Introduction

This year marks the 21st edition of the *Workshop on Innovative Use of NLP for Building Educational Applications*. As usual, we are happy to welcome papers on various aspects and types of educational applications – from traditionally popular tasks around language learning to novel applications related to teaching math and programming languages. This year, BEA continues being a 2-day workshop, with one significant change: we have one hybrid day and one fully virtual day. This change did not only allow us to accept more valuable work from our community, but also ensured better visibility for authors presenting online.

This year, we have received a total of 132 submissions, and from these, we have accepted 19 papers as talks and 44 as poster and demo presentations, for an overall acceptance rate of 48 percent. As in previous years, we have put the main emphasis on the high quality of research when selecting the papers to be accepted, but we also hope that we have managed to bring together a diverse program, with various languages, subject domains, and educational applications covered.

In addition to the diverse oral, poster and demo presentations, this year, we are hosting a panel on *Transitioning from Academia to the EdTech Industry*, with four distinguished speakers involved: Christine Bagarino (Social AI), Kai North (Cambium Assessment), Keelan Evanini (NBME), and Mariano Felice (British Council). BEA 2026 will also include, for the second time, a half-day tutorial on *Theory of Mind and Application in Educational Context*, organized by Effat Farhana (Auburn University), Maha Zainab (Auburn University), Qiaosi Wang (Carnegie Mellon University), Niloofar Miresghallah (Carnegie Mellon University), Ramira van der Meulen (Leiden University), Max van Duijn (Leiden University). Last but not least, this year we have also hosted two shared tasks – on *Vocabulary Difficulty Prediction for English Learners* by Mariano Felice (British Council) and Lucy Skidmore (British Council), and on *Rubric-based Short Answer Scoring for German* by Sebastian Gombert (DIPF), Zhifan Sun (DIPF), Fabian Zehner (DIPF), Jannik Lossjew (IPN), Tobias Wyrwich (IPN), Berrit Katharina Czinczel (IPN), David Bednorz (IPN), Sascha Bernholt (IPN), Knut Neumann (IPN), Ute Harms (IPN), Aiso Heinze (IPN), and Hendrik Drachslar (DIPF). Both tasks attracted a large number of participants, and the program includes oral presentations on the shared tasks from the organizers as well as talks from the tasks' winners and extended poster sessions for shared tasks participants presenting their systems.

Finally, we would like to thank everyone who has been involved in organizing the BEA workshop this year. We are particularly grateful to our sponsors who keep providing their support to BEA: this year, our sponsors include Cambridge University Press & Assessment, Duolingo English Test, Squirrel Ai Learning, CATALPA, and British Council.

BEA 2026 Organizing Committee

Organizing Committee

General Chair

Ekaterina Kochmar, MBZUAI / University of Victoria

Program Chairs

Andrea Horbach, CAU Kiel / Leibniz Institute for Science and Mathematics Education

Ronja Laarmann-Quante, Ruhr University Bochum

Marie Bexte, FernUniversität in Hagen

Publication Chair

Anaïs Tack, KU Leuven, imec

Shared Tasks Chairs

Victoria Yaneva, National Board of Medical Examiners

Bashar Alhafni, MBZUAI

Sponsorship Chairs

Zheng Yuan, University of Sheffield

Jill Burstein, Duolingo

Virtual Chair

Stefano Bannò, Cambridge University

Program Committee

Chairs

Bashar Alhafni, MBZUAI
Stefano Bannò, University of Cambridge
Marie Bexte, FernUniversität in Hagen
Jill Burstein, Duolingo
Andrea Horbach, CAU Kiel / Leibniz Institute for Science and Mathematics Education
Ekaterina Kochmar, MBZUAI / University of Victoria
Ronja Laarmann-Quante, Ruhr University Bochum
Anais Tack, KU Leuven; imec
Victoria Yaneva, National Board of Medical Examiners
Zheng Yuan, University of Sheffield

Program Committee

Rania Abdelghani, Hector Institute of Educational Sciences and Psychology, University of Tübingen
Tazin Afrin, NBME
Soroosh Akef, Leibniz-Institut für Wissensmedien
Syeda Sabrina Akter, George Mason University
Vennela Akula, Auburn University
Erfan Al-Hossami, University of North Carolina at Charlotte
Ali Al-Laith, University of Copenhagen
Giora Alexandron, Weizmann Institute of Science
David Alfter, Gothenburg University
Norah Almousa, University of Pittsburgh
Aitor Arronte Alvarez, University of Hawaii at Manoa
Nischal Ashok Kumar, University of Massachusetts Amherst
Sina Bagheri Nezhad, Independent Researcher
Xiaoyu Bai, University of Potsdam
Mohmaed Basem, MSA University
Michael Gringo Angelo Bayona, Trinity College Dublin
Lee Becker, Pearson
Beata Beigman Klebanov, Educational Testing Service
Milena Belosevic, Bielefeld University
Enrico Benedetti, Utrecht University
Luca Benedetto, Telecom SudParis, IP Paris
Maryam Berijanlian, Michigan State University
Ummugul Bezirhan, Boston College, TIMSS and PIRLS International Study Center
Abhidip Bhattacharyya, University of Massachusetts, Amherst
Ted Briscoe, MBZUAI
Dominique Brunato, Institute of Computational Linguistics A. Zampolli (ILC-CNR), Pisa
Andrew Caines, University of Cambridge
Jie Cao, University of Oklahoma
Dumitru-Clementin Cercel, University Politehnica of Bucharest
Bharathi Raja Chakravarthi, University of Galway, Ireland
Imran Chamieh, Hochschule Ruhr West
Ignatios Charalampidis, University of Tuebingen
Andreas Chari, University of Glasgow

Mei-Hua Chen, Department of Foreign Languages and Literature, Tunghai University
 Artem Chernodub, Zendesk
 Luis Chiruzzo, Universidad de la Republica
 Hyundong Cho, USC, Information Sciences Institute
 Declan Clowry, Social AI
 Longwei Cong, DIPF | Leibniz Institute for Research and Information in Education
 Yan Cong, Purdue University
 Mark Core, University of Southern California
 Steven Coyne, Tohoku University / RIKEN
 Orphee De Clercq, LT3, Ghent University
 Kordula De Kuthy, IWM Tübingen
 Jasper Degraeuwe, Ghent University
 Carrie Demmans Epp, University of Alberta
 Yuning Ding, Leibniz Institute for Science and Mathematics Education
 Rahul Divekar, Bentley University
 George Duenas, Universidad Pedagogica Nacional
 Marius Dumitran, University of Bucharest
 Andreea Dutulescu, National University of Science and Technology Politehnica Bucharest
 Yo Ehara, Tokyo Gakugei University
 Walid El Hefny, Leibniz-Institut für Wissensmedien (IWM)
 Effat Farhana, Auburn University
 Mariano Felice, British Council
 Michael Flor, Educational Testing Service
 Jennifer-Carmen Frey, EURAC Research
 Momoka Furuhashi, Tohoku University / National Institute of Informatics
 Thomas Gaillat, Rennes 2 university
 Martina Galletti, Sony Computer Science Laboratories - Paris | Sapienza University of Rome
 Diana Galvan-Sosa, University of Cambridge
 Ashwinkumar Ganesan, Amazon Alexa AI
 Lingyu Gao, Duolingo
 Jie Gao, McGill University
 Rujun Gao, Texas A&M University
 Ritik Garg, Extramarks Education Pvt. Ltd.
 Voula Giouli, Aristotle University of Thessaloniki / ILSP, ATHENA RC
 Aron Gohr, Independent
 Sebastian Gombert, DIPF | Leibniz Institute for Research and Information in Education
 Kiel Gonzales, University of the Philippines Diliman
 Mark Edward Gonzales, Agency for Science, Technology and Research (A*STAR), Singapore
 Cyril Goutte, National Research Council Canada
 Stuart Grey, University of Glasgow
 Viktor Gulbrandsen, University of Oslo
 Pranav Gupta, Cisco
 Abigail Gurin Schleifer, Weizmann Institute of Science
 Ibrahim Hallac, Østfold University of Applied Sciences
 Ching Nam Hang, Assistant Professor, Yam Pak Charitable Foundation School of Computing and Information Sciences, Saint Francis University, Hong Kong
 Jiangang Hao, Educational Testing Service
 Hasnain Heickal, University of Massachusetts Amherst
 Nicolas Hernandez, Nantes University
 Jingying Hu, Purdue University
 Chung-Chi Huang, Frostburg State University

Aiden Huang, Acton-Boxborough Regional High School
 Phoebe Huang, University of Florida
 Anna Huelasing, CAU
 Catherine Ikae, Applied Machine Intelligence, Bern University of Applied Sciences, Switzerland
 Fareya Ikram, University of Massachusetts Amherst
 Joseph Marvin Imperial, University of Bath
 Radu Tudor Ionescu, University of Bucharest
 Md. Rakibul Islam, Ahsanullah University of Science and Technology
 Elsayed Issa, Purdue University
 Raunak Jain, Intuit
 Abhishek Jariwala, Auburn University
 Helen Jin, University of Pennsylvania
 Léane Jourdan, Nantes University
 Indika Kahanda, University of North Florida
 Tomoyuki Kajiwara, Ehime University / The University of Osaka
 Anisia Katinskaia, Swiss Data Science Center
 Fatemeh Kazemi Vanhari, McMaster University
 Elma Kerz, Exaia Technologies
 Samin Khan, Stanford University
 Sachiko Kimura, Rikkyo University, Dokkyo University
 Mamoru Komachi, Hitotsubashi University
 Maxim Konca, Goethe University Frankfurt
 Katsunori Kotani, Kansai Gaidai University
 Joni Kruijsbergen, LT3, Ghent University
 Andrei Kucharavy, HES-SO Valais-Wallis
 Aayush Kucheria, Aalto University
 Roland Kuhn, National Research Council of Canada
 Gaurav Kumar, University of California San Diego
 Ravi Kumar, Florida International University (FIU)
 Alexander Kwako, University of California, Los Angeles
 Antonio Laverghetta Jr., Pennsylvania State University
 Jaewook Lee, UMass Amherst
 Seolhwa Lee, Technical University of Darmstadt
 Bernardo Leite, Faculty of Engineering - University of Porto
 Arun Balajiee Lekshmi Narayanan, University of Pittsburgh
 Hannah Levin, Stanford University
 Jiazheng Li, King's College London
 Xu Li, Southwest Petroleum University
 Junhong Liang, MBZUAI
 Wen Liang, Columbia University
 Chuan-Jie Lin, National Taiwan Ocean University
 Yudong Liu, Western Washington University
 Zhexiong Liu, University of Pittsburgh
 Denise Loefflad, Leibniz-Institut fuer Wissensmedien Tuebingen
 Julian Lohmann, Christian Albrechts Universität Kiel
 Benny Longwill, Educational Testing Service
 Anastassia Loukina, Grammarly Inc
 Wanning Lu, Stanford University
 Li Lucy, University of Washington
 Sarah Löber, University of Tübingen
 Jakub Macina, ETH Zurich

Nitin Madnani, Duolingo
 S.M Afridi Mahmud, Bangladesh University of Engineering and Technology
 Maria Monica Manlises, De La Salle University
 Zhenjiang Mao, University of Florida
 Jacek Marciniak, Adam Mickiewicz University
 Arianna Masciolini, Språkbanken Text; Department of Swedish, Multilingualism, Language Technology; University of Gothenburg
 Sandeep Mathias, Presidency University
 Hunter McNichols, University of Massachusetts Amherst
 Detmar Meurers, Leibniz-Institut für Wissensmedien (IWM)
 Daniel Mora Melanchthon, CAU Kiel / Leibniz Institute for Science and Mathematics Education
 Phoebe Mulcaire, Duolingo
 Laura Musto, Universidad de la Republica
 Farah Nadeem, LUMS
 Sungjin Nam, ACT, Inc
 Diane Napolitano, The Washington Post
 Léo Nebel, LIP6 - Sorbonne Université
 Seyed Parsa Neshaei, EPFL
 Duy Anh Nguyen, Independent Researcher
 Huy Nguyen, Oracle
 S Jaya Nirmala, National Institute of Technology Tiruchirappalli
 Sergiu Nisioi, Human Language Technologies Research Center, University of Bucharest
 Adam Nohejl, RIKEN
 Kai North, Cambium Assessment Inc.
 Similoluwa Okunowo, AIMS South Africa
 Kostiantyn Omelianchuk, Grammarly
 Amin Omidvar, PhD student at the Department of Electrical Engineering and Computer Science, York University
 Daniel Oyeniran, University of Alabama
 Alonso Palomino, DFKI (German Center for Artificial Intelligence Research)
 Nisarg Parikh, University of Massachusetts, Amherst
 Jeiyoon Park, Smilegate
 Kseniia Petukhova, MBZUAI
 Tomasz Pilka, Adam Mickiewicz University in Poznan
 Pagnarith Pit, University of Melbourne
 Lucie Polakova, Charles University
 Long Qin, Alibaba
 Mengyang Qiu, Saint Elizabeth University
 Chatrine Qwaider, MBZUAI
 Md. Abdur Rahman, Islamic University of Technology (IUT), OIC
 Pranil Raichura, Independent Researcher
 Anmol Rao, Arizona State University
 pranshu rastogi, Independent Researcher
 Sparsh Rastogi, Thapar Institute of Engineering and Technology
 Manav Rathod, University of California, Berkeley
 Hanumant Redkar, Goa University, Goa
 Saed Rezayi, National Board of Medical Examiners
 Luisa Ribeiro-Flucht, University of Tuebingen
 Frankie Robertson, University of Jyväskylä
 Shadman Rohan, Center for Computational & Data Sciences, IUB
 Aiala Rosá, Instituto de Computación, Facultad de Ingeniería, Universidad de la República

Mahule Roy, University of Oxford
 Alla Rozovskaya, Queens College, City University of New York
 Josef Ruppenhofer, Fernuniversität in Hagen
 Mariam Saeed, Applied Innovation Center
 Pravish Sainath, Vanier College, Université de Montréal
 Jonathan Sakunkoo, University of Oxford
 Alexander Scarlatos, University of Massachusetts Amherst
 Nils-Jonathan Schaller, Leibniz Institute for Science and Mathematics Education
 Stephanie Schoch, University of Virginia
 Dhruv Shah, Sardar Patel Institute of Technology
 Natarajan Balaji Shankar, University of California Los Angeles
 Matthew Shardlow, Manchester Metropolitan University
 Qian Shen, University of Florida
 Gyu-Ho Shin, University of Illinois Chicago
 Hyo Jeong Shin, Sogang University
 Ziqi Shu, Stanford University
 Astha Singh, Iowa State University
 Li Siyan, Columbia University
 Lucy Skidmore, British Council
 Anastasia Smirnova, San Francisco State University
 Mariia Soliar, Leibniz-Institut für Wissensmedien (IWM)
 Alexey Sorokin, Moscow State University
 Shankhalika Srikanth, Independent Researcher
 Felix Stahlberg, Google Research
 Katherine Stasaski, Google DeepMind
 Helmer Strik, Centre for Language and Speech Technology (CLST), Centre for Language Studies (CLS), Radboud University Nijmegen
 Parisa Suchdev, University of Vermont
 Hakyung Sung, Rochester Institute of Technology
 Andreas Säuberli, LMU Munich
 Kyosuke Takami, Osaka Kyoiku University
 Wenjia Tan, University of Macau
 CheeWei Tan, Nanyang Technological University
 Takehito Utsuro, University of Tsukuba
 Martin Vainikko, University of Tartu
 Sowmya Vajjala, National Research Council
 Piper Vasicek, Brigham Young University
 Justin Vasselli, Nara Institute of Science and Technology
 Hariram Veeramani, UCLA
 Giulia Venturi, Institute of Computational Linguistics Antonio Zampolli (ILC-CNR)
 Anthony Verardi, Duolingo
 Elena Volodina, University of Gothenburg
 Anh-Duc Vu, University of Helsinki
 Deliang Wang, The University of Hong Kong
 Nikhil Wani, OpenThreads AI / University of Southern California
 Taro Watanabe, Nara Institute of Science and Technology
 Alistair Willis, The Open University
 Yiheng Wu, University of Helsinki
 Bushi Xiao, University of Florida
 Hiroaki Yamada, Tokyo Metropolitan University
 Bi-Cheng Yan, National Taiwan Normal University

Haiyin Yang, University of Florida
Roman Yangarber, University of Helsinki
Sahar Yarmohammadtoosky, NBME
Tahreem Yasir, North Carolina State University
Su-Youn Yoon, EduLab
Marcos Zampieri, George Mason University
Fabian Zehner, DIPF | Leibniz Institute for Research and Information in Education
Torsten Zesch, Computational Linguistics, FernUniversität in Hagen
Jing Zhang, Emory University
Yiling Zhao, Stanford University
Yang Zhong, University of Pittsburgh
Ej Zhou, University of Cambridge
Yiyun Zhou, NBME
Jessica Zipf, University of Konstanz
Michael Zock, CNRS-LIS
Robert Östling, Department of Linguistics, Stockholm University

Keynote Talk

Transitioning from Academia to the EdTech Industry

Christine Bagarino
Social AI

Bio: Christine Bagarino is the founder of Social AI, an AI native startup based in Tokyo, Japan, that builds AI technology for positive social impact. A former educator, curriculum developer, and Silicon Valley product manager, Christine developed Japan's first LLM-powered English learning chatbot approved for K12 public education. In 2023, she traveled to rural Vietnam for an EdTech pilot funded by the Asian Development Bank, which inspired her to make fun and quality English learning accessible to children all over the world.

Keynote Talk

Transitioning from Academia to the EdTech Industry

Kai North
Cambium Assessment

Bio: Dr. Kai North is a Senior Data Scientist at Cambium Assessment Inc. Kai earned his PhD in Information Technology at George Mason University, Virginia. He specializes in machine learning and natural language processing applied to educational and assessment technologies and has multiple top-tier publications at venues such as ACL, COLING, and ACM computing surveys.

Keynote Talk

Transitioning from Academia to the EdTech Industry

Keelan Evanini
NBME

Bio: Keelan Evanini has been a researcher in the field of natural language processing (NLP) for educational and conversational applications for more than 15 years. He is currently a Lead NLP Scientist at the National Board of Medical Examiners, where he conducts research into using conversational AI for interactive, scenario-based learning applications for medical students. Prior to joining NBME in 2025, he served as SVP of engineering and AI at Kasisto, a New York-based startup company that provides conversational AI solutions to financial institutions. From 2009-2020, he worked at Educational Testing Service as a research scientist and research director, where he conducted research into automated scoring of non-native spoken English for language proficiency assessment and spoken dialog systems for language learning applications. Keelan received a PhD in linguistics from the University of Pennsylvania in 2009 and is a Senior Member of the IEEE. He has published over 90 peer-reviewed papers and has been awarded 11 US patents.

Keynote Talk

Transitioning from Academia to the EdTech Industry

Mariano Felice
British Council

Bio: Mariano leads the artificial intelligence (AI) strategy for language learning and assessment at the British Council. His role involves researching the application of natural language processing (NLP) to language assessment, providing strategic guidance for the development and adoption of AI solutions, and promoting AI literacy and responsible use of new technologies.

With over a decade of experience, Mariano has worked on a wide range of topics, including grammatical error correction, automatic error typing, system evaluation, automated cloze test generation and item difficulty prediction. He has published numerous scientific papers in top-tier NLP conferences and is a regular speaker at international conferences as well as a reviewer for workshops, journals and conferences in his field. Mariano is also a visiting scholar at the University of Reading and the University of Cambridge.

Table of Contents

Theory of Mind and Application in Educational Context

Effat Farhana, Maha Zainab, Qiaosi Wang, Niloofar Miresghallah, Ramira van der Meulen and Max van Duijn 1

Inferring Student Engagement via Real-Time Thermal–Visual Voice Activity Detection

Bradley Goodman 7

Investigating Context-aware CTC for Pronunciation Assessment: Mitigating Peaky Behavior and Context Independency Assumption

Jiun-Ting Li, Tien-Hong Lo, Bi-Cheng Yan, Shih-Hsuan Chiu, Fu-An Chao and Berlin Chen . 21

A Survey of Automated Presentation Coaching: Systems, Methods, and Open Challenges

Wen Liang, Li Siyan, Zackary Rackauckas and Julia Hirschberg 34

The Aftermath of DrawEduMath: Vision Language Models Underperform with Struggling Students and Misdiagnose Errors

Li Lucy, Albert Zhang, Nathan Anderson, Ryan Knight and Kyle Lo 48

Criterial Features in German: Towards Interpretable NLP in Readability Assessment

Denise Loefflad, Sofia Kathmann, Heiko Holz and Detmar Meurers 63

Letting Tutor Personas Speak Up for LLMs: Learning Steering Vectors from Dialogue via Preference Optimization

Jaewook Lee, Alexander Scarlatos, Simon Woodhead and Andrew Lan 78

Towards Just-in-Time Adaptive Feedback: Enhancing Student Learning via Knowledge-Grounded LLM

Younghun Lee, Amir Bralin, Nobel Sanjay Rebello and Dan Goldwasser 93

RABIT: Rationale-Based Distillation Towards Interpretable Automatic Speaking Assessment via a Small Language Model

Bi-Cheng Yan, Hong-Yun Lin, Fu-An Chao, Jiun-Ting Li and Berlin Chen 108

Towards Pedagogically Aligned LLM Tutors for Math Mistake Remediation

Kseniia Petukhova, Tien Dat Nguyen and Ekaterina Kochmar 118

Challenges in Machine Translation of Interactive Multimodal Exercises

Lucie Polakova, Miroslav Hrabal, Věra Kloudová, Michal Novák, Mariia Anisimova and Martin Popel 141

Evaluating LLM Workflows for Generating Clinical Communication Assessment Items: A Comparative Study with Subject-Matter Experts

Christopher Runyon, Peter Baldwin, Ian Micir, Kevin Frome, Stephanie Mann, Saed Rezayi, Keelan Evanini and Victoria Yaneva 153

Towards Self-Referential Analytic Assessment: A Profile-Based Approach to L2 Writing Evaluation with LLMs

Stefano Banno, Kate Knill and Mark Gales 174

Using Interaction Log Data to Evaluate and Improve Feedback Accuracy in an Intelligent Language Tutoring System

Mariia Soliar, Leona Colling, Stephen Bodnar and Detmar Meurers 190

A Bigger Catch: Fine-Grained Curriculum Standards Alignment on the MathFish Benchmark

Xinman Liu, Mayank Sharma and Xinyu Shi 208

<i>Through the Sentence Lens: Explainable Essay Scoring through Fine-Grained Predictions</i>	
Daniel Mora Melanchthon, Stefan Keller and Andrea Horbach	221

Program

Friday, July 3, 2026

06:00 - 07:30 *Early Poster Session*

Using k-Shot Prompting with Large k for the Automated Scoring of a German Written Elicited Imitation Test

Malte Sternik, Ronja Laarmann-Quante and Anastasia Drackert

Fine-Grained Content Zone Prediction in German Argumentative Essays Using LLMs

Xiaoyu Bai and Manfred Stede

Sharing is Caring: Advantages of Sharing a Language Background with Learners as an Annotator of Learner Data in UD

Caroline Grand-Clement and Arianna Masciolini

The Effects of Structured LLM-Generated Feedback on Programming Assignment Performance

Tsvetomila Mihaylova, Evanfiya Logacheva, Arto Hellas, Jing Fan, Francisco Castro, Bitá Akram, Narges Norouzi, Peter Brusilovsky and Juho Leinonen

HFT at BEA 2026 Shared Task 2: Blunt-Edge Models for Hybrid Grading

Ulrike Pado

WSE Research at BEA 2026 Shared Task 2: Multi-Strategy Rubric-Based Short Answer Scoring for German

Jonas Gwozdz and Andreas Both

07:30 - 08:45 *Early Oral Session*

Domain-Adaptive Pre-training for Automated Short Answer Grading in Conceptual Physics: Reliability, Question-Level Analysis, and Error Reduction

Shirin Lade, Alistair Willis, Jonathan Nylk and Oli Howson

Using Interaction Log Data to Evaluate and Improve Feedback Accuracy in an Intelligent Language Tutoring System

Mariia Soliar, Leona Colling, Stephen Bodnar and Detmar Meurers

Towards Pedagogically Aligned LLM Tutors for Math Mistake Remediation

Kseniia Petukhova, Tien Dat Nguyen and Ekaterina Kochmar

What Aggregate Scores Hide: Per-Rule Evaluation of Russian Grammatical Error Correction

Anna Smirnova, Artyom Kopan, Vladislav Makeev and George Chernishev

Friday, July 3, 2026 (continued)

IWM-DKM at BEA 2026 Shared Task 2: Supplementing Supervised Fine-Tuning for Rubric-Based Short Answer Scoring

Kate Belcher, Marius De Kuthy Meurers, Kordula De Kuthy and Detmar Meurers

09:00 - 10:30 *Tutorial Session A*

Theory of Mind and Application in Educational Context

Effat Farhana, Maha Zainab, Qiaosi Wang, Niloofar Miresghallah, Ramira van der Meulen and Max van Duijn

10:30 - 11:00 *Coffee Break*

11:00 - 12:30 *Tutorial Session B*

Theory of Mind and Application in Educational Context

Effat Farhana, Maha Zainab, Qiaosi Wang, Niloofar Miresghallah, Ramira van der Meulen and Max van Duijn

12:30 - 14:00 *Lunch Break / Birds of a Feather*

14:00 - 15:45 *Oral Session A*

Using Interaction Log Data to Evaluate and Improve Feedback Accuracy in an Intelligent Language Tutoring System

Mariia Soliar, Leona Colling, Stephen Bodnar and Detmar Meurers

Estimating LLM Grading Ability and Response Difficulty in Automatic Short Answer Grading via Item Response Theory

Longwei Cong, Sonja Hahn, Sebastian Gombert, Leon Camus, Hendrik Drachsler and Ulf Kroehne

LLM-Powered but Rule-Grounded: Pedagogically Relevant Grammatical Error Characterization for Learner Model Construction

Soroosh Akef, Amália Mendes, P Rebuschat and Detmar Meurers

KEYSCORE — Keystroke-enhanced Automated Essay Scoring

Nils-Jonathan Schaller, Daniel Mora Melanchthon, Thorben Jansen, Olaf Köller and Andrea Horbach

15:45 - 16:00 *Coffee Break*

Friday, July 3, 2026 (continued)

16:00 - 17:30 *Poster Session A*

Inferring Student Engagement via Real-Time Thermal–Visual Voice Activity Detection

Bradley Goodman

Letting Tutor Personas Speak Up for LLMs: Learning Steering Vectors from Dialogue via Preference Optimization

Jaewook Lee, Alexander Scarlatos, Simon Woodhead and Andrew Lan

A Bigger Catch: Fine-Grained Curriculum Standards Alignment on the MathFish Benchmark

Xinman Liu, Mayank Sharma and Xinyu Shi

Through the Sentence Lens: Explainable Essay Scoring through Fine-Grained Predictions

Daniel Mora Melanchthon, Stefan Keller and Andrea Horbach

Kelvi: A Morphological Parser to Support Tamil Literacy

Shankhalika Srikanth, Sabrina Yu, Sophia Chan and Madeline Solis de Ovando

From Questions to Assessment Tuples: A Multi-Agent Framework with Bloom-Specialized Agents and Automated Verification

Gee-Lyle Wong, Runcong Zhao, Yulan He and Jiazheng Li

Multi-step Large Language Model for Fine-Grained Feedback in Stepwise Linear Equation Solutions

Imran Chamieh, Torsten Zesch and Klaus Giebertmann

Comparative Evaluation of AI-Generated vs. Expert-written Answer Explanations for a Medical Education Self-Assessment

Yiyun Zhou, Francis O'Donnell and Victoria Yaneva

Multi-component student writing profiles for expert-aligned automated evaluation of English learner essays.

Russell Moore, Andrew Caines and Paula Buttery

Policy-Sensitive Fairness Evaluation in Automated Scoring of Clinical Communication

Saed Rezayi, Le An Ha, Victoria Yaneva, Polina Harik, Janet Mee and Jason Snyder

Friday, July 3, 2026 (continued)

Rubrics as Semantic Subspaces: A Unified Approach to Rubric-based Constructed Response Scoring across Short Answers and Essays

Sebastian Gombert, Sonja Hahn, Nico Andersen, Leon Camus, Zhifan Sun, Ngoc Nhu Hao Nguyen, Fabian Zehner, Longwei Cong, Alexander Mehler and Hendrik Drachslar

Assessment of L2 speech global dimensions using large audio language models

Elsayed Issa and Mahmoud Ali

Children's English Reading Story Generation via Supervised Fine-Tuning of Compact LLMs with Controllable Difficulty and Safety

Qian Shen, Fanghua Cao, Min Yao, Shlok Gilda, Bonnie Dorr and Walter Leite

Transformer-based readability classifiers are worse than you think: Evidence from cross-domain Arabic readability assessment

SARH ALZU'BI and Robert Reynolds

Predicting Item Difficulty and Generating Reading Comprehension Items via an Annotated Repository

Radhika Kapoor, Mayank Sharma, Sang Truong, Nick Haber, Ben Domingue and Maria Ruiz-Primo

Generative-Evaluative Agreement: A Necessary Validity Criterion for LLM-Enabled Adaptive Assessment

Grandee Lee, Yue Wang, Che Yee Lye and Luke Peh

Teaching Through Analogies: A Modular Pipeline for Educational Analogy Generation

Mariam Barakat and Ekaterina Kochmar

From Dialogue to Learner Modeling: Identifying Candidate Signals of Productive Use in LLM-Based Grammar Practice

Luisa Ribeiro-Flucht, Lanhua Huang and Xiaobin Chen

Toward Cross-Domain Automated Feedback: A Comparative Evaluation of Open-Source Models across Diverse Student Assessment Types

Muhammad Haseeb, Min Paing Hmue, Ahmad Imam Amjad, Maaz Amjad and Victor Sheng

SAAKTH at BEA 2026 Shared Task 1: L1-Aware English Vocabulary Difficulty Prediction with Hybrid Transformer and Psycholinguistic Features

Karthik Mattu, Adit Dhall, Arshad Naguru, Shubh Sehgal, Thejas Gowda and Hakyung Sung

SDPA at BEA 2026 Shared Task 2: Efficient LLM Fine-Tuning for Rubric-based Short Answer Scoring

Zhexiong Liu and Jing Zhang

Friday, July 3, 2026 (continued)

*TOEBM at BEA 2026 Shared Task 1: Improving Lexical Difficulty Prediction
with Context-Aligned Contrastive Learning and Ridge Ensembling*

wicaksono M., Joanito Lopo, Tsamarah Nugraha, Ahmad Adi and Muhamad Nur-
fajri

Saturday, July 4, 2026

09:00 - 10:30 *Oral Session B*

The Aftermath of DrawEduMath: Vision Language Models Underperform with Struggling Students and Misdiagnose Errors

Li Lucy, Albert Zhang, Nathan Anderson, Ryan Knight and Kyle Lo

Interpretable Difficulty-Aware Knowledge Tracing in Tutor-Student Dialogues

Shuyan Huang, Alexander Scarlatos, Jaewook Lee and Andrew Lan

Measuring Optimal Challenge: Trajectory-Based Difficulty Alignment in Open-Ended Language Tutoring

Ziqi Shu, Shuman Wang and Michael Hardy

Findings of the BEA 2026 Shared Task on Vocabulary Difficulty Prediction for English Learners

Mariano Felice and Lucy Skidmore

Sakura at BEA 2026 Shared Task 1: What Makes Vocabulary Difficult?

Adam Nohejl, Xuanxin Wu, Yusuke Ide, Maria Riera Machin and Yi-Ning Chang

Report on the BEA 2026 Shared Task on Rubric-based Short Answer Scoring for German

Sebastian Gombert, Zhifan Sun, Fabian Zehner, Jannik Lossjew, Tobias Wyrwich, Berit Czinczel, David Bednorz, Sascha Bernholt, Knut Neumann, Ute Harms, Aiso Heinze and Hendrik Drachslar

10:30 - 11:00 *Coffee Break*

11:00 - 12:30 *Oral Session C*

EduMUSE: A Multimodal Educational Dataset with Automatically Extracted Instructional Context

Andreea Dutulescu, Stefan Ruseti, Mihai Dascalu and Danielle McNamara

Confirming Correct, Missing the Rest: LLM Tutoring Agents Struggle Where Feedback Matters Most

Tahreem Yasir, Wenbo Li, Sam Gilson, Sutapa Tithi, Xiaoyi Tian and Tiffany Barnes

Towards Just-in-Time Adaptive Feedback: Enhancing Student Learning via Knowledge-Grounded LLM

Younghun Lee, Amir Bralin, Nobel Sanjay Rebello and Dan Goldwasser

Saturday, July 4, 2026 (continued)

Evaluating LLM Workflows for Generating Clinical Communication Assessment Items: A Comparative Study with Subject-Matter Experts

Christopher Runyon, Peter Baldwin, Ian Micir, Kevin Frome, Stephanie Mann, Saed Rezayi, Keelan Evanini and Victoria Yaneva

Zero Shot Phonics: Evaluating Constraint-Adherent Phonics Story Generation in Large Language Models

Maria Monica Manlises and Ethel Ong

Evaluating Adaptive Personalization of Educational Readings with Simulated Learners

Ryan Woo, Anmol Rao, Aryan Keluskar and Yinong Chen

12:30 - 14:00 *Lunch Break / Birds of a Feather*

14:00 - 15:30 *Poster Session B*

Investigating Context-aware CTC for Pronunciation Assessment: Mitigating Peak Behavior and Context Independency Assumption

Jiun-Ting Li, Tien-Hong Lo, Bi-Cheng Yan, Shih-Hsuan Chiu, Fu-An Chao and Berlin Chen

A Survey of Automated Presentation Coaching: Systems, Methods, and Open Challenges

Wen Liang, Li Siyan, Zackary Rackauckas and Julia Hirschberg

Criterial Features in German: Towards Interpretable NLP in Readability Assessment

Denise Loefflad, Sofia Kathmann, Heiko Holz and Detmar Meurers

RABIT: Rationale-Based Distillation Towards Interpretable Automatic Speaking Assessment via a Small Language Model

Bi-Cheng Yan, Hong-Yun Lin, Fu-An Chao, Jiun-Ting Li and Berlin Chen

Challenges in Machine Translation of Interactive Multimodal Exercises

Lucie Polakova, Miroslav Hrabal, Věra Kloudová, Michal Novák, Mariia Anisimova and Martin Popel

Towards Self-Referential Analytic Assessment: A Profile-Based Approach to L2 Writing Evaluation with LLMs

Stefano Banno, Kate Knill and Mark Gales

Assessing the Quality and Consistency of Automated Knowledge Component Generation using Instructor-generated Questions and LLMs

Jordan Esiason, Priyanka Khare, Wookhee Min, Seung Lee, Gamze Ozogul, Xiaoying Zheng and Yeil Jeong

Saturday, July 4, 2026 (continued)

Intent vs. Surface: Recovering Acoustic Realization from Modern ASR for Pronunciation Training

Seongjin Park

Opportunities and Challenges of LLMs in Education: An NLP Perspective

Sowmya Vajjala, Bashar Alhafni, Stefano Banno, Kaushal Maurya and Ekaterina Kochmar

Quality-Conditioned Agreement in Automated Short Answer Scoring: Mid-Range Degradation and the Impact of Task-Specific Adaptation

Abigail Gurin Schleifer, Moriah Ariely, Beata Beigman Klebanov, Asaf Salman and Giora Alexandron

Using LLMs for item creation: Validating the potential of automatically generated sentence repetition test items for language assessment

Sarah Löber, Björn Rudzewitz, Yuan Chu, Mengyuan He, Shiqin Liu, Yushan Ye and Xiaobin Chen

FinnGEC: Benchmarking Grammatical Error Correction for Finnish

Anh-Duc Vu, Mikhail Zolotilin, Jue Hou, Anisia Katinskaia, Yiheng Wu and Roman Yangarber

From Metrics to Meaning: Rule-Grounded LLM Explanations for Data Literacy in the Case of Youth Football

Tomasz Piłka, Tomasz Kuczyński and Mateusz Czajka

Classification of Student Struggle in Mathematics

Hannah Levin, Madhura Padwal and Nchimunya Mwiinga

PERSA: Reinforcement Learning for Professor-Style Personalized Feedback with LLMs

Ravi Kumar, Utkarsh Grover, Xiaomin Lin and Agoritsa Polyzou

Data-lean fine-tuning of models for evaluating teacher performance in a GenAI-led elicitation simulation

Beata Beigman Klebanov, Andrew Hoang, Jamie Mikeska, Benny Longwill, Sanjna Kashyap, Shreyashi Halder and Aakanksha Bhatia

Noise Steering for Controlled Text Generation: Improving Diversity and Reading-Level Fidelity in Arabic Educational Story Generation

Haziq Khalid, Salsabeel Shapsough and Imran Zualkernan

PeerMathDial: A Middle School Dialogue Dataset for Student Collaborative Math Problem Solving

Murong Yue, Desmond Mcglone, Emily Slutz, Wenhan Lyu, Yixuan Zhang, Jennifer Suh and Ziyu Yao

Saturday, July 4, 2026 (continued)

Evaluating LLM-Generated Formative Feedback for Undergraduate Mathematics Through the Lens of Feedback Theory

Aron Gohr, Marie-Amelie Lawn, Kevin Gao, Inigo Serjeant and Stephen Heslip

Retrieval-Augmented Tutoring for Algorithm Tracing and Problem-Solving in AI Education

Mragisha Jain, Tirth Bhatt, Griffin Pitts, Aum Pandya, Peter Brusilovsky, Narges Norouzi, Arto Hellas, Juho Leinonen and Bitu Akram

Edit-level Majority Voting Mitigates Over-Correction in LLM-based Grammatical Error Correction

Takumi Goto, Yusuke Sakai and Taro Watanabe

Abstract

This tutorial examines the integration of Theory of Mind (ToM) into AI-driven tutoring systems, with a focus on how large language models (LLMs) can represent learners' cognitive and emotional states to enable adaptive, personalized feedback. Participants will learn foundational ToM concepts from cognitive science and psychology and how these ideas can be operationalized in AI systems. We discuss mutual ToM, in which both tutors and learners model each other's mental states, and address challenges including misconception detection, metacognitive modeling, and privacy in data-driven tutoring. The tutorial also includes hands-on demonstrations of machine ToM in programming education using benchmark datasets such as CS1QA and CodeQA. By combining theoretical foundations, empirical insights, and practical exercises, this tutorial will provide an overview of designing human-centered, ethically aware, and cognitively informed AI tutoring systems.

1 Introduction

This tutorial explores the intersection of Theory of Mind (ToM) and AI-driven tutoring systems, focusing on how LLMs can be used to model students' cognitive states. We position this tutorial within the *cutting-edge* category and present a comprehensive overview of *evolution of cognitive modeling* in AI-driven tutoring systems: from rule-based and single-agent systems to reinforcement learning approaches and multi-agent LLM frameworks. Participants will learn about recent advances in this field, along with key limitations including privacy, mutual ToM, and the handling of student misconceptions, as well as practical tools and resources for deploying ready-to-use models in real-world educational NLP applications.

2 Tutorial Outline

The tutorial will be organized into three parts, covering the fundamentals of ToM, reflection, and ToM in educational contexts.

2.1 Part 1: Background (35 min)

Introduction (10 min) We will start with the core principles of ToM from cognitive science and psychology, explaining how humans attribute beliefs, desires, intentions, and emotions to themselves and others (Yeung et al., 2024). We will then discuss the importance of ToM and how ToM can be operationalized in human-centered AI systems (Mutaliyevich et al., 2025) to enhance human-AI interaction (Wang et al., 2024). Finally, we will motivate the integration of ToM into online tutoring systems, highlighting its potential to improve learner engagement, personalization, and adaptive feedback.

Modeling Cognition in AI Tutor (10 min) We will provide an overview of AI tutoring systems and the role of cognitive state modeling in such systems. We will discuss adaptive tutoring systems (MacLellan et al., 2016; MacLellan et al., 2014), emphasizing methods for real-time assessment of student knowledge (Feng et al., 2009), engagement (Baker et al., 2008), and learning difficulties. The discussion will illustrate how AI can provide personalized hints, guidance, and feedback based on learners' cognitive states (Abdelshiheed et al., 2024). We will also examine the challenges in modeling complex learning behaviors (Gao et al., 2023, 2024; Farhana et al., 2022) to give participants a clear understanding of the current capabilities and limitations of existing AI tutoring platforms.

LLM Adaptation in AI Tutoring (15 min) We will focus on the adaptation of LLMs in educational contexts: examples from programming, mathematics, and other domains where LLMs are used to provide explanations, hints, and interactive feedback. Examples include automated scoring of

math questions using LLM (Morris et al., 2025), automated feedback generation in argumentative writing (Baffour and Crossley, 2024), personalized coach in online learning (Dass et al., 2025). The discussion will highlight the strengths of LLMs in generating contextually appropriate responses while also pointing out limitations in recognizing and responding to students’ cognitive states. This sets the stage for exploring research gaps and the integration of ToM with LLM-based systems.

2.2 Part 2: Reflections and Questions (25 min)

In the first **15 minutes**, we will examine the gaps in current LLM-based tutoring systems and opportunities for ToM integration. We will also focus on the limitations of evaluating and measuring ToM in LLM-based systems (Wang et al., 2025; Chen et al., 2025; Ma et al., 2023; Ullman, 2023). Participants will understand implications of this gap and the need for ToM-informed AI in education. We will conclude the session with a **10-minute** reflection and open discussion outlining future research directions for the BEA community to advance human-centered evaluation methods and educational applications.

2.3 Part 3: ToM in Education (120 min)

We will cover core ideas of the tutorial in four interconnected themes: mutual ToM, addressing misconceptions, privacy considerations, and Machine ToM in source code comprehension.

Mutual ToM in AI Tutoring (25 min) We will introduce **mutual ToM**, where both the AI tutor and the learner maintain models of each other’s cognitive states (Wang and Goel, 2024; Ashktorab et al., 2025). This reciprocity allows the system to anticipate learner needs while learners understand AI intentions, improving trust, engagement, and learning outcomes. The discussion will cover strategies for implementing mutual ToM in online platforms, including cognitive state modeling, adaptive feedback, and interactive scenarios. Participants will explore how mutual understanding can be operationalized to enhance adaptive learning.

Addressing Misconceptions (25 min) This section examines the identification and correction of learners’ misconceptions in AI tutors. We will highlight the importance of integrating ToM principles to ensure that AI tutors do not overgeneralize or misinterpret learner behaviors. Recent research identifies common misconceptions in computational ToM, including the belief that AI should imple-

ment ToM as a singular module, that all social interactions require advanced ToM reasoning, that ToM is uniform across individuals, and that current LLMs already possess genuine ToM (van der Meulen et al., 2025). In practice, these insights suggest that LLM-based tutors should selectively apply cognitive modeling, account for variations in learners’ backgrounds and knowledge states, and avoid assuming ToM competence based solely on benchmark performance. Participants will learn methods for combining LLM pattern recognition with explicit cognitive modeling to detect misconceptions, deliver targeted feedback, and support students accurate reasoning. The section also highlights how misconception-aware tutoring can enhance learner engagement and outcomes while remaining aligned with human-centered AI principles.

ToM and User Privacy (25 min) Privacy and ToM are deeply intertwined: deciding what to share, with whom, and in what context requires reasoning about others’ knowledge, expectations, and interpretation of information. Education is a key domain where this is especially relevant, as learner data is sensitive and shared across multiple stakeholders, though the issue extends beyond education. We organize this section around a progression that mirrors how the field has come to understand the problem: from *whether* models reason about contextual privacy at all, to *what* they should disclose, to *how* users experience disclosures and inferences made on their behalf (Borkar et al., 2025).

We begin with the contextual integrity framing (Miresghallah et al., 2024a,b), which defines privacy as appropriate information flow rather than secrecy of fixed attributes. ConfAIde (Miresghallah et al., 2024b) shows that even frontier LLMs leak information in contexts where humans would not, and interventions such as privacy-inducing prompts and chain-of-thought reasoning fail to close the gap. The failure is linked to ToM, as models struggle in tracking knowledge and reasoning mental states of parties involved in an information exchange.

We then turn to persistent memory, which is increasingly central to LLM-based assistants. CIMemories (Miresghallah et al., 2025) shows that contextual integrity violations compound as memory accumulates and models are deployed across multiple tasks, with GPT-5 violations increasing from 0.1% to 9.6% across tasks and up to 25.1% under repeated prompts. The diagnosed failure mode is a *granularity failure* in which models identify the right information *domain* but cannot

distinguish relevant details from unnecessary disclosures. This naturally raises the next question of what a model *should* disclose, leading to data minimization as an operational principle (Zhou et al., 2025). Recent work shows LLMs are systematically biased toward oversharing and struggle to identify the minimal information they actually need—a capability gap, not just a policy gap.

Finally, we consider the user perspective, focusing on how LLMs not only *disclose* but also *infer* sensitive attributes such as (emotional states, health conditions, life circumstances) from interaction patterns. Recent user-centered (Monteiro et al., 2026) shows that users are more concerned with misrepresentative or unexpectedly shared inferences than with inference itself, and they prefer granular control over how such inferences are generated, stored, and shared. We conclude with best practices for privacy- and ToM-aware systems, particularly in education, emphasizing transparency of inferred states, user control over memory and inference scope, contextual-integrity-aware data flows, and default minimization in prompts/persistent storage.

Q&A and Machine ToM in Source Code Comprehension (45 min) We will present a demonstration of **Machine ToM**, including ToM among AI agents (Zhou et al., 2024) applied to programming and code comprehension tasks (Nikiema et al., 2025). The system models a learner’s misunderstanding patterns and selectively intervenes with explanations, or scaffolding (Bućinca et al., 2025). Participants will see how teacher–student LLM architectures simulate human-like tutoring interactions, guiding learners toward better reasoning and problem-solving (Liang et al., 2025). The demo will include examples of adaptive interventions and strategies for evaluating their effectiveness.

3 Specification of the Tutorial

Expected Audience Background The audience is expected to have foundational knowledge of NLP, machine learning, and evaluation methods, including supervised learning, classification, and metrics such as accuracy, precision, and recall. Familiarity with HCI, LLMs, and AI ethics is encouraged for participation in Q&A and discussions. We expect about 70–100 participants, based on growing interest in ToM and attendance at a recent workshop on [generative AI and ToM at IJCAI 2025](#) organized by one of the organizers.

Preferred Venue We strongly prefer ACL 2026 to

be held in the U.S. due to visa re-entry uncertainties, as many visa holders—including organizers, favor a U.S. location to reduce travel risks and support broad participation.

Diversity Considerations and Others This tutorial emphasizes in its instructional team, participant access, and content. The instructional team represents multiple career stages, from Ph.D. students to assistant professors, across four institutions on two continents and interdisciplinary backgrounds. To support accessibility, virtual participation will be available via Zoom. Approximately 33% of the session is devoted to related work from the wider research community, as reflected in the schedule and materials. The tutorial requires a standard Python environment with PyTorch. All code, data, and experimental scripts are openly released to facilitate reproducibility <https://github.com/MahaZainab/tom-in-education>.

Reading List To deepen participants’ understanding of ToM, we recommend the references cited in this tutorial as well as the readings listed below.

4 Presenter Biographies

Effat Farhana is Assistant Professor in the Department of Computer Science and Software Engineering at Auburn University. Her work has pioneered designing cognitive theory-informed AI systems for personalized learning, designing interpretable ML algorithms, and behavioral data mining within education and autism research. In 2021, she was named a Rising Star in Data Science by the University of Chicago for her PhD research. Effat is also an active community builder, serving as co-chair of the AI in Education Track at EAAI/AAAI 2024 and 2025, leading the organization of Theory of Mind workshop at IJCAI 2025, and serving as a Research Fellow at the NSF AI Institute for Adult Learning and Online Education (ALOE).

Maha Zainab is a Graduate Research Assistant in the Computer Science and Software Engineering Department at Auburn University. She is also a Gavin Graduate Student Fellow. She has participated in multiple international coding competitions and has also won some of them. Her research is in Generative AI, especially LLM evaluation, theory of mind and multi-agent reasoning. Her work is published in an IEEE conference, and her current research focuses on the Theory of Mind in intelligent systems. She has also taught national and international audiences.

Qiaosi Wang (Chelsea) is a Carnegie Bosch Postdoctoral Fellow at Carnegie Mellon University. Her work has proposed and empirically examined the Mutual Theory of Mind interaction paradigm to facilitate communications between online learners and AI agents in various social roles (e.g., teaching assistant, social facilitator) in online education. She has frequently presented her work at AI workshops and led the organization of the Theory of Mind in Human-AI Interaction (ToMinHAI) workshop series at multiple HCI venues (e.g., CHI, CUI).

Nilofar Mireshghallah is a Research Scientist at Meta AI's FAIR Alignment group in San Francisco. Beginning Fall 2026, she will join Carnegie Mellon University's Engineering & Public Policy (EPP) Department and Language Technologies Institute

(LTI) as an Assistant Professor. She received her Ph.D. from the CSE department of UC San Diego in 2023. Her research interests are privacy, natural language processing, and the societal implications of ML. She is a recipient of the National Center for Women & IT (NCWIT) Collegiate award in 2020 for her work on privacy-preserving inference, a finalist of the Qualcomm Innovation Fellowship in 2021, and a recipient of the 2022 Rising Star in Adversarial ML award.

Ramira van der Meulen is a Ph.D. student at Leiden University's Institute of Advanced Computer Science. She studies decision-making in Human-Machine Collaboration, with a special interest in its communicative requirements. Her current work focuses on the moment of 'agreement' in scenarios with incomplete information, where humans and AI establish their 'common ground' through varying levels of communication. This work concerns with Theory of Mind: the ability to take the perspective of others' beliefs, intentions and knowledge, and the use of this perspective to make sense of their behaviour and attitudes towards the world.

Max Johannes van Duijn is an Assistant Professor at Leiden University's Institute of Advanced Computer Science (LIACS) and Principal Investigator of the Social Intelligence Modelling [SIM] lab. He is a lecturer in Leiden's Data Science and Artificial Intelligence (DSAI) and Creative Science and Technology (CrIT) education programmes. In 2023 he was elected a member of The Young Academy, where he co-heads the Science and Society track. He is the associate editor for Machine Behaviour and Cognition of *Behaviour*. Research in the SIM lab combines methods from cognitive science, linguistics, and AI to study social intelligence, in particular empathy, perspective-taking, and Theory of Mind. Their work includes modeling these capacities in humans as well as in AI systems such as LLMs. His work is published in English and Dutch, in scholarly as well as popular venues, and has regularly attracted media attention.

5 Ethics Statement

As our tutorial will focus on modeling student cognition and providing personalized feedback, we will address ethical best practices for data collection and algorithmic design. We will emphasize inclusivity and fairness by supporting diverse learners and mitigating biases, aiming to advance safe, transparent, human-centered AI in education.

Inferring Student Engagement via Real-Time Thermal–Visual Voice Activity Detection

Bradley A. Goodman^{1,2}

¹The MITRE Corporation, ²Brandeis University,

Abstract

We introduce a thermal–visual fusion approach to improve non-invasive Voice Activity Detection (VAD) for classroom engagement monitoring. In noisy multi-speaker classrooms using a single microphone, acoustic-only methods fail to reliably isolate individual speakers. Our method integrates facial thermal signatures—capturing respiratory and speech-related heat patterns—with visual lip-motion cues to provide an acoustic-independent speech signal. This provides a localized, privacy-preserving, and acoustic-independent indicator of speech activity.

This system acts as a visual-diarization front-end, informing Automatic Speech Recognition (ASR) and Natural Language Processing (NLP) systems not only when speech occurs, but precisely which student is speaking. Using up to 19 engineered features, our Thermal-Only Random Forest classifier achieved a Recall of 0.9234 and an F1-score of 0.8105 in subject-independent evaluations, outperforming visual-only baselines. The system was validated as a proof-of-concept on a Raspberry Pi 5 in a controlled laboratory setting, demonstrating real-time feasibility. These results demonstrate that thermal–visual fusion enables more reliable linguistic analysis of collaborative learning and provide critical input for AI agents to facilitate group participation in real-world educational settings that lead to more successful learning outcomes.

1 Introduction and Research Motivation

Voice Activity Detection (VAD) is fundamental to acoustic monitoring and classroom behavioral analysis. Existing solutions, outside of those focused

solely on audio, typically rely on visible-spectrum video and suffer from severe degradation in performance due to variability in lighting, occlusions, and person identity changes. The objective of this research was to investigate the efficacy of integrating facial thermal signature data—which captures the distinct heat patterns associated with respiration and articulation—to create a system that is robust and highly generalizable across different scenarios. Thermal cameras, once limited to industrial (Wilson et al., 2023) and medical (Ioannou et al. 2014; Manullang et al. 2021; Kwon et al. 2023) applications, have become increasingly viable for a wider range of uses due to recent reductions in both cost and size. The incorporation of Artificial Intelligence (AI) into classroom settings aims to promote effective peer learning by facilitating better team dynamics and ensuring equitable engagement among students. A critical component of this AI-Student teaming approach is the ability to accurately track active student engagement during collaborative tasks. Previous research into engagement detection in noisy classroom environments has faced significant challenges:

- **Acoustic Limitations:** Efforts relying on speech understanding and speaker identification were hindered by the use of a single microphone and the highly noisy nature of multiple peer groups working concurrently in a classroom. This resulted in relatively poor speech recognition with high Word Error Rates (WER) and an inability to reliably isolate the speaker (Cao et al. 2023; Wang et al. 2024). These acoustic failures often prevent NLP systems from performing accurate group dynamics analysis, knowledge-sharing tracking, or peer-learning modeling, as the input text is either missing or heavily corrupted.

- **Visual Limitations:** Multi-modal gesture recognition (e.g., pointing or looking at a peer) successfully determines engagement but fails to account for instances when a student is actively

speaking but not looking directly at another student or activity-related object (Palmer et al., 2025). Furthermore, attempts at purely visual lip-reading are highly restrictive, requiring the speaker’s mouth to be clearly aligned with the camera, which is often impractical in a dynamic classroom. Lip-reading can, however, potentially increase the accuracy of speech recognition (Yoshida et al. 2008; Guan et al. 2024; Guan et al. 2025). Given the inherent limitations of both purely acoustic and constrained visual methods, a more passive and robust detection mechanism is required to reliably determine who is speaking, regardless of noise or precise facial orientation.

2 Related Work

Foundations of Collaboration and Engagement:

Early efforts in modeling team dynamics by Goodman et al. (2006) established that individual and group user models could detect faltering collaboration. By utilizing indicators such as dialogue acts, backchannel utterances (e.g., "uh-huh"), and prosodic speech features, they demonstrated that machine learning (ML) can effectively predict listener engagement and shared focus in distributed environments. Similarly, Oztoprak (2022) confirmed that prosodic cues alone—specifically pitch and intensity—are significant predictors of emotional engagement in child-robot interactions, achieving 73.9% accuracy with artificial neural networks. D’Mello et al. (2012) developed a model to explain the dynamics of affective states during learning activities that included states of engagement. Their model establishes engagement as a dynamic, temporally evolving cognitive–affective process, motivating the need for sensing approaches that can capture rapid state transitions during authentic learning activities. While the early research focused on prosodic features and affective states (Cao et al., 2014), more recent work has explored automated scoring of collaborative classroom discussion (Tran et al., 2025).

Audio-Visual and Nonverbal Modalities:

Building on these theoretical foundations, subsequent work has operationalized engagement through observable behavioral and physiological signals such as facial expression, gaze, head motion, and speech. Bosch et al. (2016) showed that visible-spectrum video features, including facial expressions and head pose, can infer learner affect in classroom settings, while more recent multi-

modal approaches (e.g., Sharma et al., 2023) incorporate eye tracking and head movement to improve engagement detection. However, these methods remain sensitive to lighting conditions, occlusion, and expressive variability, limiting robustness in unconstrained educational environments. To address these limitations, researchers have explored multimodal architectures. Tao et al. (2021) proposed TalkNet, an active speaker detection framework that uses audio-visual cross-attention and long-term temporal features to align lip motion with speech, improving performance under overlapping speech and visual noise. It processes raw video instead of running in real time. To empirically assess TalkNet’s applicability as a baseline for thermal-domain VAD, we ran TalkNet on the same thermal false-color video used for real-time evaluation. TalkNet detected a stable face track across 3,218 frames (128.7 seconds), yet only 54 frames (1.7%) were classified as speaking, compared to 72% ground-truth speech in the same session. The audio-visual synchrony model relies on visible-spectrum lip texture to align mouth motion with audio; thermal false-color imagery suppresses this texture, rendering the model’s visual stream uninformative regardless of acoustic content. This confirms that RGB-trained audio-visual models do not transfer to thermal input without retraining, empirically motivating the purpose-built thermal feature pipeline described in Section 3. Abdrakhmanova et al. (2021) introduced the large SpeakingFaces dataset, combining thermal, visual, and audio recordings of voice commands across 142 subjects; however, its clips range from 2–7 seconds (50–175 frames at 28 fps), each beginning with a brief silence, which is insufficient to populate the 125-frame rolling window required for our spectral breathing features (*Breathing_Power_In_Band_RA*, *Breath_BRSI*) to stabilize — causing both features to evaluate to zero across the entire dataset and producing near-random classification when the trained model was applied to continuous thermal video. Palmer et al. (2025) further argue that speech recognition alone is insufficient in noisy classrooms and advocate integrating nonverbal cues such as gaze, posture, and gesture for context-aware modeling of group interaction and engagement.

Classroom Implementation and Constraints:

Translating these models to the classroom remains a primary challenge. Xu et al. (2023) successfully predicted tutoring engagement using a combination of face exposure and speech duration met-

rics. In more complex group settings, Wang et al. (2024) utilized Whisper ASR and SpeechBrain for speaker diarization, achieving a moderate correlation (≈ 0.62) with human annotations despite the high-noise classroom environment. Baker et al. (2014) examined cost-effective engagement detection.

Research Gap: While these studies leverage prosodic, acoustic, and visual cues, they remain susceptible to background noise, ambient lighting variability, and the physical occlusions or motion artifacts inherent in unconstrained settings. Our research addresses this gap by proposing a passive, multi-modal fusion of thermal and visual signatures, offering an acoustic-independent physiological signal for reliable VAD in real-time.

3 Research Hypothesis and Methodology

Our core hypothesis is that thermal imaging of the mouth and nasal regions can provide a novel, reliable, and passive method to determine speech activity by tracking the localized temperature changes caused by respiration. We further hypothesize that a fusion model integrating this thermal data with robust lip motion data will provide a superior capability to detect speech even when the speaker is not fully facing the camera (e.g., Bennett et al. (2020) showing side-view of respiratory plume using a thermal camera).

To test this hypothesis, we collected thermal videos of individuals engaging in both episodes of speaking and non-speaking in a laboratory setting. The thermal video set included single and multi-party participants (Figure 1). Using the trained Yolov8n face-detection model (Vemulapalli et al., 2023), we isolated the face, mouth and nasal regions in each thermal video frame to permit localized extraction of temperatures. This visual tracking data was combined with automatic audio annotation using a widely-used neural-acoustic VAD tool (Silero VAD (Silero, 2024)) to segment periods of active speech. From this multi-modal data stream, we developed a suite of metrics—including rolling thermal averages, derived thermal deltas, and continuous lip motion kinetics—which were then used to train and evaluate ML classifiers for speech prediction.

Our research focuses on one aspect of student engagement detection, episode-level speech detection, which can be fused with other forms of engagement such as gesture, pointing, gaze, and speech recog-

Figure 1: Single and multiple participant data collection.

nition.

3.1 Dataset and Preprocessing

The final dataset used for model development and evaluation included synchronized audio, thermal video, and their associated feature streams. The raw ground truth was generated using the open-source Silero Voice Activity Detector (VAD) that looked for speech activity versus background noise, labeling each frame with a binary Speech_Present flag (TRUE/FALSE) based on whether or not the probability of speaking exceeded a certain value. As the ground truth source, Silero VAD achieves perfect agreement with its own labels by definition; the thermal classifier’s performance reported in Section 4 therefore represents the degree to which thermal physiological signals can replicate an acoustic oracle operating under controlled laboratory conditions. A total of 40,855 frames (approximately 27.2 minutes at 25 FPS) were aggregated from twenty distinct recording sessions, encompassing both single- and multiple-subjects. The single-subject data (17 distinct recording sessions, $\approx 28,000$ frames) formed the foundation for our Generalization Test Set. For rigorous model evaluation, the entire dataset was partitioned using Leave-One-Experiment-Out (LOEO) cross-validation. This methodology ensured strictly subject- and experiment-independent testing by training the model on the data from 16 experiments and validating its performance on the single remaining, unseen experiment. Six model types were considered during LOEO: Fusion Random Forest (RF) (Liaw and Wiener, 2002), Visual-Only RF, Thermal-Only RF, Fusion Multi-Layer Perceptron (MLP) (Chan et al., 2023), Fusion Support Vector Machine (SVM) (Noble, 2006), and Histogram-based Gradient Boosting Classification (HGBC) (Guryanov, 2019).

Frame-level VAD is inherently susceptible to noise, resulting in intermittent suppression of Speech_Present flags during continuous speech segments due to brief drops in vocal energy dur-

ing breath inhalation or soft phoneme articulation. Rather than applying a rolling mean to the binary signal, we addressed this at the source by setting Silero VAD’s internal confidence threshold to 0.70, which suppresses low-confidence transient detections while preserving sustained speech intervals. Each detected speech interval was then extended forward by 0.3 seconds (1–2 frames at 5 fps) to capture residual thermal signal that persists briefly after speech cessation. To compensate for an initial estimate of the audio-thermal synchronization lag, labels were shifted 2 frames earlier prior to assignment; subsequent manual alignment revealed the true lag to be 12 frames, as discussed in Section 4.2. Finally, during training, segments shorter than 8 frames (1.6 seconds) were excluded to remove transition-zone frames where the lag correction is insufficient to guarantee correct labeling. Before this segment filter, approximately 77% of frames carried a TRUE label; after filtering, the proportion remained stable at 76–78% across sessions, confirming that the filter removed short segments of both classes proportionally rather than biasing the label distribution.

- **Thermal Data:** Extracted features from thermal camera at 25 frames per second (AMPBANK M256 thermal camera, 256x196 pixels, 56° x 42° Field of View) focused on the thermal gradient changes around the mouth-nasal regions, indicating exhalation and subtle muscle movements during speech and sent to a local Raspberry Pi 5 8GB.
- **Audio Data:** Audio from a single USB microphone.
- **Preprocessing:** All data streams were normalized and aligned temporally before being passed to the ML architecture. The YOLOv8 model (Vemulapalli et al., 2023) was used for face, nose, and mouth detection in each thermal video frame as the frames were assembled and aligned with the audio stream. Thermal data was extracted and stored into a CSV file.

3.2 Feature Engineering and Preprocessing

The raw thermal and visual data were rigorously preprocessed to derive the final feature set used in the analysis. Crucially, due to the high volatility of instantaneous thermal readings, we introduced Temporal Rolling Average (RA) features to capture the sustained thermal signature of speech activity. Table 1 lists the thermal and visual features collected and calculated. These features do not just detect activity; they provide the temporal ‘gating’

required to provide corroborating evidence of ASR events when a specific student is speaking, thereby reducing ‘hallucinations’ or noise-injection.

3.3 Model Architecture and Optimized Validation

We evaluated the fusion approach using a refined dataset of 17 single-speaker subject-sessions (28,000 frames) to establish a reliable generalization baseline. A rigorous Leave-One-Experiment-Out (LOEO) cross-validation was employed. After systematic hyperparameter tuning of candidate architectures—including Histogram-based Gradient Boosting Classification (HGBC) and Multi-Layer Perceptron (MLP)—the Random Forest (RF) classifier emerged as the optimal architecture. HGBC is a ML algorithm designed to train efficiently on large datasets. It speeds up the training process by grouping continuous feature values into discrete bins, which simplifies how decision trees determine split points (Guryanov, 2019). To maximize temporal stability, a 125-frame Rolling Average (RA) window was applied to the final 19-feature set, as a temporal sweep confirmed this window size provided the highest subject-independent generalization.

4 Results and Performance Analysis

The comparative classifier evaluation study (Table 2) confirms that thermal-only and thermal-visual fusion significantly outperform the visual-only baseline.

4.1 Discussion of Performance Metrics

The Thermal-Only RF (no *MAR_Variance*) achieved F1=0.8105 and Recall=0.9234 under rigorous LOEO cross-validation, confirming the system captures physiological markers of respiration and articulation rather than superficial environmental cues. The 11.64% F1 gain over the visual baseline (Visual-Only_RF) validates that thermal features provide non-redundant complementary information. While Precision (0.7308) indicates some false alarms from heavy-breathing artifacts, the high Recall confirms thermal signatures are the primary drivers for capturing continuous speech indicators. The Fusion_RF model ranked second, with *MAR_Variance* providing the greatest visual contribution.

Feature	Type	Signal captured	Speech vs. quiet
<i>Optimised temporal thermal cues (rolling averages)</i>			
Avg_Mouth_Temp_RA ₁₂₅	Thermal	Mean mouth temp, 125-frame rolling avg	Elevated during speech
Avg_Nostril_Temp_RA ₁₂₅	Thermal	Mean nostril temp, 125-frame rolling avg	Lower during speech
Center_Mouth_Temp_RA ₁₂₅	Thermal	Center-mouth temp, 125-frame rolling avg	Elevated during speech
<i>Engineered thermal contrast</i>			
Delta_AvgTemp_Mouth_Roll_Avg	Thermal	Rolling mean face—mouth temperature delta	Increases during speech
Breathing_Power_In_Band_RA	Spectral	Nostril spectral power, 0.1–0.5 Hz band	Lower during speech
Breath_BRSI	Spectral	Nostril rhythm stability (100-frame FFT)	Lower during speech
Delta_Mouth_Min	Thermal	Mean mouth temp minus min face temp	Higher during speech
Center_Mouth_Contrast	Thermal	Center-mouth / mean-mouth temperature	Higher during speech
Center_Mouth_Delta_Face	Thermal	Center-mouth minus mean face temperature	Higher during speech
<i>Instantaneous thermal components</i>			
Avg_Mouth_Temp_C	Thermal	Mean mouth ROI temperature (current frame)	Elevated during speech
Avg_Nostril_Temp_C	Thermal	Mean nostril ROI temperature	Lower during speech
Avg_Temp_C	Thermal	Mean temperature across full face ROI	Baseline reference
Center_Mouth_Temp_C	Thermal	Center-mouth temperature (current frame)	Elevated during speech
Min_Temp_C	Thermal	Minimum temperature across face ROI	Lower during speech
Nostril_Temp_Diff_Min	Thermal	Mean nostril temp minus min face temp	Higher during speech
Face_Temp_Spread	Thermal	Max—min temperature across face ROI	Higher during speech
Nostril_Temp_Max_Slope	Thermal	Max $ dT/dt $ nostril, 100-frame window	Lower during speech
Mouth_Temp_Max_Slope	Thermal	Max $ dT/dt $ mouth, 100-frame window	Higher at onset
<i>Visual mouth motion</i>			
MAR_Variance	Visual	Mouth aspect ratio variance, 25-frame	Higher during speech

Revised feature set: A subsequent 13-feature revision replaces the three RA₁₂₅ features and redundant instantaneous temperature columns with slope-based dynamics (*Airflow_Dominance*, *Slope_Coupling*, *Mouth_Slope_Accel*) and spectral coupling features (*NM_Xcorr*, *Mouth_Breath_BRSI*). A 12-feature thermal-only version drops *MAR_Variance*. Results using the revised set are reported in Table 2 and discussed in Section 4.3.

Table 1: Thermal and visual features used in the original 19-feature classifier. $S_m = \text{Max } |dT/dt|$ mouth, $S_n = \text{Max } |dT/dt|$ nostril: max temperature slopes in mouth and nostril ROIs. RA₁₂₅ denotes a 125-frame rolling average.

4.2 Feature Importance Analysis

For the original 19-feature model (Table 1), the Permutation Feature Importance rankings (Table 3) provide a clear "biological" map of how the model makes these decisions. Feature importance analysis substantiates the top thermal cues that drive the model’s predictive power. The top feature, *Center_Mouth_Delta_Face*, highlights that the temperature difference between the mouth and the rest of the face is the most critical indicator of speech. This is closely followed by *Breathing_Power_In_Band_RA* which is calculated over a continuous rolling window of 500-frame and then a 125-frame window for smoothing, which confirms that rhythmic respiratory signals captured by the thermal sensor are vital for distinguishing speech from silence. Notably, the many negative values at the bottom of the list (such as *Mouth_Temp_Max_Slope*) reveal multicollinearity: because many thermal features are highly correlated, the model sees them as redundant. These results suggest the model might be simplified by focusing only on the top 5–6 unique thermal and breathing markers without losing sig-

nificant performance. Correlation analysis reveals that the feature set naturally separates into 3 partially independent clusters corresponding to baseline facial thermal state, thermal gradients associated with respiratory airflow, and breathing rhythm and motion dynamics. This separation suggests that the classifier exploits complementary physiological signals rather than redundant measurements.

The visual cue, *MAR_Variance*, ranked first overall in a Permutation Importance Analysis of the Fusion RF Model (results not shown here). *MAR_Variance* captures continuous lip deformation changes rather than binary motion events. Together, the Permutation findings for the Thermal-Only RF and Fusion RF models demonstrate that both model’s performance gains arise from carefully engineered feature sets that utilize stable thermal physiology or refined visual motion descriptors, leveraging the strengths of both modalities.

Manual alignment of VAD labels against thermal frames revealed a systematic 12-frame lag (2.4 s at 5 fps) from Silero VAD onset latency combined with audio-thermal synchronization offset. Correcting this lag in a revised 12-feature thermal-only

Model	F1	Accuracy	Precision	Recall	Δ F1	Training Details
<i>Visual-Only_RF</i>	0.7260	0.6196	0.7413	0.7150	–	500 trees (tuned)
<i>Thermal-Only_RF</i> ^a	0.8105	0.7079	0.7308	0.9234	+11.64%	500 trees (tuned)
<i>Thermal-Only_RF(revised)</i> ^b	0.8300	0.7407	0.7830	0.8967	+14.33%	500 trees (tuned)
<i>Fusion_MLP</i>	0.6574	0.5878	0.7240	0.6286	–9.45%	layer_sizes=(100,50,25), max_iter=500

^a Silero VAD threshold=0.70, 0.3s hysteresis tail, 2-frame onset correction, 8-frame transition-boundary exclusion (76.2% TRUE frames). Without segment filter: F1=0.8133, Accuracy=0.7192, Precision=0.7734, Recall=0.8693.

^b Revised 12-feature thermal-only set, 18 sessions including one balanced session (37% speech); *NM_Xcorr* and *Mouth_Breath_BRSI* rise to top-2 permutation importance after 12-frame VAD lag correction (see Section 4.2); adding *MAR_Variance* gives the 13-feature Fusion RF variant (F1 = 0.8267).

Table 2: Model performance comparison.

model elevated *NM_Xcorr* (nostril–mouth temperature correlation, which decouples during speech as oral exhalation displaces nasal breathing) to rank 1 (+0.030) and *Mouth_Breath_BRSI* (oral breathing rhythm stability, disrupted by phonation) to rank 2 (+0.028), with 11 of 12 features positive; the sole exception, *Nostril_Temp_Max_Slope* (–0.005), is subsumed by *NM_Xcorr* and *Airflow_Dominance* which capture nostril-mouth dynamics more directly. Both features had shown negative importance in prior runs attributed to insufficient quiet data; the lag correction reveals systematic label misalignment as the true cause, validating thermal channel decoupling as the dominant physiological marker of speech. Revised results are shown in Table 2 and discussed in Section 4.3.

4.3 Future Work and Generalization

Iterative Feature Refinement. Correlation analysis of the original 19-feature set (Table 1) revealed substantial redundancy among the three 125-frame rolling average temperature features and the instantaneous temperature columns from which they are derived, as these cluster into a single highly-correlated group encoding overall facial thermal state rather than speech-specific dynamics. A revised 12-feature thermal-only set replaces these redundant columns with slope-based dynamics (*Airflow_Dominance*, *Slope_Coupling*, *Mouth_Slope_Accel*) and spectral coupling features (*NM_Xcorr*, *Mouth_Breath_BRSI*) that more directly characterize the physiological contrast between oral speech exhalation and quiet nasal breathing. Evaluated on 18 sessions—including one session with extended alternating quiet and speech periods (37% speech, compared to a mean of 77% across the original 17 sessions)—and with

an 8-frame minimum segment filter and 12-frame VAD label correction applied at training time, the revised Thermal-Only RF achieved F1 = 0.8300, Accuracy = 0.7407, Precision = 0.7830, and Recall = 0.8967 (Table 2). The 12-frame offset (2.4 s at 5 fps) reflects the combined effect of Silero VAD’s onset latency and audio-thermal synchronisation delay, as identified through manual annotation alignment and discussed in Section 4.2. Transitioning this approach into a high-confidence classroom solution requires refinement in three key areas.

4.3.1 Feature and Tracking Robustness

The success of the temperature differences and rhythmic respiratory signals confirms that temporal context is paramount. Future iterations will explore advanced time-series features to better characterize the frequency of speech expulsion. Furthermore, replacing the current 5-point YOLOv8n landmarks with high-density facial models (e.g., 68-point landmarks) could increase the predictive weight of visual features like *MAR_Variance*. Finally, to handle multi-student interactions, we intend to replace our basic tracker with Deep SORT (Wojke et al., 2017) to maintain subject identity across thermal transients and occlusions. An initial effort with Deep SORT maintains identity through head turns via joint appearance embedding and Kalman-filter position prediction, holding tracks alive across brief occlusions rather than creating new identifiers when a face temporarily exits the detector.

4.3.2 Dataset Expansion and Kinematics

By expanding the dataset to include longer data collection sessions, a broader population, and collecting data across various speech styles and ambi-

Rank	Feature	Avg.	Rank	Feature	Avg.
1	<i>Center_Mouth_Delta_Face</i>	0.0031	10	<i>Center_Mouth_Temp_C</i>	-0.0014
2	<i>Breathing_Power_In_Band_RA</i>	0.0030	11	<i>Delta_AvgTemp_Mouth_Roll_Avg</i>	-0.0024

7	<i>Center_Mouth_Contrast</i>	-0.0006	16	<i>Avg_Nostril_Temp_125Frame_RA</i>	-0.0041
8	<i>Nostril_Temp_Max_Slope</i>	-0.0011	17	<i>Avg_Mouth_Temp_C_125Frame_RA</i>	-0.0053
9	<i>Face_Temp_Spread</i>	-0.0012	18	<i>Mouth_Temp_Max_Slope</i>	-0.0067

Table 3: Permutation feature importance analysis (Thermal RF model). *MAR_Variance* (visual) excluded from Thermal-Only RF; 18 remaining features shown.

ent temperatures, the model will be forced to learn the universal physical principles of speech kinematics and thermal signatures. This is essential for achieving a high-confidence, deployable solution that generalizes across multiple individuals and conditions.

4.3.3 Integrated Multimodal Framework for Classroom Dynamics

Our long-term goal is to transition from a supplementary thermal VAD to a fully integrated framework for analyzing peer-learning dynamics such as Palmer et al. (2025). Thermal signatures will be fused with gaze, posture, and gesture recognition (VanderHoeven et al., 2023) to triangulate referential intent, and coupled with lip-reading (Guan et al., 2025) and diarization (Wang et al., 2025) to improve acoustic resilience in high-noise classrooms. This combined approach should achieve better results at speech and engagement detection.

5 Towards a Real-Time Implementation and Deployment – Engagement Detection System

5.1 Edge-Computing Architecture

The objective of this real-time system is to assess whether a thermal-visual VAD can reliably identify one form of student engagement, defined here as the presence of speaking activity overlapping with true speaking episodes. The system is not intended to perform precise speech segmentation; instead, it aims to robustly detect whether a student speaks during an interaction which can indicate active engagement in a peer-learning activity. The evaluation of the system focuses on episode-level detection and engagement-oriented metrics rather than frame-level accuracy that was pursued during classifier training.

To evaluate the practical utility of the thermal-

visual fusion model, we developed a custom Python runtime on a local and cost-effective Raspberry Pi 5. The system utilizes an AMPBANK M256 thermal camera. Facial landmarks are isolated using a YuNet/YOLOv8-face algorithm, while thermal statistics from the mouth and nasal regions are extracted and summarized over the 125-frame rolling window.

5.2 Adaptive Calibration and Hysteresis

To improve classification robustness across individuals and recording environments—and to account for deployment conditions that may differ from those encountered during classifier training—we introduced a silent buffering period followed by an interactive calibration phase at the beginning of each session. The buffering period, during which participants remained silent, lasted 20 or more seconds (depending on the frame rate achieved by the Raspberry Pi 5 processor) and served to stabilize the thermal camera and determine participants’ breathing rates while allowing participants to acclimate to the data collection environment. During the subsequent calibration phase, participants first remained silent for 5 seconds and then spoke continuously for 5 seconds. Median classifier prediction probabilities from these two segments were used to compute an adaptive decision threshold T_{base} .

This buffering and adaptive calibration strategy successfully stabilized speaking-state detection for a single speaker across short (one to three minute) test sessions under varying ambient conditions. However, thermal speech detection remains sensitive to head and upper-body motion: movement can displace the air surrounding the face, mouth, and nostrils, causing thermal signatures to lag behind physical landmarks and resulting in transient temperature artifacts. Such effects can lead to false-positive speech detections.

To address this, the speech detection pipeline fol-

lows a staged decision process designed to enforce temporal stability under noisy thermal conditions. First, the Random Forest classifier produces a raw frame-level speech probability. This signal is temporally smoothed using a rolling median filter to suppress short-lived fluctuations. Next, a motion-gating mechanism (Meyers et al., 2022) computes the Euclidean distance between the tracked face bounding box centers in consecutive frames. If the displacement exceeds a predefined threshold, a Motion Lock is triggered, and the current thermal contribution is suppressed by substituting a neutral probability value. This prevents thermal transients caused by head movement from influencing the speech decision.

The stabilized probability is then passed through a hysteresis-based state machine, a standard control strategy for preventing rapid state oscillations (Meister et al., 2015), with separate entry and exit thresholds derived from T_{base} . This mechanism prevents rapid state oscillations near the decision boundary—analogueous to thermostat control—by requiring stronger evidence to enter the speaking state than to remain in it.

5.3 Engagement Confidence Index

Because the objective of the classroom system is to identify active peer interaction rather than precise speech segmentation, we developed the Engagement Confidence Index (ECI). ECI is a composite score that estimates the likelihood and strength of a user’s future engagement based on observed behavioral signals and interaction patterns. This metric prioritizes episode-level detection over frame-level accuracy. ECI and a subset of related metrics we used are defined in Table 4.

5.4 Runtime Results and Discussion

Only a small initial test has been conducted using three different subjects and five thermal video sessions. Figure 2 shows probability trajectories and adaptive decision boundaries during runtime for a single subject. For the evaluated session, Engagement Recall was 0.620, Engagement Precision was 0.795, temporal stability score was 0.826, Episode Recall was 0.400, and ECI was 0.551. The gap between frame-level Recall (0.923 under LOEO cross-validation; 0.788 in the Figure 2 runtime session) and Episode Recall (0.400) reflects that short episodes fall below the temporal smoothing threshold or are interrupted by Motion Lock; the conservative calibration strategy favors precision over

Metric	Definition
Engagement Confidence Index (ECI)	Multi-objective engagement score over a temporal window; clamped to $[0, 1]$ with weights $w_1 = 0.5, w_2 = 0.3, w_3 = 0.2$: $\text{clamp} \left(\frac{w_1 R_{\text{ep}} + w_2 C_{\text{speech}}}{+ w_3 S_{\text{temp}}}, 0, 1 \right)$
Episode Recall (R_{ep})	Fraction of GT speech episodes matched by a predicted ENGAGED episode (IoU ≥ 0.5 , one-to-one, ± 1 frame tolerance): $R_{\text{ep}} = N_{\text{matched}} / N_{\text{GT}}$
Coverage (C_{speech})	Temporal overlap between predicted engagement and GT speech: $\sum_i (\text{Engaged}_i \cdot \text{GT}_i) / \sum_i \text{GT}_i$
Temporal Stability (S_{temp})	Penalty for rapid state flicker where $F = \text{Transitions} / \text{Duration}_{\text{sec}}$ $e^{-0.5F}$

Table 4: Engagement Confidence Index (ECI) and component metrics.

episode-onset sensitivity. These results suggest the acoustic-independent thermal stream, stabilized by temporal smoothing, provides a useful engagement signal in real time.

The Episode Recall of 0.400 warrants interpretation in the context of the deployment pipeline. A speech episode is counted as detected only if a predicted ENGAGED interval overlaps the ground-truth episode by at least 50% (IoU ≥ 0.5 , where IoU is the ratio of the temporal intersection to the union of predicted and ground-truth episode boundaries). Three pipeline stages each independently reduce the probability of achieving this threshold. First, the 125-frame rolling window introduces an onset delay before features stabilize at the start of a new speaking episode, causing the classifier to respond slowly at speech boundaries. Second, the Motion Lock mechanism suppresses thermal contributions during head movement, which frequently co-occurs with speech onset as a speaker turns to address a peer. Third, the conservative hysteresis entry threshold—set to favor precision over recall to minimize false-positive alerts to the AI agent—requires sustained evidence before transitioning to the ENGAGED state, penalizing short episodes. Together these stages create a system that detects the interior of long speaking episodes reliably (reflected in the 0.923 frame-level Recall) while frequently missing the onset of short or movement-accompanied episodes (reflected in the 0.400 Episode Recall). For the classroom engagement use case this tradeoff is acceptable: the system is designed to confirm sustained engagement rather than react to every utterance, and false-

Figure 2: Real-time speech probability trajectories for a single subject. Gray: raw RF output; green: 5-frame smoothed probability; black dashed: calibrated threshold T_{base} ; red/blue dotted: hysteresis ON/OFF boundaries; light blue shading: predicted speaking intervals. Ground truth shown below (black = speaking, white = quiet).

positive interventions by an AI agent are more disruptive than missed short episodes.

Figure 3 summarizes the overall system architecture, highlighting the interaction between offline model training and the real-time inference pipeline incorporating buffering, adaptive calibration, motion gating, and hysteresis.

6 Conclusion and Future Impact

This research moves towards a high-confidence, acoustic-independent solution for detecting student speech in noisy, multi-peer environments. By successfully validating the fusion concept on a Raspberry Pi 5, we demonstrate the feasibility of an edge-computing architecture for classroom deployment. Future work will transition this proof-of-concept into a split-computing framework where the Raspberry Pi performs real-time feature extraction while a remote pipeline (Zhu et al., 2026) on an HPC platform fuses multi-modal components—gaze, posture, gesture, speaker diarization, and spoken language understanding—to build educational applications. The future work will integrate the thermal-visual front-end with large language models (LLMs) to provide real-time feedback on group dynamics, enabling AI agents to facilitate more equitable and linguistically-rich peer learning interactions.

Limitations

The current focus of this research was modeling each person’s thermal properties in a classroom peer group to determine whether or not someone was speaking and whether or not they were engaged in the learning activity. Some limitations exist in the current implementation:

- Thermal camera resolution and field-of-view become an issue as the scene includes more people. The ROIs will cover fewer pixels which reduces the quality of thermal data. We must explore how this affects our models if we are to continue to utilize inexpensive thermal cameras.
- A simplistic face tracker was employed but it was not effective in continuously distinguishing each person as the same person especially when one turned his or her head quickly or moved. For that reason, the current research results focused on one person to better model thermal characteristics of speaking or not speaking. Future work must examine multiple participants in a scene since that is what one expects in a classroom peer-learning event. Better face tracker algorithms, such as Deep SORT, are available. We are currently modifying a version of Deep SORT to handle not only multiple participants but to avoid confusion when someone turns their head or looks away, thinking they are now someone else. We have plans to collect multiple participant data once it is working.
- Our real-time component requires per-person calibration at the beginning of a session. This is time-consuming and provides a poor user-experience but necessary given different ambient conditions. A more user-friendly approach is needed.
- The current training data was collected in a laboratory and not in a classroom where different room temperature characteristics and ventilation conditions could be expected (e.g., fans running in the classroom blowing air towards the peer group). A broader and much larger dataset, with more participants and varied collection environments, is necessary for full validation of our approach. We have plans to collect such data.
- The data collected for training was only from adults and not the targeted middle school students due to privacy concerns yet

school-age children’s thermal properties are likely to differ from those of adults. The face/mouth/nostril region detection was computed on individually-stored thermal video frames in a separate detection phase after the data collection phase to preserve the 25 fps thermal camera capture rate. The addition of a Raspberry Pi AI module could increase the frame rate substantially for real-time detection so that no potentially personally-identifiable information (namely the thermal video frames of a student) would need to be retained. Instead, only the thermal temperature data and the coordinates of the face/mouth/nostril regions would need to be stored for use in calculating the features used for training the classifier. Similarly, the real-time thermal VAD/engagement system could perform all calculations without retaining the thermal video frames. We are testing the Raspberry Pi AI module and have had great results for face/mouth/nostril detection achieving 25 fps. However, the AI module does not speed up the trained classifier limiting the system to 5 fps.

- Currently, we have only employed our Visual-Only_RF model as a baseline but recognize another baseline could provide valuable insight. We tested TalkNet as a baseline and found it does not run in real-time and cannot detect facial regions in thermal false-color imagery, as the audio-visual synchrony model relies on visible-spectrum lip texture absent in thermal imaging. Future work will add a parallel RGB camera to enable a proper audio-visual comparison on aligned video footage to provide another baseline.
- We currently only explore a laboratory setup as proof-of-concept. We will perform additional validation in more realistic settings once the full iSAT pipeline is tested.

Acknowledgments

I would like to acknowledge the Brandeis iSAT team for helpful comments on my draft. A Appendix

A.1 Updated Tables and Figure for Revised Feature Set

Table 5 shows permutation feature importance for the revised 12-feature model after 12-frame VAD label correction; *NM_Xcorr* (+0.030) and *Mouth_Breath_BRSI* (+0.028) rise to rank 1–2, with 11 of 12 features positive, validating thermal channel decoupling as the dominant physiological marker of speech. Table 6 defines this revised 12-feature thermal-only set, replacing the original 125-frame rolling averages and redundant instantaneous temperature columns with slope-based dynamics and spectral coupling features. Figure 4 shows one sample result applying the revised 12-feature model to detect speech and quiet segments in real time. A per-session logistic recalibration layer, fitted on a short calibration sequence and applied with baseline correction for slow-responding breathing features, compensates for inter-subject variability in the RF classifier and achieves an ECI of 0.724 with mean speech-offset detection latency of 3.4 seconds on this example session. Much more testing will be required to determine if this holds up in practice with different subjects and ambient conditions.

Feature	Importance	Rank
<i>NM_Xcorr</i>	+0.0304	1
<i>Mouth_Breath_BRSI</i>	+0.0281	2
<i>Breath_BRSI</i>	+0.0096	3
<i>Center_Mouth_Contrast</i>	+0.0058	4
<i>Mouth_to_Face_Delta</i>	+0.0044	5
<i>Nostril_to_Face_Delta</i>	+0.0031	6
<i>Mouth_Slope_Accel</i>	+0.0010	7
<i>Slope_Coupling</i>	+0.0010	8
<i>Mouth_Temp_Max_Slope</i>	+0.0006	9
<i>Airflow_Dominance</i>	+0.0004	10
<i>Face_Temp_Spread</i>	+0.0002	11
<i>Nostril_Temp_Max_Slope</i>	−0.0048	12

Table 5: Permutation feature importance for the revised 12-feature Thermal-Only RF model (18 LOEO folds, 12-frame VAD label correction applied). Importance is mean F1 decrease when feature is permuted. Compare with Table 3 (original 19-feature model).

Feature	Type	Signal captured	Speech vs. quiet
<i>Thermal airflow gradients</i>			
<i>Mouth_to_Face_Delta</i>	Thermal	Z-scored mouth temp minus mean face temp	Higher during speech
<i>Nostril_to_Face_Delta</i>	Thermal	Z-scored nostril temp minus mean face temp	Lower during speech
<i>Face_Temp_Spread</i>	Thermal	Max–min temperature across face ROI (°C)	Higher during speech
<i>Center_Mouth_Contrast</i>	Thermal	Center-mouth / mean-mouth temperature ratio	Higher during speech
<i>Airflow velocity dynamics</i>			
<i>Mouth_Temp_Max_Slope</i>	Thermal	Max $ dT/dt $ mouth ROI, 100-frame window	Higher at speech onset
<i>Nostril_Temp_Max_Slope</i>	Thermal	Max $ dT/dt $ nostril ROI, 100-frame window	Lower during speech
<i>Airflow_Dominance</i>	Thermal	$ S_m / (S_m + S_n + \varepsilon)$	Approaches 1 in speech
<i>Slope_Coupling</i>	Thermal	$\min(S_m , S_n) / (\max(S_m , S_n) + \varepsilon)$	Low during speech
<i>Mouth_Slope_Accel</i>	Thermal	Second derivative of mouth temperature	Peaks at onset/offset
<i>Breathing rhythm and spectral coupling</i>			
<i>Breath_BRSI</i>	Spectral	Nostril rhythm stability index (100-frame FFT)	Lower during speech
<i>Mouth_Breath_BRSI</i>	Spectral	Mouth rhythm stability index (100-frame FFT)	Lower during speech
<i>NM_Xcorr</i>	Spectral	Nostril–mouth temperature Pearson correlation	Decouples during speech

Table 6: Revised 12-feature thermal-only set used in the updated classifier. S_m, S_n : maximum temperature slopes in mouth and nostril ROIs; ε : stability constant. Z-scoring of the 2 delta features (normalized by a per-session mean and standard deviation, then clipped to ± 3) helps handle session-to-session room temperature variation. Other features like *Face_Temp_Spread* and the slope features might also benefit from z-scoring. *MAR_Variance* (visual) is excluded from the Thermal-Only RF but included in the Fusion RF variant (13 features, F1 = 0.8267).

Figure 4: Real-time speech probability trajectories for a single subject using 12-feature thermal-only model. ECI=0.724; Episode Recall=1.0; Frame Precision=0.698; Frame Recall=0.886. Gray: raw RF probability output; green: 5-frame smoothed probability; black dashed: calibrated threshold T_{base} ; red/blue dotted: hysteresis ON/OFF boundaries; light blue shading: predicted speaking intervals. Abstract

Automatic pronunciation assessment (APA) provides L2 learners with scalable and timely feedback on pronunciation proficiency in a target language, typically through goodness of pronunciation (GOP) features. GOP quantifies how well a pronounced phoneme matches the expected target sound by comparing acoustic features against the model's posterior probabilities. Traditional GOP relies on forced alignment to obtain these posteriors, but it suffers from acoustic-induced misalignments that degrade assessment reliability. Although the standard CTC-GOP approach bypasses forced alignment, it is limited by the inherent peaky behavior of CTC-based ASR models, which produces sparse posteriors and lacks stable temporal information. To address these issues in standard CTC, we propose a context-aware CTC framework incorporating output context dependency (OCD) in the CTC topology, along with label prior (LP) and maximum conditional entropy (EnCTC) regularization, to mitigate peakiness and produce more stable ASR logits suitable for GOP computation. Experiments on the speechocean762 corpus demonstrate that our best context-aware configurations achieve superior phoneme-level performance, outperforming the TDNN-F baseline and standard CTC in unified GOPT (phoneme PCC 0.641 vs. 0.612; word total PCC 0.582 vs. 0.549) while narrowing the gap in hierarchical HierCB scoring. These improvements widen the scoring margin between correct and mispronounced phonemes from 0.708 to 0.816 in GOPT. They also reveal that mitigating CTC peakiness and incorporating context dependency significantly enhance CTC-GOP stability and robustness, especially for alignment-free APA models.

1 Introduction

Goodness of pronunciation (GOP) (Witt and Young, 2000; Hu et al., 2015) aims to evaluate whether pronunciation is in the correct way (mispronunciation detection and diagnosis, MDD) (Parikh et al.,

2025) and assess their pronunciation proficiency (automatic pronunciation assessment, APA) (Zhang et al., 2021; Chao et al., 2022; Gong et al., 2022; Do et al., 2023; Pei et al., 2024; Yan et al., 2024, 2025). The conventional GOP uses the hidden Markov model, operating force alignment to retrieve the time mapping with logits and the given phoneme sequence, then computing the similarity with aligned phonemes and logits (Zhang et al., 2021). The GOP score and feature have been widely adopted in MDD and APA tasks.

Despite the success, the conventional GOP has a major drawback. It depends on accurate audio-text alignments. Any misalignment degrades assessment quality. To solve this issue, an alignment-free method, named CTC-GOP (Cao et al., 2024), was proposed. CTC-GOP is based on connectionist temporal classification (CTC) (Graves et al., 2006)-based automatic speech recognition (ASR) models, utilizing path-wise decoding results to compute GOP scores and features. It does not need the force alignment procedure, avoiding the misalignment issues.

However, despite its significant contributions, CTC-GOP is not without its limitations. While traditional DNN-HMM systems are precise in timing but often too rigid to accommodate the disfluencies of L2 speech. In contrast, standard CTC is highly flexible but suffers from inherent peaky behavior, where the model strongly prioritizes what was said over when it occurred. Since accurate temporal information is essential for APA tasks, this remains a critical drawback. In detail, the CTC topology introduces a special blank token to act as a symbol boundary. During training, the ASR model over-identifies blank tokens, reinforcing this tendency until most frames are classified as "blank" token (Zeyer et al., 2021). Consequently, the probability distributions of non-peaky frames are underestimated, with optimal phoneme distributions restricted to only a few sharp spikes, making it

difficult to handle pronunciation uncertainty in ambiguous pronunciation. While this peaky behavior and the resulting ambiguity in word boundaries do not hinder general ASR tasks, this lack of temporal density degrades the efficacy of CTC-GOP, which relies on stable frame-level posteriors.

Inspired by content-aware GOP (Shi et al., 2020), we explore two methods to alleviate peakiness and improve the accuracy of token onset and offset predictions: (1) a label prior (LP) to the CTC loss to penalize blank-heavy paths (Huang et al., 2024), and (2) maximum conditional entropy-based regularization for CTC (EnCTC), which can be conducted without frame-level supervision due to the lack of labels for phoneme boundaries (Chen et al., 2023). These adjustments aim to produce more informative, less peaky posteriors suitable for phonetic modeling. Furthermore, CTC primarily stems from the core assumptions of context independence. Although modern end-to-end (E2E) architectures, such as TDNN-F (Peddinti et al., 2015; Povey et al., 2018) and attention-based models (Baevski et al., 2020; Hsu et al., 2021), incorporate input context dependency (ICD) through contextualized representations, the standard CTC topology remains constrained by a strong conditional independence assumption. In natural speech, continuous phonemes exhibit significant coarticulation, suggesting that modeling dependencies between preceding and succeeding units may be superior to the standard independence model. To address this, we use context dependency (CD) symbols in CTC topology (Chorowski et al., 2019), referred to as output context dependency (OCD), to investigate the implications of the OCD impact on APA.

After these attempts to fix CTC, we utilize the resulting ASR models to compute CTC-GOP features for two distinct scoring architectures: the unified GOPT (Gong et al., 2022) and the hierarchical HierCB (Yan et al., 2025). Because GOPT maps phoneme-level CTC-GOP features directly to scores, serving as an alignment-free APA model. In contrast, HierCB incorporates additional inputs that require explicit time alignment (TA) information, such as phoneme-level acoustic embeddings and duration features, serving as an alignment-dependent APA model.

To sum up our contributions: (1) We develop a context-dependent CTC framework that incorporates OCD and regularization techniques to mitigate the inherent peaky behavior of standard CTC. (2) We systematically analyze how architectural

choices, such as OCD, label priors, and stress markers, impact time alignment (TA) accuracy across multiple speech corpora. (3) We evaluate these improvements across both unigram and hierarchical APA architectures, demonstrating that mitigating CD is a factor for achieving trustworthy scoring results in alignment-dependent assessment models.

2 Methodology

2.1 CTC training with LP

ASR task aims to predict the most probable token sequence $\hat{Y}$. Given a speech feature matrix X , whether it can be raw speech or a sequence of feature vectors, is conveyed to an audio encoder. It processes X into a sequence of contextualized hidden features. Subsequently, it can be applied to MLP (Popescu et al., 2009), or CD embedding layers (Chorowski et al., 2019), then culminating in a softmax activation function. This process yields the probability distribution over each token in $\hat{Y}$. CTC models the posterior probability $P(Y|X)$ by marginalizing all possible alignments $\mathcal{B}^{-1}(Y)$ between X and Y with the conditional independence assumption.

$$P(Y|X) = \sum_{\pi \in \mathcal{B}^{-1}(Y)} \prod_{t=1}^T p_t(\pi_t|X), \quad (1)$$

where $\mathcal{B}(\pi)$ collapses an alignment sequence π , merging repeated neighbouring tokens and then removing any blank labels. $p_t(\pi_t|X)$ is the posterior probability of token at time t .

To reduce the number of blanks in the optimal alignment paths, we can apply unigram LPs on each token in π to penalise paths containing too many blank symbols.

$$P^{LP}(Y|X) = \sum_{\pi \in \mathcal{B}^{-1}(Y)} \prod_{t=1}^T \frac{p_t(\pi_t|X)}{P(\pi_t)^a}, \quad (2)$$

where the hyper-parameter $a \in \mathbb{R}$ is a scalar. When $a = 0$, this is exactly the standard CTC loss. If π has more blank tokens, it will have a larger prior $P(\pi_t)$, in other words, get a larger penalty in its posterior probability, so $\mathcal{B}^{-1}(Y)$, including the optimal one, will avoid blank tokens. Notably, the LPs are applied during training. And if using LP while training, there is no further need to apply LPs while decoding.

2.2 EnCTC

While LP ensures the ASR model is fair to rare symbols, EnCTC ensures the ASR model is cautious and doesn't overfit to its own predictions. We utilize EnCTC to prevent the ASR model from converging prematurely to a single, overconfident alignment path. This is achieved by adding a maximum conditional entropy term to the standard CTC objective:

$$\mathcal{L}_{\text{EnCTC}} = \mathcal{L}_{\text{CTC}} - bH(\pi|Y, X), \quad (3)$$

where b regulates the intensity of the regularization. The entropy $H(\cdot)$ measures the uncertainty across all feasible alignment paths. By maximizing this entropy, the ASR model is encouraged to distribute probability mass across multiple nearby paths, leading to less peaky posteriors and more informative frame-level distributions for GOP computation.

2.3 DWFST implementation for standardized CTC

To benefit from HMM's highly accurate time alignment (TA), and simultaneously imitate the CTC, which can be considered to have a one-state-HMM topology with a single self-loop. In literature, it can easily be done by defining a topology (Zhao and Bell, 2024), integrated into an E2E ASR framework with a differentiable weighted finite state transducer (DWFST) (Hannun et al., 2020). The posterior $P(Y|X)$ can be rewritten as

$$P(Y|X) = \sum_{\pi \in \Pi(Y; \mathbf{T} \circ \mathbf{L})} p(\pi|X), \quad (4)$$

where $\mathbf{T}$ and $\mathbf{L}$ denote the topology and the lexicon finite-state transducer (FST), and $\Pi(Y; \mathbf{T} \circ \mathbf{L})$ represents the set of all the token sequences, whose corresponding output sequence is Y , in the composed FST, $\mathbf{T} \circ \mathbf{L}$.

To compute the score of each probable π , we first need to intersect the decoding graph, which is $\mathbf{T} \circ (\mathbf{L} \circ \mathbf{G})$, where $\mathbf{G}$ is the target word sequence, with the emission FST constructed $\mathbf{E}$ from the ASR model's logit outputs, which is like

$$\sum_{\pi \in \Pi(Y; \mathbf{T} \circ \mathbf{L})} p(\pi|X) = \text{TotalScore}(\mathbf{E} \circ (\mathbf{T} \circ (\mathbf{L} \circ \mathbf{G}))). \quad (5)$$

2.4 Decoding with alignment graph built without lexicon

The Viterbi decoding does not guarantee the alignment output to be identical to the canonical phone sequence, even if the same word sequence is output. To solve this problem, we follow the idea in Zhang et al. (2021) to build the lexicon-to-grammar FST directly using the provided canonical phone sequence. We first create a linear FST in which input labels are the canonical phone sequences, and the output labels are the corresponding words and epsilons. The disambiguation symbol is added at the tail of LG to ensure the determinization of FST.

2.5 CTC training with context-dependent symbols

To address the limitations of context-independent targets, we transition from monophone to diphone units by following the idea in Chorowski et al. (2019). For a target sequence such as $[q, v, v]$, the corresponding extended transcript is mapped to $[\emptyset q, qv, vv]$, where $\emptyset q$ and qv are variant units for q unit, $\emptyset$ is the blank token, following the alignment constraints:

$$\emptyset^* \emptyset q \emptyset q^* \emptyset^* qv qv^* \emptyset^* vv vv^* \emptyset^*,$$

While this expansion captures local phonetic context, it significantly increases the output dimensionality and computational complexity. To mitigate this, we adopt a context-dependent embedding network to replace the standard final linear layer. This approach generates co-dependent prototype vectors for the diphone units, effectively reducing parameter overhead while enabling the ASR model to generalize across unseen phonetic contexts.

2.6 CTC-GOP computation

The definition of CTC-GOP adopts the approach of enumerating all possible transcription paths involving deletions and substitutions of specific tokens. We denote the canonical phoneme sequence as Y_c . In place of the original GOP-NN (Hu et al., 2015), this method first defines the log posterior probability (lpp) scalar as

$$lpp = \log p(Y_c|X). \quad (6)$$

The vector of log posterior ratios (**LPR**) for the i th phoneme in Y_c is then defined as

$$\mathbf{LPR}(i) = \log \left(\frac{p(Y_c|X)}{p(Y_{sdi}|X)} \right), \quad (7)$$

where the Y_{sdi} is the deletion and substitutions for the i th phoneme in Y_c . The features of the i th phoneme in Y_c is then defined to be:

$$\text{CTC-GOP}(i) = \{lpp, \mathbf{LPR}(i)\}. \quad (8)$$

Regarding the dimensionality of $\text{CTC-GOP}(i)$, for a 39-phoneme set, the $\mathbf{LPR}$ vector consists of 40 dimensions (accounting for 38 possible substitutions, one deletion, and the canonical phoneme itself). Including the lpp scalar, the total feature vector length is 41.

We also describe the details for how to extract CTC-GOP features from a CTC-based ASR model in Appendix A. The pipeline consists of three stages: (1) reduction of the phone inventory from full phone sets to pure phones, (2) batched CTC loss computation over substitution and deletion hypotheses, and (3) construction of $\mathbf{LPR}$.

3 Experimental Results

3.1 Corpus

We fine-tune the ASR models on the 960-hour LibriSpeech (Panayotov et al., 2015) corpus using a 72-phoneme inventory (including stress markers). To evaluate TA accuracy, we utilize two standard American English corpora with gold-standard phonetic alignments: TIMIT (Garofolo et al., 1993) (read speech) and Buckeye (Pitt et al., 2005) (conversational speech).

Our evaluation set includes 400 dev and 192 test samples from TIMIT, totaling 177,080 phonemes. For Buckeye, we evaluate 7,492 samples containing 858,386 phonemes. These datasets provide the verbatim timed transcriptions necessary to measure the impact of mitigated peaky behavior on boundary precision. Detailed hyperparameters and implementation are provided in Appendix B.

Both TIMIT (61 pure phones) and Buckeye (76 pure phones) were standardized to the CMU 39-pure phone units. This ensures a uniform phonetic label space across the three corpora, regardless of their original inventory sizes. Then, we add the stress markers back to their phoneme sequences L_{ref} . We first use the TDNN-F model pretrained on LibriSpeech¹ to transcribe the phoneme sequence L_{hyp} . Then, we apply a positional transfer function to map the possible stress markers from transcription to the converted non-stress labels, by

identifying vowel indices V_{ref} and V_{hyp} and applying a conditional mapping strategy:

- Linear mapping: If $|V_{ref}| = |V_{hyp}|$, stress markers are transferred via a direct 1-to-1 ordinal correspondence in L_{ref} and L_{hyp} .
- Relative alignment: If vowel counts diverge, we apply a nearest-neighbor approach based on relative sequence position. For each V_j^{ref} in L_{ref} , the stress digit is borrowed from the V_j^{hyp} in L_{hyp} that minimizes the normalized distance: $\hat{i} = \arg \min_i \left| \frac{i}{|L_{ref}|} - \frac{j}{|L_{hyp}|} \right|$

This mechanism ensures that the hypothesis sequence maintains a rhythmic structure consistent with the reference, even in the presence of phoneme insertions or deletions.

In addition to investigating the effect on acoustic variants, we evaluate ASR models trained on two distinct phoneme inventories: a comprehensive 72-unit set and a reduced 39-unit set, to provide a controlled benchmark against the original set.

For APA evaluation, we conducted experiments on the speechocean762 corpus (Zhang et al., 2021), a publicly available dataset specifically designed for APA research. This dataset contains 5,000 English-speaking recordings spoken by 250 Mandarin L2 learners. Each of the training and test sets has 2,500 utterances, where annotates utterance-level scores (accuracy, stress, completeness, fluency, prosodic, total), word-level scores (accuracy, stress, total) and phoneme accuracy score.

3.2 Backbone ASR models

WavLM (Chen et al., 2022) improves upon wav2vec 2.0 (Baeovski et al., 2020) and HuBERT (Hsu et al., 2021), enhancing the model’s robustness for APA by incorporating gated relative position bias and speech denoising capabilities during pre-training. While it is similar to HuBERT, improving upon wav2vec 2.0 by predicting hidden unit clusters, WavLM’s unique focus on simulating noisy and overlapped speech during training allows for more discriminative acoustic representations. These features help capture the small phonetic changes needed for accurate, high-resolution pronunciation scores.

3.3 Metrics

To access TA quality at the word- and phoneme-level, we adopt both absolute and marginal metrics

¹<https://kaldi-asr.org/models/m13>

Figure 1: The time stamp error (TSE), alignment accuracy (ACC) and blank ratio (BR) figures. These ASR models test on TIMIT’s dev and eval dataset and the whole Buckeye corpus.

(Zhao and Bell, 2024). For the absolute one, we use the time stamp error (TSE), which is defined as:

$$\text{TSE} = \frac{\sum_w |r_s - h_s| + |r_e - h_e|}{N_w}, \quad (9)$$

where the N_w represents the phoneme or word count in each utterance, and r_s , h_s , r_e , h_e indicate the reference, hypothesis’ start time and end time, respectively. Another one is alignment accuracy (ACC) for a threshold τ milliseconds, $\tau = \{10, 20, 25, 30, 40, 50\}$, which is defined:

$$\text{ACC}(\tau) = \frac{\sum_w \mathbf{1}(r_s - \tau \leq h_s \cap h_e \leq r_e + \tau)}{N_w}, \quad (10)$$

for each phoneme or word that satisfies the condition, $\mathbf{1}(\star)$ outputs 1, otherwise 0.

To estimate the efficacy of those methods in mitigating CTC’s peaky behavior, we also count the blank ratio (BR) to understand whether it decreases with those methods. BR is defined as

$$\text{BR} = \frac{\sum_u N_b}{\sum_u N}, \quad (11)$$

where N_b denotes the number of occurrences of the blank state within an evaluation utterance, and N represents the total number of frames in that utterance. The summation $\sum_u$ is executed across all evaluation utterances. This evaluation metric allows us to quantify the proportion of frames that are classified as blank states by our models.

To evaluate the APA model’s performance, the Pearson correlation coefficient (PCC) is adopted, while the mean squared error (MSE) is only used for the phoneme accuracy.

ASR Models	Phoneme Score		Word Score (PCC)			Utterance Score (PCC)

Table 1: Evaluation results for the GOPT model. *CTC** denotes the standard CTC baseline. Results are reported as the mean and standard deviation ($\pm$) across five seeds. Bold and underlined text indicate performance exceeding the baseline, with bold representing the best result for each aspect. Models labeled (39) utilize the CMU 39-phone set, while (DP) refers to the proposed diphone units. (LP) and (EnCTC) represent label prior and conditional maximum entropy regularizations, respectively. Shaded rows distinguish models utilizing content-aware CTC.

3.4 Results

We compare our proposed context-dependent CTC methods with the TDNN-F (Kaldi) and standard CTC to evaluate their efficacy on Time Alignment (TA) accuracy and the resulting series of GOP features on the APA models. The TDNN-F baseline is well-known for its outstanding ability in audio-text alignment (Rousso et al., 2024), providing stable posteriors that serve as a robust benchmark for APA tasks. It outperforms all the other methods in the HierCB model, as shown in Table 2. But in GOPT shown in Table 1, WavLM(DP)(39) and WavLM(DP)(39) series outperform the TDNN-F (Kaldi) and standard CTC, and show the best results

in many phone- and word-aspects. This observation shows that the content-aware CTC can really help access pronunciation at fine-grained levels. HierCB relies on external hard alignments which may not benefit from the soft posterior density. GOPT is alignment-free and looks at the global feature sequence; it benefits more from the enriched acoustic information in our dense posteriors.

3.4.1 Phone-set Granularity: 39 Phones vs. Full Phoneme Set

We investigated whether the granularity of the units affects alignment and GOP quality. As shown in Figure 1, ASR models using the CMU 39-phone

ASR Models	Phoneme Score		Word Score (PCC)			Utterance Score (PCC)				
	MSE ↓	PCC ↑	Acc. ↑	Stress ↑	Total ↑	Acc. ↑	Comp. ↑	Fluency ↑	Prosodic ↑	Total ↑

Table 2: Evaluation results for HierCB (Yan et al., 2025) model.

set (pure phones) consistently outperformed their full-phoneme (stress-marked) counterparts across nearly all metrics. On TIMIT, WavLM(39)(LP) achieved a word TSE of 5.9% on the test set, compared to 6.6% for the standard WavLM(LP). This performance gain is likely due to the reduced confusion between acoustically similar phonemes, which simplifies the alignment task for the CTC loss.

3.4.2 Comparison of CTC Peak Mitigation Methods

We evaluated two primary methods for mitigating the peaky behavior and overconfidence in CTC models, LP and EnCTC, respectively. LP ensures the ASR model remains fair to rare phonetic symbols by normalizing the posteriors. Our results indicate that while standard WavLM-CTC lags behind the Kaldi baseline in word TSE (9.3% vs. 9.0%

on Buckeye), the integration of LP significantly closes this gap. As shown in Figure 1, WavLM(LP) achieves a word TSE of 7.3% on Buckeye, outperforming the Kaldi baseline by approximately 2% absolute. This suggests that accounting for the prior distribution of phones effectively mitigates the "lazy" alignment typical of standard CTC, leading to more precise boundary estimation.

Specifically, LP ensures the ASR model remains fair to rare phonetic symbols by normalizing the posteriors. This yields substantial gains in high-precision scenarios; for instance, the word ACC-50 on Buckeye increases from 44% (Standard CTC) to 69% with the addition of LP and phoneme level from 48% to 52%, shown in Table 3 and Table 4. In contrast, while EnCTC acts as a regularizer to ensure the ASR model remains cautious and avoids

Figure 2: Distribution of GOPT phoneme scores for correct vs. mispronounced speech across various CTC-based ASR backbones.

overfitting to its own predictions, we observed that EnCTC is less effective than LP at reducing the BR.

Finally, we conducted experiments on the combination of both methods (LP+EnCTC). This hybrid approach yielded the best overall performance across all metrics. On the Buckeye dataset, WavLM(39)(LP+EnCTC) achieved the highest word ACC-50 score of 77.2%. These findings confirm that simultaneously addressing data bias (via LP) and model overconfidence (via EnCTC) is essential for achieving high-fidelity alignment suitable for downstream APA tasks.

3.4.3 DP vs. Regularizers

A notable observation is that LP still collapses on content-independent ASR models. Empirically, LP forces the model to predict rare phones more often. In a standard (monophone) CTC model, this might lead to insertion errors of rare phones into the blank spaces, destroying the alignment. However, in DP+39, the output space is more context-sensitive. The DP targets provide a stronger acoustic constraint that prevents LP from hallucinating rare symbols, instead using that prior to sharpen the transitions between phones.

3.4.4 Relational Studies: Alignment vs. APA Performance

We observed a clear correlation between TA accuracy and the PCC of the APA models. As shown in the comparison between Buckeye and TIMIT results, models with lower TSE (better alignment) consistently produced GOP features that led to higher word and utterance-level PCC in APA. For instance, the transition from standard WavLM-CTC

ASR Models	Buckeye / TIMIT dev / TIMIT test		
	P-TSE↓	P-ACC@25↑	P-ACC@50↑

to WavLM(39)(LP+EnCTC) reduced phone TSE from 26.3% to 25.2% on Buckeye, which directly contributed to more reliable GOP feature extraction.

3.5 Scoring Results: Correct vs. Incorrect

We use the alignment-free APA model GOPT, which relies solely on CTC-GOP features, to test if our ASR changes actually help tell the difference between good and bad speech. As shown in Figure 2, the standard WavLM-CTC baseline has a scoring gap of 0.708. However, our best setup, WavLM(DP)(39)(LP), widens this gap to 0.816.

This 15% improvement in the scoring margin is a big deal for learners. While correct speech (score ≥ 1.6) gets high marks in all models, our new method is much better at catching mistakes. By fixing the peaky issue in CTC, the ASR model becomes more sensitive to the small acoustic errors that learners make. This makes the final scores more reliable and easier for a teacher to trust.

4 Discussion and Conclusion

Our results show that standard CTC’s “blank” dominance and peaky behavior are major barriers to stable pronunciation scoring. We demonstrate that context-aware CTC, which combines peaky mitigation and OCD targets, overcomes these limits. Our WavLM(DP)(39) series with LP or EnCTC has

ASR Models	Buckeye / TIMIT dev / TIMIT test		
	W-TSE↓	W-ACC@25↑	W-ACC@50↑

(DP)(LP)	<u>7.9/7.7/7.9</u>	<u>29.6/24.6/22.4</u>	63.9/54.7/54.8
(DP)(EnCTC)	10.9/9.7/9.8	11.3/10.8/11.2	42.9/40.0/39.9
(DP)(LP+EnCTC)	11.0/10.2/10.3	11.1/7.7/7.0	41.6/34.2/35.4
(DP)(39)	10.4/9.6/9.7	13.0/11.0/11.6	45.3/40.1/41.0
(DP)(39)(LP)	10.5/9.7/9.8	12.1/10.2/10.2	44.6/40.1/41.1
(DP)(39)(EnCTC)	10.4/9.6/9.7	13.0/11.0/11.6	45.3/40.2/41.0
(DP)(39)(LP+EnCTC)	10.6/9.8/10.0	12.7/9.0/9.0	44.2/36.7/37.5

Table 4: A simplified result shows the TSE and ACC on Buckeye corpus, TIMIT dev and test datasets, which only select the word level (W-) and the tolerance at 25ms (@25) and 50ms (@50).

now surpassed TDNN-F baseline. For APA, this soft and context-sensitive posterior provides a rich feature that captures the small acoustic details of a learner’s mistakes.

In conclusion, the context-aware CTC framework fixes standard CTC’s flaws for pronunciation tasks. We increased the scoring margin by 15% over the baseline. These findings prove that temporally dense and context-sensitive posteriors are essential for building reliable APA systems that provide stable, helpful feedback to learners.

5 Related Works

5.1 APA

APA systems evaluate second-language (L2) speech by providing fine-grained feedback across phoneme, word, and utterance levels (Gong et al., 2022; Yan et al., 2025). Most modern frameworks follow a two-stage pipeline: extracting segmental-level features and predicting scores through either unified (Gong et al., 2022; Chao et al., 2022) or hierarchical (Yan et al., 2025; Chao et al., 2023; Do et al., 2023) neural architectures. While unified models assess all granularities in a single decision, hierarchical models aggregate information from phoneme-level features up to the utterance level.

A fundamental building block in these models is the GOP feature, which measures the acoustic deviation between learner speech and native references

(Gong et al., 2022). While early systems relied on traditional ASR-derived GOP, current state-of-the-art models increasingly leverage self-supervised learning (SSL) backends, such as Wav2vec 2.0 (Baevski et al., 2020), HuBERT (Hsu et al., 2021), and WavLM (Chen et al., 2022)—to extract robust contextual representations. These SSL models capture complex phonological patterns, significantly enhancing phoneme-level precision. In this work, we evaluate our proposed context-aware CTC-GOP features using both a unified architecture, GOPT (Gong et al., 2022), and a hierarchical model, HierCB (Yan et al., 2025).

Limitations

While the proposed method shows promise, several limitations remain. First, our evaluation is restricted to English as the target language with Mandarin L1 speakers. The efficacy of this approach for other language pairs and diverse L1 backgrounds requires further investigation.

Second, the transition from monophones to diphone units introduces a significant increase in the output layer dimensionality—from 39 to 39^2 possible combinations. This expansion increases computational overhead and may lead to data sparsity issues, as certain diphone transitions occur infrequently in training corpora.

Finally, our methodology is specifically designed to address the architectural constraints of CTC. Consequently, the adopted diphone-based context modeling may not be directly applicable or beneficial to non-CTC-based ASR frameworks, such as Transducer models.

Ethical Impact

We utilize publicly available and anonymized datasets (Librispeech, TIMIT, Buckeye, and speechocean762) for model training and evaluation. Our methodology focuses on improving speech technology for educational purposes and does not involve human subjects or the collection of private data. All authors comply with the ACL Code of Ethics and the relevant code of conduct for this venue.

A CTC-GOP implementation

A.1 Phone Inventory Reduction

When the acoustic model operates over a context-dependent phone set (e.g., with stress markers such as AA0, AA1, AA2), the log-probability matrix must be reduced to a pure-phone inventory before GOP computation. This mirrors the `ComputeLpps()` procedure in the speechocean762 official implementation² (Zhang et al., 2021).

Given a log-probability matrix $M \in \mathbb{R}^{T \times C}$, where T is the number of frames and C is the full phone inventory size, and a surjective mapping $\phi : \{0, \dots, C-1\} \rightarrow \{0, \dots, K-1\}$ from tokens to pure phones, we compute the reduced log-probability matrix $M' \in \mathbb{R}^{T \times K}$ as:

$$M'_{t,k} = \log \sum_{j: \phi(j)=k} \exp(M_{t,j}) \quad (12)$$

To ensure numerical stability, we apply the grouped log-sum-exp (log-space marginalization) trick. For each frame t and pure phone k , let $m_{t,k} = \max_{j: \phi(j)=k} M_{t,j}$. Then:

$$M'_{t,k} = m_{t,k} + \log \sum_{j: \phi(j)=k} \exp(M_{t,j} - m_{t,k}) \quad (13)$$

If no token maps to a particular pure phone k at frame t (i.e., the set $\{j : \phi(j) = k\}$ is empty), we define $M'_{t,k} = -\infty$. This reduction is implemented efficiently using `scatter_reduce` with the `amax` operator for computing $m_{t,k}$, and `scatter_add` for the shifted exponential summation, avoiding explicit loops over the vocabulary.

²<https://github.com/kaldi-asr/kaldi/blob/master/src/bin/compute-gop.cc>

A.2 GOP Feature Computation

Let $Y_c = (s_1, s_2, \dots, s_N)$ denote the canonical phone sequence for a given utterance, where N is the number of phones. We define the *LPP* of the canonical sequence as:

$$lpp = -\mathcal{L}_{\text{CTC}}(X, Y_c) \quad (14)$$

where $\mathcal{L}_{\text{CTC}}$ denotes the CTC loss (i.e., the negative log-likelihood under the CTC formulation). It is notable that the input posterior to the CTC loss could select log posterior rather than pure probability one (Cao et al., 2026) to avoid numerical underflow errors when multiplying probabilities over longer speech segments.

For each phone position $i \in \{1, \dots, N\}$, we construct a set of hypothesis sequences through two operations:

- **Deletion:** Remove the phone at position i , yielding $Y_c^{(i, \text{del})} = (s_1, \dots, s_{i-1}, s_{i+1}, \dots, s_N)$.
- **Substitution:** Replace the phone at position i with every phone $q \in \{1, \dots, K-1\}$, yielding $Y_c^{(i, q)} = (s_1, \dots, s_{i-1}, q, s_{i+1}, \dots, s_N)$.

This produces $N \times K$ hypothesis sequences in total (one deletion and $K-1$ substitutions per position). All hypothesis sequences are batched into a single padded tensor and evaluated simultaneously via PyTorch(Paszke et al., 2019)’s `F.ctc_loss` with `reduction='none'`, enabling efficient GPU-parallel computation.

The **LPR** for position i and hypothesis q is defined as:

$$\text{LPR}_{i,q} = \mathcal{L}_{\text{CTC}}(X, s^{(i,q)}) - lpp \quad (15)$$

This quantity measures how much less likely the modified sequence is compared to the canonical pronunciation. A positive **LPR** for the substitution with the canonical phone at position i indicates correct pronunciation; values near zero or negative suggest mispronunciation.

A.3 Feature Representation

For each phone position i , the extracted feature vector is:

$$\mathbf{f}_i = [\phi(s_i), lpp, \text{LPR}_{i,0}, \text{LPR}_{i,1}, \dots, \text{LPR}_{i,K-1}] \quad (16)$$

where $\phi(s_i)$ is the pure phone identity and $\text{LPR}_{i,0}$ corresponds to the deletion hypothesis. The resulting feature matrix $\mathbf{F} \in \mathbb{R}^{N \times (K+2)}$ is stored per utterance for downstream mispronunciation detection or scoring.

A.4 CTC Forward Algorithm

For reference, the CTC forward log-probability is computed via the standard dynamic programming recursion. Let $\mathbf{s}' = (\emptyset, s_1, \emptyset, s_2, \emptyset, \dots, \emptyset, s_N, \emptyset)$ be the blank-augmented label sequence of length $L = 2N + 1$. The forward variable $\alpha_{l,t}$ represents the log-probability of emitting the partial sequence $\mathbf{s}'_{1:l}$ over frames 1 through t :

$$\alpha_{l,t} = \log p(\mathbf{s}'_{1:l}, X_{1:t}) \quad (17)$$

Let $\Psi(t-1, \mathcal{L}) = \log \sum_{l' \in \mathcal{L}} \exp(\alpha_{l',t-1})$. The recursion proceeds as:

$$\alpha_{l,t} = \begin{cases} \Psi(t-1, \mathcal{A}(l)) + \log p(\mathbf{s}'_l | t), & \text{if } l \bmod 2 = 0 \\ \Psi(t-1, \mathcal{B}(l)) + \log p(s_{\lfloor l/2 \rfloor} | t), & \text{otherwise} \end{cases}$$

where $\mathcal{A}(l) = \{l, l-1\}$ for blank positions, and $\mathcal{B}(l) = \{l, l-1\}$ when $s_{\lfloor l/2 \rfloor} = s_{\lfloor l/2 \rfloor - 1}$ (repeated label), or $\{l, l-1, l-2\}$ otherwise. The total sequence log-probability is obtained as:

$$\log p(\mathbf{s} | X) = \text{logaddexp}(\alpha_{L,T}, \alpha_{L-1,T}) \quad (18)$$

A.5 Implementation Details

The pipeline operates as follows: (a) a pre-trained CTC acoustic model produces frame-level log-probabilities from audio; (b) canonical phone sequences are derived either from a lexicon-based word-to-phone expansion or from an explicit phoneme-level transcript; (c) GOP features are computed per utterance and saved as NumPy arrays. The batched CTC evaluation avoids the $\mathcal{O}(N \times K)$ sequential forward passes that would be required by a naïve implementation, yielding substantial speedup on GPU hardware.

B ASR and APA models training configures

In this work, we conduct experiments to train the ASR models on the Librispeech (Panayotov et al., 2015) corpus, a 960-hour training set. We utilize `torchaudio.bundle` to implement the backbone,

selecting WAVLM_LARGE as its initialized model parameters³. For some control groups, such as WavLM(39) and WavLM(DP)(39), they are based on WavLM and WavLM(DP), respectively, and further finetuned on the train-clean 100 hours training subset. In detail, we freeze all the WavLM encoder layers, and finetune only the output layers. For the DP ones, the output layer was designed with a single feedforward layer following two CD embedding layers (Chorowski et al., 2019)⁴. The feature extractor component of the WavLM model remains unchanged. Our models use phonemes as the modeling units. For the standard CTC, we adopt the implementation of Cao et al. (2024)⁵, but change the backbone SSL model from wav2vec2.0 to WavLM. For the ASR model optimization, we employ the AdamW (Loshchilov and Hutter, 2019) optimizer, with a learning rate initialized from 10^{-4} .

Throughout our experimental setup, we utilize Zhao and Bell (2024)⁶ project to conduct ASR experiments, in which Kaldi (Povey et al., 2011) for data preparation and PyTorch (Paszke et al., 2019) for neural network training, with k2-fsa⁷ serving as the backend for the DWFST framework. The computation of CTC-GOP features follows the idea in Cao et al. (2024) but is further optimized for its stability and the running speed.

For the comparative methods, LP and EnCTC, we adopt the implementations^{8 9}, adjusting them to fit in the implementation of computing loss in the k2-fsa (Yao et al., 2024)¹⁰ framework. For LP, we change to a smart strategy, accumulating its label prior to each mini-batch to achieve a gradual adjustment. The a for the label prior weight is set to 0.2, while the b for the conditional maximum entropy weight is set to 0.1.

For GOPT and HierCB models training, we adhere to the hyperparameters from Gong et al. (2022); Yan et al. (2025) for training of our APA model. To quantify epistemic uncertainty, we train

with five different random seeds.

{wl2904, siyan.li, zcr2105}@columbia.edu, julia@cs.columbia.edu

Abstract

Automated coaching for oral presentations sits at the intersection of computer-assisted pronunciation training (CAPT), prosody modeling, and speech synthesis, yet no prior work has systematically surveyed and compared existing systems along these dimensions. This survey reviews and categorizes automated presentation coaching systems, spanning pronunciation tutors, fluency and prosody coaches, multimodal trainers, and conference Q&A practice tools. We introduce a five-dimensional task taxonomy—covering segmental pronunciation, lexical stress, suprasegmental prosody, pacing, and content faithfulness—and explicitly map surveyed systems onto it to reveal coverage gaps. We further review the core technical methods these systems employ: TTS-based exemplar generation and diagnostic methods for pronunciation, prosody, and fluency assessment. Key open challenges include the scarcity of annotated presentation corpora, achieving accent-fair feedback across diverse L1 backgrounds, and delivering low-latency diagnostics for real-time rehearsal.

1 Introduction

Oral presentations in English, including technical talks, research seminars, and product demos, impose demands well beyond everyday conversation. Presenters must articulate specialized terminology accurately, manage pacing relative to slide transitions, and modulate prosody so that discourse structure is clear to listeners. For English as a Second Language (ESL) speakers, these demands are compounded by the tendency to carry over sound patterns from one’s native language into English, accent-specific prosodic patterns, and limited opportunities for realistic rehearsal (Munro and Derwing, 1995; Derwing and Munro, 2005).

