingly, the specialization for one domain seems to generally lead to downstream gains in related domains too: the gains are most prominent for pairs of domains that frequently co-occur in dialogs – *Hotel* pretraining for the *Restaurant* downstream (and vice versa) and *Taxi* pretraining for downstream tasks in the *Restaurant* and *Attraction* domains.

Multi-Domain Specialization. In many real-world scenarios, a single model needs to be able to handle multiple domains because (a) multi-domain (MD) dialogs exist and (b) simultaneous deployment of multiple single-domain (SD) models may

---

[6] Note that 5% of the training data in the *Taxi* domain amounts to 83 dialogs.

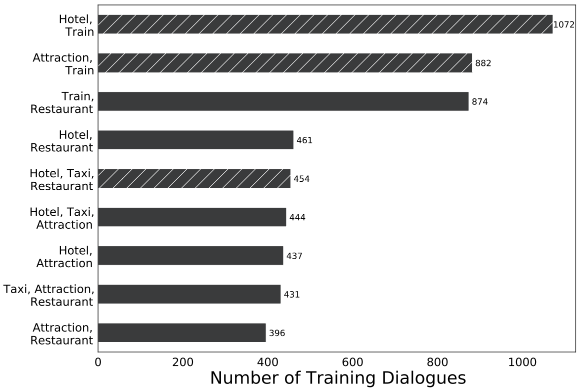

Figure 4: Number of dialogs in the MultiWOZ 2.1 training dataset when joining several domains. Striped bars indicate the domain combinations used for multi-domain specialization.

not be feasible. To simulate this scenario, we conduct an additional analysis, in which we concatenate dialogs from respective MultiWOZ portions that cover concrete combinations of two or three domains. We choose three domain combinations with the largest number of MD dialogs, namely the two largest 2-domain combinations and the largest 3-domain combination (Figure 4): *Hotel+Train*, *Attraction+Train*, and *Hotel+Taxi+Restaurant*.

As baselines, we report the performance of BERT and TOD-BERT fine-tuned on the respective MD TOD training sets. We test the effect of MD specialization in two variants: (1) *fully specialized model trained for multiple domains* (**Full-FT**): as RS-Class has proven to be effective in our SD-specialization experiments, we run RS-Class training on the concatenation of the selected domains from DOMAINREDDIT that correspond to the domains of the joint training sets. Accordingly, the training data is roughly twice (or three times) as big as that used for SD specialization; (2) *composition of SD adapters for multiple domains*: while for Full-FT, a new intermediate training is necessary for each domain combination, with adapter-based specialization we can simply combine the adapters of relevant domains in downstream fine-tuning. In this setup, we combine the SD adapters by sequentially stacking them (Pfeiffer et al., 2020) (**Stacking**) or by fusing them, i.e., interpolating between their outputs (Pfeiffer et al., 2021) (**Fusion**).

The MD specialization results are shown in Table 6. Interestingly, combining SD adapters in downstream training (via Stacking or Fusion) performs *en par* with full-sized two-domain specialization on DOMAINREDDIT by means of RS-Class training. In contrast to TOD-BERT-RS-Class (Full-FT), which requires full retraining of the model on the unlabelled domain-specific corpora for each combination of the domains, combining SD adapters is much more efficient as it does not require any further intermediate domain training for domain combinations. In the 3-domain setup (*Hotel+Taxi+Restaurant*), the Fusion approach even outperforms the full 3-domain specialization (TOD-BERT-RS-Class Full-FT) by 2 points.

Model	**Special. Method**	**Hotel+ Train**	**Attraction+ Train**	**Hotel+Taxi+ Restaurant**
BERT	–	42.66	45.06	37.00
TOD-BERT	–	46.38	46.40	42.47
TOD-BERT-RS-Class	Full-FT	**47.39**	**47.33**	42.39
	Stacking	47.19	46.68	42.15
	Fusion	44.25	45.57	**44.02**

Table 6: DS-TOD performance on DST in multi-domain scenarios. We compare the fully multi-domain-specialized variant (Full-FT) of the TOD-BERT-RS-Class model with its variant that combines readily available single-domain adapters (Stacking and Fusion) on three multi-domain evaluation sets.

Overall, we find that the adapter compositions provide a simple and effective way to combine information from several domain-specialized adapters, removing the need for additional MD specialization in the face of MD dialogs downstream.

6 Related Work

TOD Datasets. Datasets for task-oriented dialog can be divided into single-domain (Wen et al., 2017; Mrkšić et al., 2017) and multi-domain ones (Budzianowski et al., 2018; Rastogi et al., 2020). The latter are generally seen as closer to real-world situations and intended usages of personal assistants, where strict adherence to a single domain is unlikely. While downstream TOD datasets exist for specific domains, corresponding large(er)-scale datasets that would enable domain-specific pretraining have been limited to the general domain (Henderson et al., 2019a).

Pretrained Language Models in Dialog. The advantages of large-scale pretraining of deep language models on massive amounts of text (Devlin et al., 2019; Radford et al., 2019; Lewis et al., 2020), ubiquitous in natural language tasks, have also spilled over to task-oriented dialog. Recent research focused on either (1) leveraging general-domain dialogic resources (e.g., Reddit, Twitter) in order to improve downstream TOD tasks (Henderson et al., 2019c, 2020; Zhang et al., 2020; Bao et al., 2020; Liu et al., 2021b) or (2) using TOD datasets to inject dialogic structure into PLMs (Wu et al., 2020; Peng et al., 2021; Su et al., 2021). Neither of the two, however, considers domain adaptation or domain-specific pretraining.

Domain Adaptation and Knowledge Reuse. Common unsupervised approaches for extracting domain-specific portions of large general domain corpora, rely on term and document frequencies (Kim et al., 2009), learn a candidate retrieval-based classifier (Glavaš et al., 2020) or perform unsupervised domain clustering with PLMs (Aharoni and Goldberg, 2020). In this work, we address the lack of in-domain resources by creating large-scale domain-specific corpora – flat as well as dialogic – for the five domains of the MultiWOZ dataset using a simple TF-IDF based term filtering approach.

Intermediate training is the prevalent approach for injecting domain knowledge into PLMs, either as a step before the downstream task-specific fine-tuning (Glavaš et al., 2020) or in parallel with it (i.e., in a multi-task training setup) (Gururangan et al., 2020). In the narrower context of TOD, Whang et al. (2020) present the lone effort on domain specialization for TOD: they focus on easier, single-domain TOD and investigate the specialization effect with a single task, response retrieval. In this work, in contrast, we focus on dialogic domain-specific pretraining and show its effectiveness in multi-domain TOD. For efficiency and to avoid catastrophic forgetting, adapter modules have been widely used for parameter-efficient fine-tuning of PLMs for new tasks (Houlsby et al., 2019) and languages (Pfeiffer et al., 2020). Non-destructive adapter compositions (e.g., stacking or fusion) can be beneficial if multiple knowledge facets, stored in separate adapters, need to be leveraged (Pfeiffer et al., 2020, 2021).

7 Reproducibility

We provide the complete lists of keywords used for domain-specific corpus filtering in Table 2, and a transparent description of the filtering approach in §2.1. We also release the filtered corpora for each domain. This makes our approach completely transparent and fully reproducible. All resources developed as part of this work are publicly available at: `https://github.com/umanlp/DS-TOD`.

8 Conclusion

We introduced **DS-TOD** – a novel framework for domain specialization of PLMs for task-oriented dialog. Given a collection of in-domain dialogs, we extract domain terms and use them to filter in-domain dialogic corpora. Our experimental study, on five domains of the MultiWOZ dataset, shows that domain specialization, especially by means of response selection objectives on the dialogic in-domain corpora, leads to consistent gains in TOD tasks: dialogue state tracking and response retrieval. We hope that our domain-specific resources catalyze research on domain specialization for TOD, especially for multi-domain setups. Our future efforts will focus on the joint domain- and language-specialization for task-oriented dialog.

Ethical Considerations

In this work, we have focused on domain specialization of task-oriented dialog models. While the limited scope of this manuscript prevents us from an in-depth discussion of potential ethical issues related to conversational AI in general, we would like to highlight the sensitivity of many of the envisioned future applications and the corresponding potential harms, e.g., unfair stereotypical biases encoded in pretrained language models, both general purpose (Nadeem et al., 2021; Lauscher et al., 2021) and conversational PLMs (Barikeri et al., 2021) alike and exclusion and misrepresentation within the large spectrum of users' (gender) identities (Dev et al., 2021; Lauscher et al., 2022), which might arise depending on the sociotechnical deployment environment. Further, in light of potential environmental harms arising from training large PLMs (Strubell et al., 2019), we would like to point the reader to the computational efficiency of our adapter-based specialization approaches, specifically in a multi-domain setup.

A Domain-Specific Corpora

In this section, we show examples from both DomainCC (Table 7) and DomainReddit (Table 8). Both these resources were created starting from the salient domain terms listed in Table 2.

Domain	**“Flat” Text**
Taxi	***Taxis****: licensed black* ***cabs*** *operate a 24-hour, 365 day service from directly outside the arrivals area of the terminal building. Each* ***taxi*** *can carry up to five passengers (some can carry up to eight), with luggage and all are able to take wheelchair passengers.*
Restaurant	***Asian food*** *is very easy to like because it hits your mouth very differently than* ***European food*** *does. In* ***European food****, there may be two things to hit - maybe sweet and salty, maybe salty-savory, but Asian kind of works around, plus you have that distinct in the evening, a five course wine tasting dinner will be served in a gastronomic 2 Michelin starred* ***restaurant****.*
Train	*Getting to centre* ***London*** *is very easy as it take only one underground* ***train*** *and it takes only 20-25 minutes to get to Oxford Circus.* ***Stansted airport*** *is only 31 minutes away and all major motorways (M1, M11, North circular) is 5-10 minutes away.*
Hotel	*Beautifully restored 1920’s* ***guesthouse****, comfortable and spacious bedrooms, lush gardens to explore, friendly and super helpful host, secure* ***parking****. What more could you ask for! I would definitely recommend 6 on Kloof.*
Attraction	*On 31 august we travelled to Ely by train from kings cross and visited the Cathedral’s interesting stained glass* ***museum****. We also visited Oliver Cromwell’s house nearby and sat outside for lunch, an extra bonus as it was a beautiful summer day. There was also time to look around Ely’s* ***town centre*** *before heading home.*

Table 7: Example from DomainCC dataset, where the salient domain terms are marked as **bold**. The texts are displayed in the original version, without correcting typos.

Domain	Dialogic Data	
Taxi	**Context:** *I wager that is majorly low. All the* ***taxi*** *drivers around me drive brand new hybrid* ***Lexus****'s. If you consider the fuel, cars upkeep, the car itself and the insurance. They must be owning a good scoop to make all that worth it.*	**True Response:** *A lot of* ***taxi*** *drivers round my way are working two jobs and have it as their second gig filling in what little free time they have from their main job.* **False Response:** *Buying vehicles (converged ones in my fathers case) is a huge expense which I don't think can be fully tax offset.*
Restaurant	**Context:** *Interesting. Thanks for the post and thanks for mentioning Normandie. I will definitely check that out and look at staying somewhere other than Zocalo. Any other recommendations for stuff you really liked? I'm a huge food guy so any awesome* ***restaurants*** *(already have a Pujol* ***reservation****) are welcome.*	**True Response:** *You're welcome. Thanks for reading. Don't get me wrong Zocalo has some historic significance etc. and is nice to visit for the day, but that's about all the time you need there. For some* ***cheap*** *but still good tacos, ...* **False Response:** *Zocalo is hectic and filled with tons of people. IMO after 1 day there you'll want out. Roma Norte and Condesa have some beautiful parks and are filled with cool cafes, restaurants and bars ...*
Train	**Context:** *You just need to hope you don't need to walk all the way to the back of the* ***train****.*	**True Response:** *I have to do I multiple times a day with the TGV's. Those are only 200m short. I don't working on this 400m* ***train*** *often. But yes it happens.* **False Response:** *We need a sub for European trains!*
Hotel	**Context:** *Thanks for the info. I didn't book a* ***hotel*** *yet and plan to do that by tomorrow. Wasn't aware that most don't have* ***free parking****. I'll try to find one with* ***parking*** *included.*	**True Response:** *You are not likely to find a* ***hotel*** *with* ***free parking*** *in the old city. And, to be honest, unless budget is a big deal, for a short trip it's entirely worth the experience to stay in either the upper or lower old city ...* **False Response:** *Where is your hotel? Many either have parking, or arrangements for parking in nearby lots and garages. If you're at or near the Frontenac there is a public garage under city hall that is much less expensive than many hotel options.*
Attraction	**Context:** *Thank youuu! I'll better pack a coat to keep myself warm! Hmm you're right I might just skip the day trip! I like history/****museum****, art,* ***architecture*** *and scenery/nature! What are the top few places do you recommend though?*	**True Response:** *In terms of* ***museums*** *and history, you're really spoilt for choice in London. The Natural History* ***Museum****, Imperial War* ***Museum*** *and National Maritime* ***Museum*** *are my personal favourites. If you like nature go check out the wildlife in Richmond* ***Park****. It's a ...* **False Response:** *The UK is due to be extremely cold this winter so I'd have some extra warm clothes just in case. November is usually fine, a bit rainy, but this year might be a special case. You can visit Camden but I personally wouldn't spend ...*

Distinguishing Non-natural from Natural Adversarial Samples for More Robust Pre-trained Language Model

Abstract

Recently, the problem of robustness of pre-trained language models (PrLMs) has received increasing research interest. Latest studies on adversarial attacks achieve high attack success rates against PrLMs, claiming that PrLMs are not robust. However, we find that the adversarial samples that PrLMs fail are mostly non-natural and do not appear in reality. We question the validity of current evaluation of robustness of PrLMs based on these non-natural adversarial samples and propose an anomaly detector to evaluate the robustness of PrLMs with more natural adversarial samples. We also investigate two applications of the anomaly detector: (1) In data augmentation, we employ the anomaly detector to force generating augmented data that are distinguished as non-natural, which brings larger gains to the accuracy of PrLMs. (2) We apply the anomaly detector to a defense framework to enhance the robustness of PrLMs. It can be used to defend all types of attacks and achieves higher accuracy on both adversarial samples and compliant samples than other defense frameworks. The code is available at https://github.com/LilyNLP/Distinguishing-Non-Natural.