The last two decades have seen growing interest in *automated coaching* for oral presentations,

spurred by progress in computer-assisted pronunciation training (CAPT) (Witt and Young, 2000; Cucchiaroni et al., 2009), neural text-to-speech (TTS) (Chen et al., 2024; Ren et al., 2021), and multimodal analysis (Baltrušaitis et al., 2019). Systems such as Rhema (Tanveer et al., 2015), Mirror Mirror (Schneider et al., 2015), and recent LLM-augmented Q&A coaches (Aiba et al., 2024) each target different facets of presentation skill. Yet the field currently lacks a unified survey that (a) catalogs and compares these systems, (b) identifies which presentation dimensions they address, and (c) exposes the problems that remain.

This paper fills that gap. We survey automated coaching systems for oral presentations, focusing on speech-based dimensions: pronunciation, lexical stress, prosody, pacing, and content faithfulness. Our scope spans both L2-specific and general public-speaking tools, since many techniques transfer across these settings. We deliberately set aside visual and gesture coaching (Schneider et al., 2015; Damian et al., 2015) except when they are integrated with speech feedback, and we do not aim to cover the full literature on general-purpose ASR or spoken language assessment.

Contributions. Concretely, this survey: (1) introduces a five-dimensional task taxonomy for presentation coaching and maps surveyed systems to reveal coverage gaps; (2) systematically reviews and categorizes existing automated presentation coaching systems; (3) reviews the core technical methods – TTS-based exemplar generation and diagnostic approaches – that underpin these systems; and (4) discusses open challenges in corpora, accent fairness, real-time deployment, and the gap between research and industry practice.

Literature Search Strategy. To ensure comprehensive coverage, we conducted a systematic search across ACL Anthology, IEEE Xplore, ISCA Archive, Google Scholar, and Semantic Scholar using queries combining terms such as “presenta-

tion coaching,” “pronunciation training,” “CAPT,” “prosody assessment,” “speech fluency,” “TTS coaching,” and “L2 speaking.” We included peer-reviewed publications from 1997 to 2025 that directly address automated coaching or assessment of oral presentation or spoken language skills. We supplemented keyword-based search with citations from key papers (Witt and Young, 2000; Golonka et al., 2014; Aiba et al., 2024), following established survey methodology (Frederick Eneye et al., 2025). Studies focused exclusively on visual or gestural coaching without a speech component were excluded, as were general-purpose ASR or TTS papers. This process yielded 15 representative systems and approximately 50 supporting references spanning CAPT, prosody modeling, TTS, and educational technology.

Organization. Section 2 reviews foundational technologies. Section 3 presents the five-dimensional task taxonomy that organizes the remainder of the paper, along with the system inputs, outputs, and operating modes that connect the taxonomy to practical coaching workflows. Section 4 surveys existing systems and maps them onto the taxonomy. Section 5 reviews the core technical methods these systems employ. Section 6 covers datasets and evaluation. Section 7 discusses remaining open problems and future directions, including the gap between research and industry deployment. Section 8 concludes.

2 Background: Foundational Technologies

We briefly review the core technologies that underpin automated presentation coaching: pronunciation assessment, prosody analysis, shadowing pedagogy, and neural TTS. See detailed discussions of diagnostic and synthesis methods in Section 5.

Computer-Assisted Pronunciation Training (CAPT). CAPT systems localize segmental errors using Goodness of Pronunciation (GOP) scores (Witt and Young, 2000) or ASR confidence measures (Cucchiarini et al., 2009). Earlier approaches relied on HMM forced alignment (Rabiner, 1989; Franco et al., 1997); modern systems leverage CTC (Graves et al., 2006; Cao et al., 2024) and self-supervised representations (Baevski et al., 2020; Hsu et al., 2021) for alignment-free mispronunciation detection (Xu et al., 2021; Gong et al., 2022). These methods form the diagnostic backbone of most pronunciation coaching systems.

Prosody Analysis. Effective presentations utilize prosody (intonation, phrasing, rhythm) to signal structure (Hirschberg, 2004). Listener-impression studies (Shoda et al., 2023) confirm that even small pitch and timing adjustments significantly affect perceived speaker competence. Assessment typically compares log- F_0 contours and duration patterns between learner and reference utterances (Sakoe and Chiba, 1978; Rosenberg, 2010).

Shadowing Pedagogy. Exemplar-guided shadowing (imitation) is well established for improving L2 pronunciation, prosody, and fluency (Hori, 2008; Kadota, 2019; Hamada, 2018). When mimicking short auditory demonstrations with explicit focus on speech rate and prominence, learners experience improvements in timing, stress, and intonation (Hsieh et al., 2013). This pedagogy directly motivates the use of TTS to generate controllable, adjustable exemplars for coaching at scale.

Neural Text-to-Speech (TTS). Recent non-autoregressive flow-matching TTS models (e.g., F5-TTS (Chen et al., 2024), Voicebox (Le et al., 2023), CosyVoice 2 (Du et al., 2024)) synthesize highly natural speech with real-time factors below 1. These systems offer fine-grained control over speaking rate, pause insertion, and emphasis, making them well-suited for generating coaching exemplars. Zero-shot style transfer from short enrollment clips enables personalized references (Jia et al., 2018; Casanova et al., 2022).

3 Presentation Coaching Taxonomy

Building on the foundational technologies reviewed above, we formalize a five-dimensional taxonomy for automated presentation coaching. The taxonomy organizes presentation skills by the nature of the feedback they require and the methods available to assess them, providing a systematic framework for comparing existing systems and identifying coverage gaps. Figure 1 illustrates the structure.

3.1 Taxonomy Dimensions

We define each dimension, its assessment methods, and the kind of feedback it yields; Section 4 maps the full set of surveyed systems onto these dimensions, and Table 1 provides the complete mapping.

Pronunciation (segmental) covers phone- and word-level correctness, including salient vowel/-consonant contrasts and technical terminology. Assessment relies on GOP (Witt and Young, 2000),

Figure 1: Five-dimensional taxonomy for automated presentation coaching. Existing systems (Table 1) cover different subsets; lexical stress and content faithfulness are the least-addressed dimensions.

CTC-based (Cao et al., 2024), or self-supervised methods (Xu et al., 2021); feedback for this dimension identifies top- k error phones. This is the most widely addressed dimension in the literature.

Lexical stress addresses syllable prominence in multi-syllabic words (e.g., *AL-go-rithm*). Feedback identifies the incorrect stress position and proposes re-stress drills. Despite its documented impact on comprehensibility (Munro and Derwing, 1995), this dimension is almost entirely neglected by existing systems (Korzekwa et al., 2021).

Prosody (suprasegmental) includes intonation (F0), phrasing, rhythm, and intensity contours that signal discourse structure. Feedback often includes F0 RMSE and Pearson r vs. a reference. Several systems address prosody with varying granularity.

Pacing covers words-per-minute (WPM), articulation rate, and pause placement relative to punctuation and slide boundaries. Feedback highlights WPM deviation and pause statistics.

Content faithfulness measures coverage of key content without insertions or omissions, flagging missing keywords per slide. Providing the ASR with a list of expected technical terms from the slides helps it correctly transcribe domain-specific vocabulary that a general-purpose model might otherwise miss. This is the least-addressed dimension in the literature.

3.2 Inputs, Outputs, and Assumptions

Beyond the five coaching dimensions, systems also differ in their input requirements and output granularity, with each input-output pattern tied to specific taxonomy dimensions. On the **input** side, systems targeting the *pronunciation* and *lexical stress* dimensions require, at minimum, a text transcript and a learner recording for forced alignment (Witt and Young, 2000; Neri et al., 2002; Strik et al., 2009; Xu et al., 2021). Systems addressing *prosody* and *pacing* additionally assume slide-aligned scripts

with section boundaries to enable discourse-level analysis (Hincks, 2005; Chen et al., 2014; Schneider et al., 2015). Systems targeting *content faithfulness* require the reference slide content for keyword matching. Systems that support personalized exemplars across any dimension may further accept a brief enrollment clip for voice cloning (Jia et al., 2018; Casanova et al., 2022).

On the **output** side, feedback granularity maps directly to the taxonomy. *Pronunciation* and *lexical stress* systems produce per-word or per-phone error flags (Witt and Young, 2000; Cao et al., 2024; Korzekwa et al., 2021). *Prosody* and *pacing* systems report global scores such as F0 deviation, articulation rate, and pause frequency (Shen et al., 2021; Saito et al., 2023). *Content faithfulness* systems flag missing keywords and WER per slide (Aiba et al., 2024). Multimodal trainers additionally output behavioral feedback on gaze and gesture (Schneider et al., 2015; Damian et al., 2015; Ramanarayanan et al., 2015). Across these systems, text normalization, grapheme-to-phoneme conversion, and forced or CTC-based alignment are standard preprocessing steps, while phonetic labels from the learner are generally not required.

3.3 System Modes

Given these inputs and outputs, coaching systems operate in three complementary modes, each serving different taxonomy dimensions. **Exemplar generation** (Section 5) produces controllable target reads per slide and for glossary items, directly supporting the *pronunciation*, *lexical stress*, and *prosody* dimensions by providing reference audio that models correct segment production, stress patterns, and intonation contours. **Comparative assessment** (Section 5) aligns learner audio with a reference to localize deviations, enabling diagnostics across all five taxonomy dimensions—from phone-level pronunciation errors to slide-level con-

tent omissions. A **mixed-initiative practice loop** turns diagnoses into focused drills targeting the weakest dimensions (e.g., re-stress a syllable for *lexical stress*; maintain a pre-equation pause for *pacing*), allowing the learner to re-record and track progress. This loop is implicit in several prior systems (Shen et al., 2021; Saito et al., 2023; Aiba et al., 2024) but rarely articulated explicitly for slide-based presentations. The next section surveys existing systems and maps them onto the taxonomy dimensions defined above.

4 Survey of Existing Presentation Coaching Systems

With the taxonomy in place, we now survey automated systems that target presentation or spoken English coaching. We organize them into four categories: CAPT-based pronunciation systems, prosody and fluency coaches, multimodal trainers, and Q&A/interaction coaches. Table 1 maps each system onto the five taxonomy dimensions.

4.1 CAPT-Based Pronunciation Systems

Early pronunciation coaching focused on segmental accuracy. Franco et al. (1997) pioneered automatic pronunciation scoring for language instruction using HMM-based forced alignment and log-likelihood scores, establishing the feasibility of system-generated feedback on individual phones. Neri et al. (2002) examined the pedagogy-technology interface in CAPT systems, showing that explicit error localization and corrective feedback improve learner outcomes beyond passive listening. Strik et al. (2009) compared GOP, posterior-based, and ASR-confidence approaches for automatic pronunciation error detection, finding that methods vary considerably across L1 backgrounds, motivating per-cohort calibration. More recently, Xu et al. (2021) demonstrated that wav2vec 2.0 representations substantially outperform HMM-based systems on L2 English mispronunciation detection benchmarks. Korzekwa et al. (2021) specifically addressed lexical stress detection in L2 English, using data augmentation and attention-based models to identify incorrect primary-stress placement in multi-syllabic words.

However, these systems share a common limitation: they operate on isolated words or short, read sentences, not on the semi-scripted, long-form speech characteristic of presentations. Feedback is typically provided post-hoc as a list of error flags,

with no practice loop or exemplar generation.

4.2 Fluency and Prosody Coaching

Moving beyond segmental accuracy, a second line of work targets fluency and suprasegmental quality. Hincks (2005) developed one of the earliest computer-aided systems specifically targeting spoken English for academic presentations, providing visual feedback on speaking rate and pitch variation. Shen et al. (2021) presented an interpretable model predicting L2 fluency from acoustic features including articulation rate, pause frequency, and phonation time, identifying the features that most strongly correlate with human ratings across diverse L1 backgrounds. Saito et al. (2023) conducted a comprehensive program on automated L2 comprehensibility assessment, arguing that comprehensibility, rather than narrow segmental accuracy, is a more robust target for coaching.

On the synthesis side, prior work (Onda et al., 2024, 2025) showed that generative spoken language models can simulate and modulate foreign-accented prosody, enabling the generation of corrected exemplars that retain the learner’s vocal identity while gaining similarity to target prosody patterns.

Zechner et al. (2009) developed automated scoring of non-native spontaneous speech for high-stakes testing (e-rater), covering fluency, pronunciation, and prosody holistically.

4.3 Multimodal Presentation Trainers

A third wave of systems extends speech coaching to the full presentation context, incorporating visual and behavioral signals together with audio. Schneider et al. (2015) developed *Mirror Mirror*, a multimodal presentation coaching system that provides automated feedback on body language, eye contact, and filler words in addition to speech rate. Damian et al. (2015) presented an intelligent tutoring system that analyzes posture, gesture, and vocal quality to generate structured coaching advice for novice presenters, grounded in public speaking pedagogy (Lucas, 2014). Ramanarayanan et al. (2015) assessed multimodal communication skills—including speech, gaze, and gesture—using behavioral signals extracted automatically, demonstrating feasibility for scalable deployment.

While the above systems combine multiple modalities, other work targets individual speech dimensions more directly. Chen et al. (2014) evaluated presentation skills in a tutoring context using

speech recognition and audience feedback. These systems demonstrate the feasibility of presentation-specific feedback loops, though they typically address only one or two of the dimensions in our defined taxonomy at a time.

4.4 Q&A and Interaction-Based Coaching

The most recent systems leverage large language models to extend coaching to the interactive components of presentations. Aiba et al. (2024) proposed a multimodal system for conference Q&A practice, combining ASR with ChatGPT-based question generation and TTS to simulate domain-relevant follow-up questions. Learners deliver a short talk; the system transcribes it, generates content-contingent questions, and reads them aloud, enabling repeated practice of spontaneous responses. Their user study reported reducing presentation anxiety and improving perceived preparedness among first-time conference participants.

Most recently, Chen et al. (2025) introduced PresentCoach, a dual-agent system in which one agent generates benchmark presentation videos from slides using personalized voice synthesis, while another evaluates the learner’s recording against these exemplars and delivers structured feedback. It is the first system to integrate slide-aware exemplar generation with multi-dimensional assessment in a single LLM-driven pipeline, covering four of the five taxonomy dimensions (pronunciation, prosody, pacing, and content faithfulness). Neural phonetic posteriorgrams (PPGs) (Churchwell et al., 2024) offer a complementary phone-level diagnostic suitable for such interactive loops.

4.5 Comparison and Discussion

Together, these four system categories cover a wide arc of presentation skills, yet no single system spans all. Table 1 compares the surveyed systems along the five coaching dimensions from our taxonomy (Section 3), whether the system provides real-time feedback, and whether it targets L2 speakers specifically.

Several patterns emerge from Table 1. First, **lexical stress is almost entirely neglected**: only Korzekwa et al. (2021) directly targets stress detection, despite its well-documented importance for L2 comprehensibility (Munro and Derwing, 1995). Second, **real-time feedback remains rare**: only two surveyed systems provide in-session feedback (Schneider et al., 2015; Aiba et al., 2024); most systems assess post-hoc. Third, **content faith-**

fulness and pacing are often decoupled: systems either check what was said (ASR-based) or how fast (WPM), but seldom do both with slide-aligned structure. Fourth, **no existing system covers all five dimensions simultaneously**: the most recent system, PresentCoach (Chen et al., 2025), covers four (pronunciation, prosody, pacing, and content) but still omits lexical stress, illustrating that integrated, multi-dimensional coaching remains an open challenge. These gaps are compounded by limitations in available data: most CAPT corpora (Zhao et al., 2018; Zhang et al., 2021; Garofolo et al., 1993) focus on isolated words or short sentences, lacking slide structure, domain terminology, and discourse-level features, while large-scale corpora such as LibriSpeech (Panayotov et al., 2015), Common Voice (Ardila et al., 2020), and TED-LIUM (Hernandez et al., 2018) are not designed for L2 coaching. In summary, existing systems address individual dimensions but do not combine exemplar-based practice with fine-grained diagnostics in a unified, presentation-specific workflow (Golonka et al., 2014).

5 Coaching Systems Methods

The systems surveyed in Section 4 draw on two complementary families of methods: **TTS-based exemplar generation**, which produces reference targets for learner practice, and **diagnostic techniques**, which assess how far a learner deviates from those targets. This section reviews both families of approaches employed by prior systems.

5.1 TTS-Based Exemplar Generation

Several surveyed systems use synthesized or recorded model speech as a reference for learner practice (Hincks, 2005; Schneider et al., 2015; Aiba et al., 2024). We review the TTS capabilities these systems exploit and the workflows they follow.

5.1.1 TTS Capabilities for Coaching

Modern neural TTS offers three capabilities that the surveyed systems leverage: **controllability** over rate, pauses, and emphasis; **code-switching** support for technical terms; and **zero-shot voice transfer** from short enrollment clips. Because recent flow-matching models (Chen et al., 2024; Le et al., 2023) and streaming architectures such as CosyVoice 2 (Du et al., 2024) achieve sub-second latency, exemplars can now be rendered on-the-fly during rehearsal. Two controls are most relevant:

System	Pron.	Stress	Prosody	Pacing	Content	Real-time	L2-specific

Table 1: Comparison of existing presentation and spoken-language coaching systems across five taxonomy dimensions: “Pron.” = segmental pronunciation; “Stress” = lexical stress; “Content” = faithfulness/content coverage; “Real-time” = feedback provided during or immediately after recording. Checkmarks indicate that the system explicitly addresses the dimension.

tempo bands that constrain WPM, and *emphasis marks* that elicit pitch accents on key terms.

5.1.2 Workflow and Pedagogical Strategies

Generalizing patterns from prior systems (Hincks, 2005; Schneider et al., 2015) and grounded in shadowing pedagogy (Kadota, 2019; Hamada, 2018), a typical TTS-based coaching pipeline proceeds as follows: (1) render an *anchor* exemplar at a conservative tempo (120–140 WPM) and an optional *target* at a faster tempo (150–170 WPM); (2) record the learner in short chunks (5–12 s per section); (3) align learner audio with the reference using CTC (Graves et al., 2006) or DTW (Sakoe and Chiba, 1978) and compute deviations; (4) surface focused drills based on the highest-error dimensions. Across these systems, effective exemplars tend to be short (<12 s) to prevent cognitive overload and offer multiple speed bands and vocabulary difficulty gradations to accommodate different proficiency levels (Schneider et al., 2015; Golonka et al., 2014). Known limitations include over-constraining style when exemplars are treated as a single correct read, and synthetic emphasis that may not match domain conventions.

5.2 Pronunciation and Fluency Diagnostics

While TTS provides the coaching *targets*, diagnostic methods provide the *assessments* (Witt, 2012; Jurafsky and Martin, 2026). The surveyed systems employ three families of diagnostic techniques,

each addressing different taxonomy dimensions.

5.2.1 GOP and CTC-Based Assessment

Goodness of Pronunciation (GOP) (Witt and Young, 2000), used by several surveyed systems (Franco et al., 1997; Zechner et al., 2009; Strik et al., 2009), scores each phone by comparing how strongly the acoustic evidence supports the intended sound vs. the most likely alternative, averaged across the phone’s duration. A high GOP score indicates correct pronunciation; a low score flags a likely mispronunciation. Modern “segmentation-free” variants (Cao et al., 2024) derive boundaries from CTC posteriors (Graves et al., 2006) rather than forced alignment, improving robustness to disfluent L2 speech. Self-supervised models (wav2vec 2.0 (Baevski et al., 2020), HuBERT (Hsu et al., 2021), WavLM (Chen et al., 2022)) further advance this line (Xu et al., 2021; Gong et al., 2022), and neural PPGs (Churchwell et al., 2024) provide an alternative backbone for fine-grained phone-level scoring. Thresholds are calibrated per L1 on small rated sets, optimizing equal error rate or UAR against human annotations.

5.2.2 Clone-and-Compare (Personalized Reference)

To control for timbre and speaker style, several systems (Onda et al., 2024, 2025) synthesize an idealized rendition in the learner’s voice via voice conversion (Qian et al., 2019) or zero-shot TTS (Jia

Corpus	Hrs	L2	Long	Accent	Prosody

et al., 2018; Casanova et al., 2022), then compute MFCC/SSL (Davis and Mermelstein, 1980; Baevski et al., 2020) distance curves aligned with monotonic DTW (Sakoe and Chiba, 1978). Distance peaks flag likely mispronunciations while controlling for speaker-specific timbre. End-to-end ASR (Radford et al., 2023; Gulati et al., 2020) also yields word durations and confidence posteriors as complementary signals.

5.2.3 Prosody, Pacing, and Faithfulness

Prosodic quality is computed on $\log-F_0$ after voicing decisions (YAAPT (Zahorian and Hu, 2008)): per-slide RMSE and Pearson r capture intonation match, while word- or phrase-level duration RMSE captures rhythmic alignment. These suprasegmental metrics are used by several surveyed systems (Hincks, 2005; Shen et al., 2021; Saito et al., 2023). Pacing metrics (WPM deviation, articulation rate, pause precision/recall) appear in systems targeting real-time feedback (Schneider et al., 2015). For content faithfulness, constrained-LM ASR with glossary bonuses reduces false omissions on domain terms (Aiba et al., 2024); WER and missing-keyword flags per slide are the primary metrics. The integration of these diagnostic methods into a complete coaching pipeline is detailed in Appendix A.

6 Datasets and Evaluation

The diagnostic methods described above require annotated data for training and evaluation. Table 2 summarizes major corpora and assesses their suitability for presentation coaching according to whether the following are present in the corpus: whether the learners are L2 speakers, long-form speech characteristic of presentations, accent or L1 annotations, and prosody labels (e.g. pitch accent).

As Table 2 shows, no existing corpus simultaneously provides L2 speech, long-form presentation structure, accent labels, and prosodic annotations. TIMIT and L2-ARCTIC focus on isolated sentences; TED-LIUM 3 and GigaSpeech (Chen et al., 2021) are long-form but not L2-specific; Common Voice provides accent labels but consists of short read sentences. Newer resources partially close the gap: EpaDB (Vidal et al., 2019) offers detailed phone-level pronunciation annotations for L2 Spanish speakers of English, and the recently released Speak & Improve Corpus (Knill et al., 2024) provides approximately 340 hours of spontaneous L2 English speech with CEFR proficiency scores and diverse L1 backgrounds. However, neither includes slide structure or presentation-specific annotations. This gap directly limits the ability to train and evaluate systems on the dimensions most critical for presentation coaching, particularly discourse prosody and slide-aligned pacing. We recommend creating small, controlled *presentation mini-sets*, consisting of 5–10 minute talks per speaker with slide markers, emphasis annotations, and diverse accent coverage, as a near-term community benchmark.

To evaluate coaching systems using such data, we consolidate metrics across five categories (Table 3), each aligned with one or more taxonomy dimensions. Importantly, the individual metrics we recommend are not novel; they are established measures drawn from prior work in prosody analysis, fluency assessment, and speech quality evaluation. Our contribution lies in their systematic alignment with the five taxonomy dimensions to form a coherent evaluation framework for presentation coaching. This alignment ensures that each taxonomy dimension has clearly defined, measurable targets, enabling researchers to evaluate coaching systems comprehensively rather than on isolated aspects.

Segmental metrics assess phone- and word-level pronunciation accuracy. Phone/word F1 measures the precision and recall of correctly produced segments, while unweighted average recall (UAR) ensures that performance on rare error types is not masked by frequent correct phones. Both are derived from GOP (Witt and Young, 2000) or CTC-based (Cao et al., 2024) diagnostic outputs.

Prosody metrics capture how well a learner’s intonation matches the reference. $\log-F_0$ RMSE quantifies average pitch deviation, and Pearson r measures the correlation of pitch contours, reflecting whether the learner’s intonation follows the same rises and falls as the target (Rosenberg, 2010;

Category	Key Metrics	Diagnostic Method
Segmental	Phone/Word F1, UAR	GOP (Witt and Young, 2000), CTC
Prosody	Log- F_0 RMSE, Pearson r	Pitch track + DTW
Pacing	WPM deviation, Pause rate	Alignment boundaries
Faithfulness	WER, Glossary hit-rate	Constrained ASR
Perceptual	MOS, PESQ	Human / Neural pred.

Table 3: Evaluation metrics for presentation coaching, organized by taxonomy dimension. We adopt individual metrics from prior work; we consolidate them into a unified framework aligned with the five coaching dimensions.

Zahorian and Hu, 2008).

Pacing metrics evaluate temporal control. WPM deviation measures how far the learner’s speaking rate falls from the target band, and pause rate captures whether pauses occur at appropriate boundaries (commas, slide breaks) rather than mid-phrase (Shen et al., 2021; Hincks, 2005).

Faithfulness metrics assess content coverage. WER measures overall transcription accuracy against the script (Radford et al., 2023), while glossary hit-rate tracks whether domain-critical terms are produced correctly, using constrained ASR with glossary bonuses (Aiba et al., 2024).

Perceptual metrics provide a holistic quality check. Mean Opinion Score (MOS) captures human judgments of overall speech quality, and PESQ (Rix et al., 2001) offers an automated proxy. Neural MOS predictors (Lo et al., 2019) can further scale these assessments without requiring human listeners for every evaluation.

Metrics alone are insufficient without evidence that they translate into actual learner improvement, and its underlying diagnostics have to remain reliable in realistic conditions. We therefore recommend three complementary validation protocols. First, **shadowing efficacy** should be tested via randomized crossover studies comparing TTS-guided (Chen et al., 2024) and unguided rehearsal, measuring whether exemplar-based practice yields measurable gains on the five taxonomy dimensions. Second, **diagnostic precision** should be evaluated by comparing GOP (Witt and Young, 2000) and clone-and-compare methods against expert annotations, since the choice of diagnostic directly affects the feedback a learner receives. Third, **robustness** should be assessed by measuring metric drift under environmental noise at multiple SNR levels, because real rehearsal settings rarely match studio-quality recording conditions.

7 Open Problems and Research Opportunities

The preceding sections reveal that while individual components of presentation coaching (pronunciation diagnostics, prosody modeling, exemplar generation) have matured considerably, integrating them into comprehensive, deployable systems remains an open challenge. Rather than restating these gaps, we identify five concrete research directions with specific actionable proposals.

Closing the lexical stress and discourse prosody gap. Lexical stress remains the most under-addressed taxonomy dimension (Table 1), yet mis-stressed words are a leading cause of reduced L2 comprehensibility (Munro and Derwing, 1995). A concrete next step is to extend self-supervised mispronunciation detectors (Xu et al., 2021; Gong et al., 2022) with syllable-level prominence classifiers trained on forced-aligned lexical stress annotations. For discourse prosody, current systems assess intonation at the utterance level, but presentations require section-level prosodic planning (e.g., pitch resets at topic boundaries, rising contours for rhetorical questions) (Hirschberg, 2004; Xu, 2005). We propose training prosodic planning models that condition on slide structure and discourse markers, enabling feedback such as “lower your pitch at the start of a new section.”

Real-time, personalized coaching. Only two of 15 surveyed systems provide real-time feedback (Table 1), yet immediate feedback is pedagogically more effective than post-hoc reports (Golonka et al., 2014). Sub-second diagnostics during live rehearsal require neural audio codecs (Défossez et al., 2022) and efficient alignment algorithms (e.g., sub-sequence DTW or streaming CTC). Beyond latency, systems should learn user-specific pacing bands and prosodic targets from minimal enrollment data rather than enforcing fixed norms (Trofimovich and Baker, 2006). A concrete proposal is to develop few-shot personalization modules that adapt pacing and prosody targets from a 2–3 minute calibration recording, enabling coaching that improves clarity without erasing the speaker’s natural style.

Evaluation infrastructure and benchmark creation. The field lacks standardized corpora with slide-aligned scripts, emphasis annotations, and diverse L1 coverage (Section 6). We recommend a community effort to create *presentation mini-sets*:

20–30 speakers from 5+ L1 backgrounds, each delivering a 5–10 minute technical talk with time-stamped slide boundaries, phone-level transcriptions, and expert prosody ratings. Such a benchmark would enable head-to-head comparison of coaching systems on all five taxonomy dimensions and support shared evaluation campaigns analogous to SUPERB (Yang et al., 2021) for speech processing. Equally important is validating that proposed metrics predict actual learner improvement, not just reference similarity; longitudinal studies measuring pre/post coaching gains on each taxonomy dimension remain rare and are critically needed.

LLM-augmented coaching and multimodal integration. The success of LLM-based coaching (Aiba et al., 2024; Chen et al., 2025) raises broader questions about how large language models can be integrated across all five taxonomy dimensions. Concrete opportunities include: (a) generating contextualized drill prompts (“Try saying *algorithm* with stress on the first syllable”) that target specific taxonomy dimensions identified by diagnostics; (b) evaluating content faithfulness through semantic similarity rather than word-level WER, enabling tolerance for paraphrasing while still catching substantive omissions; and (c) adapting coaching tone to individual learner profiles and proficiency levels. Recent work shows that speech LLMs can outperform prior baselines for L2 oral proficiency assessment (Ma et al., 2025), suggesting a path toward end-to-end systems that jointly assess pronunciation, prosody, and fluency. However, grounding LLM outputs in acoustically verified evidence, rather than generating plausible-sounding but inaccurate feedback, remains a key challenge. Future systems should also incorporate visual cues (slides, gestures) via vision-language models (Radford et al., 2021; Girdhar et al., 2023) to enable truly multimodal coaching. Extending coaching beyond English to other academic presentation languages (e.g., Mandarin-accented English, multilingual code-switching) requires corpora, phoneme sets, and G2P systems that do not yet exist at scale (Conneau et al., 2021).

Bridging the research and industry gap. Commercial L2 pronunciation and presentation coaching applications have grown rapidly. Platforms such as ELSA Speak and Speechling target segmental pronunciation, while Yoodli and Orai focus on pacing and filler-word reduction for general

public speaking. However, a significant gap exists between research prototypes and deployed systems. Commercial platforms typically address one or two taxonomy dimensions and rarely publish their technical approaches, making systematic comparison with research systems difficult. Furthermore, industry systems face practical constraints, including device heterogeneity, diverse noise environments, and the need for sub-second feedback on mobile hardware, that are rarely addressed in academic evaluations. We recommend that: (a) future surveys explicitly compare commercial and research systems where possible; (b) researchers engage with deployed platforms to identify real-world failure modes that controlled experiments may miss; and (c) standardized evaluation protocols be developed that span both research and commercial systems. The fragmentation between research (which advances methods) and industry (which addresses deployment constraints) could be reduced through shared benchmarks and open evaluation challenges.

8 Conclusion

We have surveyed automated presentation coaching systems, organizing them through a five-dimensional taxonomy (pronunciation, lexical stress, prosody, pacing, and content faithfulness) and mapping 15 representative systems onto this framework. Our comparison (Table 1) reveals that lexical stress and content faithfulness are dramatically under-addressed, that real-time feedback remains rare, and that no existing system integrates all five dimensions. We reviewed the core technical methods, including TTS-based exemplar generation and diagnostic approaches such as GOP/CTC, clone-and-compare, and prosody/pacing metrics, and showed how they relate to the taxonomy. Open challenges include the scarcity of annotated presentation corpora, accent-fair evaluation across diverse L1 backgrounds, the latency constraints of real-time coaching, and the gap between research prototypes and industry deployment. We hope this survey and its associated taxonomy serve as a useful reference for researchers developing the next generation of integrated, evidence-based presentation-coaching systems.

Limitations

This survey has several limitations that should be acknowledged. First, while we aim to cover representative work at the intersection of CAPT, TTS,

and L2 speaking systems, our coverage is not exhaustive; for space reasons we emphasize studies that directly inform pronunciation, prosody, pacing, and comprehensibility for slide-based L2 English presentations. Second, while we synthesize methods from TTS and CAPT domains, we focus primarily on English presentation training; the applicability to other languages and presentation styles (e.g., storytelling, persuasive speaking) requires further investigation. Third, our taxonomy and metrics are derived from existing literature and may not capture all dimensions relevant to real-world coaching scenarios. Fourth, the datasets we curate and recommend are limited in scale; large-scale presentation corpora with diverse accents and domains would strengthen evaluation. Fifth, we discuss voice cloning for personalized references but do not provide empirical comparisons of clone-and-compare vs. expert references across different speaker populations. Finally, while we address ethics and fairness, the practical implementation of accent-fair thresholds and privacy-preserving systems requires more extensive validation in deployed settings.

Ethics Statement

As automated coaching systems become more widely deployed, ethical concerns around fairness, privacy, and data governance are core design requirements. Many surveyed systems collect sensitive voice data and generate personalized feedback, making the following principles essential for trustworthy deployment.

Accent fairness. Calibrate thresholds per L1 cohort to account for systematic phonetic differences (Flege, 1995; Best and Tyler, 2007); report subgroup metrics (e.g., precision/recall by L1) to identify potential biases; and avoid penalizing identity-marking phonetic features (e.g., rhoticity patterns, vowel quality (Wells, 1982; Ladefoged and Johnson, 2015)) when intelligibility is unaffected (Munro and Derwing, 1995; Derwing and Munro, 2005). Systems should help learners improve clarity without erasing accent identity (Isaacs and Trofimovich, 2018).

Voice cloning and data governance. Obtain explicit consent before creating voice clones, clearly explaining how embeddings will be used and stored; encrypt voice embeddings both in transit and at rest; support deletion/expiry mechanisms;

and allow non-clone baselines (e.g., generic TTS or expert references) for users who opt out. For data governance, disclose TTS licenses, avoid retaining raw audio longer than needed (consider on-device processing), and clearly communicate data collection practices.

Prosodic perception. Listener-impression studies (Shoda et al., 2023) highlight that minor pitch/timing adjustments can change perceived competence and speaker traits. Ethical coaching systems should avoid reinforcing biased mappings between prosody, accent, and personas, presenting feedback as optional stylistic guidance rather than prescriptive judgments.

A System Architecture and UI Patterns

Translating the methods and metrics discussed above into a usable coaching system requires careful attention to architecture, latency, and user interface design (Hincks, 2005; Chen et al., 2014). This section outlines practical technical considerations drawing on principles from public speaking pedagogy (Lucas, 2014; Morreale et al., 2014) and computer-assisted language learning (Golonka et al., 2014).

A typical coaching pipeline consists of seven stages: (1) script ingest & glossary extraction; (2) exemplar synthesis (anchor/target bands, emphasis) using modern TTS systems (Chen et al., 2024); (3) user recording in short chunks; (4) alignment (CTC timing (Graves et al., 2006); DTW (Sakoe and Chiba, 1978) fallback); (5) diagnostics (segmental GOP (Witt and Young, 2000)/DTW + prosody/pacing); (6) drill generation; and (7) progress tracking with per-slide thresholds. This architecture generalizes patterns found in prior L2 speaking and presentation systems (Aiba et al., 2024; Shen et al.,

2021; Saito et al., 2023), clarifying the interaction between TTS, diagnostics, and UI components.

To support interactive rehearsal, systems must meet strict latency constraints, targeting sub-second feedback per chunk. This includes TTS rendering in under 200ms for 5–8s text (achievable with non-autoregressive models like F5-TTS (Chen et al., 2024)), alignment and metric computation within 300ms, and UI updates in under 200ms. Privacy-sensitive applications should prioritize on-device inference and defer computationally intensive voice cloning to an offline enrollment step with explicit consent.

Finally, effective coaching interfaces should visualize these metrics through multiple synchronized views: (1) **waveform overlay** with log- F_0 contours (extracted using robust pitch trackers (Zahorian and Hu, 2008)) for comparing learner and reference prosody; (2) **word-level heatmap** color-coded by pronunciation scores (GOP (Witt and Young, 2000) or DTW (Sakoe and Chiba, 1978) distance) to identify problematic segments; (3) **twin playheads** for scrubbing corresponding moments in user and reference audio; (4) **per-slide checklist** highlighting top issues (e.g., “stress on *algorithm*”); (5) **pacing gauge** showing band compliance; and (6) **one-click drills** that auto-loop on error spans for focused practice.

The Aftermath of DrawEduMath: Vision Language Models Underperform with Struggling Students and Misdiagnose Errors

Abstract

Effective mathematics education requires identifying and responding to students' mistakes. For AI to support pedagogical applications, models must perform well across different levels of student proficiency. Our work provides an extensive, year-long snapshot of how 11 vision-language models (VLMs) perform on DrawEduMath, a QA benchmark involving real students' handwritten, hand-drawn responses to math problems. We find that models' weaknesses concentrate on a core component of math education: student error. All evaluated VLMs underperform when describing work from students who may require more pedagogical help, and across all QA, they struggle the most on questions related to assessing student error. Thus, while VLMs may be optimized to be math problem solving experts, our results suggest that they require alternative development incentives to adequately support educational use cases.

1 Introduction

The use of vision language models (VLMs) in education has received increasing attention in both academic research (Küchemann et al., 2025; Lee et al., 2025b) and commercial AI products. Examples of the latter include Google Classroom with Gemini integration,¹ and Khan Academy's AI tutor Khanmigo,² powered by OpenAI models. However, the integration of these models into tutoring and classroom settings often lacks transparent, open, and realistic evaluation. With this gap in mind, we previously released DrawEduMath (Figure 1), a dataset consisting of 2,030 teacher-annotated images of real students' hand-drawn responses to K-12 math problems (Baral et al., 2025). In contrast to other multimodal math understanding

or problem solving benchmarks (Alshammari et al., 2026), DrawEduMath involves noisy, naturalistic data pulled from an online learning platform (Figure 1). In the year since its release, we continuously updated the benchmark's leaderboard³ with newer models.

Our paper offers a snapshot of how 11 VLMs have performed on DrawEduMath in the year after its release (Figure 2).⁴ We surface two key findings:

F1: VLMs are worse at describing the contents of student work that contains math errors than student work without errors.

F2: VLMs still struggle the most on question types related to assessing students' correctness.

These findings suggest that VLMs underperform with students who need additional pedagogical support (**F1**), and they also fail to appropriately identify cases when support is needed (**F2**).

To investigate these patterns further, we conduct five analyses in §4-§8 targeting factors that may relate to model performance. Our experiments show that the performance gap in **F1** persists even when controlling for problem (§4) and when image noise is reduced (§5). In addition, a possible explanation for **F1** is that VLMs expect mathematically correct input images. Indeed, we find that some models' wrongly predicted answers for erroneous student work are similar to gold answers for non-erroneous student work (§6).

We also find that models do improve in assessing student correctness (**F2**) when provided gold natural language descriptions of student work (§7). However, their performance on these questions with extra textual support still lags behind their out-of-the-box performance on other question types. Finally, though models seemingly perform better

¹<https://blog.google/outreach-initiatives/education/classroom-ai-features/>

²<https://www.khanmigo.ai/>

³<https://drawedumath.org/>

⁴DrawEduMath was released to accompany an initial non-archival paper in Dec 2024 (Baral et al., 2024, 2025).

Figure 1: On the left is a math problem, where students are asked to draw $x < 5/2$ on a number line. The right side shows two example student responses that differ in correctness. DrawEduMath pairs each math problem with one student response, and prompts VLMs to answer questions about the student response.

Figure 2: VLMs consistently perform worse on answering DrawEduMath benchmark questions pertaining to erroneous student responses. Performance on non-erroneous student responses (○) is labeled with specific VLMs’ names; that same model’s performance on erroneous student responses is directly below (□). Error bars are 95% CI.

on binary correctness questions (e.g. “Does the student do ___ correctly?”) than open-ended ones (e.g. “What errors does the student make in their response?”), some VLMs’ performance can sometimes be barely better than chance (§8).

Altogether, our in-depth error analysis of VLMs’ performance on real student math responses provides a clearer picture of their current weaknesses in supporting K-12 math education. We release data and scripts for reproducing our findings.⁵

2 Background & Related Work

Multimodal math benchmarks. Mathematical content, rich with diagrams, is ripe for evaluating models’ multimodal abilities. Thus, many vision-language benchmark creation efforts have targeted math (Alshammari et al., 2026; Zhang et al., 2024; Lu et al., 2024; Yan et al., 2025). Educational settings offer additional challenges, where VLMs may be assessed on their abilities to make higher-

level pedagogical inferences and handle handwritten, hand-drawn content (Parsaeifard et al., 2025; Latif et al., 2025; Nath et al., 2025; Nguyen et al., 2025). For example, MathCog asks models to diagnose students’ cognitive skills using binary yes/no questions and a digitally handwritten dataset (Jin et al., 2025). Within this landscape of prior work, DrawEduMath remains a significant evaluation resource, given its diversity of image and question types, its use of noisy, real student work, and its inclusion of experienced teacher annotations (Baral et al., 2025).

AI & student error. Student mistakes and misconceptions have long been a focal point in education research (Smith III et al., 1994; Radatz, 1979; Borasi, 1994; Metcalfe, 2017). With increased attention towards AI as tutors and teaching assistants, research has focused on models’ abilities to identify student error (Srivatsa et al., 2025; Kochmar et al., 2025; Daheim et al., 2024), reason about patterned misconceptions (Rittle-Johnson et al., 2025; Ross and Andreas, 2025), correct errors (Mita et al.,

⁵https://github.com/lucy3/aftermath_drowedumath

2024), and provide feedback (Kaliisa et al., 2026; Botelho et al., 2023; Stahl et al., 2024). There is some research around model robustness to user error, but much of it focuses on linguistic errors in prompts (Gan et al., 2024; Chatterjee et al., 2024). There is little work on how math errors impact model performance: one example is Daheim et al. (2024), who show that language models are worse at verifying the correctness of erroneous student math than non-erroneous math. Our work reaches a similar conclusion across more QA types and with multimodal data, though our results around models’ correctness & error assessments paint a less straightforward picture (§8).

Risks of AI in education. The field of AI & education could be considered a form of AI for “social good” (Cowls et al., 2021), driven by goals that counter AI’s negative impacts on human skill formation and cognitive thinking (Bastani et al., 2025; Klimova and Pikhart, 2025; Shen and Tamkin, 2026; Lee et al., 2025a). However, though its end-goals may be optimistically framed, AI in education is not without risk (Blodgett and Madaio, 2021; Holstein and Doroudi, 2021). Our work is aligned with literature that investigates how AI may disparately impact different student populations (Schaller et al., 2024; Capraro et al., 2024; Hadar Shoval, 2025); our distinct approach is that we group student inputs based on demonstrated math proficiency.

3 Evaluating VLMs with DrawEduMath

3.1 Data

DrawEduMath is an English-language dataset of 2,030 images of students’ handwritten responses to K-12 math problems (Baral et al., 2025). Images are provided by the online learning platform ASSISTments and contain math problems drawn from open educational resources (Heffernan and Heffernan, 2014; Feng et al., 2025). Each image includes a math problem on the left and a student’s response on the right, and is accompanied by three types of data:

1. **Free-form captions** (2.0k+) from teachers describing each student response image.
2. **Synthetic QA pairs** (44.4k+), produced by Claude-3.5 Sonnet and GPT-4o reformatting facets of teachers’ captions into QA, e.g. *On the left-hand side of the image, the student wrote the word syrup → What word did the*

student write on the left-hand side of the image? Syrup.

3. **Teacher-written QA pairs** (11.6k+). Teachers wrote a set of shared questions for each math problem, followed by answers for each student response to each problem. Teachers answered two additional generic questions, *What errors does the student make in their response?* and *What strategy does the student use to solve the problem?* across all problems and student responses.

DrawEduMath includes a taxonomy of seven question types. In our analysis, we simplify this taxonomy into three types: *image creation and medium* (12.3%), *correctness & errors* (8.5%), and *content description* (79.2%). The first two match the benchmark’s original taxonomy, while the third question type is an aggregation of all other question types, ranging from the student’s problem solving strategy to the meaning, positioning, and frequency of drawn/written elements. We aggregate these question types in our main text, because our main findings generalize across more fine-grained types (Appendix A). The original DrawEduMath paper includes additional dataset statistics and QA examples (Baral et al., 2025).

3.2 Evaluation Setup

Scoring metric. Baral et al. (2025) used Mixtral 8x22B to judge the similarity of VLMs’ generated answers to gold answers on a scale of 1 (*quite different answers*) - 4 (*basically the same*), and then binarized these ratings when computing models’ accuracy. As LMs update over time, older ones like Mixtral 8x22B become deprecated in model API services. Thus, all evaluation in our work uses an updated LLM judge. We take the majority vote from three judges: Claude Sonnet 4.5, Gemini 2.5 Pro, and GPT-4o.⁶ Our updated judge achieves similar correlation (Spearman $\rho = 0.808$) with the same set of human judgements as Baral et al. (2025)’s original judge ($\rho = 0.801$). We compute and report binarized model accuracies; 1-2 are counted as incorrect, and 3-4 are correct.

Models. We evaluate 11 VLMs released in 2025 on DrawEduMath. Models span four developers: Open AI (GPT-4.1, GPT-4.5 Preview, o4-mini,

⁶Though GPT-4o is an older model, it has higher individual correlation with human annotations than the two newer models. So, we included it in our set of judges.

Figure 3: Content description QA consistently drives the gap in VLM performance between student responses that contain errors versus those that do not. Appendix A includes additional VLMs that expand this finding.

GPT-5), Anthropic (Claude Sonnet 3.7, Claude Sonnet 4, Claude Sonnet 4.5), Google (Gemini 2.0 Flash, Gemini 2.5 Pro, Gemini 2.5 Pro Preview), and Meta AI (Llama 4 Scout). Though our main findings **F1** & **F2** pertain to all of these models, the analyses in §5-§8 focus on four representative models: Gemini 2.5 Pro, Claude Sonnet 4.5, GPT-5, and Llama 4 Scout.

Labeling student error. To categorize whether students’ math responses contain an error or not, we use teachers’ answers to the question, *What errors does the student make in their response?* We ask GPT-5-mini to interpret each open-ended answer and classify it as *yes*, as in, the teacher describes some error, or *no*, for when teachers’ answers are variations of *There is no error* or *The student did not make an error* (Appendix B.1). We validate this LM annotator on a manually checked random sample of 200 examples (F1 = 0.984, Cohen’s κ = 0.970).

3.3 Main Findings

On average, models tend to perform worse when the student response contains an error (Figure 2). We find that this pattern is mostly driven by content description QA (**F1**, Figure 3). In addition, a weakness reported by Baral et al. (2025) in older VLMs persists in newer ones: questions related to students’ correctness and errors are still the most difficult (**F2**). In the next few sections, we dive into five factors that we hypothesize to relate to these findings: problem effects (§4), image noise (§5),

Model	β_1
Gemini 2.0 Flash	0.0944***
Gemini 2.5 Pro Preview	0.0888***
Gemini 2.5 Pro	0.0889***
GPT-4.1	0.0865***
GPT-4.5 preview	0.0874***
o4-mini	0.0612***
GPT-5	0.0585***
Claude Sonnet 3.7	0.0922***
Claude Sonnet 4	0.0816***
Claude Sonnet 4.5	0.0842***
Llama 4 Scout	0.1013***

Table 1: Estimated effects of student correctness (β_1) on VLMs’ accuracy on content description QA, where all $p < 1.0^{-12}$.

problem response defaults (§6), visual understanding bottlenecks (§7), and question open-endedness (§8).

4 Models underperform on erroneous student responses even when controlling for problem

One possibility is that the model performance gap observed by **F1** is actually not affected by the presence or absence of student error, but rather by some math problems being more difficult for VLMs to understand. DrawEduMath contains 188 unique math problems targeting concepts ranging from geometry to fractions. These problems span multiple grade levels, and on average, each problem has 12.64 student responses (Baral et al., 2025). Here, we show that the effect of student error on VLMs’ content description QA performance is statistically significant even when controlling for problem.

We estimate an ordinary least squares regression with problem fixed effects:

$$y_{ij} = \beta_0 + \beta_1(s_{ij}) + u_j + \epsilon_{ij}$$

In the equation above, y_{ij} is the average score a model has across content description QA for a student response i and problem j , u_j is a fixed effect for each problem, and ϵ_{ij} is the residual. If the student response is correct, $s_{ij} = 1$, otherwise $s_{ij} = 0$. Table 1 presents β_1 values across VLMs. These values show that even after controlling for problem, non-erroneous student responses significantly correspond with higher VLM performance.

Figure 4: An example of how a student response image (top) is transformed and cleaned up by our digital redrawing process (bottom). This student uses a place value chart to show how digit values change for 345 after division by 100.

5 Models’ performance gaps are not strongly impacted by image noise

Another possible explanation for **F1** is that students who make math errors may simply submit noisier images. Students on ASSISTments may submit their answers by drawing digitally, or by uploading photographs of pen & paper work, which may include smudges and blur. In this section, we ask, does the model performance gap described by **F1** remain even when students’ responses are redrawn on a digital canvas in a standardized manner?

5.1 Experimental Setup

Redrawing images is a time-intensive process, requiring careful interpretation of each math problem and the intent of the original student response. So, for this experiment, we stratify sample one erroneous student response and one correct response from each problem, yielding 336 images in total. Though this sample is small, it retains statistically significant gaps in VLM performance on content description QA between erroneous and non-erroneous student response images (Table 2).

To encourage consistency, the lead author redrew all sampled student responses using a digital pen and the drawing application Procreate. This redrawing author retained students’ original positioning of content, and consulted teachers’ captions of images to navigate ambiguity and avoid faulty interpretation of problems and student responses. If needed, the author recreated elements such as graph paper grids and typed content in Figma. Figure 4 provides an illustrative example of how redrawing transforms students’ responses.

Figure 5: Models’ performance for content description QA generally improves after images are redrawn. Error bars are 95% CI.

Model	Original Images	Redrawn Images
Gemini 2.5 Pro	-0.089***	-0.096***
Claude Sonnet 4.5	-0.100***	-0.058**
GPT-5	-0.055**	-0.043**
Llama 4 Scout	-0.092***	-0.073***

Table 2: Differences in average scores on content description QA between erroneous and non-erroneous student images persist after redrawing. ** $p < 0.01$, *** $p < 0.001$.

5.2 Results

On redrawn images, VLMs’ performance shift in the expected direction, where scores generally improve with less image noise (Figure 5). Though requesting students to only submit born-digital content may make their work more interpretable for AI, not all classrooms have resources and policies that make such standardization feasible. In addition, pen-and-paper work remains vital, with studies showing that this traditional mode of learning can sometimes allow students to surpass their digital-only peers (Mueller and Oppenheimer, 2014; Altamura et al., 2025; Anthony et al., 2007; Umejima et al., 2021). Thus, one implication of Figure 5 is that the integration of VLMs in education may disparately impact analog and digital learners.

Importantly, we also find that models’ performance gap between erroneous and non-erroneous student images remains in redrawn images (Table 2). This result complements that of §4, by further isolating student error as a weak point in the use of VLMs in educational settings. Thus,

mitigation efforts around **F1** should focus on improving models’ understanding of erroneous mathematical content, across all levels of image noise and medium types.

6 Models default to assuming error-free math solutions

Why might erroneous student images be so challenging for VLMs? During a manual examination of VLMs’ QA errors, we observed that models sometimes produce plausible, though wrong, answers to benchmark questions, especially considering the context of the provided math problem (Figure 6). This observation suggests a possible explanation for **F1**: VLMs perform better on content description QA for error-free student responses, because models default to assuming error-free math solutions.

6.1 Analysis Setup

To quantify our observation using existing DrawEduMath annotations, we filter for content description QA shared across different student response images for the same math problem. Then, for each incorrect model answer to questions pertaining to erroneous student responses, we compare the model’s answer against true answers for non-erroneous student responses, and see whether the model’s incorrect answer matches the majority of these true ones. We compare model answers using the ensemble LM judge from §3.2. We only consider cases where we have at least two non-erroneous student response images associated with the given question, to ensure that we have sufficient signal of correct student behavior.

6.2 Results

Across four representative VLMs, incorrect model responses for erroneous student responses sometimes do match non-erroneous student solutions, with percentages ranging from 29% of content description QA mistakes for Gemini 2.5 Pro to 35% for Claude Sonnet 4.5 (Table 3). So, a sizable portion of benchmark answers may be inferable based on a math problem and a typical correct solution. There are many more ways a student response can be wrong than it can be correct, and so benchmark QA corresponding to correct student solutions navigate a narrower space of plausible possibilities.

Qualitatively, we observe that models especially tend to predict incorrect answers that match correct problem solutions when benchmark questions

Question How many dots did the student include in their array?	
For an erroneous student response:	
Model answer 12	True answer The student didn't include an array.
True answer for a non-erroneous student response: The student included 12 dots in their array.	

Question How many squares did the student draw to show the number of cups of red paint?	
For an erroneous student response:	
Model answer The student drew 9 squares to show the number of cups of red paint.	True answer The student drew 12 squares to represent the cups of red paint.
True answer for a non-erroneous student response: The student drew 9 squares to show the number of cups of red paint.	

Figure 6: Illustrative examples of the phenomenon where models predict answers for erroneous student responses that match true answers for non-erroneous students.

Model	%	<i>N</i>
Gemini 2.5 Pro	0.2923	1,355
Claude Sonnet 4.5	0.3519	1,921
GPT-5	0.3125	1,357
Llama 4 Scout	0.3060	2,134

Table 3: The percentage of times for which an incorrect model answer for a content description question and erroneous student image matched the majority of true answers for non-erroneous student images. *N* is the number of incorrect model answers in the denominator of the percentage.

involve false presuppositions. Figure 6 illustrates an example; there, the wording of the top teacher-written question assumes that the student has drawn any array at all. Teacher-written questions in DrawEduMath are those that teachers would like VLMs to answer across all student responses to a problem, mimicking potential uses of VLMs for learning analytics. Models’ susceptibility to false premises or suppositions is well-documented in prior work (e.g. Yu et al., 2023; Srikanth et al., 2024), and our work illustrates a consequence of this weakness for education-related applications.

Generally, language models are developed to be good math problem solvers. Math solving benchmarks are continuously emphasized in leaderboards and commercial LM releases (Cobbe et al., 2021; Hendrycks et al., 2021; Google DeepMind, 2025). To encourage mathematically correct outputs and hill-climb on these benchmarks, models are mostly exposed to “high quality”, correct math content during training (Mahabadi et al., 2025; Paster et al.,

2024). The challenge of understanding, but not generating faulty content has received attention in other domains. For example, toxicity is another case of an understanding vs. generation tradeoff; we want models that can detect, address, and understand toxic content, without generating it (Longpre et al., 2024; Wang et al., 2025). Our findings suggest that education is another domain where the application of alternative training methods on erroneous data, such as Wang et al. (2025), could be applicable.

7 Textual support can improve models’ correctness assessments to some extent

DrawEduMath QA range from low-level content description (e.g. “How many triangles did the student draw?”) to higher-level correctness judgments. Now, we move on from examining **F1**, which focuses on content description QA, to digging deeper into **F2**, which pertains to correctness & errors QA. Earlier, we saw that the latter remain difficult even after images are digitally cleaned up (Figure 5). Perhaps, image understanding is a bottleneck for models answering these more reasoning-intensive questions. To what extent can models improve their assessment of student error when given textual descriptions of student work?

7.1 Experimental Setup

As mentioned in §3.1, DrawEduMath includes teacher-written, gold captions of students’ response images. Baral et al. (2025) used these captions to synthetically generate a subset of the QA pairs in the benchmark. If a caption produces synthetic QA that fall in the correctness & error question category, we exclude that image from the current analysis to avoid input-output contamination.⁷ We append to each DrawEduMath input prompt these gold captions (prompt in Appendix C.1), and re-evaluate models’ performance on correctness & error QA. In addition, we also evaluate a setup where we ask models to generate their own descriptions of students’ responses, and provide those captions in place of gold ones.

7.2 Results

Results are in the expected direction, in that VLM performance on correctness & errors QA improves

⁷We remove 262 images out of a total of 2,030. We considered editing captions rather than remove images, but correctness-related content was sometimes integrated with other caption content and would require intensive rewriting.

Figure 7: Model performance on correctness & error (C&E) QA, with and without natural language description (NLD) support. We evaluate with a subset of input images and captions as described in §7.1. Error bars are 95% CI.

with natural language support (Figure 7). However, this improved performance on correctness & errors QA with captions still lags behind VLMs’ caption-less performance in all other question categories for the same set of images. So, it is challenging for VLMs to make higher-level inferences useful for pedagogy even with gold textual support. A fully automatic two step caption-then-answer-QA process is a form of test-time scaling. We find that providing models their own generated captions of images can get models close to, but not match, their performance with teacher-written gold captions (Figure 7).

8 Binary judgements of student correctness remain challenging

Open-ended questions are inherently more difficult than binary (e.g. yes/no) questions, as the latter is more guessable. Correctness & errors QA (**F2**) in DrawEduMath provide a natural testbed for comparing open-ended questions (“What errors does the student make in their response?”) and binary questions that assess whether some aspect of a student’s response is correct/incorrect.

8.1 Analysis Setup

Our analysis splits correctness & error QA into the following three subcategories:

- Generic questions (45.0%). This is the open-ended question that DrawEduMath includes for all student images: “What errors does the student make in their response?”

- Binary assessments of specific solution components (50.4%), e.g. “Does the student put the decimal in the correct place in the product?”
- Other questions (4.5%), which mostly pertain to the nature of a student’s error, e.g. “What incorrect product did the student calculate for 667 times 5?”

We use GPT-5-mini as an annotator to label whether non-generic questions are binary or other (prompt in Appendix B.2). We validate this LM annotator on a manually labeled random sample of 200 unique questions ($F1 = 0.975$, Cohen’s $\kappa = 0.934$). We focus on binary and generic in the main text; Appendix D includes some results involving other.

Do models tend to predict that students make errors when they don’t, or do they tend to overlook errors instead? For binary QA, we use GPT-5-mini to annotate whether questions and gold answers indicate that student is correct or incorrect (prompt in Appendix B.3). For example, for the ground truth binary QA pair “*Q: Is there an error in the way that the number line has been drawn? A: Yes*”, the LM annotator would output that the student is *incorrect*. We validate this LM annotator on a sample of 200 manually annotated random examples ($F1 = 0.911$, Cohen’s $\kappa = 0.854$). In total, the LM annotator labels 59.01% of 2,274 binary QA as cases where the specified aspect of the student’s response is correct, and the rest as ones where the specified aspect is incorrect.

We also examine model performance on generic QA, disaggregated by whether the student’s response is overall incorrect or correct. In DrawEduMath, successfully answering this question for correct students requires simply stating that there is no error, while for models to score well for erroneous students, they must also faithfully describe error specifics.

8.2 Results

Figure 8 shows that performance patterns on correctness & error QA, in relation to student correctness, generally and specifically, tend to be idiosyncratic. Some models tend to overreport errors being present, with lower scores on student images with *no error*. Others struggle to detect and, in the case of generic, articulate errors that are present, with lower scores on student images with *error*. Model behavior patterns are not shared

Figure 8: VLMs’ performance on the two main subtypes of correctness & error QA, disaggregated by whether a student response is overall correct (generic) or correct based on specific aspect of their solution (binary). Error bars are 95% CI.

across model versions from the same family or developer. Figure 8 also indicates that some VLMs’ binary QA scores hover closely around a random baseline of 0.5. Overall, assessing student error is incredibly challenging for VLMs, even though a substantial proportion of correctness & error QA in DrawEduMath have high by-chance floor for performance.

9 Conclusion

Despite increasing attention towards the use of multimodal AI in education, our evaluation of 11 models released in 2025 demonstrates that their application on real student data remains challenging. Our findings suggest that erroneous student work is inherently more difficult for VLMs than correct student work (F1). VLM training and evaluation pipelines that favor correct mathematical content are at tension with the promise of AI for education, where incorrect math requires extra emphasis and attention. We also show that QA involving assessments of student correctness are particularly tricky (F2), across both text and image inputs, and across open-ended and binary question forms.

Though this present paper presents a detailed error analysis of VLMs’ performance on one vision-language K-12 math benchmark, our evaluation approach can be re-applied to other education-related benchmarks as well. That is, the evaluation of AI in education should be disaggregated in a man-

ner that pinpoints whether models can actually discern when a student may need pedagogical support (F2), and whether they equitably serve students across different levels of proficiency (F1). Without a careful eye on the latter, models’ capabilities may be overstated, and rushed integration into classrooms may exacerbate existing academic achievement gaps.

Limitations

Scope and data representativeness. Our study focuses on a single English benchmark, which involves student response images drawn from one online learning platform, ASSISTments. Thus, our findings may not map directly onto other languages and learning contexts. Based on school-level data provided by ASSISTments, we estimate that 85% of images come from Title I schools, which are public schools in the U.S. that receive federal funding to support low-income students. ASSISTments partners with teachers and schools located across multiple location types (e.g. rural, suburban, town, city) and regions (e.g. West Coast, Midwest, East Coast, South), but self-selection is at play when it comes to which teachers, schools, and districts use the platform. DrawEduMath also contains questions that represent what was salient to Teaching Lab’s teacher annotators (Baral et al., 2025); it is not comprehensive of all of the ways in which educators may interpret and support student learning. Still, our high-level evaluation approach can be re-applied to other benchmarks and contexts, because transparency around the impact of student error on model performance is relevant to nearly all education-related settings.

Data and evaluation granularity. We examine performance on DrawEduMath on aggregate with a binary scoring approach, both for students’ correctness and LMs’ VQA correctness. We acknowledge that the evaluation of VLMs may benefit from a more nuanced approach that captures multiple constructs beyond judgments of correct/incorrect. For example, future work should consider the form of student error present (e.g. arithmetic versus conceptual error). Future work should also consider more sophisticated evaluation frameworks that consider the context and complexity of different math problems, and the evaluative goals of different QA items (e.g. QA that pertain to VLMs’ descriptive abilities, versus those that pertain to pedagogical abilities).

Data constraints. Some of our experiments and analyses navigate practical, data-related constraints. For example, our image redrawing experiment in §5 uses a small sample rather than the full dataset, since redrawing is a time-intensive process. Our other analyses rely on pre-existing teacher annotations and data present in DrawEduMath. For example, in §7, we removed some images from our analysis because their captions contained correctness & error information, because models’ performance with textual support on those images would be inflated. In addition, the content description QA under consideration for the results shown in Table 3 are only questions shared across multiple student images for a problem, for which we could gather sufficient signal for what correct student response behavior should be. So, our results in that section (§6) primarily serve to illustrate one possible explanation for models’ performance, and is not comprehensive of all of DrawEduMath.

Ethical Considerations

Education is a high-stakes setting for VLM use and deployment. The intermixing of AI and education involves delegating pedagogy to automated systems, impacting vulnerable underage populations, with possible life-long downstream effects related to economic mobility. Though there is optimism around AI’s ability to support education (Demszky et al., 2025), there should also be caution that it does not exacerbate existing inequities or introduce new ones (Winters et al., 2020; Harvey et al., 2024). We acknowledge that our work focuses primarily on technical harms measurable from model outputs, and does not capture broader harms that may emerge via interaction of AI with students, teachers, and school systems (Harvey et al., 2025). In addition, AI research often involves a deployment-first mentality, where deployment may occur before a system has been deemed functional or necessary (Raji et al., 2022). Our work advocates for robust evaluation and auditing of AI prior to deployment (Raji et al., 2020), and accountability behind claims around model functionality and its social benefits (Kou et al., 2025; Wang et al., 2024).

Acknowledgments

We are grateful for valuable feedback from Douglas Jaffe, who encouraged us to dig further into the impact of student error on model performance. We are also grateful for data-related support from Sami

Baral, Neil Heffernan, and Cristina Heffernan. Our work is funded by the Gates Foundation.

A Model Performance by Question Type

In the main text, Figure 3 shows that the gap in VLM performance between erroneous and non-erroneous student responses is primarily driven by content description QA. Figure 10 expands upon that finding, by disaggregating content description QA’s overall pattern into finer-grained question categories and showing results for all 11 VLMs. Across these expanded plots, we see that the performance gap between erroneous and non-erroneous student responses persists across finer-grained content description QA categories.

B Language Model-Assisted Data Annotation

For each LM-assisted labeling task, we iteratively developed prompts that yield solid performance on small samples, before validating our final prompts on larger samples. The main text details the performance of each prompt on the intended task.

B.1 Student Error

One of our main findings, **F1**, pertains to how models perform differently between student responses that contain errors versus those that do not. To

determine whether a student response contains an error or not, we rely on teachers’ free-form descriptions of student error. Since teachers’ written responses may span a variety of phrasings, we use GPT-5-mini to decisively label whether the teacher indicates that the student response contains an error. Here, *ans* is the teacher’s answer to the question, *What errors does the student make in their response?* We use the following prompt:

When asked about what errors a student makes in their response to a math problem, a teacher writes, '{ans}'. Based on the teacher's feedback, does the student make any error? Respond 'yes' or 'no'.

B.2 Finer-grained Correctness & Error Questions

In §8.1, we discuss how correctness & error QA span both binary assessments of specific student errors and more-open-ended questions. We use GPT-5-mini as an annotator to label whether each Correctness & Error question is binary or other. We use the following prompt:

Is the following question a binary question that asks whether a student does something correctly or not?
Question: '{question}'
Decide whether the question above is a binary question that judges a student's correctness. Your response should start with 'Yes' or 'No':

B.3 Binary Student Correctness

In §8.2, we’re interested in investigating whether models tend to under- or over-report student error on binary correctness & error questions. We use GPT-5-mini to annotate whether binary QA’s questions and gold answers indicate that student is correct or incorrect. We use the following prompt:

Teacher A is examining a student's solution to a math problem. Teacher B asks Teacher A, '{question}'
Teacher A says, '{answer}'.
Does this exchange indicate that the student's solution has an error? Respond "yes" or "no":

Figure 9: VLMs’ performance across different subtypes of correctness & error questions, as defined in §8.1.

C Natural Language Description Experiments

In §7, we investigate whether the inclusion of textual descriptions of students’ work can support VLMs’ abilities to make higher-level inferences around students’ correctness and errors.

C.1 Prompts

Our prompt that adds in natural language descriptions/captions is intuitive and simple:

```
Description of image:
{caption}

Answer the following question: {question}
```

To generate descriptions or captions using language models, we use the following prompt: Describe the Student Response on the right side of the image in one paragraph.

D Additional Correctness & Error Results

The relative performance ranking of binary, other, and generic correctness & error QA is consistent across all 11 VLMs (Figure 9).

Figure 10: An expanded version of Figure 3, showing which question categories contribute to the gap in VLM performance between student responses that contain errors versus those that do not. Questions below the dotted line in each subplot are content description QA.

Criterial Features in German: Towards Interpretable NLP in Readability Assessment

Abstract

This paper presents an empirical evaluation of the German Grammar Profile (GGP), a CEFR-aligned resource of criterial features, and its corresponding extraction system PALME.

We design a systematic test suite in which each feature extractor is evaluated on controlled positive and negative examples. The results show that PALME achieves high precision and recall across all CEFR levels, with over 90% of features achieving scores above 0.8. Qualitative analysis shows that lower performance primarily results from morphological ambiguity in noun and adjective case marking.

To evaluate the usefulness of the criterial features of the GGP for CEFR-aligned readability assessment, we assess their predictive power using Explainable Boosting Machines on graded readers. The model achieves strong performance (precision: 0.75, recall: 0.73). Our qualitative analysis shows that features related to specific verb constructions follow patterns consistent with developmental stages predicted by Processability Theory. These findings underline the value and relevance of criterial features for modeling language development in readability assessment.

1 Introduction

The quality of available language input plays an important role in second language acquisition (SLA), with reading serving as a crucial source of input. Automatic Readability Assessment (ARA) aims to predict the readability of a text and can support teachers in selecting appropriate texts more efficiently. Different approaches to ARA have been implemented in the past, including approaches based on surface-based readability formulas (Collins-Thompson, 2014), or using machine learning methods based on aggregated language characteristics (Weiss and Meurers, 2021; Vázquez-Ingelmo et al., 2026). These approaches typically assign a level to

an entire text, allowing for a holistic view of readability. However, while such methods often achieve strong predictive performance, they offer limited insight into the specific language constructions in a text that contribute to its difficulty. This limitation is particularly relevant in language education, where on the one hand input needs to be comprehensible to be effective, but it should also systematically offer developmentally proximal language structures, as pointed out by SLA approaches since the *i+1* Input Hypothesis of Krashen (1985) and Pienemann’s Teachability Hypothesis (Pienemann, 1989, 2015).

Criterial features (CFs; Hawkins and Buttery, 2010; Hawkins and Filipović, 2012) have been proposed as more linguistically and pedagogically grounded measures for proficiency and ARA. They play a central role in operationalizing the Common European Framework of Reference for Languages (CEFR; Council of Europe, 2020). As CEFR descriptors define purely communicative competences in the form of language-agnostic Can-Do statements, they deliberately refrain from specifying concrete linguistic realizations. Reference level descriptors aim to capture links between linguistic properties of texts or learner production and CEFR levels, and CFs are linguistic properties that are characteristic of specific stages of proficiency. CFs can thus be understood as an attempt to characterize the communicative purposes of CEFR descriptors linguistically, making them measurable and analyzable using computational linguistic methods.

For English, the English Grammar Profile (EGP, O’Keeffe and Mark, 2017) offers a resource of CFs that link linguistic aspects to CEFR levels. The EGP has been used as starting point to build computer-based systems to automatically extract those features (Sagirov and Chen, 2025). For German, comparable resources such as the German Grammar Profile (GGP) and the corresponding extraction system PALME exist, but they have not yet

been systematically evaluated or empirically validated (Löfflad et al., 2025). However, the lack of systematic evaluation leaves open questions about both the reliability of feature extraction and the validity of the underlying features. This raises two key questions: How can such systems be evaluated, and how can the underlying features be validated?

In this paper, we address these gaps by proposing (i) systematic methods for evaluating and validating CF-based system from both technological and pedagogical perspectives, (ii) a dedicated resource for evaluating German CF extraction systems, including potential applications for Large Language Models (LLMs), and (iii) a contribution to the theoretical understanding of CFs through a comparison with developmental trajectories (Pienemann, 1998). More broadly, we aim to provide a framework that can be transferred to other languages, supporting the extension of CEFR- and CF-related resources.

We investigate the computational operationalizability and empirical validity of CFs as indicators of CEFR readability in German graded readers and ask two research questions:

- RQ1 How can criterial features reliably be operationalized and automatically extracted?
- RQ2 To what extent do automatically detected criterial features predict CEFR levels and link to developmental trajectories?

To address the first question, we construct a systematic test suite of example sentences to evaluate the automatic extraction system PALME. For the second question, we use PALME to extract all 153 CFs in the GGP from a graded reader corpus and train an Explainable Boosting Machine (EBM) to predict readability levels. The EBM further enables us to analyze developmental trajectories and examine how CFs evolve across readability levels.

2 Background

2.1 Criterial Features and Developmental Trajectories

Criterial features reflect linguistic properties that are reliably acquired at specific stages of second language development and can thus serve as indicators of proficiency (Hawkins and Buttery, 2010) and are typically aligned with the CEFR. Recent research has increasingly turned to criterial features as a concrete, developmentally informed and transparent possibility to measure linguistic phenomena (Salamoura and Saville, 2010; Hawkins

and Filipović, 2012; Gaillat et al., 2022). The goal of criterial feature research is to identify the linguistic phenomena that formalize underspecified descriptors as part of a more systematic resource.

Developmental trajectories (also stages or themed sequences) assume that certain grammatical aspects are acquired in predictable sequences. One influential theoretical framework, the Processability Theory (PT), proposes that the acquisition of grammatical structures follows a hierarchical order (Pienemann, 1998). Although criterial feature research aims to capture developmental trajectories, the relationship between trajectories and CEFR descriptors is still under-researched. Previous studies have analyzed the acquisition trajectories of individual grammatical constructs in detail (e.g., Wisniewski, 2020). Importantly, developmental trajectories are primarily based on learner language production. Nevertheless, they should also be examined in reading input such as graded reading materials, which are designed to slightly exceed the learner’s current competence (i+1, Krashen, 1985). Since graded readers are pedagogically designed to align with learner proficiency levels, the distribution of criterial features in such texts should, in principle, reflect the developmental stages associated with those levels.

The EGP offers a well-established resource of criterial features for English (O’Keeffe and Mark, 2017), expanding on CEFR descriptors by mapping them onto fine-grained grammatical structures. There is work for other languages to develop reference level descriptors (Mohamed, 2023; Cuberos Vicente and De Cock, 2023), however, the EGP is a unique resource of language-specific grammatical features. Nevertheless, a similar yet smaller resource for German was developed by Löfflad et al. (2025) as described in the following.

2.2 The German Grammar Profile

The GGP (Löfflad et al., 2025) is a resource of German criterial features developed on the basis of the English Grammar Profile (EGP, O’Keeffe and Mark, 2017) and the *Profil Deutsch* (Glaboniat, 2010), a functional grammar for German as a second language learners and teachers. Following a theory-driven approach, the GGP defines a set of 153 criterial features mapped to CEFR levels based on the functional grammar provided by Glaboniat (2010), and not derived from corpus data (example features can be seen in Appendix A). Of these 153 features, 47 are assigned to level A1, 49 to

level A2, 35 to level B1, and 22 to level B2. The distribution of features across levels is somewhat imbalanced. This is partly due to fewer new grammatical features being introduced at higher levels and partly because higher level features tend to be usage-based, which is not in the scope of the GGP. Nevertheless, this can impact subsequent data analyses, as A level features might be more prominent.

Moreover, the theory-driven approach used to create the GGP, in contrast to the data-driven approach used in the development of the EGP, may lead to mismatches between the levels assigned in the GGP and the levels observed in graded readers or learner data. Such mismatches are plausible given that previous research on the EGP has already found limited agreement between statistically derived feature mappings and the mappings proposed by the EGP (Verratti-Souto et al., 2025).

2.3 The PALME System

To automatically extract the measures defined in the GGP, Löfflad et al. (2025) developed the PALME system, the *Pedagogically Oriented Linguistic Feature Extraction* (*Pädagogisch Ausgerichtete Linguistische Merkmalsextraktion*). PALME relies on rule-based NLP components. While designing such components is labor-intensive, it offers advantages in comparison to Generative AI in terms of reliability and transparency. Once the system has been systematically tested, its behavior is predictable and performance does not depend on changes in black-box AI models.

The system is related to other approaches supporting automatic grammatical feature extraction and annotation. The POLKE system (*Pedagogically Oriented Language Knowledge Extractor*, Sa-girov and Chen, 2025), for example, extracts more than 600 measures from the EGP using a comparable rule-based framework that includes Java and RUTA-based preprocessing. POLKE primarily focuses on the large-scale implementation and evaluation of EGP-based measures. For Portuguese, the SABER system (*Sistema de Análise e Busca de Estruturas Relevantes*, Akef et al., 2025) provides a related approach to grammatical feature extraction.

2.4 Test Suite vs. Corpus-Based Evaluation

Test suite-based evaluations inherently differ from corpus-based evaluations: While corpus-based evaluations assess systems on naturally occurring language data, test suites consist of carefully constructed, focused examples of language use

(Lehmann et al., 1996; Prasad and Sarkar, 2000). Both methods come with advantages and disadvantages. Corpus-based evaluations facilitate testing a system’s robustness against authentic language and are well-suited for frequent linguistic constructs. However, many linguistic constructs occur only rarely in natural data. Test suites address this limitation by supporting a controlled evaluation that systematically evaluates the coverage of specific constructs (Lehmann et al., 1996).

For a similar extraction system for English, Sa-girov and Chen (2025) used a corpus-based evaluation approach. They randomly selected 15 features for each CEFR level and automatically extracted sentences containing the respective features from the Corpus of Contemporary American English (Davies, 2009). In addition, they randomly selected sentences that did not contain the feature as negative examples.

3 Methods

3.1 System Evaluation

To evaluate the system and answer RQ1, we opted for a test suite-based approach. This allowed us to control the evaluation sentences, particularly the negative examples, enabling us to construct challenging cases that stress-test the system. Moreover, our goal was to evaluate every measure extracted by PALME. As mentioned previously, some features occur only rarely in natural language data, which makes them difficult to capture reliably through corpus-based sampling. Although there are, to the best of our knowledge, no widely accepted guidelines on writing test suites, Balkan et al. (1994) recommend to include both positive and negative examples of the target feature. They further suggest covering a range of instantiations and to intentionally add misleading inputs and traps for the system. We thus constructed a systematic test suite consisting of positive and negative examples for each feature in the GGP. For every feature, the test suite contains ten sentences: five positive examples that include the target feature and five negative examples that do not.

To ensure variability and linguistic diversity, the sentences were developed collaboratively by three experts: the first author, the second author as a natural language processing (NLP) expert, and a pedagogical expert in second language teaching. The positive examples were informed by reading and learner corpora, but were adapted or constructed

where necessary to ensure controlled evaluation, for example by avoiding multiple instances of the same feature or by including theoretically motivated constructions. We deliberately included different structural and lexical realizations of each feature to capture its range of possible realizations. For the negative examples, we constructed sentences that were closely related to the target feature, either structurally, linguistically, or pedagogically, but did not actually instantiate it. For example, in the case of adjectival case marking without an article, accusative constructions were contrasted with structurally parallel sentences in other cases. Similarly, for verbal features, negative examples were designed to resemble the relevant constructions while differing in tense, agreement, or syntactic realization. This design ensured that the evaluation tested the system’s ability to distinguish subtle contrasts. After constructing the test suite, we evaluated the system’s performance on all features. We computed precision and recall for each feature and identified those with scores below a threshold of 0.8. As each feature is represented by five positive and five negative examples, a score of 0.8 or higher corresponds to at least four correctly classified instances within a set of five (i.e., at most one error). These features were subsequently revised and improved, and the sentences targeting the revised features were updated with new examples to prevent overfitting to the original test sentences. Following each revision cycle, the system was re-evaluated on the test suite. Features that continued to fall below the performance threshold were further refined. This iterative process was conducted for two improvement cycles and concluded with a final evaluation. Although additional cycles might have led to further performance gains, we stopped after the third evaluation round to minimize the risk of overfitting the system to the test suite.

3.2 Feature Validation

After completing the system optimization phase, we validated the extracted CFs on graded reader data to answer RQ2. We used texts provided by *Deutsch Perfekt*¹, a magazine that publishes reading materials for second language learners.

While this dataset does not consist of learner production, graded reading materials provide an approximation of proficiency levels and are therefore a suitable starting point for evaluating the usefulness

of criterial features in readability classification. Given that this study represents an initial step toward a broader validation of CFs, we focus here on input texts, which play a central role in language development. In line with pedagogical principles such as the *i+1* hypothesis (Krashen, 1985), reading materials should be designed to be just above the learner’s current proficiency level, thereby reflecting increasing linguistic complexity across levels.

The corpus is categorized into three proficiency levels: easy (approximately CEFR A2), intermediate (approximately B1), and advanced (approximately B2/C1). In total, the dataset consists of 4,906 texts spanning these proficiency levels. Table 1 shows a descriptive overview of the corpus.

Level	Num. Texts	Num. Tokens
Easy	2,535	447,287
Intermediate	1,463	830,158
Advanced	908	461,446
Total	4,906	1,738,891

Table 1: Overview of the Deutsch Perfekt corpus

The classes are imbalanced, with most tokens in the corpus being part of texts in the intermediate class. We conducted a predictive evaluation by training an Explainable Boosting Machine (EBM) on the extracted CFs to predict CEFR levels using an 80–20 train–test split. We normalized raw feature counts by calculating feature occurrences per 1,000 tokens to control for differences in text length. EBMs are generalized additive models that learn each feature function using gradient boosting and maintaining additive structures, thus enabling high interpretability (Nori et al., 2019; Lou et al., 2013). EBMs train each feature function one at a time, allowing for each feature function to be examined individually. They belong to so-called "glassbox" models providing transparent feature effects, in contrast to post-hoc explanation methods (e.g., LSTMs or SVMs). Using EBMs instead of other machine learning models allowed us not only to assess predictive performance but also to interpret the contribution and shape of individual features in relation to proficiency level.

4 Results

4.1 System Evaluation

We first report system performance aggregated of CFs by CEFR level in order to assess overall robustness across proficiency bands. Table 2 presents

¹<https://www.spotlight-verlag.de>

precision, recall, and F1 scores for A1–B2. Performance is consistently high across proficiency levels, with precision ranging from 0.956 (A1) to 0.981 (B1). Recall shows a slight decrease with increasing proficiency, ranging from 0.932 at A1 to 0.855 at B2.

Macro-averaged performance across levels yields a precision of 0.968, recall of 0.886, and an F1 score of 0.925. Micro-averaged performance across all 1,530 instances is similarly high. Our results are in line with those reported by [Sagirov and Chen \(2025\)](#) for the POLKE system, indicating state of the art performance.

Level	Precision	Recall	F1	N
A1	0.956	0.932	0.944	470
A2	0.978	0.894	0.934	490
B1	0.981	0.863	0.918	350
B2	0.959	0.855	0.904	220
Macro Avg.	0.968	0.886	0.925	–
Micro Avg.	0.969	0.893	0.929	1530

Table 2: Precision, recall, and F1 scores per CEFR level. Macro averages are computed across levels; micro averages are computed across all instances.

Across the 153 evaluated measures, 138 measures (90.1%) achieved both precision and recall values of at least 0.8. Table 3 lists the 15 measures (9.9%) that fell below this threshold in at least one of the two metrics. As described in Section 3, the threshold of 0.8 corresponds to at most one error within the five positive or five negative test instances per feature. Table 5 in Appendix A

shows feature descriptions from the GGP and examples sentences in German and English for all features discussed in this paper.

Overall, the results indicate robust and reliable detection performance for the large majority of measures. The measures with lower scores are largely explainable. Several involve case marking (e.g., adjectival inflection without an article or genitive marking), which depends on accurate morphological analysis. We found that the taggers are currently not able to reliably annotate the accusative case, as the form is often similar to the nominative case, which leads to subsequent errors in the rule-based system.

Feature 32148 (subjunctive II) is primarily form-based and involves subtle semantic distinctions that are difficult to operationalize computationally. The comparatively lower recall for *indefinite pronouns* (3168) is less immediately expected and warrants further inspection. Importantly, precision is consistently high across measures, with the large majority reaching a value of 1.0. This indicates that false positives are rare. For subsequent corpus-based analyses, this is particularly desirable, as it minimizes the risk of overestimating the frequency of linguistic structures. A full table of performance for all features can be seen in Appendix B – each feature is assigned a construct ID that encodes the CEFR level: IDs beginning with 21 correspond to A1 features, 22 to A2 features, 31 to B1 features, and 32 to B2 features.

ID	Level	Feature	Precision	Recall
3132	B1	Superlative of B1 level adverbs	1.00	0.20
2264	A2	Adjectives in the accusative after zero articles	1.00	0.40
2268	A2	A2 level Indefinite Pronouns	1.00	0.40
32148	B2	Subjunctive II	1.00	0.40
2111	A1	Negation article ‘kein’ in the accusatives	1.00	0.60
2113	A1	Personal pronouns in the accusative	0.75	0.60
2263	A2	Adjectives in the nominative after zero article	1.00	0.60
2265	A2	Adjectives in the dative after zero article	1.00	0.60
2281	A2	Past Participle	1.00	0.60
3168	B1	B1 level Indefinite pronouns	1.00	0.60
31120	B1	Articles in genitive case	1.00	0.60
3134	B1	Adverbial temporal determinations	1.00	0.60
3256	B2	Genitive after indefinite article	1.00	0.60
3257	B2	Genitive after zero article	1.00	0.60
2282	A2	Perfect Tense	1.00	0.60

Table 3: Precision and recall scores for features below the 0.8 threshold in at least one metric.

4.2 Feature Validation

We evaluated the predictive performance of the extracted criterial features for regression as well as classification models, using EBM for both approaches. Results are reported in Table 4. In addition, we report global and feature-specific results from the EBM. In the regression setting, the model achieved a Root Mean Squared Error (RMSE) of 0.501 and a Mean Absolute Error (MAE) of 0.396. To enable comparison with the classification setup, regression predictions were rounded to the nearest CEFR level. Under this discretized evaluation, the model achieved an accuracy of 0.704, a macro-averaged F1 score of 0.667, a macro-averaged precision of 0.692, and a macro-averaged recall of 0.656. In the classification setting using an EBM, the model achieved an overall accuracy of 0.769. Macro-averaged F1 was 0.740, with a macro-averaged precision of 0.750 and a macro-averaged recall of 0.733. Direct comparison of the regression results and the classification model shows higher performance for the classification approach across all reported metrics. Subsequent analyses are therefore based on the classification model.

Category	Metric	Value
Regression	RMSE	0.501
	MAE	0.392
Classification	Accuracy	0.769
	F1 (macro)	0.740
	Precision (macro)	0.750
	Recall (macro)	0.733
Regression	Accuracy	0.711
	F1 (macro)	0.678
	Precision (macro)	0.724
	Recall (macro)	0.665

Table 4: Model performance metrics for regression, classification EBM, and rounded regression outputs.

Figure 1 shows the confusion matrix for the classification model. Consistent with previous findings (e.g., Lagutina et al., 2023), most errors occur between adjacent levels, especially at the intermediate level. This is especially interesting considering the class imbalance: As most data exists for the intermediate level, it would be expected that the model tends to overestimate this level, which is not the case for this model. Misclassifications spanning two levels are comparatively rare. Interestingly, recall for A1 level is surprisingly high, and the

confusion matrix shows that, if misclassified, intermediate texts are more frequently classified as easy texts, meaning that the models has a slight tendency to underestimate CEFR levels.

Figure 1: Confusion Matrix showing results in percent for the classification model.

It is important to note that there currently is no work on using German CFs as features for machine learning classifiers, however there is work using linguistic complexity measures. Our results are lower than classification results reported in previous work on linguistic complexity for German on the same corpus (Weiss et al., 2021), but are comparable to studies using criterial features for English classification tasks (Gaillat et al., 2022).

Figure 2 shows the development of the ten most strongly changing B1/B2 features across the three readability levels. Overall, most features show a

Figure 2: Developmental trajectories of B1 and B2 features with strongest development.

clear increase from easy to advanced texts, indicating that higher-level grammatical constructions tend to occur more frequently in more difficult texts. The overall trend suggests that the frequency of B1/B2 features increases with text difficulty, as

would be expected. The strongest increase is observed for feature 31109 (simple past), which rises substantially from easy to advanced texts. One interesting observation is the development of feature 3131 (comparative of B1-level adverbs), which shows a slight decrease across levels.

As can be seen in Figure 3, global term importances derived from the EBM (mean absolute weighted scores) indicate that features 31109 (simple past) and 2182 (perfect tense of A1 verbs) were the most influential predictors. These were fol-

Figure 3: Global term importances for ten most informative features derived from the EBM.

lowed by features 2116 (A1 level verbs in present tense), 2118 (*to be* in present tense), 2112 (nominative of personal pronouns), 2105 (nominative of A1 nouns), 3203 (B2 level conjunctive adverbs), 2274 ("that" clauses), 2117 (*to have* in present tense), 2206 (relative pronouns in nominative case), 32135 (*to become* in passive present tense), 32148 (sub-junctive II), and 2281 (past participle).

Figure 4 shows the learned score contributions of feature 2182 and 31109. For feature 2182 (perfect tense of A1 verbs), the contributions vary across its observed frequency range (0–42). The distribution of this feature shows a concentration of observations in the lower frequency intervals. As the frequency of feature 2182 increases, the model increasingly favors class 1 (easy) while simultaneously decreasing the likelihood of class 3 (advanced), with class 2 (intermediate) exhibiting comparatively small changes. Thus, higher frequencies of feature 2182 are strongly associated with class 1 predictions, whereas low frequencies are more indicative of class 3.

For feature 31109 (simple past), score contributions vary across its observed frequency range (0–155), with most observations concentrated in the lower frequency intervals. In contrast to feature 2182, increasing frequencies of feature 31109 strongly increase the likelihood of class 3 (advanced) while reducing the likelihood of class 1

Figure 4: EBM shape functions and value distributions for the two most informative features. Top: Feature 31109. Bottom: Feature 2182. The upper panels show the learned score contributions across feature values, and the lower panels show the empirical value distributions.

(easy), again with comparatively smaller effects for class 2 (intermediate). High frequencies of feature 31109 therefore act as a strong indicator for class 3. As seen before, of all B1/B2 level features, feature 31109 also showed the strongest increase from easy to advanced texts. The results will be discussed in the following.

5 Discussion

This study addressed two research questions concerning the operationalization and predictive power of CFs for German. Overall, the analyses provide promising results that CFs can be operationalized computationally and that they capture meaningful aspects of language development.

Regarding RQ1, the results indicate that CFs can be reliably operationalized and automatically detected. The results across CEFR levels indicate that the system maintains very high precision across all proficiency levels, meaning that identified structures are highly reliable. The decrease in recall at higher levels likely reflects increasing linguistic complexity, which introduces greater structural variation and thus poses additional challenges. Moreover, 90% of individual features achieve precision and recall above 0.8. This demonstrates that the linguistic constructs defined in the GGP can be translated into computational rules and identified in language data. In addition, the use of a targeted test suite proved to be a useful methodology for

evaluating the performance of the extraction system, as it allowed us to systematically assess the performance of individual features and to improve the system cyclically, incorporating challenging negative examples.

With respect to RQ2, the results show that automatically detected CFs provide meaningful information for predicting CEFR levels. Several CFs were found to be highly informative for the EBM classifier. Notably, the most informative feature was the use of simple past (31109), followed by the perfect tense (2182), which involves the characteristic German split verb construction. Two additional features related to the split verb construction (2281, past participle and 32135, *to become* (*bekommen*) in passive present tense), also appeared among the most informative predictors. These findings suggest that verb-related features play an important role in distinguishing CEFR levels and reflect developmental patterns in second language acquisition.

An interesting observation concerns the distribution of the perfect tense feature of A1 level verbs (2182). While constructions involving the perfect tense and participle formation are theoretically related to the German split verb pattern, the model indicates that feature 2182 is particularly associated with easier texts, corresponding roughly to A2 levels. This appears to diverge from predictions made by PT, where verb-splitting phenomena are expected to emerge only at stage three (out of five stages) of the developmental hierarchy (Pienemann, 1998). One possible explanation is that certain perfect tense forms, particularly with high-frequency verbs such as *to be* (*sein*) and *to go* (*gehen*) (e.g., *I went*, *Ich bin gegangen*), may be introduced early in language instruction as formulaic constructions for communicative purposes. Learners may therefore acquire these forms initially as fixed expressions rather than as fully productive grammatical structures. In this sense, the presence of perfect tense forms in lower-level texts does not necessarily indicate that learners have acquired the underlying verb-splitting mechanism. Instead, the productive use of separable verb constructions may still develop later, in line with the predictions of developmental theories such as PT.

The results also show the importance of case marking (features 2112, 2105 and 2208, respectively, personal pronouns, nouns, and relative pronouns in nominative case), which showed as highly informative features in the classification model. In

PT, case marking is treated as a diacritic feature associated with a lexical item, rather than being a central developmental structure. However, previous research has highlighted the importance of morphological development for German L2 learners (Weiss, 2024), and the functional grammar underlying *Profile Deutsch* (Glaboniat, 2010) also assigns a prominent role to case marking. Our results provide further empirical evidence supporting this, suggesting that case marking contributes to distinguishing readability levels in graded readers.

As briefly mentioned in Section 4, classifiers based on linguistic complexity measures achieve higher performance on the same corpus than the approach presented in this paper (Weiss et al., 2021). This difference can be attributed to several factors. First, Weiss et al. (2021) extract a large set of over 300 features capturing multiple linguistic dimensions, including syntactic, lexical, and discourse-level properties. Second, linguistic complexity measures are inherently aggregative, which may be better suited for classification tasks. Finally, differences in model architecture, such as the use of Support Vector Machines (SVMs) compared to EBMs, may also contribute to performance differences. Nevertheless, criterial features offer distinct advantages that make them particularly valuable in educational contexts. In contrast to complexity measures, CFs provide a transparent and linguistically grounded representation of language, as they can be directly linked to CEFR levels and interpreted in terms of developmental trajectories. This allows for a more fine-grained and interpretable analysis of learner-relevant structures, which is not straightforward with aggregative complexity measures.

From a pedagogical perspective, the GGP and the PALME system enable targeted readability assessment by identifying whether a text is suitable for a specific learner group (e.g., B1 learners of German), while also highlighting specific linguistic structures that contribute to its difficulty. This opens up possibilities not only for text selection but also for diagnostic applications, such as identifying particularly challenging constructions within a text. At the same time, the two approaches are not mutually exclusive. Combining criterial features with linguistic complexity measures may lead to more robust and accurate classification systems, while preserving interpretability and pedagogical relevance.

6 Future Work

Several directions for future research emerge from the present study. First, the test suite developed for evaluating the automatic detection of CFs could be used to assess the capabilities of LLMs in identifying and analyzing linguistically motivated grammatical constructs. In particular, LLMs could be explored as a complementary approach in cases where rule-based detection proves difficult or insufficient. Another approach to address limitations of upstream tagging could be to explore the use of constituency parsing. Second, the test suite could be expanded to include authentic learner language data. Incorporating learner corpora would allow us to assess how well the system performs on naturally occurring learner language and to examine how CFs manifest in real learner production. Third, future work could investigate the relationship between automatically detected CFs and CEFR level assignments in more detail. Following approaches such as Verratti-Souto et al. (2025), statistical analyses would contribute to a better understanding of how closely criterial feature mappings correspond to actual proficiency development.

7 Conclusion

In this paper, we presented a systematic, test suite-based method to evaluate rule-based feature extractions systems by analyzing the reliability of the PALME system. We showed that PALME reliably extracts 90% of the extracted features with precision and recall above .8 using positive and negative examples. We moreover used the system to analyze graded reading material, thus contributing to interpretable ARA.

The findings indicate that criterial features capture aspects of developmental trajectories, but they also extend beyond them. PT predicts that certain grammatical phenomena emerge at specific stages of development, such as the split verb pattern associated with separable verb constructions. Our results partially align with these predictions. At the same time, the model also relies on a broader set of linguistic constructs, including morphological features. This suggests that criterial features not only reflect developmental stages but also capture additional dimensions.

8 Limitations

While the present study provides promising results, several limitations point to important directions for

future research. First, the evaluation of the PALME system is based on a manually constructed, corpus-informed test suite rather than a fully authentic corpus. Although this allows for controlled testing of individual features, it may not fully capture the variability of real-world language use. In addition, each feature is represented by only a small number of examples, which constrains the range of linguistic realizations covered.

Second, the system depends on upstream preprocessing components such as part-of-speech tagging and parsing. Errors in these components may propagate and affect feature detection, particularly for more complex constructions.

Third, the validation of criterial features is limited to a single corpus of graded readers, raising questions about the generalizability of the findings across different corpora and text types. Future work should therefore investigate cross-corpus performance to assess the robustness of the approach.

Finally, the study does not include learner language data. While graded readers approximate proficiency levels, they do not fully reflect actual learner production. Evaluating the system on learner corpora would therefore provide a more direct validation of criterial features as indicators of language development.

Acknowledgments

We would like to thank the LEAD Graduate School and Research Network for its support. Our research was supported by the WoLKE project (Ministerium für Wissenschaft, Forschung und Kunst Baden-Württemberg) and the EU Project LATILL (Level-Adequate Texts in Language Learning, Reference number 2021-1-AT01-KA220-SCH-000029604). We also thank Sarina Doster for her contribution to the development of the test suite.

A Appendix

ID	Level	Feature	Example	Translation
2105	A1	Nominative of A1 Nouns	Die Frau arbeitet.	The woman is working.
2111	A1	Negation article 'kein' in the accusatives	Er sieht keinen Hut.	He has no hat.
2112	A1	Nominative of Personal Pronouns	Ich wohne in Tübingen.	I live in Tübingen.
2113	A1	Accusative of Personal Pronouns	Sie besucht ihn .	She visits him .
2116	A1	Present Tense of A1 Verbs	Wir fahren nach Hause.	We drive back home.
2117	A1	<i>to have</i> in Present Tense	Wir haben das nicht.	We do not have that.
2118	A1	<i>to be</i> in Present Tense	Es ist Donnerstag.	It is thursday.
2182	A1	Perfect Tense of A1 Verbs	Ich habe das Buch gelesen .	I have read the book.
2206	A2	<i>Nominative of Relative Pronouns</i>	Die Frau, die ich sehe.	The woman that I see.
2263	A2	Nominative of Adjectives after Zero Article	Kleine Kinder spielen dort.	Small children play there.
2264	A2	Accusative of Adjectives after Zero Article	Sie sollten frisches Obst essen.	They should eat fresh fruit.
2265	A2	Dative of Adjectives after Zero Article	Guten Freunden gibt man das.	You give that to good friends.
2268	A2	A2 Level Indefinite Pronouns	Das kann nicht jeder .	Not everyone can do that.
2274	A2	"that" Clauses	Ich hoffe, dass sie kommt.	I hope that she comes.
2281	A2	Past Participle	Wir haben dich besucht .	We visited you.
3131	B1	Comparative of B1 Level Adverbs	Er geht öfter als ich.	he goes there more often than me.
3132	B1	Superlative of B1 Level Adverbs	Er geht am öftesten dorthin.	He goes there more often .
3168	B1	B1 Level Indefinite Pronouns	Es gibt nur noch wenige .	There is only few left.
31109	B1	Simple Past	Sie wandte sich ab.	He turned away.
31120	B1	Genitive of Articles	Das Nest der Wespen.	The nest of the wasps. - The wasps' nest.
3134	B1	Adverbial Temporal Determinations	Er hat mit 21 geheiratet.	He got married at 21.
3203	B2	B2 Level Conjunctive Adverbs	Anschließend gingen wir weg.	We left afterwards .
3256	B2	Genitive after Indefinite Article	Das Nest eines jungen Spechts.	The nest of a young woodpecker.
3257	B2	Genitive after Zero Article	Der Geruch frischen Kaffees.	The smell of fresh coffee.
32135	B2	<i>to become</i> in Passive Present Tense	Der Brief wird geschrieben .	The letter is being written .
32148	B2	Subjunctive II for unrealistic Wishes	Wäre ich ein Vogel, flöge ich zu dir.	If I were a bird, I would fly to you.

Abstract

With the emergence of large language models (LLMs) as a powerful class of generative artificial intelligence (AI), their use in tutoring has become increasingly prominent. Prior works on LLM-based tutoring typically learn a single tutor policy and do not capture the diversity of tutoring styles. In real-world tutor–student interactions, pedagogical intent is realized through adaptive instructional strategies, with tutors varying the level of scaffolding, instructional directiveness, feedback, and affective support in response to learners’ needs. These differences can all impact dialogue dynamics and student engagement. In this paper, we explore how tutor personas embedded in human tutor–student dialogues can be used to guide LLM behavior without relying on explicitly prompted instructions. We train a steering vector using preference optimization: an activation-space direction that guides model responses toward specific tutor personas. We find that this steering vector captures tutor-specific variation across dialogue contexts, improving semantic alignment with ground-truth tutor utterances and increasing preference-based evaluations, while largely preserving lexical similarity. Analysis of the learned scaling coefficients further reveals interpretable structure across tutors, corresponding to consistent differences in tutoring behavior. These results demonstrate that activation steering offers an effective and interpretable way for controlling tutor-specific variation in LLMs using signals derived directly from human dialogue data.

1 Introduction

With the emergence of large language models (LLMs) as a powerful class of generative artificial intelligence (AI), their use in educational tutoring has become increasingly prominent, spanning both general-purpose systems (Google, 2023; OpenAI, 2023) and education-specific tutors (Carnegie Learning, 2024; Khan Academy, 2023). Recent

work has also connected LLMs with Knowledge Tracing (KT), using KT-derived or LLM-assisted student-state estimates for tasks such as student error simulation and mastery modeling in tutoring dialogues (Huang et al., 2026; Duan et al., 2026; Scarlatos et al., 2025a).

Approaches to building LLM tutors vary in how pedagogical behavior is specified and optimized. Many approaches simply prompt LLMs with dialogue policies and guardrails to elicit best-practice pedagogy, including reducing solution leakage, encouraging scaffolding, and enforcing Socratic-style questioning (Pal Chowdhury et al., 2024; Puech et al., 2025; Zhang et al., 2024). Other approaches instead train LLMs using supervised fine-tuning (SFT) to mimic human tutor behavior or use reinforcement learning (RL) on synthetic tutoring dialogues. These approaches optimize proxies of pedagogical quality, such as improving feedback correctness and alignment with tutoring goals (Scarlatos et al., 2024), directly optimizing for pedagogical alignment signals derived from preference data over tutoring behaviors (Sonkar et al., 2024), or leveraging pedagogical rubrics and LLM-based simulated students in-the-loop to encourage greater learning outcomes (Dinucu-Jianu et al., 2025; Scarlatos et al., 2025b).

Despite making improvements on pedagogical quality, these approaches only learn a single tutor policy and do not attempt to capture the diversity of tutoring styles. Figure 1 illustrates how real tutors differ in their instructional style when addressing the same problem. One noticeable difference is the use of emojis and affective language, which conveys emotional support and rapport. Another key difference is instructional approach: the first tutor provides increased emotional support and guides the student step-by-step, whereas the other provides minimal rapport-building and asks the student to test a solution, emphasizing student self-completion. Therefore, we ask a research question:

Figure 1: Real math tutoring dialogue on inequalities (Zent et al., 2025), showing how tutors 17 and 102 differ in instructional style when solving the same problem.

“how do we capture differences in tutoring styles and steer LLMs to exhibit these styles?”

1.1 Contributions

In this paper, we explore how implicit tutor personas embedded in human tutor-student dialogues can be used to guide LLM behavior, rather than relying on explicitly prompted instructions. We use preference optimization to learn a steering vector and a scaling coefficient that capture and control the persona direction in the model’s representation space. Using these learned parameters, we then steer the LLM in a tutor-specific manner. We find that our approach enables consistent recovery of tutor-specific steering across dialogue contexts, shifting the model away from population-mean behavior and toward the behavior exhibited by individual tutors. We further show the strength of this effect can be controlled at inference time through a global scaling factor, allowing for smooth adjustment of the intervention. Finally, analysis of the learned scaling coefficients reveals an interpretable structure over tutors that corresponds to variation in tutoring behavior, supporting activation steering as an effective way for capturing and controlling tutor-specific variation.

2 Related Work

2.1 Tutoring Strategies

Effective tutoring relies on a set of practical strategies rather than a single teaching approach, with tutors adjusting what they do in response to the learner’s needs. One core strategy is scaffolding, in which tutors provide support that helps learners solve problems they could not complete on their

own, and then gradually reduce that support as learners become more capable (Wood et al., 1976). Tutors also vary how directly they teach, moving between clear explanation or demonstration and guided practice that helps learners take on more responsibility over time (Rosenshine, 2012). In tutoring conversations, questioning strategies are used to prompt learners to explain their thinking while keeping the interaction focused on the learning goal (Graesser et al., 1995). During early stages of learning, tutors often use worked examples to show how problems can be solved and to make new skills easier to grasp (Sweller and Cooper, 1985). As learners practice, tutors provide formative, error-focused feedback to identify misunderstandings and support improvement (Shute, 2008). Finally, effective tutoring includes affective strategies such as encouragement, building rapport, and managing frustration in order to maintain engagement and persistence (D’Mello and Graesser, 2012).

2.2 Embedding Personas in LLMs

Research on embedding personas into LLMs generally follows two approaches: text-based conditioning and data-driven learning. In the text-based approach, personas are explicitly specified using structured descriptors such as the Five-Factor Model (Big Five) (McCrae and John, 1992), with prior work demonstrating that prompting an LLM with predefined Big Five trait profiles can induce consistent personality-aligned behaviors, which are validated by administering standardized personality questionnaires to the model (Serapio-García et al., 2023). In the context of intelligent tutoring systems, related work adopts explicit persona specifications to construct personality-aware student simulations

that combine cognitive attributes and personality traits, enabling systematic analysis of how different learner personas elicit and evaluate adaptive tutoring strategies (Liu et al., 2024b).

In contrast, data-driven learning induces personas from examples rather than explicit textual descriptions, and is commonly implemented either through SFT or by manipulating representation-level features (Chen et al., 2025; Mazaré et al., 2018). In this paper, we focus on activation steering using steering vectors, which estimate a direction from contrastive behaviors and inject that direction into a model’s hidden states to bias generation toward a target persona. A steering vector can be computed from differences in internal activations produced by paired inputs or outputs that reflect desired versus undesired traits, and then applied at selected layers and token positions during the forward pass to produce consistent behavioral shifts (Liu et al., 2024a; Rimsy et al., 2024; Turner et al., 2023; Wang and Shu, 2024). Our work follows BiPO, which itself builds on Direct Preference Optimization (DPO) by combining preference-based learning to train a steering vector with activation steering to achieve finer-grained control over model behavior (Cao et al., 2024; Rafailov et al., 2023). Like DPO, BiPO uses relative preferences between model outputs rather than absolute likelihood targets, yielding a contrastive learning signal that enables bidirectional steering between preferred and non-preferred behaviors.

3 Methodology

In this section, we detail our approach to learning a steering vector from tutor-student dialogues. We introduce the notation used throughout the paper:

$$\mathcal{D} \triangleq \bigcup_{i=1}^I \{(q_j, d_j^i)\}_{j=1}^{J_i},$$

$$d_j^i \triangleq (s_{j,0}, t_{j,1}^i, s_{j,1}, \dots, t_{j,K_j}^i, s_{j,K_j}).$$

$\mathcal{D}$ denotes a human tutor-student dialogue dataset, where I is the total number of tutors and $i \in \{1, \dots, I\}$ indexes a specific tutor. For each tutor i , J_i denotes the number of dialogues conducted by tutor i , and $j \in \{1, \dots, J_i\}$ indexes an individual dialogue. Each dialogue d_j^i is associated with a math question q_j . Each dialogue d_j^i consists of an alternating sequence of student turns $s_{j,k}$ and tutor turns $t_{j,k}^i$. $k \in \{1, \dots, K_j\}$ indexes (student, tutor) turn pairs in the dialogue, where K_j is the

total number of such turn pairs. The initial student turn $s_{j,0}$ is included when the student initiates the dialogue. We refer to the textual content of each turn as an *utterance*.

A steering vector encodes a direction in an LLM’s activation space, and when added to the activations induces changes in the LLM’s behavior. Learning a tutor-specific vector requires making explicit what the model is being steered away from and toward. In our setting, we define this direction relative to an *average* tutor: for a given dialogue context, the steering vector should shift the model from a population-mean tutor utterance toward the utterance produced by a particular tutor. We first SFT the LLM to condition on the dialogue context and generate an appropriate tutor response. The adaptation ensures that the model can perform the tutoring-response generation task before we estimate tutor-specific directions in activation space. We then use the fine-tuned model to generate a population-mean tutor utterance for each dialogue context and pair this generated utterance with the corresponding ground-truth tutor utterance. Finally, we learn a steering vector from these paired examples, so that the resulting vector captures tutor-specific stylistic variation beyond the population-average tutoring behavior. See Appendix Algorithm 1 for overall procedure to learn the steering vector.

3.1 Constructing Pairs

We use SFT to fine-tune an LLM to serve as a proxy for population-mean behavior, reducing response diversity and encouraging convergence toward a generic average-tutor behavior (Li et al., 2025); the resulting model is used to generate population-mean utterances. Let π_θ denote an LLM parameterized by θ ; we train π_θ via SFT by minimizing the negative log-likelihood of tutor utterances in $\mathcal{D}$ conditioned on the associated question q_j and the preceding dialogue context $(s_{j,\leq k}, t_{j,<k}^i)$:

$$\frac{1}{I} \sum_{i=1}^I \frac{1}{J_i} \sum_{j=1}^{J_i} \frac{1}{K_j} \sum_{k=1}^{K_j} -\log \pi_\theta(t_{j,k}^i | s_{j,\leq k}, t_{j,<k}^i, q_j).$$

For the preceding dialogue context, we construct a pair in which the ground-truth tutor utterance is the preferred response and a response generated by the SFT model is the dispreferred response. The SFT-generated response serves as a proxy for population-mean tutor behavior, so each pair explicitly defines the direction from the average tutor

response $\bar{t}_{j,k}$ toward the tutor-specific response $t_{j,k}^i$. See Appendix Tables 5 and 6 for examples of such contrastive pairs.

3.2 Learning a Steering Vector

We now detail what a steering vector is and how we learn it using the pairs. We introduce a steering vector v , shared across tutors, which we use to modify the model’s activation during inference by adding it to the latent activations $A_L(\cdot)$ at layer L . We assign each tutor a positive scaling coefficient δ_i that scales a shared steering direction v . We constrain these coefficients to have unit mean across tutors to eliminate a scale ambiguity, since the intervention depends only on the product $\delta_i v$ and could otherwise be left unchanged by scaling δ_i up while scaling v down (or vice versa) without affecting the loss. To parameterize δ_i while enforcing positivity, we introduce a tutor-specific learnable scalar u_i and define $\delta_i = \exp(u_i) / (\frac{1}{T} \sum_{m=1}^T \exp(u_m))$. We jointly optimize each u_i and the shared steering direction v in training. We initialize $u_i = 0$ for all tutors ($\delta_i = 1$), and initialize v from a standard Gaussian scaled by 0.5 to ensure a sufficiently strong initial steering magnitude. We note that while we learn the steering vector through preference optimization inspired by BiPO (Cao et al., 2024), we differ in that, rather than using bidirectional steering, we learn a scaling coefficient that scales a shared steering direction:

$$\min_{v,u} \mathbb{E}_{i,j,k} \left[-\log \sigma \left(\beta \log \frac{\pi_{\theta}(t_{j,k}^i | A_L(\cdot) + \delta_i v)}{\pi_{\theta}(t_{j,k}^i | A_L(\cdot))} \right. \right. \\ \left. \left. - \beta \log \frac{\pi_{\theta}(\bar{t}_{j,k} | A_L(\cdot) + \delta_i v)}{\pi_{\theta}(\bar{t}_{j,k} | A_L(\cdot))} \right) \right].$$

For tutor i , dialogue j , turn k , our objective includes two relative preference terms. The first log term encourages the steered LLM to have higher likelihood in generating actual tutor utterance $t_{j,k}^i$ compared to the unsteered SFT model. The right term does the exact opposite, encouraging the steered model to have lower likelihood in generating the population-average tutor utterance. All likelihoods in these terms are sequence log-likelihoods computed by summing next-token log-probabilities over the response tokens only, with prompt tokens masked out. The logistic loss encourages learning a shared steering direction v and tutor-specific coefficients δ_i such that applying $\delta_i v$ consistently favors tutor-specific outputs across tutors, dialogues, and turns. The hyperparameter β encourages similarity

to the base model’s behavior without the steering vector applied. We optimize this objective by iterating for T steps until the loss converges.

At test time, we introduce a global scaling factor α and apply activation steering as $A_L(\cdot) \leftarrow A_L(\cdot) + \alpha \delta_i v$. We observe that $\alpha = 1$ leads to longer utterances, because of the objective uses unnormalized sequence log-likelihoods, so the log-ratio accumulates over all response tokens. Consequently, longer tutor utterances can contribute larger preference margins than shorter ones, making the learned intervention at $\alpha = 1$ overly strong on continuing generation rather than stopping. While the training objective identifies a shared steering direction v and relative tutor-specific strengths δ_i with respect to the unsteered SFT model, a separate scaling factor is necessary to control the overall strength of the intervention during inference.

4 Experimental Settings

4.1 Dataset

We use the Question-Anchored-Tutoring-Dialogues-2k dataset (Zent et al., 2025), containing dialogues from web-based conversations between expert tutors and real students in an online math learning platform. The conversations are initiated by tutors or students requesting assistance while working through a lesson. We split the dataset into training, validation, and test sets at the dialogue level using an 80/10/10 split for each of the 21 unique tutors. On average, each tutor has 74.19 ($\sigma = 75.47$) dialogues in the training set, 8.90 ($\sigma = 9.45$) dialogues in the validation set, and 10.10 ($\sigma = 9.42$) dialogues in the test set. The average number of turns per dialogue is 11.75 ($\sigma = 1.10$) in training, 12.06 ($\sigma = 2.43$) in validation, and 12.25 ($\sigma = 1.73$) in test.

4.2 Evaluation Setup and Metrics

We evaluate how closely the steered tutor utterances match the corresponding ground-truth on a per-tutor basis, along two main axes: *lexical similarity* and *semantic similarity*. For each tutor i , we compare steered outputs $t_j^{\delta_i}$ to ground-truth utterances t_j across turns j . For lexical similarity, we measure surface-form overlap using ROUGE-L (R) (Lin, 2004) and BLEU(B) (Papineni et al., 2002). For semantic similarity, we assess semantic alignment using cosine similarity in embedding space (C) and a pairwise preference-based win rate

(W). We define $C(\delta_i) = \mathbb{E}_j [\cos(\phi(t_j^{\delta_i}), \phi(t_j))]$, where $\phi(\cdot)$ denotes a sentence embedding function from a pretrained SentenceBERT encoder (Reimers and Gurevych, 2019). For Win Rate, we use LLM-as-a-judge with Prometheus-Eval, given a dialogue and a ground-truth turn and chooses which of the steered or unsteered utterances more closely aligns with the tutoring style and language used (Kim et al., 2024). We report the win rate over unsteered SFT utterances, where 0.5 indicates the two perform equally. We do not report ties because they are rare. All metrics are computed per tutor and then averaged across tutors.

4.3 Model Parameters

We use Llama-3.1-8B-Instruct as the base model for SFT, which we adapt using LoRA (Hu et al., 2022) with a learning rate of 5×10^{-5} over 3 epochs, setting the LoRA rank to $r = 32$ and the scaling factor to $\alpha = 64$. Our SFT setup follows Scarlatos et al. (2026), adopting their prompts and training procedure. For learning v and u_i , we use the validation set, applying each u_i to the dialogues corresponding to tutor i and selecting hyperparameters by tracking validation loss; we set $\beta = 1.0$ and learning rate = 0.01, and apply activation steering at the final transformer layer (layer 32). Text generation uses a temperature of 1.0 and top- p sampling with $p = 0.95$, yielding a final validation loss of 0.543 at $T = 17$. The learned u_i have a mean of 0.053 and a standard deviation of 0.106. The activation steering mechanism follows the persona vector approach (Chen et al., 2025), where the learned steering vector is added to the layer activations at all token positions. All training and evaluation are conducted on a single NVIDIA A40 GPU with 48 GB of VRAM.

5 Experimental Results

5.1 Quantitative Results

We quantitatively evaluate activation steering for tutoring along two dimensions: (1) how well it recovers tutor-specific behavior at different stages of a dialogue, and (2) how this behavior varies with the strength of the steering intervention. Specifically, we first compare steered tutor utterances $\hat{t}_j$ with population-mean utterances $\bar{t}_j$, using ground-truth tutor utterances t_j as reference, in different stages of the dialogue (Table 1). We then analyze the effect of varying the global scaling factor α on both stylistic alignment and lexical similarity

Table 1: Comparison of population-mean utterances $\bar{t}_j$ and steered tutor utterances $\hat{t}_j$ against the ground-truth tutor utterances t_j across dialogue stages. Metrics are computed per tutor and then averaged across tutors.

Stage	Count	Method	R [†]	B [†]	C [†]	W [†]
early	326	$\bar{t}_j$	0.285	0.070	0.392	–
		$\hat{t}_j$	0.206	0.041	0.321	0.571
mid	1971	$\bar{t}_j$	0.165	0.019	0.385	–
		$\hat{t}_j$	0.157	0.018	0.426	0.587
late	326	$\bar{t}_j$	0.157	0.025	0.330	–
		$\hat{t}_j$	0.121	0.017	0.349	0.564

Table 2: Comparison of varying the strength of the steering vector by applying a scaling factor α in activation steering for all stages: $A_L(\cdot) \leftarrow A_L(\cdot) + \alpha \delta_i v$.

Count	Method	α	R [†]	B [†]	C [†]	W [†]
2623	$\bar{t}_j$	0.0	0.179	0.026	0.379	–
		0.3	0.181	0.027	0.400	0.536
	$\hat{t}_j$	0.5	0.187	0.028	0.407	0.539
		0.7	0.176	0.026	0.404	0.562
		1.0	0.159	0.021	0.403	0.582

(Table 2).

We conduct a stage-wise analysis because different parts of a dialogue serve different purposes. Early and late turns are largely greetings, encouragement, and closing remarks, which tend to follow common conventions and thus provide limited signal about a tutor’s instructional style. In contrast, the middle portion of the dialogue contains the core problem-solving interaction, where tutors explain concepts, provide hints, and respond to student errors. These turns are where tutor-specific strategies and language use are most evident. For this reason, we define the *mid stage* as the 10–90% interval of turns within each dialogue and focus our analysis on this region.

Table 1 shows the results on all metrics. Beyond early dialogue stages, steering leads to a clear improvement in semantic alignment with the ground-truth tutor: in the mid stage, cosine similarity increases from 0.385 for $\bar{t}_j$ to 0.426 for $\hat{t}_j$, and the LLM judge prefers $\hat{t}_j$ over the unsteered baseline in 58.7% of comparisons. At the same time, lexical overlap is only slightly reduced; ROUGE-L decreases from 0.165 to 0.157 and BLEU remains almost unchanged (0.019 to 0.018). This result suggests that steering improves tutor-specific style primarily by altering phrasing and discourse struc-

ture rather than by matching exact word sequences. Only in the early stage, the cosine similarity for $\hat{t}_j$ is worse than $\bar{t}_j$. The result is likely due to greetings in the early turns being inherently generic, which means that adding the steering vector over-exaggerates the effect of tutor style in these turns. A solution may be dynamically setting α to lower values for turns that are intended to be more generic.

Table 2 examines the effect of steering strength aggregated across all dialogue stages. Moderate values of α (0.3 and 0.5) slightly improve ROUGE-L and BLEU relative to the population-mean baseline, while also increasing cosine similarity. As α increases, Win Rate rises steadily from 0.536 to 0.582, indicating stronger expression of tutor-specific behavior. However, higher values of α also lead to lower ROUGE-L and BLEU scores, reflecting a trade-off in which stronger steering enhances stylistic alignment at the cost of lexical similarity.

Based on these results, we select $\alpha = 0.5$ for our qualitative analysis, since it provides a good balance between improving semantic and stylistic alignment with the target tutor while largely preserving lexical similarity.

5.2 Qualitative Results

5.2.1 Interpreting the steering direction

We visualize the scaling coefficient δ_i in Figure 2. To examine how δ_i correlates with tutoring styles or language use, we put tutors into three groups that each address a common math question in the dataset¹: from the left end to the middle (Tutors 283, 346, and 102), from the middle to the right (Tutors 283 and 1430), and from the middle to the right end (Tutors 19 and 2488). Table 3 provides an overview of the math questions and ground-truth utterances, where tutors with lower δ_i are placed on the left and those with higher δ_i are placed on the right.

Table 3 shows three example math questions (ratios, linear sequences, and order of operations) together with short tutor-student dialogue snippets. The table is organized to make the learned direction δ_i interpretable: tutors are arranged from left to right according to their position in the heatmap ordering (e.g., 283 $\rightarrow$ 346 $\rightarrow$ 102 $\rightarrow$ 1430 $\rightarrow$ 19 $\rightarrow$ 2488). For each question, the “Lower δ_i ” column contains tutors closer to the left side of this ordering, while the “Higher δ_i ” column contains tutors closer to the right side. The blue-highlighted

text marks the target tutor utterance to be predicted. Therefore, snippets show how the same dialogue context elicits different conversational moves and tutor utterances, as we move along the δ_i direction.

Tutor 283 who appears at the left end shows relational and pedagogical investment through explicit encouragement and step-by-step scaffolding. In the ratios example, Tutor 283 uses affective markers and praise (“:-”), “Yes, great!”) and then connects the student’s correct operation on the first term to the required operation on the second term: “the 3 in the ratio has been divided by 3, so you now need to divide the 2 by 3 as well.” In the linear sequence example, the tutor validates the student (“Great!”), explains the structural role of $4n$, and checks understanding with a concrete substitution prompt (“When $n = 1$, $4n = ?$ ”). These turns prioritize both student confidence and conceptual clarity.

Tutors positioned toward the middle of the δ_i direction, including Tutors 102, 1430, and 19, share a more efficiency-oriented style. Across examples, these tutors rely on short, task-focused prompts and corrective feedback, with reduced affective language and limited elaboration. Tutor 102 narrows the student’s response space through a fill-in-the-blank equation (“ $3 \div ___ = 1$ ”) and provides brief correction (“Almost, try again?”). Tutor 1430 advances the linear sequence problem through a series of concise checkpoints (“Great, now pattern 2?”, “Great, now pattern 3?”) and a minimal continuation of the sequence (“6, 10, 14,”). Tutor 19 similarly emphasizes efficient progression by providing succinct procedural guidance (“we multiply before we add”) and a short conceptual reminder (“Remember the fraction line means divide”), occasionally accompanied by a small positive signal with thumbs up emoji. Together, these tutors demonstrate consistent pedagogical engagement while prioritizing error diagnosis and progress over extended explanation or rapport-building.

At the right end of the δ_i direction, Tutor 2488 closely aligns with a low-investment style, focusing on just getting the task completed. The tutor gives short answers (“It means divide”) and follows up with a confusing justification (“it’s a weird one because you’d normally do division before the addition”), which does not clearly resolve the student’s uncertainty about expression structure. Compared to Tutor 19’s concise but accurate guidance, Tutor 2488’s response prioritizes moving the interaction forward, even at the expense of clarity in their explanation. Taken together, these examples

¹Question IDs: 104637, 91697, and 77628, respectively.

Figure 2: Heatmap of δ_i across 21 tutors with different tutoring styles.

Table 3: Examples of tutor-student dialogue across different math topics. Blue denotes our target utterance.

Question	Lower δ_i	Higher δ_i
Ratios <i>Lila and Elijah share some sweets in the ratio 3 : 2. What is this ratio in the form 1 : n?</i> A. 1 : 1.5 B. 1 : $\frac{2}{3}$ C. 1 : 0 D. 1 : 6	Tutor 283 T: :-) So, you need to find an equivalent ratio to 3 : 2. That is, instead 1 : n S: im not sure T: So, what would you divide 3 by, to get the answer 1? S: 3 divide by 3 T: Yes, great! So, the 3 in the ratio has been divided by 3, so you now need to divide the 2 by 3 as qwell. *well	Tutor 102 T: Ok let's take a look. What do we need to divide by to get the start of the ratio down from 3 to 1? S: i dont know T: $3 \div \underline{\quad} = 1$ S: 1 T: Almost, try again?
Linear sequence <i>How many dots would there be in Pattern n ? [Image: 6 dots, 10 dots, 14, and 18 dots]</i> A. $4n + 2$ B. $4n - 2$ C. $2n + 4$ D. $n + 2$	Tutor 283 T: Yes of course, let's have a look So, how many dots are being added each time? S: 4? T: Great! So that tells us that the first part of our formula will be $4n$ S: so does the $4n$ refer to how many dots are being added each time? T: Yes, that's how we work out that bit Then, we need to see if that works, or if we need to add/subtract anything When $n=1$, $4n = ?$	Tutor 1430 T: Great, now pattern 2? S: 10 T: Great, now pattern 3? S: 14 T: So what is the pattern going up in? S: 4 T: 6, 10, 14,
Order of operations <i>What is the value of $\frac{1+3 \times 4}{2}$?</i> A. 12.5 B. 8 C. 7 D. 6.5	Tutor 19 T: Yep no worries With a fraction like this we would need to calculate the value of the numerator first What is $1 + 3 \times 4$ S: well 1 add 3 is 4 and 4 times 4 is 16 so will it be $16 <$ T: Not quite. Remember with the order of operations we multiply before we add so we need to do 3×4 first then add 1 S: oh 3 times 4 is 12 add the 1 is 13 T: 👍 So now we have $13/2$ Remember the fraction line means divide	Tutor 2488 S: What do I do after 3×4 T: With the fraction line what does that actually mean? S: I'm not sure what it means T: It means divide S: So 12 divided by 2 T: So it's a weird one because you'd normally do division before the addition but because it's all of the $1+12$ divided by 2

indicate that the learned direction δ_i corresponds to changes in tutoring style, from rapport-rich scaffolding on the left, through diagnostic instruction in the middle, to procedural assistance that emphasizes task completion over teaching on the right.

5.2.2 Case studies

Table 4 shows predicted utterances from unsteered SFT and steered generations with $\alpha = 0.5$. Overall, steering makes the generations better aligned with the ground-truth tutor utterances in Table 3, particularly in how the LLM matches the tutoring approach associated with δ_i . In many cases, the unsteered model produces reasonable tutoring moves, but it often misses the specific dialogue act or tone that distinguishes lower- δ_i tutors (rapport and scaffolding) from higher- δ_i tutors (corrective or short/concise continuations). With $\alpha = 0.5$, the model

more consistently reproduces the intended style difference between the two ends, yielding utterances that are closer to the ground-truth utterances in both tutoring style and language use.

In the ratios example, the ground-truth utterance of Tutor 283 first affirms the student and then explains that whatever is done to the 3 must also be done to the 2. The unsteered prediction (“Amazing!! And 2 divide by 3?”) has a friendly tone, but moves directly to $2/3$ without introducing additional steps. The steered prediction, however, provides a conceptual step while maintaining a friendly tone, thereby exhibiting a tutoring style similar to the ground truth. The ground-truth utterance of Tutor 102 is a brief correction (“Almost, try again?”) following an incorrect student answer. The unsteered prediction instead shifts into an elaborated instructional explanation (“So we need to divide

Table 4: Predicted utterances for the target utterances shown in Table 3.

α	Lower δ_i	Higher δ_i
0.0	Amazing!! And 2 divide by 3?	So we need to divide both sides by 3 $3 \div 3 = 1$ What would the ratio become?
0.5	And what would happen to 2? 😊 $3 \div 3 = 1$ So, we would have to divide both parts by 3 $2 \div 3 = ?$	Nearly, not 1... What do we need to divide by to get from 3 to 1?
0.0	Exactly, so if it's pattern 1 it will have $4n$ dots in the pattern	Great, so to get pattern n , we have $4(n)$ How many is it missing?
0.5	$4n$ refers to the number of times 4 is being added So, $4n$ means the number of terms we're adding 4 to And then, we have to account for the fact that in the first pattern ($n=1$) there are 6 dots, not 4 So, we start with $4n$ and then add 2	So in pattern 1 how many were there and what is this times by??
0.0	So when we have $1 + 3 \times 4$, this is different from $3 \times (1 + 4)$ Are you ok with why that's different?	You have to carry out both operations
0.5	brilliant Now we have $13 / 2$	Yes 👍

both sides by 3 ... What would the ratio become?"), which does not match Tutor 102's concise corrective move. The steered prediction "Nearly, not 1... What do we need to divide by to get from 3 to 1?" is much closer in style: it is explicitly corrective ("Nearly, not 1...") and prompts the student to retry the same subproblem, matching the ground-truth tutor strategy even if the exact wording differs.

In the linear sequence example, there is a similar pattern. The ground-truth utterance of Tutor 283 answers the student's clarification question about what $4n$ represents and then immediately transitions into a structured check ("When $n = 1$, $4n = ?$ "). The unsteered prediction ("Exactly, so if it's pattern 1 it will have $4n$ dots ...") moves the problem forward but does not directly address the student's question, which differs from the tutor's explanatory move. The steered prediction shows an explicitly explanatory turn that attempts to clarify what $4n$ means and then addresses it by referencing the mismatch at $n = 1$, introducing an offset ("we start with $4n$ and then add 2"). While the steered text is more verbose and uses some slightly awkward phrasing, it is closer in tutoring strategy because it responds to the student's conceptual query and uses a concrete consistency check to motivate the adjustment, which is the same pedagogical move that Tutor 283 uses. The ground-truth utterance of Tutor 1430 is extremely concise ("6, 10, 14,"), functioning more like a checkpoint or continuation than an explanation. The unsteered prediction introduces additional scaffolding ("How many is it missing?"), and the steered prediction becomes even more diagnostic ("So in pattern 1 how many were there and what is this times by?"). Neither matches the concise tutoring style in the ground truth, but the steered utterance aligns better in that it remains concise and task-driven.

In the order of operations example, steering yields the clearest improvement. The ground-truth utterance of Tutor 19 ends with a short affirmation with a procedural reminder, "(thumbs up) So now we have $13/2$ Remember the fraction line means divide." The unsteered prediction instead introduces a conceptual aid, contrasting two different expressions ("this is different from $3 \times (1 + 4)$ "), which is pedagogically plausible but does not match the ground-truth target's concise confirmation-and-next-step structure. The steered prediction shows "brilliant Now we have $13 / 2$," which is substantially closer in both tone and function, echoing the short praise and the immediate transition to the next step. The ground-truth utterance of Tutor 2488 is a long, somewhat muddled explanation about why the fraction is "weird," a term rarely used to explain order of operations. Therefore, both predictions struggle, and the steered one incorrectly assesses the student response as correct. The unsteered prediction is overly generic while the steered shows an acknowledgment, saying yes.

Across all examples, steering consistently improves alignment between model-generated utterances and ground-truth ones, capturing the specific tutoring strategy, tone, and style along the δ_i spectrum that unsteered SFT often misses. With $\alpha = 0.5$, steered outputs more reliably reflect the intended tutoring stance and underlying tutoring function, such as rapport-building and scaffolding, affirming before explaining, or concise, corrective continuations, suggesting steering effectively controls pedagogical intent beyond surface style.

6 Conclusions and Future Work

In this paper, we explored how implicit signals in human tutor-student dialogues can be used to guide LLMs towards different tutoring styles. We proposed an activation steering method that learns a shared steering direction and tutor-specific coefficients from real tutor-student dialogues, relative to a population-mean reference, enabling personalized, controlled tutor-specific behavior. We show that the learned steering direction and strengths lead to improved replication of individual tutor behavior. We also qualitatively show that it encodes changing tutoring styles from scaffolded, rapport-building through efficient, task-focused guidance to minimal, task-completion-oriented instruction.

There are several directions for future work. First, although our objective captures tutor-specific behavior via preferences, it does not explicitly encode pedagogical principles. Integrating pedagogical rubrics, learning-theoretic goals, or student outcome-based rewards could better align models with effective tutoring practices. Second, beyond steering tutor behavior, future work could learn complementary steering vectors for student models, enabling simulated tutor-student interactions driven by latent student personas. This would allow analysis of how interaction dynamics and tutor-student compatibility influence learning outcomes. Finally, extending the method to learn multiple steering directions, for example through low-rank subspaces from dimensionality reduction, could enable more fine-grained and disentangled control over distinct pedagogical attributes.

Acknowledgments

This work is partially supported by Renaissance Philanthropy under the learning engineering virtual institute (LEVI) initiative and the NSF under grants 2153481 and 2237676.

Limitations

There are several practical limitations to our work. First, we evaluate our method on a single math dialogue dataset, so it is unclear how well the results generalize to other datasets, domains, or tutoring settings. Second, our baselines are limited to supervised fine-tuning methods; future work should compare against prompting-based approaches as well. Third, we do not include human evaluation, so our findings rely on automatic metrics and model-based judgments.

Ethical Considerations

Our experiments use the Eedi dataset (Zent et al., 2025), in which dialogues are associated with pseudonymous identifiers rather than real names. We therefore do not identify any individual tutors or students in this work. Beyond this, we do not foresee additional ethical concerns specific to our experimental setup.

A Appendix

As mentioned earlier, our prompting and supervised fine-tuning (SFT) approach builds on the framework of [Scarlatos et al. \(2026\)](#), using the code available on <https://github.com/umass-ml4ed/sim-student-eval>. In this section, we outline the setup required to train a steering vector.

A.1 Implementation Details

We implement the method in two stages: (i) construction of turn-level preference pairs from tutor-student dialogues, and (ii) optimization of a shared steering direction v together with tutor-specific scaling coefficients $\{\delta_i\}_{i=1}^I$. The implementation follows the formulation in the main text, but includes several practical choices for efficient training and evaluation.

Sequence log-likelihoods. Given a prompt-response pair (q, r) , we compute the conditional sequence log-likelihood

$$\log \pi_\theta(r \mid q)$$

by summing next-token log-probabilities over the response tokens only. Prompt tokens are masked out and do not contribute to the score. These log-likelihoods are computed both for the unsteered

model and for the steered model. Since the baseline values

$$\log \pi_\theta(t_{j,k}^i \mid q_{j,k}^i), \quad \log \pi_\theta(\bar{t}_{j,k} \mid q_{j,k}^i)$$

are reused throughout optimization, they are pre-computed and cached for efficiency.

Parameterization of tutor-specific strength. As in the main text, we learn a shared steering direction v and tutor-specific coefficients δ_i . To enforce positivity and remove scale ambiguity, we optimize unconstrained parameters $u_i \in \mathbb{R}$ and set

$$\delta_i = \frac{\exp(u_i)}{\frac{1}{I} \sum_{m=1}^I \exp(u_m)}.$$

This ensures $\delta_i > 0$ and $\frac{1}{I} \sum_{i=1}^I \delta_i = 1$. In practice, we initialize $u_i = 0$ for all tutors, so that $\delta_i = 1$ initially, and initialize v from a Gaussian distribution.

Training loss. While the main text presents the objective at the turn level, in implementation we group examples by (j, i) , i.e., all tutor turns from dialogue d_j^i associated with tutor i . For each turn k in such a group, we compute the margin

$$m_{j,k}^i = [\log \pi_\theta(t_{j,k}^i \mid C_i) - \log \pi_\theta(\bar{t}_{j,k} \mid C_i)] \\ - [\log \pi_\theta(t_{j,k}^i \mid C) - \log \pi_\theta(\bar{t}_{j,k} \mid C)],$$

where $C_i = A_L(\cdot) + \delta_i v$ and $C = A_L(\cdot)$. The corresponding turn loss is

$$\ell_{j,k}^i = -\log \sigma(\beta m_{j,k}^i).$$

We then average $\ell_{j,k}^i$ across turns k within a given (j, i) group, and average again across groups in the minibatch. Thus, the implementation preserves the same BiPO-style preference structure as the main objective, while stabilizing optimization by aggregating at the dialogue-tutor level.

Steering intervention. During training and inference, the intervention is applied by adding the scaled steering vector to the hidden activations at a designated transformer layer:

$$A_L(\cdot) \leftarrow A_L(\cdot) + \alpha \delta_i v.$$

During training, α is absorbed into the learned parameterization, whereas at test time we expose a global scaling factor α to control overall steering strength independently of the relative tutor-specific coefficients δ_i .

Optimization and model selection. We optimize only the steering parameters $\{v, u_1, \dots, u_I\}$, keeping the underlying language model fixed. Validation loss is computed using the same grouped objective, with cached baseline log-likelihoods for the unsteered model. The best checkpoint is selected according to validation performance, and the learned parameters are then used for test-time generation.

Inference. At test time, for a target tutor i , generation is performed with the intervention $A_L(\cdot) + \alpha \delta_i v$. This yields tutor-conditioned outputs while retaining a single shared steering direction across all tutors. The unsteered SFT model serves as the baseline condition.

Algorithm 1: Learning a steering vector and activating steering using the vector

Input: Dialogue dataset $\mathcal{D}$, SFT model π_θ , steering layer L , temperature β , training steps T

Output: Shared steering vector v , tutor-specific coefficients $\{\delta_i\}_{i=1}^I$

Pair construction:

foreach tutor i , dialogue d_j^i , tutor turn k **do**

 Construct prompt $q_{j,k}^i$ from the dialogue context

 Set chosen response to $t_{j,k}^i$

 Generate rejected response $\bar{t}_{j,k} \sim \pi_\theta(\cdot \mid q_{j,k}^i)$

 Store pair $(q_{j,k}^i, t_{j,k}^i, \bar{t}_{j,k})$

Precompute and cache $\log \pi_\theta(t_{j,k}^i \mid q_{j,k}^i)$ and $\log \pi_\theta(\bar{t}_{j,k} \mid q_{j,k}^i)$

Initialization:

Initialize $u_i \leftarrow 0$ for all i , and initialize v randomly

Set

$$\delta_i \leftarrow \frac{\exp(u_i)}{\frac{1}{I} \sum_{m=1}^I \exp(u_m)}.$$

Training:

for $t = 1, \dots, T$ **do**

 Group examples by (j, i)

foreach group (j, i) **do**

foreach turn k in d_j^i **do**

 Compute steered log-likelihoods

$$\log \pi_\theta(t_{j,k}^i \mid A_L(\cdot) + \delta_i v), \quad \log \pi_\theta(\bar{t}_{j,k} \mid A_L(\cdot) + \delta_i v)$$

 and retrieve cached baseline log-likelihoods

$$\log \pi_\theta(t_{j,k}^i \mid A_L(\cdot)), \quad \log \pi_\theta(\bar{t}_{j,k} \mid A_L(\cdot)).$$

 Form margin

$$m_{j,k}^i = \left[\log \pi_\theta(t_{j,k}^i \mid A_L + \delta_i v) - \log \pi_\theta(\bar{t}_{j,k} \mid A_L + \delta_i v) \right] - \left[\log \pi_\theta(t_{j,k}^i \mid A_L) - \log \pi_\theta(\bar{t}_{j,k} \mid A_L) \right].$$

 Compute turn loss

$$\ell_{j,k}^i = -\log \sigma(\beta m_{j,k}^i).$$

 Average $\ell_{j,k}^i$ over turns k in group (j, i)

 Average loss over groups in the minibatch and update v and $\{u_i\}$

 Recompute $\delta_i \leftarrow \exp(u_i) / (\frac{1}{I} \sum_m \exp(u_m))$

Inference:

for target tutor i **do**

 Apply activation steering

$$A_L(\cdot) \leftarrow A_L(\cdot) + \alpha \delta_i v$$

 during autoregressive generation

Table 5: Examples of our DPO dataset to train a steering vector (Part 1).

1988	[system] Cutting Knowledge Date: December 2023 Today Date: 26 Jul 2024 You are a tutor guiding a student through a math problem. [user] Question: $\frac{1}{2} \times 3 =$ A. $\frac{3}{2}$ B. $3\frac{1}{2}$ C. $\frac{3}{6}$ D. $\frac{1}{6}$ First Student Turn: hi [assistant] hello 🙌 how can I help you? [user] all of this [assistant] I'm just reading the question let's think about 3 lots of $\frac{1}{2}$ so first I'm going to think about what I get if I add 3 of them together what is $\frac{1}{2} + \frac{1}{2}$? [user] 1 [assistant] great! and then add another $\frac{1}{2}$. so what is $1 + \frac{1}{2}$? [user] 1 and $\frac{1}{2}$ [assistant] 👍😊 so the answer to three times $\frac{1}{2}$ must be 1 and $\frac{1}{2}$ oh, look at the options in the question. which is the same as 1 and $\frac{1}{2}$ [user] $\frac{1}{6}$ [assistant]	no sorry, $\frac{1}{6}$ is much smaller than $\frac{1}{2}$ it's like you share something between 6 people instead of just 2 people. Each person gets less when there's 6 people to share something between instead of just 2 people sharing it have another look at the ABCD options we now know it's not D	A is $\frac{3}{2}$ 😞😞😞

Towards Just-in-Time Adaptive Feedback: Enhancing Student Learning via Knowledge-Grounded LLM

Abstract

Educational interventions are effective tools for enhancing student learning. While Large Language Models (LLMs) allow for generating adaptive feedback at scale, current studies lack clear methodologies for providing Just-in-Time (JiT) feedback in authentic instructional settings. In this paper, we present a framework that provides adaptive feedback by grounding LLMs with domain-specific expert knowledge. Our approach collects written reasoning logic (strategy essays) from students, analyzes potential error types based on the content of that reasoning, and delivers non-intrusive feedback designed to clarify missing or incorrect concepts. We deploy this framework in a large-scale university course ($N > 1,000$), where it improved student performance by over 80% compared to previous semesters. Lastly, we validate the framework’s pedagogical utility by analyzing the learning trajectories; we demonstrate how iterative conversations with LLM facilitate shifting one’s misconception to correct understanding.

1 Introduction

In STEM education, students are often observed to engage in “Recursive Plug-and-Chug”—also known as “Formula Hunting”—where the goal is simply to fill a slot in a formula rather than to make sense of the problem (Chi et al., 1981; Tuminaro and Redish, 2007). Existing studies indicate that while experts analyze problems based on their deep logical structure and principles, novices are often primed to surface features, leading to unsuccessful problem-solving approaches. (Mestre et al., 1993).

Strategy writing has emerged as a powerful intervention to tackle this problem. Research has shown that asking students to articulate their strategies for solving problems can improve their problem-solving skills (Leonard et al., 1996). With a combination of argumentation and appropriate prompts,

students focus more on deep structure rather than the surface features of the problem and starts solving the problem with conceptual analysis, avoiding novice, unproductive strategies (Dufresne et al., 1992; Mestre et al., 1993; Docktor et al., 2010; Rebello and Piedrahita Uruena, 2019).

Despite the benefits, strategy writing is difficult to implement at scale. The primary impediment is the feedback bottleneck. Feedback is most effective when it is integrated into the learning process through formative assessment (Hattie and Timperley, 2007), and provided prior to completion (Henderson et al., 2021). However, providing real-time, formative feedback to thousands of students is prohibitively time-consuming for human instructors. Thus, the true potential of strategy writing to enhance student learning remains largely unrealized. The advance of generative Large Language Models (LLMs) offers a promising pathway toward overcoming the scalability barrier. Recent work proposes adaptive scaffolding frameworks that utilizes LLMs to help students understand course materials (Taneja et al., 2024; Kweon et al., 2025; Kestin et al., 2025; Zhang et al., 2025). However, they lack exploration of intervention-oriented interactions as well as grounding the models with domain-specific knowledge.

In this paper, we address these challenges by exploring dimensions of adaptive feedback and implementing a framework that provides Just-in-Time interventions using knowledge-grounded LLMs. First, we collect strategy essays from students over a couple of semesters and obtain historical data that connect the essays to the types of errors students had made. Human experts then annotate feedback on a small portion of the data considering the content of the essays, as well as the error types. Using these annotated instances as few-shot examples, the LLM identifies misconceptions in the strategy essays and provide real-time, adaptive feedback. Rather than providing a ‘shortcut’ to the correct

Figure 1: **Overall framework** of our Just-in-Time adaptive feedback LLM. In the first phase, we obtain domain knowledge from human experts regarding the appropriate feedback for students’ strategy essays and the types of errors they made. At deployment, we ground the LLM with this knowledge and provide adaptive feedback to the students based on their written strategy essays.

answer, the feedback directs the student’s attention to the underlying concepts and their reasoning logic (see Figure 4 and Figure 7 for examples). This ensures the intervention disrupts the ‘formula-hunting’ heuristic by letting students reflect on the problem’s deep structure. Figure 1 illustrates the overall framework we propose.

We experiment our framework on a large-scale university physics course ($N > 1,000$). Experimental results show that the overall student performance is improved when the feedback framework is deployed, by over 80% compared to previous semesters. Based on further analyses on self-reported survey and conversational instances, we argue that the framework effectively facilitates a shift from initial misconceptions to the correct understanding.

2 Related Work

Educational research has shown that feedback is one of the important drivers of learning (Wisniewski et al., 2020; Foster, 2024). Feedback can facilitate improvements in learners’ understanding and skills (Henderson et al., 2021) by narrowing the gap between actual and desired performance (Burgess et al., 2020). The effectiveness of feedback increases with the information that it contains. Previous research (Kluger and DeNisi, 1996) has also shown that moderators such as timing, specificity, and task complexity affect how learners receive and use feedback (Hattie and Clarke, 2018; Brooks et al., 2019).

Feedback is effective if it is sufficiently detailed (Price et al., 2010), usable (Winstone et al., 2017), and facilitates change (Ryan et al., 2016), such

that learners can test their new understandings (Pitt and Norton, 2017). In asynchronous and isolated online settings (Orlando, 2016), interactive dialogues can be especially useful (Wolsey, 2008) as students cannot easily interact with their peers (Furnborough and Truman, 2009) which put significant weight on the feedback comments they receive (Ortiz-Rodríguez et al., 2005).

Recent research on educational LLM applications has shifted from general assistance to specialized interventions. For instance, Phung et al. (2024) used GPT-4 as a teacher to provide non-intrusive hints but relied on LLM-simulated student agents using a weaker LLM (GPT-3.5), rather than applying it to real classroom settings. In contrast, Dai et al. (2023) and Jia et al. (2024) designed LLM feedback to apply to students, but their evaluation metrics focused on student-reported helpfulness survey and qualitative analysis of feedback content, rather than measuring actual improvements in student performance. More recent studies have shown LLM-generated feedback can help improve student performance in class. Hashmi and Rebello (2025) used an LLM-based Socratic chatbot to scaffold expert-like reasoning. Zhang et al. (2025) implemented a persona-driven multi-agent dialogue system, showing the student’s performance in problem-solving improves as they interact more with LLMs. Kestin et al. (2025) integrated an AI tutor in a college Physics course and compared student’s performance on a quiz between an AI tutor and in-class lessons. The results show that when the model is applied to a class size of 200, the AI tutor almost doubled the learning gains compared to in-class lessons.

In this paper, we introduce three novel contri-

butions. Unlike reactive chatbots that are susceptible to formula-hunting behaviors of the students, our system proactively analyzes the reasoning logic within the strategy essays that guides students to focus on deep structures in solving quiz problems. Additionally, we ground LLMs with domain-specific knowledge that is carefully annotated by human experts, which brings significant benefits compared to persona-based prompt engineering. Lastly, we provide a robust, automated intervention that remains pedagogically sound at a massive scale ($N > 1,000$).

3 Problem Formulation

3.1 Instructional Setting

Our research context is a large enrollment calculus-based physics course for engineers and physical scientists at a large U.S. Midwestern land grant university. The focus of the course is the development of problem-solving skills focused on applying key physics principles pertaining to mechanics across three units: Newton’s Laws and linear momentum, work and energy, and angular momentum. The annual enrollment of the course is around 3,300 students (1,500 in fall, 1,800 in spring), about 25% women, 10% underrepresented minorities, and 8% international students.

Each week, students complete an online quiz administered via the Learning Management System, along with an online proctoring system to maintain integrity. Students have 40 minutes to complete each online quiz. In this work, we focus on the quiz data from four consecutive semesters, from the Fall 2024 to the Spring 2026 semester.

3.2 Strategy Essays

Strategy essays refer to the student’s written reasoning logic in solving the quiz problem (Leonard et al., 1996). For one of the quiz questions, students are instructed to write a strategy essay that is at least 50 words long and does not include any numbers, symbols, or formulae. This was designed to evaluate the consistency between a student’s written reasoning logic and their performance on the quizzes. To maintain the quality of the essays, the instructors offer extra credit¹ for writing a strategy essay. In the Fall 2024 semester, for example, we gathered 11,948 essays from 1,418 students from a total of 11 quizzes.

¹Extra credits equal to 10% of the total points on the quiz

3.3 Desired Properties of LLM Feedback

LLM feedback refers to the LLM-generated text that is given to each student. The primary purpose of LLM feedback is to help students better understand the course materials related to the quiz problem and solve it correctly.

One of the most critical constraints in providing feedback is **to facilitate the student’s own problem-solving process**. The LLM should not disclose a direct solution or correct answers to the quiz problems when generating feedback to students. Another aspect we consider in designing the feedback is **adaptiveness**; rather than generating universal feedback, it is conditioned on student-specific features such as their in-class performance (e.g. pre-semester assessment scores, midterm exam scores, other quiz scores, etc.) and their strategy essays. Lastly, we focus on **grounding LLMs with domain-specific knowledge**. General-purpose LLMs often exhibit unreliable performance in understanding college-level STEM courses that require multi-step logic (Arora et al., 2023; Pang et al., 2025). To minimize the knowledge gap, we distill domain-specific knowledge from experts (i.e. instructors) and ground LLM generations with it.

3.4 Post-Hoc vs. Just-in-Time (JiT)

LLM feedback can be presented to students in two different ways: after students finish solving the quiz (post-hoc) and in real-time while they solve it (JiT). These two methods serve different benefits. In this paper, we utilize LLM post-hoc feedback to mainly survey the student’s preference for the feedback style. Students’ preference patterns ultimately help identify how LLM feedback needs to be generated. We consider LLM JiT feedback as a means of real-time interventions which help students solve the quiz problem.

4 Designing Adaptive Feedback

4.1 Student Preference Survey

Existing studies suggest the necessity of adaptive guidance that aligns with the student’s level of knowledge; unlike the way novice students perform better with detailed explanations, more experienced learners find it redundant and even show negative consequences (Kalyuga, 2007; Walker et al., 2012; Albacete et al., 2019). Since there is limited work that verifies this finding with LLM-based feedback, we conduct a series of surveys to find out whether

Figure 2: **Survey results regarding preference** between novice and advanced feedback in two quizzes. Regardless of their level of knowledge, students prefer LLM feedback that is targeted to the novice group.

students with different knowledge levels show a contrasting preference for the complexity of LLM feedback.

We provide post-hoc LLM feedback to the students for two quizzes in the Fall 2025 semester. Students are asked to write a short strategy essay that they employ to solve the problems. After having strategy essays from the students, we prompt LLMs to generate two different versions of the feedback, one for the novice-level and the other for the advanced-level. LLMs are instructed to differentiate not only linguistic styles such as tone and vocabulary, but also how feedback is framed with respect to the focus and goal². Students are instructed to participate in the survey on a separate webpage showing two feedback texts, one targeting the novice-level and the other for the advanced-level, and are asked to indicate which version they prefer. The presentation order of the feedback was randomized to mitigate potential order effects and minimize response bias. Figure 10 shows the survey webpage (see Appendix A).

To find the relevance between the student’s level of knowledge and the complexity of the LLM feedback, we categorize students into two buckets, novice and advanced. Students were categorized as novice if they performed below average for all relevant assessments; this includes a pre-semester assessment³, mid-term exam, and relevant previous quizzes. In contrast, students who consistently exceeded the average score for all relevant assess-

Quiz Problem

Question
 What is the horizontal component of the force that top block exerts on the bottom block?

Answer Options

A. $-m_2 \frac{\vec{F}}{m_1 + m_2}$	B. $m_2 \frac{\vec{F}}{m_1 + m_2}$
C. $-m_1 \frac{\vec{F}}{m_1 + m_2}$	D. $m_1 \frac{\vec{F}}{m_1 + m_2}$

Figure 3: **Example quiz problem.** While A is correct, other options map to common errors: B represents a direction error (misunderstanding force directions); C represents a position error (incorrect mass/location consideration); and D represents confusion involving both concepts (position-direction error).

ments were categorized as advanced.

Figure 2 shows the results. Although the portion of students who favor advanced-level feedback is larger among students with advanced knowledge, both novice and advanced groups prefer feedback that is targeted to the novice group. This implies that LLMs are inadequate to generate advanced feedback that is pedagogically effective, suggesting that simply instructing LLMs to increase vocabulary complexity and reduce scaffolding may hinder rather than help the learning process.

4.2 Just-in-Time Intervention

Using insights from the survey results, we focus on a different aspect of adaptive LLM feedback for JiT intervention: **error types**.

All incorrect multiple-choice options in the quizzes are designed to elicit specific error types. Consider an example quiz in Figure 3. The question asks to find the force that the top block exerts on the bottom block, given a certain amount of horizontal force, $\vec{F}$, is applied to the bottom block and the two blocks move together. The correct answer is multiplying the mass of the top block by acceleration which is the opposite direction to the $\vec{F}$. Common errors can be made by not considering that the direction has to be opposite (B. direction

Figure 4: Example of a strategy essay and annotated feedback. Although the student in this example got the correct answer, the feedback mentions the importance of considering direction as it was missing in the essay.

error), or by multiplying the mass of another object (C. position error), or by having confusion involving both concepts (D. position-direction error). We posit that LLMs offer effective interventions by predicting a student’s likely error type and providing adaptive feedback that guides them to reconsider those aspects in their final answer.

4.3 Grounding LLM Feedback with Domain Knowledge

As stated in 3.3, LLMs need to be grounded with domain-specific knowledge to provide more effective feedback with a better understanding of the concepts. We integrate human-expert knowledge into LLMs’ feedback generation process.

Using historical data from previous semesters, we collected students’ strategy essays and their corresponding answer choices, enabling us to associate written reasoning with particular error types. Teaching experts (i.e. faculty and instructors) then manually wrote feedback tailored to the content of these essays and error types.

Such nuanced feedback annotation is naturally a challenging task for LLMs. For example, students who selected the correct answer might still write imperfect strategy essays by not explicitly mentioning the force direction. Conversely, a semantically similar essay written by another student might lead to the direction error. Human experts are more competent in capturing these subtle differences between strategy essays and answer choices. Figure 4 illustrates an example of the annotation process, where experts identify missing concepts regardless of whether the student’s final answer was correct.

Once the feedback annotation is completed for a small representative set (50 examples), they serve as the few-shot examples for in-context learning, enabling the real-time classification of error types

Method	Accuracy	Macro F1
Fine-tuned Classifier	50.00 $\pm$ 0.001	28.39 $\pm$ 0.001
Zero-shot LLM	21.00 $\pm$ 0.004	12.74 $\pm$ 0.006
Zero-shot LLM w/ Secondary	37.00 $\pm$ 0.003	28.34 $\pm$ 0.005
Few-shot LLM	42.42 $\pm$ 0.001	33.50 $\pm$ 0.002
Few-shot LLM w/ Secondary	60.61 $\pm$ 0.002	54.24 $\pm$ 0.003

Table 1: Classification performance of different models in predicting error types (i.e. correct, direction, position, position-direction) given strategy essay. LLMs perform better when they are prompted with few-shot examples and Chain-of-Thought reasoning while considering secondary label.

using student’s strategy essays. Recognizing that strategy essays are often non-trivial to categorize into potential error types, we move beyond single-label prediction; we prompt the LLMs to identify both the primary and secondary most likely labels. The model then produces feedback via Chain-of-Thought reasoning (Wei et al., 2022), conditioned on this expanded label space to ensure more robust instructional support. Detailed explanations regarding prompts and JiT intervention framework are provided in Appendix C.

5 Experiments and Results

5.1 Error Type Predictions

In this experiment, we measure the accuracy of error type prediction across different models. The task is formulated as a multi-class classification where the model gets a strategy essay as input and predicts one of four classes: correct, or one of the three error types—direction, position, and position-direction. Table 1 describes the accuracy and macro F1 score of the models.

As a baseline, we first implement a sentence classifier using a pre-trained BERT-based checkpoint using the quiz data from Fall 2024 semester. Since the number of data instances is small (1.1K), the trained model shows zero accuracy on labels with insufficient amount of training instances, results in a very low macro F1 score.

As the number of training data instances is limited, we use high-performance LLMs to classify the error types without fine-tuning. We try prompting the LLMs with zero-shot and few-shot settings (3 examples per label). Although adding few-shot examples improve the performance, the accuracy and macro F1 scores are not strong enough. After we prompt the model to consider the secondary most likely labels, the performance increases signif-

Figure 5: Student’s performance in the same quiz question over four semesters. When the students solved the problem with the LLMs providing JiT adaptive intervention, the overall portion of correct students boosted significantly.

icantly, implying that the LLM can generate more robust feedback with expanded label space. Detailed explanations regarding prediction models are described in Appendix B.

5.2 Quiz with JiT Interventions

We administered JiT interventions during a specific quiz in the Spring 2026 semester. The problem and its corresponding multiple-choice options are illustrated in Figure 3. Students accessed the quiz through their standard Learning Management System, with the LLM feedback interface integrated directly into the problem description. A comprehensive view of the user interface and the interaction flow is provided in Figure 13 (see Appendix C). Upon engaging with the system, students were informed that the LLM would not provide direct solutions or answers. Instead, they were instructed to use the framework to get advice on specific concepts requiring further attention, based on the content of their strategy essays.

5.3 Student Performance Improvements

To measure the effectiveness of LLM-generated feedback, we compare student performance on the same quiz question over four consecutive semesters. As shown in Figure 5, more than half of the class in previous semesters made errors. In contrast, the error rate drops to less than 10% with the help of JiT LLM intervention.

Notably, the feedback remains highly effective despite sub-optimal performance of LLMs in predicting error types. We attribute this to domain-

Figure 6: Survey results regarding why LLM’s feedback was helpful. Aside from confirmation, students indicate that LLM was useful in clarifying overlooked / missing aspects in the essays

knowledge grounding, which incorporated expert-generated feedback that addresses potentially missing or incorrect concepts regardless of the predicted error class.

After students solve the quiz with LLM feedback, we ask whether the feedback was helpful and why. Approximately 77.59% of the students reported the feedback was helpful; their qualitative responses are clustered using HDBSCAN, and shown in Figure 6.

There are two major themes emerged from the clusters. Around half of the students valued the feedback for concept verification and confirmation, while the other half stated that the LLMs clarified overlooked or missing items in their strategy essays. This illustrates the adaptiveness of JiT LLM feedback; for students with a correct understanding,

Metric	Value
Total instances	1,042
Conversational instances	209 (20.05%)
Mean # conv. turns (std)	2.77 (1.52)
Min/Max # conv. turns	2 / 14
Conv. turn dist. skewness	3.57
% of Model Prediction as Correct	
Turn 1 (Initial essay)	42.79%
Last turn (Final essay)	71.64%

Table 2: Statistics of conversational instances. The skewness of the number of conversation turn distributions is computed by Fisher-Pearson coefficient of skewness where the value greater than 2 is normally considered extremely skewed.

the LLM provides essential validation, whereas for those prone to errors, it guides them rethink or pay more attention to specific concepts.

5.4 Learning through Conversations

One of the emergent behaviors of students in interacting with feedback-generating LLM is that they have conversations with the LLMs to improve their understanding. This observation is impressive considering that students are not directed or incentivized to iteratively chat with the LLMs. Students are notified as solving the quiz with LLMs will give them a bonus credit regardless of the correctness of their answers. Nevertheless, there are around 20% of the students who voluntarily spent more time interacting with the LLM so that they could improve their learning experience. Basic statistics of the conversational instances are reported in Table 2, and more detailed statistics are reported in Appendix D.

Figure 7 shows an example of conversation between a student and LLM. As the student receives LLM’s feedback that tackles missing or incorrect points in the strategy essay, they add these components to their strategy essay. By continuing conversations, students incrementally add missing points and gain more comprehensive understandings. Table 2 illustrates such instances: while only 43% of students’ initial essays were predicted as correct, the portion boosted to 72% after having conversations.

We visualize learning trajectories by analyzing the sequence of conversation turns with the LLM. This involves tracking the intermediate strategy essays and their corresponding predicted error types throughout the interaction. Figure 8 illustrates how students modify their strategy essays and how the

Figure 7: **Example Conversation** of a student modifying their strategy essays with the help of LLM. LLM generates feedback based on its error type prediction, and informs different aspects as the student fixes errors one by one.

predicted error types change while they have conversations with LLMs. The figure represents a subset where students’ strategy essays are initially classified as having a direction error.

As conversation proceeds, students keep modifying their essays by applying LLM’s advice, and there exists multiple learning trajectories based on how they improve their essays. In the end, approximately 80% of the students corrected their essays and the LLM classified them as ‘correct’. Other students, even though their final version of essays are not classified as ‘correct’, they solved the quiz correctly. We assume that this is the case where students skip the final validation step after having their perspectives corrected. Overall, 91.43% of the students (32 out of 35) solved the quiz correctly by iteratively getting feedback from LLM and developing their understandings.

We conducted a further analysis to validate the hypothesis that students who engage more actively with the LLM feedback improve their strategy essays better. We defined “activeness” through two metrics: reflective latency (the time in seconds between conversation turns) and degree of revision (the change in word count between consecutive essay versions). Specifically, we posit that spending more time refining an essay or making more substantial text changes indicates a more active adaptation of the feedback.

Figure 8: **Learning Trajectories** for students starting with Direction error. Each trace represents a sequence of essay error types as predicted by the feedback-LLM at each conversation turn. Terminal markers are labeled with the specific Path Sequence and the Path Outcome. For instance, ‘D-C: 17/19’ indicates that out of 19 students whose essays the LLM classified as ‘Direction error’ and then ‘Correct’, 17 got correct answers in the end.

Figure 9: **Correlation between word count differences and essay correctness.** We compute the correlation between the word count differences in strategy essays between each conversation utterances and the correctness of essay. When the students make more changes to their essays, they are more likely getting their essays correct.

To evaluate these hypotheses, we compute the Pearson correlation coefficients. The results indicate a negligible relationship between time spent and essay correctness ($r = 0.06$, $p = 0.27$). In contrast, the correlation between word count dif-

ference and essay correctness is statistically significant ($r = 0.18$, $p < 0.001$). Figure 9 illustrates how word count differences are distributed differently for the essays that are classified as correct or not. These findings suggest that simply spending more time on the interface is insufficient; rather, the degree of revision is the primary factor of success. This implies that while the LLM provides the necessary feedback, the likelihood of achieving a correct understanding depends heavily on the student’s willingness to actively reformulate their reasoning.

6 Conclusion

In this paper, we explore how LLMs can be utilized efficiently in higher education through Just-in-Time (JiT) adaptive interventions. By analyzing strategy essays from students, our framework identifies potential errors and provides adaptive feedback grounded in domain knowledge. Experimental results show that our framework significantly improves the overall student performance by providing validation and guiding re-evaluation of incorrect concepts. Qualitative analysis further demonstrates that students engage in conversations with LLMs to improve their understanding, highlighting the potential for LLMs to serve as sophisticated pedagogical tools.

Limitations

One of the limitations of this work is the sub-optimal accuracy of the error type classification. Predicting error types solely from strategy essays is a non-trivial task even for humans. Students often omit important details, whether due to oversight or lack of conceptual understanding. LLM feedback falls into a catastrophic failing mode when the LLM incorrectly classifies an essay as ‘correct’ and does not provide necessary interventions as a result of that. While we mitigate this risk by considering second most-likely label, the reliability and robustness of the framework can be improved with better classification. In future iterations, we could improve it by using relevant metadata (e.g. student’s level of knowledge, tone and vocabulary used in the essay, etc.), or by enforcing a more structured essay format to ensure all necessary concepts are articulated.

Another limitation is the small number of JiT interventions, as the framework was applied to only a single quiz during the semester. Although we observe significant performance improvements with the LLM feedback, a broader deployment across multiple topics and quiz types is necessary to validate these findings. Expanding the scope would allow for a more granular analysis of which specific subject matters or problem types benefit most from LLM-based interventions, providing deeper insights in how LLM feedback should be designed.

Our student preference survey shows that while the LLM is highly effective for novice-level feedback, it struggles to generate feedback that is more suitable to students with advanced knowledge; students with over-the-average performance still preferred LLM feedback that is targeted to novice-level over the advanced-level. This opens a new direction for designing LLM feedback in future studies to provide minimal interventions considering the knowledge level of students.

From a technical point of view, approximately 4% of the students experienced server failures due to the high volume of synchronous API calls, mainly due to the size of the course being very large ($N > 1,000$). To make the framework more scalable, future implementations need to address rate-limiting and asynchronous processing. Furthermore, the current LLM lacks a memory function that help efficient conversations; the current version processes updated strategy essays in isolation without the context from previous versions. In

future work, we aim to incorporate student-specific memory and conversation history that reduces the number of turns required for a student to reach a correct understanding.

Ethics Consideration

This research was declared ‘Exempt’ under IRB protocol number IRB-2023-391. The participant pool consisted of undergraduate students enrolled in a large-scale introductory Physics course. All personally identifiable information, including student names and university IDs, was removed from the data before being processed by the LLMs. Student essays used for qualitative analysis in this paper have been further anonymized, truncated, and paraphrased.

Our framework contains risks when generating feedback to students, primarily because of hallucinations and incorrect classification of error types. To mitigate these risks, the LLM was grounded with expert-annotated domain knowledge as well as its secondary predictions. Furthermore, we prioritized equity of treatment and algorithmic fairness throughout the study. The LLM was prompted using a standardized, invariant template for all participants, ensuring that the feedback was controlled solely by the student’s essay rather than any external variables such as student’s personal information or prior performance levels. By maintaining a uniform prompting strategy, we ensured that no specific group of students was prioritized or discriminated against, providing consistent pedagogical support to the entire students.

We disclose that LLMs are used for checking grammatical errors and exploring paraphrases. All core research contributions including motivation, experiment designs, and results analyses were developed by the authors.

A Feedback Preference Survey

We survey student’s LLM feedback preference in the Fall 2025 semester for two quizzes. Students are instructed that they will get extra credits for participating in the survey, and the number of participants for each iteration was 1,074 and 1,160. The two options for feedback is generated with the prompt described in Figure 11; it first evaluates the student’s strategy essays using expert-annotated rubrics, then generate two different versions of feedback using gpt-5.1, one for novice and the other for advanced.

Once the feedback generation is completed, we hosted a separate survey webpage from the student’s standard Learning Management System as shown in Figure 10. The two options are randomly swapped to minimize any potential biases. Students are instructed to read the quiz problem and essay they authored to remind themselves of the context, and choose one of the feedback texts they prefer with a set of pre-defined reasons (students can choose multiple reasons). For both surveys, the most selected reason was “Helps me better understand the concept”, followed by “Better explains the errors in my strategy” and “Aligns better with my level of knowledge”.

B Error Type Prediction Model Details

For fine-tuned classifiers, we randomly split the data into 80-10-10 ratio for train-validation-test sets. We use DeBERTa-v3-small model with learning rate of $2e-5$ and batch size of 16. The model is fine-tuned and tested on a single NVIDIA A100 GPU with 80GB memory, takes around 10 minutes to fine-tune 5 epochs.

Quiz 11 Survey. Which Feedback Do You Prefer?

Review the feedback options for your strategy essay and choose an option which you find most helpful.

Quiz Question

In the Atwood's Machine on the inclined plane as shown, the rope does not slip over the pulley with bearings that have negligible friction. The masses of the two blocks shown are known. The inclined plane makes a known angle with the horizontal. The coefficient of friction between the block m_1 and the inclined plane is known. The pulley is a disk of known mass and known radius. What is the linear acceleration, a , of each block?

Your Essay

To find the acceleration of each block, I must first set up the Momentum Principle for each block, which states that the net force acting on the block is equal to its mass times its acceleration. However, since that gives me only two equations with more than two unknowns, I must also use the Angular Momentum Principle for the pulley, which states that the net torque on the pulley is equal to its moment of inertia times its angular acceleration. I can write the angular acceleration in terms of the linear acceleration of each block since the rope is not slipping. Then I will plug in known variables, and use substitution to solve the system of equations for the acceleration of each block.

Feedback Options

Feedback A

You've identified the correct governing principles and the no-slip kinematic relation, but your plan is missing some critical structural details—most notably the need to treat the tensions on either side of the pulley as distinct and to explicitly include friction and weight components in your force balances. Before plugging in variables, try to write three fully specified equations: two linear momentum equations with properly resolved components (including friction for m_1 and weight components along the incline) and one rotational equation with torque from the two different tensions and the correct disk moment of inertia. As you refine your strategy, ask yourself: where exactly does the torque on the pulley come from if the tensions were equal, and how does the frictional interaction on the incline qualitatively affect the sign and magnitude of the acceleration you expect?

Feedback B

You've made a very strong start by correctly naming the two big ideas: using Newton's Second Law (momentum principle) for the blocks and rotational Newton's Second Law (angular momentum principle) for the pulley. One important next step is to be more explicit about the forces: write separate force equations for each block that include gravity (weight), friction on the incline, and the tension pulling each block, and also remember that the tension on each side of the pulley can be different so that there is a net torque on the pulley. It's great that you know to connect angular acceleration to linear acceleration with the no-slip condition; if you now carefully list all forces and write three equations (one for each block and one for the pulley), you'll have everything you need to solve for the acceleration with confidence.

1. Choose better feedback

☐ A ☒ B

2. Why do you prefer this feedback?

Please select all that apply. At least one option is required.

- ☐ Helps me better understand the concept
- ☐ Better explains the errors in my strategy
- ☐ Aligns better with my level of knowledge
- ☐ Other

Please specify

Submit

Figure 10: Survey webpage. Students answer two questions; choosing better feedback and the reason why.

For LLM-based inference, we used the deepseek-r1:70B checkpoint, hosted on-premise at the authors' institution, to make sure the student's essay data is not shared outside.

All fine-tuning and inferences are performed with 2 trials and the average score was reported with the confidence interval in Table 1.

C JiT Feedback Implementation

When the LLM is deployed for generating JiT feedback, we host a web app using Flask API, which is later embedded to the Learning Management System that students use for the course. The web app is a simple text box where students put their strategy essays and clicks a button to get the feedback from the LLM. In the back-end, we use pre-defined few-shot examples with Chain-of-Thought reasoning so that the model considers primary and secondary class of the strategy essay. The example of an actual prompt and the quiz page students have accessed is shown in Figure 12 and Figure 13.

D Conversation Analysis

From \ To	Correct	Position	Direction	Pos-Dir
Correct	0.6797	0.1328	0.1250	0.0625
Position	0.3491	0.3585	0.1415	0.1509
Direction	0.5278	0.1250	0.2917	0.0556
Pos-Dir	0.3750	0.2969	0.0781	0.2500

Table 3: Transition probabilities between error types across conversation turns

In this section, we report additional analyses on conversational instances. Table 3 shows the transition probabilities between conversation turns. When the student's strategy essay at the i -th conversation turn is predicted as correct, it is still going to be classified as the same label with the 67.97% chances, but there exists slightly more than 30% chances the essay is classified as one of the error types. While majority of the strategy essays with direction and position-direction errors are likely developed into correct strategy, essays with position error is more likely going to stay at the same error type. This implies that LLM's ability to guide students avoid errors differ based on the types.

Prompt Sample: Generating Post-hoc Feedback for Preference Survey

You are an expert College Teaching Assistant and Pedagogical Specialist. Your goal is to provide feedback on a student's "Strategy Essay" regarding a quiz problem. First, analyze the student's written strategy to infer their Knowledge Level based on the complexity and accuracy of their writing. Then, regardless of their actual level, generate two distinct versions of feedback (one adapted for a "Novice" and one for an "Advanced" student) to provide options for instruction. Generate each feedback in 3 sentences.

Input Data Provided:

1. The Quiz Problem: The specific question the student attempted to solve.
2. Student's Strategy Essay: The student's written explanation of how they approached the problem.
3. Expert's Strategy Essay: A sample strategy essay written by an expert, that can serve as a rubrics for evaluating student's essay

Instructions for Adaptation:

- If Knowledge Level is "NOVICE":
 - Tone: Highly encouraging, supportive, and patient. Use the "Sandwich Method" (Praise -> Gentle Correction -> Praise).
 - Vocabulary: Avoid jargon where possible. If technical terms are used, briefly define them or use analogies.
 - Focus: Focus on identifying misconceptions and solidifying the fundamental concept.
 - Scaffolding: Break down the next steps into small, manageable pieces. Guide them toward the correct starting point.
 - Goal: To build confidence and ensure they understand the basic mechanism of the problem.
- If Knowledge Level is "ADVANCED":
 - Tone: Professional, peer-to-peer, challenging, and concise.
 - Vocabulary: Use precise, high-level academic/technical terminology appropriate for the field.
 - Focus: Focus on optimization, edge cases, and connecting this problem to broader course concepts. Point out subtle logic flaws or inefficiencies.
 - Scaffolding: Do not hand-hold. Ask Socratic questions that force the student to re-evaluate their own logic.
 - Goal: To refine their reasoning, improve efficiency, and deepen metacognition.

Feedback Structure (Output Format) Please output the response in the following json format:

```
{ "Essay_Evaluation": "1-2 sentences summarizing their approach based on the expert sample",  
  "Inferred_Level": "Either Novice or Advanced",  
  "Feedback": {  
    "Novice": "The core feedback paragraph. Apply the Instructions for Adaptation logic for NOVICE here strictly.",  
    "Advanced": "The core feedback paragraph. Apply the Instructions for Adaptation logic for ADVANCED here strictly.",  
  } }
```

[INPUT DATA]

The Quiz Problem: quiz_description_input

Student's Strategy Essay: student_strategy_input

Expert's Strategy Essay: expert_strategy_with_rubrics

Figure 11: The full system prompt used for generating post-hoc feedback

Prompt Sample: Generating Just-in-Time Feedback for Quiz Problem Solving

You are an expert Physics Education Researcher and Cognitive Scientist. Your goal is to analyze student essays describing their strategy for solving a problem. You must determine if the student's proposed strategy will lead to the Correct Answer or a specific type of Misconception.

TASK DESCRIPTION: I will provide you with a physics problem statement and a "Strategy Essay" written by a student.

1. Analyze the student's essay. Look for specific keywords or logical steps.
2. Identify if they are applying correct principles/concepts or falling into misconceptions.
3. Output your final reasoning and label as strictly valid JSON.

Label Categories & Definitions

- 'correct': The reasoning and final answer are physically sound.
- 'direction': The student makes an error where their answer is in the exact opposite direction of the correct vector OR The student does not specifically state the direction they want to apply.
- 'position': The error arises from calculating forces or properties on a different object than the one asked OR The student does not specifically state the particular object they want to calculate for.
- 'position-direction': Both a 'position' error and a 'direction' error occur simultaneously in the student's response OR The student does not specifically state the direction nor the object they want to consider.

Few-Shot Examples

[Examples of student's sample strategy essay, its error type, and feedback generated by human experts]

TEST CASE {quiz_problem}

{STUDENT_STRATEGY_ESSAY}

INSTRUCTIONS: Analyze the "Student Essay" above and provide the JSON output.

OUTPUT FORMAT:

{ "classification": Choose one from [correct, direction, position, position-direction],

"confidence": How confident the classification is (scale of 1 to 5, 5 being most confident),

"secondary_classification": What would be the second most likely label?

"feedback": Feedback message (in 50 words) to students based on their essay. If their essay is classified to make a certain type of mistake, the feedback should highlight that aspect. If it is classified as correct, the feedback can be general and notify some common mistakes that can be made. If the secondary classification is different from classification, take both classes into consideration.

}

Constraint

- Output ONLY the json.
- Do NOT provide reasoning, explanations, or introductory text.

Figure 12: The full system prompt used for generating JiT feedback

Figure 13: Overall flow of JiT feedback. The feedback snippet is placed below the quiz question. Students type in their strategy essays, click a button, and gets a feedback after a few seconds.

RABIT: Rationale-Based Distillation Towards Interpretable Automatic Speaking Assessment via a Small Language Model

Bi-Cheng Yan, Hong-Yun Lin, Fu-An Chao, Jiun-Ting Li, Berlin Chen

National Taiwan Normal University, Taipei, Taiwan

{bicheng, fuanchao, berlin}@ntnu.edu.tw

Abstract

Automatic speaking assessment (ASA) manages to quantify the language competence of foreign language learners by providing a proficiency score based on their spoken response. Existing efforts in ASA typically employ a neural grader integrated with a set of hand-crafted features to assess learners' oral proficiency from multiple facets. Despite decent performance, the black-box nature of these neural graders remains a significant barrier to providing interpretable explanations for the grading results. In light of this, we propose RABIT for ASA, a novel rationale-based knowledge distillation framework for interpretable grading decisions via a small language model. Specifically, RABIT first extracts multi-faceted grading rationales from a large language model (LLM) pertaining to the learner's response and the scoring guidelines. Subsequently, a compact yet efficient language model, equipped with distinct output heads, is jointly optimized to estimate a proficiency score while generating a sequence of grading rationales in an autoregressive manner. A series of experiments conducted on General English Proficiency Test (GEPT) dataset validates the feasibility and superiority of our method over several cutting-edge baselines.

1 Introduction

Spurred by the global demand for foreign language proficiency in both the workforce and academia, there is a growing need for the assessments of language competence (Davis and Norris, 2024). In response, the development of automatic speaking assessment (ASA) systems has garnered significant attention, figuring prominently in the fields of computer-assisted language learning (Zechner and Evanini, 2019) and large-scale language testing (Singla et al., 2021). Such systems offer a broad spectrum of applications to mitigate the disproportion between the limited number of instructors and the expanding population of foreign language learn-

Figure 1: Motivations of our approach. (a) Assessment in the free-speaking scenario, where the ASA models aim to evaluate learner's language proficiency based on the spoken response. (b) Existing ASA systems often operate as a black-box process, lacking transparency in their grading decisions. (c) Our proposed method (RABIT) jointly optimizes proficiency estimation and rationale generation to achieve transparent and reliable assessment results.

ers, ranging from low-stakes contexts (e.g., providing informative feedback for both instructors and learners in course placement (Evanini and Wang, 2013)), to high-stakes scenarios (e.g., serving as a reliable reference for professionals in admission testing (Evanini et al., 2017; Chen and Li, 2016)).

ASA seeks to quantify the extent of language proficiency in foreign language learners across multiple dimensions, including delivery (fluency and pronunciation), language use (vocabulary and grammar), topic development (content and discourse) (Qian et al., 2019; Zechner and Evanini,

2019), and others. One of the de-facto archetypes of ASA is instantiated in free-speaking scenarios, as shown in Figure 1(a), where the language learner is presented with short, open-ended questions and instructed to respond based on their personal experiences or opinions. A leading strand of research in ASA derives a set of handcrafted features from the synergy of learners’ spoken responses and the presented short questions. These features are then fed into a neural grader to predict either a holistic score (i.e., a categorical value of overall speaking proficiency) or analytic scores (i.e., continuous numerical scores for specific aspects). Specifically, to characterize learners’ pronunciation clarity and spoken delivery, commonly used features include confidence scores of recognized linguistic units (e.g., words or phones), time-alignment information (e.g., speaking rate, pause frequency, and filled pauses), and statistical measures of fluency and pitch contours (Zechner et al., 2009; Chen et al., 2010). Grammatical accuracy and syntactic complexity are captured by the transcriptions of the learner response through part-of-speech tagging, syntactic dependency parsing, and morphological analysis (Moore et al., 2015; Qian et al., 2018). Lastly, content coherence and topical relevance are assessed by evaluating the learner response and the presented short questions, where the BERT-based semantic features combined with graph-based neural networks have been extensively investigated (Li et al., 2023; Bannò and Matassoni, 2023; Singla et al., 2021; Li et al., 2024).

Although existing efforts have achieved commendable performance on various spoken assessment tasks by leveraging a set of handcrafted features to qualify learners’ language competence, the opacity of scoring decisions remains a crucial challenge. The interpretability of scoring decisions is nearly sidelined, which might undermine the efficiency of language acquisition and diminish pedagogical utility, as depicted in Figure 1(b). In light of this, we propose a novel two-step knowledge distillation framework for ASA, termed rationale-based distillation for interpretable grading decisions (RABIT). By harnessing the reasoning capabilities of large language models (LLMs), RABIT first distills grading rationales into a lightweight yet effective small language model, which then in turn learns to generate interpretable, fine-grained scoring decisions while assessing the language proficiency of foreign language learners. To explicitly illustrate how the learner responses align with the scor-

ing rubrics, RABIT first prompts an LLM (e.g., LLaMA3.1-8B and LLaMA3.2-3B (Touvron et al., 2023)) with systematic rubric guidelines to elicit multi-faceted grading rationales conditioned on the transcriptions of learner responses and the associated short questions. Afterwards, a small language model (e.g., SmolLM2-135M-Instruct (Allal et al., 2025)) augmented with two distinct output heads is jointly optimized to predict proficiency scores and generate corresponding grading rationales in an autoregressive manner. Extensive experiments on the General English Proficiency Test (GEPT) dataset demonstrate that our methods consistently outperform several competitive baselines. Beyond performance gains, exploring a small LLM to generate grading rationales for foreign language learners introduces an additional layer of transparency to the field of ASA research.

In summary, the main contributions of this work are at least three-fold: (1) As one step towards interpretable grading decisions, RABIT is among the first attempts to evaluate language proficiency of foreign language learners while offering grading rationales, opening up a new research avenue for ASA; (2) Furthermore, to adapt small language models for ASA, we introduce prompt vectors in conjunction with a score prediction head to stabilize proficiency score estimation while maintaining the computational efficiency; (3) Extensive experiments on a realistic spoken assessment dataset, comprising authentic oral responses and expert annotations, confirm the practical and pedagogical utilities of RABIT.

2 Rationale-based Distillation for Interpretable Grading Decisions (RABIT)

This section sets out with a problem definition of ASA task and then sheds light on the proposed knowledge distillation framework, rationale-based distillation for interpretable grading decisions (RABIT). Our approach aims to improve the transparency and the practical utility of ASA through two pivotal steps, namely LLM rationale probing and small language model training, as illustrated in Figure 2(a). In the first step of RABIT, we leverage an LLM to generate multi-faceted grading rationales by conditioning on the transcriptions of learner responses, the short questions, the rubric guidelines, and the expert-annotated proficiency score. Subsequently, in the second step, these dis-

Figure 2: Overview of the proposed RABIT framework for interpretable knowledge distillation. (a) The two-stage training process, comprising LLM rationale probing and small language model (SLM) distillation. (b) A running example illustrating the rationale generation and distillation process in the first stage of RABIT.

titled rationales serve as additional supervision for a small language model, which is jointly trained to estimate proficiency scores while producing the corresponding grading rationales.

2.1 Problem Definition

Given a sequence of short questions Q , a foreign language learner is instructed to produce a spoken response X that reflects their personal experiences or opinions. An ASA system is then tasked with estimating a categorical proficiency score $y \in \{1, 2, 3, 4, 5\}$ for X , where y denotes a distinct level of language competence across multiple facets including delivery, language use, and topic development.

2.2 Step1 of RABIT: LLM Rationale Probing

For each instance of training data, consisting of a spoken response X paired with the short questions Q and the corresponding proficiency score y , we first transcribe X into a sequence of words T via a speech recognizer (e.g., Whisper-large-v3 (Radford et al., 2023)). Subsequently, a structured prompt template P is curated to elicit a sequence of grading rationales R from an LLM. The prompt template $P = [G; I; Y; Q; T]$ comprises the following components: the rubric guidelines G , which outline scoring rubrics used by human experts; the instruction I , which describes the role of the LLM in gen-

erating multi-faceted proficiency scores along with explanations; the score reference Y , which specifies y for the LLM to guide rationale elicitation; and the short questions Q coupled with the transcribed response T . The first step of RABIT is illustrated with a running example in Figure 2(b). Notably, since the rationale generation relies on the ASR transcriptions, the instruction I positions LLM as a language instructor to elicit multi-faceted grading decisions from a textual perspective, focusing on the grammatical accuracy, content relevance, and overall proficiency score. To ensure the reliability of distilled rationales, we filter out instances where the LLM-generated scores conflict with y . In preliminary experiments, we evaluated the feasibility of large multimodal language models (e.g., Phi-4-multimodal (Abouelenin et al., 2025), and QwenAudio (Chu et al., 2023)) to generate grading rationales directly from the speech signal X and the task instruction I . However, these models are prone to generating hallucinated feedback. We attribute this to the scarcity of expert-annotated ASA data and its underrepresentation during the training of these multimodal foundation models.

2.3 Step2 of RABIT: Small Language Model Training

Although LLMs have demonstrated remarkable performance on various NLP benchmarks, the high computational overhead hinders practical deployment in real-world ASA applications, particularly on resource-limited edge devices such as mobile phones or personal computers. To this end, following the extraction of rationales in Step 1, we fine-tune a small language model (e.g., SmolLM2 (Allal et al., 2025)) in Step 2 to build a computationally efficient and interpretable ASA model. As illustrated in Figure 3, we employ a small language model as the backbone, which jointly learns to predict the proficiency score and generate grading rationales based on a set of handcrafted features via parameter-efficient instruction tuning (Hu et al., 2022). Our interpretable ASA model consists of three components: proficiency-specific encoders, proficiency-specific projectors, and a small language model. In the following, we delve into the functional details of each component.

Proficiency-specific Encoders. To capture the supra-segmental pronunciation cues in the learners’ speech, we leverage a pre-trained audio encoder (e.g., Wav2vec2.0 (Baevski et al., 2020)) for delivery feature extraction (Lo et al., 2024; Chao et al., 2022; Yan et al., 2025), which takes the speech signal X as input and maps it to a sequence of high-level acoustic representations H_0^D . The language-use features H_0^L are derived from one-hot encodings of part-of-speech tags, syntactic dependency labels, and morphological features, all of which are linearly projected and packed together via individual linear transformations to form a unified representation (Peng et al., 2024). To capture the content coherence between a learner’s response and short questions, a pre-trained text encoder (e.g., BERT (Devlin et al., 2019)) is adopted to extract content features H_0^C by formatting an input text sequence as the concatenation of short questions Q and the transcribed response T , delimited by the [SEP] token to model their inter-textual relationships.

Proficiency-specific Projectors. To bridge the proficiency-specific encoders and the small language model, the projectors map the respective proficiency features into token representations, aligning the proficiency features with the latent space of the small language model. In this work, we employ a convolutional projector that encapsulates fine-grained linguistic cues into compact token rep-

Figure 3: The proposed multi-modal ASA model in the second stage of RABIT, which jointly estimates proficiency scores and generates corresponding grading rationales.

resentations with a Macaron-style neural structure, where a Transformer block is sandwiched between two separate depth-wise convolutional layers. Each convolution layer incorporates a GELU activation function ((Lee, 2023)) and a kernel size of 3. For down-sampling, the first layer utilizes a kernel stride of $k/2$, and the second employs a kernel stride of k . We compress the delivery, language-use, and content features along the temporal dimension at reduction rates of 64, 32, and 32, respectively (i.e., $k = 16, 8$, and 8).

Small Language Model. Conditioned on a set of handcrafted features extracted from proficiency-specific encoders, our language model aims to generate a sequence of grading rationales and estimate proficiency scores for language learners. Empirically, we found that training a small language model to output both the rationale sequence and a proficiency score within a single natural language sequence often leads to inconsistent output formats. In contrast to prior works (Chu et al., 2025; Hsieh et al., 2023), our approach introduces learnable prompt vectors H^P to the inputs, which are integrated with the handcrafted features for the small language model. Following forward propagation through the language model, the outputs of these prompt vectors are pooled by an averaging operation and subsequently passed to a classification head to predict the proficiency score y . A bit more terminology: The input sequence to our language model, denoted as $H = [H^D; H^L; H^C; H^I; H^P]$, comprises prompt vectors H^P , instruction embeddings H^I and a set of handcrafted features, where H^D, H^L, H^C are the projected features derived from

the delivery, language-use, and content coherence representations (i.e., H_0^D , H_0^L , and H_0^C) via their respective projectors. H^I denotes the textual representation of the instruction I , projected through the embedding layer of the small language model. Our ASA model employs a small language model parameterized by θ to generate the grading rationales $R = (r_1, r_2, \dots, r_N)$ by minimizing the negative log-likelihood:

$$\mathcal{L}_{rat} = -\log \mathcal{P}_\theta(R|H), \quad (1)$$

$$= -\sum_{i=1}^N \log \mathcal{P}_\theta(r_i | R_{0:i-1}, H), \quad (2)$$

where $R_{0:i-1}$ denotes previously generated tokens. On a separate front, our model also predicts a proficiency score $\hat{y}$ via a classification head. To stabilize the score prediction, the classifier relies on the mean-pooled representation $\bar{h}^P$, derived by applying an average pooling operation to the output representations of prompt vectors H^P after processing through the language model. Proficiency score estimation is optimized by minimizing the cross-entropy loss between the distributions of predicted score $\hat{y}$ and the ground-truth score y (represented as a one-hot vector $\mathbf{y}$):

$$\mathcal{L}_{score} = -\sum_{c=1}^5 \mathbf{y}_c \log \hat{\mathbf{y}}_c, \quad (3)$$

$$\hat{\mathbf{y}} = \mathcal{P}_\theta(\hat{\mathbf{y}} | \bar{h}^P) = \text{softmax}(W\bar{h}^P + \mathbf{b}), \quad (4)$$

where W and $\mathbf{b}$ are learnable weights of the classification head. In the training phase, we keep the small language model frozen and integrate a LoRA module to minimize the following objective function:

$$\mathcal{L} = \mathcal{L}_{score} + \alpha \mathcal{L}_{rat}, \quad (5)$$

where $\alpha \in [0, 1]$ is a control parameter balancing the losses of rationale generation and proficiency score estimation.

3 Experimental Setups

GEPT Dataset. In this paper, a series of experiments were carried out on an in-house dataset derived from General English Proficiency Test (GEPT), a standardized assessment administered by the Language Training and Testing Center (L TTC) in Taiwan. The GEPT dataset targets English learners across various proficiency levels, comprising listening, reading, writing, and speaking.

Dataset		Human-rated Score				
		S1	S2	S3	S4	S5
Train		4	61	317	310	27
Dev		0	6	39	39	6
Test	Seen Prompt	0	11	37	39	3
	Unseen Prompt	0	4	142	137	17

Table 1: Statistics of Picture-description Section in GEPT Dataset.

For our ASA experiments, we specifically focus on the picture description section of the GEPT dataset, in which foreign language learners are presented with a picture and instructed to answer short questions. This subset consists of 1,199 recordings, each paired with an expert-annotated proficiency scores, the short questions, learner response and the corresponding pictures. Each spoken response was independently evaluated by two qualified experts adhering to the same standardized rubric. To derive a single categorical proficiency score, we averaged the two ratings and applied the floor function. The GEPT dataset was partitioned into training, development, and seen-prompt test sets in an 8:1:1 ratio. An isolated unseen-prompt test set comprising 300 recordings was reserved to evaluate the generalization capability of the proposed model to novel picture description learning scenario. The dataset statistics are provided in Table 1.

Implementation Detailed. In the first step of RA-BIT, we employed LLaMA-3.1-8B-Instruct for rationale generation. In the second step, we used SmolLM2 model family as the backbone for our interpretable ASA model. To extract various hand-crafted features, we adopted Wav2vec2.0¹ to extract delivery features. Content coherence was modeled using a BERT-based text encoder², while language-use features were derived from word-level linguistic units. Following Peng et al. (2024), language-use features include POS tags, dependency labels, and morphological features processed by the spaCy toolkit³ based on the transcription of learner responses. As for the model training, we employed the Adam optimizer with a learning rate

Table 2: Performance comparison with state-of-the-art methods on the GEPT dataset in terms of Accuracy (%), Weighted F1-score (%), and Macro F1-score (%). Standard deviations over 3 runs are reported in parentheses.⁺Results for Qian2019 and SAMAD are reported in Peng et al. (2024).

of 0.001 and a batch size of 3. A warm-up strategy was applied, initiated with 1/100 of the maximum learning rate, and adjusted over steps with a cosine scheduler. All experiments were implemented with PyTorch and executed on a single NVIDIA 2080Ti GPU. To ensure reproducibility and mitigate the effects of randomness, we conducted three independent trials with different random seeds. Each model was trained for 100 epochs, and performance is reported as the average across the three runs. The optimal checkpoint for each trial was selected based on the minimum validation cross-entropy loss. We are committed to making all code, configurations, and logs available upon acceptance.

Evaluation Metric. We evaluate the performance of our model using the following metrics: 1) Classification accuracy (%), representing the percentage of correctly predicted proficiency levels ranging from 1 to 5; 2) Macro F1-score (%), which averages the F1-scores across all proficiency levels, treating each class with equal importance; and 3) Weighted F1-score (%), which weights the F1-score of each proficiency score by its support (number of true instances) to account for label imbalance. The weighted F1-score is particularly crucial for multi-class classification tasks involving imbalanced or skewed labels, as it offers a more representative evaluation of overall performance.

Comparative Methods. To evaluate the performance of our proposed framework, we compare RABIT with the following state-of-the-art (SOTA) methods. 1) Conventional methods: **Qian2019** is an iconic ASA model that extracts various handcrafted features from transcriptions and the cor-

responding time-alignment information derived from learner speech (Qian et al., 2019). Subsequently, **SAMAD** advances the neural architecture of Qian2019 by incorporating Transformer blocks to capture long-term dependencies of linguistic cues, while introducing soft-label optimization to mitigate the label imbalance problem in ASA model training (Peng et al., 2024). 2) Multi-faceted neural graders: **Multi-ASA** employs the same proficiency-specific encoders as RABIT to extract delivery, language-use, and content-related features. In contrast to the use of small language model for proficiency assessment, Multi-ASA adopts a simple concatenation for feature fusion. The fused features are subsequently passed through a linear projection layer followed by a mean pooling operation to predict the proficiency score. Moreover, to assess the efficacy of grading rationales in ASA, **Multi-ASA-Rat** integrates grading rationales as auxiliary input. We leverage a BERT encoder to extract semantic representations from the grading rationales, which are then fused with handcrafted features within the Multi-ASA to collaborative proficiency enhance proficiency score estimation. 3) Single-faceted neural graders: To analyze the contribution of each modality-specific encoder in RABIT, we report the assessment performance using only the content encoder (**Content Model**) and delivery encoder (**Delivery Model**). Both models extract the corresponding features and assess the proficiency score via simple mean pooling followed by a linear classifier.

4 Experimental Results

Main Results and Performance Benchmarking.

At the outset, we compare the proposed approach (viz. RABIT) with existing state-of-the-art ASA methods. From the results shown in the Table 2, we have the following observations. 1) The proposed RABIT consistently outperforms all baseline methods on both seen- and unseen-prompt test sets in terms of accuracy and F1-scores, demonstrating that RABIT surpasses conventional baselines as well as single- and multi-faceted neural graders, while highlighting the strong generalization capability of our framework across diverse evaluation scenarios. 2) Regarding multi-faceted neural graders, Multi-ASA-Rat achieves notable performance gains over its base model (Multi-ASA). By incorporating LLM-generated grading rationales as auxiliary inputs, the results demonstrate that semantic encodings of rationales are highly complementary to other handcrafted features, leading to enhanced assessment accuracy in ASA. In contrast, RABIT formulates rationale generation as a primary learning objective and predicts language proficiency through a small language model, which not only achieves superior performance compared to Multi-ASA-Rat but also significantly enhances the transparency of the assessment results. Furthermore, in a comparison within the single-faceted neural graders, it is evident that the Content Model achieves better results than the Delivery Model. This finding suggests that content coherence exerts a greater influence than spoken delivery in ASA, aligning with observations reported in previous studies (Qian et al., 2019; Bannò and Matassoni, 2023). Moving beyond individual model components, Multi-ASA integrates handcrafted features from content and delivery, alongside language-use features, into a unified neural architecture, resulting in superior performance over its single-faceted counterparts (viz. Content and Delivery models). 3) As to the conventional methods, SAMAD exhibits strong performance on both test sets, significantly outperforming Qian2019 and achieving competitive results to Multi-ASA-Rat. Moreover, SAMAD achieves superior results on the test set with unseen-prompts compared to other baseline methods. These performance gains primarily stem from its delivery modeling, which leverages ASR transcriptions coupled with the spoken signals to capture prosody and fluency of learner speech, effectively boosting the generalization capability

across evaluation scenarios.

Ablation Study on RABIT Parameters. In this section, we perform an ablation study to systematically examine the assessment performance of RABIT under various parameter configurations on both seen- and unseen-prompt test sets. We first investigate the impact of the number of prompt vectors (i.e., $|\mathbf{H}^P| \in \{1, 3, 5\}$) employed in RABIT. The corresponding results are summarized in the first part of Table 3. Notably, RABIT facilitates proficiency score prediction through the integration of prompt vectors into the model input, rather than relying solely on natural language generation. As the number of prompt vectors increases, we observe performance gains on the unseen-prompt test set; however, these improvements remain marginal. Conversely, a noticeable decline in performance is evident on the seen-prompt test set. To strike an optimal balance between generalization across test sets and computational efficiency, we configure the RABIT with $|\mathbf{H}^P| = 3$.

Subsequently, we investigate the combination weight α that balances the two learning objectives (i.e., proficiency estimation $\mathcal{L}_{score}$ and grading rationale generation $\mathcal{L}_{rat}$), as defined in Eq. (5). The weight parameter α is selected from

$\{0.3, 0.5, 0.7\}$. Furthermore, $\alpha = 0.0$ is included as a reference baseline variant, representing the performance without rationale guidance. As demonstrated in the second part of Table 3, our results suggest that the rationale generation task is crucial for the performance of ASA; when this task is omitted (i.e., $\alpha = 0.0$), the corresponding performance is significantly inferior to all other settings with rationale guidance ($\alpha > 0.0$). Furthermore, we find that the choice of combination weight has a relatively modest impact on overall performance. Increasing α from 0.3 to 0.7 produces only marginal gains on the seen-prompt test set, while inducing a slight performance degradation in unseen-prompt test set.

Finally, the third part of Table 3 examines how the scale of the backbone language model impacts ASA performance. Notably, our results demonstrate that RABIT, when configured with SmolLM-135M-Instruct, consistently outperforms its larger 360M counterpart across all evaluation metrics. This finding suggests that for RABIT, a compact model offers a more balanced model capacity, which is sufficient to capture grading nuances on seen prompts while effectively generalizing to the unseen-prompt test set. Considering both predictive power and computational efficiency, RABIT adopts SmolLM2-135M-Instruct as its default backbone model.

Qualitative Examination of Grading Rationales.

Building on the evidence that rationale generation enhances the ASA performance of RABIT, we further conduct a qualitative comparison to evaluate the interpretability of the grading rationales generated by RABIT against those from the teacher LLM (viz. the source LLM used for distillation). As shown in Figure 4, the majority of the grading rationales produced by RABIT and the source LLM share similar semantic content (sentences highlighted in green). However, as illustrated by the sentences marked in purple, RABIT provides grammatical feedback by identifying errors rather than generating full corrected sentences. Notably, RABIT retains the emergent capabilities inherited from its base model, SmolLM2, allowing it to offer nuanced grading opinions or instructive feedback on the spoken response (sentences highlighted in orange). Moreover, as the rationale generation process is conditioned on the expert-annotated proficiency score, the generated rationales and proficiency scores exhibit a high degree of consistency. These qualitative results confirm that RABIT not only effectively captures the grading rationales of

Figure 4: Qualitative comparisons of rationales generated by RABIT and the source LLM. Sentences highlighted in green indicate semantic consistency with the rationales generated by the LLM, while those in purple reflect semantic divergence. Sentences in orange highlight emergent capabilities exhibited by RABIT.

the teacher model but also preserves the intrinsic reasoning capabilities of the underlying small language model.

5 Conclusion and Future Work

In this paper, we presented an ASA model designed to provide a transparent grading process without compromising computational efficiency. This advancement highly broadens the scope of ASA system in the real-world applications. As a pivotal step toward interpretable assessment, we proposed RABIT, a rationale-based distillation framework that produces grading decisions while simultaneously estimating the proficiency scores of language learners via a small language model. To enhance the stability of proficiency score estimation, we introduced prompt vectors for the small language model, making a pioneering effort within the field of ASA. Extensive experiments on the picture-description section of the GEPT dataset validate the superiority of RABIT, revealing that integrating rationale generation during the learning process further elevates ASA performance.

Limitations

The proposed method is limited by the quality of the rationales generated from LLMs. Additionally, the visual information contained in the prompts (i.e., pictures) is nearly sidelined in current work. Despite this minimal integration of visual data, RABIT remains consistent with the standard ASA rubrics of the GEPT. These scoring rubrics prioritize spoken delivery and language use, while treating topic development as only a secondary facet of the overall proficiency score. To address these limitations, future work will investigate integrating visual features from the picture prompts and improving the reliability of rationale generation through multi-agent prompting or human feedback mechanisms. Furthermore, we plan to enhance the diversity of the generated rationales of RABIT by leveraging back-translation techniques (Shen et al., 2025).

Ethics Statement

This study adheres to the ACL Code of Ethics. We utilized anonymized datasets provided by LTTC under authorized access, ensuring that data curation aligns with ACL standards. While RABIT provides automated proficiency assessments, it is designed to supplement human raters and provide informative feedback for language learners and instructors in low-stakes learning scenarios. We also acknowledge potential biases inherent in teacher LLMs and encourage cautious interpretation of automated feedback.

Abstract

Large language models have strong potential for use in intelligent tutoring systems, but they often fail to follow effective pedagogical strategies, such as guiding students without revealing final answers. We study the application of a two-stage alignment pipeline for math mistake remediation, combining supervised fine-tuning on tutoring dialogs with Direct Preference Optimization on synthetic preference pairs. We construct a dataset that integrates existing tutoring corpora with synthetic data generated along pedagogical dimensions, such as scaffolding and factuality, and study different input configurations that incorporate solution correctness and gold answers. Experiments show that this approach improves both factual accuracy and pedagogical quality over base models and existing tutoring models. Human evaluation further indicates that our best model is competitive with a strong proprietary baseline, while providing additional benefits in terms of openness, transparency, and reproducibility. Our results highlight the effectiveness of preference-based pedagogical alignment, while also revealing challenges in reliably evaluating tutoring quality. The code and data are released at <https://github.com/Kpetyxova/towards-aligned-math-tutor>.

1 Introduction

Human tutoring plays a fundamental role in education, supporting learner development and contributing to broader societal advancement. One-on-one tutoring has long been shown to be highly effective (Bloom, 1984), yet the scarcity of qualified human tutors limits its large-scale adoption. Recent progress in large language models (LLMs) has opened new opportunities for educational applications (Wang et al., 2024; Gan et al., 2023), enabling the development of LLM-driven intelligent tutoring systems (ITSs) (Pal Chowdhury et al., 2024; Liu et al., 2024b) as well as tutoring through prompting approaches (Jurenka et al., 2024; McNichols

Figure 1: Overview of our two-stage pedagogical alignment pipeline. We first perform SFT on tutoring dialogs, then apply DPO using synthetic preference pairs for mistake remediation. We compare four input configurations (V1–V4) that vary in access to the student answer correctness flag and the gold solution.

et al., 2023; Mollick and Mollick, 2024). These AI-based tutors support a wide range of instructional goals (Wollny et al., 2021), with particular emphasis on addressing student errors and misunderstandings – an area that continues to drive research in AI tutoring (Macina et al., 2023; Wang et al., 2023).

Although LLMs are capable of producing natural-sounding conversations and performing well on various reasoning tasks, including commonsense and elementary mathematical reason-

ing (Achiam et al., 2023; Kojima et al., 2022; Laskar et al., 2023; Yang et al., 2024), they are not immediately suitable for deployment in educational settings without careful adaptation. High-quality tutoring involves more than generating fluent responses – it requires guiding learners toward constructing their own understanding. Effective tutors rely on pedagogical strategies such as providing hints, engaging students through Socratic questioning (Carey and Mullan, 2004), and promoting active problem-solving. Consequently, LLM-based tutoring systems should be designed to align with established human tutoring practices (Nye et al., 2014) and active learning principles that have been shown to improve learning outcomes (Freeman et al., 2014).

To build reliable and pedagogically sound tutoring systems, models must embody these instructional principles. In particular, they should be factually accurate, avoid prematurely revealing final answers, and instead guide students toward understanding and self-correction. Existing tutoring models attempt to incorporate these principles to varying degrees. For example, SocraticLM (Liu et al., 2024a) adopts a Socratic “thought-provoking” paradigm, guiding students with step-by-step questions that encourage active participation and independent reasoning rather than directly providing answers. In contrast, TutorRL-7B (Dinucu-Jianu et al., 2025) optimizes tutoring behavior through reinforcement learning over simulated student-tutor interactions, using reward functions that balance pedagogical quality and student success (solve rate). While these approaches demonstrate promising results, they also highlight the remaining challenges. SocraticLM relies on the supervised imitation of pedagogical behavior, which may limit control over specific pedagogical attributes. Similarly, TutorRL-7B optimizes tutoring as a holistic policy using scalar rewards, where pedagogical behaviors are learned implicitly through interaction and reward design. This makes it difficult to explicitly control or disentangle individual aspects of tutoring, such as factual accuracy, mistake identification, or the degree of solution revealing. We argue that explicitly modeling and controlling these aspects can lead to more robust and interpretable tutoring systems. Motivated by this, we propose a two-stage pedagogical alignment pipeline (Figure 1) that combines supervised fine-tuning (SFT) with direct preference optimization (DPO) to align tutor responses with desired pedagogical behaviors

directly. We further study different input configurations, varying the information provided to the model (e.g., correctness flags and gold solutions) to better disentangle sub-tasks such as error detection and response generation.

In summary, our key contributions are as follows:

- We construct a dataset for math mistake remediation by combining existing tutoring datasets with synthetic data derived from math-task datasets containing LLM-generated solutions. We treat these solutions as student responses and generate corresponding tutor responses using GPT-5, along with degraded variants across multiple pedagogical dimensions, resulting in a set of preference pairs for DPO.
- We study different input configurations, analyzing how access to additional information (e.g., student solution correctness flags and gold solutions) affects model performance.
- We fine-tune both open-source and proprietary models using SFT and DPO on the constructed dataset, showing that our best open-source-aligned model outperforms a strong proprietary baseline in the human evaluation.
- We release all resources developed in this work, including the synthetic dataset, trained models, and code, to support further research on pedagogically aligned AI tutors: <https://github.com/Kpetyxova/towards-aligned-math-tutor>.

2 Related work

2.1 Pedagogical alignment methods for LLM-based tutors

Large language models are frequently optimized for general-purpose helpfulness, which often leads to tutoring behaviors that are suboptimal for learning, such as prematurely revealing solutions or failing to diagnose student misconceptions. We refer to the objective of shaping the model’s behavior toward guided problem-solving, targeted feedback, and adaptive scaffolding as *pedagogical alignment*. Early approaches address this by using tutoring-specific SFT, in which models are trained to imitate the pedagogical dialog style. SocraticLM (Liu et al., 2024a), for instance, fine-tunes ChatGLM3-6B (GLM et al., 2024) on large-scale Socratic dialogs

generated via a Dean-Teacher-Student multi-agent pipeline, yielding consistent gains across multiple teaching skill dimensions. However, its training remains a supervised imitation of synthesized teacher responses, rather than an explicit optimization of a preference-based objective over pedagogical attributes, which can limit direct control over trade-offs (e.g., hint granularity vs. answer revealing) and robustness to unseen tutoring situations.

In parallel, LearnLM (Team et al., 2024) introduces *pedagogical instruction following*, applying reinforcement learning from human feedback (RLHF) with human preference data to improve adherence to system-level pedagogical instructions in multi-turn settings. Although effective, this approach depends on large-scale human preference collection and expert evaluation infrastructure.

More recently, online reinforcement learning has been explored over simulated student-tutor interactions to optimize multi-turn teaching behavior. TutorRL (Dinucu-Jianu et al., 2025), for instance, trains tutoring policies via on-policy reinforcement learning using simulated student dialogs, optimizing rewards that reflect both student learning outcomes (student solve rate) and pedagogical quality assessed by LLM-based judges.

A more scalable alternative is offline preference optimization with synthetic supervision. Sonkar et al. (2024) show that DPO (Rafailov et al., 2023) and related objectives (KTO (Ethayarajh et al., 2024), IPO (Azar et al., 2023)) consistently outperform SFT in shifting model behavior toward scaffolded guidance, with gains that remain stable across longer multi-turn dialogs. The effectiveness of such methods depends critically on preference data quality: RMBoost (Shen et al., 2024) addresses this by pre-selecting a preference label and conditionally generating a contrastive response guided by predefined multi-aspect evaluation criteria, reducing label noise in synthetic pair construction. Our work follows the offline preference optimization paradigm, applying preference-conditional generation to pedagogical dimensions for remediation of math mistakes.

2.2 Datasets for pedagogical alignment and mistake remediation

Training pedagogically aligned tutoring models requires data that capture both tutoring interaction structure and student error patterns. On the dialog side, SocraTeach (Liu et al., 2024a) provides large-scale synthetic Socratic tutoring di-

alogs with various student cognitive profiles, while MathDial (Macina et al., 2023) is collected by pairing human teachers with LLM-simulated students exhibiting common math errors, annotated with a taxonomy of teacher moves that captures realistic scaffolding strategies. In our work, both datasets serve as instruction tuning data for the SFT stage, where each tutor turn is treated as a supervised target conditioned on the prior dialog context. Beyond dialog structure, grounding of mistake remediation scenarios also requires fine-grained signals about student errors. MR-GSM8K (Zeng et al., 2023) provides structured error-centric instances by defining the evaluation as meta-reasoning over solution correctness, while PRM800K (Lightman et al., 2023) contributes step-level correctness labels on MATH (Hendrycks et al., 2021) solutions, enabling precise identification of where reasoning errors occur. We repurpose both datasets to construct preference pairs, where tutor responses are generated to contrast pedagogically effective responses with suboptimal ones.

2.3 Evaluation methods for pedagogical ability

Evaluating tutoring quality is inherently multi-dimensional: an effective tutor response must identify the student’s mistake, locate where it occurs, provide guidance without revealing the answer, and offer actionable next steps. Previous work, such as Liu et al. (2024a) and Team et al. (2024), relies on human ratings or scenario-based expert rubrics, which are reliable but expensive and difficult to scale. This has motivated the development of automated taxonomy-based evaluation frameworks grounded in learning sciences.

Maurya et al. (2025) propose a unified eight-dimension taxonomy for mistake remediation and release MRBench; they further directly assess LLM-based judging and find that Prometheus2’s (Kim et al., 2024) pedagogical annotations correlate poorly (often negatively) with human labels on MRBench, suggesting that LLM-as-judge evaluation is unreliable for fine-grained tutoring dimensions. In parallel, the BEA 2025 Shared Task (Kochmar et al., 2025) formulates four pedagogical dimensions as supervised prediction problems and shows that scalable automatic evaluation remains challenging (best 3-class macro F1 ≈ 0.58 – 0.72), despite substantial inter-annotator agreement (Fleiss’ $\kappa \approx 0.65$).

AITutor-EvalKit (Naeem et al., 2025) ad-

dresses this by providing an end-to-end evaluation toolkit for student mistake remediation (SMR), featuring a lightweight multi-task model (LoMTL) trained to assess the quality of tutor responses along these four dimensions jointly. We adopt this evaluation framework in our work because it aligns closely with our task definition and provides scalable, aspect-level feedback matching our training objectives.

3 Experimental Setup

3.1 Data

We use the MathDial and SocraTeach datasets to fine-tune our models on dialog data. Since both datasets consist of tutor-student conversations (2,861 in MathDial and 35K in SocraTeach), we preprocess each conversation by splitting it into dialog turns. Each tutor turn is treated as a training instance, where all preceding turns serve as context, and the current tutor utterance is used as the gold response. For each instance, we have the gold solution to the underlying math problem and a flag indicating whether the student has solved the task correctly. In MathDial, we assign the flag *No* to all student turns except the final one; for the final turn, we assign *Yes* if the self-correctness flag provided in the dataset is *True*. In SocraTeach, we assign *No* to all student turns except the final one, as dialogs are constructed to terminate after the student provides a correct solution and the tutor acknowledges it. This preprocessing yields 18,609 instances from MathDial and 171,296 from SocraTeach.

To align the models with pedagogical values and to augment the data beyond MathDial and SocraTeach, we adopt the RMBoost approach (Shen et al., 2024) to generate synthetic data from the MR-GSM8K and PRM800K datasets. Since PRM800K includes mathematical problems spanning a wide range of difficulty levels, with metadata indicating topic and difficulty (where levels correspond to relative difficulty tiers of competition-style math problems rather than curriculum-based grade levels), we filter it to leave only algebra problems of levels 1-2, number theory problems of level 1, and pre-algebra problems of levels 1-3. We convert each instance in these datasets into a single dialog turn: the tutor first introduces the task, and the student responds with a solution. The student response corresponds to the LLM-generated step-by-step solution provided in the original datasets. When the solution is incorrect, we use GPT-5 to generate an

appropriate tutor response. Conditioning on this response, we then use GPT-4.1 to generate a lower-quality version by degrading specific aspects of the response. We use GPT-5 to generate high-quality tutor responses, motivated by its stronger capabilities compared to GPT-4.1; this assumption was validated through manual inspection of generated responses. We use GPT-4.1 to produce degraded variants, as it does not require a model of comparable capacity. We adapt the prompt structure from RMBoost, modifying the evaluation aspects to reflect pedagogical criteria. Specifically, we define the following pedagogical criteria: (1) *Factuality* – the response should be factually correct, should not contradict what the student has said, and should not contain irrelevant information; (2) *Mistake Identification* – the response should identify, either explicitly or implicitly, that there is a mistake in the student’s solution (for example, saying “Nice try” would miss this aspect); (3) *Targetedness* – the response should address the core misconception/misunderstanding of a student; (4) *Revealing Answer* – while it is sometimes necessary and acceptable to share the answer to a substep, the tutor should avoid giving away the final answer; (5) *Clarity* – the tutor’s response should be free of awkward, confusing or misleading wording. The prompts used in this process are shown in Appendix A. This results in a dataset of 29,390 preference pairs.

Because MR-GSM8K and PRM800K also include instances with correct student solutions, we use these cases to create dialog examples without student errors, ensuring that the model does not always assume that the student’s solution is incorrect. For these instances, we prompt GPT-5 to generate tutor responses appropriate for correct solutions and randomly assign them as follow-up turns. This process yields 3,769 additional instances. The prompt used for this procedure is shown in the Appendix B.

The statistics of the collected dataset are shown in Table 1.

3.2 Model Training

We train our models using a two-stage pipeline consisting of SFT followed by preference optimization via DPO (Rafailov et al., 2023). All stages use parameter-efficient fine-tuning via LoRA (Hu et al., 2021).

We first fine-tune the base model on tutor feedback data using standard cross-entropy loss on the tutor responses. Training runs for up to 5 epochs using the AdamW and a cosine learning rate sched-

Dataset	SFT Turns		DPO Pairs
	Correct	Incorrect	
MathDial	2,855	15,754	–
SocraTeach	46,104	125,192	–
MR-GSM8K	1,390	1,387	6,935
PRM800K	2,379	4,491	22,455
Total	52,728	146,824	29,390

Table 1: Overview of the dataset statistics. Synthetically generated pairs are used for both DPO training and SFT (on preferred responses).

ule. We apply early stopping based on validation loss to prevent overfitting. The resulting LoRA is used to initialize the next training stage.

In the second stage, we align the model with pedagogical preferences using DPO on the synthetic preference dataset.

Manual inspection of our preference data revealed that responses with degraded *Clarity* are not consistently worse; in many cases, they are simply paraphrases that preserve similar pedagogical value (see Appendix F). Therefore, we do not treat this aspect as equally important as the others. Specifically, we weight each training sample by a factor w_i reflecting the importance of its associated pedagogical aspect: *Factuality*, *Mistake Identification*, *Targetedness*, and *Revealing Answer* are each assigned a weight of 1, while *Clarity* is assigned a weight of 0.5. Full details of the weighted DPO objective are in Appendix G.

We use Qwen3-4B-Instruct-2507 and Qwen3-8B (Yang et al., 2025) as our pre-trained base models. In addition, we include GPT-4.1-nano,¹ a proprietary model from a different family, to provide cross-family comparison. For GPT-4.1-nano, fine-tuning is performed using the SFT and DPO functionality available through the provider’s interface. As a result, the training procedure is not fully identical to that used for the Qwen models.

3.3 Experiments

We compare four configurations:

- V1: The model conditions only on the dialog context when generating the next tutor response;
- V2: The model is additionally provided with a binary flag indicating whether the student’s

solution is correct;

- V3: The model is additionally provided with the gold solution to the underlying math problem;
- V4: The model is additionally provided with both the correctness flag and the gold solution.

This setup allows us to isolate the effect of different levels of available information on response quality. In particular, configurations that provide the correctness flag and/or the gold solution (V2-V4) assume access to signals that may not always be directly available in real-world deployment. However, such settings are consistent with the standard human tutoring practice, where tutors have access to the correct solutions when providing feedback. In practice, such information would need to be obtained either from curated solution sources or by automatically solving the task. The latter introduces an additional source of error, as mistakes in the solution process may propagate to the generated feedback. Our current work does not model this setting explicitly. Therefore, configurations with access to gold solutions can be interpreted as upper bounds on performance, reflecting a scenario with reliable solution supervision. The prompt template used for training is provided in Appendix C.

3.4 Baselines

We compare our models against the following baselines:

- Base models: Qwen3-4B-Instruct-2507, Qwen3-8B, and GPT-4.1-nano.
- GPT-5: An advanced proprietary model.
- SocraticLM: ChatGLM3-6B fine-tuned on the SocraTeach dataset (Liu et al., 2024a).
- TutorRL-7B: A fine-tuned variant of Qwen/Qwen2.5-7B-Instruct, aligned with pedagogical principles using reinforcement learning (GRPO) in a synthetic multi-turn classroom setting (Dinucu-Jianu et al., 2025).

Note that SocraticLM and TutorRL-7B use the V1 configuration, as we adopt their original training prompts.

3.5 Evaluation

We randomly sample 1,000 responses from the test set, equally distributed across datasets, and evaluate them using models from AITutor-EvalKit (Naeem et al., 2025) – namely, GPT-5 and LoMTL. We assess four pedagogical dimensions: *mistake identification*, *mistake location*, *providing guidance*, and *actionability*. Before conducting this evaluation, we perform a factuality check using GPT-5 with the prompt provided in Appendix D. This ensures that we assess pedagogical qualities only for factually correct responses, as responses containing factual errors are considered poor by default.

In addition, we conduct a small-scale human evaluation on an additional randomly sampled subset of the test set.

4 Results & Analysis

4.1 Automatic Evaluation

We first evaluate 1,000 randomly sampled responses from the test set for factuality using GPT-5. This evaluation is intended to identify cases in which a tutor response contains factual errors, such as introducing incorrect numbers from the task definition or hallucinating details about the student’s solution. Table 2 reports the factuality results, while Appendix E provides a breakdown of the error categories assigned by GPT-5 to responses judged as non-factual. As shown in Table 2, GPT-5 achieves the highest factuality scores, whereas GPT-4.1-nano performs substantially worse. While GPT-5 may exhibit some degree of bias when evaluating its own outputs, the high scores may also reflect its strong factual accuracy. The open-source baselines are also considerably less factual overall. Although SocraticLM is factually correct in roughly 50% of cases, our manual analysis suggests that this is partly because it often produces generic follow-up questions about the task or the student’s solution, rather than directly engaging with the specific misconception, thereby avoiding factual errors. For our models, both SFT and DPO generally improve factuality compared to their respective base models. For the Qwen models, DPO often provides additional gains beyond SFT, whereas for GPT-4.1-nano, DPO degrades factuality relative to SFT. For Qwen3-8B, the configuration that conditions on both the correctness flag and the gold solution (V4) yields the strongest factuality results, indicating that access to this additional in-

Table 2: Factuality metrics (%) across models. Columns report overall factuality, factuality when the student is incorrect (Stu. Inc.), and when they are correct (Stu. Cor.). Best results per group are in **bold**. Qwen3-8B + DPO V4* denotes the rerun of the DPO stage using the extended dataset.

formation is beneficial. Our manual analysis further shows that the best-performing configuration, Qwen3-8B + DPO V4, still frequently fails by copying an incorrect number from either the task definition or the student’s solution. To address this issue, we automatically created 20,000 additional preference pairs by perturbing the numerical values in the reference responses used during training. We then reran the DPO stage with this extended dataset. This led to an absolute factuality improvement of approximately 10 percentage points, resulting in the final Qwen3-8B + DPO V4* model.

Table 3 presents the results of the automatic evaluation for the pedagogical dimensions of *Mistake Identification (MI)*, *Mistake Location (ML)*, *Providing Guidance (PG)*, and *Actionability (AC)* as assessed by GPT-5 and LoMTL. These metrics are

computed only for responses classified as factually correct in the previous stage. A notable observation is the substantial disagreement between the two evaluators. In particular, GPT-5 assigns significantly higher scores to its own responses than LoMTL does, especially for the Actionability dimension (76.23 vs. 20.49). Manual analysis suggests that GPT-5 responses often reveal the full solution and final answer to the student. While this may appear helpful, it leaves little room for further student engagement. It therefore reduces the student’s opportunity to solve the problem actively, making such responses less actionable from a pedagogical perspective. This behavior may indicate a potential bias of GPT-5 when evaluating its own outputs.

SocraticLM is rated poorly by both evaluators on the MI, ML, and PG dimensions, but receives relatively high Actionability scores from LoMTL (92.08). Our manual analysis shows that SocraticLM frequently produces general follow-up questions about the task, which are actionable because they prompt the student to respond. However, these questions are often not directly related to the student’s specific mistake. Because LoMTL is based on a smaller 2B model, it may fail to detect this lack of targeted feedback, whereas GPT-5 appears better able to capture this issue, resulting in lower Actionability scores (64.58).

TutorRL-7B is consistently rated as highly actionable by both evaluators, but performs poorly on MI and ML according to GPT-5 evaluation.

For GPT-4.1-nano fine-tuning, SFT V4 outperforms DPO V4 across all dimensions under GPT-5. However, under LoMTL, DPO V4 achieves uniformly strong results, with zero “No” cases across all dimensions. Notably, GPT-4.1-nano + DPO V4 is the top-performing model according to LoMTL.

Finally, Qwen3-8B + DPO V4* outperforms existing tutoring models (SocraticLM, TutorRL-7B) and GPT-4.1-nano fine-tuned models across most dimensions under GPT-5, with the exception of Actionability. Under LoMTL, it slightly underperforms GPT-4.1-nano fine-tuned models but still consistently surpasses SocraticLM and TutorRL-7B.

Examples illustrating models outputs are shown in Appendix I.

4.2 Human Evaluation

In addition to automated metrics, we conducted a human evaluation with 10 annotators, including Master’s and PhD students in NLP and professors. The study was designed to test two hy-

potheses: **(H1)** within a fixed backbone, our post-training pipeline improves pedagogical tutoring quality (DPO > SFT > Base); and **(H2)** our best post-trained model is competitive with a strong proprietary baseline.

We randomly selected 35 dialogs from the test set, balanced across dataset sources, and conducted pairwise comparisons. Each annotator evaluated a subset of dialogs (5 shared and 3 unique per annotator), resulting in 105 total pairwise comparisons (15 shared and 9 unique per annotator). For each dialog, we included one response from each of the following models: Qwen3-8B Base, Qwen3-8B SFT V4, Qwen3-8B DPO V4*, and GPT-5. This setup resulted in the following evaluation pairs: **H1a**: Qwen3-8B Base vs. Qwen3-8B SFT V4; **H1b**: Qwen3-8B SFT V4 vs. Qwen3-8B DPO V4*; and **H2**: Qwen3-8B DPO V4* vs. GPT-5. Annotators were shown the dialog context, the reference (gold) solution, and the flag indicating whether the student’s solution was correct. They were then asked to select which response was better or whether both were equally good or poor (see Figure 2 and Appendix J). Based on majority voting and individual annotator judgments over pairwise comparisons, Qwen3-8B SFT V4 was preferred over Qwen3-8B Base in 67.6% of cases, Qwen3-8B DPO V4* was preferred over Qwen3-8B SFT V4 in 35.3% of cases, and Qwen3-8B DPO V4* was preferred over GPT-5 in 54.3% of cases. Inter-annotator agreement, measured using Fleiss κ , was 0.55, indicating moderate agreement.

Analysis of the reasons chosen by annotators shows consistent patterns across comparisons. Qwen3-8B Base is frequently judged as factually incorrect, less clear, and less coherent, and as providing less helpful guidance than Qwen3-8B SFT V4. Similarly, Qwen3-8B SFT V4 is often rated worse than Qwen3-8B DPO V4* for the same reasons. Compared with Qwen3-8B DPO V4*, GPT-5 is most often not chosen for revealing the final answer and providing less effective scaffolding for student reasoning.

We also evaluated the same responses with GPT-5 and LoMTL, again applying factuality filtering first. We then converted the four pedagogical annotations into scalar scores (1 for *Yes*, 0.5 for *To some extent*, and 0 for *No*; non-factual responses were assigned a score of 0 by default), summed these scores, and compared the resulting totals for the same response pairs used in the human evaluation. Under GPT-5-based evaluation, GPT-5 was ranked above Qwen3-8B DPO V4* in

Table 3: Feedback quality metrics (%) across models, evaluated along four dimensions: Mistake Identification, Mistake Location, Providing Guidance, and Actionability. Each dimension reports the percentage of responses rated *Yes*, *To some extent* (Some), and *No*. The evaluator is indicated in parentheses (GPT-5 or LoMTL). **Bold** and **bold italic** denote the highest *Yes* scores, while underline and underline italic denote the lowest *No* scores for the GPT-5 and LoMTL evaluations, respectively. Results for Qwen3-4B and V1-V3 configurations are provided in Appendix H.

most cases, whereas under LoMTL-based evaluation, our model was more often ranked above GPT-5 (see Appendix K). We further computed the average pairwise Cohen’s κ between model-based rankings and human judgments, obtaining 0.44 for GPT-5 and 0.52 for LoMTL. This indicates that LoMTL-based rankings are more consistent with human preferences than those produced by GPT-5.

5 Conclusions

In this work, we compiled a dataset for math mistake remediation by combining existing tutoring datasets with synthetic data derived from math-task datasets containing LLM-generated solutions. We treat these solutions as student responses and generate the subsequent tutor responses with GPT-5; we also generate degraded variants of the GPT-5 responses along several pedagogical dimensions, resulting in a set of preference pairs used for DPO.

We compare different input variants and show that, as expected, providing the model with additional information, such as the gold solution to the task and a flag indicating whether the student’s solution is correct, substantially improves factual correctness. This suggests that intelligent tutoring systems may benefit from being designed not as a

single model responsible for solving the task and checking the student’s work, but rather as a system of multiple components that solve the task, verify the student’s solution, and generate appropriate feedback. This setting is also natural, since human tutors typically have access to the correct solution.

We further show that applying a two-stage post-training pipeline, SFT followed by DPO, with the compiled dataset improves performance according to human evaluation, leading to a preference for our 8B model over a strong proprietary baseline. We also observe improvements for a proprietary model (GPT-4.1-nano): while factual accuracy decreases relative to its SFT variant according to GPT-5, the DPO version performs best on pedagogical dimensions according to LoMTL evaluation. This highlights the generalizability of our approach for pedagogical alignment across models.

Finally, we highlight the challenges of evaluation in this setting, demonstrating that existing automatic evaluators have significant limitations.

Limitations

Our work has several limitations. First, our evaluation focuses on the quality of tutor responses rather than direct learning outcomes. Although *Factual-*

Figure 2: Results of human evaluation (percentages). Four annotators were asked to choose the better response or indicate if both were equally good or bad.

ity, *Mistake Identification*, *Targetedness*, and other aspects are important prerequisites for effective tutoring, we do not evaluate whether students learn better from interacting with such an aligned model. Evaluating learning outcomes would require a controlled user study with real learners, including pre- and post-tests or longitudinal interaction logs. We therefore interpret our results as evidence of improved pedagogical response quality for mistake remediation, rather than as direct evidence of improved educational effectiveness. Notably, most concurrent research on LLM-based tutoring similarly evaluates response quality rather than student learning, highlighting a broader gap in the field.

Second, our evaluation relies in part on LLM-based judges. As demonstrated by our results, different evaluators (GPT-5 and LoMTL) often disagree substantially. This suggests that current automated

evaluators are not yet fully reliable for assessing tutoring quality. While we partially mitigate this through a human evaluation, it remains relatively limited in scale, as the evaluation set is small (105 pairs) and relies primarily on single-annotator judgments, which may introduce noise despite moderate inter-annotator agreement. Similarly, due to resource constraints, the automatic evaluation is conducted on 1,000 test samples only.

Third, the preference data is generated using LLMs. We note that constructing fully human-authored preference data for math mistake remediation is prohibitively costly, as it would require expert tutors to inspect student solutions, identify mistakes, write pedagogically appropriate feedback, and provide controlled lower-quality alternatives across multiple dimensions. Therefore, we view synthetic preference generation as a scalable approximation, but not a substitute for richer human-authored or human-validated data. Moreover, our synthetic preference pairs are generated through minimal revisions produced by two proprietary models from the same family (GPT-5 and GPT-4.1). As a result, the generated data may reflect family-specific stylistic biases and may not fully capture the diversity of natural student-tutor interactions.

Future work should, therefore, focus on several directions. First, it is important to evaluate whether pedagogically aligned models improve learning outcomes for real students. In addition, future work should scale up human and automatic evaluation, incorporate multi-annotator judgments, explore larger backbone models, and design multi-model or human-in-the-loop generation pipelines to improve data diversity and reliability.

Ethical Considerations

The proposed models are trained on synthetic data, which may encode biases in phrasing, tone, or instructional style. As this work is exploratory and the model outputs have not been evaluated with real students, we do not anticipate immediate risks associated with the current study. However, we acknowledge that LLMs may pose risks when deployed in real-world educational settings. In particular, they may generate outputs that appear plausible but are factually incorrect or nonsensical, potentially leading to misguided learning outcomes or reinforcing existing biases. While no direct risks arise from the present work, future applications of these methods in real-world settings should

incorporate appropriate safeguards, such as fact-checking, human oversight, and bias-mitigation strategies.

Acknowledgments

We are grateful to the Google Academic Research Award (GARA) 2024 for supporting this research.

A Prompt Templates for Preferred and Non-Preferred Next Tutor Turns

See Figures 3 and 4.

Preferred Tutor Response Generation Prompt (Template)

You are an expert math tutor helping a student understand and fix a mistake in their solution. Your goal is to guide the student toward the correct reasoning without revealing the final answer. Keep your response concise and focused on the core misunderstanding. You will be shown the problem, the student's incorrect solution, and the step where the mistake occurs; produce the next helpful tutor response.

<task_description>

You will be shown:

1. A detailed guideline describing evaluation aspects of a good tutor response.
2. A math problem, the correct (gold) solution, the student's solution, and the specific step where the mistake occurs.
3. A scaffolding level that has been selected for you.

Your task is to produce a high-quality tutor response that helps the student progress meaningfully while adhering to the guideline AND the assigned level.

</task_description>

<guideline>

A good tutor response is evaluated along the following aspects:

1. Factuality + Non-contradiction + No Nonsense: The response should be factually correct, should not contradict what the student has said, and should not contain irrelevant information. Example:

Conversation history: [the task about gift cards]

Bad: If Ms. Jones received 5 gift cards worth \$10 each, then 1/3 of the thank you cards contained a gift card, meaning 3 out of every 5 cards had a gift card, and you can use this information to solve for the total number of students in her class. --> Factually incorrect

Better: That's correct! Now, if 1/3 of the thank you cards contained a gift card, how many thank you cards did she

receive in total?

2. Mistake Identification + Location: The response should identify, either explicitly or implicitly, that there is a mistake in the student's solution. For example, saying "Nice try" would miss this aspect. Example:

Conversation history: Student: yay
Tutor: Next, we have to find the value of 6 times 9 + 2. Tutor: What is the value of 6 times 9 + 2?

Student: 99

Better: That's a great start!

Remember, we need to follow the order of operations (PEMDAS). Let's multiply 6 times 9 first, then add 2.

Bad: Very good try. --> Mistake Identification + Location aspect is missing

3. Targetedness: The response should address the core misconception/misunderstanding of a student. Example:

Conversation history: [the task about eggs]

Worse: Ok, remember there are only 12 eggs to begin with --> doesn't point to any misconception

Better: It looks like you've got a good start, but let's revisit the single yolks calculation - since 5 eggs had double yolks, that means there are actually $12 - 5 = 7$ eggs with single yolks, not 12.

4. Not revealing the final answer: While it is sometimes necessary and acceptable to share the answer to a substep, the tutor should avoid giving away the final answer. Example:

Conversation history: [the task about average speed]

Worse: You're close, but let's re-examine this - if Jason already drove 30 minutes at 60 miles per hour, that means he covered 30 miles, and he still has 90 miles left, so to cover those 90 miles in 1 hour (60 minutes), not 1 hour 30 minutes, he needs to average a speed of $90/1 = 90$ miles per hour. --> Reveals the final answer

Better: You're very close, but remember the question asks for the average speed needed for the *remaining* portion of the drive, not the overall trip.

5. Clarity + Coherence: The tutor's response should be free of awkward, confusing or misleading wording. A good tutor response acknowledges the student's input and connects it to the next step. Example: Conversation history: [the task about gift cards]
Student: She got 5 gift cards since \$50 divided by \$10 is equal to 5.
Worse: That's correct! Now, if 1/3 of the thank you cards contained a gift card, how many thank you cards did she receive in total?
Better: Ok. And if she got 5 thank you cards that had gift cards in them, and these were 1/3 of the total number of thank you card, she got, how many thank you cards did she get total? --> More explicit connection between the student's input and the next step

Scaffolding level:
- Assigned scaffolding level: {level}
- Level notes: {level_notes}
</guideline>

<problem>
{question}
</problem>

<correct_solution>
{correct_solution}
</correct_solution>

<student_solution>
{attempt}
</student_solution>

<erroneous_step>
Error step: {error_step}
Reason: {error_reason}
</erroneous_step>

Read everything carefully.
Use the assigned scaffolding level above when crafting the tutor response-match its tone, pacing, and support budget.

Wrap your output in <response> >...</response> tags.

Figure 3: Prompt template used to generate preferred next tutor turn. Curly-brace fields denote placeholders filled per instance. The scaffolding level and notes used are: *L0 (metacognitive) – tone-first, Socratic nudge, and one check question, with a maximum of two sentences.*

Non-Preferred Tutor Response Generation Prompt (Template)

You are an expert tutor teaching another tutor how not to respond to a student's response .

When revising tutor responses, only focus on the following aspect(s):
{aspects}

Details for the aspect(s):
{aspect_instructions}

Your Task

Below is a task student is solving
:
{question}

The student's incorrect solution is:
{attempt}

The correct (gold) solution to the task is:
{correct_solution}

Error step: {error_step}
Reason: {error_reason}

The ideal tutor's next response is
:
{good_response}

Your job is to minimally revise the tutor's response so that it clearly fails to align with the criteria above.

- * Do not rewrite the response completely.
- * Keep as much of the original wording as possible.
- * Only adjust what's necessary to make the response misaligned.

Put your generated bad response in
<response></response> tags.

Figure 4: Prompt template used to generate non-preferred next tutor turn. Curly-brace fields denote placeholders filled per instance.

B Prompt for Correct Student Solutions

See Figure 5. Example responses include *You got it right. Would you like more practice?* Although we do not specify any particular format in the prompt, we observe that all generated responses consist of two sentences: the first acknowledges the correct-

ness of the solution, and the second asks about next steps. We therefore create combinations by mixing the first and second sentences, yielding 10,000 unique responses.

Prompt for Correct Student Solutions

You are an expert, encouraging math tutor.
Generate exactly 100 distinct one-line tutor responses suitable for cases where a student's solution is correct.
Requirements:

- Each response must be concise, natural-sounding, and encouraging.
- Vary the structure; do NOT start most lines with the same word or pattern.
- Avoid semicolons entirely.
- Avoid overly specific instructions such as asking for diagrams, substitution methods, coding, graphs, etc.
- Follow-up suggestions must be general and applicable across many math topics (e.g., ask if they'd like another problem, another challenge, a summary, questions, etc.).
- Tone should vary: praise, curiosity, invitations to continue, quick check-ins, etc.
- Number each line 1) through 100)
- No bullet points, no quotes, no emojis, no extra commentary.
- Output plain text with exactly ONE response per line and EXACTLY 100 lines.

Figure 5: Prompt template used to generate 100 tutor responses for correct student solutions.

C Prompt Template Used for Training

See Figure 6.

Tutor Response Generation Prompt (Template)

You are a careful, precise, and supportive math tutor.

Your task is to produce the next tutor response in an ongoing dialog.

You will be given:

- 1) The dialog history between the student and the tutor. # V1-V4

- 2) A boolean flag indicating whether the student's solution is mathematically correct. # V2, V4
- 3) A gold solution to the task. # V3, V4

Guidelines for your response:

- If the student's solution is incorrect, guide the student toward the correct reasoning.
- If the student's solution is correct, clearly acknowledge correctness and optionally provide brief reinforcement, intuition, or a natural next step.
- Do NOT invent errors or suggest corrections if the solution is correct.

Your Task

[Dialog History] # V1-V4
{dialog_history}

[Student solution is correct] # V2, V4
{is_correct}

[Gold solution to the task] # V3, V4
{gold_solution}

[Next tutor response]

Figure 6: Prompt template used for training. Curly-brace fields denote placeholders filled for each instance. The # symbol indicates comments included here to show which parts of the prompt are present in different configurations.

D Prompt Template for Factuality Checking

See Figure 7.

Factuality Checking Prompt (Template)

[System Prompt]

You are an expert pedagogical judge.
Your task is to evaluate a math tutor's response to a student based on factuality and categorize any factual issue.

****Factuality**:** The response should not invent numbers, calculations, or details not present in the problem or the student's history.

```

Return fields:
- is_factual: true/false
- student_has_mistake: true/false
- tutor_acknowledged_no_mistake:
  true/false/null
- category: one of
  - student_hallucination: Tutor
    hallucinates something in
    the student's solution
  - task_hallucination: Tutor
    hallucinates something in
    task definition
  - response_incorrect: Tutor's
    feedback/solution is not
    factually correct
  - other: Explain what is wrong
  If is_factual is true, set
  category to null.
- reasoning: brief explanation

Be strict: if any factual issue
exists, set is_factual to false
and choose the best-fitting
category.

Provide your evaluation in the
strictly defined structure.

```

Figure 7: Prompt template used for factuality checking.

E Breakdown of Non-Factual Error Categories

See Table 4.

F Examples of Preference Pairs

Table 5 presents an example of a generated preferred response alongside its degraded variants across different aspects. Compared to the others, the response degraded in *Clarity* is relatively less problematic; it is simply less detailed, making it slightly less clear but still appropriate. Based on this observation, we assign a lower weight to this dimension.

Model	Task H.	Resp. Inc.	Stu. H.	Other
<i>Proprietary Models</i>

+ DPO V4*	23.08	48.16	21.40	7.36

Table 4: Breakdown of non-factual (NF) error categories (%) across models, identified by GPT-5: task hallucination (Task H.), incorrect response (Resp. Inc.), student hallucination (Stu. H.), and other errors (e.g., inventing a student’s name, typos, or introducing unrelated examples).

G Training Objective

The weighted DPO loss is:

$$\begin{aligned}
\mathcal{L}_{\text{DPO}} = & - \mathbb{E}_{(x_i, y_i^+, y_i^-) \sim \mathcal{D}} \left[w_i \cdot \log \sigma \left(\beta \log \frac{\pi_{\theta}(y_i^+ | x_i)}{\pi_{\text{ref}}(y_i^+ | x_i)} \right. \right. \\
& \left. \left. - \beta \log \frac{\pi_{\theta}(y_i^- | x_i)}{\pi_{\text{ref}}(y_i^- | x_i)} \right) \right] \quad (1)
\end{aligned}$$

where y_i^+ and y_i^- denote the preferred and dis-preferred responses, respectively, and $\beta = 0.3$ (was chosen empirically based on validation performance) controls the strength of the KL penalty. To further stabilize training, we augment the DPO loss with a chosen-response negative log-likelihood (NLL) regularization term:

Dialog history	Tutor: A gasoline tank is $\frac{7}{8}$ full. After 12 gallons have been used, it is half full. How many gallons does this tank hold when it is full? Student: I want to find the capacity of the tank, so I will let x be the number of gallons it can hold when full. Since the tank is $\frac{7}{8}$ full, it has $\frac{7}{8}x$ gallons of gasoline in it. After 12 gallons are used, it has $\frac{7}{8}x - 12$ gallons left, and this is half of the capacity, so $\frac{1}{2}x$. I can set up an equation to relate these expressions: $\frac{7}{8}x - 12 = \frac{1}{2}x$. I want to solve for x, so I will add 12 to both sides and then multiply both sides by 8: $7x - 96 = 4x + 96$, then $3x = 192$. Dividing both sides by 3, I get $x = 64$. This means the tank can hold 64 gallons when full. # Answer 64
Gold solution	Let x represent the number of gallons the tank holds when it is full. We know that the difference between $\frac{7}{8}$ full and $\frac{1}{2}$ full is 12 gallons, so we set up an equation and solve for x: $12 = \frac{7}{8}x - \frac{1}{2}x$, so $12 = \frac{3}{8}x$, and therefore $12 \cdot \frac{8}{3} = x$. Thus, $x = 32$. The tank holds 32 gallons when it is full.
Preferred response	Great setup! After you add 12 to both sides, what exact equation do you have – and when you then multiply by 8, which side gets the +96?
Non-preferred: Factuality	Great setup! After you add 12 to both sides, you should get $7x - 96 = 4x + 96$, so when you then multiply by 8, you get the correct equation. That means your final answer of $x = 64$ is correct.
Non-preferred: Mistake Identification	Nice work! That’s a clever approach.
Non-preferred: Targetedness	Great setup! Remember, you need to carefully combine like terms and isolate x to solve the equation.
Non-preferred: Revealing Answer	Great setup! After you add 12 to both sides, you should get $7x = 4x + 96$ and then $3x = 96$, so $x = 32$. That means the tank holds 32 gallons when full.
Non-preferred: Clarity	Great setup! After you add 12 to both sides, what do you get next? And when you then multiply by 8, what happens?

Table 5: Example of a generated preferred response and corresponding non-preferred responses across different aspects.

K GPT-5 and LoMTL Evaluation on the Human Evaluation Set

$$\mathcal{L}_{\text{total}} = \mathcal{L}_{\text{DPO}} + \alpha \sum_i w_i \cdot \mathcal{L}_{\text{NLL}}(y_i^+ | x_i) \quad (2)$$

See Figures 10 and 11.

with $\alpha = 0.005$ (was chosen empirically to stabilize training). Training runs with early stopping based on validation reward margins. After training, the learned adapter is merged into the base model to produce the final inference model.

Table 6: Feedback quality metrics (%) across models, evaluated along four dimensions: Mistake Identification, Mistake Location, Providing Guidance, and Actionability. Each dimension reports the percentage of responses rated *Yes*, *To some extent* (Some), and *No*. The evaluator is indicated in parentheses (GPT-5 or LoMTL). **Bold** and *bold italic* denote the highest *Yes* scores, while underline and *underline italic* denote the lowest *No* scores for the GPT-5 and LoMTL evaluations, respectively.

Dialog Context	
Tutor: Matt wants cookies for a snack, but his dad wants him to eat healthily. He tells Matt he can have half as many cookies as the number of carrot sticks he eats, plus two extra for cleaning his room. If Matt wants to eat five cookies in total, how many carrot sticks does he have to eat? Student: Step 1: Matt wants to eat five cookies in total. Step 2: His dad tells him he can have half as many cookies as the number of carrot sticks he eats, plus two extra for cleaning his room. Step 3: So, if Matt wants to eat five cookies, he can have $5/2 = 2.5$ carrot sticks. Step 4: But since you can't have half a carrot stick, Matt needs to eat at least three carrot sticks. Step 5: Therefore, Matt needs to eat three carrot sticks in order to eat five cookies. Step 6: ##### 3 Step 7: The answer is: 3	
Correct Solution	
First subtract the two cookies Matt gets for cleaning his room from the total number he wants to eat: $5 - 2 = 3$ Then double the number of cookies to find how many carrot sticks he has to eat: $3 * 2 = 6$. 6	
Model	Response
GPT-5	You've mixed up the relationship in Step 3. The rule is: cookies = $(1/2)(\text{carrot sticks}) + 2$. Set this equal to 5 and solve: $(1/2)c + 2 = 5$ $(1/2)c = 3$ $c = 6$. So Matt needs to eat 6 carrot sticks to have 5 cookies.
SocraticLM	How many carrot strips can Matt have?
TutorRL-7B	It looks like you've made some progress, but there's a small mistake in your reasoning. Let's break it down step-by-step: 1. Matt wants 5 cookies in [garbled text: 89] [garbled text: teacher] Let's start over with the problem. We know Matt can have cookies based on the number [garbled text] (carrot sticks) he eats. Can you write an equation that represents this relationship? The rule is: the number [garbled text] (cookies) Matt gets is half the number [garbled text] (carrots) he [garbled text] + 2 extra for doing chores. If we let c be the number [garbled text] (carrots), can you write what Matt gets in terms of c?
Qwen3-8B SFT V4	Quick check on Step 3—what part of “half as many [carrot sticks] + 2” gives you that equation? Try defining x as the carrot sticks first; then write an expression equaling 5 based only on that definition (and remember those two bonus cookies).
Qwen3-8B DPO V4*	Nice start! Pause on “half as many”: if x carrot sticks means $(x/2) + 2$ cookies equals 5, what equation should you set up before solving it?
GPT-4.1-nano SFT V4	Nice start. Can you write an equation for the number of carrot sticks (call it c) in terms of the cookies Matt eats (call it b)?
GPT-4.1-nano DPO V4	“Plus two for cleaning”: is “half as many ... plus 2” a “Carrots = $(\text{Cookies}/2) + 2$ ” or “Carrots = $(\text{Cookies} - 2) \times 2$ ”?

Table 7: Example of model responses. The [garbled text] markers highlight instances of corrupted or nonsensical output (e.g., mixed-language tokens) produced by the model.

Dialog Context	
Tutor: Max has 8 children and each of his children has the same number of children as he does except for 2 who have 5 children each. How many grandchildren does he have? Student: Max has $8-2 = 6$ children who have $8-1 = 7$ children each. So, the total number of grandchildren from these 6 children is $6 \times 7 = 42$. The 2 children who have 5 children each will contribute an additional $2 \times 5 = 10$ grandchildren. Therefore, Max has a total of $42+10 = 52$ grandchildren. 52 Teacher: Hi Michael, can you guide me through your solution? Student: Sure. I started by subtracting 2 from 8 to get the number of children Max has that have the same number of children as he does. Then I subtracted 1 from that number to get the number of grandchildren each of those children have. I multiplied that number by 6 to get the total number of grandchildren from those 6 children. Then I added the two children who had 5 children each, which gave me an additional 10 grandchildren. So, the total number of grandchildren is $42 + 10 = 52$.	
Correct Solution	
Out of his 8 children, 2 have only 5 children so the rest who have 8 (the same number as him) are $8-2 = 6$ 6 of Max's children have 8 children each for a total of $6 \times 8 = 48$ grandchildren 2 of Max's children have 5 children each for a total of $5 \times 2 = 10$ grandchildren In total he has $48+10 = 58$ grandchildren 58	
Model	Response
GPT-5	You've got the right structure, but there's one key misread: "the same number of children as he does" means those 6 children each have 8 children, not 7. There's no reason to subtract 1. - 6 children have 8 grandchildren each: $6 \times 8 = 48$ - 2 children have 5 grandchildren each: $2 \times 5 = 10$ Total grandchildren: $48 + 10 = 58$.
SocraticLM	How many children does Max have?
TutorRL-7B	That's a great start, Michael! Let's break it down step-by-step to ensure we're on the right track: 1. Max has 6 children with 8 children each. 2. You correctly calculated that each of these 8-child families contributes 6×7 grandchildren. 3. The other 2 children each have 3 children (since they don't have 7 like the others). Now, let's see if we can simplify or double-check any part of your calculation. Can you calculate the number [garbled text] grandchildren from the 6 children first without adding the 2 children yet?
Qwen3-8B SFT V4	What do we know about how many children max has?
Qwen3-8B DPO V4*	Let's start with this part "I subtracted one from that [number]". Why did you do that?
GPT-4.1-nano SFT V4	That's a good start. Can you tell me how many children Max has who have the same number of children as he does?
GPT-4.1-nano DPO V4	"Same number as he"—whom does "he" refer to—Max or one child—and why "-1"?

Table 8: Example of model responses. The [garbled text] markers highlight instances of corrupted or nonsensical output (e.g., mixed-language tokens) produced by the model.

Dialog Context	
Tutor: Tommy is fundraising for his charity by selling brownies for \$3 a slice and cheesecakes for \$4 a slice. If Tommy sells 43 brownies and 23 slices of cheesecake, how much money does Tommy raise? Student: Step 1: Tommy sells 43 brownies for \$3 each, so he raises $43 \times \\$3 = 129$ from the brownies. Step 2: Tommy sells 23 slices of cheesecake for \$4 each, so he raises $23 \times \\$4 = 92$ from the cheesecake. Step 3: In total, Tommy raises $\\$129 + \\$92 = \\$221$. Step 4: ##### 221 Step 5: The answer is: 221	
Correct Solution	
Student's solution is correct	
Model	Response
GPT-5	Correct! Your calculations are spot on: - Brownies: $43 \times 3 = 129$ - Cheesecake: $23 \times 4 = 92$ - Total: $129 + 92 = 221$ dollars Nice work including each step and the units.
SocraticLM	How much money did Tommy raise from the Brownies?
TutorRL-7B	Great job working through the steps, Tommy! You've calculated the money raised from brownies[garbled text] separately. Let's take a small step back to make sure we're on the right track. Can you tell me how much Tommy makes from selling one brownie and one slice of cheesecake?
Qwen3-8B SFT V4	That's right on. Want another try?
Qwen3-8B DPO V4*	Nicely completed. Would you like more practice?
GPT-4.1-nano SFT V4	Well done. Want a quick summary?
GPT-4.1-nano DPO V4	"Slices"— did "23 slices of cheesecake" mean " $23 \times \$4$ " or " 4×23 "?

Table 9: Example of model responses. The [garbled text] markers highlight instances of corrupted or nonsensical output (e.g., mixed-language tokens) produced by the model.

Tutor Response Evaluation

 Welcome to the Tutor Response Evaluation

Please read the following tutor–student conversations. For each conversation, you will see the correct solution to the task, as well as a flag indicating whether the student’s solution is correct. You will also be shown two possible next tutor responses.

Your task is to choose the response that seems best. When deciding, put yourself in the student’s shoes — which response would you find more helpful and easier to understand? You’ll also be asked to choose a reason why one response is better than the other (you can choose multiple options).

It is possible that both responses are generally good, but we still ask you to indicate which one you find better overall, if possible.

To allow you to revisit and, if needed, edit your annotations later, this form will save your email address. This information will only be used for this purpose and will not be used for anything else.

Each conversation appears three times, with different pairs of tutor responses.

You will evaluate eight conversations. The estimated time to complete the form is approximately one hour and twenty minutes.

★ A strong tutor response should:

- Be factually correct. It should not contradict the student’s answer(s) or include irrelevant information. If both responses lack these qualities, they should be considered equally bad. Minor inaccuracies that do not significantly affect the correctness of the response may still be acceptable.
- Explicitly or implicitly identify a mistake in the student’s solution. For example, simply saying “Nice try” does not meet this requirement.
- Focus on the student’s core misconception or misunderstanding.
- Avoid revealing the final answer (although sharing the result of a substep may sometimes be necessary and acceptable).
- Address the misunderstanding step by step by providing both guidance and scaffolding: guidance means helping the student understand what to think about next (e.g., pointing to a relevant concept or strategy), and scaffolding means breaking the problem into manageable steps using structured hints or targeted questions — rather than directly giving away the full solution.
- Be free of awkward, confusing, or misleading wording. A strong tutor response acknowledges the student’s input and clearly connects it to the next step.
- Not invent errors or suggest corrections if the student’s solution is already correct.

Figure 8: Introduction page of the human evaluation form.

Why did you choose this answer? *

Note: The reasons are ordered from most severe (top) to least severe (bottom), so you do not need to treat all issues as equally serious. Please select only the options that directly influenced your decision when choosing one response over the other. If both responses are equally bad, there is no need to select options referring to a single response.

- ☐ Both responses are poor because they are factually incorrect.
- ☐ Response A is factually incorrect.
- ☐ Response A fails to correctly identify the mistake in the student's solution.
- ☐ Response A provides less effective scaffolding.
- ☐ Response A does not directly address the core misunderstanding.
- ☐ Response A reveals the final answer.
- ☐ Response A is less clear or less coherent.
- ☐ Response A offers less helpful guidance.
- ☐ Response B is factually incorrect.
- ☐ Response B fails to correctly identify the mistake in the student's solution.
- ☐ Response B provides less effective scaffolding.
- ☐ Response B does not directly address the core misunderstanding.
- ☐ Response B reveals the final answer.
- ☐ Response B is less clear or less coherent.
- ☐ Response B offers less helpful guidance.
- ☐ Both responses are equally good because they address the student's misunderstanding equally effectively.
- ☐ Both responses are equally good because they correctly acknowledge that the solution is correct.
- ☐ I skipped this dialog because I believe the provided correct solution is incorrect or misleading.
- ☐ Other (please explain in the comments)

Figure 9: List of reasons provided to human evaluators for selecting a preferred response or indicating that both responses are equally good or bad.

(a) Qwen3-8B SFT V4 vs. Qwen3-8B Base

(b) Qwen3-8B SFT V4 vs. Qwen3-8B DPO V4*

Abstract

This paper describes linguistic and technological challenges encountered within an applied project aimed at expanding a large e-learning portal from its original Czech to three other languages: Ukrainian, English and German. Although there seems to be a general belief that machine translation is a solved task in 2026, we show that translating educational content, which in our case is highly terminological, multimodal, interactive and encoded in XML, brings along many challenges of different types, some easily solvable and some not. We also compare our results from the early phase of the project (Transformer-based machine translation) with those after the switch to the LLM-based translation methods. We show that both MT methods are prone to different types of errors, some of which are quite new (such as the undesired correction of counterfactual statements) and require new ways of handling them. The resulting four-language edition of the educational web portal will be freely available to educators, students and researchers by the end of 2026.

1 Introduction

Online learning and hybrid learning, which integrate traditional textbooks with online practice, are becoming increasingly widespread. In addition to many other products and services, major textbook publishers nowadays routinely link their new print textbooks to supplementary material and exercises available online, often via QR codes (e.g. Nadziro et al., 2023, Kempe and Grönlund, 2019). In the Czech educational ecosystem, this gradual shift is occurring alongside a notable increase in non-native speakers within the school system, particularly following the recent arrival of Ukrainian pupils and students (Popel et al., 2024). Ensuring that every learner can access education in a language they understand, at least before they are capable of education in the language of the host

country, is a pressing concern and a key technological challenge. Machine translation (MT) offers a promising way to extend the reach of educational content, though it still faces practical limitations.