1 Introduction

Pre-trained language models (PrLMs) have achieved state-of-the-art performance across a wide variety of natural language understanding tasks (Devlin et al., 2018; Liu et al., 2019a; Clark et al., 2020). Most works of PrLMs mainly focus on designing stronger model structures and training objectives to improve the accuracy or training efficiency. However, in real industrial applications, there exist noises that can mislead the predictions of PrLMs (Malykh, 2019), which raise potential security risks and limit the application efficacy of PrLMs in practice. To solve this challenge, studies around the robustness of PrLMs have received increasing research interest. Recent studies demonstrated that, due to the lack of supervising signals and data noises in the pre-training stage, PrLMs are vulnerable to adversarial attacks, which can generate adversarial samples to fool the model (Zhang et al., 2020). A variety of attack algorithms have been proposed to use spelling errors (Li et al., 2019), synonym substitutions (Jin et al., 2020), phrase insertions (Le et al., 2020) or sentence structure reconstructions (Zhao et al., 2018) to generate adversarial samples. Some of these attack algorithms have achieved an over 90% attack success rate on PrLMs (Li et al., 2020; Garg and Ramakrishnan, 2020). Thus they claim that existing PrLMs are not robust.

However, we investigate the adversarial samples on which PrLMs fail, and find that most of them are not natural and fluent, thus can be distinguished by humans. These samples are unlikely to appear in reality and are against the principle that adversarial samples should be imperceptible to humans (Zhang et al., 2020). Therefore it is not reasonable to judge the robustness of PrLMs based on these non-natural adversarial samples. By adopting a PrLM-based anomaly detector and a two-stage training strategy, we empirically demonstrate that most of the non-natural adversarial samples can be detected by the machine. Furthermore, we adopt the anomaly score (the output probability of the anomaly detector) as a constraint metric to help adversarial attacks generate more natural samples. Under this new constraint of generating natural samples, the attack success rates of existing attack methods sharply decrease. These experimental results demonstrate that the robustness of PrLMs is not as fragile as previous works claimed.

Then we explore two application scenarios of the anomaly detector. Firstly, we wonder whether the anomaly detection can generalize to other appli-

---

cations using artificially modified sentences. Thus we think of the data augmentation scenario. The objective of data augmentation is to increase the diversity of training data without explicitly collecting new data (Wei and Zou, 2019). For an original sequence and a data augmentation technique, there exist many possible augmented sequences. We apply the anomaly detector to select among these possibilities the augmented sequence that can bring more diversity into training data. For each original sequence, we continuously generate augmented sequences until the anomaly detector distinguishes one as anomaly. The augmented data under this constraint can further increase the prediction accuracy of PrLMs than ordinary data augmentation.

Secondly, we integrate the anomaly detector into a defense framework to enhance the robustness of PrLMs. Inspired by the defense methods in the computer vision domain (Liu et al., 2019b; Das et al., 2017; Raff et al., 2019) which apply transformations like JPEG-based compression to mitigate the adversarial effect, we use textual transformations to restore adversarial samples. We consider a candidate set of transformation functions including back translation, MLM suggestion, synonym swap, adverb insertion, tense change, and contraction. For the input sequence that is detected as an adversarial sample, we randomly apply k transformation functions from the candidate set to the sequence. We send the k transformed sequences to the PrLM classifier to get their prediction scores. The final prediction is based on the average of these k prediction scores. Empirical results demonstrate that this defense framework achieves higher accuracy than other defense frameworks on both adversarial samples and compliant samples (By compliant samples, we mean the non-adversarial samples in original datasets).

2 Related Work

The study of the robustness of PrLMs is based on the competition between adversarial attacks and defenses. Adversarial attacks find the adversarial samples where PrLMs are not robust, while defenses enhance the robustness of PrLMs by utilizing these adversarial samples or modifying model structure against the attack algorithm.

2.1 Adversarial Attacks

Problem Formulation Adversarial attacks generate adversarial samples against a victim model F, which is a PrLM-based text classifier in this paper. Given an input sequence X, the victim model F predicts its label $F(X) = y$. The corresponding adversarial sample X_{adv} should alter the prediction of the victim model and meanwhile be similar to original sequence:

$$\begin{aligned} &F(X_{adv}) \neq F(X) \\ &s.t. \quad d(X_{adv}, X) < \sigma, \end{aligned} \tag{1}$$

where $d()$ measures the size of perturbations, and σ is a predefined threshold.

Classification of attacks Adversarial attacks can be conducted in both white-box and black-box scenarios. In the white-box scenario (Meng and Wattenhofer, 2020), adversarial attacks can access all information of their victim models. In the black-box scenario, adversarial attacks can only get the output of the victim models: if they get prediction scores, they are score-based attacks (Jin et al., 2020); if they get the prediction label, they are decision-based attacks (Wallace et al., 2020).

According to the granularity of perturbations, textual attacks can be classified into character-level, word-level, and sentence-level attacks. Character-level attacks (Gao et al., 2018) introduce noises by replacing, inserting, or deleting a character in several words. Word-level attacks substitute several words by their synonyms to fool the model (Jin et al., 2020; Garg and Ramakrishnan, 2020). Sentence-level attacks generate adversarial samples by paraphrasing the original sentence (Iyyer et al., 2018) or using a generative adversarial network (GAN) (Zhao et al., 2018).

Metrics to constrain perturbations To evaluate the robustness of PrLMs, it is important that the adversarial samples are within a perturbation constraint. An adversarial sample must have similar semantic meaning to the original sample, while syntactically correct and fluent as a natural language sequence. Existing attack methods adopt the following metrics to realize this requirement:

(1) **Semantic Similarity**: semantic similarity is the most popular metric used in existing attack works (Jin et al., 2020; Li et al., 2020). They use Universal Sentence Encoder (USE) (Cer et al., 2018) to encode original sentence and adversarial sentence into vectors and use their cosine similarity to define semantic similarity.

(2) **Perturbation Rate**: perturbation rate is often used in word-level attacks (Jin et al., 2020) (Li

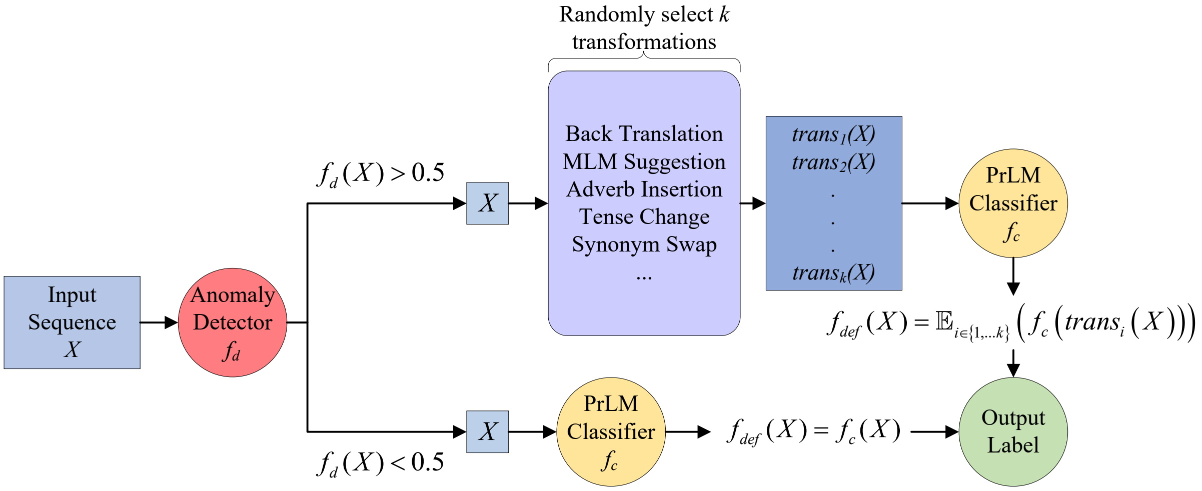

Figure 1: Defense framework.

et al., 2020) to indicate the rate between the number of modified words and total words.

(3) **Number of Increased Grammar Errors**: it is the number of increased grammatical errors in the adversarial sample compared to the original sample. This metric is used in (Maheshwary et al., 2020), (Li et al., 2021) and is calculated using LanguageTool (Naber, 2003).

(4) **Levenshtein Distance**: levenshtein distance is often used in character-level attacks (Gao et al., 2018). It refers to the number of editing operations to convert one string to another.

2.2 Adversarial Defenses

The objective of adversarial defenses is to design a model which can achieve high accuracy on both compliant and adversarial samples. One direction of adversarial defenses is adversarial training. By augmenting original training data with adversarial samples, the model is trained to be more robust to the perturbations seen in the training stage (Goodfellow et al., 2015). However, it is impossible to explore all potential perturbations within a limited number of adversarial samples. Empirical results demonstrate that the improvement of robustness brought by adversarial training alone is quite limited when faced with strong dynamic attacks (Jin et al., 2020; Maheshwary et al., 2020).

Another direction is modifying the model structure against a specific type of adversarial attack. For character-level attacks, ScRNN (Pruthi et al., 2019) leverages an RNN semi-character architecture to identify and restore the modified characters. For word-level attacks, DISP (Zhou et al., 2019) utilizes a perturbation discriminator followed by an embedding estimator to restore adversarial samples. For sentence-level attacks, DARCY (Le et al., 2021) greedily searches and injects multiple trapdoors into the model to catch potential UniTrigger attacks (Wallace et al., 2019).

Certified robustness is a particular branch of defense whose aim is to ensure that the model predictions are unchanged within a perturbation scope. For example, (Jia et al., 2019) and (Huang et al., 2019) certify the robustness of the model when input word embeddings are perturbed within the convex hull formed by the embeddings of its synonyms. However, certified robustness is hard to scale to deep networks and harms the model's accuracy on compliant samples due to the looser outer bound.

3 Methods

3.1 Anomaly Detector

We adopt a PrLM-based binary classifier as the anomaly detector to distinguish adversarial samples from compliant samples. For an input sequence X, X is firstly separated into sub-word tokens with a special token `[CLS]` at the beginning. A PrLM then encodes the tokens and generates a sequence of contextual embeddings $\{h_0, h_1, h_2, ..., h_n\}$, in which $h_0 \in \mathbb{R}^H$ is the contextual representation of `[CLS]`. For text classification tasks, h_0 is used as the aggregate sequence representation which contains the sentence-level information. So the anomaly detector leverages h_0 to predict the probability that X is labeled as class $\hat{y}_d$ (if X is adversarial sample, $\hat{y}_d = 1$; if X is compliant sample,

	Example
Original	You wonder why enough wasn't just a music video rather than a full-length movie.
Back Translation	You wonder why enough **was not** just a music video**, but** a full-length movie.
MLM Suggestion	You wonder why enough wasn't just a music video rather than a full-length **film**.
Adverb Insertion	You **profoundly** wonder why enough **aside** wasn't just a music video rather than a full-length movie.
Tense Change	You **wondered** why enough **isn't** just a music video rather than a full-length movie.
Synonym Swap	You **doubt** why **full** wasn't **only** a music video rather than a full-length movie.
Contraction	You wonder why enough **was not** just a music video rather than a full-length movie.

Figure 2: Examples of transformation functions used in the defense framework.

	Label	Example	Anomaly Score
Original	**Positive**	Seldom has a movie so closely matched the spirit of a man and his work.	0.3%
DeepWordBug	**Negative**	Seldom has a moviMe so closely matched the sptrit of a man and his work.	99.2%
TextFooler	**Negative**	Seldom has a **movies** so closely **confronted** the **esprit** of a **fella** and his **cooperate**.	98.7%
BERT-Attack	**Negative**	Seldom **possesses** a movie**,** closely matched the spirit of a man and his work **because**	98.3%
SCPN	**Negative**	**There's rarely a film of a man and his job.**	0.4%

Figure 3: Examples of adversarial samples generated by four adversarial attacks.

$\hat{y_d} = 0$) by a logistic regression with softmax:

$$y_d = \text{softmax}(W_d(dropout(h_0)) + b_d). \quad (2)$$

And we use the binary cross entropy loss function to train the anomaly detector :

$$loss_d = -y_d * \log\hat{y_d} - (1-y_d) * \log(1-\hat{y_d}). \quad (3)$$

We adopt a two-stage training strategy for the anomaly detector. In the first stage, we generate the "artificial samples" using the same way each attack modifies the sentence (details of how attacks modify the sentences are described in Section 4.2). But the artificial samples are not required to alter the prediction result of the PrLM, so the modification is only applied once. For example, to generate artificial samples simulating the word-level attack TextFooler, we substitute a portion of words by their synonyms in a synonym set according to WordNet. The training data consist of original samples (labeled as 0) in the train set and their corresponding artificial samples (labeled as 1). We train the detector on these data so that it can learn to distinguish artificially modified sequences from natural sequences. In the second stage, we generate the adversarial samples (labeled as 1) from the original samples (labeled as 0) in the train set, and train the anomaly detector to distinguish adversarial samples from original samples. In this way, the detector can distinguish non-naturally modified examples, and especially the adversarial ones among them. The experimental results in section 5.1 demonstrate that the anomaly detector can accurately distinguish adversarial samples from compliant samples.

Task	Dataset	Train	Test	Avg Len

	SST2	67K	1.8K	20
	IMDB	25K	25K	215
Entailment	MNLI	433K	10K	11

Table 1: Dataset statistics.