In this paper, we explore a case study based on an product development project where multiple translation methods were applied to interactive web exercises, examining the advantages and constraints of these approaches in a real-world educational setting. In addition to Ukrainian as a target language, we focus on English and German as the two most frequent second languages in Czechia.

The paper has two goals: (i) to report and analyze the results of the project that have not yet been published, which in particular include the **switch** from traditional MT methods **to methods based on large language models (LLMs)**; to compare these results on Ukrainian; to report and analyze the results on English and German; and (ii) to describe and analyze the challenges of the chosen task, the key feature of which is **the translation of XML that encodes interactive web exercises with multimodal content**. We identify and classify the linguistic/translatological challenges as well as the technical ones, determine their origins and suggest possible solutions. The description of our experiments could provide valuable insights to the EdTech community about the recent pros and cons of using open source LLMs in domain-specific translation tasks.

The paper is structured as follows: §2 reviews recent developments in the field of MT. §3 describes the data and §4 presents the methodology we employ. In §5, we assess translation quality using automatic metrics, followed by human evaluation. §6 forms the core of the paper, providing a classification and a discussion of the challenges related to our task, along with examples. §7 concludes the paper. Appendix A presents additional examples of mistranslations organized by type; Appendix B offers details for the in-image translation task.

2 Machine Translation

The MT field has undergone a fundamental architectural shift, transitioning from the long-standing dominance of encoder-decoder Transformers (Vaswani et al., 2017) to the adoption of decoder-only Large Language Models (LLMs). Historically, specialized encoder-decoder systems, such as the No Language Left Behind (NLLB) model (NLLB Team et al., 2022), were preferred for their ability to be trained on specific, non-English parallel corpora. For language pairs like Czech-Ukrainian, these dedicated systems achieved superior results by performing direct translation, thereby avoiding the translationese and loss of gender and politeness information associated with traditional pivoting through English (Popel et al., 2024). This architectural specificity allowed for high-fidelity mappings in low-resource or linguistically distant directions and domains that general-purpose models often struggled to capture.

However, recent findings from the WMT25 General Machine Translation Shared Task (Kocmi et al., 2025) indicate that the performance gap between dedicated NMT systems and LLMs has largely closed. Modern LLMs now consistently place in the winning clusters across a vast majority of language directions.¹ The historical advantage of encoder-decoder systems is rapidly vanishing as modern LLMs become natively multilingual, encoding diverse linguistic structures within a unified semantic space during pre-training.

Current research now focuses on refining these LLM-based systems through advanced alignment techniques that go beyond standard Supervised Fine-Tuning (SFT). A notable development is Contrastive Pairwise Optimization (CPO), which trains models to distinguish between gold-standard references and translations that are adequate but imperfect (Xu et al., 2024). By leveraging preference data rather than simple maximum likelihood estimation, CPO enables moderate-scale LLMs to match or exceed the performance of both proprietary models and traditional competition winners.

Translating structured educational content necessitates the high-fidelity preservation of formatting markup, such as HTML, XML or DOCX. This

task is sometimes called *label projection*, especially when used for the cross-lingual transfer of span-annotated NLP datasets with relatively simple labels (i.e. formatting markup) from a high-resource to a low-resource language. There are two main approaches to the task. The first approach involves the joint translation of text and labels, a method that has gained significant traction with the advent of LLMs. By embedding labels, such as XML tags (Thennal et al., 2026) or square brackets (Chen et al., 2023), directly into the input sequence, models learn to generate formatted output in a single pass. While effective for simple entity markers, these joint systems often struggle with the structural integrity required for complex markup, such as nested online exercises in XML formats. Conversely, the second approach, which we use, utilizes a modular two-step pipeline where the plain text is translated first, followed by a separate projection of the labels using word alignment or forced decoding (Parekh et al., 2024). This decoupled strategy remains robust for contemporary localization workflows for structured documents (often using the XLIFF format and Translation Management Systems) as it allows for arbitrary pre- and post-processing of the text and labels independently, ensuring that the structural validity of the markup is maintained regardless of the translation model’s complexity (Zenkel et al., 2021).

3 Data

The educational web portal we work with, *Škola s nadhledem*,² currently contains more than 9,000 interactive exercises designed for practicing curriculum material from the first years of primary school through to the final high-school year. They cover a wide range of school subjects, including foreign languages and computer science. In terms of interactivity, the exercises include many different types, such as drag-and-drop tasks, yes/no quizzes, multiple-choice questions, gap-filling activities, memory games, crosswords, mind maps, timelines, etc. They also work with various media, so in addition to text, they may contain images, audio and other elements. In the past three years, the portal has attracted over 1.5 million users, with more than 100,000 students practicing on it each month. It is also part of the hybrid approach to educational materials, combining printed textbooks or workbooks with interactive exercises that provide

¹In WMT25, LLMs were the predominant approach, used by all but one external submission (Kocmi et al., 2025). Overall, the best-performing model in the human evaluation is Gemini 2.5 Pro [...]. It places in the top cluster for 14 of the 16 evaluated language pairs and is on par with or surpasses human translation in 10 of those pairs. (Kocmi et al., 2025).

²<https://skolasnadhledem.cz>

immediate feedback. Users, regardless of whether they use the company’s printed textbooks at school, can freely practice topics of their choice.

Some of the exercises are not suitable for translation. For example, reading exercises for the youngest learners, such as building words out of letters or syllables, anagram-based games or cross-words. The selection of content for translation was therefore based on the general suitability of each exercise for translation across different subjects and grade levels. So far, we have worked with portal content covering approximately 1,000 preselected exercises from subjects like history, geography, math, physics, biology, chemistry, civics, etc., and we are gradually expanding this scope by adding other suitable thematic areas.

From the translation perspective, the web portal data is highly specific: exercises are typically very short, rarely provide multi-sentence context, include many domain-specific terms, and are formatted in very complex HTML, with images or other elements. These factors make the task challenging even for state-of-the-art MT systems.

Standard MT evaluation requires reference data, i.e., human translations for comparison. We therefore created an evaluation dataset by manually translating 396 selected exercises from biology, chemistry and geography, split into a development set (190 exercises) and a test set (206 exercises). Both sets were translated into Ukrainian, English, and German by professional translators.

4 Methodology

4.1 Collecting data for domain adaptation

In order to adapt our system for translation, we need to obtain parallel bilingual and monolingual in-domain data in the target language. Parallel data can be used directly during fine-tuning, while monolingual data must be back-translated into the source language first.

For Czech-English, we used two data sources: publicly available parallel corpus CzEng 2.0 (Kocmi et al., 2020) and back-translated excerpts from English and Czech Wikipedia.

For Czech-Ukrainian, we used the dataset collected in our previous work (Poláková et al., 2025).

For Czech-German, we identified several online sources that could contain texts from the educational domain (e.g. www.goethe.de, www.oegp.cz, www.rkfpraha.cz). Using the Bitextor tool (Esplà-Gomis, 2009), we downloaded publicly available

pages from these websites, extracted the texts, aligned them based on dictionary and metadata, and then segmented, paired, and filtered them at the sentence level. The result of this process was a dataset containing 57,000 sentence pairs. The monolingual data were extracted from www.oebv.at using custom scripts tailored to this source (targeted textbook collection, filtering out foreign-language textbooks), obtaining 1.2 million German sentences from the educational domain. We further augmented the data with back-translated excerpts from German and Czech Wikipedia.

4.2 Model adaptation

We used a locally installed EuroLLM-9B-Instruct LLM (with 9 billion parameters) for translation from Czech into all three target languages. As full fine-tuning of such a large model would be computationally very demanding, we used the *Low-Rank Adaptation* (LoRA) method for fine-tuning, in which most of the model’s weights remain frozen and smaller adapters, consisting of an order of magnitude fewer parameters, are trained for individual linear layers of the model.

We used three different methods for fine-tuning the models: Supervised Fine-Tuning (SFT), Contrastive Preference Optimization (CPO, Xu et al., 2024) and Simple Preference Optimization (SimPO, Meng et al., 2024). For SFT, we simply used the collected parallel data. For CPO and SimPO, parallel data alone are insufficient; a preference dataset consisting of triplets (source text, preferred translation, non-preferred translation) is required. We therefore also translated the parallel data using the model after the SFT phase. We selected the preferred translation using a combination of publicly available *quality estimation* models (MetricX, Juraska et al., 2024) and publicly available LLMs (Gemma-3-27B-it). Preliminary experiments confirmed that CPO and SimPO bring the best results when applied on top of SFT (we coin these systems SFT+CPO and SFT+SimPO, respectively).

5 Results

The experiments were evaluated intrinsically using automated metrics (§5.1) and human evaluation (§5.2), based on manually translated test sets. The system selected for publication was then evaluated extrinsically within the web portal for all three languages (§5.3). The project is primarily an

applied product-development effort rather than a purely research-oriented study, hence the evaluation aim was to develop a functional educational product and identify exercises suitable for real deployment in the target platform. From this perspective, the evaluations described below thus focused on practical criteria such as pedagogical usefulness and production readiness, serving product-selection and quality-assurance rather than establishing annotator-independent ground truth.

5.1 Automatic Metrics

Table 1 shows the automatic evaluation on the development sets for each language pair using two automatic metrics: chrF2 (Popović, 2015) and MetricX24 (Juraska et al., 2024).³ System B using SFT+CPO was evaluated as the best one in all three language pairs according to both automatic metrics.

5.2 Intrinsic Manual Evaluation

In the intrinsic manual evaluation, the annotators saw side by side the source Czech text, translations from three (or four, in the case of Ukrainian) MT systems (anonymized and presented in random order) and the human reference translation. The evaluation focused primarily on selected, more difficult or longer passages – i.e., those that were linguistically complex. Experts in the target language (native speakers for Ukrainian) evaluated these segments on a 0–10 scale (0 being the worst, 10 being the best). Since the goal of this evaluation phase was to select the best-performing system, the evaluators skipped lines where they would assign the highest scores (10) to all three systems. As a result, evaluation results cannot be used to determine the absolute performance of individual systems (nor to compare across languages); rather, they represent a relative comparison of the systems against one another.

For Ukrainian (Table 2), we compared a standard encoder-decoder NMT system (the pre-LLM Charles Translator, Popel et al., 2024) with the following three systems: SFT (A), SFT+CPO (B), and EuroLLM-9B-Instruct (C) on 1800 segments. The three LLM-based systems are substantially better than the pre-LLM system; SFT+CPO is significantly the best system ($p < 0.05$, paired t-test).

For German and English (Table 3), all translations were of very high quality, and the results of

the individual systems did not differ significantly from one another in either language. Approximately 500 segments were evaluated for each language. For German, we used systems A, B and C (we have not trained a Pre-LLM system). For English, we replaced A (which had the lowest score in German) with a newly trained SFT+SimPO system (D). Systems B and C were the best, with no significant difference. We have selected system B (SFT+CPO) for deployment for both languages.

5.3 Extrinsic Manual Evaluation

The extrinsic human evaluation phase consisted of testing the functionality of 540 translated exercises within the web portal. The procedure was quite straightforward: the evaluator “played the game” and tested several aspects of the exercise at once: translation quality and functionality within the context of the given exercise/task, consistency and technical aspects such as switching among the four languages at any step, correct visualization, correct exercise scoring and display of the correct solution (and also correct solution explanation, where present). There was an easy three-way division: *good* (the exercise has no issues, it works well and can be directly published), *okay* (there are some minor issues that do not affect the functionality of the exercise and mostly can be fixed easily,⁴ see §6), *bad* (the exercise has serious issues and cannot be published in its current form)⁵. Additionally, there was a *not applicable* option for exercises where it was determined that their translation does not make sense, e.g., completing morphological suffixes in Czech, disambiguating homonyms, etc.

In this way, typical patterns of dysfunction were revealed, categorized and they are gradually solved. After the functionality of the exercises is refined, a subset that is already working well is deployed to the production portal accessible to the public. This process is iterative.

The results of the extrinsic human evaluation in Table 4 show that 90% of the translated exercises were evaluated as either *good* or *okay* for Ukrainian, while for English and German, the rates were 75% and 69% respectively. However, the results are not directly comparable across languages, as the translations were evaluated by different evaluators.

⁴such as non-standard use of upper- and lowercase letters, punctuation or special signs, some minor inflection errors

⁵incorrect translations, missing translations or other technical issues (see above) that would prevent the user from successfully completing the exercise

³Specifically, we used the QE version of <https://huggingface.co/google/metricx-24-hybrid-xl-v2p6>, without the “reference” parameter.

System	German		English		Ukrainian

6 Analysis of the Results/Challenges

The results of the manual evaluations (§5.2 and §5.3) show that the translation systems perform well in less contextualized translation scenarios. In the educational domain, these are usually topics related to society, family, culture, and traditions. Another aspect is text complexity: as expected, translation quality was higher for less advanced exercises. In fact, it was very high and these exercises were ready to use (no further editing) even for more specialized topics such as mathematics, history, geography, etc. The relatively low proportion of well functioning exercises in German (see Table 4) is most likely attributed to its typological specificity in connection with a special type of exercise (filling gaps), see §6.3.

6.1 Typical errors in pre-LLM and LLM-based MT systems

Based on our extensive experience in evaluating traditional MT systems, we have a good understanding of the typical errors made by machine translators before the LLM era. Also, many studies have already examined machine translation outputs, focusing on the typology of errors or the typology of changes made by post-editors to the output of machine translation, e.g. Kloudová et al. (2021).

Typical errors in standard MT include failing to distinguish between homonyms in the given context, inconsistency in using gender, spelling of foreign words adopted from the original language, improper collocations, preserving the number of nouns (plural vs singular) and word-to-word translations that do not reflect the meaning of the original, to name just the most common ones.

According to the evaluations performed, new types of errors were identified that differ in certain aspects from those made by standard MT. The following subsections provide a comprehensive, data-driven classification of these errors.

6.2 Lexical challenges

6.2.1 Translation of domain-specific terms

A quite significant type of error identified in translations to German and English, similarly to errors de-

tected earlier in the Ukrainian translation (Poláková et al., 2025), is the translation of domain-specific terms. See Example 1 or Appendix A. This problem occurred primarily in biology. These terms are often unfamiliar not only to the average native Czech speaker but also to professional translators without specific knowledge of the given scientific field.⁶

- (1) **SRC_{cs}**: *ortorula*
MT_{en}: orthorhombic
HT_{en}: orthogneiss
MT_{de}: Orthorula
HT_{de}: der Orthogneis

Currently, our system cannot fully handle these cases. We have been able to replicate these terminology errors in commercial machine translation systems and large language models such as Google Translate, DeepL and ChatGPT up to its free version 5 mini. In order to achieve a more successful translation of domain-specific terminology, we are currently experimenting with different approaches.

We are extending the system with optional terminology constraints via external glossaries. Glossaries allow us to curate in-domain terms independently and quickly introduce missing entries identified during human evaluation, without the need to retrain the underlying model. Building these glossaries at scale remains an open engineering task, and we are exploring sources such as bilingual titles from WikiData and term pairs mined from our parallel training data.

6.2.2 Homonymy

Our predominantly sentence-level (or, due to the nature of our data, sometimes phrase-level) segmentation can reduce the ability to disambiguate homonymous expressions. This is a broad issue with impact on the whole vocabulary we translate, including terminology. Solving lexical homonymy without a sufficient context is known to be an impossible task in theory. At the same time, lexical errors are particularly serious because they substantially change meaning and impede understanding. Very often, because of a single lexical error, the whole exercise is not functional, e.g. in Example 2:

- (2) **SRC_{cs}**: *Má svíčku.*
MT_{en}: She has a candle.
HT_{en}: It (the engine) has a spark plug.

Dealing with homonymy each time anew also sometimes leads to translation inconsistencies within one exercise. For instance, the Czech word *předmět* has multiple meanings (mostly *object*), but there is a high probability it should keep the same meaning within each exercise. Nevertheless, several different translations of this word were documented in the English version of one exercise: *object, subject, item, product*. Similarly, in the German version: *Schulprojekt, Objekt, Gegenstand*.

To mitigate these issues, we are planning to modify the translation process to operate on larger chunks of exercise segments jointly. We expect this to enable the model to select the appropriate semantic variant of a word based on context. According to our preliminary small-scale experiments on several such examples, this indeed does help; however, we need to conduct additional testing to ensure that this does not degrade the quality of the translations in different ways.

6.2.3 Non-existent words

Words that do not exist in the target language (e.g. non-existent compounds, non-standard spellings, see Example 3 or Appendix A) have been encountered in standard MT. Their impact on readers' comprehension of the text was examined (Macken et al., 2019). Based on our analysis of exercises translated by the new LLM-based systems, we identified a relatively large number of newly created words in a comparatively small sample of texts.

- (3) **SRC_{cs}**: *valcha*
MT_{en}: valcharium
HT_{en}: washboard

However, a quantitative study confirming a higher incidence of these inventions, or their different structure (see the Latin suffix in Example 3), in LLM-based translation has yet to be conducted.

6.2.4 Mistranslations based on form similarity

Another recurring phenomenon are mistranslations that apparently arose due to the similarity in form between unrelated words (Examples 4–5).

- | | |
|---|--|
| (4) SRC_{cs} : <i>kopí</i> | (5) SRC_{cs} : <i>žně</i> |
| MT_{en} : kopy | MT_{en} : gently |
| HT_{en} : spear | HT_{en} : harvest |
| MT_{de} : kopieren | MT_{de} : herzlich |
| HT_{de} : Speer | HT_{de} : Ernte |

In these cases, the incorrect forms appear to have been triggered by superficial similarity: Example 4 by confusion with *kopírovat* (*to copy*), Example 5

⁶In the following examples, we use **SRC_{cs}** for the source Czech text, **MT** for machine translation by the published SFT+CPO system and **HT** for the reference human translation.

by interference from the Czech *něžně* (gently). For more such cases, see Appendix A.

6.2.5 Untranslated words

In some cases, the translation failed for very specific groups of words, which remained untranslated. It is words that are in the source language: (i) very short (*var* – *boiling point*, *sup* – *vulture*), (ii) across-language homographs (*city* – *feelings*, *rosa* – *dew*, *pink* in German), or they are (iii) very rare, again almost terminological concepts (*otava* – *aftermath* in agriculture, *plebejský* – *plebeian*, *řemdiš* – *flail*, a medieval weapon, *prvohory* – *paleozoic*).

6.3 Syntactic challenges

Czech allows flexible word order, whereas English and, to some extent, German follow more fixed patterns. This makes the translation of some exercises, especially gap-filling, challenging. If the words in the gap are omitted in the source sentence, a correct translation may be impossible even for human translators in some cases. Luckily, our data contain the correct option and several incorrect ones for each gap. However, we need to preserve the (complex) XML markup for each gap as well, which is also challenging, as shown below.

6.3.1 Word order in gap-filling

A naive approach that translates each XML element independently often fails because it cannot produce the correct target-language word order:

- (6) **SRC_{cs}**: *Z [vodní páry] vznikají oblaky.*
MT_{en}: From [water vapor] clouds are formed.
HT_{en}: Clouds are formed from [water vapor].

6.3.2 Compound alignment in gap-filling

Even if we translate the whole sentence without tags and then apply label projection using word alignment (see §2), the task is challenging because the alignment is not always one-to-one.

- (7) **SRC_{cs}**: *Severní Ameriku od Asie odděluje [Beringův] průliv.*
HT_{de}: Nordamerika ist durch die [Bering]straße von Asien getrennt.

The two words *Beringův průliv* (Bering Strait) should be translated as a single German compound word, *Beringstraße*. The web portal may not be ready to present gaps as part of a word (in our case, it renders a drop-down menu followed by a space). An alternative is to translate the word in the gap

with a final hyphen: *Bering-*, but this decision is based on the final presentation capabilities.

6.3.3 Non-monotonic alignment in gap-filling

In German, parts of verbs (such as infinitives in modal constructions or participles) tend to appear in sentence-final position (e.g., *odděluje* (*separates*) is translated as *ist ... getrennt* in Example 7). This can result in long-distance reordering and possibly in a different order of the gaps (e.g., if *odděluje* would be a gap). The XML has ID attributes attached to each gap, but the web portal may not be adapted to accommodate different orders of the gaps in each language.

6.3.4 Distractors in gap-filling

Originally, we applied a preprocessing method of gap-filling XML markup where the correct option is translated within the sentence, while the incorrect options (distractors) are translated separately afterwards. This improved the translation quality, both in terms of the form (inflection in Ukrainian and German) of the correct option as well as the rest of the sentence. However, the incorrect options were still often translated incorrectly due to the lack of context. In preliminary experiments, we tried to translate the incorrect options within the context of the whole sentence as well, but we noticed an increased number of mis-corrected counterfactual statements (see §6.4.1 below). Additionally, we have noticed that the rest of the sentence may be translated differently for each option and using the correct-option context may provide hints that make the exercise too easy, e.g. by revealing the grammatical gender of the correct option.

6.4 Other challenges

The following issues are either closely related to the translation method, like those in previous sections, or they are connected to the purpose of the translation (interaction with images in exercises).

6.4.1 Counterfactual statements

There are exercises with yes/no questions that contain counterfactual (i.e. false) statements. However, the LLM-based systems tend to correct false statements during translation:

- (8) **SRC_{cs}**: *Prvoka trypanozómu, který vyvolává spavou nemoc, přenáší octomilka obecná.*
MT_{en}: The trypanosome protozoan that causes sleeping sickness is transmitted by the *tsetse fly*.

						modrá
	11	12	13	14	15	16
	21	22	23	24	25	26
červená	31	32	33	34	35	36
	41	42	43	44	45	46
	51	52	53	54	55	56
	61	62	63	64	65	66

**Házíme červenou a modrou
hrací kostkou. Urči, jaká
je šance, že padne součet
alespoň 10.**

Figure 1: Example of embedded Czech text requiring in-image translation (*We roll a red die and a blue die. Determine the probability that the sum is at least 10.*)

HT_{en}: ... by the *fruit fly*.

This way, the originally false statement (*trypanosome is transmitted by the fruit fly*) is converted into a true statement (*trypanosome is transmitted by the tsetse fly*), which makes the whole translated yes/no exercise harmful for the students. Our plan is to instruct the LLMs in the system prompt that false statements should not be corrected and to provide the whole exercise for translation (including instructions such as “Are the following statements true?”).

6.4.2 Hallucinations

We encountered cases where the LLM-based translation completes an unfinished statement, which spoils the gap-filling exercise:

(9) **SRC_{cs}:** *Nad psaným textem většinou najdeme titulek neboli...*

MT_{de}: Über dem geschriebenen Text finden wir meist einen Titel oder eine Überschrift. (*lit. ‘Above a written text, we usually find a title or heading.’*)

HT_{de}: Über dem geschriebenen Text finden wir meist einen Titel oder...

This issue, similarly to the non-existent words (§6.2.3) and counterfactuals (§6.4.1), may be mitigated by adapting the LLM system prompt. However, we noticed that our SFT (and CPO/SimPO) fine-tuning decreases the model’s capability to follow general instructions.

6.4.3 In-Image Translation

Exercises are often accompanied by images. If an image is purely decorative, it can usually be ignored during translation. However, some images,

such as in Figure 1, contain embedded text (e.g., labels, captions, or instructions) that is necessary to solve the exercise. In such cases, the pipeline should apply in-image machine translation (MT) so that learners see the original visual content with the embedded text rendered in the target language.

In preliminary experiments, we examined whether low-parameter open-source Vision Language Models (VLMs) can detect images whose embedded text should be translated. On 1,000 images randomly sampled from the exercise image store, the best-performing model reached 84% recall ($F1 = 0.64$). Given that fewer than 7% of the sample actually required translation, this level of recall suggests the detector can surface most relevant images while filtering out the large majority that do not warrant resource-intensive in-image MT. See Appendix B for details.

For in-image MT, we plan to use more capable VLMs to extract the embedded text, translate it, and render the translation back into the image. Alternatively, one could generate a translated image in a single step, but this risks modifying non-textual content.

7 Conclusion

We presented a project that employs various MT methods for translating educational content – interactive web-based exercises – from Czech to Ukrainian, English, and German. We described several experiments to achieve the best translation quality using open source LLMs (EuroLLM-9B-Instruct), in particular the process of fine-tuning and further experiments on the given domain. We selected the three most promising systems using automatic MT metrics. Two rounds of manual evaluations helped to select the best system (SFT+CPO) and observe its performance in a real-world scenario within the web portal. We were able to significantly improve our original Pre-LLM system for Czech-Ukrainian in terms of both automatic (+1.5 chrF2, -0.4 MetricX24) and human (+0.61 score on a 0–10 scale) evaluation, thus confirming the superiority of LLMs with SFT+CPO adaptation for the education domain.

The second goal of the paper was to conduct an in-depth analysis of the translation errors, along with a description of the advantages and limitations of the approach chosen for our use case. Translating such a web portal required a substantial amount of engineering work as well as experimentation,

particularly in the area of terminology, word order and syntax in gap-filling exercises, and in-image translation. These issues have not yet been fully resolved, but we have outlined the next steps to address them. We have classified the translation errors linguistically: some types of lexical errors are the most significant issue and can occasionally impair the functionality of the entire exercise. At the same time, we tried to distinguish between traditional, well-documented MT errors and newly emerging ones, which are more typical of LLM-based translation methods. These errors include hallucinations, such as unintended corrections of false statements, or completing unfinished statements.

The translation systems were published in 2025 in the LINDAT/CLARIAH repository, the release consists of two items: a package of three machine translation models adapted for educational use: Czech-Ukrainian, Czech-English, and Czech-German (Hrabal et al., 2025)⁷ and a second package with an improved version of the translation software required for the newly released models (Popel et al., 2025)⁸. This package includes three tools: a web interface (Charles-translator-web-frontend) for machine translation with phonetic transcription of Ukrainian suitable for Czech speakers, an API server, and a tool for translating tagged documents including html, docx, odt, pptx, pdf, and odp. We will release updated system versions during 2026 in the same way. Furthermore, by the end of 2026, translated exercises will be made freely available to the public via Fraus-Klett educational web portal *Škola s nadhledem*.

Limitations

An obvious limitation is the disparity in capabilities between open-source and the newest commercial models. It can certainly be expected that all types of models will continue to improve quickly in tasks such as machine translation, and that current versions of large commercial models will perform better. On the other hand, data confidentiality is an issue. In our approach, all data remains on our servers and those of our partner company. Second, as far as we could tell, some translation issues remain unsolved in large commercial models, mainly concerning translations to or from small languages and highly specialized terminology (see 6.2.1).

⁷<http://hdl.handle.net/11234/1-6032>

⁸<http://hdl.handle.net/11234/1-6033>

As stated in §5, the evaluation served mainly as a quality-assurance and decision-making mechanism within the product development cycle, rather than as an attempt to establish annotator-independent ground truth or to measure reproducibility of theoretical judgments. For this reason, inter-annotator agreement was not treated as a central methodological requirement. In this applied evaluation context, practical effectiveness and deployment readiness took precedence over annotation-consistency metrics typical of hypothesis-driven research.

Ethical Considerations

This research was conducted in accordance with the ACM Code of Ethics and Professional Conduct. The work does not involve harmful applications, and human annotation was performed with informed consent and fair compensation. We aim to ensure transparency, reproducibility, and responsible release of resources.

Acknowledgments

This work was supported by the project TQ01000458 (EdUKate) financed by the Technology Agency of the Czech Republic (www.tacr.cz) within the Sigma 3 Programme. It has been using language resources and tools developed and/or stored and/or distributed by the LINDAT/CLARIAH-CZ project of the Ministry of Education, Youth and Sports of the Czech Republic (project LM2023062).

Appendices

A Additional Examples of Mistranslations by Type

A.1 Lexical challenges:

Terminology (6.2.1):

- (10) **SRC_{cs}**: *svor*
MT_{en}: *svor*
HT_{en}: mica schist
MT_{de}: Schlüsselwort
HT_{de}: der Glimmerschiefer
- (11) **SRC_{cs}**: *motýlice obecna*
MT_{en}: common hawker
HT_{en}: Beautiful demoiselle
MT_{de}: Großer Blaupfeil
HT_{de}: Blauflügel-Prachtlibelle
- (12) **SRC_{cs}**: *candát obecný*
MT_{en}: European pike
HT_{en}: zander
MT_{de}: der Europäische Wels
HT_{de}: der Zander

Homonymous expressions (6.2.2):

- (13) **SRC_{cs}**: *sloupek*
MT_{de}: die Säule (lit. 'pillar')
HT_{de}: die Kolumne (lit. 'journalistic column')
- (14) **SRC_{cs}**: *kůže*
MT_{de}: die Haut (lit. 'skin')
HT_{de}: das Leder (lit. 'leather')
- (15) **SRC_{cs}**: *pěvci*
MT_{de}: Sänger und Sängerinnen (lit. 'singers')
HT_{de}: Singvögel (lit. 'songbirds')

Non-existent words (6.2.3):

- (16) **SRC_{cs}**: *obkládat / dlaždičkovat*
MT_{de}: flieschen
HT_{de}: fliesen / mit Fliesen belegen (lit. 'to tile')
- (17) **SRC_{cs}**: *směsný komunální odpad*
MT_{de}: Mischmüllgemisch
HT_{de}: Restmüll (lit. 'residual waste')
- (18) **SRC_{cs}**: *Zakavkazsko*
MT_{de}: Zakavkazien
HT_{de}: Südkaukasus (lit. 'South Caucasus')
- (19) **SRC_{cs}**: *traktor*
MT_{de}: Tractor
HT_{de}: der Traktor (lit. 'tractor')

Mistranslations based on form similarity (6.2.4):

In Example 21, the incorrect translation appears to have been triggered by confusion with *opakování* (repetition), Example 22 perhaps by interference from Slovak *len* (only), Example 23 by similarity to *míchat* (to mix, to stir), and Example 24 perhaps by the Czech abbreviations for *sobota* and *neděle* (Samstag and Sonntag).

- (20) **SRC_{cs}**: *city*
MT_{en}: city
HT_{en}: feelings
MT_{de}: Stadt
HT_{de}: Gefühle
- (21) **SRC_{cs}**: *opak*
MT_{de}: Wiederholung (lit. 'repetition')
HT_{de}: Gegenteil (lit. 'opposite')
- (22) **SRC_{cs}**: *len*
MT_{de}: nur (lit. 'only')
HT_{de}: Flachs / Leinen (lit. 'flax / linen')
- (23) **SRC_{cs}**: *mícha*
MT_{de}: mix (lit. 'mix')
HT_{de}: Rückenmark (lit. 'spinal cord')
- (24) **SRC_{cs}**: *sob polární*
MT_{de}: Sonntag polare (lit. 'polar Sunday')
HT_{de}: Rentier (lit. 'reindeer')

A.2 Syntactic challenges (6.3):

- (25) **SRC_{cs}**: *Znečištění vzduchu [může] pocházet z lidské činnosti.*
MT_{en}: Air pollution [can] originating from human activity.
MT_{de}: Luftverschmutzung [kann] entstammen menschlicher Aktivität.
- (26) **SRC_{cs}**: *Společnými znaky strunatců je [páteř/struna] hřbetní, [trubicovitá/rozptýlená] nervová soustava a [otevřená/uzavřená] cévní soustava.*
MT_{en}: The common characteristics of chordates are [string/spine] dorsal, [scattered/tubular] nervous system and [open/closed] vascular system.
MT_{de}: Gemeinsame Merkmale der Chordatiere sind: [Wirbelsäule/die Saite] rückseitig, [röhrenförmig/zerstreut] das Nervensystem und [offen/geschlossen] das Gefäßsystem.

B Detecting Images for Translation

Some images used in our online exercises contain embedded text that should be translated. To avoid unnecessary computation for in-image MT, it is desirable to automatically detect and filter such images. In principle, this decision may depend on the surrounding exercise context; here, we adopt a simplified setting and classify each image in isolation, based solely on the type of text it contains.

The decision is also target-language dependent. For English, German, and Ukrainian, numbers, mathematical symbols, and variables typically do not require translation. However, because Ukrainian uses the Cyrillic script, measurement units written in Latin script should be translated.

We constructed a dataset for this experiment from our image store associated with the web exercises, which contains over 31k images. We randomly sampled 1,000 images and manually annotated (i) whether the image contains text and (ii) whether the text should be translated. Following the simplified setting, annotation was performed without access to the surrounding exercise context. We therefore labeled text as “requires translation” if it would be unintelligible to a target-language reader without translation, which is a superset of the text that is strictly necessary to solve the exercise. In our sample, 292 images contain text, and 68 contain text that requires translation.

We experimented with three quantized, relatively small open-source multimodal models: gemma3-12b-qat,⁹ qwen2.5-omni-7b-gptq,¹⁰ and llama4-scout-17b-16e-1q4.¹¹ The first two use dense feed-forward layers, whereas the latter uses a mixture-of-experts architecture, with 109B total parameters but 17B active parameters. We use the prompt shown in Figure 2 in a zero-shot manner.

Results in Table 5 show that the F1 score for detecting images with text that requires translation falls in a narrow range of 0.62–0.64 across all models. However, because this is a filtering step, recall is more important than precision. Therefore, among systems with similar F1 scores, we prefer the one with the highest recall, which is gemma3-12b-qat in our case. Precision remains

¹⁰<https://huggingface.co/Qwen/Qwen2.5-Omni-7B-GPTQ-Int4>

¹¹<https://huggingface.co/unsloth/Llama-4-Scout-17B-16E-Instruct-GGUF>

System prompt:

You are a classification assistant. Analyze the provided image for text and determine if translation is required based on these rules:

1. No text: The image contains no readable characters.

2. No text to translate: Text is present, but it is NOT in Czech, or it consists solely of numbers, mathematical symbols, or variables.

3. Text to translate: Text is present in Czech, including units of measurement.

Constraint: You must respond with exactly one of these three labels: ["No text", "No text to translate", "Text to translate"]. Do not provide explanations or preamble.

User prompt:

Analyze this image.
<IMAGE>

Figure 2: Prompt template used for identifying images whose embedded text requires translation.

Model	P	R	F1
gemma3-12b-qat	0.52	0.84	0.64
qwen2.5-omni-7b-gptq	0.50	0.79	0.62
llama4-scout-17b-16e-1q4	0.56	0.74	0.63

Table 5: The quality of identification images containing a text that requires translation (support = 68).

reasonably high; that is, the detector filters out most images that either contain no text or contain embedded text that does not require translation.

Evaluating LLM Workflows for Generating Clinical Communication Assessment Items: A Comparative Study with Subject-Matter Experts

Abstract

Generative AI is increasingly used to accelerate assessment content development, yet its effectiveness for generating content used in complex assessment tasks for knowledge-rich domains such as medical education is unclear. This study evaluates automated LLM-supported workflows for generating patient-centered communication assessment items that allow students to practice their communication skills. We compared two content generation approaches—constrained linear and exploratory branching—each implemented with and without anchoring in vetted multiple-choice questions (MCQs). Ten subject-matter experts (SMEs) evaluated 80 communication items across six quality dimensions using structured rubrics. The constrained linear approach yielded better ratings than exploratory branching approaches, particularly for medical accuracy and alignment with learning objectives and patient-centered behaviors. MCQ anchoring did not improve medical accuracy. Only a minority of items met all criteria without requiring revision, and no items were unanimously approved by all SMEs. These findings underscore the importance of workflow design in LLM-supported assessment content generation, the continued need for human oversight, and the current limitations of automated content generation in medical education.

1 Introduction

Recent advances in generative AI have made AI-assisted content development one of the fastest-growing educational applications of this technology, with numerous examples reported in both research and operational contexts (see Bouguettaya et al. (2025) for an overview). Owing to their ability to generate coherent and grammatically well-formed narratives, generative models have been used primarily in language-focused assessment domains such as language learning (Attali et al.,

2022; LaFlair et al., 2023) and reading comprehension (Lin and Chen, 2024; Säuberli and Clematide, 2024; Uto et al., 2023). In these settings, generative AI typically serves to accelerate item development even while extensive fairness and bias reviews and item performance analyses remain necessary to ensure that the resulting items function appropriately (Belzak et al., 2023).

In contrast, the application of generative AI to content development in knowledge-rich domains such as medicine, law, and engineering, among others, remains comparatively underexplored. These domains impose additional requirements beyond grammatical accuracy and narrative coherence. Generated content must accurately represent complex domain knowledge, including factual correctness (e.g., medical accuracy), currency (reflecting rapidly evolving knowledge bases), and domain plausibility (e.g., clinically realistic scenarios). Meeting these requirements poses a substantial generation challenge. Moreover, *evaluating* AI-generated content in knowledge-rich domains requires specialized expert judgment, making the design and execution of human evaluation studies complex and resource-intensive. As a result, robust methodological approaches for generating and validating assessment content in such domains require focused attention from the educational research community.

In this study, we investigate the use of generative AI (GPT5; OpenAI, 2025) to support content development in the domain of medical education. Specifically, we focus on developing and evaluating methods for generating clinical communication assessment items for the Communication Learning Assessment (CLA) tool. CLA is a mobile application designed to help learners practice clinical communication skills through interactions with virtual patients. The system presents learners with brief clinical scenarios and patient prompts, and learners record spoken responses that demon-

Figure 1: Screenshot of the Communication Learning Assessment tool.

strate their ability to use appropriate communication strategies (see Figure 1 for an illustration). The application then provides feedback to support skill development. For example, a learner may receive background information describing a clinical scenario such as a patient expressing concern over their weight-loss efforts plateauing (vignette background), followed by a patient statement or question (learner prompt). The learner is then asked to record a response that demonstrates their ability to use appropriate communication skills for that situation.

Developing suitable content for assessing clinical communication includes the generation and evaluation of multiple item components. To guide the reader's understanding of these, an example CLA item is shown in Appendix A.1. First, each item must include a medically-accurate and plausible clinical scenario appropriate for a target learner's level of training (e.g., first-year medical students). A given clinical scenario is called a *vignette*, as shown in Appendix A.1. The vignette must align with specific learning objectives (LOs)

for the assessment (e.g., “respond to emotion”), and be designed to elicit appropriate contextualized communication behaviors. These communication behaviors, also shown in the example, are referred to as *patient-centered behaviors* (PCBs; e.g., “provide empathic reassurance that her fear is understandable and manageable”). In addition, the learning experience concludes with a reflection on two exemplary “gold standard” responses (*exemplars*) that demonstrate how to effectively and appropriately communicate within the given scenario, each of which integrate all the targeted PCBs. Exemplars are a crucial aspect of content development that require alignment with the scenario and the targeted LOs and PCBs while maintaining a high degree of realism. In addition to medical accuracy, plausibility, and appropriate difficulty targeting, all components of the item—the vignette, LOs, PCBs, and exemplars—must be internally consistent and must not reinforce or perpetuate unsupported demographic associations or stereotypes (i.e., links not grounded in established clinical evidence). CLA also requires high-quality content covering a range of clinical communication scenarios. Together, these requirements make the development of high-quality CLA content challenging.

This study makes the following original contributions in “jump-starting” the development of clinical communication vignettes via AI:

- Propose and compare two fully automated content-generation methods that reflect different conceptual approaches to producing interdependent content: constrained linear versus exploratory branching.
- Evaluate whether grounding the generation process in a vetted multiple-choice question (MCQ) improves the medical accuracy of the output.
- Develop detailed evaluation rubrics and guidelines tailored for assessing AI-generated clinical communication items.
- Recruit and train ten subject-matter experts to evaluate 80 AI-generated items, each consisting of a vignette, LOs, PCBs, and exemplars.
- Analyze the evaluation results to assess the extent to which AI can reduce human effort in item development and identify areas for improving the generation process.
- Provide a detailed discussion of the contributions, limitations, and ethical considerations of using generative AI to assist in clinical con-

tent development.

Before we introduce details about the current study, Section 2 presents related work in AI-assisted content development in medicine for item formats beyond MCQs.

2 Background

2.1 Related Research

A robust medical education program teaches learners to do more than select a correct answer to an MCQ. Students must also learn to reason through complex diagnostic scenarios, such as interactions with standardized patients in objective structured clinical examinations (OSCEs). While LLMs have been used productively in MCQ item writing by supporting item development workflows (Kiyak and Emekli, 2024; Artsi et al., 2024), complex performance tasks pose a greater challenge. Yet, it is *because* these tasks are typically more resource-intensive to develop than their MCQ analogs that makes them natural—although more difficult—candidates for LLM-assisted content generation (Cusimano et al., 1994; Kiyak and Emekli, 2024; Miri et al., 2024).

Recent literature has begun to examine the potential for LLMs to assist with the generation of performance task materials, especially those materials related to OSCE and standardized-patient (SP) tasks. Misra and Suresh describe how ChatGPT can support OSCE preparation—including drafting cases, SP training materials, and grading rubrics—while emphasizing that medical accuracy, security, and compliance require systematic human validation (Misra and Suresh, 2024). Zafar et al. provide practical guidance for using AI to generate high-quality OSCE stations, recommending outcome alignment, structured prompts, iterative refinement, and faculty oversight to manage hallucinations and construct-validity threats (Zafar et al., 2026). Complementing peer-reviewed studies, the AAMC has released a workflow for generating curriculum-aligned, role-locked virtual patient profiles for simulation, explicitly positioning AI generation as scalable but educator-supervised (Quiroga Velasquez, 2026). Moving from static materials to interactive performance tasks, Brugge et al. show that LLM-simulated history-taking encounters paired with AI-generated structured feedback can improve learners’ clinical decision-making indicators, suggesting that LLMs may help generate and sustain practice-ready performance-assessment experiences when

embedded in governed workflows (Brügge et al., 2024). Prior work has explored using LLMs to support communication tasks, but these models have primarily served as the delivery mechanism for the task and its feedback (Stamer et al., 2023). In contrast, the use of LLMs to generate the content for communication tasks themselves remains underexplored.

3 Method

3.1 Generation Methods

The four generation methods are outlined below: 1a, 1b, 2a, and 2b. The core distinction between the “a” and “b” versions of each method is what anchors the generation at the start. In the “a” versions, the workflow begins with a diagnosis and communication task extracted from a retired clinical MCQ from a medical licensure examination. In the “b” versions, the workflow also includes the full text of the associated MCQ. Because these seed MCQs were previously developed in conjunction with physicians, the intent is that clinically accurate scenario details and logic can be inherited by the CLA item within the workflow. Each generation method developed a set of 20 items for a total of 80 items to be reviewed by subject-matter experts (SMEs). SMEs evaluated all four versions of each item, which were presented in randomized order.

3.1.1 Methods 1a/1b

Method 1 treats item writing as a progressive, linear build, similar to drafting a single coherent case from start to finish¹. It begins by establishing key guardrails for what the item should measure (the construct), either explicitly through encounter features defined up front (1a) or implicitly through the narrative constraints embedded in a retired MCQ stem (1b). The item is then generated in sequence, with each component checked for consistency with the selected learning objectives and intended tone/affect. Quality gates are applied throughout (e.g., accuracy and internal-consistency checks followed by revision as needed), and a final pass focuses on naturalness and readability. The build proceeds in the following steps, using the information from the preceding steps to generate subsequent content: identifying appropriate LOs based on the communication task and diagnosis → generating the communication vignette (including site of care and patient age) → generating the

¹Method 1 used gpt5-2024-12-01-preview

PCBs → generating the exemplars → stereotype check, selection of remaining demographics, and final refinement. The prompts used for Method 1a are available in the Appendix A.2.

3.1.2 Methods 2a/2b

Method 2 was designed as a deliberate alternative to Method 1 and emphasizes an exploratory branching search and refinement rather than early commitment to a single narrative². Instead of progressing along one path, it begins by generating multiple candidate cases using multiple agents (using the same LLM) and then converges through structured selection and improvement, such as ranking, justification, critique from different perspectives, and targeted revision. Early in the workflow, learning objective-mapped PCBs are used as a temporary scaffold while the vignette remains flexible, and the process relies on detailed component descriptions and repeated examples to guide both generation and critique. The workflow explores alternatives by branching across aspects of the vignette background before selecting and polishing the strongest candidate, and it delays introducing details such as site of care and patient demographics to reduce the chance that surface features steer construct specification too early. Overall, Method 2 treats alignment as something achieved through convergent optimization across the vignette, PCBs, and exemplars, rather than as a one-pass enforcement of early constraints.

3.2 Subject-Matter Expert Evaluation

Ten SMEs were recruited via NBME's Assessment Alliance network³ to provide feedback on the items. The SMEs were selected based on their involvement in the teaching of communication skills to medical students, a demonstrated research history in this area, experience in developing assessments in medical education, or a combination of these factors; nine were licensed medical doctors and the other was a PhD RDN with expertise in communication and sociocultural aspects of health care.

The SMEs evaluated each item based on the following item quality dimensions: *medical accuracy*, *LO alignment*, *PCB alignment*, *Exemplar alignment*, *presence of harmful stereotypes*, and *difficulty appropriateness* (see Appendix A.3 for a full definition of each dimension). These dimensions

were chosen because they reflected the most common areas of editorial work identified by the test development team responsible for communication item development.

For each dimension, SMEs were provided with a forced-choice Likert scale response (see Appendix A.4 for exact phrasing of the item-evaluation questions). For the first four item dimensions, the response options were about the degree of changes necessary for the accuracy / alignment, with options of “No Changes”, “Minimal”, “Moderate”, “Major”. Additional guiding language provided contextual information on response options. For stereotype inclusion, SMEs simply indicated if the vignette perpetuated any harmful stereotypes (Yes/No), and for difficulty appropriateness SMEs identified if the item was too easy, too difficult, or at the appropriate level for the student given the level of medical training targeted by the item.

It is important to note that in cases where an SME would judge a vignette to be medically inaccurate to the point of being not salvageable, they were permitted to opt out of providing ratings for subsequent item dimensions. This was a deliberate feature of the evaluation design rather than an incidental source of nonresponse. The intent was to avoid collecting downstream judgments for items that would not realistically proceed in an editorial workflow. For this reason, later-dimension analyses should be interpreted conditionally, that is, as characterizing items that satisfied the medical accuracy criterion.

3.3 Research Questions

- RQ1: How well does each generation method produce content that is aligned with each of the six item quality dimensions?
- RQ2: Does anchoring an item generation workflow with an MCQ improve the medical accuracy of the generated items?
- RQ3: How many items require no changes across all item dimensions, and thus could be directly used without human refinement?

3.4 Statistical Analysis

SME ratings of AI-generated content were analyzed using cumulative link mixed models (CLMMs; Christensen, 2019), an extension of ordinal logistic regression that accommodates clustered measures designs. CLMMs are appropriate when outcomes are ordinal categories with a natural ordering but spacing between levels is not assumed

²Method 2 used gpt5-2025-01-01-preview.

³<https://www.nbme.org/research/research-collaborations/assessment-alliance>

to be consistent; that is, the difference between "None" and "Minimal" is not assumed to be the same as the difference between "Moderate" and "Major".

CLMMs model the cumulative probability of observing a response at or below each category. The model estimates threshold parameters that define boundaries between adjacent categories on a latent continuous scale, allowing the data to determine category spacing rather than imposing assumptions. CLMMs extend standard ordinal regression by incorporating random effects, which account for systematic variation due to nested observations. In our design, all 10 raters evaluated all 80 case-method combinations (a fully-crossed design), introducing dependencies that would violate independence assumptions of standard regression. The CLMM addresses this by estimating random intercepts for raters and cases, capturing individual rater tendencies (e.g., overall harshness or leniency) and case-level variation in quality.

CLMMs also partition variance into components attributable to random effects (raters and cases) and residual variance, providing insight into sources of rating variability. Variance decomposition follows standard practice for logistic mixed models (Hedeker and Gibbons, 2006); residual variance is fixed at $\pi^2/3$ and random effect variances are estimated via maximum likelihood. The proportion of variance attributable to each random effect is computed as its estimated variance divided by the total (rater variance + case variance + $\pi^2/3$). The proportion of variance attributable to raters reflects consistency in how raters applied evaluation criteria: lower rater variance indicates that raters evaluated content similarly, while higher rater variance suggests systematic differences in stringency or leniency across raters. The proportion attributable to cases reflects genuine variability in content quality across the 20 diagnosis-communication task pairs common to all generation methods. Together, these variance components offer a complementary perspective on rating consistency alongside the fixed effects of primary interest.

Model coefficients are expressed as log-odds, with exponentiated values interpretable as odds ratios. An odds ratio greater than 1 indicates higher odds of receiving a more severe rating relative to the reference method; values less than 1 indicate lower odds. The proportional odds assumption, required for CLMMs, states that predictor effects (generation methods) are consistent across category

thresholds; this assumption was evaluated using likelihood ratio tests. Models were fit using the ordinal package in R with Laplace approximation for random effects integration (Christensen, 2019).

The cumulative link mixed model (Christensen, 2018) is specified as:

$$\text{logit}[P(Y_{ijk} \leq c)] = \theta_c - (\beta_k + u_i + v_j) \quad (1)$$

where Y_{ijk} is the ordinal rating from rater i for case j under generation method k ; θ_c are threshold parameters separating adjacent response categories, constrained such that $\theta_1 < \theta_2 < \dots < \theta_{C-1}$; β_k is the fixed effect for method k (with one method serving as reference); and $u_i \sim N(0, \sigma_{\text{rater}}^2)$ and $v_j \sim N(0, \sigma_{\text{case}}^2)$ are crossed random intercepts for raters and cases, respectively.

4 Results

4.1 Medical Accuracy

Table 1: Medical Accuracy

Method	OR (95% CI)	p
Method 1b	1.28 (0.80, 2.04)	0.29
Method 2a	2.18 (1.39, 3.42)	< 0.001
Method 2b	2.98 (1.90, 4.67)	< 0.001

We fit a cumulative link mixed model estimating the generation method as a fixed effect and random intercepts for raters and cases. Method 1a served as the reference for all analyses. Table 1 shows that items generated by Methods 2a and 2b were significantly more likely to receive ratings indicating they required additional changes for medical accuracy. Method 1b did not significantly differ from Method 1a. The proportional odds assumption was supported ($\chi^2(6) = 5.99, p = .42$). Descriptive statistics for expert ratings for each generation method across all item dimensions are reported in Appendix A.5.

About one-third of the variance in ratings (33.1%) was due to systematic differences between raters, indicating notable variability in rater stringency. Case-level differences accounted for only 8.3% of variance, suggesting that content quality was relatively consistent across cases. The majority of variance (58.6%) was residual, reflecting rating-level variability not captured by rater or case effects.

4.1.1 Effect of Using Full MCQs on Medical Accuracy

Table 2: Effect of MCQ on Medical Accuracy

IV	OR (95% CI)	p
Method 2	2.18 (1.39, 3.42)	< 0.001
"b" Methods	1.28 (0.81, 2.04)	0.29
Interaction	1.07 (0.57, 1.98)	0.84

To isolate the effect of incorporating MCQs into the generation workflow (RQ2), a separate CLMM was estimated with generation approach (Method 1 vs. Method 2), starting point (diagnosis and communication task only—the "a" methods—vs. full MCQ item content—the "b" methods), and their interaction included as fixed effects. Method 1 and the "a" generation methods were the reference groups. For the main effect of method, Method 2 produced content requiring significantly more revision than Method 1 (Table 2). The main effect for the inclusion of the full MCQ item content did not significantly affect medical accuracy ratings, and no interaction was observed, indicating that the advantage of Method 1 over Method 2 for medical accuracy was consistent regardless of generation workflow starting point. Variance decomposition indicated that rater tendencies (33.1%) exceeded case differences (8.3%), with 58.6% residual variance. The proportional odds assumption was supported for both generation method ($\chi^2(1) = 0.06, p = .80$) and starting point ($\chi^2(1) = 0.07, p = .80$).

4.2 Learning Objective Alignment

Table 3: Learning Objective Alignment

Method	OR (95% CI)	p
Method 1b	1.14 (0.45, 2.84)	0.78
Method 2a	14.25 (6.51, 31.18)	< 0.001
Method 2b	4.73 (2.12, 10.57)	< 0.001

For learning objective alignment (Table 3), generation Methods 2a and 2b showed significantly poorer alignment than Method 1a. Method 1b did not differ significantly from Method 1a. Variance decomposition indicated that rater tendencies (22.9%) and case differences (23.5%) contributed approximately equally to random variance, with 53.6% residual variance. The proportional odds assumption was supported ($\chi^2(6) = 8.01, p = .23$).

4.3 Patient-Centered Behavior Alignment

Table 4: Patient-Centered Behavior Alignment

Method	OR (95% CI)	p
Method 1b	0.56 (0.30, 1.04)	0.07
Method 2a	5.57 (3.29, 9.41)	< 0.001
Method 2b	3.56 (2.09, 6.06)	< 0.001

Here, the proportional odds assumption showed evidence of violation ($\chi^2(3) = 9.43, p = .02$). Given the modest departure and to maintain consistency with analyses of other outcomes, we retained the proportional odds model; however, results should be interpreted with appropriate caution.

For PCB alignment, Table 4 shows that content from Method 2a and Method 2b received significantly worse ratings than Method 1a content. Method 1b showed a trend toward better performance than Method 1a, though this was not statistically significant. Variance decomposition indicated that case differences (16.5%) exceeded rater tendencies (8.5%), with 75% residual variance, suggesting that raters applied criteria consistently while cases varied meaningfully in quality. As a reminder, the proportional odds assumption was violated and readers are cautioned against over interpreting these findings.

4.4 Exemplar Alignment

Table 5: Exemplar Alignment

Method	OR (95% CI)	p
Method 1b	1.36 (0.90, 2.07)	0.14
Method 2a	0.81 (0.51, 1.25)	0.34
Method 2b	0.74 (0.47, 1.18)	0.21

For exemplar alignment, no significant differences were observed between development methods (all $p \geq .14$). Variance decomposition revealed that case differences accounted for only 0.9% of variance, suggesting that content was uniformly aligned with exemplars regardless of case or method. Rater tendencies contributed 16.3% of variance, with residual variance comprising 82.8%. The proportional odds assumption was again supported ($\chi^2(6) = 9.38, p = .15$).

4.5 No Stereotypes

Stereotype inclusion was rare, flagged in only 13 of 723 ratings (1.80%) across all methods. Due to this low base rate, formal inferential comparisons were not conducted. Descriptively, rates were similarly low across methods (Method 1a: 2.7%;

Method 1b: 2.7%; Method 2a: 1.1%; Method 2b: 0.6%). Although stereotype flags were too rare to permit formal comparisons across methods, the potential consequences of stereotype inclusion are serious, underscoring the importance of maintaining vigilance throughout both item generation and subsequent human review.

Notably, the study design may have contributed to some stereotype flags. Because experts evaluated four versions of each case with potentially similar demographic characteristic combinations (race, gender, diagnosis), this may have prompted some raters to perceive stereotyping that reflected accumulated pattern recognition rather than content within any single version.

4.6 Appropriate Difficulty

Table 6: Appropriate Difficulty

Gen Method	OR (95% CI)	<i>p</i>
Method 1b	0.86 (0.48, 1.54)	0.62
Method 2a	0.66 (0.37, 1.16)	0.14
Method 2b	0.52 (0.29, 0.92)	0.02

Response options for difficulty were "too easy," "appropriate," and "too difficult," providing granular insight into the generation process. However, our primary interest was whether each method produced items at an appropriate difficulty level. We therefore collapsed responses into a binary outcome: appropriate versus off-level (combining "too easy" and "too difficult"). Across all generation methods, the majority of items were judged to be at an appropriate difficulty level (80.8%). When items were off-level, they were more commonly rated as too difficult (17.5%) than too easy (1.7%).

A generalized linear mixed model with binomial family was fit with random intercepts for raters and cases (Table 6). Method 2b produced content significantly less likely to be rated at the appropriate difficulty level compared to Method 1a; Method 1b and Method 2a did not differ significantly from Method 1a. Variance decomposition indicated that rater tendencies (16.1%) exceeded case differences (8.3%), with 75.6% residual variance. Model assumptions were evaluated and met: no overdispersion (ratio = 0.83), random effects showed no significant departures from normality, and residual distributions were acceptable.

4.7 Full Item Evaluation

Table 7: All Alignment

Gen Method	OR (95% CI)	<i>p</i>
Method 1b	0.63 (0.40, 1.01)	0.06
Method 2a	0.40 (0.25, 0.66)	<0.001
Method 2b	0.38 (0.23, 0.52)	<0.001

To evaluate the total item quality (RQ3), a composite variable was created for each item / rater combination that indicated if a particular rater felt that item needed no corrections across all 6 dimensions (medically accurate; LO, PCB, and exemplar all aligned; no stereotype; appropriate difficulty). Of the 800 item/generation method/rater combinations, only 222 (27.8%) met this criterion. A generalized linear mixed model with binomial family (outcome was binary: all aligned vs. not) was fit with random intercepts for raters and cases. Table 7 indicates that Method 2a and Method 2b had significantly lower odds of meeting all criteria compared with Method 1a. Method 1b also demonstrated a lower success rate; however, this difference was not statistically significant. Variance decomposition indicated that rater tendencies (27.9%) exceeded case differences (4.7%), with 67.4% residual variance. Model assumptions were again evaluated and met: no overdispersion (ratio = 0.94), random effects showed no significant departures from normality, and residual distributions were acceptable.

This analysis does not capture the extent of rater agreement that all item dimensions were aligned within a given item–generation method pair. To assess this directly, we summed the number of the 10 SMEs who agreed that a given item required no changes for each of the 80 item–method combinations. Table 8 shows the distribution of rater agreement across the 80 item–method combinations. For example, 11 item–method combinations received no full alignment ratings from any rater, while only 1 combination was rated as fully aligned by 7 raters—the maximum observed; no more than 7 raters agreed that an item–method combination required no edits. An average of 2.78 raters agreed all criteria were met for any item–method combination. Figure 2 in the Appendix shows the count of raters indicating full alignment by case and generation method.

Table 8: Distribution of Items by Number of Raters Indicating Full Alignment

Raters in Full Alignment	Count	Percent (%)
0	11	13.75
1	15	18.75
2	13	16.25
3	10	12.5
4	12	15
5	12	15
6	6	7.5
7	1	1.25
8	0	0
9	0	0
10	0	0

5 Discussion

This study examined the viability of fully automated generative AI workflows for producing clinical communication items suitable for formative assessment in medical education. Across three research questions, the findings provide converging evidence that generation method matters substantially for item quality, that anchoring generation in vetted multiple-choice questions does not meaningfully improve medical accuracy, and that only a modest proportion of generated items are currently suitable for direct use without human refinement, suggesting human review will remain an important aspect of AI-assisted content generation in the medical communication domain.

The results for RQ1 show consistent differences between generation methods in their ability to produce content aligned with the six item quality dimensions. Constrained linear methods (Method 1a and 1b) outperformed exploratory branching methods (Method 2a and 2b) across several core dimensions, most notably medical accuracy, learning objective alignment, and patient-centered behavior alignment. These dimensions are foundational to the validity of clinical communication assessments, as they ensure that scenarios are both medically plausible and capable of eliciting the intended communication behaviors.

In contrast, exemplar alignment showed no significant differences across methods. This finding suggests that once a successful vignette has been generated, LLMs are generally capable of producing exemplar responses that require very little revision, if any.

Stereotype flags were uncommon across all workflows. Item difficulty targeting was generally insensitive to generation method; however, Method 2b items were more likely to be judged as

falling outside the intended difficulty range, most often being too difficult.

Collectively, these results suggest that while certain classes of failure were less likely to arise, medical accuracy and alignment among items' component parts remain highly sensitive to the structure of the generation workflow.

RQ2 addressed whether anchoring generative workflows in vetted multiple-choice questions improves the medical accuracy of the generated clinical communication items. Contrary to expectations, no evidence was found that incorporating full MCQs as starting points improved medical accuracy. This null effect held across both linear and branching generation methods, and no interaction between anchoring and method was observed.

These findings suggest that the presumed benefits of grounding generation in validated assessment content may not readily transfer from selected-response contexts to more open-ended performance tasks. Although MCQs encode medically correct information, their structure and purpose differ substantially from those of clinical communication items. Expanding an MCQ into a fully developed communication item requires substantial inference and contextual detail that the MCQ format does not provide or constrain. As a result, anchoring on MCQs may offer less practical value than anticipated for supporting accuracy in complex generative tasks.

The third research question (RQ3) focused on the practical yield of the generation workflows: how many items met *all* quality criteria without requiring human revision. Across methods, only a small minority of items satisfied this stringent standard, and items produced by branching generation workflows were significantly less likely to do so than those produced by linear workflows. Importantly, the number of raters agreeing that an item-method combination required no changes varied widely and there were no items for which all raters (or even 8/10 raters) agreed that all elements were aligned. These results point to the persistent limitations of fully automated generation for high-stakes or high-fidelity assessment content in medicine, while also revealing meaningful efficiency differences across workflows.

Importantly, the composite outcome integrates judgments across all six quality dimensions, reflecting the holistic standard that assessment developers must meet in practice. That some items—particularly from constrained linear work-

flows—were judged acceptable without revision indicates that AI-assisted generation can reduce human development effort, even if it does not eliminate the need for expert review.

Overall, these findings suggest that generative AI can play a productive but circumscribed role in the development of clinical communication assessment content. Workflow design emerges as a central determinant of quality, with simpler, more structured generation approaches outperforming more complex branching strategies. The results further caution against assuming that validated content from one assessment format can be straightforwardly repurposed to support generation in another.

From a broader perspective, this study illustrates the importance of evaluating AI-generated assessment content not only for surface-level plausibility but also for deep alignment among medical context, learning objectives, and elicited behaviors, when developing complex performance tasks. As generative models continue to improve, careful attention to workflow structure and evaluation criteria will remain essential for ensuring that efficiency gains do not come at the expense of validity.

6 Limitations and Ethical Considerations

Several limitations deserve comment. First, the evaluation relied on SME judgment across six dimensions of item quality. Although SMEs completed an orientation session and practice review before formal rating began, a single training session may not have been sufficient to ensure shared interpretations of all rubric categories. The nontrivial rater-level variability observed in several analyses may, in some cases, reflect construct-relevant differences in professional judgment among SMEs; it may also reflect differences in rating severity or rubric interpretation. Interestingly, the medical accuracy dimension showed the most variance across raters, although this dimension is arguably the most objective of all dimensions. Future work would benefit from additional training and rater calibration before the formal review task begins, both to refine rubric wording and to ensure a stronger shared understanding of the evaluation criteria.

Relatedly, we report variance decomposition rather than relying exclusively on traditional interrater agreement statistics because our data structure made single-summary agreement coefficients poorly aligned with our inferential goals. The combination of multi-point ordinal scales, a large rater

panel, and ratings concentrated in modal categories created conditions under which chance-corrected agreement statistics can be difficult to interpret. Kappa-family statistics, including Fleiss's kappa, are sensitive to prevalence and marginal distributions and can yield low estimates even when observed agreement is high (Feinstein and Cicchetti, 1990). Krippendorff's alpha is more flexible with respect to number of raters and scale type, but it also summarizes reliability as observed disagreement relative to expected disagreement derived from the overall distribution of ratings, which can be difficult to interpret when rating distributions are highly restricted or skewed (Hayes and Krippendorff, 2007). Gwet's AC2 is less sensitive to prevalence effects than kappa-based statistics (Gwet, 2002), but none of these coefficients separate systematic rater severity differences from residual disagreement about item quality. Variance decomposition better matched our goals because it partitioned variation into method, item, rater, and residual components, allowing us to evaluate method differences while explicitly modeling rater variability. This approach allowed us to examine whether raters exhibited consistent relative patterns across methods despite differences in absolute rating standards. Future work could develop or evaluate agreement indices better suited to ordinal, multi-rater designs with skewed response distributions and systematic rater severity effects.

Second, the review process followed a planned conditional evaluation design. SMEs were permitted to stop rating later dimensions when an item was judged medically inaccurate to the point of being unsalvageable, on the rationale that downstream judgments are of limited practical value for content unlikely to advance in an editorial workflow. This approach increases the practical relevance of the evaluation by aligning it with how content would be screened in operational development, but it also changes the scope of inference for later outcomes. Certain constructs—such as vignette alignment—are not meaningfully defined for medically unsalvageable cases, as alignment is a property of viable cases only. Accordingly, later evaluations are best interpreted not as judgments conditional on medical accuracy, but rather as judgments about medically accurate items.

Third, despite clear workflow differences across several outcomes, each method produced only a modest number of items that required no revisions. Therefore, the absence of a measurable benefit from

anchoring generation in retired MCQs should be interpreted as a lack of evidence for improvement under the present design rather than as definitive evidence that anchoring cannot be useful. The usefulness of anchoring likely depends in part on the source items selected: some MCQs may provide a richer substrate for communication-focused vignette generation than others, depending on the amount of clinically relevant context available and the extent to which that content helps the LLM perform the generation task. Future research could consider broader and more systematic sampling of MCQ items. Likewise, statistically significant differences across workflows should not be taken to imply that the absolute quality of generated items was high or that the observed advantages would necessarily translate into large practical gains in operational item development.

Fourth, the present comparison is bounded by the specific model and implementation used in the study. All items were generated using a single LLM (GPT5) and a fixed set of workflow designs. The findings should therefore not be generalized to all models, prompting strategies, or medical education contexts. The observed advantage of the constrained linear workflow over the exploratory branching workflow may reflect a broader principle—that more tightly constrained generation is beneficial when item components must remain strongly aligned—but it may also depend on particulars of the prompts, revision logic, and model behavior used here. More generally, differences across methods may reflect implementation details as much as any intrinsic advantage of one workflow family over another. Replication across models and alternative implementations of the same workflow concepts will be necessary to determine which conclusions are robust and which are due to specific characteristics of a given implementation. For this, it may be beneficial to include factors beyond content quality that nevertheless have practical importance such as the relative costs and run times across methods. In addition, the study relied on private LLM deployments that did not log data or use prompts for model training. Such secure deployment options may not be available in all settings, which could limit the feasibility of similar workflows when safeguarding assessment content is essential.

These limitations also point to several ethical considerations. Most importantly, the fluency of generated clinical content should not be mistaken

for evidence that the content is adequate for a particular assessment purpose. Validity evidence remains necessary to support the intended interpretations and uses of any assessment. Fairness considerations are likewise central. Although stereotype flags were too rare to support formal comparisons across methods, even infrequent instances can be consequential, particularly in educational materials involving patient demographics, diagnoses, and communication challenges. Ethical oversight should therefore extend beyond item-level review to consideration of aggregate patterns in representation across generated content pools. As a whole, these considerations suggest that the most defensible near-term role for generative AI in this context is to support early drafting while preserving expert review, fairness screening, and institutional control over source materials and final content decisions.

A Appendix

A.1 Generated CLA Example Item

Field	Generated Content
Gender	cisgender woman assigned female sex at birth
Race	WHITE White or Caucasian
Affect	fear (fear, anxiety, insecurity, inferiority, panic)
SiteOfCare	Emergency: Urgent treatment center
Diagnosis	asthma
Ctask	Benefits and risks of a medication
Vignette	Megan Porter, a 35-year-old woman, comes to the urgent treatment center with a 1-week history of chest tightness and nighttime dry cough. Over the past 3 months, she had two emergency visits for acute shortness of breath treated with bronchodilators. She reports frequent upper respiratory infections, takes no medications, and has a 10-year one-pack-per-day smoking history. After confirming normal vital signs, a clear chest x-ray, and bilateral end-expiratory wheezes, you explain that the findings are consistent with asthma, advise smoking cessation, and recommend a daily controller inhaler to reduce airway inflammation, outlining expected benefits and potential side effects. She fidgets, appearing anxious, and asks,
Prompt	"I'm nervous about starting this inhaler. I smoke; how will the inhaler help breathing at night and how can you help me avoid side effects?"
CaseExemplar1	I hear this makes you anxious. A daily controller inhaler, a preventer medicine, reduces swelling in your airways. It helps calm nighttime cough and tightness. It also lowers your risk of flare-ups, meaning asthma attacks. It can still improve your breathing at night even if you smoke. To keep side effects low, we will check your inhaler technique. You will use a spacer, a tube that helps more medicine reach your lungs, and rinse your mouth after each dose. We will start with the lowest dose that keeps you well, and follow up to adjust. It is okay to feel nervous. Your reaction makes sense, and we can manage this safely together so you feel comfortable starting. What worries you most about starting the inhaler?
CaseExemplar2	Thanks for telling me that. Starting a new inhaler can feel unsettling. A daily controller inhaler calms airway swelling, so it should ease your nighttime chest tightness and dry cough, and lower your risk of flare-ups. Even if you smoke, it should still help your breathing. We can keep side effects low by going over your technique together, using a spacer (a small attachable tube), rinsing your mouth after each use, starting at the lowest dose that works, and checking in to adjust based on how you feel. We can take it step by step. What worries you most about starting this inhaler?
LO1	Solicit the patient's perspective

Field	Generated Content
PCB1	Ask what worries her most about starting the inhaler.
LO2	Accurately explain the nature of the problem and/or its management
PCB2	Explain that daily controller medicine reduces airway swelling, nighttime symptoms, and flare-ups.
LO3	Address patient emotion
PCB3	Provide empathic reassurance that her fear is understandable and manageable.
SME comments about medical accuracy	"Might be nice to confirm her vitals as stable. It's unclear how sick she is."
SME comments about learning objective alignment	"The vignette and prompt alludes to addressing how to minimize side effects. This is not clearly addressed in LO/PCB. I actually think this aspect of the case may be too complex anyway so would modify the prompt and exemplar from asking this for this level of learner." "It would be more appropriate for a student to practice smoking cessation counseling in this scenario than teach about inhaler use, which is beyond their scope of knowledge."
SME comments about pcb alignment	None.
SME comments about exemplar alignment	"Might be a bit much to expect a student at this level to know how to minimize side effects." "Ex 2 better than Ex 1, especially with the mention of being anxious which feels a touch judgmental." "Exemplar 2 could provide more direct empathic reassurance to the patient."
SME comments about appropriate difficulty	"Not sure— I think knowing how to minimize side effects could be too advanced." "Would not expect the student to know how to counsel on inhaler use, but other than that it's fine." "I think this one finally gets it all correct!"

Note. LO = Learning Objective; PCB = Patient-Centered Behavior; SME = Subject Matter Expert.

A.2 Prompts for Workflow 1a

Initial Prompt: You are an expert clinical communication content designer. You are building content for a communication tool that provides medical professionals the opportunity to practice their communication skills. The content build is occurring in a step-by-step process, and this is just one step in the process. Do not generate any other case content beyond what is requested here. Do not modify, expand, or infer additional conditions, as those will be taken care of in subsequent steps.

I will provide you with a patient diagnosis and a communication task. The communication task is the purpose of the physician-patient communication (e.g., explaining the purpose of a vaccination, information about a low-risk procedure or medication, speak with the patient about a common or easily treatable diagnosis).

In this step you will review the diagnosis and communication task, and your task is to review this information and generate 3 fields: - AGE : The plausible age range of a patient with this particular diagnosis that is appropriate for the communication task, drawn from a lower bound of 18 years old and upper bound of 90 years old. The age range you should return should reflect the most common ages where this diagnosis and communication task might occur. - GENDER : The possible sex of the patient, either MAN, WOMAN, or EITHER. For this exercise we can assume the patient is cisgendered. - Site of Care : The possible locations where this communication task is taking place. Choose only those locations that are most common given the diagnosis and the communication task. The possible options are [Specific Case Guidelines]. Choose all sites of care that are applicable.

The structure of your output should be as follows: DIAGNOSIS: the exact diagnosis provided CTASK: the communication task as provided AGE: The plausible age range of the patient GENDER: The plausible gender(s) for the patient SOC: The plausible site(s) of care where the communication may be taking place Here are the inputs you need: DIAGNOSIS: {diag} CTASK: {comtask}

LO prompt (Step 2): "You are an expert clinical communication content designer. You are building content for a communication tool that provides medical professionals the opportunity to practice their communication skills. The content build is occurring in a step-by-step process, and this is just

one step in the process. Do not generate any other case content beyond what is requested here. Do not modify, expand, or infer additional conditions, as those will be taken care of in subsequent steps. I will provide you with a patient diagnosis and a communication task. The communication task is the purpose of the physician-patient communication (e.g., explaining the purpose of a vaccination, information about a low-risk procedure or medication, speak with the patient about a common or easily treatable diagnosis). I will also provide you with: a plausible age range (AGE) for the patient; the plausible gender for the patient (GENDER); and the plausible site(s) of care where the communication task is taking place (SOC). Here is that base case information: {step1output}

You have 2 tasks: *TASK 1* Identify the learning objectives that would most naturally occur in the communication scenario given the diagnosis and plausible age, gender, and site of care. You are to select 2-5 learning objectives from the following list. The list is in the following format:[Specific Case Guidelines] REQUIREMENTS: *It is important that I am able to distinctly measure each learning objective. However, some of the learning objectives are similar to one another, and, if included for the same communication practice item, it will be difficult to distinguish between what behaviors are exemplifying the different learning objectives. *Similar to the previous requirement, ensure that the learning objectives are not all from the same learning objective CATEGORY. There will be situations when multiple learning objectives from the same category are appropriate, given they can be distinctly measured by different observable behaviors by the physician. After choosing the learning objectives from the following list, review them to ensure that they meet these criteria. Learning objectives: {thelos}

TASK 2 Identify the most appropriate patient affects that the patient might plausibly be exhibiting given the working diagnosis and the communication task. REQUIREMENT: *If the communication task is not about addressing the patient's emotion, only pick possible affects that are more subtle or neutral. The patient should not have a strong affect if the diagnosis and communication task do not indicate it.* Here are the possible patient emotions: {pt_emo}

OUTPUT STRUCTURE The structure of your output should be as follows: DIAGNOSIS: the

exact diagnosis provided CTASK: the communication task as provided AGE: the age range of the patient GENDER: the plausible genders of the patient SOC: the plausible site(s) of care of the patient LOS: the 2-4 identified learning objectives (* new information to be amended to the base case information) AFFECT: the possible affect(s) of the patient, given the other case information (* new information to be amended to the base case information)

Generate that output.

Base Case Details Generation (Step 3): You are an expert clinical communication content designer. You are building content for a communication tool that provides medical professionals the opportunity to practice their communication skills. The content build is occurring in a step-by-step process, and this is just one step in the process. Do not generate any other case content beyond what is requested here. Do not modify, expand, or infer additional conditions, as those will be taken care of in subsequent steps. I will provide you with a patient diagnosis and a communication task. The communication task is the purpose of the physician-patient communication (e.g., explaining the purpose of a vaccination, information about a low-risk procedure or medication, speak with the patient about a common or easily treatable diagnosis).

INPUTS I will provide you with: **DIAGNOSIS** : the patient's diagnosis; **CTASK** : the communication task; **AGE** : a plausible age range for the patient; **GENDER** : the plausible gender(s) for the patient; **SOC** : the plausible site(s) of care where the communication task can plausibly take place; **LOS** : the learning objectives that have been identified for the communication scenario; **AFFECT** : the plausible affect(s) for the communication scenario. Here is that base case information: {step2output} Here are additional descriptions of the selected learning objectives: {focallos}

YOUR TASK Your task is to generate the main 'case bundle'. This consists of 4 components. I will describe each of the components in more detail, and then provide examples of case bundles developed by subject matter experts. The components that you generate should adhere to the descriptions below and follow the same general structure (form, content) as the examples.

CASE BUNDLE COMPONENT DESCRIPTIONS

VIGNETTE: [Specific Case Guidelines]
BACKGROUND: [Specific Case Guidelines]
ENCOUNTER POINT: [Specific Case Guidelines]

PROMPT: [Specific Case Guidelines]
***IMPORTANT DETAILS:** [Specific Case Guidelines]

Length and style targets: [Specific Case Guidelines]

Flow and coherence checks: [Specific Case Guidelines]

*Before finalizing each case, review the output for the following details: [Specific Case Guidelines]

EXAMPLES Here are some example case bundles that have been developed. Use these to help guide the content and structure of the case bundle components: {examples}

OUTPUT STRUCTURE The output should be the 4 case components as follows: **VIGNETTE:** the generated vignette **BACKGROUND:** the generated background **ENCOUNTER_POINT:** the generated encounter point **PROMPT:** the generated prompt

Do not include any additional case details except for the 4 case bundle components. Generate that output.

Patient-Centered Behaviors (Step 4): You are an expert clinical communication content designer. You are building content for a tool that helps medical professionals practice communication skills.

Task: (1) Identify Patient-Centered Behaviors (PCBs) for the provided case. PCBs are discrete, case-specific, observable clinician behaviors that demonstrate how each Learning Objective (LO) would be satisfied. (2) Usually provide one PCB per Learning Objective identified for the case; add multiple ONLY if distinct aspects of the same LO must be addressed.

Constraints: - Only produce PCBs; do not generate any other case content. - Do not modify, expand, or infer additional conditions beyond the inputs. - Keep each PCB to the main idea; avoid parenthetical details, rationales, or sub-examples. - Do not include PCBs for Learning Objectives that are not present in the [CASE_BUNDLE].

EXAMPLES: [Specific Case Guidelines]

Inputs: Core case components [CASE_BUNDLE] containing: **VIGNETTE**, **BACKGROUND**, **ENCOUNTER POINT**, **PROMPT**.

Descriptions of the inputs are as follows: **VIGNETTE**: A brief clinical overview that introduces the primary communication issue and orients the physician to the scenario. **BACKGROUND**: Clinical and contextual information leading up to the conversation so the communication moment is understandable and plausible. **ENCOUNTER POINT**: The moment in the physician-patient interaction that places the clinician at a precise conversational moment that naturally triggers the patient's response. **PROMPT**: The patient's authentic, direct quote that launches the communication challenge and creates opportunity to practice the specified learning objectives (LOS). **LEARNING OBJECTIVES**: The learning objectives that the physician should demonstrate during the case. The format of the learning objectives are: [Specific Case Guidelines] - Example cases with completed PCBs [PCB_EXAMPLES] to illustrate how PCBs map to LOs in context. - ****IMPORTANT**: When reviewing these examples, pay close attention to how the **PATIENT CENTERED BEHAVIORS** are examples of the **LEARNING OBJECTIVES** within the context of the other core case content.

Output format: Return an array that lists the PCBs sequentially and pairs each with its LO name: PCB1: [LO_NAME] - PCB text PCB2: [LO_NAME] - PCB text ...continue until all LOs are covered. ****IMPORTANT****: the [LO_NAME] should be in the **EXACT** same format as provided in the [CASE_BUNDLE].

Do not include any additional case information. Here are case details to guide your task: [CASE_BUNDLE] : {casebundle} [LEARNING OBJECTIVES] : {focallos} [PCB_EXAMPLES] : {pcbexamples}”

Exemplar 1 Generation Prompt (Step 5):

Role: You are an expert clinical communication content designer. Your goal is to improve physician–patient communication for physicians by crafting an exemplar physician response that integrates the provided patient-centered behaviors (PCBs) and demonstrates the specified learning objectives (LOs).

Encounter Information: - Diagnosis: {ptdx} - Communication Purpose: {ctask} - Case Bundle (Vignette, Background, Encounter Point, Prompt): {casebundle} - Learning Objectives: {focallos} - Patient-Centered Behaviors (PCBs): {pcbs}

Definitions: - Vignette: A brief clinical overview

introducing the primary communication issue and orienting the physician to the scenario. - **Background**: Clinical and contextual information leading up to the conversation. - **Encounter Point**: The precise conversational moment that triggers the patient's response. - **Prompt**: The patient's direct quote that launches the communication challenge and opportunity to practice the LOs. - **Learning Objectives**: [Specific Case Guidelines]

Your Task: - Write a single, natural-sounding physician reply that immediately follows the patient's Prompt in the Case Bundle. - The reply must exemplify optimal patient-centered communication for physicians to emulate and incorporate every PCB.

Content Requirements: [Specific Case Guidelines]

Technical Requirements: [Specific Case Guidelines]

Communication Style: [Specific Case Guidelines]

Reference Examples; use these to guide the length, content, and structure of the exemplar response: {exemplarexamples}

Quality Checkpoints (self-check before finalizing): 1. Directly addresses the patient's Prompt and immediate concern. 2. Integrates every PCB seamlessly (no labels, no meta-commentary). 3. Matches tone to the patient's emotional state. 4. Stays within 50–100 words in one paragraph. 5. Sounds authentic—what a skilled physician would actually say.

Output Format: - Provide **ONLY** the exemplar response in this format: [EXEMPLAR]: Your generated physician response here

Generate the exemplar response now.

Exemplar 2 Generation Prompt (Step 6):

Role: You are an expert clinical communication content designer. Your goal is to improve physician–patient communication for physicians by crafting an exemplar physician response that integrates the provided patient-centered behaviors (PCBs) and demonstrates the specified learning objectives (LOs). Some exemplars for this clinical case have already been developed, and an additional exemplar is needed to provide an example of another way that the physician could include the PCBs while demonstrating the LOs for the specific communication task. The additional exemplar should incorporate the same PCBs, but should be

structurally different than previously generated exemplars - the new exemplar should use different wording and sentence construction.

(rest of prompt copied from Step 5)

Patient Ethnicity Selection (Step 7): You are an expert clinical communication content designer. Given the case below, select all patient race codes that could appropriately be represented for this scenario. Do not choose only the most common association; include any race code that is plausible and does not risk reinforcing stereotypes. Only exclude a race code if there is a clear, compelling clinical or contextual reason making it implausible, or if using it in this context would likely reinforce common racial stereotypes.

Inputs: - Diagnosis: {ptdx} - Communication Purpose: {ctask} - Case Bundle (Vignette, Background, Encounter Point, Patient Prompt): {case-bundle}

Key definitions: - Vignette: Brief clinical overview introducing the primary communication issue and orienting the clinician to the scenario. - Background: Clinical and contextual information that makes the communication moment understandable and plausible. - Encounter Point: The precise moment in the interaction that naturally triggers the patient's response. - Patient Prompt: The patient's direct quote that launches the communication challenge and enables practice of the specified learning objectives.

Decision rules: - Clinically plausible means the race code does not contradict the diagnosis or case details; do not use epidemiologic prevalence alone as a reason to exclude. - Avoid reinforcing stereotypes; if a race association is commonly stereotyped in the context of this diagnosis or scenario, exclude that code. - If the case does not provide a compelling exclusion reason, include the race code. - If the case explicitly specifies the patient's race, include only that specified code.

Valid race codes: [Specific Case Guidelines]

Output: - Return only the selected race codes, each wrapped in parentheses, in all caps, separated by a single space. - Do not include any explanations or additional text. - If no compelling exclusions are found, include all race codes.

A.3 Item Quality Dimensions

Items were evaluated with respect to six different dimensions:

- **Medical Accuracy** It was important that the generated item present accurate and plausible medical scenarios for the learners to practice patient-centered behaviors.
- **Learning Objective Alignment** The extent to which the vignette background naturally elicits, depends upon, or provides sufficient context for what the learning objectives are intended to measure.
- **Patient-Centered Behavior Alignment** The degree to which the generated PCBs accurately operationalize the learning objectives within the context of the specific clinical vignette.
- **Exemplar Alignment** The degree to which the exemplar responses accurately and naturally instantiate the PCBs (and, by extension, the LOs) in the vignette context. Here "naturally" means in a manner consistent with how an experienced physician would communicate with a patient (appropriate tone, sequencing, level of detail, etc.).
- **No Stereotypes** The generated item does not include or suggest harmful stereotypes pertaining to medical conditions, demographic characteristics (e.g., race, gender, age), or the association between specific groups and particular illnesses or behaviors.
- **Appropriate Difficulty** The item presents a clinical communication scenario that is suitable for a pre-clerkship medical student, requiring only the level of medical knowledge, reasoning, and communication skills typically expected for learners at this level of training.

A.4 Evaluation Questions for Subject Matter Experts

1. What level of change is needed to make this vignette medically accurate?
 - a. No change (factually correct)
 - b. Minimal (modification of one element (e.g., medical condition incorrectly described/ diagnostic test incorrect)
 - c. Moderate (multiple elements within the vignette need to be revised for medical accuracy)
 - d. Major-Not salvageable (changes would cascade throughout the vignette and exemplars)
2. What level of changes are needed for the learning objectives (LO) to align with the vignette?
 - a. N/A- vignette was not salvageable
 - b. No change (leave as is)
 - c. Minimal (LO not aligned with the case.)
 - d. Moderate (2 LOs not aligned with the case.)
 - e. Major (more than 2 LOs not aligned with the case)
3. Do patient-centered behaviors (PCBs) map to Learning Objectives?
 - a. N/A- vignette was not salvageable
 - b. Yes – no change
 - c. No- PCB requires minor revision(s)
 - d. No- Do not use PCB
4. Do the exemplars align with the PCBs? If not, what level of change is needed for better alignment?
 - a. N/A- vignette was not salvageable
 - b. No change
 - c. Minimal (change to one aspect of the exemplar)
 - d. Moderate (Multiple elements of the exemplar need to be revised)
 - e. Major-Not salvageable (several elements of the exemplars would need to be revised)
5. Does this vignette perpetuate any harmful stereotypes?
 - a. N/A- vignette was not salvageable
 - b. Yes (explain in comments)
6. Is this vignette (background, exemplars, and PCBs) at the appropriate level of difficulty for a learner ready to start clerkships?
 - a. N/A- vignette was not salvageable
 - b. Too easy for student
 - c. Appropriate for a student ready to start clerkships
 - d. Above the level of the student

c. No

A.5 Descriptive Statistics by Generation

Method by All Item Dimensions

Category	Method 1a	Method 1b	Method 2a	Method 2b	Total
Medical Accuracy					
None	146 (73.0%)	134 (67.0%)	114 (57.0%)	105 (52.5%)	499 (62.4%)
Minimal	28 (14.0%)	44 (22.0%)	53 (26.5%)	46 (23.0%)	171 (21.4%)
Moderate	9 (4.5%)	9 (4.5%)	13 (6.5%)	19 (9.5%)	50 (6.2%)

No	178 (97.3%)	180 (97.3%)	178 (98.9%)	167 (99.4%)	703 (98.2%)
Yes	5 (2.7%)	5 (2.7%)	2 (1.1%)	1 (0.6%)	13 (1.8%)

A.6 Full Rater Alignment Agreement by Item and Method

Figure 2: Number of raters indicating that the six item dimensions needed no edits for each generation method and item pair. For example, for Case 17 and Generation Method 1a, only 4 of the 10 raters indicated that no changes were necessary across all six item dimensions.

Towards Self-Referential Analytic Assessment: A Profile-Based Approach to L2 Writing Evaluation with LLMs

Stefano Bannò, Kate Knill, Mark Gales

ALTA Institute, Department of Engineering, University of Cambridge (UK)
{sb2549, kmk1001, mjfg100}@cam.ac.uk

Abstract

Automated essay scoring (AES) research often relies on rank-based correlation metrics to validate analytic assessment. However, such metrics obscure both intrinsic intercorrelations among analytic dimensions that arise from the structure of writing proficiency itself and halo effects, whereby holistic impressions bleed into fine-grained component scores. As a result, high correlations may mask a system’s true diagnostic behaviour. In this study, we propose a novel self-referential assessment evaluation framework that focuses on identifying intra-learner strengths and weaknesses rather than assessing inter-learner rankings. We conduct experiments on the publicly available ICNALE GRA, a uniquely dense second-language writing dataset annotated holistically and analytically by up to 80 trained raters. To obtain reliable reference scores, we apply two-facet Rasch modelling to calibrate rater severity and derive fair average scores across ten analytic aspects and holistic proficiency. We compare the analytic scoring performance of human operational raters and three large language models (LLMs) in a zero-shot setting. Our results show that LLMs tend to outperform single human raters in identifying relative weaknesses (negative feedback) across several proficiency aspects, while human raters remain stronger at identifying relative strengths (positive feedback). Overall, our findings highlight the limitations of rank-based evaluation for analytic assessment and demonstrate the value of intra-learner, profile-based methods for assessing and deploying LLMs in AES.

1 Introduction

Automated essay scoring (AES) has become a cornerstone of second language (L2) proficiency assessment, utilising computational systems to evaluate learner writing in educational contexts. (Klebanov and Madnani, 2022). AES systems have primarily targeted holistic assessment, focusing on

assigning a single score that reflects a learner’s overall writing proficiency. However, driven by the need for more actionable pedagogical insights, the field has recently expanded its focus to analytic scoring, i.e., the evaluation of distinct aspects of proficiency (Li and Ng, 2024). The advent of large language models (LLMs) has revolutionised this landscape. Recent work has successfully exploited LLMs for both holistic (Mizumoto and Eguchi, 2023) and analytic scoring (Bannò et al., 2024). This shift offers the potential for scalable, multi-dimensional assessment that was previously difficult to achieve with traditional supervised models.

Despite these advances, current evaluation practices predominantly rely on rank-based metrics, such as Pearson’s correlation coefficient (PCC), Spearman’s rank coefficient (SRC), or agreement metrics, such as Quadratic Weighted Kappa (QWK) (Yannakoudakis and Cummins, 2015). While these metrics effectively measure a system’s ability to rank learners globally (i.e., inter-learner agreement), they may not be suitable to validate multi-dimensional analytic assessment. In addition to intrinsic intercorrelations among analytic dimensions, a major interfering factor is the halo effect (Thorndike, 1920; Engelhard, 1994), whereby a learner’s general proficiency influences judgments across specific sub-scales. As we show in this study, an LLM can achieve high correlations on analytic aspects simply by acting as a proxy for holistic proficiency, without accurately detecting the nuances that distinguish different analytic proficiency dimensions. Consequently, high rank agreement may not guarantee diagnostic validity. To address this limitation, we propose shifting the analytic evaluation paradigm from *normative* (i.e., ranking learners against each other) to *self-referential* assessment, in which a learner’s analytic skills are evaluated within the same learner profile. Self-referential analytic assessment focuses on intra-learner variability, identifying aspects where

a student performs significantly better or worse than their average proficiency (see Figure 1), thus offering a stricter and more pedagogically relevant test of an LLM’s analytic assessment capabilities.

Ensuring the interpretability of such an evaluation requires a reference signal that is internally consistent, psychometrically calibrated, and representative of expert judgement under the known interdependence of analytic dimensions. Standard datasets often suffer from rater subjectivity and noise, which can obscure the genuine signal. We mitigate this by leveraging the publicly available ICNALE GRA (Ishikawa, 2024) (see Section 3.1), an L2 learner dataset annotated by 80 raters holistically and analytically. We employ Rasch modelling (Linacre, 1989) to rigorously filter raters based on infit statistics, constructing a fair average reference score derived solely from highly consistent human raters.

In this paper, we evaluate three LLMs in a zero-shot setting alongside operational human raters using this self-referential framework. Our contributions are as follows:

1. We demonstrate the limitations of traditional rank-based metrics in analytic assessment, showing that high correlations often mask a lack of diagnostic precision due to both intrinsic intercorrelations and the halo effect.
2. We introduce a novel self-referential analytic assessment evaluation method that disentangles absolute proficiency from relative profile deviations, creating a dual classification task for positive and negative feedback.
3. We report experimental results showing that, within this self-referential framework, LLMs outperform a single operational rater in identifying relative weaknesses (negative feedback), while human raters retain an advantage in identifying relative strengths (positive feedback).

2 Related work

Traditionally, AES systems have mainly focused on overall holistic assessment. This holistic orientation has characterised AES since its inception in the 1960s (Page, 1966) and has been predominant up to today in recent studies investigating L2 assessment with LLMs (Mizumoto and Eguchi, 2023; Yancey et al., 2023).

Research on automated analytic assessment and feedback emerged later, with only a few early exceptions (Page et al., 1997; Shermis et al., 2002). The advent of neural approaches led to a growing body of work targeting specific traits of written production, such as organisation, content, word choice, sentence fluency, and narrativity (Hussein et al., 2020; Mathias and Bhattacharyya, 2020; Ridley et al., 2021; Kumar et al., 2022; Do et al., 2023). As with holistic assessment, LLMs have also been successfully applied to analytic assessment. For instance, Naismith et al. (2023) investigated the use of GPT-4 to predict coherence-related scores. Bannò et al. (2024) explored zero-shot analytic assessment of L2 writing proficiency using GPT-4 across CEFR-aligned proficiency aspects (Council of Europe, 2020). Seßler et al. (2025) examined multiple open- and closed-source LLMs for analytic scoring of German student essays across ten traits, including content-related, syntactic, and formal dimensions. Wang et al. (2025) investigated LLMs’ ability to conduct multi-dimensional analytic writing assessment by assigning scores and generating feedback comments across nine analytic aspects, finding that LLMs can produce generally reliable analytic assessments. In another recent work, Yoo et al. (2025) introduced a new dataset annotated across three analytic traits, i.e., content, language, and organisation, combining LLM-based scoring with synthetic data generation. Using the ICNALE GRA essays, Yamashita (2024) investigated the use of GPT-4 for analytic assessment along complexity, accuracy, and fluency dimensions. Their study primarily adopts a many-facet Rasch measurement framework to analyse rater severity, consistency, and potential biases when treating GPT-4 as an additional rater alongside humans.

Automated analytic scoring has largely inherited the evaluation metrics used for holistic assessment. The studies reviewed above typically rely on rank-based metrics, such as PCC or SRC, as well as agreement measures such as QWK (Yannakoudakis and Cummins, 2015), under a normative assessment framework, whereby learners are ranked against each other for each analytic proficiency aspect. In our work, we propose shifting the evaluation paradigm for analytic assessment from normative evaluation to self-referential interpretation of analytic profiles, in which analytic traits are evaluated within an individual learner’s performance profile. In the psychometric literature, a

Figure 1: Illustration of proposed self-referential analytic assessment approach.

similar approach has been theorised as *ipsative* assessment (Cattell, 1944; Clemans, 1956). However, in some applied assessment traditions, the same term instead denotes comparison with an individual’s previous performances (Hughes, 2011), rather than within-individual, self-referenced comparison across analytic dimensions. For this reason, we prefer the term *self-referential*.

Self-referential analytic assessment directly supports diagnostic feedback by identifying relative strengths and weaknesses within a learner, rather than across a population. To the best of our knowledge, this is the first study to introduce a self-referential evaluation framework for analytic assessment of L2 proficiency and to implement automated systems for this purpose. The closest conceptual precedent is Berninger and Abbott (2010), who employed within-learner comparisons across language modalities (listening, speaking, reading, and writing), operationalising relative strengths and weaknesses as deviations from a learner’s own mean performance. While their approach focused on modality-level L1 language skills in a psychometric testing context and did not use any automatic systems, the present study applies a self-referential perspective within AES of L2 writing by comparing learners’ performance across fine-grained analytic proficiency aspects.

3 Experimental setup

In this section, we first describe the dataset used in our experiments and outline the procedures for rater selection and score calibration. We then present details on LLM prompting and the method for extracting scores from the models. Next, we discuss the limitations of rank-agreement metrics when evaluating analytic assessment. Finally, we introduce our self-referential analytic assessment system.

3.1 Data

The International Corpus Network of Asian Learners of English (ICNALE) Global Rating Archive (GRA) (Ishikawa, 2020, 2024) is a publicly available L2 learner dataset derived from a subset of ICNALE (Ishikawa, 2011), containing learner essays and speeches, of which we use only the essay section for our experiments. A notable feature of this dataset is its English as a Lingua Franca (ELF) assessment perspective (Seidlhofer, 2005), which evaluates English as a communicative tool among non-native speakers instead of relying on native-speaker norms. Although the dataset is relatively small ($N = 140$), each essay has been annotated by 80 trained raters representing diverse first-language (L1) and occupational backgrounds.¹

In addition to holistic scores, the essays have been annotated across three macro-aspects, which in turn comprise ten analytic rating aspects:

- **Language** (*Intelligibility, Complexity, Accuracy, and Fluency*);
- **Content** (*Comprehensibility, Logicality, Sophistication, and Purposefulness*);
- **Attitude** (*Willingness to communicate and Involvement*).

The analytic scores range from 0 to 10, whereas the holistic scores range from 0 to 100; both scales allow midpoint values.² Human raters were instructed to evaluate the essays holistically first, followed by analytic scoring.

To the best of our knowledge, this makes ICNALE GRA the only publicly available L2 learner

¹Four essays were written by L1 speakers; we did not discard them from the dataset.

²We identified four anomalies in the original scores: for *Intelligibility*, a score of 1.2 (recoded as 1.0) and a score of 6.6 (recoded as 6.5); for *Complexity*, a score of 19 (recoded as 10); and for *Involvement*, a score of 8.6 (recoded as 8.5).

writing dataset that supports a fully crossed rater-essay design with more than two raters, comprising 123,195 ratings.³

3.1.1 Raters selection

In a previous study by the curator of the dataset, focusing specifically on the ICNALE ratings (Ishikawa, 2023), inter-rater reliability is evaluated using Cronbach’s α (Cronbach, 1951). This statistic primarily reflects relative consistency, capturing the extent to which raters produce similar rank orderings of test-takers, while being insensitive to systematic differences in absolute scoring levels. As such, Cronbach’s α is a measure of internal consistency rather than a direct measure of inter-rater reliability (Krippendorff, 2004; Lombard et al., 2006); it reflects the extent to which raters are measuring the same underlying construct.

For this reason, we instead adopt Krippendorff’s α (Krippendorff, 2011), which is more commonly used for inter-rater reliability, as it explicitly quantifies absolute agreement among raters, i.e., the degree to which raters assign identical scores to the same test-taker. Moreover, this metric is well suited to ordinal data, multiple raters, and missing values (see Note 3). Table 1 reports inter-rater reliability in terms of Krippendorff’s α : column *All* shows the estimate computed over all 80 raters, while column *Selected* reports the estimate on 12 raters, after applying the rater selection procedure described below. As can be seen, the low Krip-

Macro-aspect	Aspect	α	
		All	Selected
Language	Intelligibility	0.270	0.531
	Complexity	0.252	0.542
	Accuracy	0.278	0.505
	Fluency	0.256	0.526
Content	Comprehensibility	0.257	0.538
	Logicality	0.237	0.499
	Sophistication	0.225	0.517
	Purposefulness	0.221	0.502
Attitude	Willingness	0.202	0.465
	Involvement	0.172	0.409
	Holistic	0.297	0.579

Table 1: Krippendorff’s α reliability estimates on ICNALE GRA.

pendorff’s α values for *All* indicate substantial disagreement among raters, which may be attributable

³That is, (140 essays $\times$ 80 raters $\times$ 11 proficiency aspects, i.e., ten analytic and one holistic) – 5 missing ratings. Five rating data points are missing from the original scores of the 80 raters; however, there are no missing values in the subset of 12 selected raters (see Section 3.1) used in our experiments.

to differences in severity, inconsistent category use, or divergent interpretations of the rating criteria.

To ensure the reliability of the rating data, we evaluate each of the 80 raters’ consistency using the infit statistic derived from a two-facet Rasch model (Linacre, 1989), i.e., one model for each of the 11 analytic and holistic language aspects, with the two facets being rater severity and learner ability. To do this, we use the Many-Facet Rasch Model estimation function, `tam.mml.mfr`, within R’s TAM (Test Analysis Modules) package.⁴ To accommodate midpoints, analytic scores are fed into the model after multiplying them by 2, whereas holistic scores are binned into 11 categories from 0 to 10, as described in Ishikawa (2024, p. 33).

Infit measures how well a rater’s scores match the model’s expectations, giving more weight to items that are close to a person’s ability level. Mathematically, for rater r and item i , the infit mean-square is computed as:

$$\text{Infit}_r = \frac{\sum_i w_{ri}(X_{ri} - E_{ri})^2}{\sum_i w_{ri}} \quad (1)$$

where X_{ri} is the observed rating, E_{ri} is the Rasch model-predicted rating, and w_{ri} is a weight reflecting the item’s information (i.e., its expected variance). An infit value between 0.5 and 1.5 indicates that a rater’s judgments are consistent with the model, whereas values substantially above 1.5 or below 0.5 indicate over- or under-discrimination, respectively (Linacre, 2002). First, we retained only raters with infit equal to or higher than 0.5 and equal to or less than 1.5, ensuring that all included raters provided reasonably consistent scores across items. Subsequently, we identified the intersection of acceptable raters across all language aspects, resulting in a subset of 12 raters (with 18,480 ratings in total) that satisfied the infit criterion for every aspect considered.

As can be observed in column *Selected* in Table 1, rater selection based on infit statistics leads to a substantial increase in observed reliability. This procedure identifies a subset of raters whose scoring behaviour falls within acceptable Rasch infit bounds and can therefore be used for score calibration and subsequent modelling. From this point onwards, all references to “raters” pertain exclusively to the subset of 12 selected raters.

⁴cran.r-project.org/web/packages/TAM

3.1.2 Score calibration

To obtain a fair average score $E(X_n)$ for a learner n , we fit a two-facet Rasch model for each language aspect, this time only with the 12 selected raters. The net cumulative difficulty barrier, $\Phi_{net,k}$, for achieving a score of k combines the average rater severity ($\bar{\lambda}$) and the global cumulative step difficulties (τ_m):

$$\Phi_{net,k} = \left(\sum_{m=1}^k \tau_m \right) + k \cdot \bar{\lambda} \quad (2)$$

where $\sum_{m=1}^k \tau_m$ is the cumulative step difficulty, defined as 0 for $k = 0$; τ_m is the estimated global step difficulty parameter (the difficulty of moving from score $m - 1$ to m); k : the score category index ($k = 0, 1, 2, \dots, K$); $\bar{\lambda}$ is the mean severity of all selected raters.

The probability of learner n achieving a score k is calculated as the exponent of the difference between the learner’s ability and the net cumulative difficulty, normalised by the sum of probabilities across all possible categories:

$$P(X_n = k) = \frac{\exp(k\theta_n - \Phi_{net,k})}{\sum_{c=0}^K \exp(c\theta_n - \Phi_{net,c})} \quad (3)$$

where θ_n is the estimated ability of learner n and K is the maximum category index.

The final expected score $E(X_n)$ is the sum of the products of each category score s_k and its probability $P(X_n = k)$. Since, for the analytic aspects, the raw scores were multiplied by 2 prior to fitting the model to accommodate midpoints, the final result is divided by 2 for normalisation:

$$E(X_n) = \frac{1}{2} \cdot \sum_{k=0}^K s_k \cdot P(X_n = k) \quad (4)$$

For holistic scores, instead, the final result is

$$E(X_n) = \sum_{k=0}^K s_k \cdot P(X_n = k) \quad (5)$$

We refer to these final scores as *fair average scores*.

Table 2 reports the average Spearman’s rank correlation coefficient (SRC) between the *average rater* (AR) and the reference fair average scores. In other words, we calculated the SRC between each of the 12 raters and the reference fair average scores, and reported the mean and standard deviation. However, in operational language assessment,

essays are typically assigned to raters at random. To simulate this scenario, we randomly selected one rater for each essay. This procedure was repeated five times using different random seeds, and the results were averaged. We refer to this condition as the *operational rater* (OR).

	AR	OR
Intelligibility	0.764 $\pm$.05	0.749 $\pm$.02
Complexity	0.770 $\pm$.04	0.737 $\pm$.02
Accuracy	0.765 $\pm$.05	0.735 $\pm$.02
Fluency	0.761 $\pm$.03	0.733 $\pm$.02
Comprehensibility	0.769 $\pm$.05	0.741 $\pm$.02
Logicality	0.748 $\pm$.04	0.723 $\pm$.02
Sophistication	0.761 $\pm$.03	0.741 $\pm$.04
Purposefulness	0.740 $\pm$.05	0.730 $\pm$.02
Willingness	0.718 $\pm$.03	0.696 $\pm$.05
Involvement	0.692 $\pm$.07	0.644 $\pm$.05
Holistic	0.788 $\pm$.04	0.775 $\pm$.02

Table 2: SRC correlations of average rater (AR) and operational rater (OR) with fair average scores.

Notably, holistic scores exhibit the highest levels of agreement, as shown in Table 1, a pattern that is further supported by the SRC results in Table 2. This observation aligns with previous research indicating that holistic scoring is generally easier and more intuitive for human raters than analytic scoring, hence tending to yield higher inter-rater reliability than fine-grained analytic judgments (Weigle, 2002; Zhang et al., 2015). Furthermore, the *Attitude* aspects (i.e., *Willingness to communicate* and *Involvement*) are inherently more subjective and consequently more difficult for raters to evaluate, as reflected in their lower SRC and Krippendorff’s α values compared with the other aspects.

3.2 LLM prompting and score extraction

We use GPT-4.1 (OpenAI, 2023), Qwen 2.5 72B (4-bit quantised) (Yang et al., 2024), and Llama 3.1 70B (4-bit quantised) (Llama Team, 2024) in a zero-shot setting to evaluate each language aspect in the essays, allowing us to compare both proprietary high-parameter and open-source, medium-size LLMs. The prompt template provided to the LLMs can be found in Appendix A. This contains an analytic rating prompt for each language aspect, originally used by human raters. Because the original analytic prompts (Ishikawa, 2024, pp. 34–36) were designed for both essays and speeches, we adapted them to include only content relevant to

essays. The revised prompts are provided in Appendix B.

To extract proficiency scores from the LLM, we use a weighted average approach (Ma et al., 2025; Bannò et al., 2025). For each analytic aspect, the LLM is prompted independently, producing a probability distribution over discrete proficiency levels via a softmax layer. Let $\mathbf{p} = [p_1, p_2, \dots, p_K]$ denote this probability distribution over K ordinal levels, and let $\mathbf{v} = [v_1, v_2, \dots, v_K]$ represent the numeric values assigned to each level (here, 0 through 9).⁵ The weighted average score for the LLM prediction is then computed as:

$$\text{WAvg} = \sum_{k=1}^K p_k \cdot v_k \quad (6)$$

Intuitively, this procedure produces a continuous estimate of the score by weighting each possible level by the LLM’s predicted probability.

3.3 Limitations of assessing analytic scoring using rank-based metrics

In real-world multi-aspect language assessment, a common characteristic is the high intercorrelation among scores assessing different aspects, as well as the strong correlation between analytic and holistic scores (Lee et al., 2008; Ono et al., 2019). This pattern is also observed in our study. Table 3 presents the SRC between predictions from various systems and the reference fair average scores for three aspects, each representing a macro-aspect: *Complexity* for Language, *Logicality* for Content, and *Willingness* for Attitude. We compare these with the correlations between holistic fair average scores and analytic fair average scores (first row). Additionally, we report the SRC correlations on analytic fair average scores when we prompt our systems for holistic scoring. As can be seen, holistic fair average scores correlate highly with analytic scores. As a result, when we use LLMs prompted to predict holistic scores, we observe strong correlations with analytic scores, in some cases even stronger than when we prompt them for the respective analytic aspect. For example, when prompted for holistic scores, GPT-4.1 shows a correlation with *Complexity* of 0.927 (vs 0.848) or Qwen 2.5 shows a correlation with *Willingness* of 0.754 (vs 0.457). Similarly,

⁵We used a 0–9 scale because including 10 would require two tokens (“1” and “0”), making it difficult to extract a probability for this score.

the operational rater (OR) achieves higher correlations with analytic scores when providing holistic ratings: $0.763_{\pm 0.02}$ for *Complexity*, $0.762_{\pm 0.01}$ for *Logicality*, and $0.750_{\pm 0.02}$ for *Willingness*, compared to $0.737_{\pm 0.02}$, $0.723_{\pm 0.02}$, and $0.696_{\pm 0.05}$, respectively, when performing analytic assessment. In addition to the presence of real intercorrelations among analytic scores, this pattern may be explained by a halo effect, in which the holistic judgments influence ratings across multiple analytic dimensions, effectively acting as a proxy for the learner’s analytic ability.

Consequently, evaluating analytic assessment quality using rank-based metrics such as SRC can be misleading:⁶ these metrics primarily capture global agreement in learner ranking, and may obscure the model’s ability to detect relative strengths and weaknesses within a single learner’s profile. In other words, a system can achieve high correlations with analytic scores simply by reflecting holistic proficiency rather than accurately differentiating performance across individual aspects. It is nevertheless noteworthy that LLMs outperform OR on *Complexity*, *Logicality*, and *Holistic* (with the exception of Qwen 2.5), whereas on the more subjective dimension of *Willingness*, OR still achieves the best – albeit comparably lower – performance, as expected (see end of Section 3.1). The scatterplots for the three selected analytic aspects and holistic proficiency are shown in Figure 3 in Appendix C.

The next section addresses this issue by proposing an alternative approach to analytic assessment.

3.4 Implementing self-referential analytic assessment

We first standardise the reference analytic fair average scores. For each analytic aspect i , we compute

$$z_i = \frac{s_i - m_i}{\sigma_i} \quad (7)$$

where s_i denotes the fair average score, and m_i and σ_i are the mean and standard deviation of that score for i across essays.

For each essay, we then compute the average of the standardised analytic scores across all A aspects:

$$\mu = \frac{1}{A} \sum_{j=1}^A z_j \quad (8)$$

⁶Due to the continuous nature of our scores, we cannot use QWK. However, because this also measures rank agreement, we expect it would yield similar patterns.

		Complexity	Logicity	Willingness	Holistic
Fair Avg. Holistic		0.993	0.982	0.976	1.000
Prompted for analytic	OR	0.737 $\pm$.02	0.723 $\pm$.02	0.696 $\pm$.05	-
	GPT4.1	0.848	0.810	0.340	-
	Qwen2.5	0.753	0.769	0.457	-
	Llama3.1	0.814	0.824	0.554	-
Prompted for holistic	OR	0.763 $\pm$.02	0.762 $\pm$.01	0.750 $\pm$.02	0.775 $\pm$.02
	GPT4.1	0.927	0.921	0.910	0.936
	Qwen2.5	0.738	0.764	0.754	0.771
	Llama3.1	0.758	0.771	0.724	0.781

Table 3: SRC of selected aspects (*Complexity, Logicity, Willingness*) with fair average scores across different systems.

We define the difference between μ and the score for aspect i as

$$\Delta_i = \mu - z_i \quad (9)$$

This difference is used to construct a dual binary classification task corresponding to negative and positive feedback. Specifically, for each aspect i , we define the negative feedback target as $\Delta_i \geq \sigma_{\Delta_i}$ and the positive feedback target as $\Delta_i \leq -\sigma_{\Delta_i}$, where σ_{Δ_i} is the standard deviation of Δ_i across essays.⁷

For model predictions, let $\hat{s}_i$ denote the predicted score for aspect i . Predictions are standardised analogously:

$$\hat{z}_i = \frac{\hat{s}_i - \hat{m}_i}{\hat{\sigma}_i} \quad (10)$$

where $\hat{m}_i$ and $\hat{\sigma}_i$ are computed over the predicted scores for aspect i . The average of the standardised predictions across aspects is then

$$\hat{\mu} = \frac{1}{A} \sum_{j=1}^A \hat{z}_j \quad (11)$$

Finally, we compute the difference between $\hat{\mu}$ and the predicted score for aspect i

$$\hat{\Delta}_i = \hat{\mu} - \hat{z}_i \quad (12)$$

which serves as a continuous scoring signal for the feedback classification task. We report the best $F_{0.5}$ score for each aspect prioritising precision over recall to minimise false positives and avoid misleading learners about their proficiency strengths or weaknesses.

In order to be able to have a fair comparison of the results across the two binary tasks, we

⁷A one-standard-deviation threshold has also been used in the aforementioned work by [Berninger and Abbott \(2010\)](#).

normalise the Precision and $F_{0.5}$ score using the method illustrated in [Raina et al. \(2023\)](#) setting the prevalence to 10% since we are working with different language aspects, each having a different original prevalence rate (see Tables 7, 8, 9, and 10 in Appendix C). To do this, we rescaled the proportion of negative cases so that the effective prevalence matched the target. Let N_+ and N_- denote the number of positive and negative samples, and let pr_{target} denote the desired prevalence. We first solved

$$\frac{N_+}{N_+ + \gamma N_-} = pr_{\text{target}} \quad (13)$$

for the scaling factor γ applied to the number of negatives. Assuming the classifier’s false positive rate per negative instance remains constant, false positives scale proportionally by the same factor γ . The normalised precision P' is then obtained by recomputing precision using this adjusted false-positive count. Normalised recall is unaffected, and the normalised $F_{0.5}$ score is subsequently computed from P' and recall R .

Given this prevalence value, if we calculate the $F_{0.5}$ score for a random classifier, where β is 0.5, P' is 0.10, and R is 1:

$$F_\beta = (1 + \beta^2) \frac{P' \cdot R}{\beta^2 \cdot P' + R} \quad (14)$$

we obtain a score of ~ 12.19 . Any results higher than this value contain information. Table 6 in Appendix C illustrates the percentage of essays receiving feedback across macro-aspects.

Before discussing the results, it is important to clarify the nature of the task. Unlike the inter-learner correlation analyses reported in Table 3, our proposed self-referential framework focuses on identifying aspects that are unusually weak or strong relative to an individual learner’s overall

profile. As a result, systems may show high correlations while still differing substantially in how they distribute strengths and weaknesses across analytic aspects within the same essay.

4 Experimental results

Tables 4 and 5 show the results for GPT-4.1, Qwen 2.5 72B, Llama 3.1 70B, and OR on negative and positive feedback, respectively.

Table 5: **Positive** feedback results in terms of best $F_{0.5}$ across systems.

As can be observed, when examining individual analytic aspects under the negative feedback condition (Table 4), LLMs, particularly GPT-4.1, tend to achieve higher $F_{0.5}$ scores than the OR on several *Language* and *Content* dimensions. GPT-4.1 notably outperforms both the other models and OR on *Intelligibility*, *Complexity*, *Fluency*, *Comprehensibility*, and *Logicality*, indicating a stronger alignment with the reference signal in identifying aspects that deviate negatively compared to the overall average score. This suggests that LLMs are especially effective at detecting relative weaknesses in linguistically and structurally grounded dimensions. By contrast, OR attains higher scores on *Accuracy* and on the *Attitude* dimensions (i.e., *Willingness* and *Involvement*), for which all LLMs

show comparatively lower performance. Given that *Attitude* aspects are inherently more subjective and have been shown to exhibit lower inter-rater agreement (see Tables 1 and 2), these differences likely reflect increased noise and variability in the reference labels rather than a systematic limitation of the self-referential assessment formulation or the models themselves. Within the group of LLMs, GPT-4.1 consistently leads across most *Language* and *Content* aspects, while Qwen 2.5 performs best on *Sophistication*, and Llama 3.1 achieves its highest scores on *Purposefulness*. However, overall, GPT-4.1 attains the highest average $F_{0.5}$ score for negative feedback.

For positive feedback (Table 5), a different pattern is observed. While LLMs continue to perform strongly on *Complexity*, *Logicality*, and *Sophistication*, the OR outperforms all models on most *Language* aspects, including *Intelligibility*, *Accuracy*, and *Fluency*, as well as on *Comprehensibility* and *Purposefulness*. Among the LLMs, Llama 3.1 achieves the highest overall average $F_{0.5}$ score under positive feedback, driven primarily by its performance on *Logicality*, *Purposefulness*, and *Involvement*. In contrast, GPT-4.1, while dominant in the negative feedback setting, shows comparatively weaker alignment with the positive feedback targets. Overall, we can observe that LLMs, especially GPT-4.1, exhibit stronger alignment with reference signals for identifying relative underperformance, whereas human raters show higher agreement with the reference in identifying relative strengths. For completeness, in addition to $F_{0.5}$, we also report the results in terms of Precision and Recall in Appendix C in Tables 7, 8, 9, and 10 for OR, GPT-4.1, Qwen 2.5, and Llama 3.1, respectively.

In addition to comparing LLMs with a single randomly selected operational rater per essay, we also report performance for ensembles of multiple raters, ranging in size from 2 to 12. Figure 2 reports the errorbars for feedback on *Logicality*. As can be seen, for this aspect, it takes an ensemble of three raters to outperform the best-performing models, i.e., GPT-4.1 on negative feedback and Llama 3.1 on positive feedback.

For completeness, we report the results for all the aspects and one, two, and three operational raters in Tables 11 and 12 in Appendix C. When averaging performance across aspects, an ensemble of two operational raters is sufficient to outperform the LLMs. However, considering individual aspects, as in Figure 2, larger ensembles are required.

Figure 2: Errorbars on feedback of ensembles with increasing number of operational raters to GPT-4.1, Llama 3.1 70B, and Qwen 2.5 72B for *Logisticality*.

5 Conclusions

This paper addresses the challenges of validating diagnostic analytic assessment in AES, particularly where rank-based metrics may overlook the influence of intercorrelations among analytic dimensions of proficiency as well as the halo effect. Through the introduction of a self-referential framework, we demonstrate how intra-learner evaluation serves as a crucial complement to standard inter-learner assessment.

Our results highlight divergent strengths: LLMs tend to outperform operational human raters in pinpointing relative weaknesses (negative feedback), while humans remain more adept at recognising relative strengths (positive feedback). While the primary focus of this paper is the proposed self-referential assessment framework, we acknowledge that our experiments are limited to zero-shot approaches. Future work will investigate alternative prompting strategies, including few-shot prompting and chain-of-thought reasoning.

Finally, while inter-learner rankings provide essential comparative data, we propose combining them with intra-learner diagnostics. This hybrid approach may offer a pathway to delivering more actionable and informative assessment and feedback to learners, teachers, and testers.

Limitations

First, we acknowledge that relying on a single dataset warrants caution; further experiments are therefore necessary to fully validate the effectiveness of our self-referential assessment framework. While the number of unique essays is relatively small ($N = 140$), the original dataset is exceptionally dense, containing over 120,000 ratings from 80 raters. This unique characteristic of the ICNALE GRA allowed us to implement Rasch modelling in a fully crossed rater-essay design, a rigorous approach not feasible with other L2 learner datasets.

Secondly, as the data focuses on Asian learners within an English as a Lingua Franca (ELF) framework, further research is required to determine if these findings generalise to learners from other L1 backgrounds or for other L2s.

Finally, regarding the self-referential framework, while the use of a one-standard-deviation threshold is a heuristic choice, it ensures a consistent data-driven approach and aligns with established methodology in psychometric literature (Berninger and Abbott, 2010). Moreover, it guarantees that a substantial proportion of learners receive both positive and negative feedback, as shown in Table 6 (Appendix C).

Acknowledgments

This paper reports on research supported by Cambridge University Press & Assessment, a department of The Chancellor, Masters, and Scholars of the University of Cambridge. The authors would like to thank the ALTA Spoken Language Processing Technology Project Team for general discussions and contributions to the evaluation infrastructure.

A Appendix A: Prompt

In the context of an examination of English as a Lingua Franca (ELF), a second language (L2) learner of English is asked to write an essay in response to the following prompt:

Do you agree or disagree with the following statement? Use reasons and specific details to support your opinion.

‘It is important for college students to have a part-time job.’

You have to score this essay by only considering the aspect of [ASPECT].

[ANALYTIC RATING PROMPT]⁸

Select a score from 0 (lowest) to 9 (highest). Only output the most suitable score without adding any comment or explanation.

Essay: [ESSAY]

B Appendix B: Analytic rating prompts

Since ICNALE GRA contains essays and speeches, the original analytic rating prompts (Ishikawa, 2024) addressed both modalities. For our experiments with LLMs, we therefore tailored the prompts to retain only the content relevant to essays.

Language

Intelligibility

To which extent can you “decode”, namely, verbally understand what is written? Factors such as spelling and sentence structure may influence it. Please note that intelligibility, which concerns the understandability of the language, should be discriminated from comprehensibility, which concerns the understandability of the content. You may sometimes find an essay that is intelligible but not comprehensible, such as a logically nonsense statement. Meanwhile, you may usually not find an essay that is comprehensible but not intelligible because if the text cannot be decoded, its content cannot be conveyed.

Complexity

To what extent do you think the writer uses morphologically and/or semantically complex words, phrases, expressions, constructions, and grammar? Complexity is seen at many levels of language. For example, “I speculate...” usually sounds more complex than “I think” (Vocabulary). “It is speculated that...” may sound more complex than “I speculate” (Voice, Construction). “If I were a bird” may sound more complex than “If I am a bird” (Subjunctive, Grammar).

Accuracy

To what extent do you think the sample is error-free in terms of vocabulary and grammar? In addition, you should examine the elements such as

punctuation. Please note that you should ignore minor and only-once errors, which may be mistakes rather than errors. Please note that the standard for evaluation should be a proficient non-native ELF speaker, not an English native speaker.

Fluency

To what extent do you think the writer is fluent in the essays? Fluency needs to be evaluated in two ways: (a) fluency and (b) disfluency. If someone writes more, the fluency score should increase, while if s/he uses more disfluency markers, the score may decrease. Disfluency markers include unnecessary connectors (and, but, so because) and semantically empty phrases (such as “I think” most typically), etc. Please note that using these disfluency markers once or twice usually does not cause any problems in communication.

Content

Comprehensibility

To what extent can you understand the content of the essay? Please note that comprehensibility, which concerns the understandability of the content, should be discriminated from intelligibility, which concerns the understandability of the language. If a writer presents a logically reasonable idea, the score should increase.

Logicity

To what extent do you think the idea presented in the essay is logical and reasonable? You need to examine whether the reasons and the conclusions are logically connected.

Sophistication

To what extent do you think the ideas presented in the essay are well-sophisticated, critically thought, unique, original, and innovative?

Purposefulness

To what extent do you think the writer consistently and consciously pays attention to the purpose of the task? The participant was requested to persuade a supervisor to allow them to show their own opinion about part-time jobs for college students in an essay. You have to examine whether the participant fully understands the purpose of the task and consistently sticks to it. Purposefulness is closely related to task completion.

⁸See Appendix B.

Attitude

Willingness to communicate

To what extent do you think the writer is willing to communicate? It is possible that a participant with a limited L2 proficiency shows a high level of willingness to communicate (WTC), and it is also possible that a participant with a high L2 proficiency shows quite a low level of WTC. Factors such as the quantity of writing, the number of ideas s/he presents, and the use of various amplifiers (e.g., “very,” “surely,” “definitely,” “I strongly believe,” etc.) may represent the participant’s WTC.

Involvement

To what extent do you think the participant tries to make the reader involved in his/her discourse rather than writing one-sidedly? The factors such as the use of the second-person pronouns (e.g., “You know,” “as you see,” “as you expect,” etc.) and mentioning the reader are usually related to the degree of involvement.

Holistic

To what extent do you think the sample is close to an ideal ELF essay? Raters have to examine each sample and decide the score (0-100) based on the overall judgment of its quality as a professional ELF output. Please note that “9 points”, for example, should be given to someone who you think is a 100% ideal professional ELF user, not to someone who you think is 100% close to English native speakers. Also, please note that the middle point is 5.

C Appendix C: Additional statistics and results

Table 6 reports the percentage of essays receiving positive and negative feedback across macro-aspects.

Figure 3 shows scatterplots comparing GPT-4.1 predictions with reference fair average scores for the three selected analytic aspects and holistic proficiency. For visualisation purposes, GPT-4.1’s predictions were linearly calibrated using the same essay test data.

Tables 7, 8, 9, and 10 show the complete feedback results in terms of Precision, Recall, and $F_{0.5}$ for OR, GPT-4.1, Qwen 2.5 72B, and Llama 3.1 70B, respectively. Tables 11 and 12 show the feedback results in terms of $F_{0.5}$ for one random operational rater (OR), an ensemble of two random

operational raters (OR2), and three random operational raters (OR3).

Abstract

Intelligent Tutoring Systems (ITS) can record learner interactions in fine-grained detail at scale. This opens the door to data-driven methods for investigating system performance and identifying points for improvement. In this paper, we draw on authentic log data from an English language ITS ($N_{logs} = 5646$, $N_{students} = 368$) to investigate the performance of its feedback algorithm. In step 1 of our analysis, we profiled feedback accuracy by exploring how well the system provided error-specific feedback to malformed student answers in gap-filling grammar exercises using an expert-created set of feedback generation rules. We then identified frequently occurring student errors that triggered incorrect or unspecific feedback and refined the rule set used to detect and respond to these errors with correct specific feedback. In step 2, we validated the rule modifications on an unseen dataset. Comparing the performance of the initial and updated rule sets, we find significant improvement that generalizes to unseen data. Our study thus illustrates how an empirical evaluation of authentic data can complement feedback creators' expertise by informing rule refinement decisions that yield significant and generalizable performance improvements to feedback in ITS systems.

1 Introduction

Among other trending approaches to computer-assisted language learning (CALL, [Huang et al., 2023](#); [Zerkouk et al., 2025](#)), Intelligent Tutoring Systems (ITS) have demonstrated a notable capacity to improve learning outcomes ([Heift, 2010](#); [Meurers et al., 2019](#)), enhance learner engagement, motivation, and foster positive social outcomes ([Ukenova and Bekmanova, 2023](#)). Both educational practice and Skill Acquisition Theory ([DeKeyser, 2007](#)) motivate the need for deliberate practice with feedback, which can be facilitated

by performing error detection and providing automatic corrective feedback ([Amaral et al., 2011](#); [Ruiz et al., 2023](#)).

Feedback plays a crucial role in language acquisition, and therefore its correctness and relevance is of high importance ([Loewen, 2013](#)). When it comes to feedback in ITSs, [Cavalcanti et al. \(2021\)](#), in their review of automatic feedback generation systems in online learning environments, concluded that automatic feedback can be as effective, or sometimes even more effective, than manual instructor feedback.

Another beneficial property of ITSs is the ability to record large amounts of user-system interactions, enabling educational data mining to draw conclusions about both learner performance and system behavior ([Romero and Ventura, 2013, 2020](#)) and, therefore, to evaluate the performance of feedback generation ([Koedinger et al., 2013](#)).

In recent years, the focus of using AI in education has shifted significantly towards Large Language Models (LLMs) and the integration of generative AI ([Dong et al., 2024](#); [Degraeuwe and Goethals, 2024](#); [Baidoo-Anu and Ansah, 2023](#); [Dai et al., 2023](#)). Research shows that LLMs can generate useful formative feedback and the accuracy of the latter is promising, but false positives are still a concern, especially in educational settings, as they might undermine learners' confidence and lead to misconceptions ([Jaganov et al., 2025](#)). Moreover, for closed exercise types and semi-open exercises (e.g., gap filling with grammatical forms) where the set of correct answers is known, a rule-based or hybrid approach to generating feedback can follow the "don't guess if you know" advice for achieving transparency and robustness.

Therefore, as [Stamper et al. \(2024\)](#) suggest, one should not disregard previous knowledge and years of experience using expert-generated and traditional data-driven approaches that allow high

levels of control over feedback provision, a system feature that is particularly crucial for beginner learners who tend to rely heavily on system feedback (Fu et al., 2022; Yang and Li, 2024).

In this paper, we analyze feedback generation performance of the FeedBook (Rudzewitz et al., 2017), a language ITS that primarily focuses on semi-open gap-filling grammar exercises (e.g., "[...] he now? He is at home now". Target answer: "Where is") and provides dynamic scaffolding feedback. We aim to showcase the value of authentic interaction logs for evaluating and refining a rule-based feedback system, such as the one in the FeedBook by addressing the following research questions (RQs):

1. How can systematic analysis of authentic logs be applied to evaluate and improve rule-based feedback generation?
2. How well does the approach generalize to unseen data?

The results of our experiment show that log analysis can be used effectively to identify rules to refine or add, and that even a small number of changes can yield significant performance improvements. We also employ statistical analysis to demonstrate the generalizability of the approach to unseen data.

2 Related Work

ITSs play an increasingly significant role in modern education, and therefore, the importance of evaluating these systems to ensure their technical reliability, usability, and overall effectiveness increases proportionally (Mousavinasab et al., 2021; Marouf et al., 2024; Latif et al., 2026).

Siemer and Angelides (1998) were among the first to specify an evaluation framework for ITSs and suggested a two-part evaluation: external and internal. External evaluation is concerned with the system’s influence on the student, e.g., on learning achievement and learning affect. As for internal evaluation, the goal is to analyze the system from within, to evaluate its functionality and efficiency.

Most ITS evaluations (e.g., Bór, 2023; Wu et al., 2022; Erümit et al., 2019; Karaci et al., 2018) focus on external system effectiveness by analyzing usability, learner performance, or motivation rather than evaluating the intelligent algorithms employed. When it comes to feedback evaluation and enhancement in ITSs, Banihashem et al.

(2022) confirm that learning achievement and pedagogical gains are the primary goals of such studies. For example, Van der Kleij et al. (2015) analyzed the effect of more elaborate feedback on learning outcomes compared to simpler feedback and the provision of correct answers. Lavolette et al. (2015) analyzed the accuracy of error detection and the respective feedback but the study focused on the effect of immediate feedback versus delayed feedback and not on fine-tuning or enhancement of the feedback itself. Inn-Chull (2019) and Fazilatfar et al. (2024) explored the effect of computer-assisted feedback on learner uptake and analyzed learner data to tailor feedback strategies (e.g., example-based or metalinguistic) based on their pedagogical effectiveness. Horbach et al. (2022) also examined the effect of automated informative tutorial feedback on learner writing performance.

Today, research often focuses on LLM-generated feedback, mainly featuring short answer and free writing assessment (Stahl et al., 2024; Jaganov et al., 2025; Emirtekin, 2025). The approaches to providing grammar feedback in these studies are partially inspired by Grammatical Error Correction (GEC) systems, and a significant amount of recent work has evaluated them (e.g., Volodina et al., 2023; Kobayashi et al., 2024). However, in their comprehensive survey Bryant et al. (2023) emphasize that most GEC systems focus on correcting errors without explaining them (e.g., Omelianchuk et al., 2024), which limits their educational value. Although some resources for generating explanatory feedback are emerging (e.g., Fei et al., 2023; Ye et al., 2025), more work is needed to develop robust, explainable GEC and to evaluate the generated feedback (Nagata, 2019; Nagata et al., 2020, 2021).

When it comes to data, Leacock et al. (2014) highlighted the importance of authentic learner texts for training GEC and feedback tools, enhancing their effectiveness in CALL and automatic writing evaluation contexts. This benefit has recently been emphasized, for example, by Song et al. (2024) in their work on Grammar Error Explanation. They propose a two-step pipeline that uses fine-tuned and prompted LLMs trained on real-world learner corpora in order to first edit erroneous input and subsequently prompt GPT-4 for explanations of the edits.

Greer and Mark (2016) also highlighted the benefits of analyzing the fine-grained data col-

lected by an ITS for its evaluation. For instance, Heift (2013) used learner interaction logs to improve the *Error Priority Queue*, i.e., to determine the relevance of feedback messages to the learning goal whenever several errors were present in student answer.

Interestingly, our research on semi-open gap-filling grammar exercises revealed that there are very few works on feedback generation for such exercises or evaluation thereof apart from the work by Rudzewitz et al. (2018). Although free production is the ultimate goal of language learning, constrained constructed responses - such as gap-fills - are effective in building explicit language knowledge and accuracy (Ellis, 2006). This learning effect, as mentioned above, can be enhanced with scaffolding feedback. However, most research involving gap-filling is concerned with the generation of the questions and the gaps themselves (e.g., Kiros Bitew et al., 2023; Hill and Simha, 2016; Knoop and Wilske, 2013), or distractors for those gaps (e.g., Yoshimi et al., 2023; Panda et al., 2022; Yeung et al., 2019), rather than feedback. These studies are also rarely associated with an ITS.

To address this gap, we adopt the data-mining approach and use authentic logs of learner interactions to perform an internal evaluation of the feedback mechanism in the FeedBook and demonstrate the benefits of the approach for gap-filling exercises.

3 Feedback Mechanism in FeedBook

The FeedBook is a web-based ITS designed for 7th grade English as a second language (ESL, L2) learners in German secondary schools. It is publicly available for use in ESL classrooms and is under ongoing development within research projects.¹ Its main function is to provide learners with language exercises and to give immediate, individualized scaffolding feedback (Rudzewitz et al., 2017). Feedback becomes available in two stages: offline *feedback generation* and real-time *feedback provision* (see Rudzewitz et al. (2018) for a detailed description of the algorithm).

FeedBook’s **feedback generation** mechanism utilizes various Natural Language Processing (NLP) tools, such as Apache Unstructured Information Management application (UIMA) (Ferrucci et al., 2009), ClearNLP (Choi and Palmer,

2012), Morpha (Minnen et al., 2001), and Sfst (Schmid, 2005) to analyze and annotate exercises, including the encoded target answer (TA; i.e., the expected correct answer), in order to predict possible learner errors and provide appropriate and helpful feedback options. TAs can be full but single sentences, phrases or single words. If a TA comprises a partial sentence, the remaining parts (i.e., to the left and right of the gap) are provided as *context* to the NLP pipeline. To account for the phenomenon of multiple admissibility (Katinskaia et al., 2019), some exercises have one or several alternative TAs.

The system utilizes a multi-layer rule-based approach (see Appendix A) that takes TAs and transforms them into ill-formed or well-formed but otherwise incorrect anticipated learner answers (*hypotheses*). The transformations are made through a variety of second language acquisition (SLA) theory-based, pedagogically driven rules, e.g.,

overregulation of irregular verbs in simple past: *did* > *doed*, *went* > *goed*;
incorrect tense or person agreement of auxiliary verbs: *do* > *did*, *was* > *were*.

Each hypothesis carries the transformed surface string information, the respective error diagnosis, and the context and matches it with the most specific feedback message for later display to learners.

In terms of **feedback provision**, once a learner enters an erroneous answer, the system compares it with the generated hypotheses, identifies the closest match and displays its associated feedback message as a popup. The messages are teacher-crafted metalinguistic error explanations tailored to our target population, e.g., “*You’ve forgotten an auxiliary verb (‘Hilfsverb’, e.g. ‘do’/‘did’).*”. The system provides one feedback message at a time, adjusting it when a learner attempts to correct their answer. The messages cover a wide range of grammar errors, spelling and capitalization errors. If the system cannot diagnose the error, it falls back to a *default feedback* message: “*This is not what I’m expecting. Please, try again.*”.

4 Evaluation Approach

In this paper, we propose an approach to systematically use authentic data to enhance a rule-based feedback system for semi-open gap-filling grammar exercises and evaluate the generalizability of

¹The system and information about the related projects are available at <https://feedbook.website/>.

improvements. The approach uses two datasets: a training dataset to identify refinement points in a data-driven way, and an unseen testing dataset to assess generalizability.

As shown in Figure 1, we suggest first establishing a baseline by processing authentic data through a pipeline that mimics the feedback system and then annotating the output to evaluate its correctness and granularity. The analysis focuses on three aspects: 1) identifying and correcting faulty rules to improve precision ², 2) extending existing rules to increase recall, and 3) introducing previously missing rules to further improve recall.

After implementing the identified changes and adjusting the system accordingly, the data is processed again to establish improvements in precision and recall. Once a significant improvement has been confirmed, we suggest testing the updated system on unseen data to avoid overfitting.

We demonstrate the approach using the FeedBook, its feedback mechanism, and data from its use in real classrooms.

4.1 Data

The FeedBook has been used in German schools for four large-scale field trials, each focusing on a different aspect of the system. For our analysis, we drew on user data from two consecutive trials (Parrisius et al., 2022; Berens et al., 2024). ³

For a concise analysis, we focused on a single learning target, ‘Questions’, selected due to the complexity of interrogative syntactic structures, their known difficulty for L2 learners, and their presence at all stages of learning (Mackey, 1999). We included only data units from semi-open gap-filling exercises, where typed student answers (SAs) provided valuable insight into actual learner needs by revealing weaknesses in students’ productive grammatical skills (see Appendix E for examples of the exercises). Each log data unit contains SA, TA, and *context*:

SA (userInput): *is*
TA (targetAnswer): *Was*
context: *he late? Yes, he was late.*

We removed units with correct SAs, fully duplicate units, and units where capitalization was the

only issue with the SA as such cases were considered correct during the second data collection.

The two data collections served as the *training* and the unseen *testing* dataset, respectively. For a more precise analysis, we divided each dataset into three subsets, based on the TA length: Word (e.g., *Where, do, is*), Phrase (e.g., *did you do*), and Sentence (e.g., *What does Jenny want to do?*).

In the second data collection, the number of users increased, leading to a much larger number of data units. To simulate one iteration of 10-fold validation per subset, we extracted a stratified random sample for the testing data (see Appendix B). Table 1 summarizes the final dataset sizes. ⁴

	Training			Testing		
	Units	TAs	Ex.	Units	TAs	Ex.
Wrd	720	48	15	80	26	8
Phr	2083	60	14	236	43	14
Sent	2273	48	8	254	43	8
Total	5076	156	37	570	112	30

Table 1: The sizes of training and testing datasets. Wrd: word, Phr: phrase, Sent: sentence, TAs: target answers, Ex.: exercises.

The training dataset contains 5076 data units from 267 students and 37 exercises. In the Sentence subset, seven TAs have alternative correct answers (e.g., *Where are you from?* for *Where do you come from?*). They are not counted as separate TAs but accounted for in the feedback algorithm and our evaluation environment (see Section 4.2). The testing dataset contains 570 data units from 101 students and 30 exercises, with nine and 17 alternative TAs in the Phrase and the Sentence subsets, respectively.

The initial hypothesis generation rule set for questions was inspired by established SLA theories on developmental sequences that postulate that learners acquire grammatical structures in a constrained and ordered manner (Petersen, 2010; Pienemann et al., 1988). These theories provided the conceptual foundation for identifying question-related linguistic phenomena that are both developmentally important and frequently problematic for L2 learners. Building on this foundation, together with an expert teacher, we structurally selected, extended, and prioritized the

²We define precision as provision of incorrect vs. correct specific feedback and recall as specific vs. default feedback.

³Ethical and ministerial approval to collect data for research purposes was granted.

⁴Data is available for download at https://osf.io/3hrud/overview?view_only=ede0c00a7e36489884bd8cf788bd16eb.

Figure 1: Proposed approach for employing authentic logs to evaluate and improve feedback in an ITS system.

rules. As a result, the initial rule set for questions contained eight rules implementing transformations such as missing or incorrect auxiliary verbs or question words, missing question marks, incorrect tense or person agreement of the auxiliary verb “do”, incorrect form of the main verb when an auxiliary is present (see Appendix C). Some rules rely on syntactic dependency, others on the token position in a sentence.

4.2 Methods

As a first step, we created an environment that simulates FeedBook’s feedback generation and provision including the SA pre-processing steps (e.g., string normalization). Unlike the actual system, our simulation takes one TA-SA pair at a time as input, generates hypotheses for the given TA, and then matches the SA with a feedback message. If the TA has alternatives, both the system and our simulation generate hypotheses for all given TA variations.

We ran four simulations to obtain the following performance data for analysis (S - seen, training data, U - unseen, testing data):

- **baseline_S** (training data with initial rules)
- **update_S** (training data with updated rules)
- **baseline_U** (testing data with initial rules)
- **update_U** (testing data with updated rules)

The output included SA, TA, and a respective fine-grained question-specific (QS) feedback label (e.g., “missing question word”). For this initial analysis, we combined all QS feedback into one score. Based on the baseline_S results, we identified rules to refine or add and implemented the changes. Next, we performed a comparative analysis of baseline_S and update_S expecting

an increased proportion of QS feedback and reduced default feedback. Then we compared the baseline_U with the update_U, expecting the same trend as evidence for generalizability to unseen data.

Two expert annotators manually labeled the fine-grained feedback⁵ to evaluate its correctness and report on precision and recall based on the following annotation schema:

- “optimal” – correct error diagnosis (true positives, see Figure 2 a)); or default feedback provided for nonsensical input (true negatives, see Figure 2 b));
- “incorrect” – incorrect specific diagnosis of an error (false positives, see Figure 2 c));
- “unspecific” – default feedback where a specific one could (with a new rule) or should (with an existing rule) have been given (false negatives, see Figure 2 d)).

It is important to point out that “unspecific”, i.e. default feedback should not be considered incorrect but only a less optimal variant of feedback that the system can provide to the students. The diagnostic process for the feedback provision is optimal if the system correctly identifies the specific error contained in the SA. If the system only detects the presence of an error, the process is still considered successful, as immediate correctness feedback is one of the mechanisms by which ITSs achieve learning gains comparable to human tutors (VanLehn, 2011).

To assess the significance of the impact that rule improvements had on system’s performance,

⁵In case of conflict, the feedback was labeled by a third independent annotator and the majority vote was used for the final scores.

	Data unit	Annotation
a)	SA: Who are you doing? TA: What are you doing? FB: INCORRECT_QW	final_label: optimal
b)	SA: rgzrg TA: What are you doing? FB: DEFAULT	final_label: optimal
c)	SA: What are you always watching? TA: What do you always watch? FB: MISSING_AUX	final_label: incorrect
d)	SA: Do you afraid of dogs? TA: Are you afraid of dogs? FB: DEFAULT	final_label: unspecific

Figure 2: Examples of data units and their respective annotations. SA: student answer, TA: target answer, FB: feedback, QW: question word, AUX: auxiliary verb.

we use McNemar’s test with continuity correction (Agresti, 2012).

5 Baseline Evaluation and Rule Set Enhancement

Table 2 shows the raw numbers of the feedback from the baseline_S evaluation as well as the annotated correctness for all three subsets. The inter-annotator agreement, measured using Cohen’s Kappa, is $\kappa = 0.97$, indicates almost perfect agreement (Cohen, 1960; see Appendix D). The corresponding precision and recall scores are summarized in Table 3.

The baseline_S results revealed that the overall success rate of the feedback provision is very high - 94.37%. However, whilst only a small proportion of errors were diagnosed incorrectly (5.63%), a significant proportion did not receive optimal feedback, i.e. a specific diagnosis (59.83%), indicating a substantial need to improve recall. To address this, we closely analyzed both SAs and TAs in each subset. Based on the distribution of linguistic constructs in TAs (see Table 4), we investigated SAs containing errors related to the targeted constructs and observed the following: in all subsets, errors such as incorrect question word, missing or incorrect auxiliary, and incorrect agreement of auxiliary “do” are the most common and are rarely diagnosed correctly (only 10.92% to 27.12% per error type). We summarize the numbers in Table 5.

Further investigation showed that errors such as incorrect agreement of the main verb “be” or its replacement by auxiliary verbs, or missing main verb were not diagnosed due to the lack of respective rules. Moreover, the Phrase and Sentence subsets contained 54 SAs where only word order was incorrect (e.g., *you do have* instead of *do you have*). It was particularly insightful to observe that such malformations as switching the tense forms of auxiliary and main verbs in simple past questions (e.g., *Do you saw?* instead of *Did you see?*) or the conjugation of “be” with the help of “do” (e.g., *does be* instead of *is*) were more common than our experts anticipated. In addition, students often omitted or added tokens to their answers.

The annotations of baseline_S also showed that most cases labeled as “incorrect” received spelling feedback where it should have been default feedback for nonsense SAs (66.81%) or QS feedback (6.64%), i.e., incorrect question word or incorrect auxiliary verb. Although we addressed the latter issue by enhancing the rule set, improving the spell-checking algorithm (not a part of the hypothesis generation) was not in focus for this paper.

Based on these observations, we refined four initial rules (i.e., missing and incorrect auxiliary verb, incorrect agreement thereof, incorrect question word), and added four new rules introducing transformations such as missing main verb, incorrect tense and person agreement of the verb “be”, verb “be” being replaced by verbs “do” or “have”, switching the tenses of auxiliary “do” and main verb in past simple tense. An additional check to account for word-order permutations was implemented.

It is worth noting that in the Phrase and Sentence subsets, 3 and 18 SAs, respectively, were grammatically and semantically correct but did not match any of the provided TAs. The system diagnosed these cases as spelling or default, and thus, they contributed to the counts for “incorrect” and “unspecific” categories. This observation suggests the refinements should include not only the feedback generation rules but also the alternative correct answers or fuzzy-matching. Addressing this was outside the scope of this paper, but is a promising direction for future work and a perfect phenomenon to explore the benefits of LLM-based or hybrid approaches.

Initial rules									
Feedback	QS		Spelling		DF		Total

Incorr. auxiliary	2 / 46	25 / 161	4 / 77
Missing auxiliary	0 / 1	43 / 267	8 / 159

Table 5: Number of selected student errors in baseline_S; diagnosed correctly/total errors made. Top-3 errors per input type are highlighted in bold. QW: question word, agr.: agreement.

grammatical number (the initial rule only transformed the lemma and the tense) and for the *Question Word Replacement Rule* we extended the list of question words based on log data observations.

5.1 Results Update_S

Table 2 shows the raw numbers of the feedback provided in the update_S as well as the annotated correctness for all three subsets. The inter-annotator agreement is $\kappa = 0.98$ (almost perfect agreement). The system with updated rules provided less default feedback (-9.02 percentage points (p.p.)) and more QS feedback (+9.83 p.p.) compared to the baseline_S, suggesting an overall positive effect of the refinements.

Interestingly, the number of “incorrect” cases decreased for the Word and Phrase subsets but increased by six for the Sentence subset. 12 “incorrect” cases in Sentence and one in Phrase received a new “missing main verb” diagnosis in

contrast to the default (or spelling in one case) in the baseline_S. Ten “incorrect” cases in Sentence were diagnosed as “incorrect word order”. These results suggest that the implemented changes are largely beneficial, but might still introduce errors.

Initial rule set	Updated rule set		Total
	✓	✗ + ◆	
✓	1752	23	1775
✗ + ◆	500	2801	3301
Total	2252	2824	5076

Table 6: Contingency table for training data.

Overall, we observed an increase in precision and an even greater increase in recall (see Table 3). The results of McNemar’s test (see Table 6) showed that the improvement of the feedback performance with the updated rule set is statistically significant: McNemar’s $\chi^2 = 433.22$, $df = 1$, p -value $< .0001$, Cohen’s $g = 0.46$ (large effect size).

6 Results of Generalizability Evaluation

Turning now to the testing dataset (U), table 7 shows the raw numbers of the feedback provided in the baseline_U and in the update_U as well as the annotated correctness for all three subsets. The inter-annotator agreement for the two runs are $\kappa = 0.96$ and $\kappa = 0.97$, respectively (almost perfect agreement). The updated rules consistently produced less default feedback (-16.85 p.p.) and more QS feedback (+14.46 p.p.) compared to baseline_U. Although some QS cases became incorrect with the update, the overall “incorrect” feedback decreased (-3.15 p.p.). The corresponding precision and recall scores are summarized in Table 3. These results suggest a positive trend and confirm the observations on the training data.

The results of McNemar’s test (see Table 8) show statistical significance of the improvements on unseen data, indicating good generalizability of the approach: McNemar’s $\chi^2 = 101.68$, $df = 1$, p -value $< .0001$, Cohen’s $g = 0.47$ (large effect size).

7 Discussion

The results show that our data-driven approach substantially improves feedback performance, in particular the specificity of provided feedback. Comparing the baseline and updated datasets, we observe more instances of specific feedback, fewer instances of default feedback, and higher recall

and precision scores. These findings show that even limited rule enhancements motivated by user interaction logs yield notable gains. Thus, regarding **RQ 1**, we find that the authentic logs provided valuable insights into actual learner needs, which, in combination with a thorough analysis of the expected target answers, enabled targeted refinement of the rule set. The evaluation results on the testing data show that the improvements to the rules are stable and, even with unseen data, increase precision and recall of the feedback performance. This suggests a positive answer to **RQ 2**: our data-driven enhancement to rule-based feedback is likely to generalize well and perform similarly on unseen data.

Although the increase in precision and recall was higher on the unseen data, an unexpected outcome, further examination of the unseen dataset identified two causes. One is a higher percentage of incorrect question-specific feedback in baseline_U (3.68%) which allowed for more room for improvement relative to baseline_S (1.26%). A second reason is the simpler linguistic structures in the testing data due to changes to FeedBook’s exercise generation and exercise selection between the first and second data collection, which potentially allowed for better NLP parsing and therefore more accurate diagnoses by the feedback system. Based on these observations, we expect the updated system to perform similarly on unseen data if the aforementioned factors are controlled for or the testing data is sampled from the same dataset as the training data.

Furthermore, the results of our student answer investigations revealed a great variety of errors and misconceptions that are challenging to handle by a system or anticipate in general. We also observed a wider range of errors in full sentence answers, concluding that while our rule-based approach is precise and easily adjustable for shorter gap-fills, an approach using LLMs could be beneficial for longer input.

8 Conclusion and Outlook

In this paper, we evaluated and improved a rule-based feedback mechanism in an ITS using authentic learner interaction logs. Our analysis demonstrated that such real-world data provides valuable insights into actual learner difficulties and can meaningfully guide refinements of rule-based feedback. The targeted rule up-

Initial rules									
Feedback	QS		Spelling		DF		Total		
	✓	✗	✓	✗	✓	◆	✓	✗	✓+◆
Word	18	20	3	3	3	33	24	23	57
Phrase	32	1	33	19	7	144	72	20	216
Sentence	38	0	50	0	0	166	88	0	254
Total	88	21	86	22	10	343	184	43	527
						(60.18%)	(32.28%)	(7.54%)	(92.46%)
Updated rules									
Word	40	0	3	3	3	31	46	3	77
Phrase	70	1	33	19	7	106	110	20	216
Sentence	92	2	50	0	0	110	142	2	252
Total	202	3	86	22	10	247	298	25	545
						(43.33%)	(52.28%)	(4.39%)	(95.61%)

Table 7: Results for initial and updated rules on **testing data**: Raw numbers of provided feedback annotated as optimal (✓), incorrect (✗) and unspecific (◆) per subset (word, phrase, and sentence).

Initial rule set	Updated rule set		Total
	✓	✗ + ◆	
✓	183	4	187
✗ + ◆	115	268	383
Total	298	272	570

Table 8: Contingency table for the testing data.

dates led to a reduction in default and incorrect feedback, while increasing both precision and recall. These improvements generalized well to unseen data, confirming that authentic logs help strengthen rule-based systems while retaining pedagogical control over generated feedback.

Although we focused on improving an existing rule set, the proposed methodological flow has wider potential. Beyond rule-based feedback, future work could apply the same data-driven evaluation approach to LLM-based feedback generation or explore hybrid models that leverage both expert knowledge and data-driven flexibility. Training LLMs on learner data to produce new rules, or applying the approach to other exercise types, linguistic structures, or learner populations, represents promising avenues for future work.

Our work also lays the foundation for a direct comparison between the refined rule-based approach and an LLM-based one. While we argue that rule-based feedback may be particularly advantageous for gap-filling grammar exercises, especially due to its transparency and reliability, this assumption has yet to be empirically tested.

Comparing both approaches within the same evaluation framework will allow a better understanding of their respective strengths and the contexts in which each approach is most suitable.

Finally, although our analysis focused on internal evaluation, authentic data also offers valuable insights for external evaluation by indicating how many learners would benefit from specific refinements. Overall, our findings demonstrate that leveraging real learner data enables systematic, generalizable improvements to feedback mechanisms and supports the development of future feedback technologies in CALL.

9 Limitations

Data. Due to differences in data collection, the data from two periods varied significantly, which might influence the results but was not controlled for in this experiment. The most relevant differences are as follows:

- In terms of feedback, in the first data collection metalinguistic information in the feedback popups was replaced with the default message for some students while others received full access to the metalinguistic information during a field trial. There were no such treatment variations in this regard during the second data collection.
- All the exercises for the first data collection were manually crafted and implemented in the system. Later, however, only the exercise specifications such as vocabulary, grammar

context and others, were designed manually, while the exercises themselves were generated automatically based on these specifications (Heck et al., 2022). As we discuss in Section 7, this may result in more exercises with similar syntactic structures in the testing data and therefore, cause better feedback performance.

- In the first data collection, students had access to all the exercises at once and could select exercises from any difficulty level. In the second data collection, however, an algorithm assigned the most appropriate difficulty level to each student according to their performance (Colling et al., 2023). Such macro-adaptive selection could potentially lead to more students completing easier exercises and, therefore, to more data with simpler linguistic structures in the testing dataset.
- In real-life application, some of the student answer processing (e.g., removal of extra white space before punctuation, replacing characters of one encoding by the ones in another) currently happens in the front-end but did not take place when the training data was collected. Thus, some student answers that the system treated as correct in the second data collection were still included in the first data collection as malformed and contributed to the numbers with incorrect spelling or default feedback in our baseline.
- In contrast to the first data collection, the system from the second data collection does not consider capitalization a potential source of error in order to facilitate tablet and smartphone usage and to avoid over-punishing students on automatic device behavior, i.e. capitalizing initial characters in an input field.

Feedback mechanism. Most of the feedback rules rely on dependency parsing and annotations provided by NLP tools, such as UIMA. However, these tools are sometimes incorrect in their annotations, which can lead to unexpected results, e.g., default feedback for *do – does – did* confusion because of incorrect lemma value in the annotation provided by the UIMA Java SDK 2.9.0 version. We acknowledge that the latest version might yield better results and we encourage the use of a newer NLP pipeline in general.

Rules selection. In this paper, we selected rules to improve based on their performance in

the baseline_S, prioritizing rules that performed poorly with certain linguistic constructs related exclusively to interrogative sentences (e.g., question words or auxiliary verbs in the simple past and simple present tense). However, we acknowledge that another approach to rule selection, for instance, to triage learner errors according to how frequently they go undiagnosed, might have shown even greater gains, especially in recall.

Moreover, many student answers were not ill-formed, but well-formed questions that are incorrect due to the context, exercise instruction, and nature of the exercise itself. We acknowledge that the data units with such student answers had a certain impact on precision and, particularly, recall scores (most of these cases received default feedback). However, the current analysis did not focus on feedback related to, for example, tense confusion or erroneous use of pronouns.

Increasing precision. Most of the incorrect feedback provided in the training baseline was spelling feedback. It was erroneously given to student answers with non-question grammatical issues, answers that contained context (text around the target answer but not part of it), nonsense answers, and only in a few cases to answers with question-specific errors. Increasing the feedback precision by accounting for all the observed issues was out of the scope of this paper, but is a promising venue for further enhancement of the feedback algorithm.

Acknowledgments

This work is based on data from the Interact4School and AI2Teach projects that were financially supported by the German Ministry of Education and Science (BMBF DLR, funding code: 01JD1905A) and by the AIM (Akademie für Innovative Bildung und Management Heilbronn-Franken gemeinnützige GmbH), respectively.

We thank Walid El Hefny for his help with data extraction as well as Daniela Verratti Suoto and Sonja Gelzenleuchter for their thorough annotation efforts. We also thank Matthew Pattemore for his support in revising and polishing the paper and Kate Belcher for insightful discussions and contributions to shaping the final version. Last but not least, we thank the reviewers for their thoughtful comments and constructive feedback.

A Rule Change Example

Figures 3 and 4 provide snippets of simplified pseudocode to illustrate a change from the token-position approach to the syntactic dependency one

in a rule. The example shows *Question Replacement* rule that searches for a question word in a target answer (TA) and, if it identifies one, replaces the question word with a different one from a provided list of question words.

Figure 5 shows the different components and the application flow of a feedback rule in the Feed-Book.

```
[...]
questionWords = "Whose", "Which", "Where",
"Whom", "What", "When",
"Why", "Who", "How"
[...]
isRuleApplicable(Configuration of TA):
    get a stringTA from Configuration
    if stringTA is null
        return false
    split stringTA by white space
    get the firstToken from stringTA
    if firstToken in questionWords
        if lastToken is "?"
            return true
        else return false
    else return false

applyRule(annotatedTA, indexTA):
    get the firstToken from annotatedTA
    replace firstToken with questionWord
    set correct value of firstToken
    set incorrect value of firstToken
    return extended annotatedTA copy
[...]
```

Figure 3: *Question Word Replacement* rule with token-position approach (simplified pseudo-code)

B Sampling Strategy for Unseen Data

As there was more data collected in the second period we did not take the entire dataset for evaluation but instead selected representative samples. We simulated one iteration of a 10-fold validation for each subset to create the testing (unseen) data.

Sampling for each subset contained two steps: 1) Random sample of exercises; 2) Stratified random sample of attempt data units from sampled exercises.

For step 1, to match the same number of exercises present in the training dataset, and thus have a similar distribution of different exercise contexts, we randomly selected exercises from the

```

[...]
isRuleApplicable(Configuration of TA):
    for every dependency in TA span:
        if dependencyType is "advmod" and
           questionWords contains dependent
            return true
    return false

applyRule(annotatedTA, indexTA):
    for every dependency in TA span:
        if dependencyType is "advmod" and
           questionWords contains dependent
            replace dependent
            set correct value of dependent
            set incorrect value of dependent
    return extended annotatedTA copy
[...]

```

Figure 4: *Question Word Replacement* rule with syntactic dependency approach (simplified pseudo-code)

second period data to be included in the testing dataset. For Word, the training dataset contained 15 exercises. However, due to the adaptive exercise selection feature introduced between data collections (see Section 9), there were fewer instances with one-word target answers. Thus, all eight available exercises were included for the Word subset.

In step 2, a stratified sampling approach on the remaining data was conducted with the different exercises as strata. During the sampling, one constraint was implemented: Once an attempt from a student was included in the sample, the entire sequence of attempts for this student and this particular exercise was included to capture entire interaction sequences as present in the training dataset. For Phrase and Sentence, this resulted in minimally more data units included in the sample than calculated according to the 90:10 ratio.

C Feedback Messages

Table 9 provides the set of teacher-crafted feedback messages for question-specific learner errors including such general messages as default, spelling, and capitalization.

Table 10 provides the set of feedback messages for the rules added according to the learner needs identified during profiling of training data.

D Inter Annotator Agreement

Table 11 shows the inter-annotator agreement results for the two independent raters.

E Gap Filling Exercises in FeedBook

Figure 6 shows examples of semi-open gap filling grammar exercises of input types “word”, “phrase”, and “sentence” for learning target “Questions” in FeedBook.

Figure 5: Feedback generation approach in the FeedBook system. Each rule consists of three methods: 1) Check whether the rule is applicable to the TA, i.e. relevant linguistic information is present in the TA to perform a specific transformation (e.g., *Question Word Replacement* is not applicable for “Did you sleep well?” but applicable for “Where did you see him?”); 2) Apply transformations to the TA in order to generate ill-formed and well-formed incorrect variations, and 3) get the error diagnosis for future feedback mapping.

Error	Message
Incorrect question word	Use another question word.
Missing question mark	You’ve forgotten to use the ‘?’.
Missing question word	You’ve forgotten to use a question word.
Missing auxiliary word	You’ve forgotten an auxiliary verb (‘Hilfsverb’, e.g. ‘do’/‘did’).
Incorrect auxiliary word	That’s not the correct auxiliary verb (‘Hilfsverb’).
Auxiliary and main verb are both in past tense	In questions with ‘did’ and a main verb (e.g., “Did you go?”), the main verb needs to be in the infinitive.
Incorrect agreement of auxiliary verb ‘do’	That’s not the correct form of an auxiliary verb (‘Hilfsverb’).
Auxiliary and main verb are both in third person	In questions with ‘does’/‘do’ and a main verb (e.g., “Where does he live?”), the main verb needs to be in the infinitive.
Spelling error	The following words in your answer seem to contain spelling errors: [the word from the student answer with a spelling mistake].
Capitalization error	There is a problem with capitalization in your answer.
Default feedback	This is not what I am expecting - please try again.

Table 9: Teacher-crafted feedback messages for the initial rules under analysis.

Error	Message
Main verb in past tense, auxiliary verb in infinitive	There seems to be a mistake in inflection. Look at this example: “What did you eat for breakfast?” and try to use the same structure in your question. Pay attention to the form of the auxiliary verb (‘Hilfsverb’, e.g. ‘did’) and the main verb.
Missing main verb	You forgot the main verb.
Main verb ‘be’ replaced by an auxiliary verb	You do not need an auxiliary verb (‘Hilfsverb’) here, because the main verb is a form of the verb ‘to be’. Remember to use the correct form of the verb ‘to be’ here.
Incorrect agreement of the verb ‘be’ as an auxiliary or main verb	You should use a different form of the verb ‘to be’.
Incorrect word order	The words in your answer are in the wrong order.

A Bigger Catch: Fine-Grained Curriculum Standards Alignment on the MathFish Benchmark

Xinman Liu, Mayank Sharma, Teah Shi

Stanford University

{xinman, masharma, teah2001}@stanford.edu

Abstract

Most existing math benchmarks for LLMs focus on evaluating correct solutions. In educational settings, however, it is equally important to understand whether LLMs understand the *pedagogical intent* behind math problems, beyond producing the right solution. Tagging curriculum standards is challenging for the same reason: distinguishing fine-grained standards requires understanding subtle pedagogical distinctions. In this paper, we use the MathFish benchmark, which frames alignment as multi-label prediction over 385 Common Core State Standards, to evaluate a three-stage pipeline inspired by baseline failure modes in retrieval and structural reasoning: curriculum-informed hard negatives (M1), a cross-encoder re-ranker (M2), and a ReAct agent paired with an LLM-as-a-judge critic (M3). We additionally evaluate a training-free alternative (A1) combining hybrid sparse-dense retrieval with curriculum graph reranking. M3 achieves 31.3% exact match, roughly $6.5\times$ the three-shot GPT-4-Turbo baseline (Lucy et al., 2024). Error analysis shows that even with these improvements, the pipeline struggles with missing predictions, grade-level misalignment, and sibling confusion, reinforcing that precise curriculum alignment is a fundamentally hard problem in educational NLP.

1 Introduction

Most existing benchmarks for mathematical reasoning in language models ask one question above all else. Can the model get the right answer? Datasets such as GSM8k (Cobbe et al., 2021) and MATH (Hendrycks et al., 2021) test whether a model can solve a problem, but they rarely examine what mathematical competencies that problem actually exercises. In actual K-12 education, though, the categorization of math content matters more than it might seem. Professional curriculum reviewers spend months mapping published math problems to fine-grained pedagogical standards (Lucy

et al., 2024). As LMs are increasingly deployed in classrooms for applications such as generating assessments or tutoring dialogues (Shi et al., 2026), it becomes important to understand whether they actually grasp the pedagogical structure behind math questions or just answer them correctly. The MathFish benchmark (Lucy et al., 2024) was introduced to evaluate exactly this, framing curriculum alignment as a multi-label prediction task over 385 math standards derived from the Common Core State Standards for Mathematics (Common Core State Standards Initiative, 2010). The standards follow the hierarchical structure of CCSSM and are commonly operationalized using resources from Achieve the Core (Student Achievement Partners, 2024). Each math problem is annotated with the standards it assesses, requiring models to predict the relevant labels from the full taxonomy.

This task turns out to be surprisingly **hard**. Many standards share enough surface vocabulary that telling them apart demands genuine understanding of pedagogical intent. When GPT-4 is evaluated with three-shot prompting and no hierarchy hints, exact-match accuracy reaches only 4.8% (Lucy et al., 2024). Most incorrect predictions fall on structurally nearby standards (siblings). In this paper, we present a three-stage pipeline where each stage is motivated by a specific failure mode of the previous one: off-the-shelf embeddings fail to separate pedagogically similar standards, so we train a contrastive bi-encoder with curriculum-informed hard negatives (M1); independent encoding misses fine-grained problem-standard interactions, so we add a cross-encoder re-ranker (M2); and threshold-based selection cannot reason about pedagogical intent, so we attach a ReAct agent with an LLM-as-a-judge critic (M3). We additionally evaluate a training-free alternative (A1) that replaces the learned retrieval front-end with hybrid sparse-dense retrieval and curriculum graph reranking, testing whether structured graph knowledge can substitute

for fine-tuning. Each stage is described in detail in Section 3.

Using M3, we achieve **31.3% exact match, roughly $6.5\times$ the GPT-4 baseline** (Lucy et al., 2024), and discuss the roles of retrieval, reranking, and LLM reasoning in achieving precise alignment, as well as further challenges in performing this task. Our code is available at <https://github.com/yo-lxmmm/a-bigger-catch-mathfish>.

2 Related Work

Early research framed standards alignment as a multi-label text categorization problem. Using manually aligned benchmarks as training data, SVMs with bag-of-words features were applied to map curricular content to standards, showing feasibility but highlighting challenges from short standard texts and substantial lexical overlap between unrelated concepts (Yilmazel et al., 2007). Fine-tuning LMs such as BERT on task-specific educational text substantially improves classification accuracy (Shen et al., 2021), and sentence embedding models have been used to align educational resources with skill taxonomies in a shared embedding space (Li et al., 2024). However, off-the-shelf embeddings remain unreliable for math specifically: cosine similarities between different skill category embeddings often exceed 0.88 because problems share a homogeneous vocabulary of numbers, operations, and geometric terms (Xu et al., 2025). Together, these studies motivate task-specific representation learning as a prerequisite for reliable curriculum retrieval, which is the role M1 is designed to fill.

2.1 Retrieval and Reranking for Educational Tagging

TagRec (V et al., 2021) and TagRec++ (Viswanathan et al., 2022) are the closest prior applications of dense retrieval to education, framing question-to-taxonomy tagging as a similarity-based retrieval problem and showing that retrieval-based models outperform flat multi-class classifiers on hierarchical educational taxonomies. Standard contrastive objectives treat closely related labels as equally negative as completely unrelated ones; hierarchy-aware contrastive learning approaches such as Use All The Labels (Zhang et al., 2022) incorporate label structure directly into the loss. Our hard negative sampling strategy in M1 follows this intuition by

oversampling standards nearby in the ATC graph, reflecting where real confusion occurs. However, bi-encoders encode problems and standards independently, limiting fine-grained interaction between them. Two-stage retrieve-then-rerank pipelines address this limitation: BEIR (Thakur et al., 2021) confirms that cross-encoder re-ranking achieves strong performance across diverse domains, motivating our M2 stage.

2.2 Agentic Reasoning and Graph-Augmented Retrieval

The ReAct framework (Yao et al., 2023) allows an LLM to interleave reasoning steps with tool calls, grounding decisions in external knowledge rather than parametric memory alone. Our M3 stage pairs a ReAct agent with an LLM-as-a-judge critic (Zheng et al., 2023) that prunes the candidate set before committing to a final prediction. As a training-free alternative, A1 replaces the learned retrieval front-end with a hybrid sparse-dense retriever (Luan et al., 2021) combining BM25 (Robertson and Zaragoza, 2009) with dense embeddings, reranked via GraphRAG (Edge et al., 2025). Recent work in educational retrieval (Jain et al., 2025) shows that graph-augmented retrieval generates more relationally coherent responses to curriculum-level queries than flat vector-based RAG, supporting the graph reranking design in A1.

2.3 The MathFish Benchmark

Our work builds directly on MathFish (Lucy et al., 2024), which frames curriculum alignment as multi-label prediction over 385 CCSS standards organized in a four-level hierarchy (grade, domain, cluster, standard) with 1,040 conceptual links in the Achieve the Core coherence map. Even GPT-4 with three-shot prompting achieves only 0.048 exact-match accuracy, and errors are structured rather than random: performance degrades as distractor standards become conceptually closer to the correct one, particularly within shared domains or ATC graph neighbors. This structured error pattern directly motivates our pipeline design—curriculum-informed hard negatives in M1 target the confusion clusters identified in MathFish’s error analysis, and the ReAct agent in M3 is equipped with tools to explicitly traverse the ATC graph during reasoning.

3 Approach

Figure 1: Overview of our pipeline. M1 (top left) trains a contrastive bi-encoder with curriculum-informed hard negatives to retrieve top-20 candidate standards from a shared embedding space. M2 (middle left) re-ranks the top-20 candidates using a roberta-base cross-encoder that jointly scores each problem-standard pair. A1 (top right) is a training-free alternative that replaces M1 and M2 with sparsedense hybrid retrieval followed by ATC curriculum graph reranking. All pipelines pass their top candidates to M3 (bottom), a ReAct agent powered by gemini-2.0-flash that iteratively reasons over standard descriptions and curriculum graph neighbors, followed by an LLM-as-a-judge critic that prunes the final prediction set.

3.1 Contrastive Bi-Encoder with Hard Negatives (M1)

For our first stage, we frame standard alignment as retrieval over 385 candidates without hierarchy hints, and adopt a bi-encoder architecture

for its ability to precompute all standard embeddings and retrieve efficiently. The encoder uses BAAI/bge-large-en-v1.5 (335M parameters) as a shared transformer backbone, with separate 256-dimensional linear projection heads for problems and standards. All embeddings are L2-normalized and scored by dot product. Given a problem embedding $\mathbf{q} = g_p(\text{enc}(x))$, a positive standard embedding $\mathbf{s}^+$, and n hard negatives $\{\mathbf{s}_j^-\}_{j=1}^n$, the model minimizes the InfoNCE contrastive loss

$$\mathcal{L}_{\text{bi}} = -\log \frac{\exp(\mathbf{q} \cdot \mathbf{s}^+ / \tau)}{\exp(\mathbf{q} \cdot \mathbf{s}^+ / \tau) + \sum_{j=1}^n \exp(\mathbf{q} \cdot \mathbf{s}_j^- / \tau)} \quad (1)$$

where τ is the temperature parameter controlling the sharpness of the similarity distribution. What distinguishes our approach is **curriculum-informed hard negative sampling**. MathFish’s error analysis reveals that model confusions follow predictable structural patterns along the ATC hierarchy. We therefore construct hard negatives that reflect where real confusion occurs. For each (problem, positive standard) pair, we sample $n = 8$ negatives from the curriculum graph following a fixed ratio of 40% siblings (same cluster), 30% conceptual neighbors (ATC coherence links), 20% grade-adjacent standards (± 1 grade), and 10% random, excluding all gold standards for that problem. This ratio was chosen to approximate the distribution of structured confusions reported in the MathFish error analysis (Lucy et al., 2024), where sibling and conceptual-neighbor errors account for the majority of misclassifications. At inference, each problem is encoded and scored against all 385 precomputed standard embeddings, returning the top- k candidates.

3.2 + Cross-Encoder Re-Ranking (M2)

Our second stage builds on the bi-encoder (Section 3.1) by adding a cross-encoder re-ranker that jointly processes each (problem, standard) pair through full bidirectional attention. While the bi-encoder retrieves candidates efficiently, it encodes problems and standards independently, limiting the depth of interaction between them. The cross-encoder addresses this, returning the top- n re-ranked candidates as the final prediction.

We use roberta-base (125M parameters) with a binary classification head that outputs a relevance score $\hat{y}_{ij} \in [0, 1]$ for each candidate pair (x_i, s_j) . For each of the bi-encoder’s top- k candidates ($k = 20$),

the problem text and standard description are concatenated into a single input sequence and passed through the full transformer. The model is trained with binary cross-entropy loss

$$\mathcal{L}_{\text{re}} = -\frac{1}{|P|} \sum_{(x_i, s_j) \in P} [y_{ij} \log \hat{y}_{ij} + (1 - y_{ij}) \log(1 - \hat{y}_{ij})] \quad (2)$$

where $y_{ij} \in \{0, 1\}$ indicates whether standard s_j is a gold alignment for problem x_i . Training pairs come from the trained bi-encoder’s top-20 predictions on the training set; gold standards that appear in this candidate list serve as positives, and the rest as negatives. At inference, the cross-encoder scores all 20 bi-encoder candidates per problem, re-ranks them by score, and returns the top- n ($n = 5$) as the final prediction. The two-stage pipeline separates the retrieval task, which must search efficiently across all 385 standards, from the re-ranking task, which can afford deeper cross-attention over a focused candidate set.

3.3 + ReAct with LLM-as-a-judge (M3)

Our third stage builds directly on the first two (Sections 3.1 and 3.2), reusing the trained bi-encoder and cross-encoder as the retrieval and reranking front-end, then attaching a ReAct-based LLM agent (Yao et al., 2023) and an LLM-as-a-judge critic (Zheng et al., 2023) to the cross-encoder’s top-5 output. This replaces threshold-based top- n selection with deliberative multi-step reasoning over the candidate set, addressing the limitation that the retrieve-then-rerank pipeline lacks the capacity to identify the precise gold set.

Agent. The cross-encoder’s top-5 candidates are passed as the initial candidate list to a ReAct agent (Yao et al., 2023) powered by gemini-2.0-flash-001 on Vertex AI (see Appendix A.1). The agent reasons over the candidate set through repeated THOUGHT $\rightarrow$ ACTION $\rightarrow$ OBSERVATION cycles, up to a maximum of 12 steps per problem. At each cycle, the agent assesses whether the current candidates sufficiently capture the problem’s mathematical intent before invoking one of three tools: `get_standard_detail` to retrieve a standard’s full description; `get_related_standards` to explore sibling and conceptual neighbors in the curriculum graph; or `search_standards` to issue a new lexical query when candidates appear misaligned. Each tool response is returned as an observation, informing the next reasoning step. Once the agent determines a final alignment, it ends with `Final Answer: <standard IDs or none>`.

Critic. An LLM-as-a-judge critic (Zheng et al., 2023) powered by the same model (gemini-2.0-flash-001) prunes the predicted standard set (see Appendix A.2). Given the problem and the agent’s predictions with their full descriptions, the critic returns the smallest subset that directly matches the mathematical skills being assessed, or none if no candidate clearly aligns. The final prediction is formed by intersecting the critic’s output with the agent’s original set, guarding against hallucinated identifiers.

3.4 Hybrid Retrieval with Graph Reranking and ReAct Agent (A1)

We also explore a training-free alternative (A1) which replaces the trained bi-encoder and cross-encoder with a training-free hybrid retriever and curriculum graph reranker while reusing the same ReAct agent and critic from Section 3.3, serving as a training-free comparison to the pipelines above.

Retrieval and reranking. Standards are indexed via a sparse-dense hybrid retriever (Luan et al., 2021) combining BM25 (Robertson and Zaragoza, 2009) and all-MiniLM-L6-v2, returning $k = 25$ candidates per problem. These are reranked by assigning each candidate a base score $\frac{1}{1 + \text{rank}}$ and a coherence bonus computed against the top-5 retrieved candidates as seeds. For each (candidate, seed) pair we apply a priority cascade consistent with the ATC hierarchy, with weights reflecting the relative strength of each proximity signal: +0.10 for a shared CCSSM cluster (stopping further seed comparisons), +0.05 for a shared domain code, or +0.03 for a shortest path of ≤ 2 hops on the undirected ATC coherence graph, with domain and graph bonuses accumulating across seeds. All 25 reranked candidates are then passed to the ReAct agent and critic, providing a broader pool than M3’s top-5. This architecture was selected after evaluating several retrieval variants on a 100-problem development subset (Appendix B), where graph reranking over hybrid-retrieved candidates outperformed sparse, hybrid, and graph-first retrieval-only alternatives.

4 Experiments

4.1 Dataset

We use MathFish (Lucy et al., 2024)¹, a dataset of approximately 21,776 math problems (13,065 train

¹<https://huggingface.co/datasets/allenai/mathfish>

/ 4,356 dev / 4,355 test) drawn from Illustrative Mathematics and Fishtank Learning curricula, each labeled with fine-grained Common Core State Standards (CCSS). The 385 standards are organized hierarchically across four levels (grade $\rightarrow$ domain $\rightarrow$ cluster $\rightarrow$ standard), with 1,040 conceptual connections between them and natural language descriptions provided for each. Using ATC standard metadata², we filter to problems containing at least one *Addressing* or *Alignment* label, yielding 5,956 training, 1,942 development, and 2,025 test problems. Following the evaluation protocol of the original MathFish paper (Lucy et al., 2024), which reports all results on its evaluation set rather than a held-out test split, we report on the development set throughout to enable direct comparison with the baseline. The bi-encoder and cross-encoder were trained exclusively on the filtered training set; the A1 variant selection (Appendix B) used a separate 100-problem subset of the development data, and no other hyperparameters were tuned on this set. An example problem and its associated standard labels is shown in Appendix C. Label distribution is skewed: across the 584 standards with at least one training example, n_s ranges from 1 to 139 (median 11, mean 15.0). 20.7% of standards have fewer than 5 training examples, and 44.0% have fewer than 10, reflecting the uneven coverage of K-12 curricula across open educational resources (see Appendix D for the full distribution).

4.2 Evaluation

We evaluate using the following metrics: *Exact Match* requires the predicted standards to exactly match gold; *Weak Accuracy* requires at least one overlap. *Micro/Macro F1* capture token-level and standard-level agreement. *Ret* and *Rerank* report recall@5 before and after reranking (cross-encoder for M2/M3, curriculum graph for A1). *GraphDist* measures the average minimum graph distance between predicted and gold standards in the ATC graph ($\downarrow$ better), and *SibConf* measures the fraction of errors landing on a same-cluster sibling ($\downarrow$ better). *Avg Pred* tracks the average number of predicted standards per problem.

4.3 Experimental Details

Bi-Encoder (M1). We initialize from BAAI/bge-large-en-v1.5 (335M parameters) and train on 5,956 problems using AdamW (learning rate $2 \times$

10^{-5} , batch size 16) for 15,000 gradient steps with temperature $\tau = 0.03$ and $n = 8$ curriculum-aware hard negatives per positive. The best checkpoint is selected by minimum validation loss. Training uses FP16 on a single NVIDIA H100 (80 GB) and completes in approximately 50 minutes.

Cross-Encoder Re-Ranker (M2). We fine-tune roberta-base (125M parameters) for 3 epochs using AdamW (learning rate 2×10^{-5} , batch size 32, max sequence length 256). Training pairs are constructed by running M1 on the training set with $k = 20$, yielding 119,120 scored pairs per epoch and 11,169 gradient steps total. Training completes in approximately 20 minutes on the same H100.

ReAct Agent and LLM-as-a-Judge (M3). M3 requires no training and operates at inference time. Both the ReAct agent and LLM-as-a-judge use gemini-2.0-flash-001.

Hybrid Retriever and Graph Reranker (A1). A1 also requires no training. BM25 sparse retrieval is combined with dense embeddings from all-MiniLM-L6-v2 and candidates are re-ranked using the ATC curriculum graph via GraphRAG before being passed to the same agentic reasoning mechanism as M3.

4.4 Results

Table 1 presents the main results for all pipeline stages and the training-free alternative against the results of three-shot GPT-4-Turbo under self-guided tree traversal reported in the original MathFish paper (Lucy et al., 2024) as the baseline; all evaluated on the same development set (Addressing/Alignment labels only).

The curriculum-aware contrastive bi-encoder (M1) achieves strong retrieval coverage with 20 standards per problem. Adding the cross-encoder re-ranker (M2) tightens the prediction set to 5 candidates and cuts graph distance from 4.24 to 2.42, confirming that cross-attention over concatenated problem-standard pairs captures alignment signals that independent embeddings miss. Both M1 and M2 reach 0.000 exact match despite strong weak accuracy, which is expected given that predicting 20 and 5 candidates respectively against a gold average of 1.47 makes exact match nearly impossible by construction—these are fixed-size prediction sets, not threshold-based ones. A fairer evaluation of reranking alone would apply a score threshold to M2’s cross-encoder outputs to produce a variable-size prediction set; we leave this to future work and note that the single-pass critic (28.4% EM)

²<https://huggingface.co/datasets/allenai/achieve-the-core>

Table 1: Main results on the full Addressing/Alignment-filtered development set (1,942 problems). — denotes metrics not reported.

Method	Accuracy				Recall@5		Graph Quality		Avg Pred*

A1: Hybrid + Graph Rerank + ReAct	0.275	0.541	0.401	0.432	0.271	0.311	1.047	0.100	1.438

[†]Three-shot GPT-4-Turbo under self-guided tree traversal, as reported in the original MathFish paper (Lucy et al., 2024); evaluated on the same development set (Addressing/Alignment labels only).

*Gold average = 1.47 for the A+A filtered set.

provides a practical estimate of what M2’s candidate pool can support with a downstream selector. This confirms that retrieval and reranking alone are insufficient without a mechanism to identify the precise gold set and reason over pedagogical intent.

As demonstrated in M3, attaching the ReAct agent and critic to M2’s top-5 candidates produces the largest gain in the ablation: exact match rises from 0.000 to 0.313, roughly 6.5 times the three-shot GPT-4-Turbo baseline (0.048) (Lucy et al., 2024). The agent’s multi-step reasoning (e.g., inspecting standard descriptions, exploring graph neighbors, and invoking the critic to prune over-predictions) converts a ranked list into a substantially more precise prediction set, reducing average predictions from 5.00 to 1.37 (close to the gold average of 1.47) and achieving the best Micro-F1 (0.455) and Macro-F1 (0.478) across all stages and the alternative. M3 also achieves the best graph distance at 0.93, suggesting that the cross-encoder’s structurally tightened candidate pool effectively guides the agent toward predictions that are close in the curriculum graph even when they do not exactly match gold.

To situate the contribution of fine-tuned retrieval, we compare M3 against A1. Despite passing a larger reranked candidate pool to the agent (top-25 vs. top-5), A1 achieves lower exact match (0.275 vs. 0.313) and higher graph distance (1.047 vs. 0.93). The performance gap is further reflected in recall at the top-5 candidate level: A1’s untuned hybrid retriever achieves retrieval recall of only 0.271, which improves marginally to 0.311 after graph reranking. In contrast, M3’s fine-tuned bi-encoder achieves retrieval recall of 0.632, preserved and improved to 0.688 after cross-encoder reranking. We note a confound in this comparison: A1 passes 25 candidates to the agent while M3 passes only 5, meaning the

gap could reflect lower retrieval recall, a larger and noisier candidate pool confusing the agent, or both. We leave a controlled ablation varying candidate pool size to future work, but note that A1’s retrieval recall at top-5 (0.311) is already substantially lower than M3’s (0.688), suggesting retrieval quality is the primary driver.

To further isolate the contribution of the ReAct agent’s iterative tool use from simply having a zero-shot pruning LLM call, we evaluated a zero-shot single-pass critic applied directly to M2’s top-5 using the same model and prompt as M3. This ablation achieves 28.4% exact match in 48 minutes (vs. 2.64 hours for M3), indicating that the trained retrieval pipeline (M1 and M2) accounts for the majority of the improvement over the prompting-only baseline, with the ReAct loop and tool use contributing a further +2.9 percentage points and meaningfully tighter graph distance (0.929 vs. 0.981) at the cost of additional inference time.

We note that M3 uses gemini-2.0-flash-001 while the baseline uses GPT-4-Turbo, confounding pipeline design with model choice. The A1 pipeline uses the same Gemini backbone as M3 yet achieves only 0.275 exact match vs. M3’s 0.313, and the single-pass critic ablation with Gemini already reaches 0.284 without any ReAct loop, together suggesting the retrieval pipeline contributes independently of the LLM backbone. The D* ablation (Appendix B) further confirms that model choice matters within our framework. We acknowledge that cleanly isolating the pipeline contribution would require holding the backbone constant, which we leave to future work.

In terms of computational cost, over the full 1,942-problem development set, M3 completes in 2.64 hours (4.89 s/problem), averaging 4.00 Gemini API calls per problem (approximately 3 ReAct steps plus 1 critic call); A1 is slightly slower at 5.38

s/problem (2.90 h total), averaging 4.54 calls per problem. Approximate API cost is \$2.00-\$2.50 for M3 and \$3.00-\$3.50 for A1 across the full development set, suggesting both pipelines are deployable at practical scale.

5 Analysis

To better understand where and why our systems succeed and fail, we analyze performance across curriculum strata, error patterns, and system behaviors beyond aggregate metrics.

Performance across curriculum strata. Examining the results for M3 (the best-performing configuration), performance varies substantially across grade levels and domains (Tables 5 and 6 in Appendix E). Exact match is strongest at early elementary grades (K-2: 0.27-0.30) and decreases toward upper elementary and secondary levels, reaching its lowest at grade 5 (0.12) and high school (0.13). Domain-level results show similar variance: Geometry (0.30) and Number & Operations in Base Ten (0.32) achieve the strongest performance, while Functions (0.09) and Fractions (0.10) the weakest. Such variance is consistent with the original MathFish paper which reports exact accuracy ranging from 0.151 (Counting & Cardinality) to 0.011 (Functions) for GPT-4 (Lucy et al., 2024), suggesting domain difficulty reflects intrinsic properties of the task. These grade- and domain-level patterns are reflected in the systematic failure modes we characterize below.

Label frequency and performance. To disentangle whether performance gaps reflect pedagogical difficulty or data sparsity, we examine the relationship between per-standard training frequency and M3 exact match (see Appendix D). At the problem level, we find a modest but significant correlation between training frequency of the rarest gold standard and exact match ($\rho = 0.234$, $p < 10^{-24}$): problems whose gold standards appear rarely in training (Q1, $n_s \leq 10$) achieve 14.8% EM, compared to 44.9% for problems with frequently-occurring standards (Q4, $n_s \geq 31$). However, when examined at the per-standard level directly, correlating each standard’s training frequency with its conditional exact-match rate across development problems, the relationship disappears entirely ($\rho = -0.016$, $p = 0.894$, over 76 standards with ≥ 10 development problems). This dissociation suggests that the problem-level frequency effect reflects the intrinsic difficulty of problems that hap-

pen to target rare standards, rather than the model simply failing due to insufficient training signal for those standards. Pedagogical subtlety and data sparsity are thus partially confounded in this benchmark, and both likely contribute to the performance gaps we observe.

Error analysis. Qualitative error analysis of M3’s failure cases reveals three major error patterns. First, *incomplete prediction*: the system often identifies a primary standard but misses additional relevant ones. For example, for a problem asking students to graph a quadratic function and annotate its features, the agent predicts F-IF.B.4 (interpret key features of graphs and tables, and sketch graphs showing key features given a verbal description of the relationship) but misses F-IF.C.7a (graph linear and quadratic functions and show intercepts, maxima, and minima), despite the problem explicitly requiring graphing these elements. This pattern suggests the agent stops after identifying the most salient standard without verifying completeness. It also triangulates with the low exact match at high school (0.13) where problems frequently align to multiple standards (Table 5 in Appendix E). A targeted fix for future work could be an explicit verification prompt after finalization: “Are there additional standards that also apply? Check siblings and related standards before finalizing.”

Second, *grade-level misalignment*: the system predicts conceptually related standards at the wrong grade level. For example, a problem presenting a linear relationship $y = 3x + 6$ and asking students to notice patterns falsely received the high school standard prediction F-IF.B.4 (interpret key features of graphs and tables given a function modeling the relationship between two quantities), rather than the 8th grade standard 8.F.B.4 (construct a function to model a linear relationship from a table). Because the system lacks explicit grade-level calibration, and that standards across grades often share closely overlapping descriptions due to the spiral nature of math curricula (where later standards build upon earlier ones) (Ireland and Mouta, 2020), it fails to recognize that 8.F.B.4 emphasizes constructing linear functions from tables as an introductory concept, while F-IF.B.4 involves more sophisticated interpretation of more diverse functions and relationships. Future work could incorporate grade-level filtering or an explicit complexity classification step.

Third, *sibling confusion*: the system still con-

flates structurally adjacent but pedagogically distinct standards within the same cluster. For instance, for a problem asking which scenarios require multiplying $\frac{1}{8} \times \frac{2}{5}$, the agent predicts 5.NF.B.4 (apply and extend previous understandings of multiplication to multiply fractions) when the gold includes 5.NF.B.6 (solve real world problems involving multiplication of fractions and mixed numbers). In this case, while both standards share the same parent cluster (5.NF.B), there is a distinction between *applying* the operation versus *solving* contextualized problems requiring it. This validates the MathFish paper finding that models predict labels that are “close to ground truth, but differ in subtle ways” (Lucy et al., 2024), and also explains the weak performance on Functions (0.09) and Fractions (0.10) as domains with dense clusters of similar-sounding standards. A targeted improvement could be to augment the `get_standard_detail` tool of the ReAct agent with contrastive descriptions for common confusion pairs.

Implications for practitioner workflows. The pipeline offers two natural operating points for educators. M2’s top-5 ranked list (weak accuracy 0.688) supports a *suggest-and-verify* workflow in which a reviewer scans a short candidate set rather than searching across all 385 standards manually. M3’s variable-size output (exact match 0.313, weak accuracy 0.589, graph distance 0.93) supports a *draft-tagging* workflow in which the system proposes an initial alignment that humans then audit. Because M3’s graph distance of 0.93 means that even incorrect predictions typically land within the same cluster or an adjacent one, the expected correction effort is a local adjustment (e.g., swapping a sibling standard) rather than a full re-search of the taxonomy. From an instructional design perspective, not all error types carry equal cost: grade-level misalignment is arguably the most consequential because it mistargets developmental appropriateness, whereas sibling confusion preserves the correct instructional focus area, and incomplete prediction falls between the two since the primary standard is usually identified. These distinctions suggest that future deployment should surface confidence signals alongside predictions so that reviewers can prioritize verification effort accordingly.

Curriculum alignment as a fundamentally hard problem. These results underscore that curriculum alignment is harder than mathematical rea-

soning. Solving a problem requires producing a correct answer, but aligning it to standards requires inferring the pedagogical intent behind its construction, the specific competencies it targets, and how those relate to structurally adjacent standards in the curriculum hierarchy (Lucy et al., 2024; Sonkar et al., 2024). The spiral nature of math curricula (Ireland and Mouthaan, 2020), where later standards build upon earlier ones with overlapping descriptions, further compounds this difficulty. This explains why embedding-based retrieval and reranking is insufficient even with strong fine-tuned encoders (Xu et al., 2025) and why even our best system with agentic reasoning capabilities achieves only 31.3% exact match. Nonetheless, it is worth noting that out of the cases with identified errors, more than half of them achieve weak match, and M3’s graph distance of 0.93 already substantially improves over GPT-4’s 1.90 (Lucy et al., 2024), suggesting the system is frequently in the right neighborhood. This raises the question of whether exact match is the right criterion in the first place: curriculum standards alignment requires judging whether a problem enables students to learn the “full intent” of a standard—a nuanced judgment that Lucy et al. (2024) suggest professional curriculum reviewers may not always make consistently, though the degree of inter-annotator disagreement remains unquantified in the literature. Future work should move beyond binary exact match toward evaluation protocols that assign partial credit weighted by curriculum proximity, and measure human-human and human-AI agreement rather than accuracy against a single gold standard, better reflecting the inherently subjective nature of curriculum alignment.

6 Conclusion

We studied automated curriculum alignment on the MathFish benchmark, testing whether training-based retrieval and agentic reasoning can improve upon prompting-only baselines. Our ablation shows that contrastive retrieval (M1) and cross-encoder re-ranking (M2) provide strong candidate coverage but cannot predict exact matching curriculum standard sets on their own, both producing 0.000 exact match. This is expected given that their prediction sets are fixed at 20 and 5 candidates respectively, far exceeding the gold average of 1.47. Attaching a ReAct agent and LLM-as-a-judge critic (M3) raises exact match to 0.313,

approximately 6.5 times the GPT-4-Turbo baseline (Lucy et al., 2024). Notably, a single-pass LLM-as-a-judge critic without the ReAct loop already achieves 28.4%, reflecting that M1+M2’s role is to transform the 385-way alignment problem into a focused pruning task over a small, high-quality candidate set, in contrast to the prompt-only baseline (Lucy et al., 2024), which requires the LLM to navigate the full taxonomy unaided. The ReAct loop’s iterative tool use then adds a further +2.9 percentage points on top.

Limitations

As demonstrated, even our best system achieves only 31.3% exact match, and error analysis reveals three systematic failure modes: incomplete prediction, grade-level misalignment, and sibling standards confusion. These failures are partly structural: the spiral nature of math curricula means that standards across grades deliberately share overlapping language, making grade-level disambiguation fundamentally harder than lexical similarity would suggest. The system also has no mechanism to reason about the cognitive demand or instructional context of a problem, both of which human reviewers draw on when distinguishing, for example, a standard targeting procedural fluency from one targeting conceptual understanding within the same cluster. Additionally, the 40/30/20/10 hard negative sampling ratio in M1 is a fixed heuristic informed by prior error analysis rather than an empirically optimized hyperparameter, and we leave ablation of this ratio to future work. A related concern is that sibling standards sampled as hard negatives may occasionally be true positives for a given problem, potentially teaching the bi-encoder to over-suppress genuinely related standards and contributing mechanistically to the incomplete prediction failure mode we identify in Section 5. Quantifying and filtering contaminated negatives is an important direction for future work. Finally, the agent and critic in M3 share the same underlying model, limiting critic independence: while the asymmetric prompting—the agent explores, the critic prunes—produces empirically observable reduction in predictions (5.00 to 1.37), systematic errors rooted in the model’s parametric representation of CCSS standards, such as grade-level misalignment and sibling confusion, are unlikely to be caught by a critic sharing those same representations. Future work should explore using a different model family

or a trained discriminative verifier as the critic.

Beyond the model itself, exact match may not be the right evaluation criterion for this task. Curriculum alignment is inherently a judgment call: while Lucy et al. (2024) note qualitatively that professional reviewers may disagree, neither that work nor ours quantifies inter-annotator agreement directly, and establishing a human agreement ceiling remains important future work. Future work should also develop evaluation protocols that assign partial credit weighted by curriculum proximity rather than treating a single gold annotation as ground truth. On the modeling side, incorporating grade-level signals, contrastive standard descriptions for common confusion pairs, and explicit completeness verification steps could address the identified failure modes more directly.

Ethical Considerations

Curriculum alignment systems used in educational settings have real consequences for both students and teachers. Incorrect standard predictions can result in poorly targeted instruction or assessments, and may disproportionately impact students in under-resourced schools where automated tools are more likely to replace expert review. We advise against deploying these systems without human oversight. In practice, they should be co-developed with educators and curriculum specialists to ensure the outputs are pedagogically sound and interpretable, and they should be evaluated against the judgment of domain experts rather than relying solely on proposed metrics.

A Prompts for ReAct Agent with LLM-as-a-Judge

A.1 ReAct agent prompt

◇ ReAct system prompt for M3 and A1

You are an expert at aligning math problems to Common Core State Standards.

Task. Given a math problem and (optionally) an initial list of candidate standards, decide which standards the problem aligns with. A problem may align to multiple standards if it addresses multiple concepts or skills. You may use tools to:

1. `get_standard_detail(standard_id)` – fetch full description and metadata for one standard.
2. `get_related_standards(standard_id, relation)` – fetch related standards (siblings in same cluster or conceptual links; relation is “siblings” or “conceptual”).
3. `search_standards(query)` – when the initial candidates look wrong, search again with a short phrase (e.g., “fractions with like denominators”, “linear equations grade 8”) to find more candidates.

Respond in this exact format at every step:

- Thought: <your reasoning>
- Action: <exactly one tool call: `tool_name(arg1, arg2)`>

When you are done and ready to give the final set of standard IDs:

- Thought: <brief reasoning summarizing why these standards are correct and complete>
- Final Answer: <comma-separated list of standard IDs, e.g., 7.NS.A.1c, 7.EE.A.1, or none>

Rules.

- Only output standard IDs that appear in tool results (initial candidate list, `get_standard_detail`, `get_related_standards`, or `search_standards`). Do not invent new IDs.
- A problem aligns with a standard only if students could reasonably learn the full intent of that standard from the problem, not just see a related idea in passing.
- Include all standards that the problem truly aligns with; if a problem teaches multiple concepts, list all relevant IDs.
- If you are not confident that any standard clearly meets this bar, output Final Answer: none.
- Use exact CCSS IDs (e.g., 7.NS.A.1c, A-REI.D.11).

A.2 Critic prompt

◇ Critic prompt (LLM-as-a-judge) for pruning predictions for M3 and A1

You are an expert at aligning math problems to Common Core State Standards.

You will be given:

1. A math problem.
2. A list of *candidate* standards (ID + description) that another agent thinks might apply.

Your job is **only** to prune this candidate list:

- You may only select from the given IDs. Do *not* invent or add new standard IDs.
- A problem aligns with a standard only if it can enable students to learn the full intent of that standard’s description, not just mention a related idea in passing.
- Choose the smallest subset of IDs that directly match what the problem is assessing or teaching.
- If two standards are clearly redundant (same idea, different grade bands), keep the best match and drop the others.
- If you are not confident that any candidate clearly meets this bar, prefer none over guessing. If none of the candidates are good matches, you may output none.

Respond in this format **only**:

- Thought: <your reasoning>
- Final Answer: <comma-separated list of chosen IDs, or ‘none’>

B Preliminary Pipeline Variants (100-Problem Development Subset)

All variants A–F use `gemini-2.0-flash-001` with the same ReAct agent and critic, and pass top-25 retrieved candidates to the agent; only the retrieval stage (and optionally a verifier) differs. Each was evaluated on a fixed 100-problem subset of the Addressing/Alignment-filtered development set (all problems have non-empty gold labels; $N = 100$ for all rows).

- A No retrieval (no RAG).
- B BM25 only.
- C Hybrid retrieval (BM25 + dense).
- D Hybrid retrieval + ATC curriculum graph reranking (cluster and domain proximity).

- E** Graph-first retrieval: hybrid seeds ($k_{\text{seed}} = 3$) expanded via the ATC curriculum graph.
- F** Same as E, with an additional per-standard verifier (Yes/No) before the critic.

Model ablation. Variant D* replicates pipeline D but substitutes gemini-2.5-flash-lite for gemini-2.0-flash-001 to ablate the effect of model choice; it is substantially slower and predicts more standards per problem on average, but modestly improves weak accuracy.

Table 2 reports results; **the selected pipeline is Variant D.**

Table 2: Preliminary results on the fixed 100-problem development subset ($N = 100$). Bold indicates best per metric. Graph Distance (GraphDist) and Sibling Confusion Rate (SiblingConf) are graph-based alignment quality metrics where lower is better.

Variant	Exact	Weak Acc	Micro F1	Macro F1	R@5	R@20	GraphDist	SiblingConf
A	0.26	0.48	0.38	0.39	—	—	1.13	0.10
B	0.23	0.48	0.36	0.37	0.25	0.43	1.23	0.15
C	0.28	0.59	0.42	0.46	0.37	0.69	0.95	0.15
D	0.30	0.64	0.46	0.50	0.39	0.70	1.13	0.15
E	0.24	0.57	0.41	0.43	0.28	0.48	1.04	0.14
F	0.30	0.54	0.41	0.44	0.29	0.46	1.11	0.17
D*	0.17	0.70	0.35	0.43	0.40	0.70	1.49	0.08

Variants A–F use gemini-2.0-flash-001; D substitutes gemini-2.5-flash-lite on the selected pipeline (D) as an ablation on model choice.

C Example from MathFish Benchmark (Lucy et al., 2024)

◇ Example

Problem. Consider a circle with center O and let P be a point on the circle. Suppose L is a tangent line to the circle at P , that is, L meets the circle only at P . Show that $\overline{OP}$ is perpendicular to L .

Output Standards:

- **G-C.A.2** Identify and describe relationships among inscribed angles, radii, and chords (e.g., tangent line perpendicular to radius).
- **G-CO.C.9** Prove theorems about lines and angles (e.g., tangent perpendicular to radius).
- **G-CO.A** Know precise definitions of angle, circle, line, parallel line, and line segment.

D Label Frequency Distribution

Table 3 reports the distribution of training examples per standard in the Addressing/Alignment-filtered training set. Of the 385 standards in the full CCSS taxonomy, 584 appear at least once across the 5,956 training problems.³ Distribution is right-skewed: the median standard has 11 training examples, but 20.7% have fewer than 5 and 44.0% have fewer than 10, while the most frequent standard appears in 139 problems.

³The count exceeds 385 because multi-label problems increment each appearing standard, and sub-standard labels introduced via inheritance (Appendix A.2 of Lucy et al. (2024)) expand the effective label set.

Table 3: Distribution of training examples per standard (n_s) across standards with at least one training example in the Addressing/Alignment-filtered training set (5,956 problems).

Training examples (n_s)	# standards	% of standards
< 2	32	5.5%
2–4	89	15.2%
5–9	136	23.3%
10–19	174	29.8%
20–50	114	19.5%
> 50	39	6.7%
Total	584	100%

Summary statistics: min = 1, median = 11, mean = 15.0, max = 139.

Table 4 reports M3 exact match stratified by training frequency of the rarest gold standard per problem ($m = \min_{s \in G} n_s$) and the two correlation analyses described.

Table 4: M3 exact match by training frequency quartile. Problems are binned by m , the training count of the rarest gold standard in their gold set. Quartiles are equal-frequency (approximately 485–486 problems each).

Quartile	n	EM	min m	max m
Q1 (lowest m)	486	0.148	0	10
Q2	485	0.332	10	18
Q3	485	0.324	19	31
Q4 (highest m)	486	0.449	31	139
Overall	1,942	0.313	–	–

Spearman ρ between $\log(1 + m_i)$ and exact match (per problem, $n = 1,942$): $\rho = 0.234$, $p = 1.31 \times 10^{-25}$. Spearman ρ between $\log(1 + n_s)$ and conditional exact-match rate (per standard, $n = 76$ standards with ≥ 10 dev problems): $\rho = -0.016$, $p = 0.894$.

E M3 Performance by Grade and Domain

Tables 5 and 6 report exact match disaggregated by grade level and domain for M3 (BiEncoder + Cross-Encoder Rerank + ReAct) on the full Addressing/Alignment-filtered development set ($N = 1942$).

Table 5: Exact match by grade level on the full Addressing/Alignment-filtered development set. N counts problem–grade pairs.

	K	1	2	3	4	5	6	7	8	HS
N	166	221	211	317	326	340	396	375	387	1027
M3: BiEncoder + Cross + ReAct	0.27	0.29	0.30	0.26	0.22	0.12	0.19	0.21	0.22	0.13

Table 6: Exact match by domain on the full Addressing/Alignment-filtered development set. N counts problem–domain pairs.

	C&C	Func	Geom	M&D	NOBT	NOF	NSQ	O&A	R&P	S&P
N	72	407	646	230	465	254	214	914	217	347
M3: BiEncoder + Cross + ReAct	0.19	0.09	0.30	0.23	0.32	0.10	0.19	0.18	0.16	0.24

*Note: C&C = Counting & Cardinality, Func = Functions, Geom = Geometry, M&D = Measurement & Data, NOBT = Number & Operations in Base Ten, NOF = Number & Operations – Fractions, NSQ = Number Systems & Quantity, O&A = Operations & Algebra, R&P = Ratios & Proportional Relationships, S&P = Statistics & Probability.

Through the Sentence Lens: Explainable Essay Scoring through Fine-Grained Predictions

Abstract

Beyond performance, model transparency is a crucial factor in Automated Essay Scoring, yet current systems often lack explainability, limiting their pedagogical value and users' trust. Existing explainability methods, such as gradient-based attribution or feature-importance approaches, either produce counterintuitive explanations or are too complex for classroom use. To address this limitation, we make use of fine-grained prediction at the sentence level as a way to enhance explainability. We propose ablation strategies to derive sentence-level pseudo scores from essay-level gold scores and use them to train sentence-level models. We evaluate their performance against essay-level baselines on two datasets (ASAP and MEWS), and compare their sentence-level output to a human baseline. Results indicate a trade-off between essay-level performance and sentence-level granularity. For the *language quality* trait, most sentence-level models achieve performance comparable to the essay-level baseline, whereas for *content*, the approach yields more positive results on prompts with shorter student texts.

1 Introduction

Automated Essay Scoring (AES) systems are tools designed to evaluate free-text written responses by assigning a score typically using machine learning algorithms. Despite their significant benefits for teachers, such as reducing the workload and making it possible to provide timely feedback to students, their implementation in real-life educational scenarios remains limited due to the lack of explainability, that is, the model's reasoning cannot be made understandable to humans (Li et al., 2022). Whether used for formative feedback or in high-stakes exams, improving such transparency for end users is essential to enhance the overall usability of AES systems (Hall et al., 2024).

Most approaches to improving model explainability have focussed on developing inherently interpretable models or applying post-hoc local explanation methods. However, these techniques often lack pedagogical value in educational contexts: gradient-based attribution methods can be counterintuitive (Parekh et al., 2020), and feature-importance approaches (Kumar and Boulanger, 2020; Urrutia et al., 2025) frequently suffer from construct validity issues (Beigman Klebanov and Madnani, 2020). Rubric-based or fine-grained predictions could offer more intuitive explanations for teachers and students, but their development is constrained by the scarcity of annotated datasets (Ramesh and Sanampudi, 2022), which limits the training of machine learning models.

To address this gap in explainability, we build on the idea of fine-grained prediction by focusing on scoring each trait at the sentence level, rather than assigning only an overall holistic score. Because there is a lack of sentence-level annotations, we propose a method for deriving sentence-level pseudo-scores from essay-level annotations using an ablation strategy. Specifically, we use a model trained at the essay-level to predict the relevance of a sentence by comparing the difference between the prediction on the full essay and the prediction when that particular sentence is missing. This difference in prediction indicates whether the sentence contributes positively or negatively to the overall score.

As a next step, we train sentence-level models using the pseudo scores we had derived. Table 1 illustrates an example output showing sentence-level predictions that can be useful for learners' writing, as receiving feedback on individual sentences helps them focus their efforts when revising their texts. Finally, we evaluate the proposed approach by comparing the performance of sentence-level models against essay-level baselines and by evaluating the automated sentence-level scores against

human annotations¹.

This research thus makes two contributions:

- **Model Performance and Ablation Impact:**

We compare the performance of different AES models architectures trained at the essay level using annotated gold scores with models trained at the sentence level using pseudo scores generated through ablation strategies on ASAP and MEWS datasets.

- **Alignment with Human Judgements:** We further examine the extent to which the sentence rankings predicted by sentence-level models align with human evaluations of sentence quality on a subset of the MEWS dataset.

Text	Score
Older children, like with the age of five or six or elder, it is of course right and possible to watch television with a time, which is given by the parents, so that the children can watch a serie for one hour and then it's finished for this day.	4.1
So all in all, I agree at some parts with the statement, but not at all.	1.4
The main thing, that is important is the bad influence by television for too young children, so it could exists problems in future, which are developed by the television.	0.9

Table 1: Sentence-level predictions for the last three sentences of a random essay in the MEWS dataset (Keller et al., 2020). Score range is 0–5.

2 Related Work

Research on transparency in AES has taken several directions, focusing on model interpretability, model explanations, trait scoring, or fine-grained predictions.

2.1 Model Interpretability

Model interpretability refers to explaining the intrinsic properties of the model that make it understandable to humans (Doshi-Velez and Kim, 2017). As the computational complexity of a model increases, however, its inherent interpretability decreases (Barceló et al., 2020; Bexte et al., 2024). For example, in a linear regression model, the prediction is expressed as a weighted sum of features, where each coefficient reflects the relevance of a feature (Molnar, 2025).

¹Source code available at <https://github.com/melanchthon19/sentence-level-aes>

In this context, Urrutia et al. (2025), Kumar et al. (2019), and Eltanbouly et al. (2025) use linear regressor and Random Forest models due to their higher degree of intrinsic interpretability and provide the most relevant features as feedback to the learner. Although complex models tend to outperform simpler ones, this is not always the case (Li and Ng, 2024), and simpler models should be preferred if interpretability is a main concern (Rudin, 2019).

The use of generative LLMs in the AES context has been widely explored, yielding mixed results (Mizumoto and Eguchi, 2023; Lee et al., 2024; Mansour et al., 2024; Yoshida, 2025). Even though generative models are able to produce explanations using natural language when instructed to provide insights into their decision-making process, these explanations could not reflect the model’s underlying reasoning, and can be yet misleading (Turpin et al., 2023). Methods such as chain-of-thought prompting and self-explanations have been proposed to improve explainability, but they remain limited, as they do not provide direct access to the internal decision process of the model (Lanham et al., 2023; Dehghanighobadi et al., 2025).

2.2 Model Explanations

If a model is too complex, an interpretation algorithm (Li et al., 2022) can be applied to reveal how the model makes decisions, usually in the form of a post-hoc local explanation (Madsen et al., 2022). Common approaches for explaining neural networks are attention-based (Dong et al., 2017; Yang et al., 2020), gradient-based (Alikaniotis et al., 2016), and feature-based attribution methods (Kumar and Boulanger, 2020).

Although post-hoc local explanations can be useful, their pedagogical value remains limited. For example, gradient-based attributions may highlight factors that do not align with human intuitions, such as different sub-tokens of the same word contributing to opposite predictions (Chefer et al., 2021), or the order and even the presence of certain words being irrelevant to the model (Parekh et al., 2020). Similarly, in feature-based attribution methods, the identified feature may be only an indirect proxy that is not explicitly assessed, such as essay length (Jeon and Strube, 2021), or it may be so heavily engineered that the model loses decomposability (Lipton, 2018).

2.3 Trait Scoring

Trait or rubric-based scoring disaggregates a holistic score into specific traits defined in a rubric. Mathias and Bhattacharyya (2018) enrich the ASAP dataset with trait-level annotations, and Yoo et al. (2025) extend this line of work by exploring augmentation strategies. Other studies focus on modelling approaches: Mizumoto et al. (2019) propose a BiLSTM model combined with supervised attention for justification identification; Kumar and Boulanger (2021) examine the relationship between groups of linguistic features and specific traits, as well as their contribution to holistic scoring; Lohmann et al. (2024) compare models and input features on trait scoring; and Eltanbouly et al. (2025) leverage generative LLMs to extract rubric-based features. While trait scoring provides more explanations than a single holistic score, the assigned scores remain at the essay level, with no finer-grained evaluation.

2.4 Sentence-Level Predictions

In addition to trait-level scoring, explainability can also be enhanced through fine-grained prediction, where models score sentences instead of providing just one overall score. Because manual annotations at the sentence level are scarce and expensive, most supervised approaches must circumvent the lack of training data.

Andersen et al. (2013) frame the task as discriminative ranking and compare two approaches. The first uses an essay-level model to rank sentences, which produces weak results. The second derives pseudo sentence scores by dividing holistic essay scores by the number of manually annotated errors per sentence, which yields stronger sentence-ranking performance. When aggregating back to the essay level, however, the sentence-level model underperforms compared to the model trained directly on holistic essay scores. No direct evaluation of the sentence rankings is reported.

Woods et al. (2017) propose an ablation strategy that avoids fine-grained sentence-level annotations. Using an essay-level model, they estimate sentence contributions by omitting sentences and measuring changes in predicted scores. To account for length bias, essay length is included as a fixed feature, and score changes are evaluated against a background distribution of unannotated essays. Results show a slight advantage over a baseline in identifying trait-relevant sentences, though no direct comparison is

made with the original essay-level model.

Hossain and Mustafa (2023) explore the use of an adjacent sentence attention mechanism designed to capture contextual dependencies between neighbouring (preceding and following) sentences. Their model underperforms compared to pretrained baselines, mainly due to the scarcity of training data.

These approaches have some limitations: they either do not directly evaluate the performance of the sentence-level model, lack comparison with essay-level models trained on manual annotations, or are constrained by small datasets. This study addresses these gaps by training sentence-level models using pseudo scores, evaluating their performance against essay-level baselines, and validating sentence-level outputs through a human annotation study.

3 Datasets

We use the ASAP² dataset and its trait-enriched extension ASAP++ (Mathias and Bhattacharyya, 2018), as well as the MEWS (Keller et al., 2020, 2024) dataset. Both corpora cover a wide range of argumentative and narrative writing tasks, and represent diverse student populations. ASAP consists of essays written by native English students from grades 7 to 10 for 8 different prompts, whereas MEWS represents English L2 learners from German and Swiss upper secondary schools with German as L1 for two prompts (TE and AD). In our experiments we also considered their combination (TEAD). Further details of the datasets are provided in the original articles.

For consistency across datasets, we select prompts that include comparable trait-level annotations. We also exclude document-level traits such as *holistic* and *organisation* given that evaluating their quality goes beyond the sentence unit.

The final set of traits used in our experiments include *content* and *language quality*. According to the evaluation rubrics, these traits include effective language command, accurate syntactic and idiomatic usage, sufficient and engaging details, relevant explanations, and well-supported ideas. Table 2 summarises the score distribution for the two traits across prompts, which follow an approximately bell-shaped distribution.

²<https://www.kaggle.com/datasets/lburleigh/asap-2-0>

Prompt	Count	Lang. Qual.	Content
MEWS			
AD	1169	2.79 ± 1.10	3.35 ± 0.96
TE	1099	3.12 ± 1.18	3.68 ± 0.84
ASAP			
1	1783	–	3.85 ± 0.99
2	1801	–	3.22 ± 1.17
3	1726	1.47 ± 0.85	1.43 ± 0.84
4	1770	1.06 ± 0.88	1.11 ± 0.97
5	1805	2.24 ± 0.94	1.88 ± 1.00
6	1800	2.05 ± 0.92	1.85 ± 1.11
7	1569	–	1.84 ± 0.80
8	723	–	3.80 ± 0.63

Table 2: Label distribution of *language quality* and *content* (mean and SD) per prompt for MEWS and ASAP.

4 Experimental Study: Sentence-Level Predictions

In order to evaluate if fine-grained essay scoring improves explainability while preserving the scoring performance, we (i) train essay-level models on the manually annotated scores, (ii) generate sentence-level pseudo scores through ablation strategies, (iii) train sentence-level models using these pseudo scores, and (iv) evaluate the aggregated essay-level predictions against the human-annotated gold standard using Quadratic Weighted Kappa (QWK) (Cohen, 1968). Figure 1 depicts the overall process.

4.1 Models

We train essay-level models representing the main AES paradigms (Xu et al., 2024): linguistic feature-based, transformer-based, and hybrid models. The corresponding architectures are shown in Figure 2 and training hyperparameters in Appendix A.1. Sentence-level models use the same architectures and hyperparameters as their corresponding essay-level baselines.

Linear Regressor (LR): This model is trained on 220 handcrafted linguistic features extracted using the tool described in Lohmann et al. (2024). The features include lexical, syntactic, cohesion-related, error-based, frequency-based, and length-based indicators. The features are scaled and multicollinear features are removed before being fed into the model.

DistilBERT (LLM): A DistilBERT³ model (Sanh et al., 2019) with pretrained weights is used to encode the input essay. The essay representation is obtained by applying max pooling to the final hidden layer, and it is then passed to a custom regression head composed of two linear layers, which

is fine-tuned on top of the encoder.

Hybrid Model (Hybrid): This model integrates the first two approaches by combining the max pooled representation of the final hidden layer from the DistilBERT encoder with a feedforward network that processes the 220 linguistic features used in the linear regression model. The two representations are concatenated and passed through a shared regression head composed of two linear layers.

4.2 Pseudo Scores via Ablation

The main intuition is that the quality of an essay is not equal across all sentences, and that some sentences have a stronger influence on a positive or negative score. Removing a sentence should cause the model to change its prediction according to the relevance of the sentence.

Using the model trained at the essay level, we estimate the magnitude and direction of this relevance by computing the difference in predictions on ablated (missing one or more sentences) and full essays. If the prediction of the ablated essay is higher compared to that of the full essay, it means that the missing fragment (one or more sentences) was lowering the score. Therefore, this fragment should be assigned a lower pseudo score compared to the score assigned at the essay level.

Once pseudo scores are generated, they are normalised to match the target scoring range. Normalisation proceeds in three steps. Z-score normalisation centres the values at zero and scales them to have a unit standard deviation. Tanh non-linear transformation then compresses outliers beyond one standard deviation, and, finally, min-max scaling maps the transformed values to the target scoring range. Figure 6 in Appendix A.2 illustrates the resulting distribution of pseudo scores after normalisation.

4.2.1 Sentence Ablation

To generate sentence-level pseudo scores, each essay is first segmented into individual sentences using spaCy (Honnibal et al., 2020). Then, the ablation strategy follows the leave-one-out method by removing one or more sentences at a time, predicting a score on the ablated essay, and computing a pseudo score for that particular fragment using the following formula:

$$\hat{y} = y - \alpha \cdot (\hat{y}_{\text{loo}} - \hat{y}_{\text{essay}} - b), \quad (1)$$

where $\hat{y}$ is the pseudo score, y is the true essay-level score, $\hat{y}_{\text{loo}}$ is the prediction without the target

³distilbert-base-uncased

Figure 1: Pipeline for training sentence-level models using pseudo sentence scores derived from essay-level annotations via ablation. The pseudo scores generation is described in Section 4.2.

Figure 2: Model architectures used for training both essay- and sentence-level models.

fragment (leave-one-out), $\hat{y}_{\text{essay}}$ is the prediction on the full essay, and b is a bias term estimated as the mean difference between $\hat{y}_{\text{loo}}$ and $\hat{y}_{\text{essay}}$ across the entire dataset, which accounts for the model’s tendency to prefer longer inputs with more context. A scaling factor α amplifies the contribution difference, given that the model is generally stable on ablated essays, and its predictions have a low variance within the same essay. For the experiments, we varied α across the values 1, 10, 20, and 30.

For multi-sentence ablation, a sliding window n is used for leaving out several contiguous sentences when making a prediction. The contribution of a single sentence is then computed as the average contribution across all windows in which the sentence appears. For the experiments, the window size parameters n was varied between 3 and 5.

4.3 Models’ Performance Results

Figure 3 depicts the performance of the best sentence-level models compared to their essay-level baseline across traits and prompts. The primary benefit of this comparison is to highlight the setups in which the sentence-level model trained on pseudo-scores matches the performance of the essay-level model trained on annotated gold scores while offering greater granularity.

4.3.1 Essay-Level Results

Across the three models, the ASAP dataset yields higher and more stable results (mean QWK 0.61 ± 0.08) than MEWS (0.50 ± 0.18). Across both datasets, LR performs best (average QWK 0.63), achieving the best score in 67% of cases, followed by Hybrid (0.59; best in 28% of cases) and LLM (0.50). The embeddings alone used by the LLM are not sufficient to model both *content* and *language quality* across the two datasets, compared to the other models that included linguistic features.

Comparing LR and Hybrid models, concatenating embeddings with linguistic features did not consistently improve performance, with gains observed only for three prompts. Essay baseline results suggest that using simpler models preserves performance while retaining intrinsic interpretability, as also demonstrated in Li and Ng (2024).

4.3.2 Sentence-Level Results

Language Quality: Overall, sentence-level models show similar performance compared to their essay-level baselines. The LLM model has higher QWK variance compared to LR and Hybrid models. The LLM obtains similar results on two prompts, decreases by -0.21 on average on four prompts, and increases by +0.17 on one prompt. The LR and Hybrid model achieve comparable performance on

Figure 3: Performance (QWK) of the essay-level baseline (white dot) and the best sentence-level model on the ASAP and MEWS datasets per prompt and trait. All differences are statistically significant based on 95% bootstrap confidence intervals. Full results are in Appendix B.

all prompts, except on prompt 5 (ASAP), in which there is a decline of -0.17 points on average. The highest increase of +0.35 is obtained by the Hybrid model for the TE prompt (MEWS).

Figure 4 presents the confusion matrices for the essay- and sentence-level hybrid models trained on the TE prompt. The essay-level model predicts scores clustered around the middle of the scale, with a narrow range (1.5–4.0), often assigning a score of 3.0 to essays whose true scores span 1.0–5.5. In contrast, the sentence-level model, benefitting from more distributed pseudo scores, covers a wider range (1.0–5.5), and its predictions of 3.0 align more closely with true scores between 2.0 and 4.0.

Content: Results vary depending on the dataset and prompt. For the MEWS dataset, models show

Figure 4: Confusion matrices of the Hybrid essay- and best sentence-level models trained on the TE prompt for the *language quality* trait.

similar performance compared to their essay-level baselines. Exceptions include the LLM model on the TEAD prompt and the Hybrid model on the AD prompt, both showing a decrease of less than

one point. The Hybrid model, on the contrary, shows improvement of +0.12 when both prompts are combined (TEAD).

For the ASAP dataset, models obtained a lower performance on prompts 1, 2, 7, and 8 for all three models. The LR model, however, maintains comparable performance compared to its essay-level baseline on prompts 3 to 6.

This difference in performance for the *content* trait seems to be primarily related to variation in essay length across prompts. Prompts 3 to 6 that have similar results between essay- and sentence-level models include both source-dependent and independent tasks, but the student essays for these prompts are shorter on average than those for prompts 1, 2, 7, and 8.

Ablation Strategy: A comparison of single versus multi-ablation strategies reveals that the best performances across traits and prompt setups are achieved in 69% of cases with single ablation and in 82% with an alpha value of one. The LLM model is the only one to improve further with higher alpha values, likely because its ablated predictions remain nearly constant across ablated essays, with a variance closer to 0.1. Therefore, amplifying these differences enhances the model’s ability to discriminate between sentences. For the LR and Hybrid models that use linguistic features, removing one or more sentences causes a substantial shift in the input features. This shift is sufficient to determine both the relevance and polarity of a given sentence during the ablation process, which explains why an alpha value of one was the most effective setting for these two models. The window size of 5 was beneficial to some extent (19% of cases) for all three models, with higher improvements for the *content* trait.

Sentence-level results indicate that the proposed approach can provide more detailed and informative feedback without sacrificing performance for some of the prompts and traits. This granularity allows for clearer differentiation between essays of varying quality and offers more actionable insights for teaching and learning.

5 Annotation Study: Sentence-Level Language Quality Scores

In addition to model performance comparisons, we also conduct a human annotation study. The goal is to assess whether the proposed methods agree with human judgement on identifying sentences

that contribute most positively or most negatively to the overall essay quality, focusing on *language quality* as the main criterion as it is more easily identifiable at the sentence level.

5.1 Annotation Task

To this end, five expert evaluators independently annotated a stratified random sample of 100 essays drawn from the MEWS test set. The sample was filtered according to essay length in terms of number of sentences (10–15) and character count (1,000–2,000). We manually screened the essays and excluded one partially written in a language other than English. The final sample includes 14 low-, 70 mid- and 15 high-scoring essays, evenly distributed across prompts (54 from TE and 45 from AD), resulting in 99 essays in total.

The annotators selected three sentences with the most positive impact and three with the most negative impact on the overall essay based on language command, syntactic variety, and idiomatic usage. These core aspects define the *language quality* trait as specified in the evaluation rubric.

5.2 Annotation Results

Each annotation is mapped to a numerical value (positive = 1, negative = -1, neutral = 0) and summed up across annotators. A given sentence can receive an overall score between -5 and +5, where extreme values indicate complete agreement and zero represents neutral annotations or multiple annotations balanced out. Table 3 shows an example of annotated sentences.

Text	+	-	=
That is the reason why I think, it’s impossible being nasty, if you are a friendly person normally.	0	4	-4
Another reason, why I think it’s better to have a good relation between students and teachers, is that students often learn about the behaviour of their teachers.	2	1	+1
So if a teacher wants them to learn about a subject as best without any kind of happiness or confidence, the students couldn’t learn about patience and any kind of stuff which they have to know in their future, like being comfortable and friendly.	1	4	-3

Table 3: Human annotations on three consecutive sentences from a randomly sampled essay regarding their positive (+) or negative (-) contribution to the overall essay considering *language quality* as the criterion.

The distribution of aggregated scores is shown in Figure 5: almost 20% of sentences are consid-

ered neutral (10% without any annotations and another 10% balanced out after aggregating conflicting contributions), there is higher agreement among positive sentences (score of 4 or 5), and a greater proportion of negative sentences with lower agreement (score of -1 or -2). Roughly 15% of sentences show high agreement, reaching an aggregated score greater than 4 in both the positive and negative directions. This pattern is also reflected in inter-annotator agreement measures: Krippendorff’s alpha score is 0.17 and pairwise inter-annotator Cohen’s kappa ranges from 0.14 to 0.22.

5.3 Validation of the Sentence Level: Human–Model Correlation

We evaluate the alignment between human annotations and model outputs by computing the Spearman correlation between the aggregated expert scores and the model outputs, including both the generated pseudo scores per model and sentence-level predictions. Table 4 reports the average correlation across essays and the corresponding standard deviation for both model outputs.

There is a modest Spearman correlation between the LR, LLM, and Hybrid models trained on both prompts (TEAD), based on their pseudo scores and predictions, compared with the aggregated annotation scores. The LLM model achieves the highest averaged correlation (0.29), followed by the Hybrid model (0.17), whereas the LR model shows a negative correlation (−0.15). Although the correlation is weak overall, all models nevertheless capture a meaningful underlying pattern compared to a random baseline.

The positive correlations obtained by the LLM model suggest that its sentence-level outputs are more aligned with human annotations, even though averaging sentence scores leads to lower QWKs as seen in Figure 3. This indicates that this model is better able to capture the lexical and syntactic patterns that annotators consider when judging the *language quality* of a sentence, which is likely due to the use of word embeddings. The Hybrid model also shows a meaningful correlation, though weaker, suggesting that the inclusion of linguistic features do not substantially enhance the model’s ability to identify the most positive and most negative sentences, but instead add noise.

Although the best sentence-level LR model has a similar performance compared to its essay-level baseline on 13 out of the 18 different prompts, as

Figure 5: Distribution of aggregated sentence-level human annotations. ± 5 indicates complete agreement among all five annotators on sentence polarity.

shown in Figure 3, its sentence-level predictions diverge from human annotations with a negative correlation. This indicates that, even though aggregated sentence-level predictions correlate with overall essay scores, the individual predictions do not reflect human judgements of which sentences contribute positively or negatively. This difference can be explained by the fact that linguistic features at the sentence level are less informative, as many rely on frequencies, ratios, and distributions that require broader context.

Model	Predictions	Pseudo Scores
LLM	0.30 (0.26)	0.11 (0.25)
Hybrid	0.19 (0.28)	0.14 (0.29)
LR	-0.15 (0.28)	0.16 (0.30)

Table 4: Spearman correlations (mean and SD) between aggregated human annotations at the sentence level and models’ output (predictions and pseudo scores).

6 Conclusion

In this work, we explore fine-grained prediction as a means of enhancing the explainability of AES models. To address the lack of manual sentence-level annotations, we propose ablation strategies to generate pseudo scores for training sentence-level models and we evaluate their effectiveness against essay-level baselines using ASAP and MEWS datasets. We further examine how the outputs of these models correlate with human sentence-level annotations of the *language quality* trait on a subset of the MEWS dataset.

Overall, there is a trade-off between essay-level performance and sentence-level granularity, though it varies depending on the specific trait and ablation setup. The proposed approach is more effective for the *language quality* trait than for *content*, and for *content*, it performs better on shorter texts. Both model outputs and human judgements show relatively weak correlations, highlighting the subjective nature of the task. Despite this, averaging predictions across sentences yields strong essay-level results even when the underlying sentence-level predictions do not closely align with human reasoning. This points to the need for alternative aggregation strategies, such as assigning different weights to sentences rather than treating them all equally when averaging.

Our experiments also show that simpler models, such as a linear regressor, are able to produce competitive results at a lower computational cost and with a higher degree of intrinsic interpretability. This highlights that the trade-off between complexity and performance does not always hold, and that it might also be preferred in educational settings where transparency is crucial. Applying further explainability methods to sentence-level models would offer a clearer understanding of their internal reasoning and enhance model transparency.

Limitations

This study is limited to traits that are conveyed within the span of a sentence, such as *content* and *language quality*. The ASAP and MEWS datasets consist of English texts, and results may differ for other languages. Different encoders for the LLM and Hybrid model might have an impact on performance.

7 Ethical Considerations

All data annotation procedures were conducted by qualified annotators who were compensated in accordance with legal standards. The models were trained using data representatives of the population from which the data were obtained. Consequently, any application of these models to new or distinct populations should be undertaken with appropriate measures to ensure fairness, validity, and the minimisation of potential biases.

Instruction-Following LLMs for Grammatical Error Correction: Analyzing Neutral-Anchored Instructional Sensitivity Across Editing Modes

Abstract

Grammatical Error Correction (GEC) requires models to make edit decisions under competing objectives: correcting errors while either minimizing changes or maximizing fluency. However, we lack a principled characterization of how instruction-following Large Language Models (LLMs) shift their edit decisions across such *editing modes*, and whether standard evaluation setups faithfully reflect these shifts. We address this gap by defining three modes—*Neutral*, *Minimal-Edit*, and *Fluency-Edit*—and measuring *neutral-anchored* performance shifts to quantify instructional sensitivity. We benchmark seven LLMs, including proprietary and open-weight models, in a unified zero-shot prompting schema on CoNLL-2014, BEA-2019, and JFLEG datasets. The Minimal-Edit instruction mitigates over-editing and typically boosts precision; in some settings, strong models also improve recall, suggesting more selective and effective corrections. In contrast, the Fluency-Edit instruction often encourages broader paraphrastic rewriting that may improve perceived fluency while lowering GLEU, suggesting both a metric-objective mismatch and a shift away from targeted local correction. Notably, Claude-Sonnet-4.5 demonstrates superior zero-shot capabilities, outperforming previously reported scores and matching or even exceeding few-shot results across CoNLL-2014 ($F_{0.5}$: 67.05), BEA-2019 ($F_{0.5}$: 64.91), and JFLEG ($GLEU$: 66.09).

1 Introduction

GEC is a well-established natural language processing task that involves automatically correcting grammatical errors in text. From a computational perspective, GEC is commonly modeled as a text-to-text transformation problem, where an errorful input is transformed into a corrected output while preserving the author’s intended meaning. Depending on the target application, GEC systems

face distinct requirements: high-quality text generation use cases necessitate fluency-focused revisions on the text to achieve more natural-sounding expression, whereas pedagogical settings often prioritize conservative, minimal edits to gradually introduce learner feedback tailored to the learner’s proficiency level to facilitate a more effective and pedagogically grounded learning experience (Wood et al., 1976; Lyster and Ranta, 1997).

These divergent objectives imply an inherent trade-off: strictly adhering to minimal edits often leaves unnatural or awkward phrasing untouched, whereas aggressively pursuing fluency often leads to broader rewrites that can inadvertently shift the author’s intended meaning. For over a decade, shared tasks and benchmarks for GEC (e.g., CoNLL (Ng et al., 2013, 2014), BEA (Bryant et al., 2019), JFLEG (Napoles et al., 2017), MultiGEC (Masciolini et al., 2025)) have both driven progress and standardized evaluation practices, making the *minimal-edit* and *fluency-edit* distinction central to assessment of GEC systems.

Recent advances in LLMs—particularly their ability to follow complex instructions and produce high-quality outputs—have motivated researchers to investigate their effectiveness for a wide range of tasks, which have traditionally relied on task-specific models developed over many years. In the context of English GEC, a growing body of work (Wu et al., 2023; Fang et al., 2023; Coyne et al., 2023; Loem et al., 2023; Davis et al., 2024) has begun to explore this potential, analyzing the out-of-the-box performance of LLMs under zero- and few-shot settings across standard benchmarks. While these studies provide a valuable baseline, there remains an opportunity to systematically assess contemporary models’ intrinsic capability by examining how their performance shifts across different editing modes, especially when these objectives are specified through structurally consistent instructional framing. To address this, we present an eval-

uation of six contemporary LLMs—ranging from high-capacity systems to efficient mini variants, and including both proprietary and open-weight families—together with a legacy model used to assess the quality of instructions, under a tripartite instructional framework in a zero-shot setting. We define three distinct editing modes: *Neutral*, *Minimal-Edit*, and *Fluency-Edit*, using structurally consistent prompts to observe how models modulate their output in response to different instructional goals. By quantifying the shifts from a *neutral-anchored* baseline, we characterize the instructional sensitivity of these models. To support future benchmarking efforts in the GEC community, our complete experimental framework, including implementation code, instructions, and model-generated outputs, is released for public use.¹

Our primary contributions are: (I) To the best of our knowledge, we achieve the state-of-the-art performances for English prompt-based GEC, with Claude-Sonnet-4.5 achieving the highest reported zero-shot $F_{0.5}$ scores on CoNLL-2014 (67.05) and BEA-2019 (64.91), thereby redefining the zero-shot baseline for the task, (II) we provide empirical evidence for an evolution in instructional sensitivity, contrasting the behavioral rigidity of legacy models like GPT-3.5-Turbo with the higher instructional sensitivity of current frontier models, (III) we characterize the precision-recall (P-R) dynamics across editing modes, demonstrating that while minimal-edit instruction typically acts as a precision filter, it can effectively circumvent the traditional P-R trade-off in top-tier models by aligning generative priors with GEC-specific objectives, (IV) we provide an analysis for the metric-objective mismatch on the JFLEG benchmark, showing that as models exhibit higher instructional sensitivity, their native-like enhancements are penalized by the rigid word-matching constraints of GLEU.

2 Related Works

Initial prompt-based GEC studies primarily focused on the GPT-3.5 family. Wu et al. (2023) compared ChatGPT against specialized tools like Grammarly² and GECTOR (Omelianchuk et al., 2020), noting that its performance on automated metrics was hindered by a tendency to go beyond localized edits to modify surface expressions and

sentence structures. This was further characterized by Fang et al. (2023), who demonstrated that ChatGPT’s human-like fluency often comes at the expense of precision on traditional benchmarks due to its over-correction tendencies. Coyne et al. (2023) extended this analysis to GPT-4, demonstrating a clear performance gap between benchmarks: while the model set a new high score on the fluency-based JFLEG dataset, it significantly underperformed on BEA-2019. Their findings confirm that the GEC performance of LLMs is highly dependent on the targeted edit settings, as prompt-driven fluency often results in extensive revisions that are penalized by minimal-edit metrics.

While initial work established a performance baseline, subsequent research has shifted toward investigating the instructional sensitivity of LLMs and the extent to which their correction behaviors can be strategically modulated. Loem et al. (2023) demonstrated that GPT-3 can be effectively steered toward either *minimal-edit* or *fluency-edit* objectives through instructions. However, their analysis revealed that while instructions can guide the model, the provided examples for few-shot settings play a more critical role in controlling editing behavior and achieving the desired correction style. This sensitivity to prompting is further emphasized by Davis et al. (2024), who conducted an extensive comparison between seven open-source and three commercial LLMs across four benchmarks. They found that while commercial models remain superior in fluency-oriented tasks, open-source models can achieve competitive performance if the prompting strategy is carefully optimized. The requirement for structured, objective-specific instructions is further reinforced by Zeng et al. (2024), showing that a uniform prompting approach is insufficient for addressing the varying error patterns across different language proficiency levels, as over-correction tendencies become more pronounced in advanced learner texts.

A critical challenge in modern GEC is the inherent bias of traditional metrics, where LLMs are often penalized for valid, native-like corrections that deviate from the conservative, minimal edits found in standard references (Östling et al., 2024). To mitigate the metric penalties associated with non-mandatory edits, Staruch et al. (2025) explored methods to steer models toward the principle of least change, effectively constraining the output to adhere to minimal-edit requirements. Alternatively, Liang et al. (2025) introduced edit-wise

Neutral	Minimal-Edit	Fluency-Edit
ROLE: You are a helpful language error correction assistant. TASK: Correct the sentence provided inside <code><input>...</input></code> tags. RULES: Process: • Read the full sentence to understand its meaning. • Identify errors in the sentence. • Apply edits. Constraints: • Preserve the original meaning. Output: • If the sentence is already correct, return it unchanged. • Return ONLY the corrected sentence as plain text. • Do NOT include explanations, steps, or additional text.	ROLE: You are a helpful language teaching assistant for second language learners. TASK: Correct the sentence provided inside <code><input>...</input></code> tags with MINIMAL edits. RULES: Process: • Read the full sentence to understand its meaning. • Identify grammatical, spelling, and punctuation errors. • Apply only the edits necessary to fix those errors. Constraints: • Do NOT rewrite for style or fluency. • Preserve the original meaning, tone, and sentence structure as much as possible. Output: • If the sentence is already correct, return it unchanged. • Return ONLY the corrected sentence as plain text. • Do NOT include explanations, steps, or additional text.	ROLE: You are a native English speaker. TASK: Correct grammatical errors in the sentence provided inside <code><input>...</input></code> tags and make it sound natural to a native speaker of English. RULES: Process: • Read the full sentence to understand its meaning. • Identify errors. • Apply edits to correct errors and improve fluency of the sentence. Constraints: • Preserve the original meaning and intent. Output: • If the sentence is already correct, return it unchanged. • Return ONLY the corrected sentence as plain text. • Do NOT include explanations, steps, or additional text.

Table 1: Instructions defining the three editing modes: *Neutral*, *Minimal-Edit*, and *Fluency-Edit*.

preference optimization, an alignment technique that helps models distinguish between mandatory grammatical fixes and optional enhancements.

A different methodological angle pursues automatic optimization of the prompt. Chernodub et al. (2025) proposed APIO, an automatic prompt induction and optimization method that iteratively refines a list of instructions through beam search over an LLM-generated candidate pool, using validation-set performance as the optimization signal.

Building on these efforts to modulate model behavior, our work introduces a structured tripartite instructional framework to systematically characterize how contemporary LLMs navigate these competing objectives of minimal-edit and fluency-edit.

3 Instructions

To isolate the impact of different editing modes, we designed a unified prompting schema following widely accepted best practices for prompt engineering. Each prompt is structured as a consistent interface between the user and the model, consisting of five core components: role framing, task description, processing rules, constraints, and output formatting. This modular design ensures that

model behavior is strictly governed by the intended correction regime while minimizing extraneous output.

We define three editing modes to probe model capabilities: (I) *Neutral*, which serves as an anchor to observe default correction behavior without specific constraints; (II) *Minimal-Edit*, which restricts changes to the smallest set of edits required for correctness while preserving sentence structure; and (III) *Fluency-Edit*, which targets native-like naturalness and flow while only requiring meaning preservation.

All prompts utilize a consistent interface where the source text is encapsulated in `<input>...</input>` tags. To eliminate the need for post-processing on model-generated outputs, we enforce a strict output contract: models are required to return only the corrected sentence, without any additional text. Table 1 shows the instructions we used.

Unlike the other modes, the *Fluency-Edit* instruction explicitly incorporates the term *grammatical errors* in the task to provide a tighter constraint on the model’s editing behavior. This design choice aims to mitigate the common over-editing issue observed in prompt-based GEC studies by guid-

Table 2: Summary of evaluated LLMs.

ing the model to prioritize grammatical correctness while striving for native-like flow. To avoid potential conservative bias from corrective roles, we used a *native speaker* persona to prioritize naturalness. As a robustness check, we also tested other personas to see if this choice contributed to the performance decline detailed in Section 5. However, preliminary evaluations—including tests with alternative persona (role) assignments—revealed that these instructional refinements did not alleviate the persistent performance degradation in this mode.

4 Experiments

As listed in Table 2, in our experiments, we evaluate seven models across three tracks to cover various scales and deployment tiers. The High-Capacity track represents the performance upper bound for our experiments, comprising large-capacity commercial models known for superior instruction-following alongside leading open-weight representatives. To reflect the industry trend toward compact intelligence, the Efficient Mini track includes models optimized for low-latency and cost-efficiency. Finally, the Legacy track includes GPT-3.5-Turbo as a historical reference point to measure the quality of the instructions used in the study and the progress made by newer generations in zero-shot GEC.

Experiments are conducted on three standard benchmarks: CoNLL-2014 (Ng et al., 2014), utilizing alternative gold references to better account for the diverse but valid outputs of LLMs in minimal-edit tasks; BEA-2019 (W&I + LOCNESS) (Bryant et al., 2019), providing a large-scale evaluation across the full CEFR spectrum and native student essays; and JFLEG (Napoles et al., 2017), which targets overall naturalness and native-like flow to assess fluency-oriented rewriting capacity.

Our experimental framework is intended to minimize formatting or inference-related inconsistencies, allowing the performance metrics to more

accurately reflect the actual correction capabilities of the models. To do that, we utilize a series of alignment steps that first optimize the source text and then reformat the generated outputs to meet specific benchmark requirements.

Pre-processing. Since the source sentences in the benchmarks are typically provided in tokenized format, we need to detokenize the sentences before LLM processing to provide a more natural linguistic context. Following the practices established by Davis et al. (2024), we employ the *Moses detokenizer* (Koehn et al., 2007) and implement a specific rule to resolve split negative contractions (e.g., *do n’t* $\rightarrow$ *don’t*). We expect this processing to help align the input format with the models’ pre-trained capabilities.

Evaluation Alignment. To facilitate precise scoring, model-generated responses must be re-tokenized to match the specific requirements of each benchmark’s evaluation script. For the BEA-2019 test set, we conduct tokenization via *spaCy*³ to facilitate the creation of .m2 files, directly aligning with the official shared task proposal (Bryant et al., 2019). For CoNLL-2014, we apply the *NLTK tokenizer*⁴ to generate text-based result files, following the conventions suggested in the shared task (Ng et al., 2014). These steps ensure that the model outputs are perfectly aligned with the gold references before being processed by the M^2 and ERRANT scorers.

Inference Details. All evaluations are conducted in a zero-shot setting to assess the out-of-the-box capabilities of the models. To minimize sampling variability, we set the temperature parameter to 0 for all models. Furthermore, to accommodate the varying Tokens Per Minute (TPM) and Requests Per Minute (RPM) constraints of the different API providers, a tailored `delay_per_request` value is implemented for each model. This en-

³<https://spacy.io/>

⁴<https://www.nltk.org/>

sured optimal throughput while strictly adhering to provider-specific rate-limit quotas. The corresponding TPM and RPM values are provided in the GitHub repository. The maximum output length is set to 2048 tokens to avoid overly long generations.

Experimental Design. To align the instructions with each benchmark’s objectives, and to quantify how much model performance shifts from the Neutral prompt (which imposes no specific editing bias), we evaluate CoNLL-2014 and BEA-2019 under Neutral and Minimal-Edit instructions, and JFLEG under Neutral and Fluency-Edit instructions. This design probes whether models can suppress inherent over-editing tendencies under the minimal-edit mode or, conversely, leverage their generative capacity to produce more fluent, natural-sounding output. For this measurement to be interpretable, we restrict our evaluation to a zero-shot setting in order to isolate the effect of instructional framing: introducing in-context demonstrations would conflate instruction-driven behavioral shifts with example-driven imitation, undermining the *neutral-anchored* sensitivity measurements that motivate this work.

5 Results and Analysis

Table 3 summarizes our findings across model scales and editing settings. We categorize the evaluated LLMs into three tracks: High-Capacity, Efficient Mini, and Legacy. For each model, results are reported under three distinct instructions—*Neutral*, *Minimal-Edit*, and *Fluency-Edit*. Following standard practice and recommendations provided in the recent survey by Bryant et al. (2023), we report the $F_{0.5}$ score using the MaxMatch (M^2) scorer (Dahlmeier and Ng, 2012) for CoNLL-2014, the ERRANT scorer (Bryant et al., 2017) for BEA-2019, and we employ GLEU metric (Napoles et al., 2015) for JFLEG.

To benchmark our results, we include two comparative tiers: (I) Prior LLM Baselines, which present best findings from prior prompt-based LLM evaluations reported in the literature, and (II) single-system state-of-the-art (SOTA) task-specific models.

5.1 Comparative Evaluation

Minimal-Edit Mode. As shown in Table 3, the majority of the evaluated LLMs demonstrate a substantial performance leap over prior prompt-based studies under minimal-edit evaluation settings. In

our experiments, **Claude-Sonnet-4.5** emerges as the top-performing model, achieving the best reported results among prompt-based LLM evaluation studies—presented in the middle part of the table—with an $F_{0.5}$ score of **67.05** on CoNLL-2014 and **64.91** on BEA-2019. Notably, these scores do not merely surpass previous prompt-based GEC studies; they redefine the expected zero-shot baseline for the task.

Results indicate a notable shift in the GEC zero-shot baseline across CoNLL-2014 and BEA-2019. On CoNLL-2014, all evaluated LLMs under the minimal-edit setting outperform prior prompt-based studies, regardless of shot count. Similarly, the majority of high-capacity models surpass previous BEA-2019 prompt-based baselines. While Mistral-Large-3 and Llama-4-Scout trail the 16-shot peak of 57.41, both exceed the zero-shot performance of 53.07 reported by Loem et al. (2023). This suggests that recent open-weight models have reached a level of inherent instruction-following capability where their zero-shot baselines can match or even exceed the few-shot results of earlier models.

A more recent prompt-based comparison point is APIO (Chernodub et al., 2025), which reports a BEA-2019 $F_{0.5}$ of 59.40 using GPT-4o with a validation-tuned, automatically optimized 10-instruction prompt. APIO is methodologically distinct from the few-shot baselines discussed above: rather than supplying in-context demonstrations, it iteratively refines the prompt itself on a validation set drawn from BEA-2019-Dev. Despite this active optimization, three of our four high-capacity models—Claude-Sonnet-4.5 (64.91), GPT-4.1 (64.70), and Llama-3.3-70B (61.61)—surpass APIO under the minimal-edit setting using fixed, manually authored prompts that receive no benchmark-specific tuning. Importantly, a direct comparison between automatic prompt optimization and fixed prompts is not possible from these results, as the underlying models differ. What these results do indicate is that careful zero-shot prompt design, when paired with contemporary high-capacity LLMs from a model class comparable to GPT-4o, surpasses APIO on BEA-2019.

However, when compared to previous single-system SOTA models, a distinct performance disparity emerges between the two benchmarks. While our top-performing LLM, Claude-Sonnet-4.5, achieves highly competitive results on CoNLL-2014 (67.05 $F_{0.5}$, trailing Liang et al. (2025)’s

Model names in the top part are abbreviated for clarity; full model identifiers can be found in Table 2.

70.26 by 3.21 points), a clear performance gap remains on BEA-2019. Even under the minimal-edit setting, the best zero-shot LLM performance (64.91) still trails behind the current empirical upper bound of 78.70 (Staruch et al., 2025), highlighting the continued necessity of task-specific solutions for high-complexity GEC datasets.

This performance gap—rather than indicating a

fundamental lack of GEC capability in LLMs—highlights the effectiveness of domain-specific training and benchmark-centric optimization. Specialized models benefit from exposure to the specific correction styles and error distributions inherent in the benchmark training sets. This exposure allows them to internalize benchmark-specific repair patterns—patterns that are not accessible

to general-purpose LLMs in a zero-shot setting, where the only available signal is the instructional framing and task constraints provided in the prompt.

Fluency-edit Mode. The results on the JFLEG benchmark reveal a counter-intuitive relationship between fluency constraint and model performance. As shown in Table 3, **Claude-Sonnet-4.5** again emerges as the leader among the evaluated models, achieving a peak GLEU score of **66.09** under the neutral setting. Interestingly, across all model tracks, the fluency-edit instruction leads to a slight but consistent performance degradation compared to the neutral prompt. This observation suggests a potential overshooting effect: when explicitly tasked with maximizing fluency while maintaining adherence to grammatical correctness, LLMs can be driven toward excessive paraphrasing that diverges from the gold-standard references. A discussion of this phenomenon is provided in Appendix A.

Claude-Sonnet-4.5, GPT-4.1, and GPT-3.5-Turbo surpass prior zero-shot baselines. Although trailing the 64-shot peak (69.25 GLEU) of [Loem et al. \(2023\)](#), our zero-shot top result (66.09) exceeds their zero-shot baseline of 64.51. Notably, GPT-3.5-Turbo outperforms Efficient Mini models, suggesting smaller contemporary architectures still trail their larger predecessors on this benchmark.

Compared to previous SOTA results, the fluency performance of most of the LLMs is remarkably competitive. Claude-Sonnet-4.5 and GPT-4.1 both surpass the specialized model baseline of 64.7 reported by [Stahlberg and Kumar \(2021\)](#). Most of the high-capacity models and even the legacy GPT-3.5-Turbo outperform the recent task-specific model ([Staruch et al., 2025](#)) on this benchmark. This suggests that for fluency-centric GEC, the broad linguistic knowledge of general-purpose LLMs is now reaching a level where they can exceed the performance of models specifically tuned for error correction, as long as the prompt maintains a balance between fluency correction and original structure.

To further investigate the linguistic drivers behind the consistent performance decline observed in the Fluency-Edit setting, we conduct a qualitative case study on a representative subset of models. This analysis reveals that the lower scores often stem from a metric-objective mismatch rather than a failure in instruction adherence. While the

Fluency-Edit prompt successfully triggers more naturalizing, global paraphrastic reformulations, these high-quality enhancements are frequently penalized for their structural divergence from the rigid n-gram boundaries of the gold references. We provide a granular discussion of these behavioral shifts and model-specific failure cases in Appendix A.

5.2 Prompt Quality through Legacy Benchmarking

To assess the effectiveness of instructions used in this study, we conduct a comparative analysis using GPT-3.5-Turbo as a reference point against prior prompt-based studies. We acknowledge that an exact one-to-one comparison is hindered by the temporal nature of proprietary model snapshots; while earlier studies utilized versions such as gpt-3.5-turbo-0613 or text-davinci-003, our experiments employ the 0125 snapshot, which was the most recent available version at the time of this study.

As shown in Table 3, our minimal-edit prompt yields a substantial performance gain on GPT-3.5-Turbo compared to previous scores reported for GPT-3.5 family. On CoNLL-2014, our zero-shot configuration achieves an $F_{0.5}$ of 63.05, which not only beats the zero-shot baselines but also exceeds every few-shot score recorded in prompt-based GEC studies to date. Remarkably, this performance even surpasses the results reported for subsequent and more advanced iterations; for instance, our zero-shot GPT-3.5-Turbo score significantly outperforms the 58.2 $F_{0.5}$ achieved by GPT-4-0613 in [Omelianchuk et al. \(2024\)](#). This trend is even more pronounced on BEA-2019, where it reaches 56.63 and 56.39 $F_{0.5}$ in neutral and minimal-edit settings respectively, nearly rivaling the 16-shot performance (57.41) of [Loem et al. \(2023\)](#) and outperforming [Fang et al. \(2023\)](#)’s 38.4 and even [Coyne et al. \(2023\)](#)’s 52.79 with GPT-4.

Regarding the evaluation on JFLEG, GPT-3.5-Turbo GLEU results for both neutral (64.67) and fluency-edit (63.99) settings outperforms all GPT-3.5 family zero-shot and low-shot baselines reported in prior work ([Fang et al., 2023](#); [Coyne et al., 2023](#); [Davis et al., 2024](#)). Although [Loem et al. \(2023\)](#) achieves a higher score with an extensive 64-shot setup (69.25), our zero-shot performance for GPT-3.5-Turbo surpasses their zero-shot baseline of 64.51.

Collectively, these results demonstrate that the primary driver of performance in prompt-based GEC is not merely the raw parameter count of the

Figure 1: Delta changes in performance when switching from the Neutral baseline to Minimal-Edit or Fluency-Edit

underlying model, but the clarity of the task framing and instructional specificity of the prompts. We argue that the consistent superiority of our prompts—even over significantly larger models like GPT-4—stems from their ability to navigate the correction-preservation trade-off with higher sensitivity. In the minimal-edit configuration, our instructions impose rigorous decision boundaries that successfully inhibit the over-editing bias common in LLMs, allowing the model to prioritize precision over aggressive rewriting. Conversely, in the fluency setting, score divergence reflects a shift toward paraphrastic reformulation rather than instructional failure. This overshooting effect triggers a metric-objective mismatch, where idiomatic enhancements are penalized by rigid n-gram boundaries of the metric (Appendix A).

5.3 Instructional Sensitivity and P-R Dynamics

Editing mode transitions reveal distinct behavioral shifts. $F_{0.5}$ score deltas (Figure 1) highlight P-R dynamics, offering insights into a model’s instructional sensitivity. Given that $F_{0.5}$ weights precision twice as much as recall, these performance shifts (deltas) reflect models’ capacity to refine their output under restrictive constraints.

Minimal-Edit instruction consistently improves $F_{0.5}$ scores over the Neutral baseline, a gain primarily driven by sharp increases in Precision as can be seen in Table 3. By explicitly requiring models to preserve original structure and apply minimal

changes, we effectively mitigate the common zero-shot pitfall of over-editing. A notable exception is the legacy GPT-3.5-Turbo. It exhibits behavioral rigidity, with minimal performance deltas indicating a limited response to varying instructional objectives and constraints. This implies that the model is reaching a performance ceiling under the neutral setting and is leaving little headroom for further optimization through explicit instructional objectives.

One of the important trends observed in Table 3 is the significant boost in Precision at the expense of Recall when switching to the Minimal-Edit mode. GPT-4.1 serves as a textbook example of this dynamic on CoNLL-2014, where its Precision jumps from 57.26 to 70.37 (+13.11), while its Recall undergoes an equivalent drop from 65.84 to 52.73 (−13.11). This suggests that for certain models, the Minimal-Edit instruction acts primarily as a conservative filter, successfully suppressing the inherent tendency to perform excessive rewrites. However, for Claude-Sonnet-4.5, GPT-5-mini, and Mistral-Large-3, the Minimal-Edit instruction effectively circumvents this traditional P-R trade-off on the BEA-2019 dataset. Unlike the typical inverse relationship, these models exhibit simultaneous gains in both metrics. This phenomenon indicates that the instruction does not merely impose a restrictive bottleneck; rather, it aligns the model’s generative priors with given GEC-specific objectives. By providing a clearer operational boundary, the prompt enables these models to target actual

errors more accurately while inherently reducing the noise generated by non-corrective rewriting.

Claude-Sonnet-4.5 exhibits a unique performance profile, maintaining the highest $F_{0.5}$ scores with significantly narrower deltas than its peers (Figure 1). Unlike other models that require explicit minimal-edit constraints to mitigate over-editing, Claude’s strong neutral performance suggests an intrinsic minimalist prior. This out-of-the-box maturity indicates the model is relatively better aligned for conservative GEC, bypassing the need for the explicit guidance required by other models.

5.4 Error Type Analysis

The aggregate $F_{0.5}$ shifts reported in Section 5.3 characterize *how much* model behavior changes between editing modes, but they leave the precision-recall mechanics underspecified at the linguistic level. To address this, we conduct an ERRANT-based error-type breakdown for our top-performing model, Claude-Sonnet-4.5, on the BEA-2019 test set under both neutral and minimal-edit instructions. Table 5 (Appendix B) reports precision, recall, and $F_{0.5}$ for the 15 most frequent error categories, which jointly cover approximately 77.27% of the gold-reference edits enumerated by ERRANT for this evaluation.

The breakdown reveals that the aggregate minimal-edit benefit decomposes into three distinct behavioral patterns: rewrite suppression in open-ended substitution categories such as R:VERB and R:OTHER; simultaneous precision and recall gains in rule-governed morphosyntactic categories such as R:MORPH and R:VERB:SVA; and minimal change in already-saturated categories such as R:SPELL. The full breakdown and accompanying analysis are presented in Appendix B.

6 Conclusion

In this study, we evaluated six contemporary LLMs to analyze their performance in GEC. We tested these models under three different editing modes using *Neutral*, *Minimal-Edit*, and *Fluency-Edit* instructions to analyze their responses.