3.2 Evaluation of Robustness under Anomaly Score Constraint

Existing adversarial samples have applied some thresholds to limit the anomaly of adversarial samples. However, the generated adversarial samples are still not natural, indicating that existing metrics are not effective enough. In order to measure the robustness of PrLMs with more natural adversarial samples, we use a new metric: anomaly score, to constrain the perturbations. Given a sentence X, we leverage the probability that X is adversarial sample predicted by anomaly detector as the anomaly score of X:

$$Score(X) = Prob(\hat{y_d} = 1|X). \quad (4)$$

For existing attacks, we add a threshold on anomaly score to enforce the attacks to generate more natural and undetectable adversarial samples.

Table 3: The attack success rate of attacks using BERT as victim model without and with the anomaly score constraint on MR, SST2, IMDB, MNLI.

The attack problem formulation now becomes:

$$\begin{aligned} &F(X_{adv}) \neq F(X) \\ &s.t. \quad d(X_{adv}, X) < \sigma, \\ &\qquad Score(X_{adv}) < 0.5, \end{aligned} \tag{5}$$

where $d()$ measures the perceptual difference between X_{adv} and X. Each attack has its own definition of $d()$ and threshold σ. And we add on a new constraint that the anomaly score of X_{adv} should be smaller than 0.5. We investigate the robustness of PrLMs under the constraint of anomaly score and find that PrLMs are more robust than previously claimed.

3.3 Application in Data Augmentation

In data augmentation, PrLM is trained on original sentences and their artificially augmented sentences to improve the diversity of training data. We consider random synonym substitution as the augmentation technique for experiments. For an original sequence of n words, we randomly select $p\% * n$ words and substitute them with their synonyms to form the augmented sequence. For each replaced word, the replacing synonym is randomly selected among its s most similar synonyms. So we will have in total $C_n^{p\%*n} * s^{p\%*n}$ possible augmented sequences. In order to select the augmented sequence that can bring more diversity into training data, we apply the anomaly detector to select the augmented sequence that is distinguished as anomaly. For each original sequence, we continuously apply random synonym substitution to form candidate augmented sequences until the detector distinguishes one as anomaly.

3.4 Application in Enhancing Robustness

There are two ways to apply the anomaly detector in enhancing the robustness of PrLMs: (1) detect and then directly block the adversarial samples; (2) distinguish the adversarial samples and conduct operations on them to make the PrLMs give correct predictions. The first application is trivial so we explore the second way.

We propose a defense framework as shown in Figure 1. We firstly build a transformation function set containing t transformation function candidates: *Back Translation* (translate the original sentence into another language and translate it back to original language); *MLM Suggestion* (mask several tokens in the original sentence and use masked language model to predict the masked tokens); *Adverb Insertion* (insert adverbs before verbs); *Tense Change* (change the tense of verbs into another tense); *Synonym Swap* (swap several words with their synonyms according to WordNet), *Contraction* (contract or extend the original sentence by common abbreviations). We implement these transformation functions based on (Wang et al., 2021) [1]. The examples of these transformation functions are displayed in Figure 2.

For each input sequence X, we apply the anomaly detector f_d to identify whether it is adversarial ($f_d(X) > 0.5$) or not ($f_d(X) < 0.5$). If the X is recognized as compliant sample, it will be directly sent to the PrLM classifier f_c to get the final output probability of the defense framework: $f_{def}(X) = f_c(X)$. If X is recognized as adversarial sample, we will randomly select k transformation functions from the transformation candidate

Table 5: The accuracy of no augmentation, after the data augmentation without and with the selection of detector on MR.

set and apply them to X. We send the k transformed sequences $trans_i(X), i \in \{1, ..., k\}$ to the PrLM classifier to get their prediction probabilities $f_c(trans_i(X)), i \in \{1, ..., k\}$, and the final prediction probability of the defense framework is the expectation over the k transformed probabilities $f_{def}(X) = \mathbb{E}_{i\in\{1,...,k\}}(f_c(trans_i(X)))$.

Since the detector is not perfect, there always exist a small number of compliant samples that are misclassified into adversarial samples. In order to minimize the harm to the accuracy of PrLMs on compliant samples, during the training stage of PrLMs, we augment the training data with their transformed data. In this way, the PrLMs are more stable to transformations on compliant samples, and data augmentation itself also brings gains to the accuracy of PrLMs.

4 Experimental Implementation

4.1 PrLMs

We investigate three PrLMs: BERT$_{\text{BASE}}$ (Devlin et al., 2018), RoBERTa$_{\text{BASE}}$ (Liu et al., 2019a) and ELECTRA$_{\text{BASE}}$ (Clark et al., 2020). The PrLMs are all implemented in their base-uncased version based on PyTorch [2]: they each have 12 layers, 768 hidden units, 12 heads and around 100M parameters. For most experiments on attacks and defenses, we use BERT$_{\text{BASE}}$ as the victim model for an easy comparison between our results and those of previous works.

4.2 Adversarial Attacks

We investigate four adversarial attacks from character level, word level to sentence level. Examples of adversarial samples generated by these four attacks are demonstrated in Figure 3.

Character-level attack For character-level attack, we consider Deepwordbug, which applies four types of character-level modifications (substitution, insertion, deletion and swap) to words in the original sample. Edit distance is used to constrain the similarity between original and adversarial sentences.

Word-level attack We select two classic word-level attack methods: TextFooler (Jin et al., 2020) and BERT-Attack (Li et al., 2020). They both sort the words in the original sample by importance scores, and then substitute the words in order with their synonyms until the PrLM is fooled. TextFooler selects the substitution word from a synonym set of the original word according to WordNet (Mrkšić et al., 2016). BERT-Attack masks the original word and uses the masked language model (MLM) to predict the substitution word. Semantic similarity and perturbation rate are used to constrain the perturbation size.

Sentence-level attack We select SCPN [3] (Iyyer et al., 2018) to generate sentence-level adversarial samples. SCPN applies syntactic transformations to original sentences and automatically labels the sentences with their syntactic transformations. Based on these labeled data, SCPN trains a neural encoder-decoder model to generate syntactically controlled paraphrased adversarial samples. Semantic similarity is used to ensure that the semantic meaning remains unchanged.

4.3 Datasets

Experiments are conducted on four datasets: **SST2** (Socher et al., 2013), **MR** (Pang and Lee, 2005), **IMDB** (Maas et al., 2011), **MNLI** (Nangia et al.,

2017), covering two major NLP tasks: text classification and natural language inference (NLI). The dataset statistics are displayed in Table 1.

For text classification task, we use three datasets with average text lengths from 20 to 215 words in English: (1) **SST2** (Socher et al., 2013): a phrase-level binary sentiment classification dataset on movie reviews; (2) **MR** (Pang and Lee, 2005): a sentence-level binary sentiment classification dataset on movie reviews; (3) **IMDB** (Maas et al., 2011) : a document-level binary sentiment classification dataset on movie reviews. For the NLI task, we use **MNLI** (Nangia et al., 2017), a widely adopted NLI benchmark with coverage of the transcribed speech, popular fiction, and government reports. When attacking the NLI task, we keep the original premises unchanged and generate adversarial hypotheses.

4.4 Experimental Setup

The hyperparameter k in the defense framework is 3. For the victim PrLMs under attack, we fine-tune PrLMs on the training set of each dataset. For the anomaly detector, we use $\text{BERT}_{\text{BASE}}$ as the base PrLM and fine-tune it on the training data indicated in Section 3.1. For the data augmentation, we fine-tune PrLMs on the augmented training set of each dataset. During the fine-tuning of all these PrLMs, we use AdamW (Loshchilov and Hutter, 2018) as our optimizer with a learning rate of 3e-5 and a batch size of 16. The number of training epochs is set to 5. To avoid randomness, we report the results of applications in data augmentation and defense framework based on the average of 3 runs.

5 Experimental Results

5.1 Anomaly Detector

We consider three metrics to evaluate the performance of the anomaly detector: *F1 score* (F1); *True Positive Rate* (TPR): the percentage of adversarial samples that are correctly identified; *False Positive Rate* (FPR): the percentage of compliant samples that are misidentified as adversarial. The experimental results are shown in Table 2. The results of SCPN on the IMDB dataset are unavailable since SCPN cannot tackle document-level texts. Empirical results demonstrate that the anomaly detector can achieve an average F1 score over 90%, an average TPR over 88%, and an average FPR less than 10% for adversarial attacks from character-level, word-level to sentence-level.

5.2 Evaluation of Robustness under Anomaly Score Constraint

We now conduct different types of attacks under the constraint that the anomaly score of generated adversarial samples should be less than 0.5. Table 3 compares the attack success rate of different attacks with and without the anomaly score constraint when the victim PrLM is BERT. We can observe a sharp decrease in attack success rate with the new constraint for all levels of attacks. This result is surprising in that the attackers examined are dynamic. Despite their iterative attempts to attack the model, the attackers fail to generate a natural adversarial sample that can bypass the anomaly detector.

To ensure that this phenomenon holds for other PrLMs, we conduct experiments on RoBERTa and ELECTRA. As shown in Table 4, the attack success rates also drop markedly under the constraint of anomaly score for these PrLMs. These empirical results demonstrate that PrLMs are more robust than previous attack methods have claimed, given that most of the adversarial samples generated by previous attacks are non-natural and detectable. However, there still exist a little portion

Table 8: The performance of our defense framework compared with other word-level defenses using BERT as PrLM and TextFooler as attack. Orig% is the original accuracy and Adv% is the adversarial accuracy.

of undetectable adversarial samples that can successfully mislead PrLMs.

5.3 Application in Data Augmentation

We consider the random synonym substitution that substitutes 30% words with their synonyms selected in 50 most similar words. Table 5 compares the accuracy after data augmentation without and with the selection of anomaly detector. We can observe a further increase in accuracy with the selection of the anomaly detector. However, the stronger the PrLM is, the smaller the increase is.

5.4 Application in Enhancing Robustness of PrLMs

We evaluate the performance of the defense framework based on original accuracy and adversarial accuracy. The original accuracy is the prediction accuracy of the defense framework on original compliant samples. The adversarial accuracy is the accuracy of the defense framework after the attack. Here we consider the situation that the attack algorithm can iteratively generate adversarial samples against our defense framework until it succeeds or exceeds the upper limit of attempts.

Table 6 shows the adversarial accuracy with and without the defense using BERT as the victim PrLM. We can see a large improvement in the adversarial accuracy with the defense for all levels of attacks. Table 7 shows the original accuracy with and without the defense. We find that the original accuracy gets even higher with the defense. This is because with anomaly detection, the transformations are only applied to detected adversarial examples. For the very few compliant sentences that are detected by mistake as anomaly and then applied transformations, the data augmentation in the training stage has trained the PrLMs to be stable to transformations on compliant samples. Besides, the data augmentation alone brings an increase to the original accuracy. Therefore the proposed framework does not harm and even increases the prediction accuracy for non-adversarial samples, which is important in real application scenarios.

Since word-level attacks are the most influential and widely-used type of attack, we compare the performance of our defense framework with several state-of-the-art word-level defenses (adversarial training, DISP, SAFER) while facing TextFooler as the attack model. DISP (Zhou et al., 2019) detects and restores adversarial examples by leveraging a perturbation discriminator and an embedding estimator. SAFER (Ye et al., 2020) smooths the classifier by averaging the outputs of a set of randomized examples. As shown in Table 8, although DISP and SAFER are especially designed for word-level attacks, our defense framework outperforms them in most cases on both original accuracy and adversarial accuracy.

6 Discussion

There are two trade-offs for the defense framework:

(1) The trade-off between original accuracy and adversarial accuracy. If we abandon the anomaly detector and apply random transformations to all input sequences, then the adversarial accuracy can further increase by 5-7%, but the original accuracy will decrease by 1-3%. Since in real applications it is not reasonable to sacrifice too much precision for possible security problems, we adopt the anomaly detector to preserve the original accuracy. However, by developing a stronger detector with a higher TPR, the defense framework has the potential to achieve higher adversarial accuracy.

(2) The trade-off between training efficiency and original accuracy. To preserve the original accuracy, we apply data augmentation in the training stage of the defense framework to make it more stable to transformations on compliant samples. However, the training cost is now multiplied by the size of the transformation set n ($n = 6$ in the experimental realization). If we abandon the data augmentation in training stage, the training effi-

ciency of the defense framework is the same as the vanilla fine-tuning of PrLM, but the original accuracy will decrease by 0.5-1.5%.

A limitation of our work is that the attacks we examined are black-box or grey-box attacks, but do not include white-box (gradient-based) attacks. However, since more than 75% of the existing textual attacks are not based on gradient [4], the defense framework is effective for the majority of attacks. We will investigate white-box attacks in future works.

7 Conclusion

In this study, we question the validity of the current evaluation of robustness of PrLMs based on non-natural adversarial samples, and propose an anomaly detector to evaluate the robustness of PrLMs with more natural adversarial samples. To increase the precision of PrLMs, we employ the anomaly detector to select the augmented data that are distinguished as anomaly to introduce more diversity in the training stage. The data augmentation after selection brings larger gains to the accuracy of PrLMs. To enhance the robustness of PrLMs, we integrate the anomaly detector to a defense framework using expectation over randomly selected transformations. This defense framework can be used to defend all levels of attacks, while achieving higher accuracy on both adversarial samples and compliant samples than other defense frameworks targeting specific levels of attack.

Abstract

We present a comprehensive study of sparse attention patterns in Transformer models. We first question the need for pre-training with sparse attention and present experiments showing that an efficient fine-tuning only approach yields a slightly worse but still competitive model. Then we compare the widely used local attention pattern and the less-well-studied global attention pattern, demonstrating that global patterns have several unique advantages. We also demonstrate that a flexible approach to attention, with different patterns across different layers of the model, is beneficial for some tasks. Drawing on this insight, we propose a novel Adaptive Axis Attention method, which learns—during fine-tuning—different attention patterns for each Transformer layer depending on the downstream task. Rather than choosing a fixed attention pattern, the adaptive axis attention method identifies important tokens—for each task and model layer—and focuses attention on those. It does not require pre-training to accommodate the sparse patterns and demonstrates competitive and sometimes better performance against fixed sparse attention patterns that require resource-intensive pre-training.

1 Introduction

The wide adoption of the Transformer architecture (Vaswani et al., 2017) in contextual language representations such as BERT (Devlin et al., 2019) has spurred interest in making transformers more efficient via sparse attention patterns (Li et al., 2019; Guo et al., 2019; Gong et al., 2019; Zaheer et al., 2020; Child et al., 2019).

The typical process for learning a transformer model (*e.g.*, BERT) with a sparse attention pattern is to replace the full attention calculation with that pattern, then pre-train the model with the usual pre-training task and fine-tune the model to downstream tasks. The use of sparse attention pattern does not necessarily significantly improve the run time of the models[1] but it does reduce the model memory requirement during inference time. This reduction is helpful when deploying models on mobile devices or other memory-limited devices.

In this paper we offer an extensive analysis of attention patterns, organized around the following questions: (1) is *pre-training* essential or is it possible to employ sparse patterns during *fine-tuning* only? (2) which *types* of *attention patterns* are important? (3) should *the same* attention pattern be applied to different downstream tasks and to all layers of the model?

The answer to the first question carries critical implications for the practical adoption of sparse attention approaches. Most current transformer-based approaches learn fixed patterns during pre-training and then apply these to fine-tuning as well. However, it is costly and impractical to pre-train a new model from scratch when a different attention pattern is expected to be more appropriate for a task. Learning the sparse attention pattern model during fine-tuning is more reasonable.

With this motivation in mind, we perform a controlled experiment on the eight tasks in the GLUE (Wang et al., 2019a) benchmark. We find that pre-training with sparse patterns is not a crucial ingredient for good performance—learning the model solely during fine-tuning sacrifices only one or two performance points on most tasks. Grounded in this finding, we perform all other experiments efficiently, starting with the same pre-trained model and varying sparse attention patterns during fine-tuning alone.

We start to answer the second question by analyzing the two most popular patterns: local and global (Tay et al., 2020). Local patterns allow each token to attend only to other tokens within a given window. Global patterns allow some specially des-

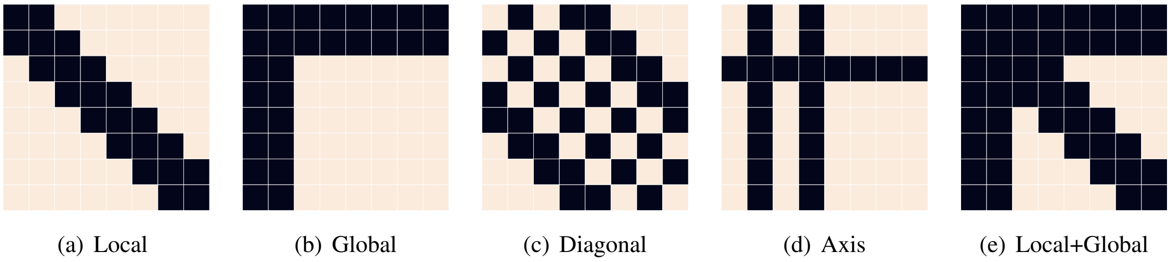

Figure 1: Five attention patterns (with $N = 8$): Local, Global, their generalized forms: Diagonal and Axis, and a combination of Local and Global attention: Local+Global.

ignated tokens to attend to all other tokens while the remaining tokens are allowed to attend only to the specially designated tokens. We show that global pattern exhibits unique and complementary strengths that local patterns cannot capture. This finding is aligned with the design choices for recent models that benefit from the combination of both patterns (Beltagy et al., 2020; Zaheer et al., 2020).

For the third question, we extend SparseBERT (Shi et al., 2021) to an adaptive diagonal attention model. With this model, we are able flexibly learn task-wise and/or layer-wise diagonal patterns. Adapting attention patterns to tasks and layers improves performance over fixed attention pattern baselines and yields equivalent memory gains/sparsity levels.

Motivated by these findings, we design an adaptive sparse pattern that is learned during fine-tuning and that adapts to the task, layer as well as to the input sample. Our pattern is an instance of axis patterns (Figure 1(d)), which are a more general form of global patterns; we name it Adaptive Axis Attention (AAA). AAA samples the *important* tokens by applying a fully connected layer that is followed by Gumbel Softmax (Jang et al., 2017) applied to the token representations on each Transformer layer. The tokens identified as important are then designated as the global tokens and are used to form an axis-aligned attention pattern.

Through extensive experiments we verify that learning such an adaptive axis attention can outperform the fixed patterns adopted in Longformer (Beltagy et al., 2020), BigBird (Zaheer et al., 2020) and SparseBERT (Shi et al., 2021). AAA rivals or outperforms the fixed patterns even when compared with their pre-trained variants, which require extensive time and resources for pre-training.

We also show that AAA can be integrated into lightweight models, *e.g.*, MobileBERT (Sun et al., 2020). The benefits for MobileBERT indicate that our work is complementary to other methods for reducing hidden dimensions or attention heads.

Our comprehensive study of different sparse attention patterns in Transformers advances the field with several key insights.

- We show that pre-training sparse attention pattern models does bring benefits but that a fine-tuned only approach maintains competitive performance while saving cost and time for pre-training.
- We present an in-depth comparison between the two most common patterns in sparse attention design and verify that they provide different complementary strengths.
- We demonstrate that adapting attention patterns to tasks and layers is an impactful aspect of sparse pattern designs. We propose a new attention pattern—Adaptive Axis Attention and demonstrate that AAA outperforms fixed attention patterns.

2 Background

Here we highlight some of the core definitions related to self-attention and describe prior work on sparse self-attention.

2.1 Revisiting Self-Attention

BERT (Devlin et al., 2019) uses Masked Language Modeling (MLM), a self-supervised pre-training objective that allows a transformer encoder to encode a sequence from both directions simultaneously. Specifically, for an input sequence of N tokens, let $\boldsymbol{X}^{\ell} \in \mathbb{R}^{N \times D}$ be the encoded features at the ℓ-th transformer layer, where D denotes the embedding dimension. The features at the $(\ell+1)$-th layer are obtained by applying a transformer block:

$$\boldsymbol{H}^{\ell+1} = \mathrm{LN}\left(\boldsymbol{X}^{\ell-1} + f^{\ell}_{\mathrm{MHA}}(\boldsymbol{X}^{l})\right) \tag{1}$$

$$\boldsymbol{X}^{\ell+1} = \mathrm{LN}\left(\boldsymbol{H}^{\ell+1} + f^{\ell}_{\mathrm{FF}}(\boldsymbol{H}^{\ell+1})\right) \tag{2}$$

where LN denotes the layer normalization, $f_{\mathrm{FF}}(\cdot)$ is composed of two fully-connected sub-layers, wrapped in residual connection.

The Multi-Head Self-Attention (MHA) operation $f^{\ell}_{\mathrm{MHA}}(\cdot)$ in Eq. 1 is calculated as:

$$f^{\ell}_{\mathrm{MHA}}(\boldsymbol{X}) = [f^{\ell,1}_{\mathrm{Head}}(\boldsymbol{X}); \dots ; f^{\ell,h}_{\mathrm{Head}}(\boldsymbol{X})]\boldsymbol{U} \tag{3}$$

$$f^{\ell,i}_{\mathrm{Head}}(\boldsymbol{X}) = \sigma\left(\boldsymbol{A}/\sqrt{D_h}\right)\boldsymbol{V} \tag{4}$$

where $\sigma(\cdot)$ is a softmax function, $\boldsymbol{A} = \boldsymbol{Q}\boldsymbol{K}^T$ is the self-attention matrix, d is the model dimension, h is the number of heads, $\boldsymbol{Q} = \boldsymbol{X}\boldsymbol{W}_q, \boldsymbol{K} = \boldsymbol{X}\boldsymbol{W}_k, \boldsymbol{V} = \boldsymbol{X}\boldsymbol{W}_v \in \mathbb{R}^{N \times D_h}$. $\boldsymbol{W}_q$, $\boldsymbol{W}_k$, $\boldsymbol{W}_v \in \mathbb{R}^{D \times D_h}$ are the head-specific weights for query, key, and value vectors respectively, $D_h = D/h$ is the head dimension size, and $\boldsymbol{U}$ is the weight matrix that combines the outputs of the heads. The computing of self-attention matrix $\boldsymbol{A} \in \mathbb{R}^{N \times N}$ requires multiplying $\boldsymbol{Q} \in \mathbb{R}^{N \times D_h}$ and $\boldsymbol{K}^T \in \mathbb{R}^{D_h \times N}$, which is $O(N^2)$ in time and space complexity. This quadratic dependency on the sequence length has become a bottleneck for Transformers (Wang et al., 2020; Mehta et al., 2021).

2.2 Attention Patterns

Attention patterns can be classified into two general categories: (1) the diagonally shaped *Diagonal Patterns* and their particular case *Local Patterns*; (2) the vertically and horizontally shaped *Axis Patterns*, and their particular case *Global Patterns*. A pictorial representation of the categories is shown in Figure 1.

To represent the patterns intelligibly, we view such sparse attention patterns as an attention mask $\boldsymbol{B}^S \in \mathbb{R}^{N \times N}$, and treat it as an additive mask to the original self-attention mask $\boldsymbol{A}$. The new attention mask $\bar{\boldsymbol{A}}$ can be written as:

$$\bar{\boldsymbol{A}} = \boldsymbol{A} + C \cdot \boldsymbol{B}^S \tag{5}$$

where C is a large negative constant value, and $B^S_{ij} \in \boldsymbol{B}^S$ is 1 if and only if token i needs to attend to token j, and is zero otherwise.

Local vs. Diagonal Patterns Formally, we define diagonal pattern of size N_o as a set of user-designed offsets $\mathcal{O} = \{o_k\}_{k=1}^{N_o}$, and define diagonal attention mask as:

$$B^L_{ij} = 1 \iff |i - j| \in \mathcal{O} \tag{6}$$

where $o_k \in [0, N-1]$ is the offset value that measures the distance between token i and token j.

Most sparse attention pattern designs contain a local pattern constraint on the window around each token where attention is allowed. Specifically, local patterns can be viewed as a special case of diagonal patterns, where $o_k = k$, and the offset set is $\{0\} \cup \mathcal{O}$. For simplicity, and with a slight overriding of the definition of sizes, we refer to a local attention of size N_o as a diagonal attention with offsets $\{0, 1, ..., N_o\}$.

Global vs. Axis Patterns As shown in Figure 1(d), the Axis Attention mask is composed of two separate sets $\mathcal{R} = \{r_k\}_{k=1}^{N_r}$ and $\mathcal{C} = \{c_l\}_{l=1}^{N_c}$, and we define the axis attention mask as:

$$B^G_{ij} = 1 \iff i \in \mathcal{R} \text{ or } j \in \mathcal{C} \tag{7}$$

where $r_k \in [1, N]$ and $c_l \in [1, N]$ are offset values indicating the selected k-th row or l-th column.

Global patterns are a special case of axis patterns, where $r_k = k$ and $c_l = l$. In other words, in global patterns, there is no difference between horizontal (row) patterns and vertical (column) patterns, and picked rows and columns are at the start of the input. In most prior work, global patterns are discussed as a way to enable long range dependencies.

Random Patterns We introduce random patterns mainly for the sake of completeness. They were proposed in BigBird (Zaheer et al., 2020) and are obtained by randomly selecting some positions in the attention mask $\boldsymbol{B}^S$. We refer to the size N_r of a random pattern as the number of positions selected divided by $2N$ to approximately match the definition of the size of local and global patterns.

Prior work typically combines local and global patterns rather than committing to only using one of these broad categories. The combination of two patterns involves an *or* operation between them. Given the fixed sparse patterns defined in Eq. 6 and Eq. 7, we have the combined sparse pattern represented by:

$$\bar{\boldsymbol{A}} = \boldsymbol{A} + C \cdot (\boldsymbol{B}^L \vee \boldsymbol{B}^G) \tag{8}$$

where $\vee$ denotes the logical OR operation. Note that the size of the attention mask when local pattern size increases by one, is very similar to the size of the mask when the size of a global pattern increases by one. We will use this property to compare local and global patterns.

2.3 Sparse Self-Attention

Several sparse attention variants have been introduced to reduce the quadratic complexity of the full attention model (Guo et al., 2019; Shi et al., 2021). Longformer (Beltagy et al., 2020) and BigBird (Zaheer et al., 2020) are two notable models that make use of pre-defined patterns. Both utilize a combination of local and global attention patterns; BigBird also introduces a randomly generated and a fixed attention pattern.

Most closely related to our approach is Sparse-BERT (Shi et al., 2021). The authors of Sparse-BERT study the importance of the main diagonal attention pattern and propose a method to learn diagonal attention. Their method learns layer-agnostic diagonal patterns during pre-training, therefore the pattern is both layer- and task-unaware. Their experiments are designed to show that the main diagonal attention is not important. In contrast we carry out experiments to show that 1) the global attention is an important component in sparse attention designs, and 2) task adaptiveness and layer-awareness can bring good improvements to sparse attention designs, 3) combining the findings above, we can design a task and layer (and also input) adaptive global sparse attention pattern, and such pattern performs extremely well even without pre-training the model to adapt the pattern.

Traditional sparse attention approaches usually learn the sparse attention by replacing the full attention with pre-defined sparse attention pattern in a transformer model, then learning to operate with such patterns via a normal pre-training and fine-tuning pipeline. Despite the promising results achieved by the recent sparse attention approaches, rarely have there been studies done to provide a good understanding of such practices. Our paper is a comprehensive study on the roles of pre-training, different attention patterns, and the power of adaptiveness of the patterns.