Claude-Sonnet-4.5 set a new performance record for prompt-based GEC, with its zero-shot results outperforming even previously reported few-shot scores. Using a minimal-edit instruction helps improve precision and overall $F_{0.5}$ scores across various model scales. This approach reduces the tendency of models to edit sentences more than

necessary. Furthermore, we found that switching to the Fluency-Edit instruction led to a consistent drop in GLEU scores. This is because models perform rewrites that are mostly correct but do not match the exact words in human references, leading to penalties from the n-gram-based metric. Our results show a clear difference in how models follow instructions. The legacy GPT-3.5-Turbo is markedly less sensitive to editing modes, exhibiting consistently smaller *neutral-anchored* shifts than contemporary LLMs. We argue that the design of the prompt is as critical as the size of the model for effective grammar correction. While general LLMs are becoming competitive with specialized systems, future evaluation methods must account for the fact that GLEU may not accurately capture the quality of fluency improvements.

7 Limitations

We acknowledge some constraints in our study that should be considered. First, while we attribute the performance drop in Fluency-Edit mode to a metric-objective mismatch, this claim remains to be validated through large-scale human evaluation to confirm if LLM-generated rewrites are preferred over gold standards. Second, our experimental design intentionally restricts evaluation to a zero-shot setting in order to isolate instructional sensitivity from in-context example effects. Although few-shot prompting is known to improve absolute performance on GEC, augmenting our best configuration with in-context demonstrations was beyond the scope of this study and is left as a complementary direction for the broader research community. Third, recent work shows that LLM behavior can be sensitive to prompt formatting variations (e.g., delimiter choice, instruction ordering, or layout conventions) (Sclar et al., 2024); our study, which adopts a single fixed structural template, does not address this dimension, and the format-level robustness of editing-mode shifts remains an open empirical question. Fourth, our error-type analysis characterizes instructional sensitivity within zero-shot settings but does not provide a direct head-to-head comparison with fine-tuned specialized systems at the category level. Such a comparison is currently constrained by the absence of category-level breakdowns in published fine-tuned baselines and remains unexplored. Finally, our English-only focus limits generalizability to morphologically rich or low-resource languages.

A Qualitative Analysis

While the quantitative results provide an empirical foundation, they do not fully capture the nuanced linguistic modifications of the selected LLMs. In particular, the Fluency-Edit instruction on the JFLEG benchmark yields a consistent performance decline as presented in Table 3. To clarify this discrepancy, we examine the relationship between model outputs and metric responses through a representative case study (Table 4).

For this analysis, we select three models that represent distinct behavioral profiles based on the quantitative results: Claude-Sonnet-4.5 as the overall performance leader, Mistral-Large-3 for its high instructional sensitivity (max Δ), and GPT-3.5-Turbo as a representative of behavioral rigidity (min Δ).

Table 4 provides a representative illustration of the broader quantitative trends discussed earlier, serving as a clear instance of the model-specific behavioral patterns identified in previous subsections. For each model, the table displays the generated outputs under both Neutral and Fluency-Edit instructions, alongside their respective sentence-level GLEU scores which are evaluated for each hypothesis against the set of four gold references.

Claude-Sonnet-4.5 is particularly informative because it is our strongest overall model, and its outputs reveal a subtle but important distinction between reference proximity and perceived fluency. Under the Neutral setting, it corrects the clear grammatical error *didn’t expected* to *didn’t expect* and also repairs *were flock to* to *were flocking to*, but otherwise remains highly conservative. Notably, its output remains very close to Ref3, but the omission of the infinitival marker *to* after *expect* leaves the *didn’t expect* construction slightly incomplete and somewhat less natural from a native-speaker perspective. Despite this residual awkwardness, the output receives a relatively strong sentence-level GLEU score (0.69), which is consistent with the metric’s sensitivity to n-gram overlap across the available references rather than to fine-grained judgments of naturalness. Under the Fluency-Edit

Original Sentence:

As a result, she could get a job that she badly wanted but she didn't expected because many people were flock to this company.

Gold References:

Ref0: As a result, she was able to get a job that she badly wanted but didn't expect because so many people were flocking to this company.

Ref1: As a result, she could get a job that she badly wanted but she didn't expect to get because many people flocked to this company.

Ref2: As a result, she could get a job that she badly wanted but didn't expect to get because many people were flocking to this company.

Ref3: As a result, she could get a job that she badly wanted but she didn't expect to because many people were flocking to this company.

Model	Mode	Model Output	GLEU
Claude-4.5	Neutral	As a result, she could get a job that she badly wanted but she didn't expect because many people were flocking to this company.	0.69
	Fluency	As a result, she got a job that she badly wanted but didn't expect because many people were flocking to this company.	0.62
Mistral-L3	Neutral	As a result, she could get a job that she badly wanted but didn't expect because many people were flocking to this company.	0.64
	Fluency	As a result, she got the job she badly wanted, though she hadn't expected it because so many people were flocking to the company.	0.29
GPT-3.5	Neutral	As a result, she could get a job that she badly wanted but she didn't expect because many people were flocking to this company.	0.69
	Fluency	As a result, she could get a job that she badly wanted but she didn't expect because many people were flocking to this company.	0.69

Table 4: Comparison of outputs of the models for the Sentence ID 217 in the JFLEG test set with sentence level GLEU scores.

setting, it makes a more ambitious change by replacing *could get* with *got*, which moves the sentence toward a more natural and direct formulation. However, it still leaves the construction *but didn't expect* unresolved, rather than producing the more complete and idiomatic *didn't expect to* or *didn't expect to get it*. In other words, the fluency-oriented instruction does trigger a more naturalizing edit, but it does not fully repair the most awkward local structure. This makes Claude's pair of outputs especially useful for illustrating that higher fluency intent does not automatically translate into a uniformly better correction, while higher GLEU under the neutral prompt may partly reflect reference closeness rather than superior overall well-formedness.

Mistral-Large-3 exhibits an even clearer contrast between conservative correction and fluency-driven editing. Under the Neutral setting, its output is nearly identical to Claude's neutral response: it corrects the obvious grammatical errors but preserves most of the original sentence structure, yielding a relatively strong GLEU score (0.64). This suggests that, even without explicit editing guidance, the model already performs a balanced correction that lies somewhere between minimal editing and moderate fluency improvement. Under the Fluency-

Edit setting, however, it shifts much more decisively into reformulation: *could get a job* becomes *got the job*, but becomes *though*, *didn't expect* becomes *hadn't expected it*, *many people were flocking to this company* becomes *so many people were flocking to the company*. These revisions make the output more globally rewritten and, at first glance, more polished. At the same time, they substantially increase lexical and structural distance from the references, which likely explains the sharp drop in sentence-level GLEU (0.29). More broadly, this example is consistent with the general qualitative findings: among the evaluated models, Mistral-Large-3 exhibits the largest behavioral shift, making it the clearest case of high instructional sensitivity. Accordingly, the drop in GLEU reflects not only the behavior of the metric, but also a broader change in the model's response to the Fluency-Edit prompt. This is partly consistent with a metric-objective mismatch, insofar as the prompt encourages native-like reformulation while the metric still rewards proximity to a limited reference set. At the same time, the example indicates that the lower score cannot be explained by the metric alone. Some of Mistral's changes are plausibly motivated by fluency, but they also extend the revision beyond targeted local repair. Overall, the Fluency-Edit

prompt shifts the model from balanced correction toward broader paraphrastic rewriting, reducing reference alignment without delivering a clearly proportional gain in local correction quality.

GPT-3.5-Turbo shows a different pattern, remaining unchanged across prompts. Its Neutral and Fluency-Edit outputs are identical, indicating that the fluency instruction has little or no effect on its correction behavior in this example. This is also in line with the general quantitative results: among the evaluated models, GPT-3.5-Turbo shows the smallest change, consistent with its overall profile of low instructional sensitivity. At the sentence level, this low sensitivity is reflected in a restrained editing strategy: the model fixes the obvious grammatical errors but leaves the larger phrasing intact, including the somewhat incomplete *she didn't expect* segment. This yields a relatively high GLEU score (0.69), likely because the output remains reference-close and avoids broader paraphrastic divergence. One interpretation is that GPT-3.5, as a legacy model, is comparatively rigid in following higher-level stylistic instructions such as *make it more fluent* or *more native-like*, especially when these instructions compete with a simpler default strategy of surface-level error correction. This contrasts with Mistral's behavior: whereas Mistral shifts toward more aggressive rewriting under the fluency-edit prompt, GPT-3.5 remains largely unchanged in how it edits. In this sense, the example also provides a concrete instance of the broader behavioral rigidity observed in the quantitative results.

B Error Type Analysis

This appendix complements the Error Type Analysis introduced in Section 5.4 by presenting the full ERRANT-based breakdown and a regime-by-regime discussion of the observed shifts. Table 5 presents a per-category breakdown for the 15 most frequent ERRANT categories, reporting their gold-edit frequency, precision, recall, and $F_{0.5}$ under neutral and minimal-edit instructions, together with the $\Delta F_{0.5}$ between the two modes.

Of the 15 categories examined, 14 exhibit a positive $\Delta F_{0.5}$ when switching from neutral to minimal-edit, with a mean gain of +2.95 points. Crucially, this improvement is not driven by a uniform precision boost across the board: while the average precision increases by +3.70 points, the average recall stays nearly flat (−0.13). The category-

level distribution, however, hides three distinct behavioral profiles that together explain the P-R dynamics observed in Section 5.3.

The largest $F_{0.5}$ gains concentrate in open-ended substitution categories—R:VERB, R:PREP, and R:OTHER—which often involve multiple plausible alternatives or contextually optional changes, and where the minimal-edit prompt produces large precision improvements alongside stable or declining recall, indicating that a substantial portion of the neutral baseline's edits in these categories are filtered out under the minimal-edit constraint. R:VERB ($\Delta F_{0.5}=+8.68$) is the clearest case: precision jumps by +13.75 points while recall drops by −7.87, indicating that the minimal-edit instruction sharply suppresses non-mandatory verb substitutions. R:OTHER ($\Delta F_{0.5}=+5.97$; $\Delta P=+7.35$, $\Delta R=-1.52$) and R:PREP ($\Delta F_{0.5}=+5.25$; $\Delta P=+6.53$, $\Delta R=-1.03$) follow a similar pattern. This pattern provides a category-level localization of the “over-editing” tendency identified in prior prompt-based GEC studies (Wu et al., 2023; Fang et al., 2023), and our results indicate that the minimal-edit mode substantially suppresses it in these categories.

A second, distinct group of categories shows simultaneous gains in both precision and recall. R:MORPH ($\Delta P=+9.14$, $\Delta R=+1.77$), R:VERB:FORM ($\Delta P=+2.98$, $\Delta R=+2.69$), R:VERB:SVA ($\Delta P=+2.40$, $\Delta R=+1.86$), and R:NOUN:NUM ($\Delta P=+3.33$, $\Delta R=+1.39$) all improve on both axes. These categories share a common property: they are governed by relatively deterministic grammatical rules—subject-verb agreement, morphological inflection, number marking—rather than admitting multiple plausible alternatives. For such categories, the minimal-edit instruction yields gains beyond what a purely restrictive filter would predict. A filter operating on neutral outputs could remove false positives and raise precision, but it could not introduce true positives that the neutral run failed to produce. The simultaneous improvement therefore suggests that the prompt influences the correction process itself rather than acting only as a post-hoc constraint, consistent with the observation in Section 5.3 that in top-tier models the minimal-edit prompt may not simply impose a restrictive bottleneck.

A third pattern emerges in error categories where neutral performance is already near ceiling, leaving little headroom for the minimal-edit instruc-

Error Type	Freq.	Neutral			Minimal-Edit			$\Delta F_{0.5}$
		P	R	$F_{0.5}$	P	R	$F_{0.5}$	
M:PUNCT	761	64.56	61.98	64.03	64.90	66.10	65.14	+1.11
R:OTHER	629	34.43	44.76	36.10	41.78	43.24	42.07	+5.97
R:ORTH	464	56.36	68.45	58.42	57.29	71.12	59.61	+1.19
R:SPELL	343	87.79	96.85	89.47	88.36	97.38	90.03	+0.56
R:PREP	340	65.86	76.62	67.76	72.39	75.59	73.01	+5.25
R:NOUN:NUM	313	74.26	87.11	76.52	77.59	88.50	79.55	+3.03
M:DET	306	78.75	75.08	77.98	79.80	77.45	79.32	+1.34
U:DET	257	71.09	83.68	73.30	74.63	77.82	75.24	+1.94
R:VERB:TENSE	223	64.00	68.97	64.94	67.56	68.16	67.68	+2.74
R:VERB	214	52.71	57.87	53.67	66.46	50.00	62.35	+8.68
R:VERB:FORM	200	76.11	84.31	77.62	79.09	87.00	80.56	+2.94
R:MORPH	193	64.02	85.79	67.44	73.16	87.56	75.65	+8.21
R:VERB:SVA	167	75.38	90.36	77.96	77.78	92.22	80.29	+2.33
R:PUNCT	161	36.19	46.34	37.85	32.92	49.69	35.30	-2.55
R:DET	134	67.11	71.33	67.91	70.40	65.67	69.40	+1.49

Table 5: ERRANT error-type breakdown for Claude-Sonnet-4.5 on BEA-2019 under Neutral and Minimal-Edit instructions. We report the 15 most frequent error categories, which together account for approximately 77.27% of all gold edits in the test set. Frequency is computed as TP + FN from the Minimal-Edit run; the Neutral counterpart yields a near-identical ranking, with minor count differences arising from ERRANT’s hypothesis-conditioned alignment. $\Delta F_{0.5}$ denotes the absolute change in $F_{0.5}$ from the Neutral to the Minimal-Edit instruction.

tion to act on. R:SPELL improves only marginally ($\Delta F_{0.5}=+0.56$) because it operates close to a saturation point with both precision (87.79%) and recall (96.85%) already very high under neutral mode. R:ORTH ($\Delta=+1.19$) and M:PUNCT ($\Delta=+1.11$) behave similarly. The instructional framing has limited influence on phenomena whose correction is largely deterministic and where model behavior is already well-calibrated.

R:PUNCT is the only category in the top-15 that shows a negative $\Delta F_{0.5}$ (-2.55), driven by a precision drop (-3.27) accompanied by a recall gain ($+3.35$). This pattern runs counter to the dominant trend and likely reflects a category-specific interaction. Under the minimal-edit mode, the model attempts more punctuation replacements, but its replacement choices are not sufficiently selective. Replacement punctuation is intrinsically context-dependent, with multiple plausible alternatives often available for the same source position. The observed precision drop may reflect the difficulty of aligning model choices with the specific replacements chosen by reference annotators, though we cannot rule out a genuine selectivity issue without examining individual cases.

Assessing the Quality and Consistency of Automated Knowledge Component Generation using Instructor-generated Questions and LLMs

Abstract

Lecture-style instruction is one of the most prevalent forms of learning in postsecondary education in the United States. Despite the factors that make lectures a convenient format, they tend to present few opportunities for meaningful engagement between students and the course materials being presented due to factors such as the overhead associated with interacting with large numbers of students. By utilizing large language models, we have created a pipeline built upon the EXPLAINIT classroom response system for processing student self-explanations produced during lectures using automatically generated knowledge components. This pipeline can facilitate deeper engagement with course materials, offer traceability in assessment results, and allows instructors to respond to student errors or misconceptions in real-time during lecture. While previous work using a proprietary large language model has examined the basic functionality of this pipeline, this work more closely examines the consistency and quality of this pipeline using both a large closed-weight model and a smaller open-weight model, with or without retrieval-augmented generation (RAG). The use of open-source models could allow institutions deploying EXPLAINIT to maintain control of their student data without substantially sacrificing performance. We find that while there are small statistically significant differences in performance between the RAG conditions of each LLM, they are nearly comparable at this task. Additionally, the LLM-generated knowledge components are of higher quality when relevant course material is provided for RAG, although consistency is not improved. These results indicate that both large closed-weight and smaller open-weight models show promise in this task, but fine-tuning may be necessary to improve performance further.

1 Introduction

Lecture-style instruction is one of the most popular teaching formats in the United States due to factors such as course size and the availability of appropriate classrooms (Stains et al., 2018). However, this style of lecture suffers from drawbacks such as a lack of interactivity that can lead to poorer learning outcomes compared to students in more interactive (or dialogic) learning environments (Grissom et al., 2017). Classroom response systems (CRSs) may represent a path to improving student engagement by allowing instructors and students to interact during lectures through question and answer sessions mediated by laptops, handheld devices, or other technological devices, but many CRSs that rely on less engaging question types such as multiple-choice responses may have low or negligible impacts on learning gains (Hunsu et al., 2016). A CRS implementing self-explanation in a real-time lecture format may represent a path to substantially improving engagement and learning gains. While automated assessment of written responses is an active area of study (Gao et al., 2023; Urrutia et al., 2025; Bexte et al., 2024), it still represents a substantial computing challenge, particularly in the context of real-time assessment during lectures. Large language models (LLMs) provide a promising method of explainable automated assessment but require further evaluation with regards to their consistency and correctness. Additionally, privacy concerns such as attack vulnerabilities and data governance have arisen around the use of large private closed-weight LLMs (Li et al., 2024). Small, open-weight models can enable institutions to have total control over their implementations.

In this paper, we expand upon a previously developed explainable LLM-powered pipeline (Esiason et al., 2026a) used to generate knowledge component (KC) sets from a variety of instructor-generated questions, tag student responses with

Figure 1: The EXPLAINIT CRS. Instructors are able to use the ExplainIt interface to pose self-explanations questions during lecture, and students can respond to those questions in their own words using a student interface on their handheld devices or laptops. Students receive LLM-generated feedback on their answer and instructors receive a class-level summary of student performance on the question.

these KCs, and summarize topic-level classroom performance by testing a popular closed-weight model (ChatGPT GPT-4o-mini) against a relatively lightweight open-weight model (MistralAI Mistral-3-3B-Instruct). In this work, we explore how consistently KCs are generated when the same instructor questions are used as input across multiple generations of KC sets. We also qualitatively evaluate how RAG utilizing course materials affects KC generation by examining whether or not generated KCs are within the scope of the intent of the question being posed, and whether or not the generated KCs are sufficient in capturing a “correct” response from a student.

Specifically, we seek to evaluate the following research questions:

- RQ1: Does including course materials as RAG context for these models result in the generation of higher quality KCs as measured by the scope of the generated content and the sufficiency of the generated KCs in capturing correct responses?
- RQ2: How consistent are the output of these models over multiple generation cycles as measured by the proportion of times that semantically similar KCs are generated across all generations given the same input? Does consistency vary by the type of question (e.g. factual recall, procedural knowledge, etc.)?
- RQ3: What, if any, other qualitative or quantitative patterns appear in generated KCs with regards to their quality?

By addressing these research questions, we contribute to the understanding of how these two models qualitatively behave in this novel application context, whether or not they are capable of generating useful KCs consistently, and whether or not closed- and open-weight model performance is comparable. Additionally, the human evaluation of this work establishes an expert dataset of KCs that can be used for future work on this style of system, such as fine-tuning.

2 Related Work

This work sits at the intersection of CRSs, real-time automated assessment, KC generation, and LLMs. All of these domains individually encompass broad swaths of work but the study of their intersection is relatively limited.

2.1 Classroom Response Systems

CRSs have been deployed in various forms at various grade levels in classrooms around the world to improve learning outcomes and engagement. CRSs can take many forms, from simple multiple-choice “clicker”-style CRSs to more elaborate systems that support freeform text answers (Sianturi and Hung, 2023; Tyagi and Alyammahi, 2025; Serrada-Sotil et al., 2025). These CRSs can improve student outcomes in these lecture environments in a number of ways. They can improve engagement, cognitive outcomes such as learning gains, and non-cognitive outcomes such as creating comfort in responding to classroom exercises (Serrada-Sotil et al., 2025; England et al., 2017). However, many of these

An instructor posed the following question during an undergraduate computer science lecture:
 {question}
 Create a list of knowledge components covered by an ideal response to this question. Your answer should consist of ONLY the list of knowledge components described in a few words each.

Figure 2: The KC generation prompt for the No RAG condition.

An instructor posed the following question during an undergraduate computer science lecture:
 {question}
 The following context was given for the question:
 {RAGcontent}
 Create a list of knowledge components covered by an ideal response to this question. Only generate knowledge components that you think are explicitly covered by this question and the provided context. Your answer should consist of ONLY the list of knowledge components described in a few words each.

Figure 3: The KC generation prompt for the RAG condition.

existing classroom response systems that are deployed during lectures are limited to formats such as multiple-choice questions that may not encourage students to think deeply about course material or may only support relatively shallow analyses of text responses that are of limited use for measuring student knowledge. A system that could solicit and analyze short self-explanation responses from students could greatly improve interactivity, measure learning in lectures, provide immediate feedback to students, and allow instructors to perform real-time instructional pivots during lectures based upon student understanding of course material. Self-explanation has been shown to be a powerful tool for improving student learning over other question formats (Chi et al., 1994; Chi and Wylie, 2014), but presents more difficulty in analysis.

2.2 Assessing Short Self-explanations with Automated Short Answer Assessment

Assessing short self-explanations in real time for such a classroom response system presents a substantial technological hurdle for several reasons. Much of the existing work on assessing student written responses investigates the effectiveness of automated assessment in homework, exams, longer essay questions, or intelligent tutoring systems intended to be used during testing or outside of the classroom (Gao et al., 2023; Urrutia et al., 2025; Chamieh et al., 2024; Bexte et al., 2024). In com-

parison, student explanations posed in the classroom tend to present some unique challenges. Student self-explanations in this format tend to be very short, fragmented, may use implication that can obscure semantic meaning in order to answer questions more quickly, and contain frequent errors made in the haste of responding (Esiason et al., 2026a). Assessing many responses like this in a lecture format with many students may simply not be feasible for an instructor to do themselves due to time constraints. Additionally, probabilistic assessments have some drawbacks. If we wish to automate the process of assessing this type of response during a lecture, then we must do so with strong theoretical grounding such that we minimize errors that risk misleading students or harming their confidence in themselves or the assessment tool (Kerslake et al., 2025; Chamieh et al., 2024; Stowe et al., 2024).

2.3 Knowledge Components and Generation

Knowledge components represent a promising avenue for automatically assessing student responses for the presence of key units of knowledge or understanding. KCs have been used across a number of disciplines in the past to assess responses to a number of different question formats such as multiple-choice, short answer, or coding exercises (Koedinger et al., 2012). While sets of KCs have historically been laboriously generated by experts, recent work has demonstrated the effectiveness

Model	Scope	Sufficiency
ChatGPT-4o-mini (N)	0.881	0.778
ChatGPT-4o-mini (R)	0.637	0.941
Mistral-3B-Instruct (N)	0.778	0.593
Mistral-3B-Instruct (R)	0.709	0.754

Table 1: Median scope and sufficiency scores across all five generations, by model and RAG (R) or No RAG (N) condition. Scope and sufficiency range from [0,1], with values closer to 0 being desirable for Scope and values closer to 1 desirable for Sufficiency.

of KCs for arbitrary questions using LLMs (Esiason et al., 2026a; Moon et al., 2025; Moore et al., 2024a; Wei et al., 2025). This enables an automated path to producing CRS that can automatically generate KCs for instructor-generated questions. In addition to being adaptable to a variety of input and scalable, a KC tagging approach enables transparency of assessment since the KC tags can be traced and corrected throughout the assessment process.

2.4 Large Language Models

LLMs have risen to prominence in generating knowledge components, as they have in many other text-generation tasks. LLMs have proven to be reasonably effective in this task in various contexts and question formats (Esiason et al., 2026a; Moon et al., 2025; Moore et al., 2024a; Wei et al., 2025). Models used for this purpose must be carefully selected, however. While “black box” LLMs frequently provide state-of-the-art performance on a variety of tasks, open models are rapidly approaching parity (Kaggle, 2025) and there are concerns about using black-box models for educational purposes. Some of these concerns include security issues, such as data storage compliance or attack vulnerabilities (Li et al., 2024). Other concerns include hardware and support limitations. Larger models can avoid hardware costs by being deployed remotely in the cloud, but may come with API costs and are infeasible to run locally in the event of data security concerns. On the other hand, smaller models deployed locally may incur up-front hardware costs but ensure total control over student data. As a result, exploring both large and small or open- and closed-weight models is necessary.

There are many options to choose from, but two models have been selected for this work for the sake of expedience in human assessment. OpenAI’s ChatGPT-4o-mini (OpenAI, 2023, 2025) was se-

lected as the closed-weight model for use in this experiment due to its prior use in KC generation and short assessment work (Moon et al., 2025; Moore et al., 2024b). MistralAI’s Ministral-3-3B-Instruct (Liu et al., 2026) was chosen as the open-weight model for use in this experiment due to its reasonable performance in benchmarks (Kaggle, 2025) and open-weight status.

Figure 4: Example question, KCs generated from the question, and a related student self-explanation.

2.5 The EXPLAINIT Classroom Response System

EXPLAINIT is a multi-stage CRS that allows instructors to prepare short open-response questions, present them to students during lectures, gather responses from students, and provide automated feedback on those responses (Figure 1) (Carpenter et al., 2024). Instructors utilize the Instructor Dashboard to prepare questions ahead of time, and then present them to students who respond on a laptop or hand-held device of their choice through EXPLAINIT’s web platform (Figure 4). This engages students in self-explanation, allowing for deeper learning than pure lecturing or other CRSs that may use question formats that do not promote deeper learning, such as multiple-choice. LLM-driven,

	GPT (R)	Mistral (N)	Mistral (R)
GPT (N)	18.62, $p < 0.001$	4.45, $p = 0.035$	9.88, $p = 0.002$
GPT (R)	-	5.89, $p = 0.015$	1.31, $p = 0.253$
Mistral (N)	-	-	1.21, $p = 0.272$

Table 2: McNemar’s pairwise tests for differences in proportion of KCs that were out of scope by model and RAG (R) or No RAG (N) condition.

	GPT (R)	Mistral (N)	Mistral (R)
GPT (N)	12.25, $p < 0.001$	14.05, $p < 0.001$	0.08, $p = 0.775$
GPT (R)	-	39.93, $p < 0.001$	17.36, $p < 0.001$
Mistral (N)	-	-	5.97, $p = 0.015$

Table 3: McNemar’s pairwise tests for differences in proportion of KCs that were sufficient for identifying correct responses by model and RAG (R) or No RAG (N) condition.

immediate, personalized feedback then aids students in troubleshooting their response. Instructors are also presented with a real-time analytical dashboard of student responses, ensuring that a human is kept in the loop of the assessment process. An important design principle of EXPLAINIT is to create a low-overhead tool for instructors to use such that integration of the tool provides benefits without adding to their workload. This has informed the automated design choices underlying this system.

Recent work with this system has assessed its ability to provide real-time instructional support in undergraduate lectures (Esiason et al., 2026a,b) (Figure 1). In this system, instructors first utilize an authoring tool to prepare questions to pose to the class, categorized by topic and stored using EXPLAINIT web platform. Then, the system uses an LLM to derive a set of relevant KCs from the question. Next, the instructor uses the Instructor Dashboard to deliver a question to students during their lecture. Students respond to this question using a web interface on their phones, laptops, or other devices. At this point, the pipeline again uses an LLM to tag student responses with the boolean presence or absence of each KC from the set generated earlier. Once all student responses are assessed, an LLM is used to generate a summary of student performance based upon the question, the student responses, and their respective KC taggings. This KC approach allows for LLM assessments to be traced from question creation to summarization, and inherently supports human-in-the-loop interfacing by allowing instructors to drill down into student responses from the summaries, all the way back to the original question posed.

Prior work has found that the system performs

with a reasonable degree of accuracy with regards to agreement with human grader expectations for assessments of student responses and instructor preferences in how class-level summaries of student performance on questions should be formatted for easy and meaningful interpretation (Esiason et al., 2026a,b). While this previous work has established broad feasibility of this system, the reliability of the KC generation phase over repeated generation has not been established. The current work focuses exclusively on this stage.

3 Methods

All data collection activities were approved by IRB ANONYMIZED and were carried out in accordance with the relevant guidelines and regulations. Students were asked to review the study information sheet and electronically sign the IRB approved consent form to allow their data to be used for research purposes. Then all students were given a generic ID to interact with the system such that no personally identifiable information was included or collected by any systems external to the institution at which the research was being conducted. EXPLAINIT was deployed in one undergraduate computer science course on applied learning and data analytics in the fall semester of 2024. 27 instructor-generated questions were collected for use in this study through the Instructor Dashboard.

Models were selected to represent a balance between the state of the art in LLMs, prior work, and (in the case of Mistral-3-3B-Instruct) a relatively lightweight, open source option that could conceivably be deployed locally by an education agency. Both models were used as is out of the box. ChatGPT-4o-mini (OpenAI, 2025, 2023) was se-

Model	Median [Min,Max] KCs		
	Over (C>1)	Exact (C=1)	Under (C<1)
ChatGPT-4o-mini (N)	1 [0,4]	3 [0,5]	8 [0,16]
ChatGPT-4o-mini (R)	1 [0,3]	2 [0,6]	9 [1,13]
Mistral-3-3B-Instruct (N)	3 [0,10]	1 [0,7]	9 [3,24]
Mistral-3-3B-Instruct (R)	1 [0,4]	3 [0,7]	9 [3,25]

Table 4: Distributions of median over- and under-generated KCs per question as measured by consistency across 5 runs (C), by model and RAG (R) or No RAG (N).

Model	N Semantically Distinct KCs Generated	Median Semantically Distinct KCs per Question (Median [Min,Max])
ChatGPT-4o-mini (N)	347	12 [6,19]
ChatGPT-4o-mini (R)	325	13 [6,16]
Mistral-3-3B-Instruct (N)	374	12 [5,32]
Mistral-3-3B-Instruct (R)	395	13 [6,29]

Table 5: Total, median, minimum, and maximum number of KCs generated by model and RAG (R) or no RAG (N).

lected as a baseline based upon prior work with this system (Esiason et al., 2026a,b; Carpenter et al., 2024) and related assessment and KC generation tasks (). MistralAI’s Mistral-3-3B-Instruct (Liu et al., 2026) was chosen in order to evaluate the performance of an open source, relatively lightweight model that could be reasonably be expected to run locally on institution hardware rather than relying on third-party closed-source APIs. All models were run at a low temperature (0.1) in order to align with previous work (Esiason et al., 2026a) and increase the reliability of the system. Outputs of each model were limited to 2,000 tokens, although outputs were frequently shorter.

Each model was used on the same question sets to produce knowledge components by RAG and non-RAG approaches. This was done to compare the performance of the two approaches and attempt to control for previously identified issues with this pipeline generating sets of knowledge components that were out of scope of the question being asked (Esiason et al., 2026a). We theorized that a RAG approach would narrow the generated knowledge component sets to what could be considered fairly expected of students, given that these questions are deployed after the students have only just been introduced to the material either by assigned reading or the lecture itself.

For the RAG models, one reference material per question was obtained from one of three sources. All materials produced were in text or table format, with figures excluded. Firstly, we attempted to obtain reference material from the course textbook

(Tan et al., 2019) and transcribed the relevant paragraph(s) and/or tables. Occasionally, the questions referenced content that was not available in the textbook; in these cases reference materials were sourced from other comparable locations appropriate for an undergraduate student lecture (Simon et al., 2018; Boehmke). We attempted to retrieve comparably useful and relevant text for RAG across questions, but RAG material varied in length from a few sentences to several pages depending on the question.

Once RAG material were selected, the instructor questions were paired with their RAG material and ingested by the EXPLAINIT pipeline. The same prompt was used for each model, with the only variation being in the inclusion of the RAG material between RAG and No RAG conditions. In the No RAG condition, only the instructor question was passed to the LLM through the prompt (Figure 2). In the RAG condition, both the instructor question and the RAG material were passed to the LLM through the prompt (Figure 3). All models and RAG combinations were run 5 times for each input data, once with RAG utilizing course materials, and once without RAG. This resulted in 135 generated KC sets per model/RAG combination.

Two raters divided up the task of evaluating these KC sets along the metrics of scope and sufficiency. “Scope” intended to measure the whether or not a given KC was within the intent of the question being posed. For example, if the question was “what are the steps of k -fold cross validation” and one of the generated KCs involved comparing k -fold

	GPT (R)	Ministral (N)	Ministral (R)
GPT (N)	$V = 132.00, p = 0.577$	$V = 156.00, p = 0.583$	$V = 164.00, p = 0.562$
GPT (R)	-	$V = 103.50, p = 0.746$	$V = 139.00, p = 0.239$
Ministral (N)	-	-	$V = 133.50, p = 0.186$

Table 6: Wilcoxon signed-rank pairwise tests for differences in consistency of KC generation between models by RAG (R) or No RAG (N).

cross validation to other training algorithms then this KC would be out of scope. Sufficiency, on the other hand, is intended to measure whether or not a given set of KCs is sufficient for identifying a correct response from a student (regardless of whether or not it contains KCs that are out-of-scope). For example, if the question is “what are the steps of k -fold cross validation” and the LLM does not generate a KC corresponding to “divide the training data into k folds” then the generated KC set would be insufficient to identify a correct response since one of the first steps of k -fold cross validation is to divide the training data into k folds. Inter-rater reliability was computed using Gwet’s AC1 (Gwet, 2002) using a stratified sample of the KCs such that each question and a respective KC set were each represented. Questions were also grouped by one expert grader using Bloom’s revised taxonomy (Anderson and Krathwohl, 2001) as a guide to creating more narrowly-defined question types. Questions were grouped into the categories of procedural knowledge (e.g. recalling the steps of an algorithm), comparison (e.g. comparing two algorithms), explaining specific concepts of an algorithm (e.g. modulating the number of starting clusters in a clustering algorithm), or factual recall (e.g. recalling the definition of a term). While Bloom’s revised taxonomy contains other criteria for categorizing questions, these four categories were the only ones observed in the data.

All knowledge components generated were qualitatively semantically matched to each other by an expert grader where appropriate in order to evaluate consistency of KC generation. For example, if two or more runs generated closely-related variations of the knowledge component “divide data into k folds” for the question “what are the steps of k -fold cross validation?”, then these knowledge components were matched. Consistency was measured as the number of times a matched KC was generated divided by the number of runs. Ideally this value would approach 1, indicating that a KC was likely generated once per run. A value over 1

would indicate overly repetitive generation, while a value under 1 indicates inconsistent generation.

4 Results

One generated KC set was excluded from analysis of the Ministral-3-3B-Instruct model with RAG due to substantial generation failure. An exorbitant number of repetitive KCs were generated in this case (126 in total), indicating that the model may have gotten stuck in a generation loop due to the low temperature. No other models or runs demonstrated any otherwise equivalently catastrophic looping failures, although one run of one question (“what are the common properties of similarity?”) for the Mistral-3-3B-Instruct produced completely topically irrelevant content in the form of software engineering advice.

IRR was achieved in the first round of coding for sufficiency (AC1=0.777). Scope required an additional round of coding on a second similarly stratified sample, at which point sufficient IRR was achieved (AC1=0.704). Once sufficient IRR was achieved for both metrics, the remaining data were divided up among the raters and coded. Differences in scope and sufficiency shown in Table 1 were measured as statistically significant by Cochran’s Q test ($Q = 22.654, p < 0.001$ and $Q = 47.571, p < 0.001$, respectively). Post-hoc McNemar tests (Tables 2 and 3) demonstrate pairwise differences between models and conditions.

All models produced similar numbers of semantically distinct KCs across all runs, with the Ministral-3-3B-Instruct model producing slightly more KCs (374 without RAG, 395 with RAG) than GPT-4o-mini (347 without RAG, 325 with RAG). Both models without RAG produced a median of 12 KCs per question while both models with RAG produced a median of 13 KCs per question, although the range in number of generated KCs differed (Table 5). All models had the same overall median consistency score of 0.60. Consistency of generation for GPT-4o-mini without RAG, GPT-4o-mini with RAG, Ministral-3-3B-Instruct

without RAG, and Ministral-3-3B-Instruct with RAG ranged from [0.2,2.8], [0.2,2.4], [0.2,5.0], and [0.2,3.0], respectively. The questions that produced the most consistent KC sets (median consistency ≥ 0.80) varied by model with no readily apparent pattern. Pair-wise Wilcoxon signed rank tests were performed between model and RAG conditions (Table 6) but revealed no statistically significant difference in consistency of generation. While the dataset contains several types of questions (such as explaining the steps of an algorithm, explaining how modulating a parameter will impact algorithm performance, etc.) there appeared to be no statistical difference in the distribution of types of questions (comparison, algorithm component explanation, algorithm steps, and factual recall) between the most and least consistent questions (Fisher’s Exact $p = 1.00$).

5 Discussion

With regard to RQ1 (“Does including course materials as RAG context for these models result in the generation of higher quality KCs as measured by the scope of the generated content and the sufficiency of the generated KCs in capturing correct responses?”), clear patterns can be observed in RAG vs. No RAG as well as model choice conditions. Statistical testing indicates that the inclusion of RAG content can substantially limit the generation of out of scope KCs. In GPT-4o-mini’s case, out of scope KCs were reduced by 24.4%. In Ministral-3-3B-Instruct’s case, out of scope KCs were reduced by 6.9%. GPT-4o-mini statistically outperforms both conditions of the Ministral model, although the difference is fairly small between the RAG conditions (0.072). The inclusion of RAG material similarly improves the sufficiency of questions in capturing correct responses, with the RAG conditions of GPT-4o-mini and Ministral showing no statistically significant difference in performance. These findings indicate that, for these metrics, GPT-4o-mini and Ministral are near or equivalent in performance and thus both potentially suitable for further exploration of this task. As a result, it may be feasible to allow institutions of higher education to maintain control over their own data using smaller, open-weight models while using a CRS like EXPLAINIT. Additionally, the findings indicate that the inclusion of course material excerpts as RAG content improve the generated KCs over the No RAG condition. Since course material would pre-

sumably be readily available to these models as it has been in this experiment, RAG presents an accessible path to improving KC generation consistency.

With regard to RQ2 (“How consistent are the output of these models over multiple generation cycles?”), consistency was moderate and there was no statistically significant difference in consistency across models and conditions. This may indicate that while issues regarding scope and sufficiency can be reduced with RAG material, issues of consistency even at very low temperatures may require other avenues of model improvement in addition to RAG such as fine-tuning, different prompting strategies such as zero-shot with instructor examples, or purpose-built models. This work may also have identified a relationship between proximity of the KC to the start of the generated KC set and consistency, although this was not explicitly tested or controlled for in this work. We observed that the most consistently generated KCs appear to generally be placed earlier in the lists of KCs produced than those of lower consistency. Because of the sequential nature of the generation of lists of KCs by LLMs in this study, we theorize that the apparent high stability of KCs that are placed first in the list may be due to these KC tokens having high probabilities given the previously-generated text and low temperature. While no statistical tests were performed on this topic, consistency scores were observed to largely decrease as the KCs moved further from the start of the KC set. This may indicate that KC sets are likely to start with high-probability tokens before steadily degenerating to lower-probability, more inconsistently generated KCs as inference proceeds. This could present an avenue for improving consistency of output by eliminating low-probability tokens at time of generation, such as by examining token log probabilities during generation.

With regard to the final RQ (“What, if any, other qualitative or quantitative patterns appear in generated KCs with regards to their quality?”), no visually obvious quantitative or qualitative patterns appeared in the generation of KCs vs. the types of questions analyzed. This may indicate that the models tested are equally as effective in generating KCs for the given dataset regardless of whether the question is oriented towards formats such as factual recitation, exploring the impact of altering or explaining individual algorithmic components, asking students to reason through the steps of an al-

gorithm, or offering a comparative analysis of two or more algorithms or methods. Such flexibility will be useful, as this would theoretically allow instructors to pose a wide range of types of questions based upon the material being delivered.

6 Limitations

Several limitations apply to this work. Firstly, the question set is varied in computer science topic and question type (factual recall, explanation of algorithm components, etc.) but still relatively small with only 27 questions. This limits statistical power when attempting to examine relationships between metrics and question type. Secondly, one catastrophic KC set generation and one completely off topic generation were observed in the open-weight model. While this may simply indicate the existence of relatively rare generation errors, these errors cannot be overlooked in an educational setting and warrant further investigation into eliminating these catastrophic generations or enhancing the human-in-the-loop aspects of the EXPLAINIT system. Additionally, RAG materials varied in quality. The size of the passages varied substantially from a few sentences or bullet points to several pages and could contain irrelevant content that could misguide the LLMs generation process, resulting in KCs that are sourced from the RAG materials but ultimately out of scope of the spirit of the question being asked. Furthermore, KCs were taken as given based upon prior work and were not validated on student data. While the expert graders evaluating the data are knowledgeable about the subject matter of the questions, a more thorough analysis of the KCs on student data would improve the robustness of the status of the generated KCs as “true” KCs. Lastly, this work failed to show within-model boosts to consistency through the use of RAG so further exploration of methods to improve consistency must be pursued. But this work highlighted a potential avenue for improving this issue by identifying a potential pattern in KC generation that could be studied and exploited in order to limit generations to KCs that the LLM is more “confident” in by restricting KCs to those with high token log probabilities. Further exploration would also inform a deeper understanding of consistency of generation, which could in turn inform how a practitioner would interpret or even tweak the KCs produced by this CRS.

7 Conclusion and Future Work

The inclusion of a pipeline allowing instructors to deploy and automatically assess self-explanation questions in CRSs has significant potential to improve learning outcomes over traditional, less interactive lecture experiences or CRSs with less engaging question types by increasing interactivity and prompting students to explain their understanding of course topics and materials in their own words. Assessing the responses to these questions accurately and consistently in real time during lectures poses a substantial technological challenge, but LLMs supported by RAG using course materials may present a promising path towards tackling this challenge through the flexible automated generation of knowledge components.

Our work addresses this novel problem by evaluating the quality of KCs generated by two popular LLMs with or without relevant RAG material drawn from course materials along several metrics: whether or not the generated KCs are within the scope of the question, whether or not the generated KCs are sufficient to identify a correct answer, and the consistency of the generation of these KCs across multiple rounds of generation. Results indicate that the LLM-generated KCs are of higher quality when relevant course material is provided for RAG. Additionally, while the closed-weight model’s performance is statistically significantly better than the open-weight comparison model the gap is small. Furthermore, no statistically significant difference in consistency of KC generation is observed between RAG conditions. These results indicate that both large closed-weight and smaller open-weight models show promise in this task and that fine-tuning or improvements to the quality of RAG material may be necessary to improve consistency and quality further.

Abstract

Automated short answer grading (ASAG) with large language models (LLMs) is commonly evaluated with aggregate metrics such as macro-F1 and Cohen’s kappa. However, these metrics provide limited insight into how grading performance varies across student responses of differing grading difficulty. We introduce an evaluation framework for LLM-based ASAG based on item response theory (IRT), which models grading correctness as a function of latent grader ability and response grading difficulty. This formulation enables response-level analysis of where LLM graders succeed or fail and reveals robustness differences that are not visible from aggregate scores alone. We apply the framework to 17 open-weight LLMs on the SciEntsBank and Beetle benchmarks. The results show that even models with similar overall performance differ substantially in how sharply their grading accuracy declines as response difficulty increases. In addition, confusion patterns show that errors on difficult responses concentrate disproportionately on the *partially_correct_incomplete* label, indicating a tendency toward intermediate-label collapse under ambiguity. To characterize difficult responses, we further analyze semantic and linguistic correlates of estimated difficulty. Across both datasets, higher difficulty is associated with weaker semantic alignment to the reference answer, stronger contradiction signals, and greater semantic isolation in embedding space. Overall, these results show that item response theory offers a useful framework for evaluating LLM-based ASAG beyond aggregate performance measures.

1 Introduction

Automatic short answer grading (ASAG) is the task of using computational methods to assess short free-text student responses to content questions (Burrows et al., 2015). Earlier ASAG approaches relied on handcrafted features and classical machine learning models (Sultan et al., 2016;

Mohler et al., 2011), followed by neural architectures and encoder-based pre-trained language models (PLMs) such as BERT (Gombert et al., 2023; Camus and Filighera, 2020). More recently, generative large language models (LLMs) have attracted increasing attention for ASAG because of their strong language understanding and multi-step reasoning capabilities (Cong et al., 2026b; Frohn et al., 2025; Ferreira Mello et al., 2025).

Despite this progress, evaluation in ASAG remains dominated by aggregate metrics such as accuracy, macro-F1, and agreement coefficients (Bonthu et al., 2021). While useful for summarizing overall system performance, these measures provide only a coarse view of grading behavior and reveal little about how performance varies across responses of differing grading difficulty (Rodriguez et al., 2021; Choi et al., 2026). This limitation is particularly important in ASAG, where student answers are often brief, diverse, and semantically ambiguous (Burrows et al., 2015). Consequently, two models with similar overall scores may nevertheless differ substantially in how well they handle genuinely difficult responses.

This motivates a more measurement-oriented perspective on LLM-based ASAG. In particular, a useful evaluation framework should help characterize which student responses are difficult to grade and whether LLM graders with similar average performance are equally robust across the difficulty spectrum. Existing ASAG research has paid relatively little attention to these questions at the response level (Haller et al., 2022).

To address this gap, we draw on item response theory (IRT), a psychometric framework that models observed outcomes as a function of latent ability and item difficulty. Prior work has shown that IRT can support more informative evaluation in NLP when benchmark instances vary substantially in difficulty (Lalor et al., 2016, 2018). We argue that IRT is well suited to ASAG because it separates latent

grader ability from response difficulty, enabling a more fine-grained analysis of grading behavior than aggregate metrics alone.

In this work, we apply an IRT-based framework to LLM-based ASAG to study grading performance at the level of individual student responses. Specifically, we make the following contributions:

- We introduce an IRT-based perspective for evaluating LLM-based ASAG, estimating latent grader abilities and response grading difficulties across benchmark datasets and multiple LLM graders.
- We analyze how grading performance changes across response difficulty levels and show that LLM graders differ substantially in their robustness as difficulty increases.
- We examine semantic and linguistic correlates of response difficulty and find that difficult responses are consistently associated with weaker semantic alignment to the reference, stronger contradiction-related signals, and greater embedding-space isolation.
- We provide error analyses showing that, on high-difficulty responses, misclassifications are not randomly distributed but increasingly concentrate in the `partially_correct_incomplete` category.

2 Background

2.1 Evaluation Methods in LLM-based ASAG

Evaluation in ASAG has traditionally focused on benchmark performance over labeled response sets, typically reported using aggregate metrics such as accuracy, F1, Cohen’s kappa, RMSE, and correlation-based measures (Haller et al., 2022; Burrows et al., 2015; Sultan et al., 2016). Recent LLM-based ASAG studies largely follow this paradigm, assessing LLM graders through overall label agreement or classification performance (Ferreira Mello et al., 2025; Frohn et al., 2025; Cong et al., 2026b).

Yet recent research on LLM evaluation suggests that aggregate benchmark scores alone may provide only a limited view of model capability (Zhou et al., 2025; Li et al., 2025). Prior work shows that benchmark-level averages can obscure substantial variation in item properties such as difficulty and discriminability, while offering limited separability

among strong models (Lalor et al., 2016, 2018). Similarly, recent work on LLM-as-a-Judge argues that LLM-based evaluators should themselves be evaluated systematically, with reliability, bias, and robustness as central concerns (Gu et al., 2025).

Within ASAG, however, the response-level determinants of grading difficulty remain underexplored, particularly for LLM-based grading. Understanding which properties of student answers make them difficult to grade is important both for interpretability and for deployment, especially in human-in-the-loop settings where difficulty estimates could guide targeted review and improve grading efficiency. Although recent work has examined confidence and uncertainty in ASAG (Funayama et al., 2022; Bexte et al., 2024; Cong et al., 2026a), these signals are typically model-derived and thus only indirectly informative about the characteristics of the response itself. Analyzing difficulty as a property of the student response instead offers a more interpretable and educationally grounded perspective on the failure modes of LLM-based grading.

2.2 Item Response Theory

Item Response Theory (IRT) provides a principled framework by disentangling latent responder ability from item properties (van der Linden, 2016). In the simplest Rasch formulation, the probability that responder m correctly answers item n is modeled as

$$P(y_{mn} = 1 \mid \theta_m, b_n) = \sigma(\theta_m - b_n),$$

where θ_m denotes the latent ability of responder m , b_n the difficulty of item n , and $\sigma(\cdot)$ the logistic sigmoid. More flexible variants, such as 2PL models, additionally model item discrimination, allowing some items to be more informative than others (Hambleton and Swaminathan, 2013).

Recent work has begun to apply IRT to LLM evaluation in several ways, including diagnosing the reliability of LLM-as-a-judge systems (Choi et al., 2026) and modeling latent LLM abilities together with query difficulty and discrimination for routing and performance prediction (Chen et al., 2025). In educational technology, related work has also shown that IRT can be integrated with LLM-based modeling to predict or align item difficulty in assessment settings (Scarlato et al., 2025). Collectively, these developments suggest that psychometric modeling offers a robust lens for analyzing LLM behavior through a measurement-grounded perspective.

3 Method

3.1 Datasets and LLMs

We evaluate our approach on the five-way SciEnts-Bank and Beetle datasets (Dzikovska et al., 2013), two widely used benchmarks for ASAG. Released as part of the SemEval student-response analysis task, both datasets contain science-domain questions, reference answers, and student responses annotated by experts. An important property of these benchmarks is their fine-grained five-way label space, which enables analysis beyond binary correctness. Each instance consists of a question, a single reference answer, a student response, and a gold label from the set `correct`, `contradictory`, `partially_correct_incomplete`, `irrelevant`, and `non_domain`. An important difference between the two datasets is that Beetle is drawn from a relatively narrow tutorial domain in basic electricity and electronics, whereas SciEntsBank covers assessment responses across a substantially broader set of science topics (Dzikovska et al., 2013).

As LLM graders, we select 17 open-weight models covering multiple model families including Google, Qwen, Microsoft, Meta-Llama, MistralAI, and OpenChat, with parameter sizes ranging from 0.8B to 14B. The complete list of models is provided in Table 4 in Appendix A.2. The goal is to capture substantial diversity in grading behavior, including variation associated with model size, architectural lineage, and training characteristics.

3.2 IRT Estimation of Grader Ability and Response Difficulty

We treat each LLM as a grader and each student response as an item to be evaluated. Given a question, a reference answer, and a student response, each model is prompted to assign exactly one label from the five benchmark categories. Decoding is performed greedily with temperature set to 0 to ensure deterministic and reproducible model outputs.

Let $i \in \{1, \dots, M\}$ index LLM graders and $j \in \{1, \dots, J\}$ index student-response instances. For each grader–response pair, we define a binary observation

$$y_{ij} = \begin{cases} 1 & \text{if grader } i \text{ is correct on response } j, \\ 0 & \text{otherwise.} \end{cases}$$

Because multiple student responses are associated with the same question, we include grader-specific testlet effects to capture residual question-specific variation beyond overall grader ability and

response difficulty. Specifically, we extend the Rasch model with testlet effects and fit a testlet response theory (Wainer et al., 2007) variant:

$$P(y_{ij} = 1) = \sigma(\theta_i - b_j + u_{i,t(j)}),$$

where θ_i denotes the latent grading ability of grader i , b_j denotes the grading difficulty of student-response instance j , and $t(j)$ denotes the question-level testlet to which response instance j belongs. The term $u_{i,t(j)}$ is a grader-specific deviation associated with testlet $t(j)$, allowing graders to exhibit question-specific performance offsets beyond their overall ability. We use a 1PL testlet formulation rather than a 2PL variant because a 2PL model would introduce an additional discrimination parameter for each response instance. Given the large number of response instances, we therefore adopt the 1PL formulation and account for question-level dependence through testlet deviations.

Parameters are estimated by minimizing the regularized negative log-likelihood:

$$\begin{aligned} \mathcal{L} = & - \sum_{i,j} \left[y_{ij} \log p_{ij} + (1 - y_{ij}) \log(1 - p_{ij}) \right] \\ & + \frac{\lambda_\theta}{2} \|\theta\|_2^2 + \frac{\lambda_b}{2} \|b\|_2^2 + \frac{\lambda_u}{2} \|u\|_2^2, \end{aligned} \quad (1)$$

Following our implementation, we set $\lambda_\theta = \lambda_b = 1.0$ and $\lambda_u = 5.0$. To ensure identifiability, θ and b are mean-centered within the fitted dataset, and the testlet effects are centered across graders within each testlet. Optimization is performed using LBFGS (Liu and Nocedal, 1989).

3.2.1 Parameter Recovery

To assess whether the latent parameters are recoverable in practice, we conduct a parameter recovery study using the fitted IRT model as the data-generating process, following standard practice in IRT evaluation (Harwell, 1997). Specifically, we treat the fitted model as a generative data source and conduct a simulation-based parameter recovery analysis. For each replication, we use the estimated grader abilities, response difficulties, and grader-specific testlet effects to compute the probability of correct grading for every grader–response pair under the fitted 1PL testlet model. We then sample a new binary correctness matrix from these probabilities, re-fit the model to the simulated data using the same estimation procedure as for the original data, and compare the recovered parameters with

the original fitted parameters after alignment to a common scale.

Recovery is quantified using Pearson correlation, RMSE, and MAE, after aligning the recovered parameters to the original scale via mean and standard-deviation matching. We report these metrics for grader abilities and response difficulties. This analysis assesses whether the inferred latent quantities are sufficiently recoverable to support downstream interpretation.

3.2.2 Split-Half Stability

To assess empirical robustness on real data, we conduct a split-half stability analysis. Whereas parameter recovery evaluates recoverability under synthetic responses generated from the fitted model, split-half stability examines whether the inferred parameters remain consistent when the model is re-estimated on disjoint subsets of the observed data.

We use two complementary procedures. To assess grader-ability stability, we randomly split responses into two halves, fit the model separately on each half using the full set of graders, and compare the resulting ability estimates. Because our main model includes question-level testlet effects, response splits are performed within each question. To assess response-difficulty stability, we randomly split graders into two halves, fit the model separately on each subset using the full set of responses, and compare the resulting difficulty estimates.

We repeat both procedures over 10 random replications and quantify stability using Pearson and Spearman correlations, together with RMSE and MAE after mean–standard deviation alignment to account for scale indeterminacy. High split-half agreement indicates that the inferred latent quantities capture reproducible structure in the observed data.

3.3 Difficulty-Conditioned Analysis of LLM Grader Behavior

To analyze how grading behavior changes as response difficulty increases, we use the estimated response difficulty b_j as the primary stratification variable. We partition responses into quantile-based difficulty bins and compute each grader’s empirical accuracy within each bin. This stratified evaluation complements aggregate metrics by revealing not only whether performance declines with increasing difficulty, but also whether graders differ in their sensitivity to difficult responses.

Using these bins, we perform two analyses. First, we examine the relationship between difficulty and grading accuracy to assess how performance changes across the difficulty spectrum. Second, we inspect bin-specific confusion matrices to identify how error patterns shift with increasing difficulty.

3.4 Semantic and Linguistic Correlates of Difficulty

To examine which response properties are associated with grading difficulty, we extract a focused set of semantic and linguistic features for each student response, motivated by prior work in ASAG (Mohler and Mihalcea, 2009; Burrows et al., 2015; Dzikovska et al., 2013). These features include response length, lexical diversity, unigram and bigram overlap with the reference answer, semantic similarity to the reference answer, NLI-based features computed on the reference–response pair, embedding-space neighborhood features, and the number of missing reference segments. Sentence-embedding features are computed using all-MiniLM-L6-v2 (Reimers and Gurevych, 2019), and NLI-based features are obtained using a ModernBERT-based NLI model (Warner et al., 2025). A detailed description of the features is provided in Appendix A.1.

We treat these features as correlates of estimated response difficulty. For each dataset, we compute both Pearson and Spearman correlations between each feature and the estimated difficulty b_j , and apply the Benjamini–Hochberg procedure to control the false discovery rate under multiple comparisons (Benjamini and Hochberg, 1995).

4 Results

We report three sets of results. First, we assess the stability of the proposed IRT framework and its latent estimates of grader ability and response difficulty. Second, we examine how LLM grading performance degrades as difficulty increases, including changes in confusion patterns on more difficult responses. Third, we analyze how estimated difficulty relates to semantic alignment and response atypicality.

4.1 Parameter Recovery and Split-Half Stability

The fitted IRT model converged successfully on both datasets and produced a broad range of latent grader-ability estimates across the 17 evaluated LLMs, indicating substantial heterogeneity in

Parameter	Pearson r	RMSE	MAE	Conv.
<i>SciEntsBank</i>				
grader ability (θ)	0.999	0.029	0.024	1.000
response difficulty (b)	0.896	0.505	0.404	1.000
<i>Beetle</i>				
grader ability (θ)	0.998	0.036	0.029	1.000
response difficulty (b)	0.895	0.497	0.398	1.000

Table 1: Parameter recovery results over 10 replications on SciEntsBank and Beetle. Values are mean recovery statistics after mean–std alignment to the ground-truth scale. Conv. denotes convergence rate.

grading ability. The full model-level results are reported in Table 4 in Appendix A.2.

Parameter recovery results in Table 1 further support the stability of these latent estimates under the fitted model. For grader ability, recovery was nearly perfect on both datasets, with mean aligned Pearson correlations of 0.999 on SciEntsBank and 0.998 on Beetle, together with very low RMSE/MAE values (0.029/0.024 and 0.036/0.029, respectively). Response difficulty estimates were also recovered well, with Pearson correlations of 0.896 on SciEntsBank and 0.895 on Beetle, and comparable error levels (RMSE = 0.505 and 0.497; MAE = 0.404 and 0.398). All recovery runs converged successfully on both datasets.

Complementary split-half analyses on the observed data yielded a similar pattern (Table 2). Grader ability estimates were highly stable across response halves, whereas response difficulty estimates showed moderate-to-strong stability across grader halves, indicating that the inferred difficulty structure is reproducible but noisier than the model ability scale. Taken together, these results suggest that the IRT framework yields identifiable and empirically robust estimates of both latent grading ability and response difficulty, providing a sound measurement-oriented foundation for the subsequent analyses.

4.2 Differential Performance Degradation Across Difficulty Levels

LLM graders differ substantially in how their grading performance degrades as response difficulty increases. We grouped responses into five quantile-based bins according to their estimated difficulty b , from the easiest ($B1$) to the hardest ($B5$). Across both SciEntsBank and Beetle, accuracy declined monotonically as difficulty increased. At the same

Parameter	Pearson r	RMSE	MAE	Conv.
<i>SciEntsBank</i>				
grader ability (θ)	0.996	0.051	0.041	1.000
response difficulty (b)	0.791	0.595	0.461	1.000
<i>Beetle</i>				
grader ability (θ)	0.994	0.055	0.043	1.000
response difficulty (b)	0.786	0.595	0.464	1.000

Table 2: Split-half stability results over 10 random replications on SciEntsBank and Beetle. Values are mean agreement statistics after mean–std alignment across halves. Conv. denotes convergence rate.

time, the rate of decline varied markedly across models, indicating substantial differences in robustness to difficult responses.

On SciEntsBank, all examined models showed sharp performance degradation toward the most difficult bins, but the extent of this decline differed. Gemma-3-12B remained the most robust overall, retaining 16.6% accuracy on $B5$, whereas Qwen3.5-9B, Phi-3-medium, OpenChat-3.5, and Llama-3.1-8B fell to 4.1%, 5.8%, 15.9%, and 2.1%, respectively. On Beetle, the same overall pattern held, although the relative robustness profile differed. OpenChat-3.5 degraded more gradually than the other models and retained the strongest performance in the upper-difficulty bins, reaching 67.2% on $B4$ and 12.9% on $B5$. By contrast, Gemma-3-12B and Phi-3-medium dropped much more sharply after $B3$, while Llama-3.1-8B approached near-zero performance already by $B4$.

Additional results for the full set of models are provided in Fig. 3 in Appendix A.2. Notably, the difficulty–performance slopes are broadly consistent across the two datasets. The cross-dataset association is strong, with a Pearson correlation of 0.838 and a Spearman correlation of 0.706. This suggests that sensitivity to increasing response difficulty is not merely dataset-specific, but instead reflects a comparatively stable characteristic of LLM grading behavior.

To further characterize this degradation, we examined confusion patterns across difficulty bins. As shown in Fig. 2 and Fig. 4 in Appendix A.2, errors in high-difficulty responses are not randomly distributed across labels, but instead become increasingly structured. Across both datasets, correct, contradictory, irrelevant, and non_domain responses are increasingly mapped to partially_correct_incomplete (PCI) as difficulty rises, indicating a progressive loss of fine-

grained multi-class discrimination. At the same time, difficult PCI responses are often misclassified as correct, suggesting that higher difficulty induces both collapse toward an intermediate category and overly optimistic judgments of ambiguous answers.

4.3 Semantic Misalignment and Response Atypicality as Correlates of Difficulty

As shown in Table 3, the correlation analysis reveals a clear and largely consistent pattern across SciEntsBank and Beetle. Overall, the strongest associations with response difficulty come from features that capture semantic alignment with the reference answer and the semantic typicality of a student response relative to other responses. In both datasets, higher difficulty is associated

with lower NLI entailment to the reference answer (SciEntsBank: Pearson $r = -0.300$, Spearman $\rho = -0.303$; Beetle: Pearson $r = -0.261$, Spearman $\rho = -0.227$) and a smaller entailment-contradiction margin (SciEntsBank: $r = -0.291$, $\rho = -0.306$; Beetle: $r = -0.235$, $\rho = -0.232$). Likewise, semantic similarity to the reference answer and lexical overlap with the reference answer, including both unigram and bigram overlap, are negatively correlated with difficulty in both datasets. These results indicate that responses that are semantically closer to the reference answer tend to be easier for LLM graders to evaluate correctly.

By contrast, features reflecting semantic disagreement or atypicality show positive associations with difficulty. In both datasets, the NLI contradiction score is positively correlated with response difficulty (SciEntsBank: $r = 0.211$, $\rho = 0.309$; Beetle: $r = 0.136$, $\rho = 0.216$). A similar pattern holds for embedding-space neighborhood distance. Both average and minimum k -nearest-neighbor distance are positively associated with difficulty across datasets. This suggests that responses that are more isolated in semantic space, and therefore less typical relative to the broader response distribution, are more difficult for LLM graders to grade reliably.

At the same time, not all features are equally informative. Some shallow surface-level properties, such as token count and type-token ratio, show weak or inconsistent associations across datasets. The number of missing reference segments is positively related to difficulty in SciEntsBank, but much weaker in Beetle.

5 Discussion

Our findings support a difficulty-aware perspective on evaluating LLM-based ASAG. Although aggregate measures such as accuracy, macro-F1, and agreement coefficients are useful summaries of overall performance, they do not reveal whether a model remains robust across responses of differing grading difficulty, a limitation also noted in prior IRT-based work on NLP evaluation (Lalor et al., 2016, 2018). The simulation-based recovery and split-half analyses further support the stability of the proposed measurement framework, suggesting that the estimated latent structure is not arbitrary and remains reasonably consistent across repeated analyses. Split-half results also show that grader ability estimates are more stable than response dif-

Figure 2: Confusion matrices on SciEntsBank across five bins of IRT-derived response difficulty b . n denotes the number of responses in each bin, and Acc denotes overall grading accuracy.

difficulty estimates, likely because the former are estimated from many responses, whereas the latter are supported by far fewer grader judgments.

This difficulty-aware analysis therefore provides a more informative account of where LLM graders succeed and where they fail. More specifically, the results suggest that LLM graders should be compared not only by their overall performance, but also by how robustly they handle increasingly difficult responses. Models with similar aggregate scores may nevertheless differ substantially in the rate and form of performance degradation across difficulty levels. From this perspective, a grader that performs well on easy cases but deteriorates sharply on difficult responses is qualitatively different from one whose performance declines more gradually, even when their aggregate scores are similar. From a robustness standpoint, the latter may be better suited for practical deployment.

The error analysis suggests that high-difficulty responses do not simply produce more mistakes at random. Instead, errors become increasingly concentrated in the `partially_correct_incomplete` category.

This pattern indicates that, under uncertainty, LLM graders often default to an intermediate label rather than making a sharper distinction. One plausible interpretation is that `partially_correct_incomplete` acts as a default intermediate category when evidence is weak, mixed, or only partially supportive. In such cases, the model preserves topical plausibility without committing to full correctness.

The feature analysis helps explain why such responses are difficult. Across datasets, higher difficulty is most consistently associated with weaker semantic alignment to the reference answer, stronger contradiction-related signals, and greater isolation in embedding space. These findings suggest that difficult responses are typically not arbitrary outliers, but responses whose meaning is incomplete, weakly expressed, internally mixed, or only partially compatible with the reference answer. At the same time, the correlations are moderate rather than large, which implies that difficulty is not reducible to any single response property. Instead, grading difficulty appears to emerge from the interaction of multiple semantic factors, including

Feature	SciEntsBank		Beetle

alignment, contradiction, completeness, and local response-space structure.

Taken together, these results have practical implications for LLM-assisted grading. Most importantly, they suggest that not all responses should be treated as equally suitable for fully automatic scoring. If difficulty can be estimated directly or approximated from response features, it could support selective grading pipelines in which straightforward cases are handled automatically while difficult cases are routed to human review. Compared with uncertainty estimates derived solely from the model itself (Funayama et al., 2022; Bexte et al., 2024; Shorinwa et al., 2025), response-based difficulty also offers a more interpretable account of why particular answers are difficult to grade. This may be especially valuable in educational settings, where reliability, interpretability, and fairness are as important as efficiency (Madnani and Cahill, 2018).

The findings also have implications for rubric design, which has recently emerged as an important direction in ASAG research (Frohn et al., 2025; Cong et al., 2026b; Gombert et al., 2026). The systematic tendency to over-predict partially_correct_incomplete on difficult responses suggests that current prompting setups may not provide sufficiently clear decision boundaries between neighboring categories. More explicit rubric-based prompting or decomposed decision procedures may help address this problem. For example, grading could be structured into sequential sub-decisions such as topical relevance, presence of correct propositions, contradiction to the reference, and completeness of required content. This kind

of scaffolded evaluation may reduce the model’s tendency to collapse toward an intermediate class when evidence is ambiguous.

6 Conclusion

Overall, the present study shows that IRT offers a useful framework for analyzing LLM graders beyond aggregate performance. Rather than asking only which model achieves the highest average score, this perspective makes it possible to ask which responses are difficult, why they are difficult, and which models remain more robust as difficulty increases. For ASAG, this shift from average performance to measurement-oriented analysis provides a more interpretable basis for both evaluation and system design.

7 Limitations

This study has several limitations. First, the number of LLM graders is limited. Although we evaluate 17 models across multiple families and parameter scales, the estimated latent ability scale and robustness patterns should be interpreted with respect to this particular model set. Second, the analysis is restricted to two benchmark ASAG datasets and a specific five-way label schema. Although the main patterns are consistent across SciEntsBank and Beetle, it remains unclear how well they generalize to other domains, rubrics, or grading schemes. Third, our IRT formulation binarizes grading correctness and therefore does not model the five-way label structure directly. Future work could use polytomous IRT models to capture more fine-grained differences among label categories and error types. Finally, the feature analysis is correlational. The

observed associations help characterize difficult responses, but they do not establish causal determinants of grading difficulty. Investigating these causal mechanisms remains an important direction for future work.

A Appendix

A.1 Feature Definitions

For each student response, we compute a set of lexical, semantic, and distributional features with respect to the reference answer and the question. Let a_i denote the student answer for item i , r_i the corresponding reference answer, and q_i the question. All lexical features are computed from lower-case regex-based tokens extracted with the pattern $[A-Za-z0-9']^+$. Thus, throughout this appendix, “token” refers to these surface tokens rather than model-specific subword tokens.

Lexical overlap features. Let $U(a_i)$ and $U(r_i)$ denote the sets of unique unigrams in the student answer and reference answer, respectively. The unigram overlap with the reference is defined as

$$\text{UnigramOverlap}(i) = \frac{|U(a_i) \cap U(r_i)|}{|U(r_i)|}.$$

Similarly, letting $B(a_i)$ and $B(r_i)$ denote the sets of unique bigrams in the student answer and reference answer, the bigram overlap is

$$\text{BigramOverlap}(i) = \frac{|B(a_i) \cap B(r_i)|}{|B(r_i)|}.$$

Both measures therefore quantify reference-normalized lexical coverage rather than Jaccard similarity.

The token count is simply the number of tokens in the student answer,

$$\text{TokenCount}(i) = |a_i|,$$

and the type-token ratio is defined as

$$\text{TTR}(i) = \frac{|\text{unique tokens in } a_i|}{|a_i|}.$$

Semantic similarity features. We encode student answers, reference answers, and questions using Sentence-BERT embeddings. All embeddings are ℓ_2 -normalized, so cosine similarity reduces to a dot product. The semantic similarity to the reference is computed as

$$\text{SimRef}(i) = \cos(\mathbf{e}(a_i), \mathbf{e}(r_i)).$$

NLI-based features. We apply a pretrained natural language inference model to each reference-answer pair, using the reference answer as premise

and the student answer as hypothesis. This yields three probabilities:

$$P_{\text{ent}}(i), \quad P_{\text{con}}(i), \quad P_{\text{neu}}(i),$$

corresponding to entailment, contradiction, and neutrality. From these, we derive the following features:

$$\begin{aligned} \text{NLIEntail}(i) &= P_{\text{ent}}(i), \\ \text{NLIContradict}(i) &= P_{\text{con}}(i), \\ \text{NLINeutral}(i) &= P_{\text{neu}}(i), \\ \text{NLIMargin}(i) &= P_{\text{ent}}(i) - P_{\text{con}}(i). \end{aligned}$$

Distributional neighborhood features. To quantify how typical or atypical a student response is relative to other responses in the same dataset, we compute pairwise cosine similarities among all student-answer embeddings. For each answer, we identify its k nearest neighbors in embedding space (excluding the answer itself), with $k = 5$ in our implementation. The average k NN distance is defined as

$$\text{AvgKNNDist}(i) = 1 - \frac{1}{k} \sum_{j \in \mathcal{N}_k(i)} \cos(\mathbf{e}_i, \mathbf{e}_j),$$

where $\mathbf{e}_i = \mathbf{e}(a_i)$ denotes the embedding of answer a_i , and $\mathcal{N}_k(i)$ denotes the set of indices of the k most similar other student answers. The minimum k NN distance is defined as

$$\text{MinKNNDistance}(i) = 1 - \max_{j \neq i} \cos(\mathbf{e}(a_i), \mathbf{e}(a_j)).$$

Higher values indicate that a response is more isolated in the embedding space.

Reference-segment coverage. To approximate coverage of distinct parts of the reference answer, we split each reference answer into segments using sentence-like punctuation (. ; : ! ?), tokenize each segment, and retain only segments with at least three tokens. For each retained segment s , we compute its token overlap with the set of answer tokens:

$$\text{Coverage}(s, a_i) = \frac{|U(s) \cap U(a_i)|}{|U(s)|}.$$

A reference segment is considered covered if this value is at least 0.5. The number of missing reference segments is then

$$\begin{aligned} \text{MissingSegments}(i) &= N_{\text{segments}}(r_i) \\ &\quad - N_{\text{covered}}(r_i). \end{aligned}$$

Higher values indicate that the student answer fails to cover more reference segments.

Abstract

This paper explores the application of a Large Language Model (LLM) using k -shot prompting with large k for automatically scoring a German Written Elicited Imitation Test (WEIT), a test for assessing literacy-dependent procedural knowledge in German as a foreign language. In this test, test-takers are briefly presented with written sentences which they then have to reproduce in writing as accurately as possible. The responses are scored on an ordinal scale which differentiates between different types of errors (e.g. lexical vs. grammatical). We find that with increasing k (in a range from 1 to 700) accuracy increases significantly but it also depends on the drawn sample and varies across different runs of the same prompt. Overall, the k -shot setting which relies on in-context learning without being provided with the scoring rubric outperforms a baseline where only the scoring rubric is provided to the model. However, the LLM does not outperform previous results based on rule-based or BERT-based models.

1 Introduction

The Written Elicited Imitation Test (WEIT) is a test used for measuring procedural linguistic knowledge in writing (Timukova et al., 2026). In this computer-based test, participants view sentence after sentence for a short time duration and after a brief pause, they are asked to reproduce the sentence by typing it in a text field. The responses are rated on an ordinal scale ranging from 0 to 4 based on a scoring rubric. Responses receive higher scores when they are closer to the original while lower scores are given to grammatically, syntactically or semantically altered sentences (see Section 3 for a more detailed description of the scoring rubric).

Chiffigarov et al. (2025) were the first to explore the automatic scoring of a German WEIT. They compared two approaches: (i) a rule-based scoring model which directly implements categories

from the scoring rubric and (ii) a deep-learning-based approach where a pre-trained transformer model from the BERT family (DistilBERT; Sanh et al., 2019), henceforth referred to as BERT-based model, was finetuned on pairs of annotated stimulus and response sentences in order to learn (implicitly) which scores to apply. The results showed that both approaches had different strengths and weaknesses. While the rule-based model performed better on unseen stimulus sentences and scores at the edges of the rating scale, the BERT-based model was better at mid-range scores.

Overall, the results appear not yet robust enough to be applied in practice on the level of the individual response. At the same time, language learners and instructors would greatly benefit from an automatic scoring of WEITs, which would reduce the manual evaluation effort and thus make this instrument more widely usable. Developing a more robust scoring model is thus still a desideratum.

The present paper is a follow-up to the study of Chiffigarov et al. (2025), exploring the use of a Large Language Model (LLM) for automatically scoring a German WEIT. It focuses on one specific prompting strategy and systematically investigates different sources of variance connected to this strategy. The strategy we use is k -shot prompting, an in-context learning approach where the LLM is presented with k scored samples and in our case no explicit scoring rubric. The idea is that based on the provided examples (shots), the LLM derives the scoring principles on its own. Besides the choice of k , we study the impact of different samples drawn. Another source of variance applying to all LLM-based studies is the non-determinism of an LLM, i.e. different runs of the same prompt can produce different results even if the temperature parameter is set to 0 (Atil et al., 2025). This source of variance has rarely been studied systematically (Song et al., 2025, but see e.g. Ouyang et al., 2025).

The **aim of the paper** is twofold: (1) compar-

ing the performance of an LLM-based model with the rule-based and BERT-based models used by Chiffigarov et al. (2025), thereby contributing to the development of automatic scoring models for WEITs and (2) an in-depth investigation of the k -shot prompting strategy used for the LLM, contributing to the understanding of variability in LLM performance for this particular task. We pursue the following **research questions** related to (2):

RQ1: What is the optimal number of examples k for scoring a WEIT?

RQ2: What variance in performance arises through the use of different samples for the in-context learning examples?

RQ3: Given the non-determinism of LLMs, what variance is to be expected only by running the same prompt multiple times?

The LLM used in this paper is GPT-4o by OpenAI, which was chosen due to its popularity. Section 2 discusses related work and Section 3 presents the data and scoring rubric. In Experiment 1 (Sec. 4), we explore a large range of k ($10 \leq k \leq 700$) while in Experiment 2 (Sec. 5), we focus on small $k \leq 25$. In Section 6 we compare the results to those obtained by Chiffigarov et al. (2025). The code and data from this study are available on <https://gitlab.ruhr-uni-bochum.de/vamos-cl/german-weit-k-shot-prompting>.

2 Related Work

Chiffigarov et al. (2025) were the first to automatically score a written EIT. Previously, only the automated scoring of oral EITs (OEIT) had been explored. However, the OEITs were typically rated on a binary scale (Millard, 2011) or interval scale (Graham et al., 2008; Lonsdale and Christensen, 2011), not an ordinal scale with a rubric that distinguishes different error categories (see Sec. 3).

In other areas of the educational domain involving automated scoring, LLMs have already become popular. Different studies investigated the use of k -shot prompting, especially few-shot prompting, coming to mixed results. In the domain of automatic essay scoring, for example, Mansour et al. (2024) found that adding one example (1-shot prompting) to the scoring rubric improves the results but not across all models and all writing tasks. Yoshida (2024) investigated 1–3 shots, finding that the choice and order of examples impacts the results. Huang and Wilson (2025) found that few-shot prompting improves the results. They added

five examples to a prompt providing context and chain-of-thought instructions. In the area of short-answer scoring, Chamieh et al. (2024) explored k -shot prompting with k varying between 1 and 10. They found that increasing the number of shots was not beneficial for all models and datasets.

For other domains, there has already been evidence that in-context learning with a large k can be powerful. Bertsch et al. (2025) used long context models on different classification tasks, e.g. question classification or intent classification. They found accuracy gains of up to 50.8 points when scaling from 10 to 1,000 examples. Furthermore, with increasing k , it became less important which examples were chosen. Note that their prompts *only* contained the shots. In our experiments, we follow this approach of using large values of k and, while we provide a little bit of context in the prompt, we do not include the full scoring rubric either, which means that the model predominantly relies on the provided examples. In this respect, our approach differs from the k -shot prompting studies in the areas of short-answer scoring or essay scoring discussed above, where a rather small number of shots (≤ 10) was used to support rather than replace the scoring guidelines in the prompt. Furthermore, in the context of a WEIT, a single shot contains only one sentence pair, whereas for essay scoring, a single shot is equivalent to a whole text.

3 Data

We use the WEIT dataset published by Chiffigarov et al. (2025). Its collection, the creation of a scoring rubric and the manual scoring of the data was part of a larger research project (Timukova et al., 2026). The dataset consists of 3,900 stimulus-response pairs (195 participants responded to 20 different stimulus sentences each). Each response was scored based on an ordinal scoring rubric. In the following, we quote a scored example (Table 1) and the brief summary of the scoring rubric from Chiffigarov et al. (2025). The full rubric can be found in their supplementary material.

Score 4 The response matches the stimulus sentence exactly or 1–2 typos are present.¹

Score 3 Changes in grammar or lexical changes that preserve the original structure and result

¹Typos include: transposed letters (all present), one letter replaced by a QWERTZ-adjacent key, one letter added/omitted next to an adjacent key, or a missing space between words.

Score	Example	Explanation
0	Bein praktikum	less than half of the words repeated correctly
1	Bei einem Praktikum * * *	half of the words repeated correctly but most of the meaning lost
2	Bei ein Praktikum lernt man viel.	case wrongly marked, ungrammatical sentence
3	Beim Praktikum lernt man viel.	change in grammar (contraction of preposition + article) but still grammatical
4	Bei einem Praktikum lenrt man viel.	one typo

Table 1: Example of the scoring rubric for the stimulus sentence *Bei einem Praktikum lernt man viel*. ‘At an internship, one learns a lot’. Table taken from [Chiffigarov et al. \(2025\)](#).

in grammatically correct and meaningful sentences, e.g. confusing definite and indefinite articles (where interchangeable), or (near-)synonymic substitutions of words.

Score 2 Changes in grammar that result in ungrammatical sentences or grammatical sentences which are not meaningful, e.g. violated agreement between subject and verb, structural omissions or wrong plural formation.

Score 1 More than half of the words are repeated but a considerable part of the original meaning or structure is lost or changed.

Score 0 Less than half of the words are repeated.

We use the same split into training, development and test data as used by [Chiffigarov et al. \(2025\)](#).

4 Experiment 1: Large Samples

In the following experiments, the LLM GPT-4o (henceforth referred to as GPT model) is prompted to score the data described in Section 3 only based on examples from the training data, without explicitly providing the scoring rubric. In Experiment 1, three sources of variance are explored: (1) the number of examples k , (2) different samples drawn from the training set (consisting of 3,260 stimulus-response pairs in total) (3) different runs of the same prompt using the same examples.

4.1 Method

We vary the number of examples k between 10 and 700. Between $k = 10$ and $k = 50$, k is increased in steps of 10, above $k = 50$ in steps of 50, yielding 18 variations of k in total. For each k , two different samples (based on a fixed random seed) are drawn from the training set. For each k and each sample, four runs of the same prompt are carried out, yielding a total of 144 runs (18 different $k \times 2$ different samples $\times 4$ runs). To keep the variance as low as possible, we set the temperature parameter to 0.

Identity:

You score answers from a German Elicited Imitation test. You score between 0 and 4. The test is in german language.

Instructions:

- The training data contains answers and the original items, that are already scored between 0 and 4
- The training data has an ID at the beginning, the original second, the answer as third and the score as fourth
- Try to understand why and how the scores of the training data relate to the answer original pairs
- The training data is here: **EXAMPLES**
- You will get the same answer original pairs but with no scores, score each pair based on the training data.
- Output only the answer original pairs with the respective scores and ID of the answer original pair
- Format the output in a way that the ID, the answer, the original and the score are divided by ‘\t’

Figure 1: Prompt given to GPT-4o in the developer/system role.

Prompt The model is given a set of stimulus-response pairs to score from the user role. A simple instruction prompt from the developer/system role is added, asking the model to analyze the given examples (termed training data), see Figure 1. The examples are provided as a simple string with a new line for each stimulus-response pair and divided into four columns named *id*, *original* (=stimulus), *answer* (=response) and *score* divided by a tab. The string is included within the prompt (marked by **EXAMPLES** in Figure 1). A little bit of manual adjusting of the prompt was done in order to get the model to just output the scored items and not add an unwanted information (reasons, questions, comments etc.). We are aware that subtle prompt formatting, e.g. regarding casing or spacing can impact the result ([Sclar et al., 2024](#)). Investigating this systematically was beyond the scope of this study though.

Figure 2: Results for **Experiment 1**: Accuracy (left) and QWK (right) for each number of shots k . The red and blue line represent the two different samples. The solid line represents the mean of the four runs, the shaded area indicates the minimum and maximum value per run.

Evaluation The results are evaluated on the development set consisting of 125 stimulus-response pairs that are balanced across scores. We use accuracy and quadratically weighted kappa (QWK) as evaluation metrics. While accuracy is a strict metric, only counting exact score matches, QWK quantifies the magnitude of deviations, punishing greater deviations from the gold score more severely than smaller deviations.

4.2 Result

Figure 2 illustrates how accuracy and QWK vary with the number of shots k , the chosen sample and the different runs. Overall, QWK is rather stable across k , especially with $k > 50$, and there is almost no influence of the different runs. When $k < 400$, there is a notable difference between the two samples. Accuracy shows much more variability involving all factors. There is a clear drop in performance with very low values of k , which will be investigated more closely in Experiment 2 in Section 5.

In order to assess the influence of the different factors, we conducted a binomial logistic regression analysis with accuracy as the dependent variable and k (numeric), *sample* (categorical) and *run* (categorical) and the interaction of k and *sample* as predictors.² Rather than modeling *sample* and *run* as random effects in a generalized linear mixed-effects model, which would conceptually correspond better with their randomness, we decided to include them as fixed effects since we wanted to study whether they have a systematic influence on scoring accuracy. Furthermore, their small number

of factor levels (two for *sample* and four for *runs*) does generally not make them suitable random effects (Gomes, 2022). In our analysis, the variable *run* was effects-coded so that the coefficients reflect deviations from the overall mean of the dependent variable (in contrast to the default treatment coding, where the comparison is made against one reference level of the predictor). We found two significant effects, namely the main effects of k ($\beta < .01$, $SE < .01$, $z = 4.46$, $p < .001$), and *sample* ($\beta < .13$, $SE < .05$, $z = 2.54$, $p = .01$). This means that a higher k yields a higher accuracy and also one of the samples yields a significantly higher accuracy than the other.

One aspect that certainly influences the performance of the models is whether they have seen all 18 stimulus sentences in the examples (see also Section 6 for the performance on known vs. unknown stimulus sentences). In fact, only with $k \geq 100$, all stimulus sentences are present in the examples. To investigate this further, we conducted two separate regression analyses on the data with $k < 100$ and $k \geq 100$. In these separate regressions, none of the factors are significant anymore (all $\beta < .18$, $SE < .14$, $-.64 < z < 1.8$, $p > .08$). This indicates that the significant effects of k and *sample* arise only when considering the whole range of k between 10 and 700.

5 Experiment 2: Small Samples

In Experiment 1, we found that overall, a higher number of shots k improves the accuracy and QWK and that there is a notable drop in performance when only few examples are given. To investigate this further, Experiment 2 uses even smaller values of k .

²The regression was carried out using the `glm` function of R (version 4.5.3)

Figure 3: Results for **Experiment 2**: Accuracy (left) and QWK (right) for each number of examples k . Each line represents a different sample.

5.1 Method

In this experiment, $k \in \{1, 3, 5, 7, 10, 15, 25\}$ is used. We assume that the smaller the number of examples, the more it matters which ones are chosen. We therefore compare 4 different samples drawn from the training data with a fixed random seed per value of k . Since the different runs were not a significant factor in Experiment 1, we run each of the 28 configurations in this experiment (7 variations of $k \times 4$ different samples) only once. The prompt and the evaluation setting are the same as in Experiment 1.

5.2 Result

Figure 3 illustrates the accuracy and QWK for the different values of k and the four samples. As expected, for small k values, the chosen sample can make a big difference of over ten percentage points in accuracy. It is notable, though, that even with very few examples, the GPT model performs way above chance level (which would be 20% percent in the balanced development set on which the evaluation is carried out).

We again conducted a binomial logistic regression analysis with accuracy as the dependent variable and k (numeric) and *sample* (categorical) and their interaction as predictors. The variable *sample* was effects-coded. Only k turns out as a significant predictor ($\beta = .02, SE = .004, z = 5.53, p < .001$), with higher k yielding higher accuracy. Higher values of k are strongly correlated with the number of stimulus sentences seen (Pearson’s $r = 0.95$), which certainly influences model performance.

Model	Known It.		Unknown It.		Combined	
	acc	qwk	acc	qwk	acc	qwk
Rule-based	.71	.89	.60	.77	.64	.82
BERT	.77	.93	.58	.81	.64	.86
GPT-rubric	.51	.72	.46	.74	.47	.73
GPT-kshot	.66	.89	.55	.80	.59	.84

Table 2: Accuracy and QWK for the rule-based and BERT-based models from Chiffigarov et al. (2025) compared to the GPT-rubric and GPT-k-shot model on the test sets with known items and unknown items, respectively, and the combined test set. Numbers in bold indicate the best model per set and metric.

6 Comparison with Rule-Based and BERT-Based Models

To assess the overall performance of the GPT k -shot model, we compare it to the rule-based and BERT-based models from Chiffigarov et al. (2025).³ In this evaluation, we use the k -shot model that performed best on the development set in Experiment 1 ($k = 700$). Furthermore, we add another GPT-based baseline, where the prompt for GPT-4o contains the scoring rubric used by the human raters (henceforth referred to as GPT-rubric). In this setting, no scored examples (shots) are given but the rubric contains some concrete examples illustrating each score. The exact prompt with the rubric can be found in the online repository. Systematic tuning of this rubric-based prompt was beyond the scope and goal of this paper, so this setting is only meant as a basic point of reference for comparing the k -shot setting to.

For the evaluation, we use the two test sets from Chiffigarov et al. (2025). The first test set contains a

³In the following, the BERT-based model refers to the weighted model used by Chiffigarov et al. (2025).

Score			Precision				Recall				F1-Score			
	# answ.	%	Rule	BERT	GPT-r	GPT-k	Rule	BERT	GPT-r	GPT-k	Rule	BERT	GPT-r	GPT-k
0	92	24%	.85	.84	.63	.86	.91	.82	.29	.55	.88	.83	.40	.68
1	99	26%	.51	.66	.41	.54	.86	.61	.44	.64	.64	.63	.43	.59
2	77	20%	.29	.47	.28	.40	.17	.74	.26	.30	.21	.57	.27	.34
3	79	21%	.80	.58	.50	.57	.35	.42	.71	.68	.49	.49	.58	.62
4	34	9%	.94	.82	.72	.62	.94	.53	.97	.97	.94	.64	.82	.76
macro avg			.68	.67	.51	.60	.65	.62	.54	.63	.63	.63	.50	.60
micro avg			.64	.66	.48	.60	.64	.64	.47	.59	.61	.64	.46	.58

Table 3: Distribution of (gold) scores in the combined test set and precision, recall and F1-score per (gold) score as well as macro average and micro (=weighted) average for each model (GPT-r = GPT-rubric, GPT-k = GPT-k-shot). The numbers in bold indicate the highest value in precision, recall, and F1-score, respectively, per score.

random held-out sample of answers comprising all 18 different stimulus sentences that are also part of the training and development set (henceforth *known test set*). This test set reflects the performance on new answers to known stimulus sentences. It is balanced across all scores 0-4. The second test set (*unknown test set*) contains all answers to two completely new stimulus sentences, reflecting the performance of the models when a new test with new stimuli is used.

In contrast to Chiffigarov et al. (2025), we remove duplicates from the test set. Duplicate answers mainly concern answers that are practically identical to the stimulus sentence, therefore mostly answers with the highest score 4 are removed. Furthermore, due to a token limit for the GPT model, not all answers from the unknown test set could be processed but only a random sample. Consequently, our test set comprises the intersection of answers processed by all models and excluding the duplicates. This yields 116 answers (out of 125) in the known test set and 265 (out of 390) in the unknown test set.

Table 2 shows accuracy and QWK for each model for the known test set, the unknown test set and the combination of both test sets.⁴ We can see that GPT-k-shot outperforms GPT-rubric on all test sets and the difference in correctly scored items is significant on both sets (both $\chi^2(1) > 4.71$, $p < .03$, two-sided). However, GPT-k-shot does not perform better than the models presented in Chiffigarov et al. (2025), neither on the known nor on the unknown set. In fact, the differences in correctly

scored items between GPT-k-shot on the one hand and the rule-based and BERT-based model on the other hand are not significant (all $\chi^2(1) < 2.57$, $p > .10$, two-sided).

All models tend to perform worse on the unknown than on the known test set. The performance drop is greater for the BERT-based model than for the GPT-k-shot model although both models rely on training samples. However, the number of correctly scored items only differs significantly for the BERT-based model ($\chi^2(1) = 11.31$, $p < .001$, two-sided) not for the other models (all $\chi^2(1) < 3.53$, $p > .06$, two-sided). The GPT-rubric model has the smallest performance drop. This result is intuitive because the scoring rubric describes more general scoring rules applying to all stimulus sentences. Still, GPT-rubric shows the worst performance on the unknown test set compared to the other models.

Table 3 breaks down the results, showing precision, recall and F1-score per score for each model on the combined test set. We see that due to duplicate removal, score 4 only applies to 9% of the answers, according to the gold standard, whereas the other scores are more evenly distributed. As already noted by Chiffigarov et al. (2025), the rule-based model outperforms the other models on the edges of the rating scale, i.e. scores 0, 1 and 4, whereas the BERT-based model clearly performs better than the others on score 2. The rule-based model does not perform so well on scores 2 and 3, partly because not all categories from the scoring rubric pertaining to these scores have been implemented as they are not straightforward to be captured in rules. On score 3, GPT-k-shot has the best overall performance based on F1-score, although the rule-based model has a higher precision and GPT-rubric a slightly higher recall. As mentioned in Section 3, score 2 mainly captures grammatical

⁴Note that in Table 2, the performance of the rule-based model is slightly worse and that of the BERT-based model slightly better than reported in Chiffigarov et al. (2025). This is mainly due to the removal of duplicates, which drastically reduces the number of answers with score 4, a category where the rule-based model outperforms the BERT-based model.

Figure 4: Confusion matrix of predicted vs. gold score for each model on the combined test set.

deviations whereas score 3 applies to semantic deviations. The results therefore suggest that the GPT-based models rather pick up semantic differences between stimulus and answer sentence compared to the BERT-based model. Looking at the score confusions in Figure 4 shows that the BERT- and rule-based models tend to undervalue answers in this score range, often giving answers with gold score 3 a score of 2 whereas the GPT-based models show the opposite pattern in that answers with gold score 2 often receive a score of 3.

7 Conclusion and Future Work

This paper explored the use of an LLM for scoring a German WEIT. The experiments focused on in-context learning, using k -shot prompting with large k values up to $k = 700$. We considered three sources of variance: The number of examples k , the chosen sample and the non-determinism of LLMs when running the same prompt multiple times. We showed that accuracy varies significantly with k (higher values yielding higher accuracy) and the chosen sample but with sufficiently large k , the effects become non-significant. Furthermore,

while having no significant systematic effect in our regression model, one could see that accuracy is not stable across different runs of the same model. QWK turned out much more robust in this respect, reflecting that the deviations in the scores arising through multiple runs are only small.

Using its best configuration, our GPT k -shot model outperformed a zero-shot GPT model that uses the scoring rubric and no examples. Furthermore, we compared the GPT models to previously obtained results from Chiffigarov et al. (2025), who used a rule-based and a BERT-based model. While the GPT k -shot model could not generally outperform the other models, an interesting pattern emerged when looking at scores 2 and 3, which were previously shown to be the ones that are the most difficult to predict. The GPT k -shot model tends to overestimate responses with score 2 (responses with grammatical errors) while the BERT-based model tends to underestimate responses with score 3 (responses with lexical deviations which are still grammatical). A possible explanation could be that the GPT model relies mostly on semantic similarity between the stimulus and the response sen-

tence, ignoring other kinds of deviations, whereas the BERT-based model pays too little attention to the semantics of a sentence. In future work, we want to investigate this further.

Our study focused on one particular LLM, thus the results may not generalize to other models but may also depend on the architecture, context window etc. Rather, our results show that an LLM does not *necessarily* outperform a rule-based or BERT-based model and that its observed variability, especially when running the same prompt multiple times, may limit its practical applicability. Further investigations are necessary here to find out whether this variability occurs randomly or affects e.g. certain scores in particular.

For future work, we see two promising avenues to improve the automated scoring of a WEIT, firstly experimenting with further prompting strategies for LLMs, especially combining the k -shot approach with the scoring rubric and secondly combining different kinds of models (rule-based, BERT-based and LLMs), exploiting their different strengths and weaknesses across the different scores.

Limitations

The focus of this paper was to study in-depth one prompting strategy (in-context learning with k -shot prompting) and the associated variability when using a particular LLM (GPT-4o) to score a German WEIT. The focus on one LLM limits the generalizability of the results as other models with other architectures and characteristics, e.g. in terms of parameters and context windows, may behave differently. Although our study already captures many factors that influence the performance, there can still be even more sources of variance such as periodic differences in performance of GPT-4o at different points in time (Tschisgale and Wulff, 2026). Furthermore, we did not aim to find the overall best LLM setup for scoring a German WEIT. From our results, one cannot draw the conclusion that k -shot prompting generally works better than rubric-based prompting as we did not systematically tune the rubric-based prompt. Finding the best LLM setup would involve trying different models and more prompting strategies, especially combining the scoring rubric with k -shot prompting, as is state of the art for many applications.

Acknowledgments

The WEIT for German was conceived, developed, and the data collected as part of a research project funded by the Deutsche Forschungsgemeinschaft (DFG), grant number 462766474. We would also like to thank the anonymous reviewers for their very helpful comments.

Abstract

In this paper we discuss the development of kelvi.ca¹, an open source web-based dictionary and morphological parser designed to aid Tamil learners in developing their literacy skills. Tamil is an agglutinative language and heavily suffixal. Existing Tamil dictionaries only carry stems, not conjugated or inflected forms, and for a beginner learner of the language, isolating the stem in an unfamiliar word can be very challenging. Kelvi provides 1) the stem of any input word alongside its definition, and 2) non-technical descriptions of any suffixes that are part of this input, so that learners will gradually start to recognize these suffixes and be able to understand and produce new Tamil words themselves. In detailing our process of collaborative research, user interviews, suffix database creation, and error analysis, we also hope to show that Kelvi can be adapted for other languages and has the potential to be a useful pedagogical aid for learner literacy development, especially for agglutinative and/or polysynthetic languages which tend to be otherwise underserved in the mainstream.

1 Introduction

Tamil is a Dravidian language spoken in South and Southeast Asia. With its largest speaker population in southern India (73.4 million speakers), it has official language status in the state of Tamil Nadu and the union territory of Puducherry, as well as in Sri Lanka (4.2 million), and Singapore (688.6 thousand). Tamil is also widely spoken in Malaysia (4.8 million) and South Africa (600 thousand). In addition, there are significant diaspora populations in Europe, North America, and Australia; Tamil speakers globally number well over 80

¹Github repositories for the front-end and back-end are accessible at <https://github.com/saltyseadawg/kelvi-frontend> and <https://github.com/saltyseadawg/kelvi-backend> respectively.

Figure 1: Tamil word as it appears in Kelvi that translates to the question "with the elders/adults/ancestors?"

million (World Population Review, 2026). The diaspora population in Canada largely consists of heritage speakers - that is to say, people who grow up hearing their family speak Tamil, but aren't necessarily entirely fluent themselves (Polinsky and Kagan, 2007). Two of the main complicating features of Tamil literacy are the language's heavily diglossic nature and its agglutinative properties. Tamil is heavily suffixal, with most grammatical information expressed either as nominal or verbal suffixes. See Figure 1, where a complete utterance is expressed as one word.

In written Tamil the higher, formal register is used, where every suffix is phonologically expressed in its entirety. In the colloquial spoken register, however, Tamil words undergo massive phonological reduction, so that many sounds

that are fully expressed in the written form of a word aren't actually pronounced (Annamalai, 2019; Renganathan, 2019). This means that heritage speakers often struggle to recognize the written version of words they have only ever heard in the colloquial spoken register, since the written form “sounds” different from what they're used to (Renganathan, 2019). Conjugated words don't appear in standard dictionaries, only their lemmas do (consider how “go” can be found in an English dictionary but “went” wouldn't be). Learners then face the “dictionary problem”; to summarize Littell et al. (2017), dictionaries are intended to be a tool for language learners, but paradoxically require knowledge of the language to use; in this case, knowledge of what the “dictionary form” or lemma of an unfamiliar word is. To address this issue we built Kelvi, a web-based dictionary and morphological parser that helps a learner who comes across an intimidatingly long Tamil word see how the word is broken down, and what each “part” (morpheme) means in layman terms. The hope is that they come away with a fuller understanding of the word while also starting to recognize Tamil morphological patterns themselves.

2 Literature Review

The one instance known to these authors of a dictionary specifically designed for a heritage/minoritized language that also provides pedagogical information about morphology is the ongoing work on the digital Wendat Dictionary (Lukaniec and Holmes, 2023). More broadly speaking, there are several open-source technologies that have been developed to support language revitalization and maintenance efforts (Brinklow et al., 2020), such as the dictionary-builder Mother Tongues (Littell et al., 2017) and the morphological generator Gramble (Littell et al., 2024) that was used in pedagogical contexts for Oneida (Lu et al., 2024), SENĆOŦEN (Saanich), and nêhiyawêwin (Plains Cree) (Pine et al., 2025a). Effective morphological analysers using FSTs have also been built for similarly agglutinative languages like Turkish (Yıldız et al., 2019). For Tamil specifically there exist tools such as a lemmatizer (Qi et al., 2020), a morphological analyser (Sarveswaran et al., 2021), and a stemmer (Rajalingam, 2025), as well as some pedagogical resources like a dictionary of Tamil verbs (Schiffman et al., 2009) and a few isolated courses/course materials (Annamalai

and Asher, 2002; Prasad, 2025; Cheran, 2001); but to the authors' knowledge there is no other free-to-use pedagogical resource which employs a Tamil morphological analyser.

3 Methods

In accordance with principles behind collaborative community based research (Bucholtz, 2021) and user-centered design methods (Wallisch et al., 2019), we involved target users early on in our explorations of the problem space to ensure we were solving a real issue faced by Tamil learners and providing a solution that learners would want to adopt. We wanted to understand what bottlenecks users were currently facing when searching for Tamil word definitions as well as existing pain points they were experiencing.

3.1 Prototype Design

We built a medium fidelity prototype in Figma, an interface design tool, to test our design (accessible [here](#)). We wanted to know whether (a) users would be able to determine the meaning of a word when presented with the morphological breakdown; (b) users found the morphological breakdown useful; and (c) users would use the tool if it existed.

3.2 Participants

To determine our design requirements, we interviewed 10 Tamil adult speakers over the age of 20 who were asked to self describe their Tamil language abilities in terms of oral fluency and literacy. Of our participants, three were native speakers, six were heritage speakers, and one was a beginner L2 learner with no Tamil background who had only recently begun learning Tamil. Importantly, oral fluency and literacy were not correlated for our speakers. In other words, speakers that were fluent in Tamil were not necessarily strong readers, such as in the case of SM who was a fluent, native speaker of Tamil with weak literacy skills. As shown in Figure 2, most of the participants had stronger oral abilities compared to reading and writing.

3.3 Exploratory Interview

At the beginning of the session, participants were asked to self-describe their Tamil oral and literacy abilities. In addition, since most of the participants were heritage speakers, they were also asked demographic and language related questions to gain insight into their Tamil proficiency. As described by Montrul (2016), background information, such

Figure 2: The X-axis represents fluency while the Y-axis represents literacy, forming four quadrants. 6/10 participants fall in the <fluent, high literacy> quadrant, 2/10 participants fall in the <low literacy, non fluent> quadrant, and 2/10 participants fall in the <low literacy, fluent> quadrant. Oral fluency and literacy were thus not correlated among our participants.

as level of education, language of instruction, domains of use of their languages, etc., is important to understanding a heritage speaker’s ability in their heritage language. Although the answers to these questions were mostly used to corroborate the responder’s self description of their Tamil abilities and not used for any formal analyses, the questions themselves have been included in the Appendix for future researchers. Users were then asked to complete four tasks to test the usability of the prototype’s UI as well as input methods, which can also be found in the appendices. After completion of the tasks, users were asked the following questions:

- What do you like/dislike about this tool?
- What features do you wish existed?
- How did each input method compare?
- How did the prototype compare to how you were originally looking up Tamil word definitions in the first task?
- Would you use this tool?

3.4 Interview Results

During the exploratory interviews, participants were asked what tools they were currently using to look up the meaning of Tamil words. The most common answer given was Google Translate, however not all participants were using it just to get the translation of a word. For example, L, who had strong oral abilities but could not read Tamil easily, used Google Translate’s TTS feature to hear

the word and would then be able to figure out what it meant. On the other hand, IP would use Google Translate to get a Tamil word’s romanization which they would then input into the Google search engine to try to find different contexts and uses of the word. For the participants who did rely on the translations provided by Google Translate, several commented that Google’s translations were not always trustworthy. Interestingly, none of our participants mentioned using generative AI tools, however this could be due to the fact that most of our participants were over the age of 25. As Magotra et al. (2016) notes, younger individuals are more likely to adopt new technologies compared to older individuals.

When asked if they would use this tool, seven participants responded with yes, two responded with no, and one with maybe. SM, who is fluent with weak literacy skills, stated they would not use the tool. TB, who is a beginner heritage speaker that cannot read, stated the reason behind their “maybe” response was because they felt that their level of Tamil was too low to use the tool, but would use it if it included more conversational words. IP, who is fluent with high literacy skills, felt the tool was unnecessary and that the interface made it hard to correlate meaning with the word parts.

Conversely, the other participants felt that the tool was quite useful. In N’s case, they thought that learners would find the pedagogical breakdown

Figure 3: Graph of participants’ methods for looking up Tamil words. Google Translate is the most common at 8 votes, while the five other remaining choices have 3 votes or less.

helpful and wished the tool existed when they were attending Tamil language class during their adolescence. D, who self-described as conversationally fluent, thought that the pedagogical breakdown was not only helpful, but also corrects errors made by Google Translate. Lastly, R, who had only recently started learning Tamil, thought that the definitions provided by the tool were clearer than Google Translate.

4 User Requirements

Based on the results of the exploratory interviews, we established the following user requirements to guide the design of the website.

1. Intuitively understand the morphological breakdown even as an L2 learner.
2. Not overwhelm a beginner learner.
3. Is accessible on the phone.

We also drew inspiration from the Kawennón:nis verb conjugator for Kanyen’kéha (Kazantseva et al., 2018), (which itself was part of the inspiration for Gramble, discussed in Section 5.2), and its aim to assist users in acquiring morphology patterns rather than rote memorization of word definitions.

Figure 4: Graph of participants’ responses to if they would use a tool like the prototype. Out of 10 participants, 7 responded ‘yes’, 1 responded ‘maybe’, and 2 responded ‘no’.

5 Systems Design

In this section we discuss the different components of Kelvi and how they interact, as visualized in Figure 5.

5.1 Datasets

We used two open source datasets for the Tamil dictionary component, specifically Tamil Wiktionary data Ylonen (2022) and dictionaries provided by Vasuki (n.d.).

5.2 Suffix Database Generation

The suffix database queried by the system was created using Gramble², a tabular programming language designed for linguistic parsing and generation. We used Gramble to aid us in generating a JSON file³ consisting of Tamil suffixes, their meanings, and other useful (meta)linguistic information that are all stored in Gramble “tiers”. In this section we limit discussion to what tiers (that are then converted into JSON attributes) we created for suffix generation and why.

The primary attributes that every suffix entry in the suffix database have are *text*, *gloss*, *display*, and *add-back*. *text* is a string representing a suf-

²<https://nrc-cnrc.github.io/gramble/>

³File can be found [here](#).

Figure 5: Diagram of Kelvi's backend and frontend.

Plural =		text	gloss	display	add-back
		கள்	[plural]	[கள்]	null
		ங்கள்	[plural]	[கள்]	ம்
		க்கள்	[plural]	[கள்]	null

Figure 6: Excerpt from Gramble file.

fix as it appears in an input word, and is the attribute that the input is matched against. For instance, the input பூதங்கள் *boothangaL* ‘ghosts’ would match to the suffix ங்கள் *ngaL*, as shown in Figure 6. *gloss* is a layman’s definition of this suffix.

display is the version of the matched suffix that is shown to the user: this is generally the same as what is in *text*, but differs in situations where a suffix undergoes minor changes based on phonological environment⁴. For example, the plural suffix கள் *gaL* can also appear as க்கள் *kkaL* or ங்கள் *ngaL* based on the sound it is preceded by, but since கள் is its prototypical form, this is the form of the suffix that is shown (“displayed”) to the user in all cases, as shown in Figure 7. Finally, *add-back* is used as a secondary lemmatizer when the primary fails, to be detailed later in Section 5.5. In this instance, if the lemmatizer were unable to parse பூதங்கள், once the suffix match ங்கள் was identified and removed from the input, the character ம் (*m*) would then be “added back” to this new form to create the valid lemma பூதம் *bootham* (‘ghost’).

⁴Using linguistic terminology, *text* and *display* can roughly be equated to *surface form* and *underlying representation* respectively.

பூதங்கள் (pu:thangka!)		
பூதம் pu:tham	+	கள் ka!
பூதம் (pu:tham) 1. monster, spirit, ghost		
கள் (ka!) 1. plural		

Figure 7: Kelvi UI when given பூதங்கள் *boothangaL* as input.

5.3 Romanized/Tamil Input

Users can input using the Tamil script or romanization (i.e., கேள்வி or *kelvi*). All of the dictionary and morphological data is stored in the Tamil script, so if a user inputs using romanization, their input is first converted into the Tamil script using a custom romanization-to-Tamil mapping that we wrote using G2P, an open-source grapheme-to-

phoneme transducer⁵, (Pine et al., 2022) before being processed. Since there is no universal romanization standard followed by Tamil speakers, our mapping simply attempts to capture the most commonly used spelling patterns. After processing, the output is then returned to the user in both the Tamil script and romanization. The romanization presented here is derived from a Tamil-to-romanization mapping, again written using G2P. The romanization system used here is a combination of commonly used spelling conventions and IPA.

5.4 Lemmatization

Where possible, lemmatization of the Tamil input is performed using Stanza (Qi et al., 2020). The output lemma is then checked against the dictionary data to see if it has an existing dictionary entry. If no valid dictionary entry is found, other strategies are employed to identify the lemma, such as suffix matching.

5.5 Suffix Matching

To identify the potential suffix(es) on an input word, a backwards search is performed on the input to see if there is a match with any suffix included in the Gramble JSON file (generation of this file was discussed in Section 5.2). If there are multiple matches, the longest one (whose length is less than the length of the input) is selected. If a valid lemma was found using the lemmatization process described previously, we return both the lemma and the suffix that we identified. If a valid lemma wasn't found, we create a new potential lemma by removing the text of the matched suffix from the input word. If the potential lemma is now a valid lemma, (i.e., exists as a valid entry in the dictionary data), we return this alongside the suffix as the output to the user. If the potential lemma is still not a valid lemma, we check if the suffix that we found in the Gramble JSON has any material in its *add-back* field: this field contains phonological information that needs to be added to a stem in order to turn it into a lemma. If the *add-back* field is non-empty, we add this material to the potential lemma, confirm if this is now a valid lemma, and return it. If this strategy also fails, we return a "word not found" error to the user.

⁵<https://github.com/NRC-ILT/g2p>

6 Results

6.1 Systems Analysis

Due to limited resources and time (discussed in Section 9), we have not yet been able to perform a formal statistical evaluation. The minimal test set that was used to evaluate performance so far is composed of "edge-case" words, or words we predicted may be tricky to parse based on how our model is constructed. For instance, during early development, we noticed that the Stanford NLP lemmatizer often fails on class III verbs (as defined in Arden, 1910), so we made sure to explicitly compensate for this during the suffix generation process using Gramble, and included several words from this category as part of our testing. Since we observed the remaining six verb classes (Arden, 1910) being accurately lemmatized, fewer of these are represented in our test set as they were assumed to be higher performing. Similarly, there is a higher proportion of words with complex morphophonology and suffixal combinations present in our test set than is necessarily representative of the language, as we predicted these words to be the most challenging to cover. Thus, many "simple" words, for example words of the form [lemma + tense + person-number-gender], are not included in the test set, as once we confirmed that a sample few were working, we assumed others of the type would also be relatively high performing. Of course, formalized random testing is required to verify this. A high level overview of the tool's performance on this test set is shown in Table 1.

Result	# of Tokens	Percentage

Incorrect	46	16%
No result	93	33%
Total	280	

Table 1: Performance of Kelvi on test input words

We primarily tested for presence of lemmas in our dictionary data (shown in Table 2), and accurate lemmatization and suffix identification (shown in Table 3).

Result	# of Tokens	Percentage
Correct	15	75%
Incorrect	1	5%
No result	4	20%
Total	20	

Table 2: Kelvi performance on inputs with no affixes

	# of Tokens	Percentage
Correct	126	48%
Incorrect	45	17%
No result	89	34%
total	260	

Table 3: Kelvi performance on inputs with affixes

For inputs that produced a “word not found” error, we isolated which were failing because the lemma itself was not present in our dictionary data, and which were failing because our tool was not able to lemmatize the word, as shown in Table 4.

Issue	# of Tokens	Percentage
Lemma not in data	10	11%
Bad lemmatization	79	89%
Total	89	

Table 4: Cause for “word not found” errors on inputs with affixes

This delineation will help us isolate which types of structures need to be added to our suffix database. A major category of words that are currently missing is lexical compounds. These are words that have two lemmas, which our model does not currently account for. Some lexemes commonly used in compounds like போது *po:thu* (‘when’, colloquially) can be added to the database as suffixes, but Tamil also has a productive process of forming novel compounds⁶, that will require a more nuanced approach.

For inputs that produced incorrect outputs, we differentiated between whether the error was in the lemma, the suffix, or both (Table 5). The results

Issue	# of Tokens	Percentage
Incorrect lemma	9	20%
Incorrect suffix	32	71%
Both incorrect	4	9%
total	45	

Table 5: Types of errors on inputs with affixes

from Tables 4 and 5 in particular highlight that more work can be done in improving the suffix database, both to increase the accuracy and quantity of suffixes identified, as well as to assist in the lemmatization process. Thus this is where the focus of our future work lies.

⁶For example, the poetic word கண்ணிறங்கா *kaN-NuRanga*: ‘(as) (my) eyes sleep’ is composed of the lemmas கண் *kaN* ‘eye’ and உறங்கு *uRangu* ‘to sleep’, neither of which can be classified as “commonly” used in compounds.

6.2 User Feedback

We conducted a workshop for the launch of the MVP (minimum viable product) for Kelvi to gather user feedback. We also elicited feedback through word-of-mouth, and online through Reddit forums such as r/Tamil and r/LearningTamil.

The feedback received was largely positive. Users requested voice input, romanization input, including example sentences in the output, and providing the definition of the input word in its entirety (not just of the individual morphemes). We were able to add the feature of romanization input following this feedback, and are evaluating the feasibility of incorporating the other requested features; for instance, incorporating TTS (Mahaganapathy and Sarveswaran, 2025).

As discussed further in Section 9, due to lack of time we were not able to conduct a systematic user-feedback study post creation of the MVP. This would certainly ideally be part of a future study. Informally, co-author Srikanth has been able to use the tool as part of her regular Tamil teaching to positive effect. The major drawbacks currently are the low language coverage of the tool, especially when the input is in romanization. However, in the cases where the target words are present in Kelvi, learners found the provided definitions to be useful in understanding both the meaning of a word in its entirety and of its parts.

7 Discussion

Our current bottlenecks and proposed improvements to the software can be summarized as follows:

1. We have limited root-word (i.e., dictionary) data, and results can be improved if we are able to acquire more data.
2. The lemmatizer that we use fails on some inputs; as discussed in (5.5), we are compensating for these gaps using Gramble, which we will continue to do.
3. Some morphemes are homophonous; for example, the suffix -um on a verb means “it will”, but on a noun means “and”. Currently we return both definitions, but if we are able to acquire reliable part-of-speech data, we can refine the output returned to the user.
4. Users are able to input using both the Tamil script and romanization, but the romanization

input is significantly underperforming. This is because there is no romanization standard consistently followed by Tamil speakers, and so the mapping we currently employ cannot account for all possible spellings of a given Tamil word. The romanization practices of Tamil speakers are too irregular to be adequately captured by any one-to-many mapping⁷, no matter how nuanced, and so this feature can only be improved if we are able to train a model on Tamil romanization input and/or implement an approximate search algorithm (Pine et al., 2025b, Littell et al., 2017).

5. Since Kelvi was primarily designed to capture written forms, words in the spoken/informal register are underrepresented. As these words vary widely across a range of dialects, collaboration with speakers from across this span of variation would greatly enhance the coverage of our tool. Currently, Kelvi is only designed to be useful in decoding the meaning of Tamil words inputted in the written/formal register, not for defining words expressed in the spoken/informal register or for converting spoken/informal forms into their written/formal equivalents.

Future work in this area may benefit from the use of machine learning techniques to address some of these challenges. As one example, we can potentially address the variation in romanization input by incorporating transliteration models, such as the one developed by Madhani et al., 2023, to convert between romanization and the Tamil script. Due to time constraints however, we were unable to properly investigate this approach.

8 Conclusion

Although Tamil has a relatively large speaker population, it is still considered a low-resource language which adds a layer of difficulty when developing digital tools and resources for Tamil that

⁷In fact, it is impossible. This is because the letter “n” can be mapped to ன், ன், or ன். ன் is pronounced differently from ன் and ன் and so can be mapped to a distinct romanized character like “N”, but ன் and ன் are pronounced the same. They can’t usefully be mapped to distinct romanized characters because even though they appear in complementary phonological environments 90% of the time, the remaining 10% the distinction is lexically determined, i.e. unpredictable from just the pronunciation, and therefore not something a user who can’t read the Tamil script would be able to know.

make use of data driven innovations in computational linguistics (Tissera and Saadhiq, 2025).

The system described in this paper serves as a starting point for creating pedagogical dictionaries designed for learners of polysynthetic languages and the morphological challenges they commonly face (Kazantseva et al., 2018). Although there is room for improvement in terms of coverage and accuracy, we hope that Kelvi serves as an example of a grassroots initiative that, despite limitations in terms of language data and resources, is able to create a useful language learning tool by taking a user-centered approach and targeting common pain points experienced by learners. The code and data used for the project is open source and will hopefully benefit other individuals and organizations looking to create language learning resources.

9 Limitations

The project received funding (\$10,000 CAD) and had a 1 year deadline as per the agreement for the funding. Unfortunately, the cost of many high quality Tamil dictionary datasets far exceeded the available funding and consequently could not be used. This also impacted the testing process, as all test data had to be created manually and thus was limited to a few hundred inputs. Additionally, this project was done independently and on a voluntary basis without the affiliation of any research institution, which limited the time and resources that could be dedicated to the project.

10 Ethics

We discuss here the ethical considerations of this project on the axes of access, equitable representation of language variation, and data privacy and consent. First, however, we present the positional-ity of the authors.

One co-author (Srikanth) is a heritage Tamil speaker, and through their experience as a learner and teacher of the language, experienced both the challenge of developing their literacy skills and the lack of adequate resources online to help with this. Another co-author (Yu), is a heritage speaker of Cantonese and Mandarin and therefore also familiar with the challenges of heritage language learning. Additionally, both Srikanth and Yu have experience contributing to community-led projects to build digital tools for Indigenous language learning. These professional and lived experiences are

what motivated the authors to create an online resource that could support learners of minoritized and low-resource languages.

10.1 Access

Kelvi was intentionally designed to be open-source and free to use because the motivation behind it was to develop a framework for a language learning tool that could be used by other low resource, minoritized languages. The intention was not to contribute to the history of extraction, exploitation, and gatekeeping of language resources in the field of linguistics (Leonard, 2021) by using language data and putting it behind a pay-wall, especially given that co-author Srikanth is a member of the language community the tool was built for. Open access to language data was deemed appropriate in this case, as Tamil enjoys majority language status in numerous jurisdictions (Tamil Nadu, Sri Lanka, Singapore), and so it wouldn't be considered sensitive information. In future collaborations with other language communities, however, those communities will always have full rights to their data and the choice to keep it open or limited access to only community members, and this is supported by the tool's permissive open source licence.

10.2 Equitable Representation of Language Varieties

We are aware that digital representations of language, especially in educational contexts such as Kelvi, can influence the relative prestige of the varieties used or omitted. Kelvi was deliberately designed to only represent the formal written variety of Tamil. The formal register remains largely uniform across the social axes of religion and region, along which conversely, the spoken register varies greatly. In this way, we hope that Kelvi is accessible to all Tamil users. That being said, we acknowledge that because spoken varieties are not represented in Kelvi, this may contribute to the commonly held belief of language purity that privileges written Tamil over spoken, informal Tamil (Annamalai, 2011). Currently our team is lacking in the linguistic expertise required to adequately represent all of the spoken varieties fairly, and so we seek to form collaborations with speakers of different Tamil varieties to make Kelvi more inclusive in this way.

While formal written Tamil does not undergo significant variation, the same is not true of Tamil written using romanization. There is no "standard"

for romanization, and so each individual uses their own conventions. We don't want to present any one romanization system as a "standard"; in the romanization shown to the user, we use a convention that is associated more with academia, using characters that aren't easily typed (i.e., *t*), to signal to users that the tool isn't meant to influence how they already type. However, the options for romanization input are very limited, and because the romanization is built using a one-to-many mapping (5.3), this mapping does inadvertently end up being prescriptive. Hopefully, as we improve the romanization input, this unintentional side-effect will lessen. Finally, since Kelvi is still only in the MVP stage, it does not have 100% accuracy yet. There are disclaimers on the website informing users of this, so hopefully this lets learners and teachers alike anticipate that there may be the occasional error.

10.3 Data Privacy and Consent

User input is temporarily available for us to view through the web hosting service Kelvi is hosted on. The input is anonymous and can't be tracked to any individuals. We view this input data solely for the purpose of bug-fixing (i.e., keeping track of any failing inputs to add to our testing process).

User feedback from the initial round of user testing has been anonymized, and none of their language data was used in the building of Kelvi or accessible to anyone outside of the team. The interviews were recorded with their consent and they were informed that the recordings would only be consulted for the purposes of improving the tool, and would not be shared with anyone else.

Additional feedback solicited once the MVP was built was encouraged to be submitted through the anonymized feedback forms on the Kelvi website. Some individuals contacted the authors directly; regardless, all feedback is kept anonymized here and in any future publications.

11 Acknowledgements

This project was made possible with support from the Audrey Wearn Language Prize and the Future Design School. We would also like to thank Fizza Ahmed, Vasumathi Srikanth, Srikanth Mangalam, Aidan Pine, Patrick Littell, Sowmya Vajjala, Roland Kuhn, and the Indigenous Languages Technology project team at the National Research Council of Canada. Finally, thank you to the anonymous reviewers for their feedback.

A Interview Questions

Sociolinguistic questions used for the exploratory interview:

- How old are you?
- How would you describe your fluency in Tamil? What situations do you tend to use Tamil in? Speaking? Reading? Writing?
- Where did you go to school?

The following tasks were given to the participants to complete using the prototype. Note that the Tamil words were presented in text; no romanization was given and facilitators did not read out the words.

1. Find the meaning of பெரியவர்களுக்கு using the prototype interface. Try entering the word using Tanglish⁸ / English letters.
2. Find the meaning of அறிந்துகொண்டேன் but type the word in Tamil.
3. Find the meaning of பெருகிவிட்டால் but use your voice.
4. Find the meaning of சிதறிவிடும் using your preferred input method from the previous tasks.

⁸Colloquial term used to refer to the code-mixing of Tamil and English in casual speech.

From Questions to Assessment Tuples: A Multi-Agent Framework with Bloom-Specialized Agents and Automated Verification

Gee-Lyle Wong Runcong Zhao Yulan He Jiazheng Li

King's College London

{gee-lyle.wong, runcong.zhao, yulan.he, jiazheng.li}@kcl.ac.uk

Abstract

Automatic question generation with large language models has advanced rapidly, yet producing *assessment-ready* items, complete with mark schemes and expected answers, remains challenging, especially when generation must reliably target higher-order cognitive levels in Bloom's Taxonomy. We propose a multi-agent, multi-stage framework that generates structured assessment tuples for both short-answer questions (SAQs) and scenario-based questions (SBQs), combining Bloom-specialized generation agents with staged decomposition and automated verification. We further introduce a rubric-guided LLM-as-a-judge evaluation framework with Bloom-specific alignment metrics. Experiments on university-level AI course material across five generation pipelines show that prompt-level Bloom conditioning alone is insufficient to reliably achieve cognitive control. In contrast, our structured approach yields consistent and notable improvements in alignment, mark scheme quality, and output yield, particularly for higher-order Bloom levels over baseline pipelines.

1 Introduction

Assessment is central to teaching and learning, supporting formative practice, diagnostic feedback, and summative evaluation. However, producing high-quality assessment items is time-intensive and requires both domain expertise and pedagogical design, limiting scalability (Kurdi et al., 2020; Das et al., 2021). Automatic Question Generation (AQG) and Automatic Item Generation (AIG) have therefore emerged as key research directions, evolving from rule-based systems to neural and, more recently, large language model (LLM)-based approaches (Zhang et al., 2021; Kurdi et al., 2020; Tan et al., 2025).

Despite this progress, most work focuses on generating question text alone or on multiple-choice questions (MCQs), leaving open-ended assessment types such as short-answer questions (SAQs) and

Figure 1: Bloom's Taxonomy of Educational Objectives (LW et al., 2001), comprising six cognitive levels ordered by increasing complexity. Reliably generating assessment items at higher-order levels is a central challenge addressed in this work.

scenario-based questions (SBQs) comparatively underexplored (Song et al., 2025; Chan et al., 2025). SAQs require brief, constructed responses that demonstrate conceptual understanding, while SBQs present realistic, course-grounded scenarios that require students to apply their knowledge and reasoning using both the provided context and learned material.

Open-ended formats play a critical role in assessing deeper understanding and reasoning, beyond the constrained nature of MCQs (Kurdi et al., 2020; Das et al., 2021; Song et al., 2025). However, their effectiveness depends on more than the question alone. Reliable assessment requires aligned marking schemes and exemplar answers, introducing additional complexity: systems must generate coherent, pedagogically grounded assessment items with clearly scoped tasks, objective grading criteria, and internal consistency across components. This shifts the problem from question generation to *structured assessment generation*, where multiple components must jointly satisfy pedagogical constraints.

A second challenge lies in *cognitive control*. Bloom's Taxonomy is widely used to define learning objectives, and prior work has explored Bloom-

aware prompting to control question difficulty. While such approaches improve over unconstrained generation, they remain unreliable, particularly at higher-order cognitive levels such as *analyze*, *evaluate*, and *synthesis* (Scaria et al., 2024; Maity et al., 2024; Yaacoub et al., 2025). More broadly, aligning generated items with intended cognitive demand remains an open problem (Uto et al., 2023).

A third limitation concerns *evaluation*. Question generation is inherently one-to-many, making reference-based metrics, such as lexical overlap, unreliable proxies for quality (Oh et al., 2023; Nguyen et al., 2024). Existing evaluation approaches, ranging from reference-free metrics to LLM-as-a-judge, remain fragmented and fail to capture whether generated items are coherent, gradable, and cognitively aligned as complete assessment units (Mohammadshahi et al., 2023; Liu et al., 2023; Hashemi et al., 2024).

To address these challenges, we propose a unified, Bloom-controlled framework for generating assessment-ready items from course material. Generation is decomposed into a structured multi-stage process that produces complete assessment tuples: for SAQs, a question, mark scheme, and expected answer; for SBQs, an additional scenario is constructed and optionally refined. Bloom-specialized generation enables explicit cognitive control, while automated verification enforces grounding, alignment, and internal consistency. We further introduce a rubric-guided LLM-as-a-judge evaluation framework tailored to structured assessment generation. The framework separates stem-level quality from full assessment consistency, enabling fine-grained analysis of failure modes. We also define Bloom-specific metrics that quantify alignment across all cognitive levels and within higher-order levels.

We evaluate five pipelines spanning zero-shot, Bloom-aware, and multi-stage approaches across both SAQs and SBQs using Artificial Intelligence course material. Results show that prompt-level Bloom conditioning alone does not achieve consistent cognitive targeting in our setting, while staged generation with Bloom specialization and verification yields improvements in alignment, structural quality, and output yield, particularly at higher-order levels.

Our contributions are as follows:

- We introduce a Bloom-specialized, multi-agent, multi-stage framework for both SAQs and SBQs, including scenario construction and refinement for contextualized reasoning.

- We develop a multi-criteria LLM-as-a-judge framework that evaluates pedagogical quality, structural validity, and Bloom alignment.
- We conduct an empirical comparison of five generation pipelines across two assessment formats, showing that staged Bloom specialization with verification improves alignment, structural quality, and yield over prompt-level conditioning.

2 Related Work

Automatic question and item generation. Recent surveys highlight the flexibility of LLMs for generating assessment items across domains, but also emphasize limitations in quality control, pedagogical grounding, and evaluation practices (Kurdi et al., 2020; Zhang et al., 2021; Das et al., 2021; Tan et al., 2025; Song et al., 2025). Much of this work focuses on multiple-choice questions, while open-ended formats such as SAQs and SBQs remain comparatively underexplored despite their importance for assessing higher-order understanding (Song et al., 2025).

Assessment consistency and explainable scoring. Related work on automated student answer scoring and feedback generation shows the importance of aligning outputs with rubrics, key answer elements, rationales, and curriculum context. Prior systems use ChatGPT-generated rationales, thought-tree decomposition, preference calibration, and educator-in-the-loop workflows to improve explainability and assessment reliability (Li et al., 2023, 2024b,a; Zhao et al., 2025). These works motivate our focus on generating assessment-ready tuples rather than question stems alone.