3 Fixed Sparse Attention: A Comprehensive Analysis

In this section, we address the first two questions related to fixed attention patterns: *(i)* is pre-training with these really necessary or does fine-tuning alone suffice, and *(ii)* what are the strengths and complementary aspects of local and global patterns.

3.1 Pretraining vs. Finetuning

We start with a suite of experiments designed to find out if sparse attention models can be successful without pre-training. We compare performance on the tasks in the GLUE benchmark of: a model with full attention in pre-training and fine-tuning; a model with the same sparse attention pattern used in pre-training and fine-tuning; and a model pre-trained with full attention (as in standard off-the-shelf models) and fine-tuned on the specific task with sparse attention.

We report performance on the eight tasks from the GLUE benchmark (Wang et al., 2019b). Six of these tasks involve predictions about the degree or type of semantic equivalence between pairs of sentences and two are single sentence tasks, one involving linguistic accessibility judgements (CoLA) and the other sentiment prediction (SST-2). The amount of data for each task varies considerably from close to 400K for MNLI (one of the language inference tasks) to 2.5K examples in the RTE task. We do not perform experiments on the WNLI task, which contains fewer than one thousand samples for fine-tuning. In results presented later in the paper, the tasks are listed in decreasing order of fine-tuning data per-task.

We adopt all default training settings and hyper-parameters from Huggingface (2021) for all experiments. For pre-training, we use eight Nvidia A100 GPUs and train for 1M steps with a per-device batch size of 32 on English Wikipedia[2]. We use all default configurations from bert-base-cased. We pre-train three models, one with full attention as in the official bert-base-cased and two with sparse attention patterns that we describe below.

For fine-tuning, we use four Nvidia A100 GPUs and train for 30k steps with a per-device batch size of 32 (effectively, each device runs about three epochs over the largest dataset, MNLI). Compared to the default setting of using one device, this guarantees the model can learn to converge from a full attention model to a sparse attention one.

In this section, we consider these patterns:

- **Full** is the full attention pattern as in traditional transformer models.
- **Local + Global** are the patterns used for Longformer. We use a subscript to indicate the size of the pattern. For example **Local$_2$ + Global$_2$**

---

[2] wikipedia/20200501.en from huggingface datasets.

Table 1: Comparison of pre-trained fixed sparse attention patterns designs with fine-tuned only patterns. For the metrics, Acc stands for Accuracy, F$_1$ is the F$_1$ score, Mcc stands for Matthews correlation coefficient and Spr stands for Spearman's rank correlation. All metrics are measured out of 100 (percent), and the higher the better. The datasets are sorted by training set size, from largest (MNLI) to the smallest (RTE).

Dataset	MNLI	QQP	QNLI	SST-2	COLA	STS-B	MRPC	RTE
Metric	Acc (mm)	F$_1$	Acc	Acc	Mcc	Spr	F$_1$	Acc
Full Pattern (pre-train & fine-tune)	82	87	90	91	48	87	90	60
Local$_2$ + Global$_2$ (pre-train & fine-tune)	77	85	86	89	41	52	80	54
Local$_2$ + Global$_2$ (fine-tune)	75 (↓ 2)	78(↓ 7)	82(↓ 4)	89(↓ 0)	44(↑ 3)	29(↓ 23)	76(↓ 4)	51(↓ 3)
Local$_2$ + Global$_1$ + Random$_1$ (pre-train & fine-tune)	77	83	83	89	44	45	78	55
Local$_2$ + Global$_1$ + Random$_1$ (fine-tune)	75(↓ 2)	81(↓ 2)	80(↓ 3)	88(↓ 1)	40(↓ 4)	19(↓ 26)	78(↓ 0)	53(↓ 2)

Table 2: Experiment on the Text dataset in LRA. We vary the size of the Local Pattern with or without Global Patterns. "Pf." means the performance.

w/o Global Pattern		**w/ Global Pattern**	
Local Pattern	Pf.	Local Pattern	Pf.
512	62.80	512	61.73
128	57.72	128	63.12
16	55.58	16	71.34
2	52.88	2	77.62

stands for a Longformer that contains a local pattern of size 2 and a global pattern of size 2.

- **Local + Global + Random** are the patterns used for BigBird. Similarly, we use **Local$_2$ + Global$_1$ + Random$_1$** to denote a combination of local pattern of size 2, global pattern of size 1, and random pattern of size 1.

The last two patterns are also used in SparseBERT (Shi et al., 2021)[3].

Table 1 shows our comparison between fine-tuning only approach and pre-training approach for Local$_2$ + Global$_2$ and Local$_2$ + Global$_1$ + Random$_1$. The table also gives performance measures for the model using full attention. Performance drops for the sparse compared to full attention models. However the difference between the fine-tuning only approach and the pre-training sparse attention approach is not that big. Notably for the acceptability judgements task (CoLA), the fine-tuned sparse attention model without a random component, results are 3 points higher than for the respective pre-trained model; performance is the same for the fine-tuned only and pre-trained model for the sentiment task (SST-2). The biggest gap in performance is for the STS-B, which requires predictions about the degree of similarity on a five point scale between pairs of sentences. For this task already switching from full to sparse attention leads to a dramatic drop in performance. The average drop of performance across the task excluding this outlier is just under 3 absolute performance points.

For the sparse attention patterns with a random component, the pre-trained version is on average 2 absolute performance points better than the fine-tuned only model (again after the excluding the outlier for the STS-B task).

3.2 Comparing Local and Global Patterns

Global patterns have been somewhat neglected. For example, in the Long Range Arena (LRA) benchmark (Tay et al., 2021), the Longformer baseline does not include a global pattern.

In Table 2 we present a comparison between local patterns alone and a combination of local and global patterns on the Text dataset in the LRA benchmark. The comparison reveals the possible reason why partial evidence may suggest that adding global patterns is not helpful but that more complete evidence indicates that a combination of local and global patterns yields substantial benefits.

The first row of Table 2, shows that performance with global patterns and a local pattern of size 512 actually is a bit worse than without the global patterns. However, subsequent rows in the table reveal that as we decrease the size of the local pattern while keeping the global pattern, performance improves. Performance can reach as high as 77.62 with the global patterns, while the best performance from other baselines reported in the LRA benchmark paper is about 65.90. Global patterns bring unique information that local patterns do not capture and they should be included in future sparse attention pattern designs or baseline comparisons.

We further empirically compare local and global patterns and evaluate the performance of models with different degrees of focus on the two patterns

---

[3] The use a Random Pattern of size 2. But our definition of Random Pattern selects two times more positions than theirs, so the expected pattern size is still the same

in Figure 2. To obtain the model's performance with a certain pattern, we start with a pre-trained full attention model and fine-tune it on the datasets with the sparse pattern. We compare models that focuses on vastly different amount of local and global patterns, while controlling the overall sparsity of the attention pattern. Comparing local-pattern only models with global-pattern only models would be naive, given that most prior approaches to sparse attention combine the two. In our experiments we consider models with a baseline size of two on both local and global patterns. Then, to analyze how the global pattern affects performance, for example, we fix the size of the local pattern to be 2 and vary the size of global patterns from 1 to 8. A similar set of experiments is done for the local patterns. Recalling the previous observation that we can compare local and global attention patterns with the same size, the experiments with different focus on local and global patterns can be compared.

We present experiments only for the three tasks with the largest amount of fine-tuning data in the GLUE benchmark. Figure 2 shows that, for both types of patterns, increasing the size of the patterns from the base size improves the performance. However, the areas of improvement are different on different tasks for local and global patterns. We can see that for MNLI and QNLI, increasing global patterns is more helpful than increasing local ones, while for QQP, the local patterns are more helpful. Intuitively, this is because different tasks require differing information types for language understanding — QQP requires more local information to distinguish the sentence pairs than MNLI and QNLI.

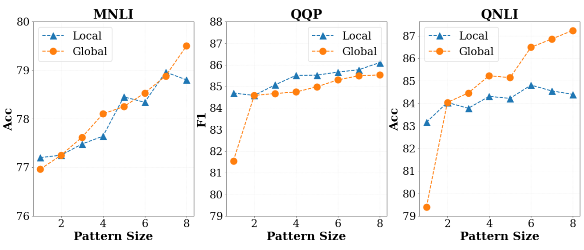

Figure 2: Comparison of Local Attention Pattern and Global Attention Pattern. We experiment with two sets of models, the first of 8 models of different sizes of local patterns and the second set of 8 models of different sizes of global patterns.

4 Beyond Fixed Sparse Attention

In this part, we discuss the importance of adaptiveness and propose an adaptive axis attention pattern.

4.1 Adaptiveness of Patterns

In the previous section we discussed evidence that global patterns and local patterns contribute differently to performance in different tasks. Should we then design *different patterns* for *different tasks*, and how can we do so? Moreover, given that different layers of BERT capture different linguistic knowledge (Clark et al., 2019; Michel et al., 2019; Kovaleva et al., 2019; Li et al., 2019)—should the patterns be *adaptive* to the *layers* as well?

We set out to study whether such adaptations to task and layer will indeed lead to better perfroamnce. To this end, we generalize SparseBERT(Shi et al., 2021) to suit our needs and conduct experiments with it. SparseBERT as originally introduced learns a diagonal attention pattern (along with a fixed global pattern) model during pre-training. The learned model is applied to downstream tasks, keeping the patterns learned during pre-training fixed. However, the attention pattern learning aspect of their approach is applicable to fine-tuning as well. In our work we make use of it to train diagonal attention pattern models during fine-tuning only, thus allowing the model to learn different patterns for different tasks.

Before proceeding with these comparisons, we introduce the notion of attention sparsity and discuss a controllable method for obtaining models with similar sparsity levels. This is necessary for a meaningful comparison of sparse attention approaches, because in general reductions from full to sparse attention leads to drop in performance, as we saw for example in the tasks from the GLUE benchmark.

Sparsity Sparsity measures the size of the sparse attention (fixed or learned) when compared with the full attention. The sparsity used in (Shi et al., 2021) is defined as: $1 - |\boldsymbol{B}^S|/N^2$, where $|\boldsymbol{B}^S| = |\{(i,j)|B^S_{ij} \neq 0\}|$ is the number of ones in the sparse attention mask matrix $\boldsymbol{B}^S$. This definition is suitable for patterns that are fixed during fine-tuning. In our work, different tasks may yield different patterns. Therefore, we propose a generalized definition of sparsity:

$$\rho = \frac{1}{|\mathcal{D}|Lh} \sum_{i=1}^{|\mathcal{D}|} \left(\sum_{l=1}^{L} \sum_{a=1}^{h} \left(1 - \frac{|\boldsymbol{B}^S_{i,l,a}|}{N_i^2} \right) \right) \quad (9)$$

where $|\mathcal{D}|$ is the size of the dataset $\mathcal{D}$, N_i denotes the sequence length of the i-th input sample, which can be different from the fixed value (128) in Shi et al. (2021) [4], L the number of transformer layers, and h number of attention heads. $\boldsymbol{B}^S_{i,l,a}$ refers to the sparse attention mask matrix for the i-th input sample, l-th layer, and a-th attention head.

The sparsity definition in Eq. 9 has several key advantages: 1) It is applicable when attention patterns are different across instances, layers, and attention heads rather than fixed; 2) It uses the actual sequence (text) length, more truthfully reflecting how much attention is used when processing a specific input. The original sparsity definition is involves only the model-wise maximum sequence length. For example, a local pattern of size 2 has a sparsity value[5]: $1 - 5/N + 6/N^2$. This is undesirable because by just changing the model maximum sequence length, sparsity changes without impacting the performance on individual inputs.

Sparsity Controllable Training Controlling the target sparsity of self-attention is beneficial for comparison purposes. Given the fixed target sparsity ρ_{target}, we define the training objective as:

$$\mathcal{L}_{\text{All}} = \underbrace{\mathcal{L}_{\text{task}}}_{\text{Finetune Loss}} + \underbrace{\alpha \cdot \max(0, \rho_{\text{target}} - \rho)}_{\text{Sparsity Loss}} \quad (10)$$

where the first term ($\mathcal{L}_{\text{task}}$) denotes the objective loss for the fine-tuning task, ρ is the sparsity during training, α is an amplifying factor of the sparsity loss. The hinge loss encourages the runtime sparsity to be close to the desired sparsity. In our experiments, we consider two variants of α: 1) a constant value and 2) an increasing linear value that reaches its maximum at half of the epochs and then stays constant. We pick the best variant of α among the two and gradually increase its absolute value until the target sparsity has been reached.

Results In our experiment, we consider three diagonal attention pattern models that have different levels of adaptiveness:

- **Fixed** is a fixed diagonal attention pattern model, where the pattern is copied from a pre-trained SparseBERT model.
- **Task-adaptive** is a model that learns the attention pattern during fine-tuning, therefore is different for different tasks.
- **Task- & Layer-adaptive** further allows different layers of the model to learn different patterns.

All attention patterns are paired with global attention, and the results are reported in Table 3. We can see clearly that the task-adaptive model is better than the fixed model, as the patterns are learned from the tasks. Further, adding adaptiveness into the layers also brings a small boost to the performance. These experiments show that having the patterns adaptive and learnable is beneficial for sparse pattern designs.

4.2 Adaptive Axis Attention

We show experiments highlighting the strengths of global attention (in Section 3.2) and of allowing adaptiveness of attention (in Section 4.1). To combine these strengths, we design a novel attention pattern that incorporates the learning of Axis Patterns, a more general form of Global Patterns. Intuitively, we want the model to learn which input tokens are important and focus on rows or columns in the attention map associated with these tokens.

Specifically, we learn a row/column-wise importance value for each token representation $\boldsymbol{x}_n \in \boldsymbol{X}$ through a fully-connected layer. This importance value is fed into a Gumbel-sigmoid operation to retrieve a 0/1 indicator:

$$\tilde{I}^k_n = f_{\text{Gumbel-sigmoid}}(f^k_{\text{FC}}(\boldsymbol{x}_n)), \ k \in \{r, c\} \quad (11)$$

where $\tilde{I}^k_n$ is the importance indicator for n-th token retrieved by the Gumbel-sigmoid operation, k indicates the column (c) or row (r). Specifically, $\tilde{I}^r_n = 1$ indicates that all attention values in row n of the attention matrix are kept. Equivalently, this means this token can attend to all other tokens in the input. Similarly, $\tilde{I}^c_n = 1$ indicates column n of the attention matrix is kept.

Given the importance indicators $\tilde{I}^r_i$ and $\tilde{I}^c_j$, the axis pattern $B^S_{ij} \in \boldsymbol{B}^S$ can be calculated as follows:

$$B^S_{ij} = \tilde{I}^r_i + \tilde{I}^c_j - \tilde{I}^r_i \cdot \tilde{I}^c_j \quad (12)$$

where $B^S_{ij} = 1$ means either the importance indicator for row i or column j is on[6]. Usually, this adaptive axis attention pattern is also paired up with some local patterns, especially the main diagonal local attention. This is to ensure that no rows are empty, which is needed because self-attention includes operations such as softmax and linear combinations, which are undefined over empty values.

---

[4] The consideration of the actual input sequence size makes our sparsity levels lower than the sparsity in SparseBERT.

[5] $1-(N+2(N-1)+2(N-2))/N^2 = 1-5/N+6/N^2$.

[6] Such calculation allows gradient to backpropogate to the fully connected layer that calculates the importance value.

Table 3: Comparison of learnable diagonal attention models that have different levels of adaptiveness. ρ is the sparsity value defined in Eq. 9. We also show the relative difference from each row to the previous row.

Adaptiveness	**MNLI**		**QQP**		**QNLI**		**SST-2**		**COLA**		**STS-B**		**MRPC**		**RTE**	
	ρ	Pf.	ρ	Pf.	ρ	Pf.	ρ	Pf.	ρ	Pf.	ρ	Pf.	ρ	Pf.	ρ	Pf.
Fixed	86	70	85	79	88	72	83	89	75	34	85	28	88	79	88	50
Task-adaptive	86	74(↑ 4)	87	79(↑ 0)	89	75(↑ 3)	83	83(↓ 6)	81	38(↑ 4)	85	36(↑ 8)	88	77(↓ 2)	89	56(↑ 6)
Task & Layer-adaptive	86	76(↑ 2)	85	81(↑ 2)	89	77(↑ 2)	83	86(↑ 3)	78	35(↓ 3)	86	38(↑ 2)	89	77(↑ 0)	89	55(↓ 1)

Following designs in Section 3.2, we pair it up with a local pattern of size 2. This adaptive axis pattern is also learned separately for each layer and different tasks, taking full advantage of the benefits of adaptiveness. Similar to the adaptive diagonal attention patterns introduced in Section 4.1, we optimize the model with Eq. 10.

4.3 Experiments with AAA

In this section, we verify empirically the effectiveness of our proposed AAA. Quantitative results are listed in Tables 4, 5, and 7.

Experiment Settings In this section, our experiments follow the setting described in Section 3.1. We also include some other patterns to show that findings are stable for different combinations:

- **Local$_3$ + Global$_1$** is a variant of the Longformer-like pattern in which we increase the size of the local attention but decrease global attention size. As discussed previously, this results in a model with comparable capacity but may provide different benefits.
- **Local$_1$ + Global$_1$ + Random$_2$** is similarly a variant for BigBird. Here we increase the size of the random patterns, so the resulting sparsity values are different from the corresponding Local$_2$ + Global$_1$ + Random$_1$ attention.
- **Diagonal + Global$_1$** represents patterns coming from SparseBERT. It combines a learned diagonal pattern with global pattern of size 1.

AAA outperforms fix pattern models We compare our AAA with several fixed attention patterns. We optimize AAA with Eq. 10, and set different targets of the final sparsity values ρ_{target} for each task. For all baselines, we report the sparsity values and performance on the development set in Table 4. We first point out an encouraging result related to sparsity: AAA exhibits a similar sparsity value in the development set as in the training set. For all datasets, AAA is able to reach the desired, and sometimes slightly better, sparsity values. Next, we compare the performance of the models. For all tasks, our model performs better than the fixed pattern approaches. For most tasks, the improvement is large. This success further confirms the strength of adaptiveness in designing attention patterns.

AAA rivals pre-trained pattern models Now we also compare with the pre-trained variant of the adaptive diagonal attention model. Rather than starting from a pre-trained BERT model with full attention, we pre-train a sparse adaptive diagonal attention model. The results, along with pre-trained variants of fixed pattern models, are shown in Table 5. We already know, from Section 3.1, that the pre-trained variants of fixed patterns improve a moderate amount of performance. The performance for the adaptive patterns is also comparable to the fine-tuned only AAA on most tasks. Furthermore, on the STS-B task where fixed patterns suffered a great drop in performance, AAA shows very strong performance. The pre-trained version of the diagonal patterns shows strong performance and is better than our model in most tasks. Overall, we show that AAA achieves a strong performance that is comparable to other sparse patterns that involve pre-training.

AAA focuses more on columns than rows AAA separates the importance learning of row-wise patterns and column-wise patterns. After fine-tuning, we examine for each input sample during evaluation the percentage of important tokens selected for rows and for columns. Table 6 shows the results. There are much more important column tokens than important row tokens. This means that for axis patterns, tokens that other tokens attended to are more important than tokens that attend to other tokens. This finding is another indication that fixed (global) patterns are not ideal.

AAA is orthogonal to MobileBERT Improving the efficiency of transformers is needed for real-world applications and several approaches have been developed to improve efficiency on resource-limited devices, such as reducing attention heads and hidden dimensions. To show that gains from

Table 4: Comparison of fixed sparse attention map designs with ours. In the first row, we show the performance when using the unchanged full attention. Since our method AAA has the ability to learn to a fixed sparsity ratio, we train our model to adapt to the specific sparsity ratio on each task when compared to other different fixed patterns.

Table 6: Percentage of row-wise important tokens and column-wise important tokens.

	MNLI	**QQP**	**QNLI**		**MNLI**	**QQP**	**QNLI**
row	0.8	0.6	1.0	column	1.6	1.3	1.7

Table 7: AAA can be integrated with MobileBERT.

Model	**MNLI**		**QQP**		**QNLI**	
	ρ	Pf.	ρ	Pf.	ρ	Pf.
BERT	0	84	0	87	0	91
BERT + AAA	77	81	73	85	82	86
MobileBERT	0	83	0	87	0	90
MobileBERT + AAA	78	78	74	83	83	86

our AAA are compatible with such approaches, we compare AAA with MobileBERT (Sun et al., 2020) in Table 7. The amount of performance dropped with the same sparsity is similar for both BERT and MobileBERT. Therefore, AAA's performance is not impeded by a model that is already compressed to reduce attention heads or hidden dimensions and can be integrated into such a model easily and effectively.

5 Conclusion

In this paper, we present a comprehensive analysis of sparse attention patterns. We demonstrate that while pre-training with sparse attention does improve performance on many tasks, using sparse attention only in fine-tuning sacrifices a bit of performance for a big gain in time and computational resource savings.

We compare the popular local and global patterns and conclude that either type provide an advantage depending on the task. We also show that allowing sparse patterns to be adaptive to the task or layers improves performance. Finally we present AAA which incorporated all these insights and learns important tokens during fine-tuning. Our model is consistently and considerably better than other sparse attention pattern models and rivals models that require extensive pre-training. For future work, we anticipate to integrate the adaptive diagonal pattern with our adaptive axis pattern to construct a fully learnable pattern.

Ethical Considerations

The work presented in this paper deals with foundations aspects of representation learning for language tasks. We present experiments on core tasks dealing with textual semantic equivalence, which do not pose ethical concerns.

Using Interactive Feedback to Improve the Accuracy and Explainability of Question Answering Systems Post-Deployment

Abstract

Most research on question answering focuses on the pre-deployment stage; i.e., building an accurate model for deployment. In this paper, we ask the question: Can we improve QA systems further *post*-deployment based on user interactions? We focus on two kinds of improvements: 1) improving the QA system's performance itself, and 2) providing the model with the ability to explain the correctness or incorrectness of an answer. We collect a retrieval-based QA dataset, FEEDBACKQA, which contains interactive feedback from users. We collect this dataset by deploying a base QA system to crowdworkers who then engage with the system and provide feedback on the quality of its answers. The feedback contains both structured ratings and unstructured natural language explanations. We train a neural model with this feedback data that can generate explanations and re-score answer candidates. We show that feedback data not only improves the accuracy of the deployed QA system but also other stronger non-deployed systems. The generated explanations also help users make informed decisions about the correctness of answers.[1]

1 Introduction

Much of the recent excitement in question answering (QA) is in building high-performing models with carefully curated training datasets. Datasets like SQuAD (Rajpurkar et al., 2016), NaturalQuestions (Kwiatkowski et al., 2019) and CoQA (Reddy et al., 2019) have enabled rapid progress in this area. Most existing work focuses on the pre-deployment stage; i.e., training the best QA model before it is released to users. However, this stage is only one stage in the potential lifecycle of a QA system.

In particular, an untapped resource is the large amounts of user interaction data produced after the initial deployment of the system. Gathering this data should in practice be relatively cheap, since users genuinely engage with QA systems (such as Google) for information needs and may provide feedback to improve their results.[2]

Exploiting this kind of user interaction data presents new research challenges, since they typically consist of a variety of weak signals. For example, user clicks could indicate answer usefulness (Joachims, 2002), users could give structured feedback in the form of ratings to indicate the usefulness (Stiennon et al., 2020), or they could give unstructured feedback in natural language explanations on why an answer is correct or incorrect. User clicks have been widely studied in the field of information retrieval (Joachims, 2002). Here we study the usefulness of *interactive feedback* in the form of ratings and natural language explanations.

Whilst there are different variants of QA tasks, this paper focuses primarily on retrieval-based QA (RQA; Chen et al. 2017; Lee et al. 2019). Given a question and a set of candidate answer passages, a model is trained to rank the correct answer passage the highest. In practice, when such a system is deployed, an user may engage with the system and provide feedback about the quality of the answers. Such feedback is called interactive feedback. Due to the lack of a dataset containing interactive feedback for RQA, we create FEEDBACKQA.

FEEDBACKQA is a large-scale English QA dataset containing interactive feedback in two forms: user ratings (structured) and natural language explanations (unstructured) about the correctness of an answer. Figure 1 shows an example from FEEDBACKQA. The dataset construction has two stages: We first train a RQA model on the questions and passages, then deploy it on a crowdsourcing platform. Next, crowdworkers engage with this system and provide interactive feedback. To make our dataset practically useful, we focus on

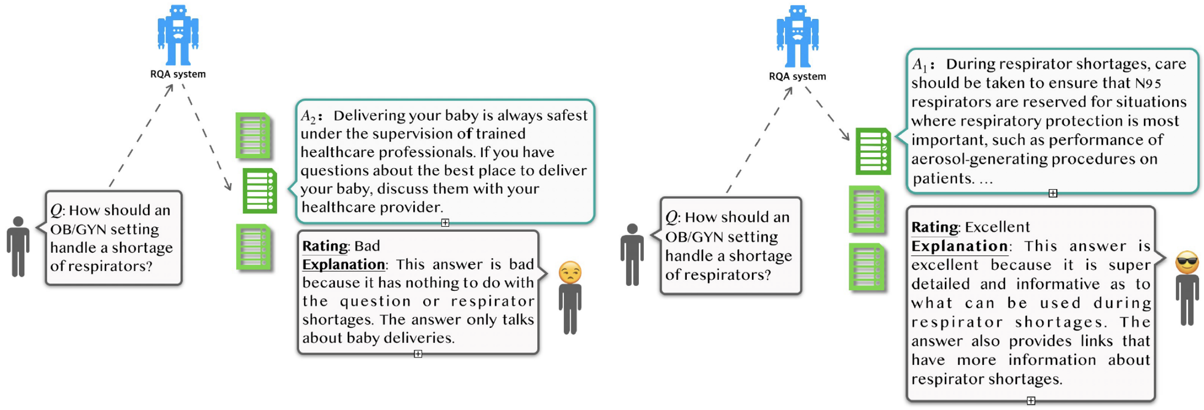
Findings of the Association for Computational Linguistics: ACL 2022, pages 926 - 937
May 22-27, 2022



Q: How should an OB/GYN setting handle a shortage of respirators?

A_2: Delivering your baby is always safest under the supervision of trained healthcare professionals. If you have questions about the best place to deliver your baby, discuss them with your healthcare provider.

Rating: Bad
Explanation: This answer is bad because it has nothing to do with the question or respirator shortages. The answer only talks about baby deliveries.

Q: How should an OB/GYN setting handle a shortage of respirators?

A_1: During respirator shortages, care should be taken to ensure that N95 respirators are reserved for situations where respiratory protection is most important, such as performance of aerosol-generating procedures on patients. …

Rating: Excellent
Explanation: This answer is excellent because it is super detailed and informative as to what can be used during respirator shortages. The answer also provides links that have more information about respirator shortages.

Figure 1: Users interact with the deployed QA model and give feedback. Feedback contains a rating (*bad, good, could be improved, excellent*) and a natural language explanation.

question answering on public health agencies for the Covid-19 pandemic. The base model for FEEDBACKQA is built on 28k questions and 3k passages from various agencies. We collect 9k interactive feedback data samples for the base model.

We investigate the usefulness of the feedback for improving the RQA system in terms of two aspects: answer accuracy and explainability. Specifically, we are motivated by two questions: 1) Can we improve the answer accuracy of RQA models by learning from the interactive feedback? and 2) Can we learn to generate explanations that help humans to discern correct and incorrect answers?