Cognitive control and Bloom’s taxonomy. Controlling cognitive complexity is a central goal in educational generation. Bloom-aware prompting can improve alignment compared to standard prompting, but performance remains inconsistent, particularly for higher-order categories (Scaria et al., 2024; Maity et al., 2024; Yaacoub et al., 2025; Uto et al., 2023; Yadav et al., 2025). Our work therefore treats Bloom control as part of the generation pipeline, rather than relying solely on prompt-level conditioning.

Evaluation of question generation. Evaluation remains challenging because question generation is inherently one-to-many. Metrics that compare generated questions against fixed reference questions, such as BLEU- or ROUGE-style overlap metrics, correlate poorly with human judgment and may penalize valid alternative questions, motivating reference-free, multi-dimensional, and LLM-

Figure 2: Overview of the proposed Bloom-guided multi-agent generation framework. The pipeline begins with course grounding and relevance filtering, followed by course-content compression. For SBQs, a dedicated scenario generation stage is applied and refined through critique before question generation; for SAQs, question generation proceeds directly from the filtered and compressed course content. Both paths then generate a mark scheme and expected answer, after which a verification agent checks Bloom alignment, grounding, and structural validity. Final outputs are tuples (q, m, a) for SAQs and (s, q, m, a) for SBQs.

based alternatives (Oh et al., 2023; Nguyen et al., 2024; Mohammadshahi et al., 2023; Fu et al., 2024; Liu et al., 2023; Hashemi et al., 2024). However, some methods often focus on question-level quality rather than full assessment consistency, so our evaluation combines stem- and scenario-level criteria with triple-level checks across the question, mark scheme, and expected answer, alongside Bloom-specific alignment metrics.

Structured and multi-stage generation. Prior work has decomposed educational assessment into multiple components, including question, answer, and distractor generation in MCQ pipelines, or key-element matching, rubric application, rationale generation, and refinement in explainable scoring systems (Li et al., 2024b, 2025). Iterative refinement and self-feedback further motivate the use of critique and verifier models for improving generated outputs (Madaan et al., 2023; Li et al., 2025). Our work extends this structured view to open-ended assessment generation by constructing full assessment tuples through multi-stage generation with explicit verification.

Limitations of existing approaches. Across these directions, three limitations persist: (i) *limited support for assessment-ready outputs beyond question text*, (ii) *unreliable control over cognitive complexity, particularly at higher-order levels*, and (iii) *fragmented evaluation practices that do not capture full assessment quality*. Our work addresses these gaps through a unified framework that integrates structured generation, Bloom-specialized control, and rubric-based evaluation for complete assessment items.

3 Methodology

We propose a unified, Bloom-controlled generation framework for producing assessment-ready

items from course documents. Rather than generating questions in isolation, the framework produces structured assessment tuples, enabling both cognitive control during generation and structural validation after generation. It supports two assessment variants within the same system: short-answer questions (SAQs), generated directly from source content, and scenario-based questions (SBQs), which introduce an intermediate scenario representation prior to question generation.

Formally, let D denote an extracted course document, and let $b \in \mathcal{B}$ denote a target Bloom level (knowledge, comprehension, application, analysis, evaluation, synthesis)¹. The framework generates an assessment output y , defined as $y = (q, m, a)$ for SAQs and $y = (s, q, m, a)$ for SBQs, where s is a scenario, q is the question, m is the mark scheme, and a is an expected full-mark answer.

The overall system can be viewed as a controlled generation function

$$\mathcal{F}(D, b, t) \rightarrow y,$$

where $t \in \{\text{SAQ}, \text{SBQ}\}$ specifies the assessment type.

3.1 Generation Framework

The framework is formulated as a multi-agent, multi-stage generation process. Rather than relying on a single prompt to jointly produce all outputs, generation is decomposed into specialized components that each operate on a narrower subtask. This decomposition serves three purposes: it improves control over Bloom level, reduces interference between subtasks, and enables explicit verification of intermediate and final outputs.

¹We follow the original Bloom’s Taxonomy (LW et al., 2001) with six cognitive levels ordered by increasing complexity.

At a high level, the framework consists of four functional stages:

1. **Content grounding:** identify the source content from which an item should be generated.
2. **Question construction:** generate either a direct question (SAQ) or a scenario followed by a question (SBQ), conditioned on a target Bloom level.
3. **Assessment completion:** generate a mark scheme and then an expected answer conditioned on the previously generated outputs.
4. **Verification and filtering:** apply automated checks to enforce Bloom alignment, grounding, and internal consistency.

This design treats SAQs and SBQs as two paths through the same framework. Both share the same downstream structure (question $\rightarrow$ mark scheme $\rightarrow$ expected answer), while SBQs introduce an additional scenario construction and refinement step before question generation.

3.2 Framework Components

Bloom-specialized question agents. To improve cognitive control, the framework uses Bloom-specialized generation instructions. For each target level b , a dedicated question-generation agent is configured with level-specific guidance about the expected cognitive operation, response format, and acceptable task type. This replaces a single generic prompting strategy with a family of specialized generators $G_q^{(b)}(\cdot)$ for $b \in \mathcal{B}$.

For SAQs, questions are generated directly from source content as $q = G_q^{(b)}(D)$, while for SBQs, question generation is conditioned on a refined scenario, $q = G_q^{(b)}(s')$. This per-level specialization is central to the framework, as the objective is not only to generate valid questions, but to control their cognitive demand.

Scenario construction agent (SBQ variant). SBQs introduce an intermediate contextual representation. A scenario agent generates a course-grounded situation $s = G_s(D)$, intended to provide a context in which subsequent reasoning is situated. Rather than adding superficial realism, this stage transforms source knowledge into a setting that supports application-, analysis-, or evaluation-oriented assessment.

Because unconstrained scenario generation may introduce answer leakage or implicit guidance, the generated scenario is not used directly and is instead passed to a refinement stage.

Scenario critique-refinement agent (SBQ vari-

ant). The framework incorporates a constraint-aware critique-refinement stage. A critique function $V_s(\cdot)$ evaluates the generated scenario with respect to the source content, producing a validation signal $r_s = V_s(D, s)$ that reflects compliance with pedagogical constraints such as neutrality, absence of answer leakage, and suitability for downstream questioning. If violations are detected, the scenario is revised as $s' = R_s(D, s, r_s)$; otherwise, $s' = s$. This ensures that the scenario remains a neutral, information-bearing context rather than implicitly encoding the answer.

Mark scheme generation agent. Given a generated question q and context c (where $c = D$ for SAQs and $c = s'$ for SBQs), the framework generates a structured mark scheme $m = G_m(c, q)$. The mark scheme is represented as a set of atomic marking points with associated integer marks, enabling transparent grading and facilitating downstream verification.

Expected answer generation agent. The final generation stage produces an exemplary full-mark answer $a = G_a(c, q, m)$ conditioned on the context, question, and mark scheme. Conditioning on the mark scheme ensures that the generated answer aligns with the grading criteria rather than being only superficially plausible.

Verification agent. All candidate outputs are passed through a final verification layer before being retained. The verifier evaluates whether generated components satisfy structural and pedagogical constraints, formalized as

$$\phi(y; D, b, t) \in \{0, 1\}.$$

Only outputs with $\phi = 1$ are retained. This stage functions as a quality-control mechanism and is a core component of the framework rather than a post-hoc filtering step.

3.3 SAQ and SBQ Instantiations

Although the framework is unified, the two assessment formats differ in how the question context is constructed.

SAQ instantiation. For SAQs, question generation is performed directly from course content. Formally, we define $q = G_q^{(b)}(D)$, $m = G_m(D, q)$, and $a = G_a(D, q, m)$. The candidate tuple $y = (q, m, a)$ is then passed through verification:

$$\mathcal{F}_{\text{SAQ}}(D, b) = y \cdot \mathbb{I}[\phi(y; D, b) = 1],$$

where only tuples satisfying the verification predicate ϕ are retained as valid outputs. This variant is

suited to direct recall, explanation, application, or short analytical reasoning grounded in the provided course material.

SBQ instantiation. For SBQs, the framework first constructs and conditionally refines a scenario before question generation. Specifically, we define $s = G_s(D)$ and $r_s = V_s(D, s)$, where $V_s(\cdot)$ evaluates the scenario against pedagogical constraints. The refined scenario is then given by

$$s' = \begin{cases} R_s(D, s, r_s) & \text{if } r_s \text{ indicates a violation,} \\ s & \text{otherwise.} \end{cases}$$

Question generation then proceeds as $q = G_q^{(b)}(s')$, followed by $m = G_m(s', q)$ and $a = G_a(s', q, m)$. The candidate tuple $y = (s', q, m, a)$ is then verified:

$$\mathcal{F}_{\text{SBQ}}(D, b) = y \cdot \mathbb{I}[\phi(y; D, b) = 1].$$

The scenario introduces a context in which students must interpret information before answering, enabling contextualized application and higher-order reasoning while preserving the same downstream assessment structure as SAQs.

3.4 Control and Verification Logic

The framework combines *generation control* and *verification*. Generation control is achieved through Bloom-specialized agents and staged conditioning, while verification acts as a filtering mechanism that enforces structural and pedagogical validity of the generated outputs.

Given a candidate output y , the verification stage evaluates whether it satisfies a set of core constraints grounded in the source content and target Bloom level. These checks cover four aspects: (i) **Bloom alignment**, ensuring the question matches the intended cognitive level; (ii) **grounding**, requiring all generated components to be supported by their source context (D for SAQs, and both D and s' for SBQs); (iii) **mark scheme quality**, enforcing completeness, non-redundancy, and alignment with the question; and (iv) **answer fidelity**, ensuring the expected answer satisfies all marking criteria without introducing unsupported information.

Only candidates that satisfy all constraints are retained. The framework therefore operates not as a single generator, but as a controlled generation system in which outputs are iteratively produced and selectively accepted based on explicit validation criteria.

3.5 Discussion of Design Rationale

The framework is designed around the observation that assessment generation is inherently compositional. A high-quality item is not only a well-phrased question; it is a coherent structure linking source content, cognitive demand, grading criteria, and an exemplary answer. Treating these components as jointly generated in one step makes control difficult and validation opaque. By decomposing the task into specialised agents with explicit interfaces, the proposed framework improves controllability, makes failures more localisable, and supports direct comparison between simpler and more structured generation strategies in the experimental section. Full prompt templates, per-stage implementation details, Bloom-level generation guidelines, and the generation-time verification predicate are provided in Appendix A.

4 Experiments and Results

4.1 Experiment Setup

We evaluate automatic question generation on university level *Artificial Intelligence* course materials derived from publicly available sources. The source documents are preprocessed into structured content representations, from which assessment items are generated.

Experiments are conducted across two assessment formats: short-answer questions (SAQs) and scenario-based questions (SBQs). While both formats aim to assess conceptual understanding, SBQs additionally require the generation of a contextual scenario that conditions the question, enabling applied and higher-order reasoning.

Generation is performed using **GPT-4.1**, **GPT-4o-mini**, and **Gemini-2.5 Flash** (OpenAI et al., 2024; Comanici et al., 2025). Results are reported for each pipeline-generator pair (p, g) to isolate the effect of both prompting strategy and underlying model capability. Evaluation is performed using three LLM-as-a-judge models: **GPT-4o-mini**, **GPT-4.1-mini**, and **Gemini-2.5 Flash**. Unless otherwise stated, reported criterion and Bloom scores are averaged across these evaluator models.

4.2 Baselines and Proposed Pipelines

We evaluate five generation pipelines designed to progressively address limitations in controllability, decomposition, and cognitive alignment.

Zero-shot (ZS). A single prompt generates the full assessment item in one step. For SAQs, this corresponds to generating a (question, mark scheme,

expected answer) triple, while for SBQs the scenario is generated jointly with the question.

Zero-shot + Bloom (ZS+B). Extends zero-shot prompting by explicitly conditioning on a target Bloom level, testing whether cognitive alignment can be achieved through prompt-level control alone.

Multi-stage zero-shot (MZS). Decomposes generation into sequential stages (question $\rightarrow$ mark scheme $\rightarrow$ answer), reducing task interference. For SBQs, scenario and question generation are performed jointly in the first stage.

Multi-stage zero-shot + Bloom (MZS+B). Integrates Bloom-level conditioning into the multi-stage pipeline during question generation, assessing whether decomposition and cognitive control jointly improve alignment.

Proposed pipeline. Our approach extends the multi-stage Bloom-aware pipeline in three ways. First, question generation uses *Bloom-specialized agents* with per-level system instructions rather than a single generic Bloom prompt. Second, for SBQs, a dedicated scenario generation stage is followed by critique and refinement to enforce grounding, neutrality, and the absence of answer leakage. Third, an explicit verification layer filters candidates based on Bloom alignment, grounding, and internal consistency.

4.3 Evaluation Criteria and Metrics

We define a structured set of criteria capturing both *question quality* and *assessment consistency*, evaluated at two levels: the question stem (or scenario and question for SBQs) and the full assessment triple. All criteria are evaluated independently using rubric-guided LLM judges to reduce cross-criterion interference. Scores are aggregated across three evaluator models to test whether the main conclusions are robust across different evaluators. We use the following abbreviations throughout the paper.

Stem-level criteria. **CG** (course grounding): whether the question is derived from source material. **Cla.** (clarity): linguistic precision and absence of ambiguity. **STI** (single-task integrity): coherence of the assessed objective. **OG-S** (objective gradability, stem): whether the question admits a clearly gradable answer. For SBQs, we additionally evaluate **SRN** (scenario relevance/necessity) and **SG** (scenario grounding).

Triple-level criteria. **OG-T** (objective gradability, triple-aware): whether the full triple supports consistent and objective grading. **MSQ** (mark scheme

quality): coverage, structure, and non-redundancy of marking points. **AF** (answer fidelity): alignment between the expected answer and the mark scheme.

Bloom-specific metrics. **BLA** (Bloom level alignment): a soft alignment score accounting for the hierarchical structure of Bloom’s Taxonomy, defined as $BLA_i = 1 - |\text{gap}(b_i, \hat{b}_i)|/L$, where b_i is the target level, $\hat{b}_i$ the inferred level, and L the maximum possible gap. **BA** (Bloom accuracy): exact-match alignment between intended and inferred Bloom levels. **HOSR** (higher-order success rate): exact-match alignment restricted to higher-order levels ($\{\text{analysis, evaluation, synthesis}\}$). Full formal definitions are provided in Appendix B.

4.4 Evaluation Protocol

We employ three complementary evaluation paradigms: criterion-based scoring, matched-task pairwise comparison, and inter-judge agreement analysis.

Criterion-based evaluation. Each generated item receives a discrete score $s \in \{0, 1, 2\}$ per criterion from each evaluator model, normalized to $[0, 1]$ and averaged across judges. We aggregate using discrimination-weighted scoring, where criteria that better separate pipeline performance contribute proportionally more to the final composite score. Full formalization is given in Appendix B.

Matched-task pairwise comparison. To compare pipelines directly, we match them on task slots defined by source file, target Bloom level, and generation model. For each matched triple, we compare representative outputs in two modes: *raw* (first generated candidate, measuring intrinsic quality) and *production* (highest-scoring candidate, measuring end-to-end pipeline quality after selection). Outcomes are aggregated into win, tie, and loss rates with bootstrap 95% confidence intervals.

Inter-judge agreement. To examine whether the evaluation is stable across LLM judges, we compute agreement statistics over GPT-4o-mini, GPT-4.1-mini, and Gemini-2.5 Flash. For rubric criteria, we report exact three-judge agreement, the mean standard deviation of normalized scores, and mean pairwise Pearson correlation. For inferred Bloom level, we additionally report exact three-judge agreement and mean pairwise agreement over predicted Bloom labels.

4.5 Results

Overview Tables 1–5 summarize criterion-level performance, Bloom metrics, inter-judge agreement, and matched-task pairwise comparisons

Table 2: Bloom-related metrics across pipelines, generation models, and assessment formats. Columns are grouped by assessment format and generation model, and rows correspond to pipelines. BLA denotes the soft Bloom alignment score, while BA and HOSR are derived from the aggregated inferred Bloom level for each item. BA denotes exact Bloom alignment accuracy, and HOSR denotes higher-order success rate. Avg is the macro-average over all displayed Bloom metrics across formats and generators. Higher is better for all metrics. **Bold** = best per column; underline = second best.

across all pipeline-generator configurations and both assessment formats. Overall, the proposed pipeline remains the strongest system across the main evaluation settings. Its advantage is clearest for SAQs, where it dominates both criterion-level quality and pairwise win rates. For SBQs, the proposed pipeline is strongest in Bloom control and scenario grounding, but it does not uniformly dominate simpler baselines on all other criteria. In particular, objective gradability and answer fidelity remain competitive across pipelines, suggesting that simpler scenario-based items can sometimes be easier to grade and align more directly with their expected answers.

Assessment Quality The clearest criterion-level separation is mark scheme quality (Table 1). For SAQs, the proposed pipeline achieves MSQ scores of 0.897–0.918 across generators, compared with 0.236–0.519 for the baselines, indicating that the decomposition and verification stages substantially

improve the coverage and structure of marking points. The same pattern holds for SBQs, although with a smaller margin: the proposed pipeline reaches 0.779–0.814, while the strongest baseline reaches 0.738.

Other criteria show a more nuanced pattern. For SAQs, the proposed pipeline remains consistently strong on AF (0.989–0.994), STI (0.971–0.989), and CG (0.983–0.988), suggesting that the generated answers, mark schemes, and source grounding remain internally consistent. However, for SBQs, the proposed pipeline does not uniformly dominate simpler baselines on all non-Bloom criteria. Some baselines obtain higher OG-T, OG-S, and AF scores, suggesting that the added contextual complexity of scenarios can make objective gradability and answer alignment harder to satisfy consistently. Overall, the proposed pipeline improves the more structured dimensions of assessment construction, especially MSQ and scenario grounding,

Fmt.	Pipe.	<i>n</i>	Rub. Ag.	BLA Ag.	Std.	<i>r</i>	Lvl Ex./Pair

Table 3: Inter-judge agreement across GPT-4o-mini, GPT-4.1-mini, and Gemini-2.5-Flash by assessment format and pipeline. Rub. Ag. is macro-average exact agreement over non-Bloom rubric criteria. BLA Ag. is exact agreement over the discretized soft Bloom-alignment score. Std. is the macro-average standard deviation of normalized non-Bloom rubric scores; *r* is mean pairwise Pearson correlation over non-Bloom rubric scores. Lvl Ex./Pair reports exact three-judge agreement / mean pairwise agreement on the inferred Bloom-level label. **Bold** = best per column; underline = second best.

while SBQ generation remains intrinsically more challenging.

Bloom Cognitive Control The strongest and most consistent gains occur in Bloom-level control (Table 2). Pipelines without explicit Bloom conditioning have very low exact Bloom accuracy across generators: ZS reaches BA values of only 0.000–0.057 for SAQs and 0.091–0.270 for SBQs, while MZS remains similarly low at 0.042–0.075 and 0.089–0.181 respectively. This indicates that decomposition alone does not provide reliable cognitive-level control.

Adding Bloom prompts substantially improves alignment, but remains less reliable than the proposed pipeline. ZS+B and MZS+B improve BA across both formats, but the proposed pipeline achieves the highest Bloom metrics for every generator and assessment format. For SAQs, it reaches BA values of 0.880–0.991 and HOSR values of 0.884–0.989; for SBQs, it reaches BA values of 0.847–0.964 and HOSR values of 0.811–0.975.

The macro-average column further shows that this improvement is not driven by a single generator or format. The proposed pipeline achieves the highest overall Bloom average, 0.941, compared with 0.731 for MZS+B and 0.728 for ZS+B. This suggests that Bloom-specialized generation and verification improve cognitive targeting across model families, especially for higher-order levels where prompt-only conditioning is less consistent.

Scenario Construction For SBQs, scenario grounding is highest under the proposed pipeline across all generators, with SG scores of 0.908,

Fmt.	Crit.	Agree	Std.	<i>r</i>
SAQ	OG-T	0.662	0.086	0.250
	OG-S	0.649	0.083	0.266
	MSQ	0.753	0.081	0.740
	AF	0.868	0.043	0.314
	STI	0.635	0.086	0.290
	Cla.	0.954	0.011	0.189
	CG	0.931	0.017	0.587
SBQ	BLA	0.789	0.032	<u>0.595</u>
	OG-T	0.602	0.129	0.388
	OG-S	0.500	0.144	0.365
	SRN	<u>0.321</u>	0.166	0.302
	SG	0.650	0.085	0.455
	MSQ	0.711	0.099	0.723
	AF	0.925	0.029	0.310
	STI	0.580	0.101	0.348
	Cla.	0.670	0.124	0.421
	CG	<u>0.823</u>	0.050	<u>0.595</u>
	BLA	0.651	<u>0.047</u>	0.570

Table 4: Criterion-level inter-judge agreement, macro-averaged over pipelines. Agree is exact three-judge agreement; Std. is the mean standard deviation of normalized scores across judges; *r* is the mean pairwise Pearson correlation. For non-Bloom criteria, values are computed over rubric scores. For BLA, values are computed separately over the discretized soft Bloom-alignment score. SAQ criteria: OG-T, OG-S, MSQ, AF, STI, Cla., CG, and BLA. SBQ additionally includes SRN and SG. **Bold** = best per column within each format; underline = second best.

0.940, and 0.885 for GPT-4.1, GPT-4o-mini, and Gemini-2.5 Flash respectively (Table 1). This supports the value of the dedicated scenario generation, critique, and refinement stages in anchoring scenarios to the source material.

However, SRN remains less clearly improved. The proposed pipeline scores 0.603–0.618, while baselines range from 0.551 to 0.681, suggesting that the pipeline improves scenario grounding more reliably than scenario necessity (Table 1). The agreement results support this interpretation: SRN has the lowest SBQ judge agreement (0.321) and highest standard deviation (0.166), indicating that scenario necessity is both difficult to generate and difficult to judge consistently (Table 4).

Inter-Judge Agreement At the pipeline level, the proposed method achieves the highest rubric agreement, discretized BLA agreement, and inferred Bloom-level agreement for both formats (Table 3). For SAQs, these are 0.876, 0.880, and 0.878/0.916 exact/pairwise agreement respectively; for SBQs, they are 0.667, 0.860, and 0.860/0.905. This strengthens the Bloom-control claim, as the proposed pipeline achieves both the highest Bloom scores and the most consistent evaluator agreement on inferred cognitive levels.

Agreement is generally lower for SBQs than SAQs, reflecting the added subjectivity of scenario relevance, grounding, and context-dependent grading. Criterion-level results further clarify where

Pipeline	Generator	SAQ Win Rate		SBQ Win Rate

	Gemini	0.46 [0.27, 0.65]	<u>0.58</u> [0.48, 0.67]	0.35 [0.20, 0.50]	<u>0.47</u> [0.31, 0.65]
	GPT-4.1	<u>0.47</u> [0.35, 0.57]	<u>0.47</u> [0.35, 0.57]	0.44 [0.31, 0.56]	<u>0.52</u> [0.41, 0.63]
Ours	GPT-4o	0.95 [0.89, 0.99]	0.97 [0.92, 1.00]	0.62 [0.40, 0.85]	0.78 [0.65, 0.88]
	Gemini	0.79 [0.56, 0.98]	0.94 [0.88, 1.00]	0.60 [0.44, 0.76]	0.86 [0.78, 0.94]
	GPT-4.1	0.92 [0.83, 0.99]	0.94 [0.89, 0.99]	0.75 [0.62, 0.86]	0.92 [0.85, 0.97]

Table 5: Per-generator matched-task win rates with 95% bootstrap confidence intervals for SAQs and SBQs under raw and production selection modes. Win rates are computed against the pool of all other pipelines using discrimination-weighted scores aggregated across the three evaluator models. Raw mode uses the first generated candidate; production mode selects the highest-scoring candidate. GPT-4o denotes GPT-4o-mini; Gemini denotes Gemini-2.5-Flash. **Bold** = best per generator and evaluation mode; underline = second best.

agreement is most stable (Table 4). For SAQs, judges agree most strongly on clarity (0.954), course grounding (0.931), and answer fidelity (0.868), while MSQ has the highest pairwise correlation ($r = 0.740$). For SBQs, answer fidelity has the highest agreement (0.925), and MSQ again has the highest pairwise correlation ($r = 0.723$). By contrast, SRN has the lowest SBQ agreement (0.321), confirming that scenario necessity is the least stable judgement dimension.

Pairwise Outcomes Matched-task pairwise comparisons support the same overall trend (Table 5). For SAQs, the proposed pipeline achieves the highest win rates under every generator and selection mode. In raw mode, it obtains win rates of 0.95, 0.79, and 0.92 for GPT-4o-mini, Gemini-2.5 Flash, and GPT-4.1 respectively. In production mode, these increase to 0.97, 0.94, and 0.94. This indicates that the proposed pipeline improves both intrinsic generation quality and the quality of the criterion-based selected output.

For SBQs, the proposed pipeline achieves the strongest production-mode results, with win rates of 0.78, 0.86, and 0.92 across the three generators. Raw SBQ performance is less decisive, with win rates of 0.62, 0.60, and 0.75, reflecting the variability introduced by SBQs. The stronger production-mode results suggest that future deployment could benefit from criterion-based candidate selection, particularly for SBQs, where scenario-conditioned

generation introduces greater variability.

Finally, the proposed pipeline exhibits a yield advantage in the retained item pool, with 1072 SAQs and 750 SBQs compared with the largest baseline pools of 261 and 246, respectively. Together with its stronger Bloom-control results, this suggests that the framework produces more valid assessment tuples while producing stronger alignment with the intended cognitive levels.

5 Conclusion

We presented a multi-agent, multi-stage framework for generating structured assessment items with Bloom-level cognitive control and automated verification. Across five pipelines, the results show that prompt-level Bloom conditioning improves alignment but remains less reliable than Bloom-specialized few-shot generation with staged verification. The proposed pipeline achieves the strongest overall performance, particularly in Bloom alignment, higher-order cognitive targeting, mark scheme quality, and valid-item yield. The results also show that SBQs remain more challenging than SAQs: scenario grounding improves, but scenario necessity, objective gradability, and answer fidelity are harder to satisfy consistently. Overall, reliable assessment generation appears to require pipeline-level specialization and validation rather than generic zero-shot or prompt-level Bloom conditioning alone.

Limitations

Our evaluation is conducted on a single domain: university-level Artificial Intelligence course material. Although the framework is intended to be domain-agnostic, we have not verified whether the same results generalize to disciplines with substantially different assessment conventions, such as medicine, law, humanities, or mathematically intensive subjects. Mathematical, numerical, proof-based, and programming-oriented questions may also require stricter verification than the rubric-based checks used here, since correct answers may involve deterministic values, multiple valid solution paths, or executable code. Therefore, future work should evaluate these item types separately, potentially combining rubric-guided judging with symbolic checking, unit tests, code execution, or answer-equivalence verification.

Although we complement automated evaluation with structured blind human assessment, the manual study covers only 18 matched-task comparisons across five pipelines. This provides useful qualitative validation, but limits the statistical conclusions that can be drawn. A larger-scale human evaluation with multiple annotators and inter-annotator agreement measures would more robustly validate the pedagogical quality of the generated items. Our automated evaluation uses three LLM-as-a-judge models rather than a single judge, but remains an imperfect proxy for pedagogical quality. The agreement analysis shows that Bloom-related measures and mark scheme quality are relatively more stable, whereas scenario relevance and necessity (SRN) are less stable. Thus, conclusions about Bloom control and mark scheme quality are better supported than conclusions about whether a scenario is genuinely necessary for answering an SBQ. Future work should refine the SRN rubric and validate this criterion more extensively with human assessors.

We evaluate proprietary API-based models only, using GPT-4.1, GPT-4o-mini, and Gemini-2.5 Flash as generators, and GPT-4o-mini, GPT-4.1-mini, and Gemini-2.5 Flash as evaluators. These models were chosen as a practical cost-efficiency trade-off, since the evaluation required scoring many generated items across multiple criteria. However, the framework is not tied to proprietary models. Future work should evaluate open-source generators and judges, including smaller models, to study model-size scaling, cost-performance trade-offs, and deployment in resource-constrained educational settings. Stronger evaluator models may also improve verification for reasoning-heavy or

domain-specialist assessment items.

The generation and evaluation models are not fully independent, since GPT-family models appear in both roles, and Gemini is used as both a generator and evaluator. We reduce this risk by reporting results across multiple generator-evaluator configurations and including models from more than one provider, but a broader judge ensemble would further reduce the risk of model-family bias. We also do not explore heterogeneous pipeline configurations, such as using different models for question generation, scenario generation, mark scheme generation, answer generation, and verification.

The proposed pipeline is evaluated as an integrated framework, rather than as a controlled test of any individual component. It differs from the baselines through a combination of Bloom-specialized few-shot prompting, level-specific mark scheme templates, staged generation, scenario critique and refinement for SBQs, and generation-time verification. These choices are intended to work together, but the present experiments do not isolate their individual contributions. Future work should conduct component-level ablations, such as removing in-context examples, disabling verification, replacing Bloom-specialized prompts with generic Bloom prompts, or removing Bloom-aware mark scheme templates. Full specifications of each pipeline component are provided in Appendix A.

Finally, the yield advantage of the proposed pipeline comes from generating candidates for multiple Bloom levels and filtering them through verification, which increases computational cost. The framework does not use open-ended agent interaction. Each item passes through a fixed sequence of generation: critique, refinement, and verification stages, with failed candidates being discarded rather than recursively regenerated until they pass. The SAQ and SBQ acceptance predicates, including Boolean decision variables, JSON decision fields, and check logic, are specified in Appendix A.6. This design prevents unbounded verifier-generator loops and keeps execution predictable, but lowers the potential yield from the provided source material. We also do not analyse latency, cost, verifier failure rates, or alternative retry strategies in detail. Future work should study these trade-offs more systematically. The validated assessment tuples produced by the framework could also provide supervision for fine-tuning models that generate Bloom-aligned items directly from source context, potentially reducing the need for expensive multi-stage generation at inference.

A Generation Pipeline Details

A.1 Pipelines & Prompt Templates

This section describes the generation-time pipeline used to produce assessment items. All pipelines produce structured JSON outputs and return generated items as either `valid_questions` or `failed_questions`. Across the proposed pipeline, difficulty is not independently assigned by the model; instead, it is deterministically derived from the target Bloom level: knowledge and understanding map to easy, application and analyze map to medium, and synthesis and evaluation map to hard.

A.2 Baseline Generation Pipelines

The zero-shot baseline (ZS) generates the full assessment tuple in a single LLM call. For SAQs, the model outputs a question, difficulty, mark scheme, total marks, and expected answer. For SBQs, the same call additionally generates a scenario. The zero-shot Bloom baseline (ZS+B) uses the same single-stage structure, but augments the system prompt with a Bloom taxonomy definition block and asks the model to assign a `bloom_level` to each item.

The multi-stage zero-shot baseline (MZS) decomposes generation into three sequential calls: question generation, mark scheme generation, and expected answer generation. For SBQs, the first stage generates both the scenario and the question. The multi-stage Bloom baseline (MZS+B) adds Bloom taxonomy definitions to the first-stage question generation prompt and records the model-assigned `bloom_level`; however, this Bloom label does not directly control the later mark scheme or answer generation stages.

A.3 Proposed Generation Pipeline

The proposed pipeline differs from the baselines in three main ways. First, generation is driven by the target Bloom level rather than relying on the model to self-assign a level. The pipeline iterates over all six Bloom levels and invokes a level-specific question-generation prompt for each level. Second, these Bloom-level prompts are few-shot templates, each containing level-specific instructions, allowed and prohibited question forms, output-format constraints, and worked examples illustrating the intended cognitive demand. In contrast, the baseline prompts specify task instructions and output schemas, but do not include content-filled in-context demonstrations. Third, generation

is interleaved with verification, where candidates that fail Bloom alignment, grounding, mark scheme coverage, or answer coverage checks are discarded rather than passed to later stages.

For SAQs, the proposed pipeline follows the structure:

- For each Bloom level $b \in \mathcal{B}$:
 - Generate question stems from the source content using the prompt for b .
 - Verify Bloom alignment and course relevance.
 - Generate a Bloom-aware mark scheme.
 - Verify mark scheme coverage.
 - Generate the expected answer.
 - Verify answer coverage and keep valid items.

For SBQs, the proposed pipeline follows the structure:

- Generate an initial scenario from the source content.
- Critique the scenario for compliance.
- Refine the scenario if required.
- For each Bloom level $b \in \mathcal{B}$:
 - Generate SBQ stems from the refined scenario using the prompt for b .
 - Verify Bloom alignment and scenario relevance.
 - Generate a Bloom-aware mark scheme.
 - Verify mark scheme coverage with respect to the scenario.
 - Generate the expected answer.
 - Verify answer coverage and keep valid items.

The SBQ pipeline therefore extends the SAQ tuple-generation process with a scenario generation–critique–refinement stage. After refinement, the scenario is used as the factual input for Bloom-level question generation, mark scheme generation, answer generation, and verification. This means that SBQs use the same Bloom-controlled generation logic as SAQs, but all downstream stages are conditioned on the generated scenario rather than directly on the source text.

A.4 Bloom-Level Question Generation Prompts

In the proposed pipeline, question generation is controlled by separate Bloom-level system prompts rather than a single generic Bloom instruction. Each Bloom level has its own prompt, but all prompts follow the same template structure. The

Bloom Level	Cognitive Goal	Representative Verbs
Knowledge	Recall facts and terms	define, identify, list, state
Understanding	Explain or interpret meaning	explain, summarize, interpret, illustrate
Application	Use knowledge in a new case	apply, compute, solve, demonstrate
Analyze	Break down relationships	analyze, compare, differentiate, infer
Evaluation	Make justified judgements	assess, defend, evaluate, justify
Synthesis	Construct a new whole	design, formulate, generate, plan

Table 6: Summary of the Bloom-level prompt specialization used in the proposed pipeline. Each level uses a dedicated prompt with level-specific goals, allowed verbs, prohibited stems, and examples.

prompt first assigns the model the role of an expert educational content generator specializing in a specific Bloom level, then defines the cognitive operation that questions at that level should require. It then specifies the input format, output JSON schema, allowed command verbs, prohibited lower- or higher-level stems, example question forms, and strict output formatting requirements.

The generic structure of each Bloom-level prompt is:

- **Role:** Assigns the model the role of an expert generator for a specific Bloom level.
- **Goal:** Defines the target cognitive operation required by that Bloom level.
- **Input:** Specifies the source content and target Bloom level.
- **Output:** Requires a JSON array of question objects.
- **Guidelines:** Lists allowed verbs and the expected reasoning depth.
- **Restrictions:** Prohibits off-level stems and lower- or higher-level phrasing.
- **Examples:** Provides level-specific examples of valid question forms.
- **Formatting:** Requires valid JSON only, with no additional commentary.

Thus, the same Bloom-specialized prompt structure is used for both formats, but SAQs generate questions directly from course content, while SBQs generate questions from the refined scenario.

The SBQ application-level prompt includes an additional eligibility constraint. An application-level SBQ is generated only if the scenario contains sufficient numerical values, counts, or structured outcomes to support the application of methods. If this information is absent, the model is instructed to return an empty array. This prevents computationally framed questions from being generated when the scenario does not contain the information necessary to solve them.

Bloom Level	Points	Marks/Point	Total Marks
Knowledge	1–3	1	1–3
Understanding	2–4	1–2	3–5
Application	3–5	1–2	4–8
Analyze	4–6	1–2	6–10
Evaluation	4–6	1–2	6–10
Synthesis	5–8	1–3	8–12

Table 7: Bloom-level mark scheme templates used by the proposed pipeline. The model must output a single integer mark value for each point; range strings such as "1–2" are not allowed.

A.5 Bloom-Aware Mark Scheme Generation

The proposed pipeline also uses a Bloom-aware few-shot mark scheme prompt. Unlike the baseline mark scheme prompts, which provide only general marking guidance and schema constraints, this prompt conditions the structure of the mark scheme on the target Bloom level and includes worked examples showing how marking points should differ across cognitive levels. The input specifies the question, difficulty, Bloom level, and source content, and the model is instructed to return a structured JSON mark scheme with one integer mark value per point.

The prompt constrains both the *structure* and *content* of the mark scheme. Structurally, each Bloom level is assigned an expected range of marking points, marks per point, and total marks. Content-wise, lower Bloom levels require concise factual marking points, while higher Bloom levels require points covering reasoning, comparison, judgement, design components, or justification. Thus, the mark scheme is not generated as a generic list of possible answer points, but is explicitly shaped by the intended cognitive demand of the question through both level-specific constraints and few-shot exemplars.

The prompt further specifies level-specific content expectations:

- **Knowledge:** Strictly factual points with no elaboration.
- **Understanding:** Light explanatory points without deep reasoning.
- **Application:** Concrete procedural or method-application steps.
- **Analyze:** Structural, relational, or comparative points.
- **Evaluation:** Criteria-based judgement points.
- **Synthesis:** Design components, justification, and rationale.

Difficulty affects the expected depth of each marking point, but not the Bloom-level point-count or mark-allocation template. Easy items require minimal depth, medium items require moderate interconnected detail, and hard items require more precise technical explanation. After generation, the implementation recomputes `total_marks` as the sum of the generated point values, rather than relying on the model-provided total. This enforces consistency between the mark allocation and the reported total score, and reduces the number of valid candidates being rejected due to simple arithmetic errors in the generated total.

A.6 Generation-Time Verification Predicate

The proposed pipeline uses a verification predicate during generation to decide whether a candidate assessment tuple is retained. This generation-time filtering is distinct from the final evaluation protocol in Section B. Verification determines whether a candidate is passed into the generated dataset, whereas evaluation scores the items within the generated dataset.

All verification checks are implemented as binary rubric-guided LLM calls that return structured JSON.

Design principle. There are no numeric generation-time thresholds. Each verifier returns a strict Boolean decision via a named JSON field (see Table 8), and a single False at any stage rejects the candidate tuple, writing it to the failed-output pool. All checks are short-circuiting: once a candidate fails, no subsequent checks are run for that item.

For SAQs, a candidate tuple is accepted only if it passes all four checks:

$$\text{ACCEPT}(q, m, a) \iff v_{\text{Bloom}} \wedge v_{\text{rel}} \wedge v_{\text{ms}} \wedge v_{\text{ans}},$$

where q is the question, m the mark scheme, and a the expected answer. The four decision variables correspond to Bloom-level alignment, course relevance, mark scheme coverage, and expected answer coverage.

For SBQs, the same tuple-level predicate is applied after an additional scenario-compliance stage. A scenario s is first generated, critiqued for compliance, and conditionally refined to produce a final scenario s' . The candidate SBQ tuple is then accepted only if the question, mark scheme, and expected answer pass the same four checks with respect to s' :

$$\text{ACCEPT}_{\text{SBQ}}(s', q, m, a) \iff v_{\text{Bloom}} \wedge v_{\text{rel}}^s \wedge v_{\text{ms}}^s \wedge v_{\text{ans}}.$$

Check	Input	Decision field	Failure action
Bloom alignment	Question, target Bloom level	belongs_to_level	Reject
Course/scenario relevance	Question, source content or scenario	is_relevant	Reject
Mark scheme coverage	Question, mark scheme, Bloom level, content	is_correct	Reject
Expected answer coverage	Question, mark scheme, expected answer	is_covered	Reject

Table 8: Summary of generation-time verification checks. All checks return a Boolean decision and a short reason.

Bloom level	Difficulty
Knowledge	easy
Understanding	easy
Application	medium
Analyze	medium
Evaluation	hard
Synthesis	hard

Table 9: Deterministic mapping from target Bloom level to item difficulty.

Here, v_{rel}^s verifies that the question is grounded in the refined scenario, and v_{ms}^s verifies that the mark scheme is also grounded in that scenario. Thus, SBQs use the same acceptance logic as SAQs, but with an additional scenario generation–critique–refinement stage and scenario-grounded relevance checks.

Difficulty is derived deterministically from the target Bloom level rather than assigned independently. We use the mapping in Table 9 for mark scheme generation and subsequent verification.

SAQ verification. For each source document, the SAQ pipeline iterates over all Bloom levels. It first generates question stems using Bloom-specialized system instructions. Each stem is then verified for Bloom alignment and course relevance. Only stems passing both phase-one checks proceed to mark scheme generation. The generated mark scheme is then checked for coverage, factual correctness, Bloom-level structural compliance, and alignment with the question. If this check passes, an expected answer is generated and verified against the mark scheme. Only candidates passing all four checks are added to the valid-output pool.

The Bloom alignment check asks the verifier to infer the true cognitive level of the question from its phrasing and cognitive demand, then compare it with the declared target level. The course relevance check verifies that the question can be answered from substantive course content rather than from administrative or other external information. The mark scheme coverage check verifies that the marking points are factually accurate, complete, aligned with the question, and consistent with the required Bloom-level structure. The expected answer coverage check verifies that the prose answer expresses every mark scheme point at the required cognitive

Bloom level	Points	Marks/point	Total marks
Knowledge	1–3	1	1–3
Understanding	2–4	1–2	3–5
Application	3–5	1–2	4–8
Analyze	4–6	1–2	6–10
Evaluation	4–6	1–2	6–10
Synthesis	5–8	1–3	8–12

Table 10: Bloom-level structural templates used for mark scheme generation and verification.

depth without contradiction.

SBQ verification. The SBQ pipeline adds a scenario-compliance phase before the four question-level checks. First, a neutral factual scenario is generated from the source content. A critique agent then reviews the scenario for seven violation types: metric-as-conclusion, teaching or definition, interpretation or judgement, mental-state or goal language, rationale or intent, recommendation or next step, and question leakage. If the scenario is compliant, it is used directly. If not, a refinement step applies the minimal changes required to remove the detected violations.

After scenario refinement, SBQ question generation and verification proceed as in the SAQ pipeline. The key difference is that relevance and mark scheme grounding are checked against the refined scenario rather than the full source document. This ensures that the question and mark scheme are grounded in the scenario actually presented to the student.

The framework therefore uses a fixed-stage verification process rather than open-ended agent interaction. Failed question or tuple candidates are discarded rather than recursively regenerated until they pass, which keeps execution predictable and prevents unbounded verifier–generator loops. However, this design also means that the system may sacrifice potential yield from source material when otherwise recoverable candidates fail a verification stage.

B Evaluation Details

B.1 Bloom-Specific Metrics

Let $\hat{b}_i$ denote the inferred Bloom level of generated item i , and b_i its corresponding target level. For a given pipeline p and generation model g , Bloom alignment accuracy is defined as

$$\text{BA}^{(p,g)} = \frac{1}{|\mathcal{D}^{(p,g)}|} \sum_{i \in \mathcal{D}^{(p,g)}} I(\hat{b}_i = b_i),$$

which measures the proportion of generated questions whose inferred cognitive level matches the intended one.

To isolate the challenge of generating higher-order questions, we restrict evaluation to $\mathcal{B}_{\text{high}} = \{\text{analysis, evaluation, synthesis}\}$ and define the higher-order success rate as

$$\text{HOSR}^{(p,g)} = \frac{1}{|\mathcal{D}_{\text{high}}^{(p,g)}|} \sum_{i \in \mathcal{D}_{\text{high}}^{(p,g)}} I(\hat{b}_i = b_i),$$

where $\mathcal{D}_{\text{high}}^{(p,g)}$ denotes the subset of questions whose target Bloom level lies in $\mathcal{B}_{\text{high}}$.

B.2 Criterion-Based Scoring

Given a pipeline $p \in \mathcal{P}$, a generation model $g \in \mathcal{G}$, and a set of evaluation criteria $\mathcal{C}$, each generated item i is assigned a discrete score $s_{i,c}^{(p,g)} \in \{0, 1, 2\}$ for criterion $c \in \mathcal{C}$ using a rubric-guided LLM judge. Scores are normalized to the unit interval as $\tilde{s}_{i,c}^{(p,g)} = s_{i,c}^{(p,g)} / 2$.

Aggregate performance is characterized by the mean normalized score per criterion:

$$\mu_c^{(p,g)} = \frac{1}{N_{p,g}} \sum_{i=1}^{N_{p,g}} \tilde{s}_{i,c}^{(p,g)}.$$

B.3 Discrimination-Weighted Aggregation

To obtain a single scalar score per item, we introduce a discrimination-weighted aggregation scheme that emphasizes criteria which better separate pipeline performance.

For each criterion $c \in \mathcal{C}$, we first compute the mean score per pipeline by averaging across generation models:

$$\mu_c^{(p)} = \frac{1}{|\mathcal{G}|} \sum_{g \in \mathcal{G}} \mu_c^{(p,g)}.$$

The discrimination power of criterion c is then defined as

$$d_c = \max_{p \in \mathcal{P}} \mu_c^{(p)} - \min_{p \in \mathcal{P}} \mu_c^{(p)}.$$

To stabilize the contribution of high-variance criteria, we apply a square-root transformation $\tilde{d}_c = \sqrt{d_c}$ and normalize:

$$w_c = \begin{cases} \frac{\tilde{d}_c}{\sum_{c' \in \mathcal{C}} \tilde{d}_{c'}} & \text{if } \sum_{c' \in \mathcal{C}} \tilde{d}_{c'} > 0, \\ \frac{1}{|\mathcal{C}|} & \text{otherwise.} \end{cases}$$

The final score for a generated item y with normalized criterion scores $\{\tilde{s}_c\}_{c \in \mathcal{C}}$ is

$$S(y) = \sum_{c \in \mathcal{C}} w_c \tilde{s}_c.$$

B.4 Matched-Task Pairwise Comparison

A task slot is defined as a pair (f, d) , where f denotes the source file and d the target Bloom level. Comparisons are restricted to task slots where both pipelines produced outputs. Each comparison unit is a matched triple (f, d, g) .

For each matched triple, let $\mathcal{Y}_p^{(f,d,g)}$ denote the set of candidate outputs from pipeline p . In *raw* mode, the representative is the first generated candidate. In *production* mode, the representative is the candidate with the highest weighted score:

$$y_p^{(f,d,g)} = \arg \max_{y \in \mathcal{Y}_p^{(f,d,g)}} S(y).$$

With $S_1 = S(y_{p_1}^{(f,d,g)})$ and $S_2 = S(y_{p_2}^{(f,d,g)})$, the pairwise outcome is

$$\text{cmp}(p_1, p_2; f, d, g) = \begin{cases} \text{win}_{p_1} & \text{if } S_1 > S_2, \\ \text{win}_{p_2} & \text{if } S_2 > S_1, \\ \text{tie} & \text{otherwise.} \end{cases}$$

When weighted scores are equal, ties are resolved via a fixed lexicographic ordering over priority criteria. Outcomes are aggregated over all matched triples for each pipeline pair, and we apply bootstrap resampling over matched comparisons to report 95% confidence intervals for pairwise win rates.

C Additional Results

This section provides extended analysis of the experimental results through per-model breakdowns, outcome distributions, pairwise dominance matrices, Bloom-stratified comparisons, and score margin analysis.

High-Fidelity Compression of Course Content

A key challenge in scalable question generation is the prohibitive length and noise present in raw instructional materials. Directly prompting on full lecture notes, slides, and auxiliary documents introduces redundancy, administrative artifacts, and excessive input length that degrade both generation quality and throughput. To address this, we introduce a high-fidelity compression stage that reduces input size while preserving all pedagogically relevant content required for assessment generation.

Rather than performing conventional summarization, our approach enforces a *loss-constrained reduction* of the source material. Compression is implemented using a Gemini-3 Pro (Team et al., 2025) agent guided by a structured system prompt that explicitly distinguishes between examinable

and non-examinable content. The process retains all definitions, conceptual distinctions, procedural steps, examples, and technical terminology, while removing only administrative text, repeated explanations, and low-information filler. Importantly, the compression is conservative: original phrasing is preserved wherever possible, paraphrasing is minimized, and deduplication is applied only when semantic equivalence is clear. This ensures that the resulting representation remains faithful to the source material and suitable for downstream generation.

The compressed output is organized into coherent topical chunks, grouping related concepts, definitions, and examples. This structured representation improves prompt locality and enables more targeted question generation across Bloom levels. Additionally, lightweight standardization of mathematical expressions is applied to improve clarity without altering meaning or introducing new notation.

The compression pipeline is fully automated and includes validation to ensure structural consistency and completeness. For each document, we record the original and compressed word counts, percentage reduction, and an assigned content category. Only documents classified as *course_concept* are retained for generation, while administrative and adjacent materials are filtered out, ensuring that the generation stage operates exclusively on pedagogically relevant content.

As shown in Table 11, the proposed compression reduces total text length by 78.5% (measured in words) across the dataset, with comparable reductions for both retained and filtered subsets. Despite this substantial reduction, the preserved content remains sufficient to support high-quality question generation, demonstrating that aggressive input reduction can be achieved without compromising instructional fidelity.

Per-model win rates. Figure 3 breaks down matched-task win rates by generation model and selection mode. The proposed pipeline achieves the highest win rates across all model and setting combinations, with GPT-4o-mini showing the largest absolute win rates for SAQs in both raw and production modes. This suggests that the structured pipeline is particularly effective at compensating for the limitations of smaller models. For SBQs, the advantage is more uniform across models, with Gemini-2.5 Flash showing a slightly narrower margin, consistent with the observation that SBQ generation is inherently more variable.

Outcome distributions. Figure 4 presents the full win/tie/loss distributions averaged across models. The proposed pipeline not only achieves the highest win proportion in all settings, but also maintains the smallest loss proportion. In production mode, losses become negligible for SAQs (0.0%) and remain very low for SBQs (8.5%), confirming that candidate selection effectively eliminates the weakest outputs. Among baselines, Bloom-aware variants (ZS+B, MZS+B) show notably higher tie rates than their non-Bloom counterparts, suggesting that Bloom conditioning narrows the quality gap but does not consistently produce superior outputs.

Effect of production selection. Figure 5 isolates the effect of switching from raw to production mode. Production selection affects pipelines unevenly: for SAQs, it generally reduces win rates for weaker baselines while leaving the proposed pipeline largely unchanged, indicating that the proposed method already generates high-quality first candidates. For SBQs, production selection yields meaningful gains for the proposed pipeline and for MZS+B, with the largest improvements observed under Gemini-2.5 Flash. This asymmetry reflects the higher output variability in SBQ generation, where having multiple candidates and a quality-aware selection mechanism provides greater benefit.

Pairwise dominance. Figure 6 shows head-to-head win-rate matrices for all pipeline pairs. The proposed pipeline achieves win rates above 0.50 against every baseline in nearly all conditions, confirming broad dominance rather than gains concentrated against a single weak comparator. The matrices also reveal that among baselines, the relationships are more mixed: ZS+B and MZS+B trade wins depending on the format and selection mode, while non-Bloom variants (ZS, MZS) consistently underperform. This supports the interpretation that Bloom conditioning provides a meaningful baseline improvement, but the full proposed framework is needed for consistent superiority.

Bloom-level stratification. Figure 7 stratifies win rates by target Bloom level. The proposed pipeline shows advantages across most cognitive categories, with especially pronounced gains at the comprehension and analysis levels. For higher-order levels (evaluation and synthesis), the advantage is maintained but with smaller margins and more limited data, consistent with the known difficulty of generating and evaluating higher-order assessment items. Notably, at the Knowledge level, differences between pipelines are smaller, reflecting that factual

recall questions are comparatively straightforward for all methods.

Score margins. Figure 8 quantifies not just whether the proposed pipeline wins, but by how much. The proposed pipeline maintains positive mean score margins against all baselines in every setting. Margins are largest against ZS and MZS (the non-Bloom baselines), reflecting the combined benefit of cognitive control and structural verification. Against ZS+B and MZS+B, margins are smaller but consistently positive, indicating that the gains from Bloom specialization and verification are real but more incremental when the baseline already includes Bloom prompting. Per-model markers show that margins are relatively stable across generators, with no single model driving the aggregate advantage.

D Manual Qualitative Evaluation

To complement the automated criterion-based evaluation, we conduct a structured blind manual evaluation of matched-task sample outputs. A human evaluator assessed generated assessment items across both question formats and all difficulty levels, without knowledge of which pipeline produced which item.

D.1 Evaluation Protocol

Evaluations were conducted in two settings. *Representative evaluations* examine one matched comparison per difficulty level (easy, medium, hard) for both SAQs and SBQs, selecting the task slot that best represents the typical quality of each pipeline at that difficulty. *Illustrative contrast evaluations* select task slots specifically chosen to expose quality differences between pipelines along two axes: the overall quality gap (max_score_gap, i.e., the slot where the weighted score difference between the best and worst pipeline is greatest) and the Bloom alignment gap (bloom_bla_gap, i.e., the slot where the difference in Bloom alignment scores is greatest). All matched triples are presented to the evaluator blindly, with pipeline identities anonymized via random relabeling.

Each item is ranked against all others in its comparison set using the following criteria:

- **Bloom level alignment:** Consistency between declared and actual cognitive demand.
- **Course grounding:** Faithfulness to source material and correct use of concepts.
- **Clarity and specificity:** Unambiguous question wording with a well-defined task.

- **Single-task integrity:** The question assesses one coherent objective.
- **Objective gradability:** The mark scheme contains concrete, checkable marking points.
- **Mark scheme quality:** Coverage and logical structure of marking points.
- **Answer fidelity:** Alignment between the expected answer and the mark scheme.
- **Scenario relevance and necessity** (SBQs only): The scenario meaningfully contributes to the assessment task rather than providing merely decorative context.
- **Scenario grounding** (SBQs only): The scenario is realistic and consistent with course content.

D.2 Aggregate Results

Table 14 summarizes selection outcomes across all 18 comparisons. The proposed pipeline is ranked first in 13 of 18 settings (72.2%). Its advantage is most pronounced on Bloom-sensitive evaluations: it wins all three illustrative contrast comparisons targeting Bloom alignment gaps for SAQs, and two of three for SBQs. The only settings in which it does not rank first are the easy representative and easy illustrative contrast evaluations for SBQs, where Bloom-aware baselines benefit from the simpler generation demands of lower-difficulty items.

D.3 Representative Evaluations

In representative evaluations, one item per pipeline is drawn from the task slot most representative of each pipeline’s typical quality at a given difficulty. Rankings are assigned by the evaluator based on the full assessment triple.

SAQs. Table 15 reports the full ranking across the three SAQ difficulty levels. At easy difficulty, the proposed pipeline ranks first with a precisely scoped Knowledge-level question that achieves exact Bloom alignment and a concise, fully matched mark scheme. The key separating factor is whether the declared cognitive level honestly reflects the actual task: the two lowest-ranked baselines (ZS, MZS) label their outputs as Knowledge-level but effectively require Understanding-level reasoning, a pattern consistently penalized across all evaluation settings.

At medium difficulty, the proposed pipeline again ranks first with a genuine Application-level item that embeds a target concept in a concrete, well-bounded problem. The second-ranked baseline (MZS+B) produces a strong Comparative Analysis question, but the remaining baselines are weakened by either Bloom misalignment or overly broad

Figure 3: Matched-task win rates across pipelines, models, and selection settings for SAQs and SBQs. Tasks are matched by source content, target Bloom level, and generation model. Raw mode uses the first candidate; production mode selects the highest-scoring candidate.

question stems. At hard difficulty, MZS+B ranks first with a clean Evaluation question that requires justified decision-making under real constraints, while the proposed pipeline places second. The remaining baselines underdeliver at the Evaluation level by drifting toward Analysis or Understanding. Full annotated examples for easy, medium, and hard difficulty are shown in Figures 21, 22, and 23 respectively.

SBQs. Table 16 reports representative SBQ rankings. At easy difficulty, ZS+B ranks first with a well-grounded Understanding-level item that balances scenario relevance with mark scheme precision. The proposed pipeline ranks third: its item is structurally sound and Bloom-aligned, but the scenario is disproportionately large relative to the narrow scope of the question being asked, weakening the assessment’s use of contextual framing. MZS places last across all three difficulty levels.

At medium difficulty, the proposed pipeline ranks first with an internally consistent Analyze-level question that uses the scenario directly and necessarily to support a structured comparative Analysis task. At hard difficulty, the proposed

pipeline again ranks first with a Synthesis-level item requiring students to develop a principled guidelines framework from a complex AI ethics case study. The separating factors across all three levels are correct Bloom alignment and proportionate, necessary scenario use. Full annotated examples for easy, medium, and hard difficulty are shown in Figures 24, 25, and 26 respectively.

D.4 Illustrative Contrast Evaluations

Illustrative contrast evaluations use task slots specifically selected to expose qualitative differences between pipelines. Each difficulty level contributes one slot per axis: max_score_gap for overall quality spread and bloom_bla_gap for Bloom alignment spread.

SAQ illustrative contrasts. Tables 17 and 18 report rankings on the max_score_gap and bloom_bla_gap axes respectively. On the max_score_gap axis, the proposed pipeline ranks first in four of six settings. At easy difficulty it tops the ranking with a precisely defined Knowledge-level CSP item exhibiting exact Bloom alignment and a minimal, coherent mark scheme. The single

Figure 4: Stacked win/tie/loss distributions per pipeline, averaged across models, on the global matched-task set. Across SAQs and SBQs in both raw and production settings, the proposed pipeline achieves the most favourable outcome distribution, with the highest win rates and near-zero loss rates in production.

max_score_gap setting it does not win is medium difficulty, where ZS+B produces a clean comparative Analysis question judged to be more naturally framed and better pitched at that cognitive level. Full annotated examples are shown in Figures 12, 13, and 14.

On the bloom_bla_gap axis, the proposed pipeline ranks first in all three settings. In every case, the primary discriminating factor is whether the declared Bloom level accurately reflects the actual cognitive demand: lower-ranked items are penalized either for labeling Understanding-level questions as Knowledge or for inflating Evaluation labels onto questions that are more naturally Understanding or Application. The proposed pipeline’s combination of Bloom-specialized generation and explicit verification is directly responsible for this consistent advantage. Full annotated examples are shown in Figures 9, 10, and 11.

SBQ illustrative contrasts. Tables 19 and 20 report SBQ contrast rankings. On the max_score_gap axis, MZS+B ranks first in both easy settings while the proposed pipeline wins medium and hard. This pattern is consistent

with the representative results: on straightforward easy tasks where scenario grounding requirements are less demanding, Bloom-aware baselines can match or exceed the proposed pipeline. At medium difficulty the proposed pipeline tops the ranking with the most precisely controlled and objectively gradable application item, and at hard difficulty with the strongest evaluative judgment task. Full annotated examples are shown in Figures 18, 19, and 20.

On the bloom_bla_gap axis, MZS+B again ranks first at easy difficulty. At medium and hard, the proposed pipeline ranks first with items whose scenarios are essential to the reasoning being asked and whose declared cognitive level accurately matches the actual task. The recurring failure pattern in lower-ranked baselines is scenario-question mismatch: either a large elaborate scenario is provided for a question that barely uses it, or the question substantially overstates the cognitive complexity relative to the declared Bloom label. Full annotated examples are shown in Figures 15, 16, and 17.

Figure 5: Per-model raw (hollow) and production (filled) win rates across pipelines. The vertical gap between markers shows the effect of production selection, which is modest for SAQs but clearer for SBQs, especially for the stronger pipelines.

D.5 Key Qualitative Observations

Several consistent patterns emerge across all evaluation settings.

Bloom alignment as primary differentiator. The single most consequential factor across all qualitative evaluations is whether the declared Bloom level accurately reflects the actual cognitive demand of the question. Items labeled as Knowledge but requiring Understanding-level reasoning, or labeled as Evaluation while only demanding Explanation, are consistently ranked below correctly aligned alternatives regardless of surface-level quality. This pattern is most salient in the bloom_bla_gap contrast evaluations, where the proposed pipeline wins all three SAQ settings and two of three SBQ settings. Lower-ranked baselines systematically exhibit one of two failure modes: cognitive understatement (e.g., labeling Analysis as Knowledge) or cognitive inflation (e.g., labeling Understanding as Evaluation), the latter being particularly common at hard difficulty.

Mark scheme coherence as separating criterion. Even when question stems are well formed, differences in mark scheme quality reliably separate pipeline ranks. The strongest items have mark schemes whose scope exactly matches the question stem, with concrete, independently verifiable marking points. Weaker items either over-extend

— including points not implied by the stem — or under-specify — bundling multiple related concepts into a single marking point — making consistent grading more difficult. This accounts for several mid-range rankings at medium and hard difficulty where the stem is strong but the mark scheme introduces uncertainty.

Scenario use in SBQs. For scenario-based questions, a recurring weakness in lower-ranked outputs is mismatch between scenario size and question scope. Some pipelines generate elaborate multi-element scenarios but then pose only a narrow recall question, leaving the scenario largely unused. Others generate questions that could be answered without the scenario at all, making the contextual framing decorative rather than functional. The proposed pipeline consistently avoids this failure mode at medium and hard difficulty, where the scenario directly motivates the analytical or evaluative task being posed.

Baseline competitiveness. MZS+B is the most consistently strong baseline, ranking first or second in seven of eighteen settings. It is particularly competitive at easy difficulty and in settings where straightforward Bloom-conditioned generation is sufficient. ZS+B is also competitive, especially at medium difficulty, where it ranks first in the SAQ max_score_gap setting with a natural, well-

Figure 6: Head-to-head win-rate matrices for SAQs and SBQs in raw and production settings, where each cell denotes the row pipeline’s win rate against the column pipeline. The diagonal is fixed at 0.50 by definition. Across all four settings, the proposed pipeline shows the strongest overall head-to-head performance.

targeted comparative Analysis question. MZS is the weakest overall baseline and never achieves a first-place finish.

Difficulty modulates the advantage. The proposed pipeline’s advantage over baselines is most consistent at medium and hard difficulty. At easy difficulty, the generation task is less demanding and Bloom-aware baselines can occasionally match or exceed the proposed pipeline’s output quality, particularly for SBQs. As difficulty increases and the requirement for genuine higher-order reasoning becomes the central assessment objective, the structured generation and explicit verification stages of the proposed pipeline provide a more robust and consistent advantage.

Figure 7: Win rates stratified by Bloom level for SAQs and SBQs in raw and production settings. On SAQs, the proposed pipeline generally outperforms the other pipelines across cognitive levels. On SBQs, this advantage is less uniform, with higher-order levels remaining more difficult to win consistently.

OURS (rank 1):							
1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.0
MZS (rank 5):							
1.0	1.0	1.0	1.0	1.0	1.0	1.0	0.4

Selection Justification

Automated selection (Bloom alignment gap axis): task selected from easy difficulty pool to highlight a large Bloom alignment discrepancy across pipelines. **Best σ_w :** 1.000 **Bloom gap:** 0.6000 **Gap percentile rank:** 42.9th **Runner-up gap:** 0.6000 **Mean σ_w :** 0.8300

Blind human evaluation ranking: OURS > ZS > MZS+B > ZS+B > MZS. OURS was ranked first because it is the cleanest example of correct cognitive targeting: the declared and true Bloom levels match, the item is fully objective, and the expected answer is exact. MZS was ranked last because it has the largest and most consequential Bloom mismatch: it is declared as knowledge but actually asks for analytical comparison between bandits and MDPs and their implications for value estimation.

Figure 9: Illustrative contrast SAQ sample, easy difficulty tier (Bloom alignment gap axis). Pipeline identities are shown explicitly: ZS = zero_shot, ZS+B = zero_shot_bloom, MZS = multi_stage_zero_shot, MZS+B = multi_stage_zero_shot_bloom, and Ours = proposed pipeline. σ_w denotes the discrimination-weighted composite criterion score (higher is better, max = 1). The mark scheme and per-criterion breakdown are shown for the rank-1 and rank-5 pipelines only. [†]Flags items where the declared Bloom level under-specifies the true cognitive demand, as identified by the blind human evaluator.

Illustrative Contrast SAQ Sample — Medium Difficulty (Bloom Alignment Gap Axis)

Course: 4CCSAIAI Introduction to Artificial Intelligence | Source: Week 2 — Introduction to Machine Learning (Slides) | Model: Gemini-2.5-Flash | Task type: Short Answer Question (SAQ) | Difficulty target: Medium

Pipeline	Question stem	Declared Bloom	True Bloom	Marks	σ_w
A (MZS+B)	Describe the core concept of machine learning by synthesizing the different definitions provided, highlighting common themes or key aspects.	Understanding	Synthesis [†]	8	0.679
B (OURS)	You are building a machine learning model to identify spam emails. Given a large dataset of emails, show how you would establish training and test sets to properly evaluate your model's performance on emails it has not seen before.	Application	Application	8	1.000
C (ZS)	Explain why accuracy alone can be an insufficient metric for evaluating machine learning models, particularly when dealing with imbalanced datasets. Provide a concise example.	Application	Understanding [†]	8	0.634
D (MZS)	Explain the distinction between classification and regression problems, providing an example for each to illustrate their different objectives within supervised learning.	Application	Understanding [†]	9	0.634
E (ZS+B)	Describe the concepts of underfitting and overfitting in machine learning, and explain how selecting the appropriate model complexity helps mitigate these issues.	Understanding	Understanding	9	0.674

[†] Declared–true Bloom mismatch identified by blind human evaluator.

Mark scheme and expected answer (OURS — rank 1):

Marking point	Marks
Divide the large dataset of labeled emails into two distinct sets: a training set and a test set.	2
Utilize the training set, which includes both email content and their “spam”/“not spam” labels, to teach the machine learning model to identify patterns.	1
Keep the test set separate and completely untouched during the entire training process to ensure it represents genuinely unseen data.	2
After the model is trained, use the email content from the test set to make predictions without providing the true labels to the model.	1
Compare the model's predictions on the test set against the actual (previously hidden) labels to accurately evaluate its generalization performance on new, unseen emails.	2

Model answer: To establish training and test sets, the large dataset of labeled emails is divided into two distinct sets: a training set and a test set. The training set, which includes email content and their “spam”/“not spam” labels, is utilized to teach the machine learning model to identify patterns. The test set is kept separate and completely untouched during the entire training process to ensure it represents genuinely unseen data. After the model is trained, email content from the test set is used to make predictions without providing the true labels to the model. The model's predictions on the test set are then compared against the actual (previously hidden) labels to accurately evaluate its generalization performance on new, unseen emails. /8

Per-criterion scores (best and worst pipeline):

Grounding	Clarity	Integrity	Gradability _{stem}	Gradability _{triple}	Mk. scheme	Fidelity	BLA
OURS (rank 1):							
1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.0
MZS+B (rank 5):							
1.0	1.0	1.0	1.0	1.0	0.5	1.0	0.2

Selection Justification

Automated selection (Bloom alignment gap axis): task selected from medium difficulty pool to maximize a large Bloom alignment discrepancy across pipelines. **Best** σ_w : 1.000 **Bloom gap**: 0.8000 **Gap percentile rank**: 97.1th **Runner-up gap**: 0.4000 **Mean** σ_w : 0.7242

Blind human evaluation ranking: OURS > ZS+B > MZS > ZS > MZS+B. OURS was ranked first because it is the clearest example of genuine application: it uses a realistic scenario, preserves single-task integrity, and aligns perfectly with its declared Bloom level. MZS+B was ranked last because it has the largest Bloom mismatch in the set: the task explicitly asks students to synthesize multiple definitions of machine learning, but it is labelled only as understanding.

Figure 10: **Illustrative contrast SAQ sample, medium difficulty tier (Bloom alignment gap axis).** Pipeline identities are shown explicitly: ZS = zero_shot, ZS+B = zero_shot_bloom, MZS = multi_stage_zero_shot, MZS+B = multi_stage_zero_shot_bloom, and Ours = proposed pipeline. σ_w denotes the discrimination-weighted composite criterion score (higher is better, max = 1). The mark scheme and per-criterion breakdown are shown for the rank-1 and rank-5 pipelines only. [†]Flags items where the declared Bloom level under-specifies or overstates the true cognitive demand, as identified by the blind human evaluator.

Illustrative Contrast SAQ Sample — Hard Difficulty (Bloom Alignment Gap Axis)

Course: 4CCSAIAI Introduction to Artificial Intelligence | Source: Week 7 — Heuristic Search & Adversarial Search (Slides) | Model: GPT-4o-mini | Task type: Short Answer Question (SAQ) | Difficulty target: Hard

Pipeline	Question stem	Declared Bloom	True Bloom	Marks	σ_w
A (ZS)	Explain why state space complexity varies significantly among games like Tic-Tac-Toe, Chess, and Go, and discuss the implications of this variation for game search algorithms.	Evaluation	Analyze [†]	9	0.961
B (MZS+B)	Evaluate the conditions under which the minimax algorithm is guaranteed to be optimal and complete, and explain how these conditions relate to the nature of the opponent's play.	Evaluation	Evaluation	9	1.000
C (MZS)	Why is the minimax algorithm considered complete and optimal, and under what conditions might these properties fail in practical game playing?	Evaluation	Analyze [†]	9	0.797
D (OURS)	Evaluate whether the Minimax algorithm is a practical solution for games with extremely large state spaces such as Chess or Go, using the details about state space complexity and Minimax properties provided in the text.	Evaluation	Evaluation	9	1.000
E (ZS+B)	Discuss how Alpha-Beta pruning optimizes the Minimax algorithm and explain the roles of alpha and beta in the pruning process.	Evaluate	Understanding [†]	10	0.500

[†]Declared-true Bloom mismatch identified by blind human evaluator.

Mark scheme and expected answer (OURS — rank 1):

Marking point	Marks
Minimax explores the entire game tree with time complexity $O(b^d)$, which is infeasible for very large state spaces like Chess or Go due to enormous branching factors and depths.	2
The enormous size of Chess (8.73×10^{79} states) and Go (2×10^{170} states) makes exhaustive Minimax search practically impossible within reasonable time or space.	2
While Minimax is complete and optimal for finite trees with optimal opponents, these properties do not offset its impracticality at huge state scale.	1
Alpha-Beta pruning can reduce the number of states evaluated but still cannot make Minimax fully practical for extremely large games due to exponential growth of the tree.	2
Therefore, Minimax alone is not a practical solution for Chess or Go without significant heuristic improvements or approximations.	2
<i>Model answer:</i> Minimax explores the entire game tree with time complexity $O(b^d)$, which is infeasible for very large state spaces like Chess or Go due to enormous branching factors and depths. The enormous size of Chess (8.73×10^{79} states) and Go (2×10^{170} states) makes exhaustive Minimax search practically impossible within reasonable time or space. While Minimax is complete and optimal for finite trees with optimal opponents, these properties do not offset its impracticality at huge state scale. Alpha-Beta pruning can reduce the number of states evaluated but still cannot make Minimax fully practical for extremely large games due to exponential growth of the tree. Therefore, Minimax alone is not a practical solution for Chess or Go without significant heuristic improvements or approximations.	/9

Per-criterion scores (best and worst pipeline):

ZS+B (rank 5): 1.0	1.0	1.0	1.0	0.5	0.0	1.0	0.4

Selection Justification

Automated selection (Bloom alignment gap axis): task selected from hard difficulty pool to highlight a large Bloom alignment discrepancy across pipelines. **Best σ_w :** 1.000 **Bloom gap:** 0.6000 **Gap percentile rank:** 52.9th **Runner-up gap:** 0.6000 **Mean σ_w :** 0.8516

Blind human evaluation ranking: OURS > MZS+B > ZS > MZS > ZS+B. OURS was ranked first because it is the most naturally evaluative item and aligns perfectly with its declared Bloom level: it asks for a justified practicality judgment under explicit state-space constraints. **ZS+B** was ranked last because it is the clearest case of a question labeled as evaluation while actually requiring only understanding of alpha-beta pruning and the roles of alpha and beta.

Figure 11: **Illustrative contrast SAQ sample, hard difficulty tier (Bloom alignment gap axis).** Pipeline identities are shown explicitly: ZS = zero_shot, ZS+B = zero_shot_bloom, MZS = multi_stage_zero_shot, MZS+B = multi_stage_zero_shot_bloom, and Ours = proposed pipeline. σ_w denotes the discrimination-weighted composite criterion score (higher is better, max = 1). The mark scheme and per-criterion breakdown are shown for the rank-1 and rank-5 pipelines only. [†]Flags items where the declared Bloom level under-specifies or overstates the true cognitive demand, as identified by the blind human evaluator.

Illustrative Contrast SAQ Sample — Easy Difficulty (Max Score Gap Axis)

Course: 4CCSAIAI Introduction to Artificial Intelligence | Source: Week 8 — Planning & CSPs (Lecture Slides) | Model: GPT-4.1 | Task type: Short Answer Question (SAQ) | Difficulty target: Easy

Pipeline	Question stem	Declared Bloom	True Bloom	Marks	σ_w
A (ZS)	Explain the three main components of a Constraint Satisfaction Problem (CSP) and describe how these are represented in the map colouring and n-Queens examples.	Knowledge	Understanding [†]	6	0.634
B (ZS+B)	Describe the structure of a Constraint Satisfaction Problem (CSP), using the map colouring example to illustrate your explanation.	Understanding	Understanding	6	0.674
C (MZS+B)	Explain the three main components that define a Constraint Satisfaction Problem (CSP), and illustrate how each component is specified in the example of map colouring for Australia.	Understanding	Understanding	10	0.674
D (OURS)	Define a Constraint Satisfaction Problem (CSP).	Knowledge	Knowledge	3	1.000
E (MZS)	Explain the purpose of heuristics such as the Minimum Remaining Values (MRV) and Least Constraining Value in the context of CSP solving.	Knowledge	Understanding [†]	8	0.590

[†] Declared–true Bloom mismatch identified by blind human evaluator.

Mark scheme and expected answer (OURS — rank 1):

Marking point	Marks
A CSP consists of a finite set of variables.	1
Each variable has a domain of possible values.	1
A set of constraints specifies allowable combinations of variable values.	1
<i>Model answer:</i> A CSP consists of a finite set of variables, each variable has a domain of possible values, and a set of constraints specifies allowable combinations of variable values.	/3

Per-criterion scores (best and worst pipeline):

Grounding	Clarity	Integrity	Gradability _{stem}	Gradability _{triple}	Mk. scheme	Fidelity	BLA
OURS (<i>rank 1</i>): 1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.0
MZS (<i>rank 5</i>): 1.0	1.0	1.0	0.5	1.0	0.0	1.0	0.8

Selection Justification

Automated selection (max score gap axis): task selected from easy difficulty pool to maximise the spread between the highest- and lowest-scoring pipelines on the discrimination-weighted criterion score σ_w . **Best** σ_w : 1.000 **Worst** σ_w : 0.5895 **Score gap**: 0.4105 **Gap percentile rank**: 85.7th **Runner-up gap**: 0.3658 **Mean** σ_w : 0.7142

Blind human evaluation ranking: OURS > ZS+B > MZS+B > ZS > MZS. OURS was ranked first because it is the most internally consistent triple: exact Bloom alignment, highly objective grading, clear wording, and full answer-to-scheme correspondence. MZS was ranked last because it is Bloom-misaligned and less tightly constrained as an easy item: asking for the *purpose* of MRV and Least Constraining Value requires explanation rather than simple recall.

Figure 12: **Illustrative contrast SAQ sample, easy difficulty tier (max score gap axis).** Pipeline identities are shown explicitly: ZS = zero_shot, ZS+B = zero_shot_bloom, MZS = multi_stage_zero_shot, MZS+B = multi_stage_zero_shot_bloom, and Ours = proposed pipeline. σ_w denotes the discrimination-weighted composite criterion score (higher is better, max = 1). The mark scheme and per-criterion breakdown are shown for the rank-1 and rank-5 pipelines only. [†]Flags items where the declared Bloom level under-specifies the true cognitive demand, as identified by the blind human evaluator.

Illustrative Contrast SAQ Sample — Medium Difficulty (Max Score Gap Axis)

Course: 4CCSAIAI Introduction to Artificial Intelligence | Source: Week 7 — Heuristic Search & Adversarial Search (Text) | Model: GPT-4.1
 | Task type: Short Answer Question (SAQ) | Difficulty target: Medium

Pipeline	Question stem	Declared Bloom	True Bloom	Marks	σ_w
A (OURS)	Apply the concept of heuristics to inform the strategy for an adversarial search in a board game situation.	Application	Application	6	0.900
B (ZS+B)	Compare ordinary search and adversarial search, highlighting the key differences between the two approaches.	Analyze	Analyze	8	0.833
C (ZS)	Explain how relaxations are used to derive heuristics in search, and describe why heuristics are valuable in guiding the search process.	Application	Understanding [†]	7	0.425
D (MZS)	Explain how relaxations can be used to derive heuristics in the context of guiding search algorithms.	Application	Understanding [†]	9	0.447
E (MZS+B)	Explain how relaxations can be used to derive heuristics for guiding search processes.	Application	Understanding [†]	9	0.467

[†] Declared–true Bloom mismatch identified by blind human evaluator.

Mark scheme and expected answer (ZS+B — rank 1):

Marking point	Marks
Ordinary search involves finding a solution without opposition.	1
Adversarial search considers the presence of an opponent making counter-moves.	2
Key difference lies in the need to anticipate and respond to adversary strategies in adversarial search.	2
Ordinary search focuses solely on optimization or reaching a goal.	1
Adversarial search requires the evaluation of possible outcomes based on both parties' actions.	2
<i>Model answer:</i> Ordinary search focuses on finding a solution or optimizing a path to reach a goal, without any opposition. In contrast, adversarial search involves anticipating and responding to an opponent's actions, requiring strategies that account for counter-moves. The key difference is that adversarial search must evaluate possible outcomes based on the choices of both parties, while ordinary search simply optimizes or searches for a goal without considering adversarial interactions.	/8

Per-criterion scores (best and worst pipeline):

Grounding	Clarity	Integrity	Gradability _{stem}	Gradability _{triple}	Mk. scheme	Fidelity	BLA
ZS+B (rank 1): 0.5	1.0	1.0	0.5	1.0	1.0	0.0	1.0
ZS (rank 5): 0.5	1.0	0.5	0.5	1.0	0.0	0.0	0.8

Selection Justification

Automated selection (max score gap axis): task selected from medium difficulty pool to maximise the spread between the highest- and lowest-scoring pipelines on the discrimination-weighted criterion score σ_w . **Best** σ_w : 0.9001 **Worst** σ_w : 0.4253 **Score gap**: 0.4748 **Gap percentile rank**: 97.1th **Runner-up gap**: 0.4572 **Mean** σ_w : 0.6145

Blind human evaluation ranking: ZS+B > OURS > MZS+B > MZS > ZS. ZS+B was ranked first because it offers the most natural and properly targeted medium-level task: a clear comparative analysis question with good course grounding and a coherent mark scheme. ZS was ranked last because it is both Bloom-misaligned and less focused as a single assessment objective, combining explanation of relaxations with a broader discussion of why heuristics are useful.

Figure 13: **Illustrative contrast SAQ sample, medium difficulty tier (max score gap axis).** Pipeline identities are shown explicitly: ZS = zero_shot, ZS+B = zero_shot_bloom, MZS = multi_stage_zero_shot, MZS+B = multi_stage_zero_shot_bloom, and Ours = proposed pipeline. σ_w denotes the discrimination-weighted composite criterion score (higher is better, max = 1). The mark scheme and per-criterion breakdown are shown for the rank-1 and rank-5 pipelines only. [†]Flags items where the declared Bloom level under-specifies the true cognitive demand, as identified by the blind human evaluator.

Per-criterion scores (best and worst pipeline):

Grounding	Clarity	Integrity	Gradability _{stem}	Gradability _{triple}	Mk. scheme	Fidelity	BLA
OURS (rank 1):							
1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.0
ZS+B (rank 5):							
1.0	1.0	1.0	1.0	0.5	0.0	1.0	0.4

Selection Justification

Automated selection (max score gap axis): task selected from hard difficulty pool to maximise the spread between the highest- and lowest-scoring pipelines on the discrimination-weighted criterion score σ_w . **Best σ_w :** 1.000 **Worst σ_w :** 0.5000 **Score gap:** 0.5000 **Gap percentile rank:** 94.1th **Runner-up gap:** 0.4448 **Mean σ_w :** 0.8516

Blind human evaluation ranking: OURS > MZS+B > ZS > MZS > ZS+B. OURS was ranked first because it is the strongest example of a true hard-level evaluative question: it requires a clear judgment on practicality, is strongly grounded in course content, and has an excellent mark-scheme structure. ZS+B was ranked last because it is fundamentally an explanatory understanding task mislabeled as evaluation: the mark scheme rewards description of alpha-beta pruning rather than genuine critique or judgment.

Figure 14: **Illustrative contrast SAQ sample, hard difficulty tier (max score gap axis).** Pipeline identities are shown explicitly: ZS = zero_shot, ZS+B = zero_shot_bloom, MZS = multi_stage_zero_shot, MZS+B = multi_stage_zero_shot_bloom, and Ours = proposed pipeline. σ_w denotes the discrimination-weighted composite criterion score (higher is better, max = 1). The mark scheme and per-criterion breakdown are shown for the rank-1 and rank-5 pipelines only. [†]Flags items where the declared Bloom level under-specifies or overstates the true cognitive demand, as identified by the blind human evaluator.

Illustrative Contrast SBQ Sample — Easy Difficulty (Bloom Alignment Gap Axis)

Course: 4CCSAIAI Introduction to Artificial Intelligence | Source: Week 2–3 — Introduction to Machine Learning & Unsupervised Learning (Annotated Notes) | Model: GPT-4.1 | Task type: Scenario-Based Question (SBQ) | Difficulty target: Easy

Pipeline	Question stem	Declared Bloom	True Bloom	Marks	σ_w
A (MZS)	If the algorithm always predicts “no disease,” calculate its accuracy, and discuss whether this is a good way to judge the algorithm’s performance in this scenario.	Knowledge	Analyze [†]	5	0.685
B (ZS+B)	Define the metrics MAE, MSE, and RMSE in the context of regression, and explain how each metric measures prediction errors.	Understanding	Understanding	5	0.965
C (ZS)	Which terms describe these two parts of the dataset, and why is it important to keep the evaluation set labels hidden during training?	Knowledge	Analyze [†]	4	0.685
D (OURS)	Identify the two data splits used for model development in the scenario.	Knowledge	Knowledge	2	0.965
E (MZS+B)	Describe the roles of the training set and the test set in supervised learning.	Knowledge	Knowledge	3	0.965

[†]Declared–true Bloom mismatch identified by blind human evaluator.

Mark scheme and expected answer (MZS+B — rank 1):

Marking point	Marks
The training set is used to fit or train the model by providing both input data and their corresponding labels.	1
The test set is used to evaluate the trained model’s performance by using input data with hidden labels during prediction.	1
The test set helps assess how well the model generalizes to unseen data.	1
<i>Model answer:</i> In supervised learning, the training set serves to train the model by providing input data along with their corresponding labels, allowing the model to learn the relationship between features and outcomes. After training, the test set is used to evaluate the model’s performance by making predictions on input data for which the labels are hidden; this process assesses how well the model generalizes to new, unseen data.	/3

Per-criterion scores (best and worst pipeline):

Grounding	Clarity	Integrity	Gradability _{stem}	Gradability _{triple}	Mk. scheme	Fidelity	SRN	SG	BLA
MZS+B (rank 1):									
1.0	1.0	1.0	1.0	1.0	1.0	1.0	0.5	1.0	1.0
MZS (rank 5):									
1.0	1.0	0.5	1.0	1.0	0.0	1.0	0.5	1.0	0.4

Selection Justification

Automated selection (Bloom alignment gap axis): task selected from easy difficulty pool ($n=11$ candidates) to highlight a large gap in Bloom alignment quality under otherwise matched generation conditions. **Best** σ_w : 0.9648 **Bloom gap**: 0.6000 **Gap percentile rank**: 72.7th **Runner-up gap**: 0.6000 **Mean** σ_w : 0.8527

Blind human evaluation ranking: MZS+B > ZS+B > OURS > ZS > MZS. MZS+B was ranked first because it most cleanly matches its declared knowledge-level target while remaining clear, grounded, and objective; it asks for the roles of the training and test sets and uses the scenario proportionately. MZS was ranked last because it has the clearest Bloom mismatch in the set: it is labelled as knowledge, but calculating accuracy and judging its appropriateness in an imbalanced setting requires analysis.

Figure 15: **Illustrative contrast SBQ sample, easy difficulty tier (Bloom alignment gap axis).** Pipeline identities are shown explicitly: ZS = zero_shot, ZS+B = zero_shot_bloom, MZS = multi_stage_zero_shot, MZS+B = multi_stage_zero_shot_bloom, and Ours = proposed pipeline. σ_w denotes the discrimination-weighted composite criterion score (higher is better, max = 1). The mark scheme and per-criterion breakdown are shown for the rank-1 and rank-5 pipelines only. [†]Flags items where the declared Bloom level under-specifies the true cognitive demand, as identified by the blind human evaluator.

Illustrative Contrast SBQ Sample — Medium Difficulty (Bloom Alignment Gap Axis)

1.0	1.0	1.0	1.0	1.0	0.0	1.0	0.5	1.0	0.4

Selection Justification

Automated selection (Bloom alignment gap axis): task selected from hard difficulty pool to highlight a large gap in Bloom alignment quality under otherwise matched generation conditions. **Best** σ_w : 0.9648 **Bloom gap**: 0.6000 **Gap percentile rank**: 81.2th **Runner-up gap**: 0.6000 **Mean** σ_w : 0.8474

Blind human evaluation ranking: OURS > ZS+B > MZS+B > ZS > MZS. OURS was ranked first because it is the clearest example of exact Bloom targeting in the set: the task is genuinely evaluative, the scenario is necessary, and the mark scheme supports a justified conclusion on whether the MDP formulation is suitable. MZS was ranked last because it has the largest and clearest Bloom mismatch: explaining a Bellman update and interpreting a value is an understanding task, not an evaluation task.

Figure 17: **Illustrative contrast SBQ sample, hard difficulty tier (Bloom alignment gap axis).** Pipeline identities are shown explicitly: ZS = zero_shot, ZS+B = zero_shot_bloom, MZS = multi_stage_zero_shot, MZS+B = multi_stage_zero_shot_bloom, and Ours = proposed pipeline. σ_w denotes the discrimination-weighted composite criterion score (higher is better, max = 1). The mark scheme and per-criterion breakdown are shown for the rank-1 and rank-5 pipelines only. [†]Flags items where the declared Bloom level under-specifies or overstates the true cognitive demand, as identified by the blind human evaluator.

Illustrative Contrast SBQ Sample — Easy Difficulty (Max Score Gap Axis)

Course: 4CCSAIAI Introduction to Artificial Intelligence | Source: Week 2–3 — Introduction to Machine Learning & Unsupervised Learning (Annotated Notes) | Model: GPT-4.1 | Task type: Scenario-Based Question (SBQ) | Difficulty target: Easy

Pipeline	Question stem	Declared Bloom	True Bloom	Marks	σ_w
A (MZS)	If the algorithm always predicts “no disease,” calculate its accuracy, and discuss whether this is a good way to judge the algorithm’s performance in this scenario.	Knowledge	Analyze [†]	5	0.685
B (ZS)	Which terms describe these two parts of the dataset, and why is it important to keep the evaluation set labels hidden during training?	Knowledge	Analyze [†]	4	0.685
C (MZS+B)	Describe the roles of the training set and the test set in supervised learning.	Knowledge	Knowledge	3	0.965
D (ZS+B)	Define the metrics MAE, MSE, and RMSE in the context of regression, and explain how each metric measures prediction errors.	Understanding	Understanding	5	0.965
E (OURS)	Identify the two data splits used for model development in the scenario.	Knowledge	Knowledge	2	0.965

[†]Declared–true Bloom mismatch identified by blind human evaluator.

Mark scheme and expected answer (MZS+B — rank 1):

Marking point	Marks
The training set is used to fit or train the model by providing both input data and their corresponding labels.	1
The test set is used to evaluate the trained model’s performance by using input data with hidden labels during prediction.	1
The test set helps assess how well the model generalizes to unseen data.	1
<i>Model answer:</i> In supervised learning, the training set serves to train the model by providing input data along with their corresponding labels, allowing the model to learn the relationship between features and outcomes. After training, the test set is used to evaluate the model’s performance by making predictions on input data for which the labels are hidden; this process assesses how well the model generalizes to new, unseen data.	/3

Per-criterion scores (best and worst pipeline):

Grounding	Clarity	Integrity	Gradability _{stem}	Gradability _{triple}	Mk. scheme	Fidelity	SRN	SG	BLA
MZS+B (rank 1):									
1.0	1.0	1.0	1.0	1.0	1.0	1.0	0.5	1.0	1.0
MZS (rank 5):									
1.0	1.0	0.5	1.0	1.0	0.0	1.0	0.5	1.0	0.4

Selection Justification

Automated selection (max score gap axis): task selected from easy difficulty pool ($n=11$ candidates) to maximise the spread between the highest- and lowest-scoring pipelines on the discrimination-weighted criterion score σ_w . **Best σ_w :** 0.9648 **Worst σ_w :** 0.6845 **Score gap:** 0.2803 **Gap percentile rank:** 90.9th **Runner-up gap:** 0.2416 **Mean σ_w :** 0.8527

Blind human evaluation ranking: MZS+B > ZS+B > OURS > ZS > MZS. MZS+B was ranked first because it is the cleanest and most internally consistent SBQ in the set: the question is a straightforward knowledge-level task, the declared and true Bloom levels match exactly, and the mark scheme is concise, objective, and fully aligned with the expected answer. MZS was ranked last because it combines numerical calculation with critique of metric suitability in an imbalanced classification setting, making it analytically demanding despite being labelled as knowledge.

Figure 18: **Illustrative contrast SBQ sample, easy difficulty tier (max score gap axis).** Pipeline identities are shown explicitly: ZS = zero_shot, ZS+B = zero_shot_bloom, MZS = multi_stage_zero_shot, MZS+B = multi_stage_zero_shot_bloom, and Ours = proposed pipeline. σ_w denotes the discrimination-weighted composite criterion score (higher is better, max = 1). The mark scheme and per-criterion breakdown are shown for the rank-1 and rank-5 pipelines only. [†]Flags items where the declared Bloom level under-specifies the true cognitive demand, as identified by the blind human evaluator.

Illustrative Contrast SBQ Sample — Medium Difficulty (Max Score Gap Axis)

Course: 4CCSAIAI Introduction to Artificial Intelligence | Source: Week 8 — Planning & CSPs (Lecture Slides) | Model: Gemini-2.5-Flash | Task type: Scenario-Based Question (SBQ) | Difficulty target: Medium

Pipeline	Question stem	Declared Bloom	True Bloom	Marks	σ_w
A (MZS+B)	Describe how Forward Checking would update the domains of variables B and C immediately after A is assigned “Red”.	Analyze	Understanding [†]	6	0.647
B (ZS+B)	Given that DevA is assigned to Task1, and knowing the “all different” constraint applies to both developers and tasks, apply the Minimum Remaining Values (MRV) heuristic to determine which unassigned developer should be selected next. Show the updated legal domains and explain your choice.	Application	Application	6	0.903
C (MZS)	Using the Most Constrained Variable (MRV) heuristic, which variable should the agent select next for assignment, and why?	Application	Application	4	0.903
D (OURS)	Compute the total number of initial, unconstrained colour assignments possible for all 7 regions of the map using the given colour domain.	Application	Application	7	0.965
E (ZS)	Explain two specific heuristics, one for variable selection and one for value ordering, that the company could implement to significantly improve the efficiency of their backtracking search.	Application	Application	4	0.965

[†] Declared–true Bloom mismatch identified by blind human evaluator.

Mark scheme and expected answer (OURS — rank 1):

Marking point	Marks
Identifies the total number of regions (variables) on the map as 7.	1
Identifies the size of the colour domain (values) as 3 (red, green, blue).	1
Applies the combinatorial principle for independent assignments, using the number of colours as the base and the number of regions as the exponent (3^7).	2
Calculates the result of 3^7 correctly.	2
States the final computed total number of initial unconstrained assignments as 2187.	1
<i>Model answer:</i> With 7 regions on the map and a colour domain size of 3 (red, green, blue), the total number of initial unconstrained assignments is calculated as 3^7 , which equals 2187.	7

Per-criterion scores (best and worst pipeline):

Grounding	Clarity	Integrity	Gradability _{stem}	Gradability _{triple}	Mk. scheme	Fidelity	SRN	SG	BLA
OURS (rank 1):									
1.0	1.0	1.0	1.0	1.0	1.0	1.0	0.5	1.0	1.0
MZS+B (rank 5):									
1.0	1.0	1.0	0.5	1.0	0.0	1.0	0.5	0.5	0.6

Selection Justification

Automated selection (max score gap axis): task selected from medium difficulty pool to maximise the spread between the highest- and lowest-scoring pipelines on the discrimination-weighted criterion score σ_w . **Best** σ_w : 0.9648 **Worst** σ_w : 0.6469 **Score gap**: 0.3179 **Gap percentile rank**: 96.7th **Runner-up gap**: 0.2484 **Mean** σ_w : 0.8767

Blind human evaluation ranking: OURS > ZS > ZS+B > MZS > MZS+B. OURS was ranked first because it is the most internally consistent and objectively gradable SBQ in the set: the task is a sharply defined application of combinatorial reasoning, the declared and true Bloom levels match, and the answer maps directly to a logically sequenced mark scheme. MZS+B was ranked last because it overstates the cognitive level: describing Forward Checking domain updates after a fixed assignment is procedural understanding rather than genuine analysis.

Figure 19: **Illustrative contrast SBQ sample, medium difficulty tier (max score gap axis).** Pipeline identities are shown explicitly: ZS = zero_shot, ZS+B = zero_shot_bloom, MZS = multi_stage_zero_shot, MZS+B = multi_stage_zero_shot_bloom, and Ours = proposed pipeline. σ_w denotes the discrimination-weighted composite criterion score (higher is better, max = 1). The mark scheme and per-criterion breakdown are shown for the rank-1 and rank-5 pipelines only. [†] Flags items where the declared Bloom level under-specifies the true cognitive demand, as identified by the blind human evaluator.

Illustrative Contrast SBQ Sample — Hard Difficulty (Max Score Gap Axis)

Course: 4CCSAIAI Introduction to Artificial Intelligence | Source: Week 9 — MDPs / Uncertainty (Slides) | Model: GPT-4.1 | Task type: Scenario-Based Question (SBQ) | Difficulty target: Hard

Pipeline	Question stem	Declared Bloom	True Bloom	Marks	σ_w
A (ZS+B)	Design a suitable reward function for the robot's navigation MDP. Briefly justify your choices for how rewards should be assigned to regular, goal, and hazardous states.	Synthesis	Synthesis	5	0.702
B (ZS)	Apply the Bellman equation to compute the updated utility $U((2, 1))$ for moving left, showing your calculation, and determine which action yields the maximum expected utility.	Evaluation	Application [†]	6	0.910
C (OURS)	Assess the effectiveness of modeling the warehouse inventory management system as a Markov Decision Process, given the described state space, actions, and transition uncertainties.	Evaluation	Evaluation	8	0.965
D (MZS)	Explain the process for updating the utility value of state (2, 1) using the Bellman equation and discuss what the value 0.655 represents in this context.	Evaluation	Understanding [†]	8	0.723
E (MZS+B)	Discuss how the reward function influences the policy derived from value iteration in such an uncertain inventory system. What might be the consequences of missing or poorly designed reward components?	Evaluation	Analyze [†]	8	0.938

[†] Declared–true Bloom mismatch identified by blind human evaluator.

Mark scheme and expected answer (OURS — rank 1):

Marking point	Marks
MDP formalism allows systematic modeling of sequential decisions, capturing inventory dynamics through defined states and actions.	1
Probabilistic state transitions in the MDP match real-world uncertainties such as customer demand variability and delivery timing.	2
The MDP reward structure effectively incorporates holding costs, ordering costs, and expected profits, supporting quantitative evaluation of policies.	1
The large state space may increase computational complexity, potentially limiting tractability for optimal policy computation.	2
MDP modeling is suitable for inventory management when transition probabilities and rewards are well-defined, but performance hinges on accurate probability estimation and scalable solution methods.	2
<i>Model answer:</i> MDP formalism allows systematic modeling of sequential decisions, capturing inventory dynamics through defined states and actions. Probabilistic state transitions in the MDP match real-world uncertainties such as customer demand variability and delivery timing. The MDP reward structure effectively incorporates holding costs, ordering costs, and expected profits, supporting quantitative evaluation of policies. The large state space may increase computational complexity, potentially limiting tractability for optimal policy computation. MDP modeling is suitable for inventory management when transition probabilities and rewards are well-defined, but performance hinges on accurate probability estimation and scalable solution methods.	/8

Per-criterion scores (best and worst pipeline):

Grounding	Clarity	Integrity	Gradability _{stem}	Gradability _{triple}	Mk. scheme	Fidelity	SRN	SG	BLA
<i>OURS (rank 1):</i>									
1.0	1.0	1.0	1.0	1.0	1.0	1.0	0.5	1.0	1.0

OURS (rank 1):							
1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.0
MZS (rank 5):							
1.0	1.0	1.0	1.0	1.0	0.0	1.0	0.8

Selection Justification

Representative matched-task selection: task selected from the easy difficulty pool ($n=7$ candidates; selected percentile = 42.9) as a representative matched-task sample rather than an extreme contrast case. **Mean σ_w :** 0.7884

Blind human evaluation ranking: OURS > ZS+B > MZS+B > ZS > MZS. OURS was ranked first because it is the most precise, controlled, and internally consistent assessment triple: the question is tightly scoped, the declared and true Bloom levels match exactly, and the mark scheme and expected answer align perfectly around a single knowledge-level objective. MZS was ranked last because, although grounded and answerable, it is less tightly structured and Bloom-misaligned: it asks for conceptual explanation of MAX/MIN roles and game-tree representation while being labelled only as knowledge.

Figure 21: **Representative SAQ sample, easy difficulty tier.** Pipeline identities are shown explicitly: ZS = zero_shot, ZS+B = zero_shot_bloom, MZS = multi_stage_zero_shot, MZS+B = multi_stage_zero_shot_bloom, and Ours = proposed pipeline. σ_w denotes the discrimination-weighted composite criterion score (higher is better, max = 1). The mark scheme and per-criterion breakdown are shown for the rank-1 and rank-5 pipelines only. [†]Flags items where the declared Bloom level under-specifies the true cognitive demand, as identified by the blind human evaluator.

Representative SAQ Sample — Medium Difficulty

Course: 4CCSAIAI Introduction to Artificial Intelligence | Source: Week 7 — Heuristic Search & Adversarial Search (Answers) | Model: GPT-4.1 | Task type: Short Answer Question (SAQ) | Difficulty target: Medium

Pipeline	Question stem	Declared Bloom	True Bloom	Marks	σ_w
A (OURS)	Apply the concept of admissible heuristics to select an appropriate heuristic for an A* search in a new maze, ensuring the optimal path is found.	Application	Application	5	1.000
B (MZS+B)	Compare the effects of scaling an admissible heuristic by a factor greater than 1 on Greedy Best-First Search versus A* search. Why do these effects differ?	Analyze	Analyze	10	0.782
C (ZS)	Describe what is meant by an admissible heuristic and discuss how admissibility and informativeness affect the performance and guarantees of A* search.	Application	Analyze [†]	8	0.797
D (MZS)	Explain the differences in the paths chosen by Greedy Best-First Search and A* Search in the given example, including the reasons behind their respective path costs.	Application	Analyze [†]	9	0.797
E (ZS+B)	Explain the difference between Greedy Best-First Search (GBFS) and A* Search in terms of the paths and path costs they find in the given example.	Understanding	Understanding	8	0.674

[†]Declared–true Bloom mismatch identified by blind human evaluator.

Mark scheme and expected answer (OURS — rank 1):

Marking point	Marks
Choose a heuristic that never over-estimates the true cost from any node to the goal, satisfying admissibility.	1
Verify the selected heuristic is admissible so A* will guarantee finding the optimal path through the maze.	2
Avoid using scaled heuristics (such as multiplying by a constant greater than 1) since this may cause over-estimation and inadmissibility.	1
Consider using a commonly admissible heuristic like Manhattan distance for maze environments, as it estimates the minimum number of steps to the goal without overestimating.	1
<i>Model answer:</i> Select a heuristic that never over-estimates the true cost from any node to the goal to ensure admissibility, verify this property to guarantee that A* finds the optimal path, do not use scaled heuristics with constants greater than 1 as they may over-estimate, and use an admissible heuristic like Manhattan distance for a maze since it does not overestimate the number of steps to the goal.	/5

Per-criterion scores (best and worst pipeline):

Grounding	Clarity	Integrity	Gradability _{stem}	Gradability _{triple}	Mk. scheme	Fidelity	BLA
OURS (rank 1):							
1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.0
ZS (rank 5):							
1.0	1.0	1.0	1.0	1.0	0.5	1.0	0.8

Selection Justification

Representative matched-task selection: task selected from the medium difficulty pool ($n=35$ candidates; selected percentile = 48.6) as a representative matched-task sample rather than an extreme contrast case. **Mean σ_w :** 0.8100

Blind human evaluation ranking: OURS > MZS+B > ZS+B > MZS > ZS. OURS was ranked first because it is the most complete and internally consistent assessment triple: it poses a genuine application-level task, operationalizes admissibility concretely, and supports highly objective grading through a tightly matched mark scheme and answer. ZS was ranked last because it is Bloom-misaligned and too abstract for its declared task type: it frames a broad conceptual discussion of admissibility and informativeness rather than a concrete application to a specific case.

Figure 22: **Representative SAQ sample, medium difficulty tier.** Pipeline identities are shown explicitly: ZS = zero_shot, ZS+B = zero_shot_bloom, MZS = multi_stage_zero_shot, MZS+B = multi_stage_zero_shot_bloom, and Ours = proposed pipeline. σ_w denotes the discrimination-weighted composite criterion score (higher is better, max = 1). The mark scheme and per-criterion breakdown are shown for the rank-1 and rank-5 pipelines only. B (MZS+B)	Given a practical scenario where delivery by helicopter is limited to a 100-mile range, justify why Complete-Linkage clustering would be preferable over other linkage criteria for forming suitable clusters.	Evaluation	Evaluation	10	1.000
C (ZS+B)	Compare and contrast the single-linkage, complete-linkage, and average-linkage criteria used in hierarchical clustering to measure cluster distances.	Analyze	Analyze	10	1.000
D (OURS)	Assess the effectiveness of running K-means multiple times with different initialisations or using k-means++ to avoid local minima, as described in the text.	Evaluation	Evaluation	8	1.000
E (MZS)	Given a practical scenario where a helicopter delivery service must cluster cities such that any city in a cluster is reachable within a 100-mile flight, discuss why the Complete-Linkage criterion is the suitable choice and how it ensures this constraint.	Evaluation	Application [†]	10	0.595

[†] Declared–true Bloom mismatch identified by blind human evaluator.

Mark scheme and expected answer (MZS+B — rank 1):

Marking point	Marks
Complete-Linkage clustering forms clusters based on the maximum distance between points, ensuring all points in a cluster are within a certain range.	2
This method tends to produce compact, tight clusters, which aligns with the helicopter’s 100-mile delivery range constraint.	2
In contrast, Single-Linkage clustering can create elongated clusters where some points are far apart, possibly exceeding the 100-mile limit.	1
Average-Linkage clustering averages distances, which may allow some points in a cluster to be beyond the 100-mile range even if the average distance is acceptable.	1
Complete-Linkage minimizes the risk of any delivery exceeding the 100-mile range, which is critical for operational feasibility and safety.	2
Using Complete-Linkage supports clear decision-making by providing well-defined cluster boundaries that respect the practical distance limit.	1
Overall, Complete-Linkage clustering better guarantees deliveries stay within the helicopter’s operational range compared to other linkage methods.	1

Model answer: Complete-Linkage clustering forms clusters based on the maximum distance between points, ensuring all points within a cluster remain within the helicopter’s 100-mile delivery range. This method produces compact, tight clusters, aligning closely with the operational constraint, unlike Single-Linkage clustering which can generate elongated clusters with points exceeding the range. Average-Linkage, by averaging distances, may also include points beyond the limit despite an acceptable average. Therefore, Complete-Linkage minimizes the risk of any delivery exceeding the range, supports clear decision-making through well-defined cluster boundaries, and overall better guarantees feasible and safe helicopter deliveries. **/10**

Per-criterion scores (best and worst pipeline):

Grounding	Clarity	Integrity	Gradability _{stem}	Gradability _{triple}	Mk. scheme	Fidelity	BLA
MZS+B (rank 1):							
1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.0
MZS (rank 5):							
1.0	1.0	1.0	1.0	1.0	0.0	1.0	0.6

Selection Justification

Representative matched-task selection: task selected from the hard difficulty pool ($n=17$ candidates; selected percentile = 47.1) as a representative matched-task sample rather than an extreme contrast case. **Mean σ_w :** 0.8458

Blind human evaluation ranking: MZS+B > OURS > ZS+B > ZS > MZS. MZS+B was ranked first because it is a clear, well-grounded evaluation task embedded in a realistic constraint-driven scenario; it requires comparison of linkage criteria, judgment under the 100-mile range constraint, and an explicitly justified decision. MZS was ranked last because it underdelivers on evaluation: although grounded in a plausible scenario, it is closer to application than genuine evaluative reasoning and does not sufficiently require comparison across methods under competing considerations.

Figure 23: **Representative SAQ sample, hard difficulty tier.** Pipeline identities are shown explicitly: ZS = zero_shot, ZS+B = zero_shot_bloom, MZS = multi_stage_zero_shot, MZS+B = multi_stage_zero_shot_bloom, and Ours = proposed pipeline. σ_w denotes the discrimination-weighted composite criterion score (higher is better, max = 1). The mark scheme and per-criterion breakdown are shown for the rank-1 and rank-5 pipelines only. [†] Flags items where the declared Bloom level under-specifies or overstates the true cognitive demand, as identified by the blind human evaluator.

Representative SBQ Sample — Easy Difficulty

Course: 4CCSAIAI Introduction to Artificial Intelligence | Source: Week 2–3 — Introduction to Machine Learning & Unsupervised Learning (Annotated Notes) | Model: GPT-4.1 | Task type: Scenario-Based Question (SBQ) | Difficulty target: Easy

Pipeline	Question stem	Declared Bloom	True Bloom	Marks	σ_w
A (OURS)	Identify the two data splits used for model development in the scenario.	Knowledge	Knowledge	2	0.965
B (ZS+B)	Define the metrics MAE, MSE, and RMSE in the context of regression, and explain how each metric measures prediction errors.	Understanding	Understanding	5	0.965
C (MZS+B)	Describe the roles of the training set and the test set in supervised learning.	Knowledge	Knowledge	3	0.965
D (ZS)	Which terms describe these two parts of the dataset, and why is it important to keep the evaluation set labels hidden during training?	Knowledge	Analyze [†]	4	0.685
E (MZS)	If the algorithm always predicts “no disease,” calculate its accuracy, and discuss whether this is a good way to judge the algorithm’s performance in this scenario.	Knowledge	Analyze [†]	5	0.685

[†] Declared–true Bloom mismatch identified by blind human evaluator.

Scenario (ZS+B — rank 1):

A data scientist builds a regression model to predict housing prices based on several features. After training the model, she evaluates it on a test set and calculates the Mean Absolute Error (MAE), Mean Squared Error (MSE), and Root-Mean-Squared Error (RMSE).

Mark scheme and expected answer (ZS+B — rank 1):

Marking point	Marks
Defines Mean Absolute Error (MAE) as the average absolute difference between predicted and true values.	1
Defines Mean Squared Error (MSE) as the average squared difference between predicted and true values.	1
Defines Root-Mean-Squared Error (RMSE) as the square root of the average squared difference.	1
Explains that MAE measures average magnitude of errors, MSE penalizes larger errors, and RMSE brings scale back to original units.	2
<i>Model answer:</i> Mean Absolute Error (MAE) is calculated as the average absolute difference between the predicted and actual housing prices. Mean Squared Error (MSE) measures the average of the squared differences, thus penalizing larger errors more heavily. Root-Mean-Squared Error (RMSE) is the square root of the MSE, providing an error value in the same units as the housing prices. MAE reflects the average error magnitude, MSE highlights the impact of large deviations, and RMSE is useful for interpreting error size in original terms.	/5

Per-criterion scores (best and worst pipeline):

Grounding	Clarity	Integrity	Gradability _{stem}	Gradability _{triple}	Mk. scheme	Fidelity	SRN	SG	BLA
ZS+B (rank 1):

[†] Declared–true Bloom mismatch identified by blind human evaluator.

Scenario (OURS — rank 1):

A supervised learning algorithm is developed to predict the presence of a rare disease D using chest X-ray images. The data is split into a training set, which includes labeled examples, and a test set, where labels are hidden during evaluation. The disease occurs in 1% of the population represented in the dataset. Upon evaluation, an accuracy of 99% was recorded on the test set. The test set maintains the same class distribution as the population, where the positive class is rare. Additionally, alternative classification metrics such as precision, sensitivity, and F1 score are considered for further analysis. In a separate regression task, predictions consist of real-valued outputs compared against true target values using error metrics including Mean Absolute Error (MAE), Mean Squared Error (MSE), and Root-Mean-Squared Error (RMSE).

Mark scheme and expected answer (OURS — rank 1):

Marking point	Marks
Classification uses discrete class labels with metrics like accuracy, precision, sensitivity, and F1 score to evaluate prediction quality.	2
Accuracy can be misleading in classification when classes are imbalanced, such as a rare disease with 1% prevalence.	1
Regression evaluates continuous outputs using error metrics like MAE, MSE, and RMSE to measure prediction errors.	2
Classification metrics assess categorical correctness and balance of false positives/negatives, while regression metrics quantify numerical deviations.	2

Model answer: Classification uses discrete class labels with metrics like accuracy, precision, sensitivity, and F1 score to evaluate prediction quality. Accuracy can be misleading in classification when classes are imbalanced, such as a rare disease with 1% prevalence. Regression evaluates continuous outputs using error metrics like MAE, MSE, and RMSE to measure prediction errors. Classification metrics assess categorical correctness and balance of false positives and negatives, while regression metrics quantify numerical deviations. //

Per-criterion scores (best and worst pipeline):

Selection Justification

Representative matched-task selection: task selected from the medium difficulty pool ($n=30$ candidates; selected percentile = 50.0) as a representative matched-task sample rather than an extreme contrast case. **Mean σ_w :** 0.8974

Blind human evaluation ranking: OURS > ZS+B > MZS > MZS+B > ZS. OURS was ranked first because it is the most internally consistent, scenario-grounded, and cognitively well-targeted item in the set: it asks for a genuine analyze-level comparison, makes full use of both the classification and regression parts of the scenario, and supports highly consistent grading. ZS was ranked last because it overstates the cognitive level: despite a useful scenario, the question mainly asks for conceptual explanation of why 99% accuracy is misleading and which alternative metrics matter, making it closer to understanding than true application.

Figure 25: **Representative SBQ sample, medium difficulty tier.** Pipeline identities are shown explicitly: ZS = zero_shot, ZS+B = zero_shot_bloom, MZS = multi_stage_zero_shot, MZS+B = multi_stage_zero_shot_bloom, and Ours = proposed pipeline. σ_w denotes the discrimination-weighted composite criterion score (higher is better, max = 1). The mark scheme and per-criterion breakdown are shown for the rank-1 and rank-5 pipelines only. [†]Flags items where the declared Bloom level under-specifies the true cognitive demand, as identified by the blind human evaluator.

[†] Declared–true Bloom mismatch identified by blind human evaluator.

Scenario (OURS — rank 1):

A software engineer at a social media company developed an ‘auto-crop’ feature that automatically cropped images attached to posts. The system was configured to identify and focus on specific image areas. A deep neural network was trained on a dataset containing images and their associated saliency data. Following its deployment, the feature led to an increase in posts containing images and an uplift in user engagement metrics, including time spent on the platform and the number of clicks. However, subsequent observations by a group of users showed systematic patterns within the auto-crop’s behavior. These patterns included a consistent focus on White individuals over Black individuals, famous men over famous women, and a frequent centering on women’s chest areas. An internal ethics review stated that this behavior exhibited characteristics concerning stereotypes, indirect discrimination, and the objectification of women.

Mark scheme and expected answer (OURS — rank 1):

Marking point	Marks
Mandate a rigorous, pre-deployment audit process for all AI training datasets, ensuring they are demographically representative and balanced to actively prevent the emergence of stereotypes and indirect discrimination.	3
Implement ethically-guided design principles for attention or saliency mechanisms in image processing AI, specifically to avoid hyper-focus on sensitive body areas and prevent objectification, perhaps using constrained optimization or negative exemplars.	3
Integrate a comprehensive bias detection and mitigation framework into the AI development lifecycle, applying quantitative fairness metrics (e.g., demographic parity, equalized odds) at multiple stages from data preparation to model deployment.	2
Establish a standing, interdisciplinary ethical AI review board, comprising engineers, ethicists, and diverse user representatives, responsible for assessing the societal impact and potential biases of new AI features from conception.	2
Develop transparent channels for user feedback specifically on AI behavior, coupled with a swift, accountable system for investigating, communicating, and rectifying identified ethical violations in deployed features.	2
<i>Model answer:</i> Future AI feature development will mandate a rigorous, pre-deployment audit process for all AI training datasets, ensuring they are demographically representative and balanced to actively prevent the emergence of stereotypes and indirect discrimination. Ethically-guided design principles will be implemented for attention or saliency mechanisms in image processing AI, specifically to avoid hyper-focus on sensitive body areas and prevent objectification, perhaps using constrained optimization or negative exemplars. A comprehensive bias detection and mitigation framework will be integrated into the AI development lifecycle, applying quantitative fairness metrics like demographic parity or equalized odds at multiple stages from data preparation to model deployment. Furthermore, a standing, interdisciplinary ethical AI review board, comprising engineers, ethicists, and diverse user representatives, will be established, responsible for assessing the societal impact and potential biases of new AI features from conception. Finally, transparent channels for user feedback specifically on AI behavior will be developed, coupled with a swift, accountable system for investigating, communicating, and rectifying identified ethical violations in deployed features.	/12

Intent vs. Surface: Recovering Acoustic Realization from Modern ASR for Pronunciation Training

Seongjin Park

Speak

360 Spear St. 4F. San Francisco, California. 94105.

seongjin@usespeak.com

Abstract

Pronunciation feedback in language learning depends on accurate detection of learner errors, but it is unclear whether modern ASR systems are suitable for this purpose. Their language models recover intended words rather than what was actually pronounced, systematically masking mispronunciations. This is a tendency we call *intent bias*. By evaluating eight ASR systems spanning three architectures on two L2 English corpora, we find that overcorrection rate correlates inversely with word error rate. In other words, ASR systems with lower WER tend to mask more pronunciation errors. We propose surface-faithful reranking, an inference-time method that uses phoneme-level acoustic similarity to select N-best hypotheses closer to what the learner actually said. Without retraining or access to model internals, the method reduces the false acceptance rate of mispronunciations by 6.0 percentage points on L2-ARCTIC and 5.6 on speechocean762. The improvement is consistent across age groups and first-language backgrounds, though substantial overcorrection remains, pointing to the need for pronunciation-aware ASR objectives.

1 Introduction

Pronunciation is among the most difficult aspects of second-language acquisition, and automated feedback has long been sought as a scalable complement to human tutors (Eskenazi, 2009; Neri et al., 2002). At the core of most computer-assisted pronunciation training (CAPT) systems lies an automatic speech recognition component whose transcriptions are compared against expected text to identify mispronounced words (Witt and Young, 2000). The accuracy of this detection step is therefore critical for providing useful feedback to learners.

Modern ASR systems, however, are optimized to report what the speaker most likely *meant* rather

than what was actually produced, since their language model components assign high probability to grammatically and lexically plausible sequences. This results in effectively correcting non-standard pronunciations before they reach the downstream tasks. For example, when a learner says “she coming” (omitting “is”), the ASR often produces “she is coming”. Also, when a learner produces something closer to “sheep” while reading “ship,” the system may output “ship” based on the context. We refer to this tendency as *intent bias* throughout the paper. In our analysis of the speechocean762 (Zhang et al., 2021) corpus using Parakeet, 82.0% of utterances contain at least one overcorrected mispronunciation in the top-ranked hypothesis, and the system tends to be most confident when it overcorrects.

Thus, we propose *surface-faithful reranking*, a method that works entirely at inference time to recover what the learner actually pronounced. Given the N-best hypotheses from any ASR system, we obtain a reference phoneme sequence from an independent phoneme recognizer, then select the hypothesis whose phonetic transcription is closest to that reference. This reranked hypothesis drives mispronunciation detection while the original top-1 output is retained for display, allowing a single system to serve both readability and diagnostic accuracy. On L2-ARCTIC (Zhao et al., 2018), the method reduces the false acceptance rate on severe mispronunciations from 80.8% to 74.8%, and on speechocean762 test, from 70.6% to 65.0%. The improvements are consistent across age groups (speechocean762) and across all six L1 backgrounds tested (L2-ARCTIC).

The contributions of this work are threefold. First, we show that overcorrection is not incidental but systematic: across eight ASR systems spanning three architectures (autoregressive, hybrid CTC-RNNT, CTC-only), lower word error rate correlates with higher overcorrection, suggesting that

WER alone is insufficient for evaluating ASR in educational contexts. Second, we propose surface-faithful reranking, an inference-time method that partially mitigates this bias without retraining or white-box access. Third, we evaluate across two corpora, multiple age groups, and diverse L1 backgrounds, showing consistent gains.

2 Related Work

2.1 Mispronunciation Detection in CAPT

Goodness of Pronunciation (GOP), introduced by Witt and Young (2000), remains foundational in CAPT. GOP computes the posterior probability ratio between forced-aligned and freely decoded phone sequences, providing a frame-level pronunciation score. It requires white-box access to the acoustic model and frame-level forced alignment, assumptions that hold for HMM-GMM or hybrid systems but not for modern end-to-end ASR or commercial APIs.

End-to-end approaches train neural networks directly on L2 speech for mispronunciation detection and diagnosis (MDD) (Leung et al., 2019; Li et al., 2017). More recently, self-supervised representations from wav2vec2 (Baevski et al., 2020) have been fine-tuned for this task as well (Xu et al., 2021; Peng et al., 2021), achieving competitive results with less labeled data. Korzekwa et al. (2021) incorporate uncertainty modeling to improve detection robustness. However, all these approaches require annotated non-native speech corpora for training, data that remains scarce for most language pairs, and produce task-specific models that must be retrained for new domains.

Transformer-based assessment systems such as GOPT (Gong et al., 2022) predict pronunciation scores at multiple granularities, but their training on specific corpora limits zero-shot generalization. The method we propose avoids these constraints, as it requires no training on L2 data, no access to ASR internals, and no task-specific model.

2.2 ASR for L2 Speech and Language Model Bias

ASR systems trained on native speech perform worse on accented and non-native speech (Zechner et al., 2009). This degradation is well documented, but a subtler problem has received less attention. When ASR *succeeds* on L2 speech, it often does so by correcting the learner’s errors rather than faithfully transcribing them. This overcorrection is a

natural consequence of optimizing the model for low word error rate, which incentivizes recovering canonical word sequences regardless of acoustic evidence to the contrary.

Cámara-Arenas et al. (2023) formalize this as a conflict between two necessary conditions for pronunciation assessment. ASR must recognize diverse speech (requiring robustness) but must also refrain from normalizing non-standard pronunciations (requiring sensitivity). They show that Google ASR cannot satisfy both conditions simultaneously. Won (2025) provides further empirical evidence that WER correlates poorly with human pronunciation judgments for high-performing ASR systems. Chen et al. (2024) demonstrate that acoustic information is often overridden by language model priors, and propose training-time modifications. Our work shares the diagnosis but differs in approach. Rather than modifying training, we intervene at inference time and provide quantitative evidence of the WER-overcorrection trade-off across architectures.

2.3 N-best Reranking

N-best list reranking has been studied extensively for improving ASR accuracy, typically using language models or neural rescorers to select the most linguistically plausible hypothesis (Salazar et al., 2020). In the present work, we try to invert this paradigm. Instead of reinforcing linguistic plausibility, we use phonetic signals to select hypotheses that best match actual pronunciation. We hypothesize that surface-faithful candidates often already exist in the N-best list but are suppressed by the language model’s preference for canonical forms.

3 Method

3.1 Problem Formulation

Standard ASR systems tend to choose the hypothesis that maximizes a combination of acoustic likelihood and language model probability. For CAPT, however, this objective is often misaligned. A hypothesis that restores a dropped word or corrects a vowel substitution scores well by conventional metrics but obscures the pronunciation error a learner needs to know about. In this study, we seek an alternative selection criterion that favors hypotheses reflecting what was acoustically produced (i.e., the *surface realization*) rather than what was linguistically intended.

Figure 1: Surface-faithful reranking pipeline. PanPhon distance selects the hypothesis closest to the phoneme recognizer output for MDD; the top-1 hypothesis is retained for display.

3.2 Surface-Faithful Reranking

Given an utterance, we extract two independent signals, which are (1) an N-best list of text hypotheses $\mathcal{H} = \{h_1, \dots, h_K\}$ from the ASR system, and (2) a phoneme sequence P from a separate phoneme recognizer that operates without a language model. The phoneme recognizer provides a language-model-free estimate of the surface realization.

Each hypothesis h is converted to an IPA phoneme sequence using grapheme-to-phoneme (G2P) system via g2p-en (Park and Kim, 2019). We then select the hypothesis whose phonetic representation most closely matches the recognized phoneme sequence:

$$h^* = \arg \min_{h \in \mathcal{H}} d_{\text{PanPhon}}(\text{G2P}(h), P) \quad (1)$$

where d_{PanPhon} is the weighted articulatory feature edit distance described below. The selected hypothesis h^* serves as the surface-faithful transcription for mispronunciation detection, while the original top-1 hypothesis h_1 is retained for display to the learner. This dual-output design allows a single ASR system to provide both a readable transcript and accurate pronunciation diagnostics. Figure 1 illustrates the complete pipeline.

3.3 Phonetic Distance via PanPhon

Standard edit distance treats all phoneme substitutions equally, but pronunciation errors often involve phonetically similar sounds. A learner who

produces /t/ instead of /θ/ (dental fricative simplification, common among many L1 backgrounds) has made a smaller error than one who substitutes /m/ for /θ/. PanPhon (Mortensen et al., 2016) captures this by representing each phoneme as a 24-dimensional binary vector encoding articulatory features (place, manner, voicing, nasality, and others). The substitution cost between two phonemes is their Hamming distance in this feature space. This representation provides implicit severity weighting: substitutions between acoustically similar phones incur lower costs than those between dissimilar phones.

All feature weights are fixed based on phonological theory and are not tuned on evaluation data. This avoids overfitting and ensures that the method generalizes across datasets without adaptation.

3.4 Word-Level Mispronunciation Detection

After selecting the surface-faithful hypothesis h^* , we align it against the canonical prompt (the text the learner was asked to read) using word-level edit distance. Any word that is substituted, deleted, or inserted relative to the prompt is flagged as a detected mispronunciation. This alignment-based approach requires no additional thresholds or classifiers.

4 Experimental Setup

4.1 Datasets

We evaluate on two L2 English corpora that differ in speaker demographics and annotation style.

L2-ARCTIC (Zhao et al., 2018) contains 26,867 read-speech utterances from 24 adult L2 English speakers across six L1 backgrounds (Arabic, Chinese, Hindi, Korean, Spanish, and Vietnamese). Each utterance has manual phoneme-level annotations marking substitutions, deletions, and insertions. We derive word-level mispronunciation labels by marking any word containing at least one phone-level error. Following the annotation guidelines, we categorize errors by severity: *severe* errors affect intelligibility (e.g., vowel substitution /t/→/i/ in “ship” heard as “sheep”, or consonant deletion making a word unrecognizable), *moderate* errors have uncertain impact on comprehension, and *acceptable* variations are accent features that do not impair intelligibility (e.g., dental fricative simplification /θ/→/t/).

Speechocean762 (SO762) (Zhang et al., 2021) contains 5,000 utterances from Mandarin L1 speakers including children (under 13), teenagers (13–17), and adults (18 and older), with word-level and phone-level accuracy scores on a 0–2 scale. We derive mispronunciation labels from phone-level scores: a word is mispronounced if any of its phones has accuracy below 2.0. For severity analysis, we distinguish *severe* errors (minimum phone accuracy < 1.0 , indicating a phone produced so incorrectly that it is not recognizable as the target) from *moderate* errors ($1.0 \leq$ minimum accuracy < 2.0 , indicating a noticeable but identifiable deviation). We report main results on the SO762 test split (samples 2500–4999, $n=2,497$ utterances) for direct comparability with GOPT (Gong et al., 2022), which was trained on the SO762 training split. The full 5,000-utterance set is used only in the WER–FAR correlation analysis of §5.2 where it is explicitly disclaimed.

4.2 ASR Systems and Baselines

Our primary ASR system is NVIDIA Parakeet, a FastConformer-based hybrid CTC-RNNT model (Majumdar and Koluguri, 2024), from which we extract $K=10$ N-best hypotheses. As a second system, we use Whisper large-v2 (Radford et al., 2023) via faster-whisper (SYSTRAN, 2023), also with $K=10$ hypotheses from beam search. Testing on two architecturally different systems (Parakeet uses hybrid CTC-RNNT decoding while Whisper uses autoregressive decoding with a stronger internal language model) lets us examine how architectural choices affect both intent bias and the potential for reranking.

The phoneme recognizer is wav2vec2-lv-60-espeak-cv-ft, a multilingual CTC-based model fine-tuned on Common Voice (Baevski et al., 2020). Its language-model-free decoding produces phoneme sequences that reflect acoustic content without linguistic correction.

Our method treats the ASR system as a black box. In other words, only the N-best text hypotheses and their ranks are used, and no internal scores, alignments, or posteriors are used for reranking.

To examine how overcorrection varies with ASR accuracy, we additionally evaluate Whisper tiny, base, small, and medium (39M to 769M parameters), wav2vec2-base-960h and wav2vec2-large-960h (Baevski et al., 2020), both CTC-only models without any language model component. This gives us eight systems spanning three architectures: au-

toregressive (Whisper family), hybrid CTC-RNNT (Parakeet), and CTC-only (wav2vec2).

We compare against: (1) ASR top-1 baselines across all systems; (2) Kaldi-based GOP (Witt and Young, 2000), which requires white-box access to acoustic model posteriors; (3) GOPT (Gong et al., 2022), a transformer trained on SO762 for pronunciation scoring; (4) word-level ASR confidence thresholding, which flags low-confidence words as mispronounced (oracle threshold); and (5) direct phoneme comparison, which bypasses ASR entirely and compares G2P of canonical text against phoneme recognizer output using PanPhon distance (oracle threshold).

4.3 Evaluation Metrics

We report two complementary metrics following Li et al. (2017). *False Acceptance Rate* (FAR) measures overcorrection, which represents the proportion of mispronounced words that the system incorrectly accepts as correct. High FAR means learner errors go undetected. *False Rejection Rate* (FRR) measures false alarms, and it represents the proportion of correctly pronounced words incorrectly flagged as errors. High FRR annoys learners by providing misleading feedback. All metrics use word-level aggregation across the full evaluation set. Statistical significance is assessed using McNemar’s test, and confidence intervals are obtained via bootstrap resampling (10,000 iterations).