To address these questions, we use feedback data to train models that rerank the original answers as well as provide an explanation for the answers. Our experiments show that this approach not only improves the accuracy of the base QA model for which feedback is collected but also other strong models for which feedback data is not collected. Moreover, we conduct human evaluations to verify the usefulness of explanations and find that the generated natural language explanations help users make informed and accurate decisions on accepting or rejecting answer candidates.

Our contributions are as follows:

1. We create the first retrieval-based QA dataset containing interactive feedback.
2. We demonstrate a simple method of using the feedback data to increase the accuracy and explainability of RQA systems.
3. We show that the feedback data not only improve the deployed model but also a stronger non-deployed model.

2 FEEDBACKQA Dataset

Recently, there have been efforts to collect feedback data in the form of explanations for natural language understanding tasks (Camburu et al. 2018; Rajani et al. 2019, *inter alia*). These contain explanations only for ground-truth predictions for a given input sampled from the training data without any user-system interaction. Instead, we collect user feedback after deploying a RQA system thereby collecting feedback for both correct and incorrect predictions. Table 1 presents a comprehensive comparison of FEEDBACKQA and existing natural language understanding (NLU) datasets with explanation data.

2.1 Dataset collection

In order to collect post-deployment feedback as in a real-world setting, we divide the data collection into two stages: pre-deployment (of a RQA model) and post-deployment.

Stage 1: Pre-deployment of a QA system We scrape Covid-19-related content from the official websites of WHO, US Government, UK Government, Canadian government,[3] and Australian government. We extract the questions and answer passages in the FAQ section. To scale up the dataset, we additionally clean the scraped pages and extract additional passages for which we curate corresponding questions using crowdsourcing as if users were asking questions. We present details on this annotation process in Appendix A. We use this dataset to train a base RQA model for each source separately and deploy them. For the base model, we use a BERT-based dense retriever (Karpukhin

et al., 2020) combined with Poly-encoder (Miller et al., 2017) (more details are in Section 3.1).

Stage 2: Post-deployment of a QA system Since each domain has several hundred passages (Table 2), it is hard for a crowdworker to ask questions that cover a range of topics in each source. We thus collect questions for individual passages beforehand similar to Stage 1 and use these as interactive questions. The question and top-2 predictions of the model are shown to the user and they give feedback for each question-answer pair. The collected feedback consists of a rating, selected from *excellent, good, could be improved, bad*, and a natural language explanation elaborating on the strengths and/or weaknesses of the answer. For each QA pair, we elicit feedback from three different workers. We adopted additional strategies to ensure the quality of the feedback data, the details of which are available in Appendix B. The resulting dataset statistics are shown in Table 2. In order to test whether interactive feedback also helps in out-of-distribution settings, we did not collect feedback for one of the domains (Canada).

2.2 FEEDBACKQA analysis

Table 3 shows examples of the feedback data, including both ratings and explanations. We find that explanations typically contain review-style text indicating the quality of the answer, or statements summarizing which parts are correct and why. Therefore, we analyze a sample of explanations using the following schema:

Review Several explanations start with a generic review such as *This directly answers the question* or *It is irrelevant to the question.* Sometimes users also highlight aspects of the answer that are good or can be improved. For instance, ... *could improve grammatically* ... suggests that the answer could be improved in terms of writing.

Summary of useful content refers to the part of answer that actually answers the question;

Summary of irrelevant content points to the information that is not useful for the answer, such as off-topic or addressing incorrect aspects;

Summary of missing content points the information the answer fails to cover.

We randomly sample 100 explanations and annotate them. Figure 2 shows the distribution of the types present in explanations for each rating label. All explanations usually contain some review type information. Whereas explanations for answers labeled as excellent or acceptable predominantly indicate the parts of the answer that are useful. The explanations for answers that can be improved indicate parts that are useful, wrong or missing. Whereas bad answers often receive explanations that highlight parts that are incorrect or missing as expected.

3 Experimental Setup

FEEDBACKQA contains two types of data. One is pre-deployment data $\mathcal{D}_{\text{pre}} = (Q, A^+, \mathcal{A})$, where Q is a question paired with its gold-standard answer passage A^+ from the domain corpus $\mathcal{A}$. The other is post-deployment feedback data $\mathcal{D}_{\text{feed}} = (Q, A, Y, E)$, where Q is a question paired with a candidate answer $A \in \mathcal{A}$ and corresponding feedback for the answer. The feedback consists of a rating Y and an explanation E. We build

Rating label	Explanation
Excellent	This answers the question directly. This answer provides information and recommendation on how people and adolescent can protect themselves when going online during the Covid-19 pandemic.
Acceptable	This answer, while adequate, could give more information as this is a sparse answer for a bigger question of what one can do for elderly people during the pandemic.
Could be improved	The answer relates and answers the question, but could improve grammatically and omit the "yes"
Could be improved	The answer is about some of the online risks but not about how to protect against them.
Bad	This does not answer the question. This information is about applying visa to work in critical sector. It does not provide any information on applying for Covid-19 pandemic visa event as asked in the question.

Table 3: Examples of explanation and its associated rating label. Span color and their types of components: generic and aspect review ; summary of useful content ; summary of irrelevant content ; summary of missing content

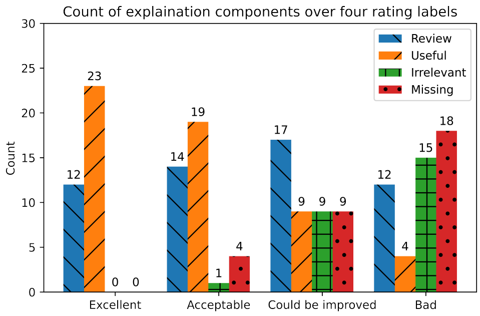

Figure 2: Distribution of component number in 100 natural language feedback of different rating labels.

two kinds of models on pre- and post-deployment data: RQA models on the pre-deployment data that can retrieve candidate answers for a given question, and feedback-enhanced RQA models on the post-deployment data that can rate an answer for a given question as well as generate an explanation for the answer. We use this rating to rerank the answer candidates. Therefore, in our setting, a feedback-enhanced RQA model is essentially a *reranker*. Keeping in mind the fact that real-world QA systems evolve quickly, we decouple the reranker model from the RQA model by using separate parameters for the reranker independent of the RQA model. We train this reranker on the feedback data. This allows for the reranker to be reused across many RQA models. We leave other ways to enhance RQA models with feedback data for future work. Below, we describe the architectures for the RQA models and feedback-based rerankers.

3.1 RQA Models (Pre-deployment)

We use dense passage retrievers (Karpukhin et al., 2020) to build the RQA models, where the similarity between the question embedding and the passage embedding is used to rank candidates. We use two variants of pre-trained models to obtain the embeddings: 1) BERT (Devlin et al., 2019), a pre-trained Transformer encoder; and 2) BART (Lewis et al., 2020), a pretrained Transformer encoder-decoder. For BERT, we use average pooling of token representations as the embedding, whereas for BART we use the decoder's final state. While Karpukhin et al. use question-agnostic passage representations, we use a poly-encoder (Humeau et al., 2020) to build question-sensitive document representations. In a poly-encoder, each passage is represented as multiple encodings, first independent of the question, but then a simple attention between the question and passage embeddings is used to compute question-sensitive passage representation, which is later used to compute the relevance of the passage for a given query. Humeau et al. show that the poly-encoder architecture is superior to alternatives like the bi-encoder (Karpukhin et al., 2020) without much sacrifice in computational efficiency.[4]

Given pre-deployment training data $\mathcal{D}_{\text{pre}} = (Q, A^+, \mathcal{A})$, the RQA model parameterized by θ is trained to maximize the log-likelihood of the correct answer:

$$\mathcal{J}_\theta = \log P_\theta(A^+|Q,\mathcal{A})$$
$$P_\theta(A^i|Q,\mathcal{A}) = \frac{\exp(S(Q,A^i))}{\sum_{A\in\mathcal{A}}\exp(S(Q,A))} \qquad (1)$$

Here $S(Q,A)$ denotes the dot product similarity between the question and passage embedding. As it is inefficient to compute the denominator over all passages during training, we adopt an in-batch negative sampling technique (Humeau et al., 2020), merging all of the A^+ in the same minibatch into a set of candidates.

---

[4] The performance results of poly-encoder and bi-encoder for our task are shown in Table 9.

3.2 Feedback-enhanced RQA models (Post-deployment)

On the post-deployment data $\mathcal{D}_{\text{feed}} = (Q, A, Y, E)$, we train a reranker that assigns a rating to an answer and also generates an explanation. We use BART parameterized by ϕ as the base of EXPLAINRATE because it is ease to adapt it to both explanation generation and rating classification. The encoder of the BART model takes as input the concatenation $[Q; \text{SEP}; A]$, and the decoder generates an explanation E; after that, an incremental fully-connected network predicts the rating Y given the last hidden states of decoder. The rating is used to score QA pairs, whereas the generated explanation is passed to humans to make an informed decision of accepting the answer. We also implement a variant where the model directly produces a rating without generating an explanation. Since each candidate answer is annotated by different annotators, an answer could have multiple rating labels. To account for this, we minimize the KL-divergence between the the target label distribution and the predicted distribution:

$$\mathcal{J}_{\phi'} = -D_{\text{KL}}(P(Y|Q, A)||P_\phi(Y|Q, A)),$$
$$P(Y_i = y|Q_i, A_i) = \frac{C_{y,i}}{\sum_y C_{y,i}} \tag{2}$$

where $C_{y,i}$ is the count of the rating label y for the i-th feedback.

In order to enhance an RQA model with the reranker, we first select the top-k candidates according to the RQA model (in practice we set $k = 5$). The reranker then takes as input the concatenation of the question and each candidate, then generates a rating for each answer. We simply sum up the scores from the RQA model and the reranker model. In practice, we found that using the reranker probability of *excellent* worked better than normalizing the expectation of the rating score (from score 0 for label *bad* to 3 for *excellent*). So, we score the candidate answers as follows:

$$\begin{aligned} S(A|\mathcal{A}, Q) =& P_\theta(A = A^+|\mathcal{A}, Q) \\ &+ P_\phi(y = \textit{excellent}|A, Q) \end{aligned} \tag{3}$$

4 Experiments and Results

We organize the experiments based on the following research questions:

- RQ1: Does feedback data improve the base RQA model accuracy?
- RQ2: Does feedback data improve the accuracy of RQA models that are stronger than the base model?
- RQ3: Do explanations aid humans in discerning between correct and incorrect answers?

We answer these questions by comparing the RQA models with the feedback-enhanced RQA models. The implementation and hyper-parameter details of each model are included in Appendix D.

4.1 RQ1: Does feedback data improve the base RQA model?

Model details. Our base model is a BERT RQA model which we deployed to collect feedback data to train the other models (Section 3.1).

For the feedback-enhanced RQA model, we use the BART-based reranker described in Section 3.2. We train one single model for all domains. We call this FEEDBACKRERANKER. We compare two variants of FEEDBACKRERANKER on validation set, one of which directly predicts the rating while the other first generates an explanation and then the rating. And we found the first one performs slightly better (Appendix Table 10). We conjecture that learning an explanation-based rating model from the limited feedback data is a harder problem than directly learning a rating model. Therefore, for this experiment, we only use the rating prediction model (but note that explanation-based rating model is already superior to the base RQA model).

To eliminate the confounding factor of having a larger number of model parameters introduced by the reranker, we train another reranker model on the pre-deployment data VANILLARERANKER and compare against the reranker trained on the feedback data. To convert the pre-deployment data into the reranker's expected format, we consider a correct answer's rating label to be *excellent*, and the randomly sampled answer candidates[5] to be *bad*. Note that this dataset is much larger than the feedback data.

Finally, we combine the training data of FEEDBACKRERANKER and VANILLARERANKER and train the third reranker called COMBINEDRERANKER.

To measure retrieval accuracy, we adopt Precision@1 (P@1) as our main metric.

---

[5] We also tried using the top predictions from the base QA model, but found this approch leads to slightly worse performance than negative sampling.

Methods	Australia	US	Canada	UK	WHO	All	Beats
BERT RQA model ✦	47.25	65.30	81.49	48.50	81.19	64.75	None

+ COMBINEDRERANKER ✤	**55.27**	**71.45**	**85.35**	**54.83**	**83.61**	**70.10**	♈♉♊

Table 5: Accuracy of the BART RQA model and its enhanced variants on the test set. Results are averaged across 3 runs.

Results. As shown in Table 4, the feedback-enhanced RQA model is significantly[6] better than the base RQA model by 1.84 points. Although VANILLARERANKER improves upon the base model, it is weaker than FEEDBACKRERANKER, and COMBINEDRERANKER is a much stronger model than any of the models, indicating that learning signals presented in feedback data and the pre-deployment data are complementary to each other. Moreover, we also see improved performance on the Canada domain, although feedback data was not collected for that domain.

From these experiments, we conclude that feedback data can improve the accuracy of the base RQA model, not only for the domains for which feedback data is available but also for unseen domains (Canada).

4.2 RQ2: Does feedback data improve the accuracy of RQA models that are stronger than the base model?

If feedback data were only useful for the base RQA model, then its usefulness would be questionable, since the RQA development cycle is continuous and the base RQA model will eventually be replaced with a better model. For example, we find that BART-based dense retriever is superior than the BERT RQA model: Table 9 in Appendix E shows the results on validation set which indicate that BART RQA model overall performance is nearly 4 points better than the BERT RQA model.

To answer RQ2, we use the same FEEDBACKRERANKER and VANILLARERANKER to rescore the BART RQA predictions, even though feedback data is not collected for this model. We observe that the resulting model outperforms the BART RQA model in Table 5, indicating that the feedback data is still useful. Again, FEEDBACKRERANKER is superior to VANILLARERANKER although the feedback data has fewer samples than the pre-deployment data, and the COMBINEDRERANKER has the best performance.

These results suggest that the feedback data is useful not only for the base RQA model but also other stronger RQA models.

4.3 RQ3: Do explanations aid humans in discerning between correct and incorrect answers?

We conduct a human evaluation to investigate whether explanations are useful from the perspective of users. Unfortunately, rigorous definitions and automatic metrics of explainability remain open research problems. In this work, we simulate a real-world scenario, where the user is presented an answer returned by the system as well as an explanation for the answer, and they are asked to determine whether the answer is acceptable or not. Jacovi and Goldberg (2020) advocate utility metrics as proxies to measure the usefulness of explanations instead of directly evaluating an explanation since plausible explanations does not necessarily increase the utility of the resulting system. Inspired by their findings, we measure if explana-

[6] We follow Berg-Kirkpatrick et al. (2012) to conduct the statistical significant test

Explanation	Accuracy	Agreement
Blank	69.17	0.31
Human-written	88.33	0.80
BART feedback model	81.67	0.71
BART summarization model	74.17	0.30

Table 6: Human evaluation results of the usefulness of explanations. Accuracy measures the utility of explanations in selecting the correct rating label for an answer, whereas agreement measures whether explanations invoke same behaviour pattern across users.

tions can: 1) help users to make accurate decisions when judging an answer (with respect to a ground truth) and 2) improve the agreement among users in accepting/rejecting an answer candidate. The former measures the utility of an explanation and the latter measures if the explanations invoke the same behavioral pattern across different users irrespective of the utility of the explanation. Note that agreement and utility are not tightly coupled. For example, agreement can be higher even if the utility of an explanation is lower when the explanation misleads end users to consistently select a wrong answer (González et al., 2021; Bansal et al., 2021).

We sample 60 feedback samples from the hidden split of the feedback data $\mathcal{D}_{\text{feed}} = (Q, A, Y, E)$ for evaluation purposes.[7] We evaluate four experimental setups on these samples which vary in the type of explanation shown to the end users: 1) no explanation; 2) human-written explanations; 3) explanations generated by the BART model trained on the feedback data (Section 3.2); and 4) summary of the answer candidate generated by a strong fine-tuned BART-based summarization model.[8] The last setting is inspired from the observation in Section 2.2 that a large portion of explanations contain summary of questions/answers. We investigate if conventional summary of an answer is as useful as an explanation. For each of these setups, two crowdworkers assign a rating label to each answer candidate indicating the quality of the answer. Each setup has its own set of workers in order to avoid information-leakage across setups (this simulates A/B testing often used by production systems).

We measure the workers' accuracy (average of the two workers) in determining the correctness of an answer with respect to the original annotation

Question: *What are the restrictions to travelers landing in the US?*

Answer: *... Under current federal regulations, pilots must report all illnesses and deaths to CDC before arriving to a US destination. According to CDC disease protocols, if a sick traveler is considered to be a public health risk, CDC works with local and state health departments and international public health agencies to contact passengers and crew exposed to that sick traveler. Be sure to give the airline your current contact information when booking your ticket so you can be notified if you are exposed to a sick traveler on a flight. ...*

Generated explanation: *This answer is irrelevant to the question. The question is asking about restrictions on travelers landing in the US and this answer provides information on what to do if there is a sick passenger on an international or domestic flight.*

Human explanation: *This information does not answer the question. The question is asking for information on the restrictions to travelers landing in the US and this answer contains information on pilots reports on illnesses and deaths before arriving to a US destinations and airline notification when passengers are exposed to sick travelers on a flight.*

Generated Summary: *The Centers for Disease Control and Prevention (CDC) is working with airlines to help prevent illness and death on flights.*

Question: *Should I wear gloves when I go out in public to prevent Covid-19?*

Answer: *No, WHO does not recommend the regular use of gloves by people in the community. The wearing of gloves may increase risks, since it can lead to self-infection or transmission to others through touching contaminated surfaces which is not followed by removal of gloves and hand hygiene. Therefore, in public places such as supermarkets, in addition to physical distancing...*

Generated Explanation: *This answer is excellent because it unequivocally states that gloves are not recommended. Therefore, it answers the question directly. It goes on to explain why gloves aren't recommended. This is a great answer.*

Human explanation: *The question is answered directly. The answer states not to wear gloves in public.*

Generated Summary: *The World Health Organization (WHO) has issued a guidance on the use of gloves in public places.*

Question: *Can students work in aged care?*

Answer:*...The Australian Government has announced that residential aged care facilities should take extra precautions to keep residents safe from COVID-19. Both individuals and management need to take responsibility for the health of visitors and staff at facilities to protect our most vulnerable community members. Aged care facilities will: closely monitor the health of staff...*

Generated Explanation: *This answer does not address whether or not students are allowed to work in aged care. This answer only provides information on precautions to be taken by aged care facilities to keep residents safe.*

Human Explanation: *The information here give explanation on guideline that aged care facility staffs should put in place and did not say anything about student working in aged care facility.*

Generated Summary: *Residents in aged care facilities across Australia are being urged to take extra precautions to prevent the spread of a deadly virus.*

Table 7: Examples of different explanation types: model-generated and human-written explanation and model-generated summary.

---

[7] For simplicity, we merge the answer feedback labels *good* and *could be improved* into one label called *partially correct*. The final set of answer labels we used are *correct* (for original label *excellent*), *partially correct* and *incorrect* (for original label *bad*).

[8] https://huggingface.co/facebook/bart-large-xsum

in FEEDBACKQA, as well as compute the agreement of workers with each other using Spearman correlation. Table 6 presents the results. All explanation types improve accuracy compared to the the model with no explanations. This could be because any explanation forces the worker to think more about an answer. The human-written explanations has the highest utility and also leads to the biggest agreement. Both the human-written explanations and the explanations generated by the BART feedback model have more utility and higher agreement than the BART summarization model. In fact, the summarization model leads to lower agreement.

These results indicate that explanations based on feedback data are useful for end users in discerning correct and incorrect answers, and they also improve the agreement across users.

Table 7 shows some examples of explanation that helps the users make more informed and accurate decision. In the first example, the model-generated explanation points out the gap between the question and the answer candidate, though there are a large number of overlapping keywords. Meanwhile, human explanations are generally more abstractive and shorter in nature (e.g., see the second example).

5 Related work

Retrieval-based question answering has been widely studied, from early work on rule-based systems (Kwok et al., 2001), to recently proposed neural-based models (Yang et al., 2019; Karpukhin et al., 2020). Most existing work focuses on improving the accuracy and efficacy by modification of a neural architecture (Karpukhin et al., 2020; Humeau et al., 2020), incorporation of external knowledge (Ferrucci et al., 2010), and retrieval strategy (Kratzwald and Feuerriegel, 2018). These methods focus on the pre-deployment stage of RQA models.

By contrast, we investigate methods to improve a RQA model post-deployment with interactive feedback. The proposed methods are agnostic to the architecture design and training methods of the base RQA model.

Learning from user feedback has been a long standing problem in natural language processing. Whilst earlier work proposes methods for using implicit feedback—for instance, using click-through data for document ranking (Joachims, 2002)—recent work has explored explicit feedback such as explanations of incorrect responses by chatbots (Li et al., 2016; Weston, 2016) and correctness labels in conversational question answering and text classification (Campos et al., 2020). However, the feedback in these studies is automatically generated using heuristics, whereas our feedback data is collected from human users. Hancock et al. (2019) collect suggested responses from users to improve a chatbot, while we investigate the effect of natural feedback for RQA models.

Explainability and Interpretability has received increasing attention in the NLP community recently. This paper can be aligned to recent efforts in collecting and harnessing explanation data for language understanding and reasoning tasks, such as natural language inference (Camburu et al., 2018; Kumar and Talukdar, 2020), commonsense question answering (Rajani et al., 2019), document classification (Srivastava et al., 2017), relation classification (Murty et al., 2020), reading comprehension (Lamm et al., 2021), and fact checking (Alhindi et al., 2018). The type of feedback in FEEDBACKQA differs from the existing work in several aspects: 1) FEEDBACKQA has feedback data for both positive and negative examples, while most of other datasets only contains explanations of positive ones; 2) FEEDBACKQA has both structured and unstructured feedback, while previous work mainly focuses on one of them; 3) The feedback in FEEDBACKQA is collected post-deployment; 4) While previous work aims to help users interpret model decisions, we investigate whether feedback-based explanations increase the utility of the deployed system.

6 Conclusion

In this work, we investigate the usefulness of feedback data in retrieval-based question answering. We collect a new dataset FEEDBACKQA, which contains interactive feedback in the form of ratings and natural language explanations. We propose a method to improve the RQA model with the feedback data, training a reranker to select an answer candidate as well as generate the explanation. We find that this approach not only increases the accuracy of the deployed model but also other stronger models for which feedback data is not collected. Moreover, our human evaluation results show that both human-written and model-generated explanations help users to make informed and accurate decisions about whether to accept an answer.

7 Limitations and Ethical consideration

The training and inference of a reranker with feedback data increases the usage of computational resources. We note that our feedback collection setup is a simulation of a deployed model. The feedback in real-world systems may contain sensitive information that should be handled with care. Moreover, real-world feedback could be noisy and is prone to adversarial attacks.

A Details of Data Collection

Passage curating After we scraped the websites, we collect the questions and answers in the Frequently-Asked-Questions pages directly. For those pages without explicit questions and answers, we extract the text content as passages and proceed to question collection.

Question collection We hire crowd-source workers from English-speaking countries at the Amazon MTurk platform to write questions conditioned on the extracted passages. The workers are instructed not to ask too generic questions or copy and paste directly from the passages.

A qualification test with two sections is done to pick up the best performing workers. In the first section, the workers are asked to distinguish the good question from the bad ones for given passages. The correct and incorrect questions were carefully designed to test various aspects of low-quality submissions we had received in the demo run. The second section is that writing a question given a passage. We manually review and score the questions. We paid 0.2$ to workers for each question.

B Details of Feedback Collection

We asked the workers to provide rating and natural language feedback for question-answer pairs. For qualification test, we labeled the rating for multiple pairs of questions and answers. The workers are selected based on their accuracy of rating labeling. We paid 0.4$ to workers for each feedback.

C Details of Human Evaluation

The worker assignment is done to make sure a worker rates the same question-answer pair only once. Otherwise there is risk that the workers just blindly give the same judgement for a certain QA pair.

We adopt the qualification test similar to the one for feedback collection. We also include some dummy QA pairs, whose answer candidate were randomly sampled from the corpora, and we filter out the workers who fail to recognize them. We paid 0.3$ to workers for each QA pair.

D Implementation Details

Throughout the experiments, we have used 4 32-GB Nvidia Tesla V100. The hyperparameter (learning rate, dropout rate) optimisation is performed for the RQA models only and standard fine-tuning hyperparameters of BART are used for building the FEEDBACKRERANKER model. We set batch size as 16. We truncate the questions and passages to 50 and 512 tokens, respectively. The models are trained with 40 epochs. For our hyperparameter search, we have used 5 trials and while reporting the final results the best hyperparameter variant's performance was averaged across 3 different runs. All experiment runs were finished within 20 hours.

	lr	Dropout
BERT (Bi-encoder)	5.0e-05	0.1
BERT (Poly-encoder)	5.0e-05	0.1
BART (Bi-encoder)	9.53e-05	0.01026
BART (Poly-encoder)	4.34e-05	0.1859
FEEDBACKRERANKER	5.0e-05	0.1

Table 8: Hyper-parameter setting of different variants of QA models as well as EXPLAINRATE and RATEONLY. There is no pooling operation in the latter two models.

E Validation performance

In addition to the Poly-encoders, we also explore Bi-encoder and we have found that its performance is consistently worse. Table 9 presents the performance of base QA models with different pretrained Transformer models and encoding methods on the validation set.

Methods	Australia	US	Canada	UK	WHO	All
BERT (Bi-encoder)	44.57	64.24	81.12	50.55	81.85	64.47
BERT (Poly-encoder)	47.25	65.30	81.49	48.50	81.19	64.75
BART (Bi-encoder)	47.13	67.62	86.01	55.06	85.48	68.26
BART (Poly-encoder)	49.17	66.98	85.75	54.27	87.46	68.73

Table 9: The accuracy of different RQA models on the validation set. All of the results are averaged across 3 runs.

Methods	Australia	US	Canada	UK	WHO	All
BART RQA model						
BART RQA model	49.17	66.98	85.75	54.27	87.46	68.73
+ FEEDBACKRERANKER with explanation-based rating	51.34	69.09	84.20	56.87	87.79	69.86
+ FEEDBACKRERANKER with rating only	51.09	68.57	86.84	58.21	88.78	70.70
BERT RQA model						
BERT RQA model	47.25	65.30	81.49	48.50	81.19	64.75
+ FEEDBACKRERANKER with explanation-based rating	51.34	70.15	83.72	53.71	84.49	68.68
+ FEEDBACKRERANKER with rating only	51.09	68.46	84.18	55.69	85.15	68.91

Table 10: Accuracy of PIPELINE models using different feedback data to train the re-ranker on the validation set. All of the results are averaged across 3 runs.

Abstract

The application of Natural Language Inference (NLI) methods over large textual corpora can facilitate scientific discovery, reducing the gap between current research and the available large-scale scientific knowledge. However, contemporary NLI models are still limited in interpreting mathematical knowledge written in Natural Language, even though mathematics is an integral part of scientific argumentation for many disciplines. One of the fundamental requirements towards mathematical language understanding is the creation of models able to meaningfully represent variables. This problem is particularly challenging since the meaning of a variable should be assigned exclusively from its defining type, i.e., the representation of a variable should come from its context. Recent research has formalised the variable typing task, a benchmark for the understanding of abstract mathematical types and variables in a sentence. In this work, we propose VarSlot, a Variable Slot-based approach, which not only delivers state-of-the-art results in the task of variable typing, but is also able to create context-based representations for variables.

1 Introduction