5 Results

5.1 Main Results

Table 1 presents the main results across both datasets. The top-1 hypothesis exhibits high FAR on both: 80.8% on L2-ARCTIC severe and 70.6% on SO762 test. Note also the inverse trend within the SO762 column: stronger language models (Whisper large-v2, Parakeet) yield lower WER but higher FAR, foreshadowing the architecture-level correlation in §5.2.

Surface-faithful reranking reduces Parakeet’s FAR by 6.0pp on L2-ARCTIC severe and 5.6pp on SO762 test ($p < 0.001$ for both), at a modest FRR cost (1.7pp and 3.9pp). Residual FAR remains high (74.8% on L2-ARCTIC severe), indicating reranking is one component of a complete CAPT pipeline rather than a standalone solution.

To contextualize this gain, we examined paired word-level decisions on SO762 test. For every word that reranking newly accepts as correct, it

Table 1: Mispronunciation detection results (%). L2-ARCTIC: severe errors ($n_{\text{misp}}=4,183$); SO762 test: $n_{\text{utt}}=2,497$, $n_{\text{misp}}=6,066$. Top-1 WER varies inversely with FAR across architectures, consistent with intent bias (§5.2). *Kaldi GOP requires white-box AM access; no transcription, so WER not applicable. †GOPT was trained on the SO762 train split. ‡Oracle thresholds. + *Ours* = surface-faithful reranking via PanPhon distance. Dashes indicate not evaluated on that dataset.

Parakeet Top-1	8.0	80.8	5.9	19.2	70.6	8.4
Parakeet + Ours	11.8	74.8	7.6	24.9	65.0	12.3

correctly rejects 3.7 previously accepted mispronunciations (Fixed:Hurt = 3.66:1, McNemar exact OR = 3.66, 95% CI [3.01, 4.49], $p < 0.001$). Detection recall rises from 29.4% to 35.0%, a 19% relative increase that closes about 41% of the $K=10$ oracle gap ($5.6 / (70.6 - 56.9)$).

The cluster-bootstrap 95% CI for ΔFAR , resampling by utterance over 10,000 iterations, is $[-6.4, -4.9]$ on SO762 test, compared with $[-6.8, -5.0]$ on L2-ARCTIC severe. The trade-off is asymmetric: each percentage point of FAR reduction comes at roughly 0.7pp of FRR increase, concentrated in short function words (§6.6). Whisper shows a smaller 1.8pp improvement on both datasets, likely due to limited N-best diversity (§6.3).

On L2-ARCTIC, GOP achieves low FAR (20.4%) but extremely high FRR (74.8%), flagging three out of four correctly pronounced words as errors. For CAPT, persistent false alarms would erode learner trust and motivation (Neri et al., 2002). GOP also requires white-box access to acoustic model internals and frame-level forced alignment, which makes it incompatible with modern API-based ASR services. Our method offers the opposite profile within the black-box paradigm, moderate FAR with low FRR.

5.2 Overcorrection Scales with ASR Accuracy

To examine whether overcorrection is a general property of ASR optimization, we measured WER and FAR for eight systems spanning three architectures on the full SO762 set (Figure 2; num-

Figure 2: WER vs. overcorrection rate (FAR) on the full SO762 set ($n_{\text{misp}} \approx 12,235$) across eight ASR systems spanning three architectures. Computed on the full set for correlation power; the test-split subset yields the same direction with wider CI. Lower WER correlates strongly with higher overcorrection ($r=-0.99$, $p<0.001$).

bers in this subsection use the full set for correlation power, in contrast to the test-only Table 1). We found a very strong trend between WER and FAR ($r=-0.99$ ($p<0.001$), Spearman $\rho=-1.00$ ($p<0.001$)). Wav2vec2-base-960h, a CTC-only model with no language model, has the highest WER (50.0%) but the lowest FAR (40.1%), making many transcription errors but rarely masking mispronunciations. Whisper large-v2, with its strong autoregressive decoder, achieves the lowest WER (17.7%) but the highest FAR (72.1%). Parakeet (hybrid CTC-RNNT, WER 20.3%, FAR 68.6%) and four smaller Whisper variants (tiny, base, small, medium) fall in between.

The trend holds across all three architecture families. Even within the CTC-only pair, the larger wav2vec2 model achieves lower WER (46.4% vs. 50.0%) but higher FAR (43.6% vs. 40.1%), consistent with the overall pattern. This suggests that overcorrection is not driven solely by explicit language models. Model capacity itself may contribute through implicit linguistic biases learned from large-scale training data. For CAPT, the practical implication is that better ASR as measured by WER may produce worse pronunciation feedback regardless of architecture.

5.3 Direct Phoneme Comparison

We also examined whether the phoneme recognizer alone, without ASR, can perform mispronunciation detection. We compared G2P-converted canonical text directly against the phoneme recognizer output using PanPhon distance, sweeping the detection threshold to find the oracle operating point. At the best threshold, this baseline achieves FAR of 15.8% but FRR of 67.4% (Table 1). This means that the system catches most mispronunciations but flags two-thirds of correctly pronounced words as errors. Because the phoneme recognizer has a $\sim 15\%$ error rate on L2 speech, it is too noisy for word-level detection on its own. Our method combines both signals: ASR provides word-level candidates and the phoneme recognizer selects among them.

5.4 Severity-Stratified Analysis

Tables 2–4 present detailed analyses for Parakeet, which shows the larger reranking gain; Whisper’s limited N-best diversity (§6.3) produces smaller improvements that do not yield informative subgroup patterns. Table 2 shows the results broken down by error severity on both datasets. On L2-ARCTIC, the improvement scales with severity. The differences were 3.1pp for acceptable-level variations, 4.3pp for moderate errors, and 6pp for severe errors. The high residual FAR on acceptable variations (92.9%) is expected and arguably desirable, since accent features like dental fricative simplification do not impair intelligibility and need not be flagged in most educational contexts.

On SO762, a different pattern emerges. Severe errors (phone accuracy below 1.0) have a much lower baseline FAR (21.5%) than moderate errors (81.9%). Pronunciations that are very different from any recognizable phone are so acoustically distinct that even a strong language model cannot map them back to the intended word. Moderate

Table 2: FAR (%) by error severity (Parakeet). L2-ARCTIC categories follow annotation guidelines; SO762 categories are based on minimum phone accuracy scores.

	L2-ARCTIC		
	Accept.	Moderate	Severe
Baseline	96.0	88.4	80.8
Ours	92.9	84.1	74.8
Δ	−3.1	−4.3	−6.0

	SO762	
	Moderate	Severe
Baseline	81.9	21.5
Ours	76.7	19.0
Δ	−5.2	−2.4

errors, by contrast, are subtle enough for the language model to override the acoustic evidence and produce the canonical word. This suggests that intent bias may be most problematic precisely for the errors that are hardest to detect by other means.

5.5 Learner Demographics: Age Groups

Table 3 presents results stratified by speaker age on the SO762 test split ($n=2,497$ utterances). Children show the largest FAR reduction (6.8pp), followed by teens (5.1pp) and adults (5.0pp). This pattern may reflect greater acoustic variability in younger speakers’ speech, where the language model’s intent-oriented bias is most pronounced. The consistency of improvement across all age groups is relevant for educational deployment, where CAPT systems must serve diverse learner populations without per-demographic tuning. FRR rises by 3.8–4.8pp across strata; the modest cost is within bootstrap CI overlap and consistent with the overall trade-off in Table 1.

Table 3: FAR / FRR (%) by speaker age on SO762 test (Parakeet, $n=2,497$). *Ours* cells show the reranked value with Δ vs. Base.

Age	n	FAR (%)		FRR (%)	
		Base	Ours (Δ)	Base	Ours (Δ)
Child	1,039	67.3	60.5 (−6.8)	11.1	14.9 (+3.9)
Teen	240	84.4	79.3 (−5.1)	7.2	12.0 (+4.8)
Adult	1,218	70.6	65.6 (−5.0)	6.9	10.7 (+3.8)
All	2,497	70.6	65.0 (−5.6)	8.4	12.3 (+3.9)

5.6 L1 Background Generalization

Table 4 shows that the method improves detection across all six L1 backgrounds in L2-ARCTIC,

with FAR reductions ranging from 3.8pp to 4.9pp. Korean and Vietnamese speakers show the largest and smallest baseline FAR respectively (96.0% vs. 81.5%), possibly reflecting differences in how well the ASR language model can normalize each L1’s characteristic error patterns. FRR rises by 1.1–3.1pp across L1 strata; Vietnamese has the smallest FRR cost (1.1pp), Chinese the largest (3.1pp). The absence of any L1 group showing degradation suggests that the method’s reliance on universal articulatory features, rather than L1-specific error models, provides robust cross-linguistic generalization.

Table 4: L1 generalization on L2-ARCTIC (Parakeet, all severity levels). *Ours* cells show the reranked value with Δ vs. Base.

L1	n_{misp}	FAR (%)		FRR (%)	
		Base	Ours (Δ)	Base	Ours (Δ)
Arabic	1,406	89.9	85.5 (−4.4)	5.1	7.7 (+2.6)
Chinese	2,250	91.0	87.2 (−3.8)	5.9	8.9 (+3.1)
Hindi	1,984	95.6	91.3 (−4.2)	3.1	5.5 (+2.4)
Korean	1,236	96.0	91.2 (−4.9)	3.1	6.2 (+3.0)
Spanish	2,451	90.8	86.4 (−4.4)	5.3	8.1 (+2.9)
Vietnamese	4,138	81.5	76.9 (−4.6)	4.0	5.1 (+1.1)

5.7 Reranking Strategy Comparison

Table 5 compares alternative reranking strategies on L2-ARCTIC. PanPhon and the *phoneme-recognizer log-posterior* (PR Log-Posterior) use the same phoneme recognizer in different ways: PanPhon measures the articulatory distance between the hypothesis IPA and the recognizer’s argmax phone sequence, while PR Log-Posterior scores the hypothesis IPA against the recognizer’s frame-wise posterior using a proportional frame alignment. Neither signal is Parakeet’s ASR decoder score, and PR Log-Posterior is not a conventional acoustic-model likelihood. On L2-ARCTIC severe errors, the two signals achieve comparable FAR (74.6 vs. 74.8), but PR Log-Posterior incurs substantially higher FRR (10.5 vs. 7.6) and WER (15.6 vs. 11.8). On SO762 test, PR Log-Posterior wins on FAR (McNemar exact OR = 0.78, 95% CI [0.68, 0.90], $p < 0.001$), but PanPhon remains better on FRR and WER (12.3 vs. 15.9 FRR; 24.9 vs. 28.3 WER). We adopt PanPhon because its CAPT trade-off is more favorable, it avoids the proportional frame alignment that PR Log-Posterior depends on, and its failure modes are more transparent through the surface-anchor audit (§6.2). PanPhon is therefore a Pareto-efficient operating point

on the WER and FRR axes.

Replacing PanPhon with unweighted Levenshtein edit distance on the same IPA sequences yields 2.9pp less FAR reduction (77.7% vs. 74.8%), confirming that articulatory feature weighting meaningfully contributes to the reranking quality. Equal-weight combination of ASR and phoneme scores yields intermediate results. The WER Oracle row shows what happens when the hypothesis closest to the canonical text is selected as an output (i.e., optimized with WER). FAR *increases* to 86.1%, indicating that optimizing for conventional ASR accuracy works against mispronunciation detection. The MDD Oracle shows the best achievable FAR from the N-best list (56.9%), representing the ceiling imposed by beam search pruning.

Table 5: Reranking strategies on L2-ARCTIC severe errors (Parakeet, $n=4,183$). PR Log-Posterior scores each hypothesis under the phoneme recognizer’s posterior, not an ASR decoder likelihood (see §5.7).

Method	WER	FAR	FRR
WER Oracle	5.1	86.1	2.7
ASR Top-1	8.0	80.8	5.9
Levenshtein	9.5	77.7	6.3
Equal Weight	10.1	76.3	6.4
PanPhon (Ours)	11.8	74.8	7.6
Log-Likelihood	15.6	74.6	10.5
MDD Oracle	13.8	56.9	5.4

5.8 N-best List Size

Increasing K from 1 to 5 reduces FAR by 3.6pp (80.8%→77.2%), and extending to $K=10$ provides an additional 2.4pp improvement (77.2%→74.8%), with FRR rising modestly from 5.9% to 7.6%. We use $K=10$ throughout as a practical trade-off.

6 Analysis and Discussion

6.1 Quantifying Intent Bias

To understand the relationship between ASR confidence and overcorrection, we examined how overcorrection rates vary across N-best ranks on SO762 (Table 6). Rank 1, the hypothesis the system is most confident about, has the highest overcorrection rate (69.4%), with the rate decreasing at lower ranks. This is consistent with language model’s preference for canonical forms being strongest at the top of the N-best list, and suggests that surface-faithful alternatives exist at lower ranks but are systematically suppressed.

This finding also explains why word-level confidence thresholding (i.e., flagging low-confidence

Table 6: Overcorrection by N-best rank on SO762 (Parakeet). % Utts = utterances with at least one overcorrection.

Rank	Overcorrection	% Utts
1 (highest)	69.4%	82.0%
3	62.5%	78.3%
10 (lowest)	59.0%	74.7%

words as mispronounced) is not an effective detection strategy. At its oracle operating point on SO762, confidence thresholding achieves only 50.4% FAR with 35.0% FRR (Table 1), which is worse than all other methods. Confidence reflects the language model’s certainty about the *intended* word, not the acoustic fidelity of the transcription.

6.2 Reliability of the Surface Anchor

Our reranker selects the hypothesis whose IPA transcription is closest to a fixed reference: the G2P transcription of the prompt, which we call the *surface anchor*. We write $d_{\text{canonical}}$ for the PanPhon distance from a candidate hypothesis to this anchor. If the anchor itself disagrees with what a correctly-pronouncing learner produces, the reranker has nothing to recover from, and the residual FRR in Table 1 reflects anchor noise rather than reranker error. We test this directly.

We isolate anchor noise on L2-ARCTIC utterances annotated as fully correct ($n=1,083$), where the canonical anchor should agree with the phoneme-recognizer output. Even in this no-error stratum, the median normalized PanPhon distance between anchor and recognizer is 0.52 (IQR=0.49), nearly matching the error-bearing stratum’s median of 0.57. The anchor is therefore systematically noisy across utterances, not selectively noisy for mispronounced speech.

Two stratifications show that this noise propagates into false rejection. First, word-level FRR scales monotonically with anchor distance: from 3.2% in the lowest $d_{\text{canonical}}$ quartile to 11.7% in the highest. Second, comparing utterances by whether their top-1 hypothesis contains an inserted word, the reranker’s helped-to-hurt ratio — newly correct accepts versus newly incorrect rejects — drops from 4.7:1 without insertions to 1.5:1 with insertions (Fisher exact OR=3.04, 95% CI [1.70, 5.46], $p < 0.001$). We therefore suggest single-pronunciation G2P as a measured limitation, and motivate multi-pronunciation lattices as the principled remedy (§6.5).

6.3 ASR Architecture and N-best Diversity

Whisper and Parakeet achieve similar baseline FAR on L2-ARCTIC (82.7% vs. 80.8%), yet Parakeet benefits substantially more from reranking (Table 1). The explanation lies in N-best diversity. Parakeet’s hybrid decoding produces an average of 10 unique hypotheses per utterance, while Whisper’s stronger autoregressive language model constrains beam search to only 4.6 unique hypotheses. In 82.7% of Whisper utterances, the top-1 hypothesis is already the closest to the oracle, leaving little room for reranking to improve. For CAPT applications, this suggests that ASR systems with weaker language models may be preferable when paired with surface-faithful reranking, since they preserve more diverse candidates.

Increasing candidate diversity through generic Whisper decoding does not close this gap: doubling the beam to $K=20$ raises Whisper’s unique-hypotheses-per-utterance only from 2.8 to 4.3 and yields a reranked FAR improvement of just 1.4pp on SO762 test, capturing only 30% of the oracle headroom (4.6pp). The added candidates are mostly linguistic variants rather than acoustically faithful alternatives. The bottleneck is candidate generation under an intent-oriented decoder, not search width; pronunciation-aware decoding (§6.5) is the principled extension.

6.4 Deployment and Educational Implications

An alternative to reranking would be to use a CTC-only model without a language model, which exhibits lower overcorrection (Figure 2). However, such models produce transcripts with 46–50% word error rate, making them unsuitable for learner display. Our approach preserves the benefits of a strong ASR system while mitigating its overcorrection: a single ASR pass produces two outputs, where the top-1 hypothesis provides a readable transcript for display while the reranked hypothesis drives mispronunciation detection internally. Reranking adds negligible compute beyond N-best extraction.

The FAR/FRR distinction maps onto two failure modes in pronunciation feedback: high FAR leaves errors undetected, while high FRR frustrates learners with false alarms (Neri et al., 2002). Our method’s profile—lower FAR with a modest FRR rise—is best suited to intermediate and advanced learners; the age-group results (Table 3) suggest particular benefit for younger learners.

Table 7: Examples from L2-ARCTIC. The top-1 hypothesis corrects the learner’s pronunciation and the reranked hypothesis preserves the surface form.

Type	Top-1 (intent)	Reranked (surface)
Omission	... she is coming...	... she coming...
Subst.	... previous wives...	... previous wise...
Acoustic	... was stream- ing ...	... were trimming...

6.5 Future Work

WER alone is insufficient for evaluating ASR in CAPT (Figure 2); we suggest the *Pronunciation Preservation Rate* ($PPR = 1 - FAR$) as a complementary metric (range 25.8%–59.0% on SO762 test). Four directions remain open. (i) **Multi-pronunciation lattices** replacing the single canonical G2P, motivated by the surface-anchor audit (§6.2) showing $3.7\times$ higher FR rate in the top $d_{\text{canonical}}$ quartile—a likely route to reducing the dominant FRR cost. (ii) **Latency-aware two-pass diagnosis**, running a wider diagnostic beam ($K=100\text{--}200$) alongside the display ASR; better offline detection at the cost of user-facing latency. (iii) **Pronunciation-aware decoding** objectives that balance LM probability against acoustic faithfulness, motivated by the §6.3 finding that wider beams ($K=20$) do not recover surface forms. (iv) **Learning-outcome user studies** to verify that the 5.6pp absolute / 19% relative recall gain translates to learning benefit.

6.6 Qualitative Examples

Table 7 illustrates three common patterns where the top-1 hypothesis masks a pronunciation error that the reranked hypothesis exposes. In the first example, the learner omits the verb, a common pattern for speakers whose L1 lacks obligatory verb marking. Here, the ASR inserts “is” because it is grammatically expected. In the second, the learner produces a word closer to “wise” than “wives,” but the language model selects the contextually appropriate word. A more complex case appears in the third example, where multiple phonetic confusions lead to a substantially different surface form.

The method can also introduce errors. The 1.7–3.0pp FRR increase (Table 1) occurs when the phoneme recognizer output happens to be closer to an incorrect hypothesis than to the canonical text, and it often happens for short function words (e.g., “a,” “the”) where phoneme sequences are

too brief for PanPhon distance to discriminate reliably. These false alarms are concentrated in high-frequency, low-information words that are less relevant for pronunciation feedback.

7 Conclusion

The results of the present study suggest that WER alone is insufficient for evaluating ASR systems intended for pronunciation training. Across eight systems spanning three architectures, lower WER consistently predicts higher overcorrection of mispronunciations. We propose Pronunciation Preservation Rate as a complementary metric that captures how well an ASR system preserves learner errors in its output.

Surface-faithful reranking provides a practical mitigation. By selecting N-best hypotheses that are phonetically closer to what was actually pronounced, the method reduces false acceptance of mispronunciations by 6.0 and 5.6pp on two datasets, across diverse age groups and L1 backgrounds, without retraining or access to ASR internals.

The method’s ceiling is bounded by beam-search pruning, and direct phoneme comparison alone produces too many false alarms; pronunciation-aware decoding (§6.5) is the principled extension.

Limitations

Several limitations remain. (1) Residual FAR is high (74.8% on L2-ARCTIC severe), and the $K=10$ oracle ceiling (56.9%) shows the N-best list lacks surface-faithful hypotheses for many utterances—a beam-search limitation. (2) We evaluate on read speech with known prompts; spontaneous L2 speech would require a different alignment formulation. (3) Our evaluation is limited to L2 English, and the G2P component is language-specific. (4) The phoneme recognizer has a 19.2% error rate on L2-ARCTIC (15.0%–24.5% across L1s), which propagates into reranking. (5) The single-canonical-G2P anchor is an approximation: §6.2 shows it disagrees with the recognizer on correctly-pronounced words and predicts false rejection; multi-pronunciation lattices (§6.5) are the principled fix. (6) We have not conducted user studies; the 5.6pp absolute / 19% relative recall gain is a necessary but not sufficient indicator of learning benefit.

Abstract

We investigate the predictive power of keystroke logging data for automated essay scoring using the newly collected PISA FLA writing process dataset. Based on 3,882 writing sessions, we extract a comprehensive set of keystroke-based process features, including temporal measures, pause and burst patterns, deletion behavior, production efficiency, and navigation activity and evaluate their ability to predict holistic essay scores on a 0–5 scale. We specifically compare process-feature-based models with content-based scoring approaches trained on data written with and without the help of an AI chatbot, and investigate how predictive power evolves over the course of a writing session by training models at multiple time thresholds. Our analysis reveals that keystroke features provide genuine early predictive signal, capturing aspects of writing fluency and revision behavior that distinguish writers before their texts are long enough to score conventionally. Additionally, our results suggest that process-based scoring is a viable complement to product-based approaches, with promise for formative, real-time feedback during writing.

1 Introduction

Feedback is most effective when it is timely and targets the writing process rather than only the finished product (Hattie and Timperley, 2007; Graham et al., 2015; Shute, 2008). However, much of the traditional automated assessment literature focuses on evaluating completed texts and their summative outcomes rather than providing in-process feedback (Cotos, 2015).

One way to achieve such feedback is by constant monitoring of the writing process, which is often hindered by a lack of suitable writing process data. To address this research gap, we present a new dataset PISA FLA, consisting of almost 4000 English-as-a-foreign-language essay writing sessions from German participants in the 2025 PISA

data collection. In this dataset, students responded to two individual argumentative writing prompts and produced texts under two conditions: with and without the assistance of a generative AI chatbot (hereafter referred to as *Chat* and *NoChat*, respectively). This dataset thus offers ample opportunities to investigate both how students write and how essays can be automatically scored already during the writing process.

We investigate the latter question in three different setups: By means of traditional transformer-based essay scoring models, through keylog-based process features and by combining the two approaches. We further address the question of how early on (within the 30 minutes of a single writing session) reliable summative feedback can be given, i.e. feedback with an accuracy similar to that of a model trained on full texts. We achieve this by comparing performance at certain points in time of the writing session. Finally, we investigate the influence of chatbot support on automated scoring.

In doing so, our paper makes the following contributions:

- We present a new dataset of EFL essays together with detailed keylog information making the writing process transparent.
- We show that reliable automated feedback does not require a complete text, but that there is a tradeoff between essay scoring performance and writing time.
- We show that integrating process features into a transformer-based model improves prediction at early writing stages.

The data is available by request until September 2027 after which it will be openly published: https://github.com/darius-ipn/keystroke_pisa2025_fla.

<i>Disagree:</i> – more important that the students learn sth about the subject – the teacher doesnt have to be in a good relationship with the students, the teacher only has to be polite – the students dont learn anything if the teacher is polite
After 10 minutes
<i>Disagree:</i> – more important that the students learn sth about the subject – the teacher doesnt have to be in a good relationship with the students, the teacher only has to be polite – the students dont learn anything if the teacher is polite but doesnt know sth about the topic <i>Argumentation:</i> Today we are talking about the question if a teacher's ability to relate well with students is more important than excellent knowledge of the subject being taught.

Figure 1: Writing snapshots from a single participant. After 5 minutes, the student has only produced planning notes in bullet-point form. By 10 minutes, an introductory sentence has been added, illustrating the transition from planning to text production.

2 Related Work

Our work builds on two lines of research: keystroke logging as a window into writing processes, and automated essay scoring. We review relevant work in each area before describing how our approach connects them.

2.1 Writing Process Research and Keystroke Logging

Writing research has long established that composing involves planning, producing text, and revising, and that writers switch between these processes rather than completing them in a fixed order (Flower and Hayes, 1981). Later models distinguish between the cognitive effort of formulating ideas and typing them out (Hayes, 2012). Keystroke logging offers a way to observe these processes (Leijten and Van Waes, 2013).

Recent work has demonstrated that providing students with keystroke-based feedback on their writing process can improve text quality (Vandermeulen et al., 2020). Allen et al. (2016) showed that keystroke indices, particularly total number of keystrokes, explain a large proportion ($R^2 = .76$)

of variance in essay scores for L1 English undergraduates writing in an intelligent tutoring system. However, Conijn et al. (2022) investigated which keystroke features are useful for predicting writing quality during the writing process but found the relationship to be limited. They did show that feature importance shifts over the course of writing, an observation our work further addresses at larger scale and with complementary text-based models.

Several keystroke corpora with quality ratings have recently become available, including KLiCKe by Tian et al. (2025) with $\sim 5,000$ argumentative essays from L1/L2 adults and KUPA-KEYS by Velentzas et al. (2024) with 1,006 EFL essays graded on the CEFR scale. Our dataset complements these resources by focusing on adolescent EFL learners in a standardised assessment context and by including an AI-assisted writing condition.

2.2 Automatic Essay Scoring

Recent work on automated essay scoring has moved toward transformer-based architectures (Li and Ng, 2024). DeBERTa has shown strong performance in this context, outperforming BERT and RoBERTa on the ASAP dataset (Susanto et al., 2024) and serving as the model of choice in top entries of the Kaggle Automated Essay Scoring 2.0 competition, where winning solutions used ensembles of DeBERTa-v3-large with two-staged training (Learning Agency Lab, 2024). Based on these results, we adopt DeBERTa-v3-base as the text encoder in our experiments.

However, many transformer-based AES systems rely solely on the learned text representation for scoring. Uto et al. (2020) demonstrated that concatenating essay-level features (e.g., readability indices, syntactic counts) with a transformer’s [CLS] representation before the scoring layer yields consistent gains, with minimal additional parameters. Building on this, Lohmann et al. (2025) systematically compared feature-based, embedding-based, and hybrid models for analytic trait scoring on argumentative essays from both L1 and L2 learners, including essays from the MEWS corpus (Keller et al., 2020) that shares our writing prompts. Their hybrid architecture, combining 220 linguistic features with DistilBERT embeddings, consistently outperformed the feature-only and embedding-only models, with the largest gains for content and organization assessment.

Additionally, they showed that linguistic features and contextual embeddings capture partially differ-

ent aspects of text quality, supporting architectures that combine both sources. More broadly, [Li and Ng \(2024\)](#) argue that AES research should move beyond optimizing scores on standard benchmarks toward new task settings and formative applications — a direction our work pursues by evaluating scoring across writing time thresholds.

Our work extends this line of research in two directions. To our knowledge, no prior work has integrated keystroke process features directly into a transformer’s prediction architecture.

First, we replace the linguistic feature vector with keystroke process features, testing whether signals from the writing process can complement a transformer’s text representation in the same way that linguistic features do. Second, we evaluate this combined model not only on completed essays but across multiple time thresholds during writing, addressing the question of how early in the writing process reliable scoring becomes feasible.

3 Data

In the following we present the PISA 2025 FLA dataset used in our experiments. The dataset was collected in the 2025 PISA assessment as an additional task for foreign language assessment in German High schools on students at the age of 15. It comprises initially 4,091 writing sessions, in which students responded to argumentative writing prompts in English as a foreign language. Students were assigned to one out of two groups: Those that had access to an AI chatbot for writing support and those without. The chatbot could be used unconditional for all kinds of prompts. The underlying model was gpt-4o-mini. After data cleaning (see Section 3.1) we are left with 3,882 essays, which are distributed roughly evenly across the two conditions, as displayed in Table 1. The two conditions differ substantially in writing outcomes. Students with chat access produced considerably longer texts (1,813 vs. 1,138 characters on average; 274 vs. 200 words) and received higher holistic scores (mean 3.2 vs. 2.1 on a 0–5 scale), with 20.2% of chat-assisted essays reaching the maximum score of 5 compared to just 2.4% without chat. Notably, chat-assisted students achieved these longer, higher-scored texts with fewer keystrokes (1,666 vs. 1,951), suggesting substantial use of copy-pasting from the chatbot. The writing was limited to 30 minutes for all conditions although the majority stopped at approximately 25 minutes.

	<i>NoChat</i>	<i>Chat</i>
N (scored)	1,911	1,971
Avg. text length (chars)	1,138	1,813
Avg. text length (words)	200	274
Avg. sentences	8.9	14.0
Score (mean)	2.1	3.2
Score (median)	2.2	3.2
% scoring 5	2.4	20.2
Avg. writing time (min)	24.7	25.2
Avg. active writing ratio	0.5	0.4
Avg. keystrokes	1,951	1,666

Table 1: Descriptive statistics by condition. Scores are on a 0–5 holistic scale. Active writing ratio is 1 minus the proportion of break time (pauses ≥ 2 s) relative to total session time.

The active writing ratio was slightly higher for *NoChat* (0.5 vs. 0.4), consistent with *Chat* students spending time interacting with the chatbot interface rather than typing continuously.

3.1 Data Cleanup

To ensure data quality, we applied two filtering criteria: (1) submissions with fewer than 10 characters were excluded as empty or trivial responses, and (2) submissions exceeding 10,000 characters (above the 99th percentile) were excluded as they reflected excessive copy-pasting behaviour rather than authentic writing processes.

Of the initial $N = 4,091$ submissions, 130 were excluded for insufficient length and 35 for excessive length, resulting in a sample of $N = 3,926$ (96.0% retention). Of these, 3,882 had valid holistic scores and are the final analytical sample.

3.2 Keystroke Measures

Keystrokes and texts were collected within a self-developed web interface. From each writing session we extract 25 process features covering six behavioural dimensions. **Temporal measures** capture total writing time (first to last keystroke) and initial pause (time from task start to first keystroke). **Pause and break patterns** characterize interruptions in typing: we count all pauses $\geq 2,000$ ms as breaks and derive their total duration, mean duration, and the ratio of break time to total writing time. **Burst characteristics** describe the production sequences between breaks or revisions, including burst count, mean burst length (in characters), and mean burst duration. **Deletion behaviour** is captured through the total number of delete/backspace keystrokes, the deletion ratio (deletions / total keystrokes) and total characters deleted. **Produc-**

tion efficiency includes final text length (characters and words), characters per minute (relative to active writing time), total keystrokes, and the process-to-product ratio (total characters typed / final text length), which indicates how much text was produced and subsequently removed. Finally, **navigation activity** is measured through copy-paste count, a linearity index reflecting the proportion of forward cursor transitions (1 = fully sequential writing), and area switches between interface regions. For sessions in the *Chat* condition, we additionally capture time allocation across four interface areas (text editor, task text, chat window, chat prompt) and the number of area switches; these features are set to zero for NoChat. All features are z-score normalised within each time threshold (see Section 3.4), so that distributions reflect the writing stage rather than the completed essay. See also Appendix A, Table 7.

The features were selected to cover established behavioral dimensions in keystroke logging research such as temporal, pause, burst, deletion, production, and navigation measures. Note that the full dataset also tracks mouse movements and other non-keyboard events, which we partially integrate such as cursor reposition events, paste events, interface area switches, and time in chat/task/editor/no area.

3.3 Dataset Annotation

In the following we describe the automatic and manual annotation efforts to obtain the holistic scores used in our scoring experiments.

3.3.1 Creating a silver standard

For our current study, we were not able to obtain human annotations for the full dataset. As a proxy for a human gold standard, we employ an automated scoring model which has been trained on essays from the MEWS dataset, i.e., essays answering the same writing task but from a slightly different learner population.

Specifically, a linear regression model was trained on the MEWS dataset (Keller et al., 2020, 2024) to predict both holistic scores and individual trait scores. The model uses 220 linguistic features extracted in the same way as in Lohmann et al. (2025). These features capture various aspects of the text, including lexical variety, syntactic structure, cohesion, as well as error-, frequency- and length-based indicators. Before training, all features are scaled using a min-max scaler, and

multicollinearity is reduced by removing highly correlated features (correlation > 0.9).

This silver standard is only used as training material. All models in this study are evaluated against the smaller human-annotated test dataset described in the following, ensuring that reported results reflect agreement with human judgments.

3.3.2 Gold Standard Scores

To obtain a gold standard test set, we drew a stratified random sample from the corpus. Strata were defined by domain (Teacher vs. Advertisement), experimental condition (*Chat/NoChat*), and a quality profile constructed from tertile bins (Low / Medium / High) of silver-standard analytic scores for Content, Organization, and Language Quality, yielding up to 27 performance clusters per domain-condition cell. Allocation was proportional to population frequency with a minimum-count floor to retain rare profiles.

The final sample comprises 429 essays (212 *NoChat*, 217 *Chat*), each double-annotated by trained raters (Krippendorff’s $\alpha = .79$).

Four student annotators with a background in education were trained on the original MEWS scoring rubrics. Each essay was randomly assigned and annotated twice. Inter-annotator agreement reached a Krippendorff’s α of 0.79 (interval metric), indicating substantial agreement. Final gold scores were obtained by averaging.

These annotations were also used to validate the silver standard: We evaluated the automatic scoring model (trained on MEWS data) against the gold annotations and obtained a QWK of 0.76 between the automatically annotated silver standard and the human gold standard. This is comparable to the inter-annotator agreement, supporting the use of the silver labels as training signal.

The gold-annotated subset serves as the held-out test set in all experiments.

3.4 Time Threshold Splits on Test Set

One core research question we aim to answer is: How early in the writing process can we give meaningful feedback to learners? To this end, we reconstruct from the keylog data for each essay its state after 5, 10, 15, 20 and 25 minutes of writing time, reflecting planning notes, partial drafts, or incomplete revisions rather than a finished product (see Figure 1 for an illustration). A small number of writing sessions (1–2 per threshold) with no keystroke activity up to that time, i.e. still empty

texts, were excluded. Note that our goal is to judge the assumed quality of the finished essay early in the writing process. Therefore we do not collect new human judgements for these incomplete texts, but propagate the label from the full essay to all earlier stages of that essay.

4 Method

In the following, we describe first the different model infrastructures for scoring, then detail the shared experimental setup covering data splits, time thresholds, and evaluation.

4.1 Scoring Models

We approach in-process essay scoring through three complementary model families: (1) process-feature models that predict scores exclusively from keystroke behaviour, without access to the essay text; (2) transformer-based models that rely on the essay text; and (3) an architecture that combines both information sources. All models are trained and evaluated separately for *Chat* and *NoChat* and at six time thresholds throughout the 30-minute writing session, allowing us to trace how prediction quality evolves over the course of composition.

4.1.1 Process-Feature Baselines

To evaluate the predictive power of keystroke features independently of essay content, we train gradient-boosted regression trees (XGBoost) that operate exclusively on the process features described in Section 3.2. Each model is trained in one of three feature configurations: (1) *all* keystroke features, (2) *length only*, using only the text length in characters at the respective time threshold as a single predictor, and (3) *no length*, using all keystroke features except text length. This decomposition disentangles the contribution of text length, a known dominant predictor in automated essay scoring (Allen et al., 2016), from the behavioural signal captured by the remaining process features such as pause patterns, burst characteristics, and deletion behaviour. Hyperparameters are selected via grid search over the number of estimators (100, 200, 500), maximum tree depth (3, 5, 7), learning rate (0.01, 0.05, 0.1), and L1 regularisation strength (0, 0.1, 1.0), with subsampling rate and column sampling fixed at 0.8. The combination maximising QWK on the dev set is selected. We also trained ordinary least squares regression models in the same configurations; results are reported in Appendix A Table 6.

4.1.2 Text-Based Scoring with DeBERTa

We fine-tune DeBERTa-v3-base (He et al., 2021) with a single-output regression head predicting the holistic score on a continuous 0–5 scale. Input texts are tokenised with the model’s default tokeniser. Due to hardware restrictions it was necessary to truncate essays to a maximum of 512 tokens. In the training set, this led to truncation in 8.0% of texts, with truncated samples losing on average 24% of their tokens. At intermediate timepoints, truncation was less frequent, as texts were naturally shorter.

Training uses AdamW with a learning rate of 2×10^{-5} and a batch size of 8 for up to 10 epochs with early stopping.

We evaluate two training variants:

Full-text model. The model is trained exclusively on complete essays. At inference, it receives either the full essay or an intermediate text snapshot at a given time threshold. This reveals how well a model trained on finished writing generalises to incomplete drafts.

Hybrid model. The model is trained on the hybrid training set described in Section 4.2.1, which combines complete essays with intermediate snapshots, exposing the model to both complete and in-progress texts.

4.1.3 Combined Text and Process Features

Following Uto et al. (2020), who concatenated handcrafted linguistic features with a transformer’s text representation, we inject keystroke process features into the DeBERTa prediction head. We concatenate DeBERTa’s pooled text representation with a keystroke feature vector and train a joint regression head on both information sources simultaneously. Concretely, we obtain the pooled CLS representation from DeBERTa-v3-base, a 768-dimensional vector produced by the context pooler, which applies a learned linear projection and activation on top of the [CLS] token. This vector is concatenated with a 32-dimensional side vector composed of two parts: (1) the 25 z-scored keystroke process features described in Section 3.2, and (2) a 6-dimensional one-hot encoding of the source timepoint (*5 min*, *10 min*, *15 min*, *20 min*, *25 min*, *full*). The timepoint indicator is necessary because the keystroke features are z-score normalised *within* each time threshold. Without this signal, the model cannot distinguish between normalisation groups. Because z-score normalisation on small per-timepoint groups can produce

Score	NoChat			Chat		
	Train	Dev	Test	Train	Dev	Test
0.0	134	15	16	60	7	5
0.5	82	9	18	34	4	5
1.0	122	13	18	47	5	10
1.5	205	23	25	94	10	12
2.0	241	27	32	142	16	20
2.5	289	32	36	212	24	18
3.0	217	24	29	218	24	39
3.5	119	13	16	179	20	23
4.0	69	8	10	153	17	23
4.5	17	2	4	119	13	19
5.0	34	4	8	320	36	43
<i>N</i>	1,529	170	212	1,578	176	217

Table 2: Distribution of holistic scores (binned to nearest 0.5) across train/dev/test splits for both conditions.

extreme values, we clip all keystroke z-scores to the range $[-5, +5]$ before training. This prevents rare outliers from destabilising gradient updates, an issue we observed during initial experiments. The combined 800-dimensional vector ($768 + 32$) is passed through a two-layer feed-forward network ($800 \rightarrow 128 \rightarrow 1$) with GeLU activation and dropout ($p=0.1$), producing a continuous regression score. For ordinal metrics (QWK, macro F_1), predictions are clipped to $[0, 5]$ and rounded to the nearest 0.5, yielding 11 categories. The entire model is trained end-to-end with the same hyperparameters as the text-only DeBERTa model.

4.2 Experimental Setup

4.2.1 Data Splits

We use the 429 gold-annotated essays described in Section 3.3.2 as our fixed test set. The remaining data is split at a 90/10 ratio using stratified sampling on holistic scores binned to the nearest 0.5. Rare score bins with fewer than 2 instances are merged into their nearest neighbour before stratification. Table 2 shows the resulting distributions. Scores in the *NoChat* condition concentrate around 2.0–3.0, whereas the *Chat* condition is right-skewed, with the 5.0 bin alone accounting for roughly 20 % of sessions.

Hybrid training set. Following Schaller et al. (2025), we construct a hybrid training set by pairing each full essay with one randomly sampled intermediate snapshot (drawn uniformly from the five time thresholds), approximately doubling the training set from 3,107 to 6,199 instances (see Table 3). This exposes the model to both complete and in-progress texts, reducing its reliance on struc-

tural cues present only in finished essays.

4.2.2 Summary

All models are trained and evaluated at six time thresholds (5, 10, 15, 20, 25 minutes, and full essay). For the process-feature models, we train one XGBoost model per combination of condition (*Chat*, *NoChat*), feature configuration (*all*, *length only*, *no length*), and time threshold, yielding 36 combinations. For the text-based models, we evaluate three DeBERTa-v3-base variants: *full-text*, *hybrid* (Section 4.2.1), and *combined*. All predictions are clipped to $[0, 5]$ and rounded to the nearest 0.5 for QWK computation.

	NoChat	Chat	Total
Full texts	1,529	1,578	3,107
5 min	306 (20.0%)	329 (21.0%)	635
10 min	266 (17.4%)	315 (20.2%)	581
15 min	330 (21.6%)	310 (19.8%)	640
20 min	303 (19.8%)	294 (18.8%)	597
25 min	324 (21.2%)	315 (20.2%)	639
Hybrid total	3,058	3,141	6,199

Table 3: Distribution of training samples in the Hybrid training set. Each essay appears once as its full text and once as a randomly sampled intermediate snapshot.

5 Results

In the following, we first present results on the process-feature-based models, then the text-based transformers and finally the combined architecture.

5.1 Process-Feature-Based Scoring

Table 4 presents results for the three keylog-based feature configurations: all keystroke features (ALL), text length only (LEN), and all features except length (NOLEN), separately for the two experimental conditions (*NoChat*, *Chat*)

Unsurprisingly, prediction quality improves steadily over the course of the writing session, rising from QWK .32 at 5 minutes to .76 at completion for *NoChat* (all features), and from .59 to .91 for *Chat*. The steepest gains occur between 5 and 15 minutes, after which performance improvements level off, suggesting that the first half of the writing session already captures most of the predictive signal. The relative contribution of text length and behavioural process features shifts markedly over time. At 5 minutes, LEN alone is a weak predictor (QWK of .14 and .31), while NOLEN already achieve substantially higher performance (.38 and

.55). This pattern reverses later: by completion, length alone reaches .77 (*NoChat*) and .92 (*Chat*), matching the full feature set. This confirms the well-established role of text length as a dominant predictor in automated essay scoring (Allen et al., 2016) while demonstrating that its dominance only holds once sufficient text has been produced.

Notably, the NOLEN configuration performs competitively with ALL across both conditions, matching it at most time thresholds, with small fluctuations in either direction that likely reflect estimation noise given the test set size. This suggests that explicit text length is largely redundant given the remaining process features.

Model performance was consistently higher in the *Chat* condition, with QWK reaching .91 at completion compared to .76 *NoChat*. This likely reflects two compounding factors: *Chat*-assisted students produced longer, more content-rich texts earlier in the session, providing a stronger signal for scoring models, and the right-skewed score distribution — with 20.2% of essays at the maximum — may additionally increase class separability across all models. A more fine-grained analysis of individual AI usage strategies, including copy-paste behaviour and prompt intent, is left for future work. These results suggest that keystroke process features provide genuine early predictive signal, capturing aspects of typing fluency, planning behaviour, and revision activity that distinguish writers before their texts are long enough to score conventionally. Linear regression models trained in the same configurations showed comparable patterns at lower overall performance (see Appendix 6), suggesting that these findings are robust to model choice.

To further investigate which features drive prediction, Appendix A Table 8 reports Pearson correlations of each feature with text length and holistic score, separately by condition. Text length is the strongest predictor of score ($r = .73$ in both conditions). That the NOLEN XGBoost configuration matches or exceeds ALL at most time thresholds (Table 4) indicates, that the combination of features can match or exceed the length signal as a predictor of score. The correlation differs between conditions: `total_keystrokes` and `break_count` are positive predictors in *NoChat* but show near-zero or negative correlations in *Chat* ($r = -.01$ and $-.14$), likely because higher keystroke counts in *Chat* reflect chatbot interaction rather than productive writing. `initial_pause` is the most condition-stable

predictor ($r_{\text{score}} = -.19$ *NoChat*, $-.16$ *Chat*), indicating that students who begin writing sooner tend to score higher regardless of final text length.

	<i>NoChat</i>			<i>Chat</i>		
	All	Len.	NoLen.	All	Len.	NoLen.

Table 5: QWK by time threshold for FULL, HYBRID, and COMBI. DeBERTa models. Δ_H and Δ_C denote differences to FULL.

Full-text model. When trained exclusively on complete essays, DeBERTa achieves strong performance at full length (QWK of .86 and .95 for

the *NoChat* and *Chat* conditions, respectively), outperforming the best XGBoost keystroke-feature models (.77 and .92; Table 4). However, performance degrades sharply on incomplete drafts: at 5 minutes, QWK drops to .15 (*NoChat*) and .21 (*Chat*). This is expected: in the training data, a short, structurally incomplete text is often a weak finished essay, whereas in the test data it may be an early snapshot of an ultimately high-scoring one.

Hybrid model. Hybrid training yields clear improvements at early time thresholds: QWK rises by +.19 at 5 minutes in both conditions, and gains persist through 10 minutes (+.11 / +.19) and, in the *Chat* condition, through 15 minutes (+.11). This is consistent with Schaller et al. (2025): training on a mix of complete and incomplete texts helps the model generalise to intermediate writing stages.

However, the hybrid model incurs a cost at later stages: from 15–20 minutes onward, QWK falls below the full-text model, with the largest gap at 25 minutes in the *NoChat* condition (−.13). The full-essay ceiling is also lower (.75 vs. .86 *NoChat*; .90 vs. .95 *Chat*), indicating that the mixed training signal dilutes the model’s ability to fully exploit the richer information available in complete texts.

Condition differences. The crossover point, where the hybrid model transitions from outperforming to underperforming the full-text model, differs between conditions. For *NoChat*, the hybrid model falls behind already at 15 minutes; for *Chat*, it remains competitive through 20 minutes and only drops at 25 minutes. This asymmetry likely reflects the role of AI chat scaffolding: chat-assisted students produce more structured, content-rich text earlier in the session, providing the hybrid model with more “scorable” material at intermediate time points. This is reinforced by consistent larger hybrid gains at early thresholds in the *Chat* condition.

Comparison with keystroke-feature models. Compared to the XGBoost keystroke-feature models, the DeBERTa models achieve higher QWK once sufficient text is available: at full length, DeBERTa (full) reaches .86/.95 vs. .76/.91 for the best XGBoost configuration. At early stages the picture reverses: the XGBoost all-features model achieves QWK of .59 at 5 minutes in the *Chat* condition, outperforming both DeBERTa (full) at .21 and DeBERTa (hybrid) at .40. In the *NoChat* condition, it outperforms the full-text model (.32 vs .15) but is on par with the hybrid model (.32 vs

.33). This confirms that keystroke and text features capture complementary signals: process features provide more robust early prediction when text is minimal, while text-based models dominate once enough content has been produced.

5.3 Combined Text and Process Feature Scoring

Table 5 extends the comparison with COMBINED, which concatenates DeBERTa text embeddings, keystroke features, and a timepoint one-hot encoding (see also Figure 2).

Figure 2: Performance of all 3 DeBERTa models.

Performance across writing stages. At early time thresholds, where essay text is still sparse, COMBINED consistently outperforms both FULL and HYBRID. At 5 minutes, the gains over FULL are substantial (+.28 *NoChat*, +.37 *Chat*), confirming that keystroke process features compensate for what the transformer cannot yet extract from minimal text. Even compared to HYBRID, COMBINED adds +.10 to +.18 QWK at the 5-minute mark. As essays grow longer, the advantage narrows: by 20 minutes in the *NoChat* condition, FULL overtakes COMBINED, and at essay completion, FULL achieves the highest QWK in *NoChat* (.86 vs .77), while in *Chat* the two models perform comparably (.95 vs .94). This mirrors the HYBRID trade-off: process-enriched training slightly reduces discriminative power on finished texts.

Aggregate performance. Across all time thresholds, COMBINED achieves the highest QWK in every condition (.67 *NoChat*, .82 *Chat*, .79 combined), outperforming HYBRID (.62/.73/.73) and FULL (.58/.57/.62). This is most relevant for practical applications where a single model serves writers at any stage of composition.

Condition asymmetry. The advantage of COMBINED over FULL is consistently larger in the *Chat* condition (+.26 vs. +.09 in aggregate). This likely reflects both the richer keystroke features available in the *Chat* condition (e.g., interface switches, time allocation across areas) and the right-skewed score distribution, which may amplify the benefit of supplementary process information for distinguishing among high-scoring essays.

6 Conclusion

We investigated whether keystroke logging data can contribute to automated essay scoring beyond its established role in describing writing processes. Additionally, we present the first scoring experiments on the PISA 2025 FLA dataset, using nearly 4,000 EFL writing sessions to compare process-based, text-based, and combined approaches across writing time thresholds, demonstrating its utility for writing process research.

Our results show that process features carry genuine predictive signal for essay quality. At early writing stages, when texts are too short for conventional scoring, process features distinguish writers at performance levels that text-based models cannot yet reach. At 5 minutes, process-feature models achieve QWK scores of .32 (*NoChat*) and .59 (*Chat*), substantially outperforming DeBERTa trained on full texts (.15 and .21). This advantage diminishes as essays grow longer: at completion, text-based scoring clearly dominates (.86/.95 vs. .76/.91), showing that process features complement rather than replace content-based assessment.

The combined text-and-process model offers the best trade-off across the writing timeline. In the aggregate evaluation across all time thresholds, it outperforms both the text-only and hybrid models, achieving the highest QWK in every condition. This extends reliable prediction: in *Chat*, the combined model reaches QWK above .70 at 10 minutes, versus 20 minutes for the text-only model.

Across all models and time thresholds, prediction quality was consistently higher in the *Chat* condition, likely because chat-assisted students produced more structured, content-rich text earlier in the session, improving scoring at intermediate stages. In addition, the right-skewed score distribution in this condition may also contribute to the observed differences.

While our results demonstrate that process features improve predictive accuracy at intermediate

writing stages, whether these predictions translate into effective formative feedback remains an open question for future intervention studies. Further work should investigate which process features drive prediction at different writing stages and evaluate the approach on human-annotated training data.

Limitations

Our models are trained on silver-standard labels from a linear regression model rather than human annotations, although all evaluations are against human-annotated gold scores. The consistent performance advantage in the *Chat* condition may partly reflect its right-skewed score distribution rather than richer behavioural signal alone. Our dataset comprises German high school students writing argumentative EFL essays in a standardised assessment context; generalisability to other populations, tasks, and settings remains to be established. Finally, we demonstrate predictive accuracy at intermediate time points, not the pedagogical effectiveness of delivering such predictions as formative feedback in practice.

Acknowledgments

We used large language model assistants for code development support and language editing. All experimental design, analysis, and scientific interpretation are our own.

Abstract

Research in AI applied to education increasingly relies on large-scale, high-quality datasets to support the development and evaluation of learning analytics and intelligent educational systems. Open educational resources provide a promising foundation, yet few datasets integrate structured instructional content with assessment materials in a multimodal form. In this study, we introduce a large-scale multimodal educational dataset (EduMUSE - Educational Multimodal Understanding & Solution Dataset) constructed from OpenStax undergraduate textbooks across multiple domains. The dataset integrates hierarchically structured instructional text, figures, exercises, and, when available, official solutions. For exercises with solutions, we introduce an automatic method that associates each exercise with a focused instructional subsection rather than entire textbook chapters, estimating subsection relevance via solution likelihood under candidate contexts using a vision-language model. We analyze the impact of contextualization on the behavior of vision-language models across different contexts. Results indicate that subsection-level instructional context has a measurable impact on model performance, with variation across model scales and task formulations. The dataset and code are released as open source at <https://github.com/upb-nlp/BEA-EduMUSE/> to support reproducible research in multimodal educational modeling and to facilitate generating similar datasets using our approach.

1 Introduction

The effectiveness of educational technologies largely depends on the quality and structure of the datasets used for training and evaluation (Chen et al., 2025). This dependency has become more evident as the use of Large Language Models (LLMs) in educational applications, such as question answering, question generation, tutoring systems, and

automated assessment, has increased (Wang et al., 2024; Dong et al., 2024; García-Méndez et al., 2025). LLMs typically require large amounts of data and are sensitive to noise, inconsistencies, and misalignment with instructional goals. As a result, the availability of clean, well-organized, and pedagogically relevant datasets remains an important factor in NLP research for education.

Many existing datasets for educational question answering and question generation are created using crowdsourcing platforms. While this approach facilitates scalable data collection, it often involves contributors without formal training in education or domain-specific expertise (Díaz et al., 2022; Klie et al., 2024). Moreover, the availability of datasets targeting college-level education is more limited, where materials often involve formal reasoning, domain-specific terminology, and structured explanations, which increases the difficulty of dataset construction and annotation.

In addition to textual content, many academic disciplines rely extensively on visual elements such as diagrams, figures, graphs, and illustrations (Jewitt, 2012). These elements play a central role in instruction and assessment across domains such as mathematics, physics, biology, chemistry, and engineering. However, a large portion of existing educational datasets remains text-centric, which constrains research on multimodal models that integrate visual and textual information in learning-oriented tasks.

To help address these gaps, we construct a large-scale multimodal educational dataset based on college-level textbooks from OpenStax (OpenStax, 2026). The dataset includes textbook text, images, exercises, and corresponding solutions across multiple domains. By sourcing content from openly licensed instructional materials, the dataset remains aligned with established curricula while enabling its reuse for research purposes. The inclusion of images supports the study of multimodal educational

tasks. An additional challenge in educational question answering is identifying the relevant instructional context required to solve a given exercise. In realistic learning scenarios, learners are expected to rely on specific portions of the instructional material rather than the full textbook. To model this aspect, we introduce an automatic, LLM-based method for extracting instructional context. The method evaluates candidate text segments based on the likelihood that an LLM produces a correct answer.

The main contributions of this work are as follows:

- The construction of EduMUSE, a large-scale, college-level multimodal educational dataset derived from OpenStax textbooks, including instructional text, images, exercises, and reference solutions across multiple domains
- An automatic, likelihood-based method for associating exercises with fine-grained instructional subsections, enabling compact contextual grounding for educational question answering
- An empirical analysis of vision–language model performance that quantifies the impact of instructional context, visual information, and model scale on solution likelihood and multiple-choice accuracy

2 Related Work

Large-scale question-answering datasets have played a central role in advancing machine reading comprehension and, more recently, LLMs. Early corpora primarily focused on factoid question answering over encyclopedic text, whereas more recent efforts have explored multi-hop reasoning, educational assessment, and synthetic data generation. However, existing datasets often trade off between scale, pedagogical structure, reasoning depth, and the explicit inclusion of instructional context and solutions.

Among the earliest and most influential datasets is SQuAD by [Rajpurkar et al. \(2016\)](#), which introduced large-scale span-based question answering over Wikipedia articles. Questions were designed by crowdworkers. Given its size and simplicity, SQuAD became a de facto benchmark for reading comprehension models. However, its questions largely emphasize local information retrieval and lexical matching, with limited requirements

for complex reasoning or synthesis across sources. To address these limitations, [Yang et al. \(2018\)](#) introduced HotpotQA, which extended the single-document paradigm by introducing multi-hop question answering over Wikipedia articles. Questions require aggregating evidence across passages, and the dataset explicitly annotates supporting facts, enabling more fine-grained evaluation of reasoning. While HotpotQA represents a significant step toward compositional reasoning, it remains grounded in encyclopedic knowledge and inherits the limitations of crowd-authored questions, with less attention paid to pedagogical intent and question quality. Moreover, both SQuAD and HotpotQA are now relatively dated and were designed prior to the emergence of instruction-following LLMs, limiting their suitability for evaluating modern educational reasoning capabilities.

In contrast to crowdsourced encyclopedic datasets, [Xu et al. \(2022\)](#) adopted an explicitly educational perspective for FairytaleQA. The dataset is curated by educational experts and is based on children’s storybooks, with questions designed to assess narrative understanding and basic comprehension skills appropriate for young learners. While FairytaleQA benefits from expert-driven design and pedagogical alignment, its scope is intentionally narrow: questions are simple, targeted at early education, and do not capture advanced academic domains.

A broader educational focus is found in EduQG by [Hadifar et al. \(2023\)](#), who introduced a multiple-choice question dataset derived from OpenStax textbooks. Questions are annotated with Bloom’s taxonomy levels ([Bloom et al., 1956](#)), enabling analysis of cognitive complexity across formats. EduQG represents an important step toward structured educational QA, particularly through its explicit linkage to pedagogical theory. However, the dataset focuses exclusively on multiple-choice questions, limiting its applicability for tasks involving explanatory reasoning or open-ended answer generation.

In a recent benchmark, [Dinh et al. \(2024\)](#) targeted higher education and expert-level assessment. SCiEx targets university exam questions and covers domains such as Artificial Intelligence, Natural Language Processing, Human–Computer Interaction, and Databases. Despite the difficulty and topical diversity of the questions, the dataset notably lacks accompanying contextual material, requiring models to rely almost entirely on parametric knowl-

edge rather than contextualized reasoning.

Similarly, [Singh et al. \(2024\)](#) propose SCIDQA, a deep reading comprehension dataset derived from scientific papers, with questions originating from peer-review discussions and answers from author responses. While positioned as a dataset for deep scientific understanding, the alignment between questions and the provided paper content is not always explicit. In many cases, answering a question may require background knowledge or interpretative reasoning beyond what is directly stated in the text, raising questions about the dataset’s suitability for controlled reading comprehension evaluation. As reasoning becomes more complex, [Zhu et al. \(2024\)](#) introduced FanOutQA, a multi-hop, multi-document QA benchmark in which answering a question requires aggregating information from a large number of articles. The dataset explicitly decomposes each question into intermediate sub-questions and associated documents, offering transparency into the reasoning process. Evaluation across several LLMs reveals substantial performance gaps, highlighting the difficulty of large-scale information aggregation. However, FanOutQA contains only development and test splits and is limited in size, making it unsuitable for model training and educational use. Additionally, the questions are primarily factual and analytic rather than pedagogically motivated.

An alternative line of work involves generating synthetic datasets. [Gong et al. \(2025\)](#) proposed PhantomWiki, a framework for on-demand dataset creation by generating a synthetic universe of entities, relations, and documents, followed by grammatically generated questions. This approach enables precise control over the complexity of reasoning and the difficulty of retrieval. However, the resulting texts and questions are highly artificial, with limited linguistic naturalness and no grounding in authentic educational content. As a result, while PhantomWiki is valuable for the evaluation of controlled reasoning, it is less suitable for modeling real-world learning scenarios. Similarly, [Naeem et al. \(2025\)](#) introduced a synthetic educational QA dataset to assess grade-level adaptability in LLMs. While it addresses an important dimension of educational alignment, the reliance on synthetic generation raises concerns regarding linguistic diversity, authenticity, and alignment with real instructional materials.

Taken together, existing educational datasets span a wide spectrum of scale, reasoning depth,

and pedagogical grounding. Large encyclopedic datasets offer scale but limited educational structure; curated educational datasets provide pedagogical alignment but are often restricted in complexity or format; expert-level and scientific benchmarks lack explicit context; and synthetic datasets enable control at the cost of ecological validity. These limitations motivate the need for a multimodal educational dataset that jointly provides rich context, well-designed questions, and explicit solutions, enabling the study of grounded reasoning, explanation generation, and learning-oriented evaluation in realistic educational settings.

3 EduMUSE Construction

This section describes the construction of the multimodal educational dataset - EduMUSE - (Educational Multimodal Understanding & Solution Dataset) - and the procedure for augmenting exercises with relevant instructional context. The method consists of two main components: large-scale scraping and normalization of college-level instructional materials from OpenStax textbooks, and an automatic context selection procedure that identifies the most relevant instructional subsections for each exercise using a likelihood-based criterion derived from a vision-language model.

3.1 Dataset Scraping

3.1.1 Source Selection

We construct EduMUSE using textbooks published by OpenStax, an initiative that provides openly licensed, college-level textbooks across multiple academic disciplines ([OpenStax, 2026](#)). OpenStax materials are aligned with standard undergraduate curricula and include a rich combination of instructional text, figures, worked examples, exercises, and solutions, making them well-suited for educational NLP tasks. EduMUSE covers textbooks from the following domains: Business, Computer Science, Humanities, Mathematics, Nursing, Science, and Social Sciences. These domains were selected to ensure diversity in reasoning styles, representational formats, and instructional practices, ranging from formal symbolic reasoning to conceptual and narrative explanations.

3.1.2 Content Extraction

OpenStax does not provide a dedicated API or bulk export mechanism for extracting structured datasets. As a result, data collection was performed

by directly scraping the textbooks in HTML representations. Although the absence of an official scraping interface increases implementation complexity, the HTML pages follow a consistent structural schema, enabling reliable content extraction. Specifically, the HTML markup includes identifiable tags and class attributes corresponding to chapters, sections, subsections, paragraphs, figures, exercises, and solutions. These structural cues were leveraged to systematically extract and hierarchically organize the textbook content.

For each textbook, we extracted the instructional content at the paragraph level, preserving the original hierarchical organization of chapters, sections, and subsections. Paragraphs were cleaned by removing extraneous HTML elements, navigation artifacts, and formatting tags, while retaining inline mathematical expressions and emphasized text. Figures and images embedded in the instructional content were also extracted. For each figure, we retained both the image itself and its associated alternative (alt) text and caption. The alt text in OpenStax textbooks typically provides a detailed description of the visual content. Retaining this serves two purposes: it supports multimodal learning scenarios for models that process images, and it provides a textual proxy for visual information when evaluating text-only models.

3.1.3 Exercise and Solution Extraction

In addition to instructional content, we extracted end-of-chapter exercises. Exercises were identified using HTML tags specific to assessment content and are associated with a corresponding chapter. Each exercise was cleaned to remove residual HTML markup, footnotes, and styling elements. Mathematical expressions originally encoded using MathJax were converted into a normalized textual representation to ensure compatibility with language models. This normalization step produces equation strings that are syntactically explicit and easily parsable by LLMs. When available, we also scraped the official solutions linked to the exercises. Exercises with solutions typically include a hyperlink to a separate solution page, which was followed and processed in the same manner as the exercise text. Solution content was cleaned using the same normalization pipeline applied to exercises. For exercises that included images or graphs in the problem statement, the visual elements and their corresponding alt text were retained, as they may be necessary to solve the exercise.

3.1.4 Limitations of Chapter-Level Context

While exercises are associated with chapters in the textbook structure, chapters are often extensive, containing thousands of tokens. Providing the full chapter as context for an exercise is impractical for many language models due to context length limitations. Even for long-context models, such large contexts can lead to diluted attention, increased inference cost, and spurious reliance on irrelevant information. This motivates the need for a more granular approach to identifying the instructional content most relevant to each exercise.

3.2 Context Augmentation

3.2.1 Motivation

In realistic educational settings, learners solve exercises by relying on specific instructional segments rather than the entire textbook chapter. However, existing datasets typically associate exercises with coarse-grained contexts (e.g., entire chapters or no context). To model a more realistic and pedagogically meaningful scenario, we aim to identify the most relevant instructional subsection for each exercise.

Each textbook chapter is hierarchically organized into sections, which are further subdivided into subsections. These subsections generally correspond to coherent instructional units focused on specific concepts, methods, or examples. As such, we consider subsections as candidate instructional contexts and aim to select, for each exercise, the subsection that provides the most relevant information for solving it.

3.2.2 Relevant Subsection Selection

The context augmentation procedure is applied to exercises for which an official solution is available. The presence of a reference solution enables an objective evaluation of how well a given instructional context supports a model’s correct answer generation.

For a given exercise with question text e , a reference solution s , and a set of candidate subsections $c_1, \dots, c_N$ from the corresponding chapter, we evaluate the relevance of each subsection by measuring how well it supports the generation of the correct solution. Formally, for each candidate subsection c_i , we compute the conditional probability: $P(s \mid c_i, e)$, where c_i and e are provided in the prompt, as instructional context and exercise statement. This probability is estimated using the

token-level logits of an instruction-tuned vision-language model. The probability is computed by decomposing the solution into a sequence of tokens $s = (s_1, \dots, s_T)$ and summing the log-probabilities assigned by the model:

$$\log P(s \mid c_i, e) = \sum_{t=1}^T \log P(s_t \mid s_{<t}, c_i, e) \quad (1)$$

where e is the target exercise, c_i is the instructional context, s is the annotated solution, and t iterates over the solution’s tokens.

This formulation captures how consistently the model predicts the annotated solution when conditioned on a given subsection.

For each exercise, we compute $P(s \mid c_i, e)$ for all candidate subsections within the chapter. The subsection that yields the highest probability is selected as the most relevant instructional context: $c^* = \arg \max_{c_i} P(s \mid c_i, e)$. This selected subsection is then associated with the exercise as its contextual grounding.

3.2.3 Experimental Setup

We employ Qwen2-VL-7B-Instruct¹ (Team et al., 2024), an instruction-tuned vision-language model that supports both textual and visual inputs. This choice allows the context evaluation procedure to incorporate not only textual instructional content but also associated images when present. Moreover, Qwen models allow for multiple images in the input, unlike other VLM families. For exercises or subsections that include figures, the images are provided according to the model’s input specifications and are correctly positioned in their original locations within the text.

3.2.4 Outcome

After applying the previous procedure, each exercise with an available solution in EduMUSE becomes paired with a specific instructional subsection that is empirically validated to be maximally supportive of correct answer generation by a vision-language model. This context augmentation enables more realistic evaluation of educational question answering and reasoning tasks while reducing context length and mitigating the effects of irrelevant instructional material.

¹<https://huggingface.co/Qwen/Qwen2-VL-7B-Instruct>

3.3 Dataset Characterization

This subsection provides a quantitative overview of EduMUSE after scraping, normalization, and context augmentation. EduMUSE was constructed from 39 textbooks across multiple academic domains. From these sources, we extracted 40,971 exercises in total. Among these, 7,195 exercises (17%) are multiple-choice questions (MCQs), reflecting the diversity of assessment formats present in the original textbooks.

A subset of the exercises includes official reference solutions. In total, 15,297 exercises (37%) are paired with solutions, of which 2,037 are MCQs. These exercises constitute the primary subset used for context augmentation, as a reference solution is required to compute solution likelihoods during subsection selection.

EduMUSE also contains substantial visual information. A total of 2,239 exercises include one or more images directly in the problem statement, such as diagrams, plots, or illustrative figures. In addition, 8,595 exercises are associated with instructional subsections that contain images. This enables the evaluation of multimodal reasoning scenarios in which visual content appears either in the question, the instructional context, or both.

Figure 1 illustrates the distribution of the number of exercises across the textbooks included in EduMUSE. The majority of textbooks contain a substantial number of exercises with official solutions, while a non-negligible subset includes no exercises with solutions. In addition, only a limited number of textbooks provide exercises in the form of multiple-choice questions. By contrast, a significant proportion of textbooks feature multiple exercises that incorporate visual elements, such as diagrams or figures, into the problem statement or instructional context.

In terms of instructional content granularity, textbook chapters are relatively long, averaging 13,133 words and reaching a maximum of 64,511 words. By contrast, subsections are significantly shorter, with an average length of 200 words and a maximum of 5,921 words. This disparity highlights the practical importance of subsection-level context selection, as subsections provide focused instructional units that are substantially more manageable for language and vision-language models than full chapters.

Overall, EduMUSE supports a wide range of educational modeling scenarios, including text-only

Figure 1: The distribution of the number of exercises per textbook in the OpenStax dataset.

and multimodal question answering, solution generation, and context-aware reasoning. The combination of diverse domains, varied exercise formats, explicit solution annotations, and fine-grained instructional context makes EduMUSE suitable for evaluating models under realistic instructional conditions.

4 EduMUSE Validation via VLM Probes

We use vision–language models (VLMs) on EduMUSE as probes to validate that it encodes meaningful instructional structure, with particular focus on the contributions of visual information and the selected instructional context (Section 3.2). We employ a VLM of a different family than the language model used for context augmentation while constructing EduMUSE. This separation ensures that the instructional signals encoded in the dataset generalize to newer and stronger vision–language models rather than reflecting model-specific biases. Specifically, we use Qwen3-VL-[8/32]B-Instruct² (Yang et al., 2025) as the answering model, evaluating two parameter sizes: 8B and 32B.

4.1 Probabilistic Evaluation of Annotated Solutions

In the first evaluation setup, we consider exercises for which a reference solution is explicitly annotated in the dataset. For each such exercise, we compute the probability that the model generates the correct solution, following Equation 1

²<https://huggingface.co/Qwen/Qwen3-VL-8B-Instruct>, <https://huggingface.co/Qwen/Qwen3-VL-32B-Instruct>

described in Section 3.2. This formulation allows us to assess how different forms of context influence the model’s likelihood of producing the correct answer, without relying on discrete generation or heuristic matching.

We consider three contextual conditions: a) *full* multimodal context: the complete instructional context, including both text and images; b) *text-only* context: the full textual context, with images removed but their associated alternative text retained; and c) *no* context: the exercise prompt alone, without any instructional context. For each exercise and model size, we compute the token-level likelihood that the model assigns to the reference (annotated) solution, given the exercise prompt and a specified context. This yields three probabilities: one with the full multimodal instructional context, one with text-only context, and one with no additional context. To enable meaningful comparison across exercises with widely varying base difficulty, we compute within-exercise probability ratios between (i) the full multimodal context and the text-only context, and (ii) the full multimodal context and the no-context condition.

To summarize these ratios across EduMUSE, we report the median (50th percentile) ratio for each model and comparison. Using the median reduces sensitivity to extreme values arising from individual exercises where probabilities are unusually small or large. Therefore, the resulting values represent a *typical multiplicative increase in solution likelihood attributable to instructional and/or visual context*. Table 1 reports these median ratios for both the 8B and 32B models.

The purpose of this evaluation is not to achieve

state-of-the-art problem-solving accuracy, but to verify that EduMUSE encodes instructional structure in a form that is operationally detectable by contemporary multimodal models and that confidence substantially increases when appropriate context is provided. If the extracted instructional context is meaningful, then conditioning on it should systematically increase the likelihood assigned to expert-annotated solutions—particularly in exercises where visual material plays a pedagogical role. The observed probability gains therefore serve as evidence that EduMUSE captures instructional signals that models can exploit, rather than as a metric of absolute task performance.

The results indicate a consistent and substantial benefit from providing instructional context, particularly when visual information is included. For the larger Qwen3-32B model, the median probability of generating the correct solution is approximately $13\times$ higher when the full multimodal context is provided compared to a text-only context without images. In contrast, the smaller Qwen3-8B model exhibits a much stronger dependency on visual information, with a $366\times$ increase in median probability in the same comparison. A similar trend is observed when comparing the full multimodal context to the no-context condition, with probability ratios of $94\times$ for the 32B model and $462\times$ for the 8B model.

These results suggest that larger models are more robust to reductions in available instructional content. The Qwen3-32B model likely compensates for missing contextual information by leveraging external knowledge encoded in its parameters, resulting in smaller performance degradation when images or context are removed. Conversely, the smaller Qwen3-8B model relies more heavily on explicit instructional signals, particularly multimodal cues, to produce correct solutions. Nevertheless, across both model scales, the inclusion of multimodal instructional content consistently yields higher probabilities of correct answers. This highlights the importance of multimodal context for educational question answering across diverse exercise types, including structured problems and open-ended responses.

4.2 Multiple-Choice Question Answering Performance

In the second evaluation setup, we assess model performance on multiple-choice questions (MCQs). For each MCQ, models are prompted to select the

correct answer option, constrained to output only a single letter corresponding to one of the choices. To ensure consistent and unambiguous outputs, we employ structured decoding that restricts generation to the available answer set.

As in the probabilistic setup, we consider three contextual conditions: full multimodal context, text-only context (without images but including alternative text), and no context. Performance is measured by accuracy, defined as the percentage of exercises answered correctly. In this setting, multiple-choice answering is used as a stress test for the dataset’s contextual structure under constrained output conditions. Unlike probabilistic solution likelihood, this formulation requires models to compress potentially rich instructional information into a single discrete decision, making it particularly sensitive to context length and model capacity.

Table 2 reports accuracy results across all MCQ exercises in the dataset, while Table 3 considers only exercises whose instructional context contains at least one image. This stratification enables a more direct analysis of the impact of visual information on question answering performance. Comparisons across model sizes and context conditions reveal how scaling and multimodal inputs jointly affect VLMs’ capability to solve college-level textbook problems.

In contrast to the probabilistic evaluation presented earlier, this setup requires explicit answer generation under a constrained output format. Under these conditions, we observe that the smaller Qwen3-8B model is negatively affected by the inclusion of large instructional contexts. For both the full set of exercises and the subset containing images, the 8B model achieves the highest accuracy in the no-context setting, with performance decreasing as more context is provided. This suggests that, for smaller models, long or information-dense contexts may negatively impact the generation. Nevertheless, this behavior does not impact subsection selection, as the selection is performed based on likelihood derived from model logits rather than on the generated output itself.

This behavior is consistent with findings reported by Hsieh et al. (2024) who show that smaller models experience more pronounced performance degradation as context length increases. Limited parameter capacity and narrower effective attention spans reduce their capability to attend to relevant information in long contexts. As a result, additional

Context Comparison	Qwen3-8B	Qwen3-32B
Full vs. Text-only Context	366	13
Full vs. No Context	462	94

Table 1: Median probability ratios (50th percentile) comparing full multimodal context against reduced-context settings for Qwen3 models.

Context Condition	Qwen3-8B	Qwen3-32B
Full Multimodal Context	31.66%	41.04%
No Context	37.65%	40.89%

Table 2: Multiple-choice question accuracy for Qwen3 models under different instructional context conditions across all exercises.

Context Condition	Qwen3-8B	Qwen3-32B
Full Multimodal Context	45.05%	58.97%
Text-only Context	47.39%	58.89%
No Context	53.74%	58.81%

Table 3: Multiple-choice question accuracy for Qwen3 models on exercises whose instructional context contains at least one image.

instructional content, while potentially useful, can hinder decision-making in constrained generation tasks such as multiple-choice answering.

In contrast, the Qwen3-32B model exhibits stable or slightly improved performance when an instructional context is provided. For the full exercise set, accuracy is comparable across the whole-context and no-context conditions, whereas for exercises containing images, the full multimodal context yields slightly higher accuracy. This indicates that larger models are better able to leverage extended and multimodal contexts, likely due to increased parameter capacity and more expressive attention mechanisms that enable effective filtering of relevant information.

Finally, across all evaluation conditions, we observe a clear performance gain when moving from the 8B to the 32B model, confirming the expected scaling effects of model size on educational question answering accuracy.

5 Conclusions and Future Directions

This work introduces EduMUSE, a large-scale, multimodal educational dataset derived from college-level OpenStax textbooks and designed to support research on solution generation and context-aware question answering in realistic instructional settings. By systematically extracting textbook text, images, exercises, and official solutions across multiple academic domains, the dataset

addresses several limitations of existing educational benchmarks, including the lack of pedagogical grounding, insufficient multimodal content, and coarse or absent instructional context.

A key contribution of this work is the proposed automatic context augmentation method, which associates each exercise with a focused instructional subsection selected based on the solution likelihood predicted by a vision–language model. This approach produces compact contexts that better reflect how learners engage with educational materials. The resulting subsection-level grounding mitigates the challenges posed by long chapters while preserving pedagogical coherence. By validating the dataset through controlled model probes, this work aligns with goals of educational technology: understanding how structure, context, and representation shape performance in learning-oriented tasks.

Overall, the dataset and accompanying analyses provide a foundation for studying multimodal educational reasoning under controlled yet realistic conditions. The combination of authentic instructional content, explicit solutions, fine-grained context, and diverse domains enables future work on curriculum-aware modeling, explanation generation, context selection, and the interaction between visual and textual information in learning-oriented tasks. The dataset also offers opportunities for investigating the impact of context length and model scaling behavior.

Limitations

Despite the strengths of EduMUSE, several limitations should be acknowledged.

First, although the dataset spans multiple academic domains, it is constructed from a finite set of OpenStax textbooks that primarily cover widely taught undergraduate subjects. As a result, the dataset may not fully capture the breadth of specialized, advanced, or less commonly taught topics. Extending the dataset to include a broader range of disciplines, including graduate-level materials and niche subject areas, would improve its coverage and applicability.

Second, the proposed context selection method relies on model-derived likelihoods to identify the most relevant instructional subsection for each exercise. While this approach provides a principled and scalable mechanism for automatic context assignment, it is inherently dependent on the behavior and calibration of the underlying model. In particular, although likelihood-based scoring using logits offers a reasonable proxy for contextual relevance, it does not disentangle whether improvements arise from genuinely informative context or from increased model confidence in generating specific token sequences.

Overall, these limitations highlight important directions for future work. Addressing these aspects should aim to improve the reliability and generalizability of multimodal educational datasets and understanding on how models leverage instructional context in realistic learning scenarios.

Abstract

Interest in the role of large language models (LLMs) in education is increasing, considering the new opportunities they offer for teaching, learning, and assessment. In this paper, we examine the impact of LLMs on educational NLP in the context of two main application scenarios: *assistance* and *assessment*, grounding them along the four dimensions – reading, writing, speaking, and tutoring. We then present the new directions enabled by LLMs, and the key challenges to address. We envision that this holistic overview would be useful for NLP researchers and practitioners interested in exploring the role of LLMs in developing language-focused and NLP-enabled educational applications of the future.

1 Introduction

Large language models (LLMs) have demonstrated remarkable capabilities across various tasks within and beyond NLP. The rapid adoption of LLMs and generative AI by EdTech companies such as Duolingo (Naismith et al., 2023a) and Grammarly (Raheja et al., 2023, 2024) and the development of fine-tuned models for educational use cases such as LearnLM (Team et al., 2024) are some examples of real-world impact in Education domain. The NLP community has a long history in this area, especially on problems such as automated essay scoring, grammatical error correction, and text simplification, to name a few. Naturally, there is a huge interest in using LLMs for educational applications within the community. While LLMs have undoubtedly caused a paradigm shift in this area, enabling new opportunities in writing assistance, personalization, and interactive teaching and learning, among other tasks, they also present novel challenges. In this paper, we delve into the opportunities and challenges presented by LLMs for educational applications by considering the use cases involving language, and instruction in natural

Figure 1: Overview of the paper.

language, and connect the recent developments to past NLP research in this area, outlining the path ahead.

Figure 1 shows an overview of the paper organization. After situating this paper in the context of others on the topic (§2), we discuss the state of the art by grouping it into two main topics: *assistive technologies* – meant to support students and teachers (§3) – and *assessment technologies* – meant to assess the performance of students (§4). Within each, we discuss the role of NLP and LLMs across specific aspects of education – reading, writing, speaking, and general tutoring. We then turn to some of the new directions enabled by LLMs in educational NLP (§5), point to some ongoing challenges (§6), and summarize our key insights (§7). In terms of scope, as we focus on language use, we exclude topics such as learning analytics, development of student models, measuring long-term educational outcomes, interactive classroom technologies, user studies, and similar.

2 Related Work

Post ChatGPT, there has been a lot of interest in the role of LLMs, and more generally, generative AI, in education. Several surveys and opinion pieces were published in the past two years outlining the potential use cases, ethical implications, and chal-

allenges of using LLMs in education, primarily by research groups focusing on the use of technology in education (Dempere et al., 2023; Fuchs, 2023; Kasneci et al., 2023; Yan et al., 2024). However, none of them take a closer look at methods (LLM-based or not) used to address the different use cases of LLMs in education, which is of primary interest with NLP.

NLP research has a long history of working on problems of relevance to the education domain, such as automated language assessment and grammatical error correction, among others. Burstein (2009) and Meurers (2012) give an overview of how NLP plays a role in the development of computational tools for language learning and assessment, and more recently, Vajjala (2024) has explored the role of generative AI in language learning technology. But these papers are primarily directed towards non-NLP audience and we are not aware of any such discussion directed towards an NLP audience, connecting recent developments supported by generative AI and large language models with past NLP research on these topics.

Caines et al. (2023) discuss the role of LLMs specifically in language teaching and assessment technologies from an NLP standpoint. However, they specifically focus on writing assessment, and do not address speaking assessment. Further, the use of language in the educational applications space is not limited to language learning alone, and it encompasses other areas such as content learning, as well as assessment and learning support for other subjects. Similarly, Chu et al. (2025c) recently focused on the use of LLM agents for educational applications in detail, while we specifically look at the development of language-based educational applications. Thus, compared to this existing work, we aim to give a broader perspective on the relevance of LLMs for the development of language-based educational applications, and how other NLP methods fit into the current scenarios. Where relevant, we also summarize the perspectives on the use of NLP and LLMs in this area from other related disciplines.

3 Assistive Technologies

We refer to the NLP problems focused on supporting learners and/or instructors as *assistive technologies*, and discuss them by splitting them into four groups: writing, speaking, reading, and general tutoring. Note that we focus on the recent devel-

opments and refer to the relevant surveys for the pre-LLM research, where needed.

3.1 Writing

Assistive technologies for writing primarily focus on **Grammatical Error Detection (GED)** and **Correction (GEC)**, both of which have a long-standing pedagogical value in writing assistance tool development. GEC has witnessed significant progress over the past two decades through the organization of several shared tasks (Ng et al., 2014; Bryant et al., 2019; Masciolini et al., 2025, *inter alia*). For a comprehensive overview of the GEC literature, see the survey by Bryant et al. (2023). While GEC has received much of the attention, GED has also evolved as a stand-alone task (Tetreault and Chodorow, 2008; Leacock et al., 2014; Rei and Yannakoudakis, 2016, *inter alia*).

Several recent studies have applied LLMs to (mainly English) GEC, comparing prompting methods along two dimensions: strategy (e.g., zero-shot, few-shot, chain-of-thought) and design (e.g., fluency-oriented vs. minimal edits). So far, few-shot prompting tends to outperform zero-shot, while chain-of-thought shows no clear benefit (Fang et al., 2023; Coyne et al., 2023; Wu et al., 2023a; Loem et al., 2023; Davis et al., 2024; Katin-skaia and Yangarber, 2024; Omelianchuk et al., 2024). In terms of performance, LLMs often outperform state-of-the-art models on some benchmarks such as JFLEG (Napoles et al., 2017) due to their strength in generating fluent rewrites, but underperform on larger benchmarks like CoNLL-2014 (Ng et al., 2014) and BEA-2019 (Bryant et al., 2019), which prioritize precision and minimal edits. This reflects the difficulty of controlling LLMs to make minimal, targeted corrections, which is essential in educational applications where the goal is to guide learners in revising their own errors while preserving intent (Nicholls, 2003).

LLMs have also been leveraged for **Grammatical Error Explanation (GEE)**, a task that combines GED and GEC to generate natural language explanations of learner errors. Recent work has introduced methods to guide LLMs in producing such explanations using detected edits (Kaneko and Okazaki, 2024; López Cortez et al., 2024). Song et al. (2024b) evaluated LLMs on GEE in English, German, and Chinese, showing that models often struggle to identify and explain errors, though performance improves when edits are included in the prompt. There is a growing interest in GEE for

other languages as well (Ye et al., 2025; Maity and Deroy, 2025). LLMs have also been shown to be useful in providing feedback on other aspects of language assessment such as vocabulary usage (Ortiz-Zambrano et al., 2024; Bannò et al., 2025a), discourse coherence (Naismith et al., 2023b) and analytical assessment of written texts (Bannò et al., 2024b; Stahl et al., 2024; Seßler et al., 2025; Wang et al., 2025b), indicating the growing interest in this direction. Note that some previous work on feedback comment generation for writing also pursued similar goals but preceded the widespread adoption of LLMs (Nagata, 2019; Nagata et al., 2020; Hanawa et al., 2021; Nagata et al., 2021).

3.2 Speaking

As with writing, a common application for supporting learners in speech is **spoken GEC**. However, compared to written GEC which typically works with well-formed inputs where punctuation and capitalization can aid in error detection, spoken GEC presents a distinct set of challenges which significantly complicate the task of identifying and correcting grammatical errors in speech compared to written text. Traditionally, spoken GEC systems have adopted a cascaded pipeline architecture, typically consisting of an automatic speech recognition (ASR) module to transcribe audio into text, followed by a disfluency detection module to produce fluent transcriptions, and finally a GEC module to correct grammatical errors (Lu et al., 2020, 2022). While this approach has shown some effectiveness, it is often hindered by error propagation across stages, which can degrade overall system performance.

This was followed by end-to-end approaches powered by large speech foundation models such as Whisper (Radford et al., 2023), which promise to decrease the number of compounded errors (Bannò et al., 2024a). To address the problem of the scale of data needed to build such systems, Qian et al. (2025a) explored data augmentation, and Qian et al. (2025b) describe a novel reference alignment process to reduce transcription errors which outperforms a fine-tuned multimodal LLM Lu et al. (2025) for this task.

Despite these advances, generating accurate and meaningful feedback from spoken input continues to be a significant challenge. The recent release of the Speak & Improve Corpus (Knill et al., 2024), the first publicly available speech dataset annotated for grammatical errors, and its associ-

ated challenge (Qian et al., 2024) represents a major milestone and is expected to catalyze further progress and innovation in the field.

3.3 Reading

Assistive technologies for reading in NLP primarily focus on **Automatic Readability Assessment** and **Automatic Text Simplification**. Readability Assessment refers to the task of assigning a reading level to a given text based on its language difficulty, to various target readers. Interest in this topic is almost a century old among the education researchers (e.g., Vogel and Washburne, 1928) while the NLP research has an over two decade history (Kevyn, 2014; Vajjala, 2022), and different approaches from feature-based machine learning to deep learning methods have been studied. Recent adaptation of LLMs to this problem so far seems to indicate that task-specific fine-tuned models achieve better results than zero- or few-shot prompting of LLMs (Naous et al., 2024; Wang et al., 2024g; Smădu et al., 2024). However, other work demonstrates better agreement between LLM-generated reading level judgments and human evaluations (Trott and Rivière, 2024), and Rooein et al. (2024) argue for new prompt-based evaluation metrics switching from the traditional static evaluation metrics while using LLMs.

Text Simplification refers to the task of generating text in a simpler, easier to understand language, given a more complex text (typically sentence-to-sentence). It is a well-studied area of research in NLP (Alva-Manchego et al., 2020; Štajner, 2021; Chi et al., 2023; Huang and Kochmar, 2024, *inter alia*) and the advent of LLMs resulted in a natural extension into new methods for developing datasets, generating diverse simplifications and going beyond sentence level generation. While Engelmann et al. (2024) propose to use LLMs to create datasets for text simplification research, several groups showed the effectiveness of few-shot, in-context learning for generating diverse simplifications in multiple languages (Kew et al., 2023a; Nozza and Attanasio, 2023a; Scalercio et al., 2024). Human user studies show better comprehension with LLM simplified text (Guidroz et al., 2025) but also substantial variation among human judgments (Trott and Rivière, 2024). In terms of modeling, some recent approaches utilize LLMs and multi-agentic workflows to explore document-level simplification, showing promising early results (Mo and Hu, 2024; Fang et al., 2025; Qiang et al.,

2025; Alva-Manchego et al., 2025). There is also a growing interest in personalizing text simplification through preference learning (Gao et al., 2025), generating texts at multiple levels of simplification (Farajidizaji et al., 2024; Barayan et al., 2025), domain specific simplification (Zečević et al., 2024), and elaborative simplification (Hewett et al., 2024).

3.4 Tutoring

Within the domain of general knowledge acquisition and tutoring, one of the most effective NLP-enabled tools are **Intelligent Tutoring Systems (ITS)**, in particular, dialogue-based ITSs. ITSs are defined as computerized learning environments that incorporate computational models and provide feedback based on students' learning progress (Graesser et al., 2001); for dialogue-based systems, such feedback and communication with the student are empowered by NLP models. Lack of individualized tutoring has been linked to less effective learning and increased learner dissatisfaction (Brinton et al., 2014; Eom et al., 2006; Hone and El Said, 2016), particularly in large classroom settings. This has led to the development of pre-LLM ITSs (Paladines and Ramirez, 2020), including systems focused on misconception identification (Graesser et al., 1999; Rus et al., 2013), model-tracing tutors (Rickel et al., 2002; Heffernan et al., 2008), constraint-based models (Mitrovic, 2005), and Bayesian network models (Pon-Barry et al., 2004) across educational levels.

LLM-powered ITSs promise to offer more personalized, one-on-one tutoring, enabling equitable and pedagogically sound learning experiences, which have long been known to lead to substantial learning gains (Bloom, 1984). Methods such as prompting (Wang et al., 2024c), fine-tuning (Jurenka et al., 2024), Reinforcement Learning from Human Feedback (RLHF) (Team et al., 2024), and human-in-loop deployment (Team L et al., 2025) have been used in state-of-the-art LLM-based ITSs, as they help to overcome the limitations of traditional systems by enabling more adaptive, generalizable, and effective tutoring models. Although still limited, a few models design their development to stimulate curiosity and thinking processes to improve learning through data curation pipelines or modular model architectures (Jurenka et al., 2024; Vendrell and Johnston, 2026). These approaches are grounded in key learning science principles such as active learning, stimulated curiosity, adaptive learning, meta-cognition, and reasoning.

One of the key limitations for ITSs is the scope and size of current educational datasets (Macina et al., 2023b; Wang et al., 2024c; Stasaski et al., 2020a). Thus, building large-scale, publicly available educational datasets for LLM pre-training and fine-tuning should be prioritized in the near future. The focus on domain-specific models optimized for educational tasks and methods and the development of methods to assess the long-term impact of LLM-driven tutoring on learners and educators, including analysis of pedagogical effectiveness and bias, should also be considered more closely.

4 Assessment Technologies

The assessment of writing, speaking, reading, and tutoring relies on a set of overlapping principles and techniques. Although each modality has its own unique features, they are deeply intertwined, particularly in the use of textual analysis and information extraction methods. Many of these techniques, initially developed within the domain of writing assessment, have been adapted for use in speaking, reading, as well as tutoring contexts, which we summarize in this section.

4.1 Writing

The origins of **automated writing assessment (AWA)** date back to the 1960s with the introduction of Project Essay Grade (Page, 1966, 1968). Notable progress was made in the 1990s and early 2000s that saw the emergence of the commercial systems such as e-rater® (Burstein, 2002), IntelliMetric™ (Rudner et al., 2006), and the Intelligent Essay Assessor™ (Landauer et al., 2002). In later years, Deep Neural Network (DNN) approaches have led to substantial progress (Alikaniotis et al., 2016). In particular, transformer-based models have achieved performance levels that surpass even human inter-annotator agreement (Rodriguez et al., 2019). Comprehensive overviews on AWA can be found in Beigman Klebanov and Madnani (2022) and Li and Ng (2024a,b).

Recent studies looked into the usefulness of LLMs for the assessment of second language (L2) writing, obtaining promising results (Mizumoto and Eguchi, 2023; Yancey et al., 2023a). In line with Liusie et al. (2024)'s observation that LLMs tend to perform better at comparative rather than absolute assessment, Cai et al. (2025) proposed a combined ranking-and-scoring framework that outperforms standard prompt-based approaches. While

most of the writing assessment research focused on evaluating the language proficiency aspect, a substantial amount of NLP research also focused on content assessment, in the form of **short answer scoring** (Burrows et al., 2015). LLM-based research on this topic is still emerging, and recent studies so far conclude that zero-/few-shot learning with LLMs fares poorly compared to fine-tuning approaches for this task (Chamieh et al., 2024; Ferreira Mello et al., 2025).

4.2 Speaking

Research on **automated speaking assessment (ASA)** began with relatively simple tasks, such as evaluating learners' ability to read individual words or sentences (Bernstein et al., 1990; Cucchiari et al., 1997; Franco et al., 2000). A significant milestone in this field was the development of SpeechRater system, which broadened the scope of automated assessment to include both spontaneous and read speech (Xi et al., 2008). Recent years have seen significant advancements in the field through the adoption of DNN approaches (Qian et al., 2012), and end-to-end neural-based methods have outperformed traditional systems such as SpeechRater (Chen et al., 2018b). A comprehensive survey of ASA can be found in Zechner and Evanini (2019).

Pre-trained language models have contributed to further progress in ASA (Raina et al., 2020; Wang et al., 2021) and recent research has explored speech embedding representations for applications such as mispronunciation detection and diagnosis (Wu et al., 2021b; Xu et al., 2021), automatic pronunciation assessment (Kim et al., 2022), and the evaluation of proficiency across both monologic (Bannò et al., 2023a; Park and Ubale, 2023) and conversational (McKnight et al., 2023) data. The application of speech LLMs in this domain is still in its early stages. Fu et al. (2024) developed a speech LLM for L2 assessment that achieved competitive performance, albeit limited to the specific task of pronunciation scoring. With respect to holistic assessment, Ma et al. (2025) recently explored the application of Qwen2-Audio (Chu et al., 2024), for ASA in both zero-shot and fine-tuned settings. In a recent related study, Bannò et al. (2025b) demonstrated that integrating analytic proficiency descriptors with a zero-shot, text-based LLM applied to automatic transcriptions outperforms a BERT-based grader fine-tuned for the task, and achieves competitive performance compared

to fine-tuned speech LLMs. Hirschi et al. (2025) use a modular pipeline in which acoustic features are extracted using dedicated models and injected into a text LLM. For analytical ASA, Parikh et al. (2026) fine-tuned Qwen2-Audio leveraging natural language rubrics to assess prosody, accuracy, and fluency, achieving promising results.

4.3 Reading

One commonly studied problem in NLP in the area of reading assessment is the generation of reading comprehension questions. Question generation research in educational NLP and AI community in general addressed different scenarios from form-focused questions (e.g., to check grammatical knowledge) to more content-focused reading comprehension questions, using a range of methods from syntactic structures to neural language models (Kurdi et al., 2020; Perkoff et al., 2023; Uto et al., 2023; Al Faraby et al., 2024a). LLMs were used for question generation in math domain (Christ et al., 2024; Scarlatos et al., 2024a) and for personalized question generation in general (Xiao et al., 2023a; Säuberli and Clematide, 2024a). Although English is the dominant language for research on this topic, cross-lingual transfer approaches have also been explored, and Hwang et al. (2024) show that smaller fine-tuned language models can achieve comparable performance to larger language models on this task.

While the past research was restricted to a smaller datasets, the advent of LLMs resulted in approaches to benchmark construction and generation of questions at various difficulty levels (Chen et al., 2024; Scaria et al., 2024b), and towards the development of novel evaluation approaches for automatically generated questions (Moon et al., 2024; Deroy et al., 2025). Flor (2025) presents an elaborate summary of automatic question generation research from traditional rule-based methods to generative AI in a series of articles, which can serve as a good reference for those interested in further studies. Item Response Theory (IRT, Lalor et al. (2024)), which has been widely used in psychometrics, has been explored in the context of vocabulary assessment (Ehara et al., 2012; Ehara, 2018) and developing questions for general language assessment (Settles et al., 2020) in NLP research in the past. However, research combining automatic question generation with IRT is yet to emerge in the NLP domain, and this appears to be a promising area where LLMs can help.

4.4 Tutoring

Tutoring systems have long served as embedded assessment technologies, using learner interactions to evaluate understanding and guide instruction. Early systems like PLATO used rule-based feedback and simple branching logic for assessment and remediation (Woolf, 2010). Later, ITSs incorporated expert system models and student diagnostic models to reason about domain knowledge and identify misconceptions (Clancey, 1987). By the 1990s, cognitive tutors like the Algebra Tutor employed cognitive models combined with model tracing and knowledge tracing to perform fine-grained, real-time skill assessment (Anderson et al., 1995). Other ITS approaches such as AutoTutor utilize NLP models and dialogue-based reasoning to assess deeper conceptual understanding (Nye et al., 2014).

Recent advances in LLMs have transformed tutoring systems into flexible, multi-modal assessment environments. LLM-based platforms like Khanmigo (Shetye, 2024) and Google’s LearnLM (Jurenka et al., 2024; Team et al., 2024) leverage generative AI to assess learner responses in natural language, interpret comprehension across reading, writing, and speaking tasks, and adapt instruction accordingly. Unlike more traditional methods, LLMs enable open-ended, personalized feedback across diverse learning tasks, integrating instruction and assessment seamlessly (Venugopalan et al., 2025; Wang et al., 2025a).

Despite their potential, LLM-based tutoring systems often lack rigorous validation linking their assessments to learning outcomes (Macina et al., 2023c). Few studies have examined their diagnostic accuracy (Maurya et al., 2025; Naeem et al., 2026a), adaptability across diverse learners (Wang et al., 2024e), or long-term impact on knowledge retention (Kosmyna et al., 2025). Ethical concerns such as feedback bias and transparency also remain underexplored (Mvondo et al., 2023). Future research should develop standardized evaluation frameworks and investigate how LLM-driven assessments can be aligned with pedagogical goals.

Compared to assistive technologies, it appears that there are relatively fewer cases of LLM integration into assessment approaches, although it is clearly increasing. One reason could be that assessment is likely subject to higher levels of scrutiny around reliability and validity of the models, considering the potential high stakes of the outcomes.

Despite that, what we have seen so far shows how LLMs are increasingly being used in some of the common educational tasks traditionally studied by the NLP community.

5 New Directions Enabled by LLMs

In this section, we turn to previously under-explored or new use cases enabled by LLMs across the four aspects (writing, speaking, reading, tutoring), for both assistive and assessment scenarios.

Content Generation: A relatively new task, introduced with the advent of LLMs capable of fluent text generation in multiple languages, is educational content generation according to expert-defined standards (Imperial et al., 2024), for a specified grade level (Bezirhan and von Davier, 2023; Jin et al., 2025), or for creation of evaluation and scaffolding exercises for different subjects (Xiao et al., 2023a; Malik et al., 2025). One interesting question to extend this line of research further could be on-the-fly content generation through LLMs, given a topic, grade and standard specifications, as well as the target audience, across multiple languages.

Multi-modal Interaction: Although text has been the dominant form of input in educational applications of NLP so far, multi-modal LLMs are starting to be developed (Chu et al., 2025d). Curating multi-modal content for education (Chaturvedi, 2024), multi-modal question generation (Luo et al., 2024), end-to-end spoken language grammatical error correction (Bannò et al., 2024a), low-resource language learning app development (Chu et al., 2025b), supporting listening assessment (Aryadoust et al., 2024), and evaluating handwritten exams (Liu et al., 2024b) are some recent examples. Given these diverse use cases, and given that human learning can be considered multi-modal as we gain information from multiple forms of content, modeling of multi-modal interactions in human learning and multi-modal content generation can be considered challenging and useful future possibilities to study, considering large multimodal models as the foundations.

Synthetic Data Generation for Fine-tuning: Synthetic data is increasingly being used at various stages of LLM training and fine-tuning pipelines, and education domain also started to see some new use cases for synthetic data such as aiding the development of educational chatbots and tutoring sys-

tems (Wang et al., 2024a; Fateen and Mine, 2024), spoken GEC (Karanasou et al., 2025), development of benchmark datasets for educational applications (Engelmann et al., 2024; Xu et al., 2025), and using LLMs as proxies for piloting educational assessments (Säuberli et al., 2025). Considering the advantages synthetic data provides in terms of alleviating the need for labeled training data, exploring the limits and limitations of LLM-based synthetic data generation approaches for educational applications would be an important direction for the future.

LLM Agents for Education: When LLMs are combined with components such as memory, tool use, and planning to solve complex tasks, they are referred to as *LLM agents* (Chu et al., 2025c; Tran et al., 2025). In an educational context, these additional components enable real-time adaptation, access to external resources, and planning of tailored learning paths, among other capabilities. At a high level, such agents function either as pedagogical agents or domain-specific educational agents (Chu et al., 2025c).

Pedagogical agents imitate tutors to assist students or instructors in tutoring sessions and simulate students for tasks such as piloting exam questions or training tutors. Furthermore, multiple agents can operate simultaneously in multi-agent setups like in WikiHowAgent (Pei et al., 2025), CAMEL (Li et al., 2023), AutoGen (Wu et al., 2023b), and PitchQuest (Mollick et al., 2024) to develop educational prototypes or solve complex problems. These agents can further support curiosity and higher-order thinking in learners, grounded in established learning theories such as student-first learning (Schwartz and Bransford, 1998), the zone of proximal (Vygotsky, 1978) development, and productive failure (Kapur, 2008), which are known to promote long-term learning gains. Domain-specific educational agents assist with learning in subjects such as science, languages, or professional development for specific domains.

However, beyond general risks such as safety, hallucinations, and bias, the responses of the current state-of-the-art models are often not grade-appropriate (Srivatsa et al., 2025), may diverge from the learning path, conflate user roles, or enter conversational loops (amplified in multi-agent settings) (Li et al., 2023; Chu et al., 2025c; Tran et al., 2025). In summary, this research direction holds huge promise, but key limitations must be ad-

dressed when deploying these systems in sensitive domains like education.

Educational Human-LLM Collaborative Systems: Human-LLM collaborative systems leverage the complementary strengths of humans and LLMs to improve performance in tasks such as data annotation, problem-solving, and decision-making across domains like education and healthcare (Yang et al., 2024; Fragiadakis et al., 2024). In education, LLM-powered systems have been deployed to support both single-turn interactions (e.g., answering questions, explaining steps) (Gao et al., 2024; Hashir et al., 2024) and multi-turn interactions (e.g., Tutor-Copilot (Wang et al., 2024e), GPTeach (Markel et al., 2023)). These systems can, among other things, deepen learner understanding and assist novice tutors in improving their teaching skills and qualities. They are not free from challenges, though. Such systems often lack interpretability, making it hard to trust AI outputs (Yang et al., 2024). They may prioritize correctness over pedagogical goals like conceptual understanding and learner support (Macina et al., 2023c). LLMs also struggle with ambiguity, personalization, and maintaining context in extended interactions, and they rarely offer adaptive feedback tailored to learners’ evolving needs or emotions (Maurya et al., 2025). Addressing these challenges is essential for building reliable and effective educational human-LLM collaborative systems.

Educational Value Alignment: Alignment with human preferences is a key driver to the success of state-of-the-art LLMs (Ouyang et al., 2022; Yao et al., 2023). This ranges from the development of general values-based LLMs (Guo et al., 2025; Team et al., 2024) to models tailored to specific age groups or domains (Nayeem and Rafiei, 2024; Chen et al., 2023). These advancements have also significantly influenced the educational domain, leading to the development of education-specific LLMs such as LearnLM (Team et al., 2024; Jurénka et al., 2024) and pedagogical tutors (Dinucujianu et al., 2025). These LLMs are grounded in pedagogical values (Team et al., 2024; Maurya et al., 2025) and draw on decades of research in the learning sciences to generate pedagogically rich datasets, which are subsequently used for instruction tuning and fine-tuning. These specialized models have proven effective across a wide range of educational applications.

However, an open research question remains –

“What should we align with?” (Yao et al., 2023), which directly affects LLM performance. Specifically, in the case of tutor LLMs, there is currently no consensus among researchers regarding the key pedagogical principles and associated teacher moves that lead to effective learning (Team et al., 2024). Future research should explore the core educational values that need to be integrated to enable the development of more effective educational models.

6 Ongoing Challenges

So far, we have seen how LLMs enabled existing NLP research on educational applications, and also paved way for new use cases. With the growth in their usage in real-world educational scenarios and the potential for personalized education, a discussion about the challenges involved becomes inevitable. In this section, we discuss some of the technical as well as broader application-related challenges in this area. While this discussion about the challenges is non-exhaustive, it broadly highlights some of the general task-agnostic issues related to the use of LLMs and NLP in education.

6.1 Datasets

A lot of NLP research on educational applications relies on the existence of labeled datasets. For most of the tasks, such datasets are created by repurposing existing online resources (e.g., using Wikipedia and Simple Wikipedia, or websites such as Newsela for automatic text simplification), and this is not an exception compared to other areas of research in NLP. Carefully crafted datasets that are specifically developed for a particular task (e.g., grammatical error detection) are not rare, but hard to develop on a large scale. Datasets that consider target user input (e.g., those that contain learner feedback or outcome information) are even rarer. Adding multilingual support to the mix makes dataset development across educational NLP tasks still more challenging.

Although LLMs could offer better zero-shot, off-the-shelf performance for many tasks and languages today, and synthetic data generation with LLMs can address the data scarcity across languages to some extent, we would still need concerted efforts to build high quality educational datasets to develop and evaluate LLMs that can provide educational support across languages. Some recent research also reports poorer performance

of LLMs across four education-related tasks beyond English and recommends verifying the LLM performance in the target language before deployment (Gupta et al., 2025). Imperial et al. (2025)’s recent effort to consolidate multilingual language proficiency assessment datasets under one unified format and license is a welcome step in this direction.

6.2 Pedagogical Evaluation

Across different NLP tasks involving the use of LLMs in the education domain, evaluation challenges have been widely discussed, along with a comparison between automated and human evaluation (Horbach et al., 2020; Vásquez-Rodríguez et al., 2021; Agrawal and Carpuat, 2024; Kobayashi et al., 2024). While most of the discussions around evaluation focused on the task-specific aspects, for technologies such as tutoring systems, a multi-dimensional view of evaluation is necessary.

Traditional evaluation of teacher effectiveness has relied on artifacts, portfolios, self-reports, and student feedback (Goe et al., 2008). More recently, text generation metrics are being explored to assess ITS or AI tutor responses. However, while effective for measuring coherence and fluency, these domain-agnostic metrics often miss deeper pedagogical aspects, depend on gold references, and can be gamed by generic responses (Tack and Piech, 2022). Efforts to capture pedagogical effectiveness more directly have included human evaluations and tailored frameworks defining specific strategies, but these face challenges such as subjectivity, lack of standardization, and limited scope (Jurenka et al., 2024). Some potential directions for evaluating tutor responses were recently proposed by Maurya et al. (2025), where a unified taxonomy was introduced to measure the quality and appropriateness of these responses. However, these rely on human evaluation, which is non-scalable and is typically conducted at the utterance level rather than the conversation level. Naeem et al. (2026a) introduces an automated evaluation model to mitigate reliance on human annotation, leveraging a lightweight multi-task LoRA-based fine-tuning approach on a 2B-parameter model, however, it only captures a limited subset of evaluation dimensions. So far, using LLMs as proxy judges shows promise but still falls short in reliably evaluating complex pedagogical traits (Gu et al., 2024).

Overall, NLP research is understandably model-focused, and that impacts the way we evaluate. But,

user-focused evaluations are also emerging. For example, some recent research points to the mismatch between the user needs and model availability in the context of graded content generation (Asthana et al., 2024; Kim et al., 2024b). Considering the increasing widespread real-world usage of LLMs in educational applications, NLP research could consider a user-first rather than a dataset- and model-first approaches in developing standardized evaluation methodologies for educational applications in future.

6.3 Ethical Issues

We found the discussion around the ethics of using LLMs in education emerging only recently in the NLP community (e.g., Härmäläinen, 2024), yet there has been some thought in this direction in the broader education technology and assessment community. For example, Yan et al. (2024) discuss the ethical implications of the increasing use of LLMs in education considering a range of use cases, and identify transparency for educational stakeholders (teachers, students, parents), privacy, support across languages, and fairness across population groups as the main ethical concerns surrounding the use of LLMs in education, calling for better reporting standards from empirical research that uses LLMs to develop new solutions. This issue of reporting standards is perhaps of most direct relevance to the NLP community.

From an assessment perspective, some recent work discussed the implications of the usage of LLMs in education for academic integrity (de Winter, 2024; Leppänen et al., 2025) and fairness (Yamashita, 2025), and the language assessment community calls for a collaboration between model developers, test creators and subject matter experts, psychometricians and the AI research community to develop education-specific standards for using AI in assessment to ensure reliability and fairness (Bolender et al., 2023; Voss et al., 2023; Xi, 2023).

Hallucination is a well-known concern with LLMs, and educational use cases are not immune to that. Some recent research on text simplification (Hewett et al., 2024; Zečević et al., 2024) pointed to how the tendency to hallucinate increases as the task gets more complex such as generating in a specific domain or in a new language, for example.

7 Conclusions

Our study on how LLMs are integrated into existing research on the NLP-driven educational applications shows that LLMs lead to several interesting new developments which hold a lot of promise for the future in terms of both effective performance as well as inclusive development of applications addressing different languages and population groups. However, there are also several ongoing challenges related to available data, evaluation, and ethical concerns. As suggested by others, we envision an increase in inter-disciplinary collaboration between NLP researchers, domain experts, and educators leading to the development of better assistive and assessment technologies to support students and teachers in the future. We hope that this paper would serve as a good starting point for NLP researchers, providing them with the necessary background on the state of the art in the educational applications of NLP using LLMs and on what lies ahead.

Limitations

We perceive two primary limitations: (a) Since our goal in this paper is to provide an overview of what lies ahead, we did not do an exhaustive survey of the current state of the art, focusing largely on post-LLM research and pointing to relevant surveys for pre-LLM approaches; and (b) We have also primarily restricted ourselves to NLP publication venues, citing research from other related disciplines to a much smaller extent. Our observations and conclusions drawn in this paper should be considered along with these limitations. However, we provide an extensive, although by no means an exhaustive, list of additional readings grouped by the four dimensions – writing, speaking, reading, and tutoring – in the Appendix Tables 1–4, for those interested in exploring these topics further.

Ethical Considerations

The study does not involve the use of any datasets with ethical concerns or training of AI models with potential ethical issues. Hence, we do not anticipate any significant risks associated with this work.

Fine-Grained Content Zone Prediction in German Argumentative Essays Using LLMs

Xiaoyu Bai and Manfred Stede

Applied Computational Linguistics

University of Potsdam

Karl-Liebknecht-Straße 24-25

14476, Potsdam, Germany

{xiaoyu.bai | stede}@uni-potsdam.de

Abstract

We introduce FDE-Arg, a newly compiled dataset of argumentative student essays in German. We use two Llama models of different sizes to label sentence-level content zones both in FDE-Arg and in an existing dataset of source-dependent argumentative essays. We investigate three approaches for improving model performance: a) Incorporating targeted task information into the prompt text; b) few-shot prompting with up to 10 examples selected on the basis of similarity with the target instance; and c) parameter-efficient fine-tuning. We observe that both incorporating additional information in the prompts and similarity-based few-shot prompting have produced highly promising performance gains over the baseline.

1 Introduction

Given that written argumentation is a central skill set taught in secondary schools, using the latest NLP applications to support the teaching and analysis of argumentation in student writing is highly desirable. One central subtask is automatically recognising what role individual text units play with respect to the overall text function and extracting those that are relevant to argumentation. As such, the task is related to argumentative zoning as established by Teufel et al. (1999), which targets a different text genre, viz. scientific writing, and analyses argumentative and rhetorical structure in academic papers. Applied to the educational domain, such an analysis of the functional components of a student’s argumentative text can contribute to a better understanding of the student’s argumentation strategy and form the basis of constructive feedback.

In our present work, we investigate the application of LLMs to this task, which we refer to as “(argumentative) content zone prediction” in German-language argumentative essays. The aim is to automatically assign one out of a set of content

zone labels to each sentence in the essay, where the label reveals the functional and argumentative role played by the sentence w.r.t. the essay. To illustrate, Figure 1 shows a fictitious example in English that is loosely adapted from an authentic essay from our German data.

At our school, there is currently an ongoing discussion on “healthy diet”. The question is: “What is better? Fast food or cooking oneself?”
One position is that cooking at home is better than fast food. That’s much healthier. It’s also a much better option when one is expecting guests, who will for sure prefer something homemade with love over something that’s just store-bought and mixed together. Cooking together with loved ones can also make for great memories.
A strong statement made by another student is this: I’d rather order a pizza than spend hours at the stove. A main argument for this position is convenience. Cooking oneself takes much more effort than just getting a pizza. We have to understand that not everyone has the energy and the motivation to cook after a long day’s work. Also, ordering fast food can save you a lot of time.
I personally think that it can be fun to cook, but it’s also time-consuming. So my take on this is this: One should generally cook at home, but it’s also ok to order a pizza from time to time.

Argumentative content zone labels

Non-argumentative: Segments that do not introduce new argumentative elements.

Thesis 1: Claim w.r.t. the topic that aligns with the writer’s stance.

Pro-argument: Premise that supports Thesis 1.

Thesis 2: Claim that aligns with the counter-position.

Con-argument: Premise that supports Thesis 2.

Central thesis: Writer’s core position on the topic.

Figure 1: Fictitious example essay with colour-coded annotations, loosely adapted from an authentic German essay from our data.

For this, we use two datasets of argumentative essays in German: The recently released GerTE dataset (Bai and Stede, 2025) featuring source-based essays that are written with reference to reading material, and our novel dataset FDE-Arg, featuring stand-alone essays. Each dataset uses its own set of content zone labels that reflect the respective writing task. For instance, labels in GerTE differentiate between arguments repeated from the reading material and original arguments by the writer (Bai and Stede, 2025), while labels in FDE-Arg differentiate between the writer’s position on a discussion topic and the counter-position that the writer concedes.

Bai and Stede (2025) have conducted baseline zone prediction experiments on GerTE using a small Llama model. We take their approach as

our starting point and investigate ways to improve LLM performance on the argumentative content zone prediction task, using both GerTE and FDE-Arg. Concretely, we experiment with the following three strategies:

- Enhancing the prompt text with task-specific background information
- Few-shot prompting with selection of example instances based on semantic similarity
- Parameter-efficient fine-tuning (PEFT) with QLoRA (Dettmers et al., 2023)

Our overall contributions are two-fold: First, We highlight a novel dataset of German argumentative essays, annotated with a fine-grained set of content zone labels. Second, our experiments reveal that both the inclusion of targeted information in the prompt and few-shot prompting are highly promising directions.

Our code and our resources for FDE-Arg, including the annotation guide as well as annotated datasets, are made publicly available.¹

2 Related Work

Scoring and analysing argumentative essays by students of different age groups is a well-established area of interest in educational NLP: Argumentative essays are featured in well-known datasets such as ASAP-AES² and ETS TOEFL11 (Blanchard et al., 2013), which have been widely used in automated essay scoring research (Bai and Stede, 2023). Moreover, the Argument Annotated Essays Corpus (Stab and Gurevych, 2017) and the PERSUADE Corpus (Crossley et al., 2022, 2024) are two prominent examples of English-language learner/student essays which have been annotated with argument mining (AM) information, such as claims and premises, and which therefore allow for the computational analysis of students’ argumentation strategies.

With respect to German, DARIUS (Schaller et al., 2024b) is a 4,500-sample corpus of argumentative essays that are written by secondary school students and labelled with multiple layers of argumentation-related annotations, including coarse-grained content zones and major claims.

Schaller et al. (2024a) have investigated automatically predicting the labels in DARIUS using both supervised models and an LLM, although their focus is on evaluating the fairness of different models while performing prediction. Stahl et al. (2024) provide a comparable, 1320-sample dataset of student essays with AM labels on multiple levels of granularity. They have also conducted baseline label prediction experiments using a BERT-based model. On the level of university education, Wambsganss et al. (2020a,b) have compiled a 1000-sample corpus of persuasive essays by business administration students and have used it to develop a tool for analysing the argumentation structure in the essays and providing feedback on them.

While to our knowledge LLMs have not yet been extensively applied to these datasets, they have been increasingly applied to the field of AM: Recent work has looked into using LLMs in different prompt scenarios to perform canonical subtasks of AM, such as argument component type recognition and classification (Chen et al., 2024) and argument relation extraction (Gorur et al., 2025). Fine-tuning smaller LLMs using PEFT have also shown to be successful for similar core AM tasks (Kawarada et al., 2024; Cabessa et al., 2025).

3 Data

We study argumentative content zone prediction with LLMs, applied to two German corpora with source-dependent and stand-alone essays.

3.1 GerTE

GerTE (Bai and Stede, 2025) is a corpus consisting of 117 essays on three topics. The essays have been collected in the context of a source-based writing exercise where the writer first reads a news article on one of three possible topics, then writes an essay that presents the topic, discusses the arguments put forward in the source article and finally concludes with a stance of their own. While the writing task is a common exercise in German secondary schools, GerTE was not collected from authentic school students due to legal concerns. Instead, the authors recruited crowd workers who took on the role of students and composed the essays.

Essays in GerTE have a mean length of approximately 270 words. After automatic sentence-segmentation, the corpus is annotated on the sentence level with functional content zones, where each zone describes a sentence’s functional role to

¹<https://github.com/discourse-lab/FairDebArgMining>

²<https://www.kaggle.com/c/asap-aes>

the essay. GerTE uses an inventory consisting of the following five class labels:

- **info_intro**: Introductory sentences that present the topic and/or give publication-related information on the source article.
- **article_pro**: Sentences denoting pro-arguments from the source article
- **article_con**: Sentences denoting contra-arguments from the source article
- **own**: Sentences denoting the writer’s own position and arguments
- **other**: Sentences that do not fit into the above four classes

The full corpus consists of 1713 sentences from the 117 essays, with each sentence being labelled with exactly one of the five content zones. Label distribution is unbalanced, with “own” being the most frequent and “other” being the least frequent class. The exact distribution is provided in Table 1.

Label	own	a_pro	info_intro	a_con	other
Count	551	460	281	243	178

Table 1: Class-specific label counts in GerTE

3.2 FDE-Arg

Our new dataset comprises stand-alone essays written by students in the 9th grade of various German secondary schools. It was originally collected by education scientists in the context of the *Fair Debating and Written Argumentation* (FDE) project, which aims to investigate and improve the written argumentation skills of 9th-grade students in Germany (Giera et al., 2025a,b). The students were asked to compose pro-and-contra argumentations that should address both sides of a discussion topic, weigh the arguments and draw a conclusion with their own position. Each essay deals with one of four possible, easily accessible topics such as “Is fast food better than cooking at home?” or “Should one undertake volunteer work?”. The full FDE dataset comprises 1,061 essays. On this basis, Bai et al. (2026) have developed a scheme for annotating the essays with argumentative content zones³, which they have applied to and validated on 50 samples. Adopting their scheme, we have annotated

³However, they refer to them as *argument component types*, following argumentation mining terminology.

another 50 essays, which yields a total set of 100 essays labelled with argumentative content zones. We refer to this 100-sample dataset as *FDE-Arg*.

On the essay level, each text is assigned an “overall argumentative constellation”, with “**decided**” denoting that the author argues in favour of a particular stance in the discussion, with or without discussing the opposing stance; “**undecided**” denotes that the author describes both sides of the discussion and refrains from taking a position of their own. Moreover, the essays have been manually segmented into sentences or phrases that form argumentative units,⁴ and each segment is labelled with one of the following six labels that describe the segment’s argumentative function in the essay:

- **central thesis (cth)**: Segment describing the author’s central stance on the topic. If the author subscribes to one side of the discussion without addressing the counter-position, this could be the only thesis/claim in the essay. In essays with the “undecided” overall constellation, “cth” can also be an explicit statement that the author cannot make up their mind.
- **thesis 1 (th1) / thesis 2 (th2)**: Segments describing the two opposing positions on the discussion topic if both are present. In an essay with the “decided” constellation, where the author, however, also acknowledges the counter-position, “th1” denotes the position of the author and is therefore in line with the author’s central stance (“cth”), whereas “th2” denotes the counter-position.
- **pro argument (pro) / con argument (con)**: Segment describing arguments that support the theses. Those supporting “th1” and/or “cth” are denoted as “pro arguments” and those supporting “th2” as “con arguments”.
- **non argumentative (n-a)**: Segment that is not considered argumentative. This includes sentences that serve to structure the essay or that present background information and should be given to all segments not covered by the above labels.

⁴Their rule for manual segmentation is that complex sentences are split into smaller segments if they individually play a role to the argumentative structure of the essay. Those that are not relevant to argumentation, e.g. because they only give background information or serve to structure the essay, are left as they are. We refer to Bai et al. (2026) and their annotation guide for details.

We refer to Bai et al. (2026) for details on the annotation process for FDE-Arg, including theoretical and practical motivations for the scheme used. Moreover, they also present an inter-annotator agreement study based on 30 essays, which has achieved an overall Cohen’s κ of 0.79.

On average, essays in FDE-Arg are longer than those in GerTE, with a mean word count of 345 per essay. The 100 essays comprise 2,595 labelled segments in total; the label distribution is shown in Table 2. It is unsurprising that there are far fewer segments labelled as “cth”, “th1” and “th2” than segments labelled as “pro” and “con” since a single position or claim can be supported by multiple arguments.

Label	pro	con	n-a	cth	th1	th2
Count	911	697	688	106	97	96

Table 2: Class-specific label counts in FDE-Arg

To summarise, Table 3 captures and contrasts central characteristics of GerTE and FDE-Arg.

4 Methods

We use two open-source, instruction fine-tuned Llama 3 models of different sizes: The smaller “Llama-3.1-8B-Instruct”⁵ with 8 billion parameters (hereafter referred to as “Llama-8B”) and the larger “Llama-3.3-70B-Instruct”⁶ with 70 billion parameters (hereafter “Llama-70B”). While newer, more powerful LLMs are a potential way to achieve better prediction results, our focus is on different strategies to enhance model performance while keeping the LLM models themselves fixed. Each of our three strategies is described in detail in the sections to come. Our experiments used the Huggingface framework (Wolf et al., 2020) and Groq API⁷.

4.1 Baselines

For GerTE, Bai and Stede (2025) have conducted first LLM-based content zone prediction experiments using Llama-8B. They experimented with a zero-shot prompt setting, with and without inclusion of the source article text in the prompt, as well as a one-shot setting using a manually selected example essay for in-context learning. They report

⁵<https://huggingface.co/meta-llama/Llama-3.1-8B-Instruct>

⁶<https://huggingface.co/meta-llama/Llama-3.3-70B-Instruct>

⁷<https://groq.com/>

their best result as a weighted-average F1 of **0.661**. In contrast, their best-performing ensemble model using BERT and SVM achieved an F1 of 0.713. We treat the prompting approach by Bai and Stede (2025) as our baseline setting on GerTE.

Bai et al. (2026) have also conducted a first set of LLM-experiments, albeit on the initial 50-sample portion of FDE-Arg which they had annotated. Their base prompt text is similar to that by Bai and Stede (2025): It asks the LLM to adopt the role of a 9th-grade teacher, explains the meaning of each label, supplies the segmented essay and asks the model to output a sequence of labels of the same length. Instead of the three-letter labels such as “cth” or “pro” in the dataset, for the prompt text, the zone labels are mapped to interpretable counterparts such as “Zentrale_These” (“central thesis”) and “Pro_Argument” (“pro argument”), respectively. The exact German-language prompt text is provided in the Appendix. Using both Llama-8B and Llama-70B, Bai et al. (2026) evaluated zero-shot prompting and two-shot prompting with two randomly chosen example essays, one with a “decided” and one with an “undecided” overall constellation. We adopt these two prompt settings as our baseline on FDE-Arg.

4.2 Additional Information in Prompt Text

As the most simple strategy, we experimented with enhancing the baseline prompt for either dataset with additional information that addresses specific challenges in the respective dataset.

4.2.1 GerTE: Summary of Source Text Content

The baseline by Bai and Stede (2025) has already explored incorporating the source article text into the LLM prompt. This has indeed benefitted the LLM’s prediction, although the resulting performance was still far below that of supervised models. According to the authors’ error analysis, a significant source of errors is confusion between pro and con arguments from the source article as well as their distinction from the writer’s own arguments. Since a solid understanding of the main arguments from the source text is essential to avoiding such confusion, we manually extracted and summarised the main arguments from each source article in concise sentences⁸ and included them in the system

⁸These summarised main arguments are in fact what has been referred to as “reference snippets” in Bai and Stede (2022). In a preparatory step to composing the essays in

	GerTE	FDE-Arg
Essay type	source-dependent	stand-alone
Mean word count per essay	270	345
Label set	own, article_pro, article_con, info_intro, other	cth, th1, th2, pro, con, n-a
Annotation unit	sentence (automatic sentence-segmentation)	argumentative segment (manual segmentation)
Total number of essays	117	100
Total number of annotated units	1,713	2,595

Table 3: Central characteristics of GerTE and FDE-Arg

prompt alongside the source article itself. A gloss of our addition is thus: *The following are the arguments that are brought up in the text. The pro arguments are these [LIST OF PRO-ARGUMENTS]. The con arguments are these [LIST OF CONTRA-ARGUMENTS].* The full system prompt for an essay on the topic of using social media in class is provided in the Appendix, including our formulation of the article’s main arguments.

4.2.2 FDE-Arg: Instructions from Annotation Guide

The annotation guide for FDE-Arg provides detailed information and annotation strategies on the dataset. Therefore, we aimed to improve LLM performance by adding relevant content from the annotation guide to the prompt text, experimenting with two sets of information in particular:

First, various authors of the essays conclude their essay by stating or repeating their overall view on the discussion topic. According to the annotation scheme, such a statement should be annotated as “central thesis (cth)” only if no previous segment has been annotated as such. Otherwise, it is considered a conclusion and thus an essay structuring element that is annotated as “non-argumentative (n-a)”. To reduce confusion between “cth” and “n-a”, we added a formulation of this annotation rule to the prompt. The exact formulation of this addition is given in the Appendix.

Second, for further analysis of an essay’s argumentation structure, it is particularly crucial that the theses, particularly the central thesis, are correctly extracted, and human annotators are instructed by the annotation guide to prioritise the labels for theses over those for arguments in cases of doubt. To encourage the same behaviour from LLMs and to target better prediction of the thesis labels, we added a short instruction based on the

recommended annotation steps from the annotation guide. A gloss of our addition is as follows: *When assigning zone labels to segments you can proceed as follows: 1. Find the central message of the essay (“cth”) ... 2. Find further theses (“th1” / “th2”) ... 3. Find the arguments (“pro” / “con”) ... 4. Mark the remaining, unassigned segments (“n-a”)* We refer to the Appendix again for the full addition.

4.3 Similarity-Based Few-Shot Prompting

In contrast to the one-shot and two-shot prompts in the baseline settings (see above), we experimented with few-shot prompting using up to 10 example essays. Moreover, previous work on example selection for in-context learning have shown that example instances in few-shot prompting are especially effective when they display high levels of similarity with the target instance (Liu et al., 2022; Ajjour and Wachsmuth, 2025). We therefore adopted a similarity-based method to individually and automatically select a set of example essays for each target essay, as described in the following.

Although we did not *train* the models in any sense, we divided our data into a training and a test set, of which the training set served as the pool of essays from which examples could be selected. For a given test essay t at inference time, we first extracted all training essays that address the same topic as t , treating them as “candidate examples” C . Next, we ranked all essays in C based on their semantic similarity with t and sorted them in descending order. From this ranked list of candidate essays, we then selected the top k essays, where k is the number of examples we used in the few-shot prompting scheme.

Semantic similarity between a given candidate essay $c \in C$ and t was computed using SBERT (Reimers and Gurevych, 2019), specifically the pre-trained model “sentence-transformers/paraphrase-multilingual-MiniLM-L12-v2”⁹, and cosine simi-

GerTE, writers were in fact asked to write out the main arguments from the source article. These summarised arguments we include in the prompts have originally been manually compiled to serve as reference answers for this preparatory task.

⁹<https://huggingface.co/sentence-transformers/paraphrase-multilingual-MiniLM-L12-v2>

larity. For this calculation, we split both c and t into three chunks, respecting sentence boundaries, and recorded the similarity between the index-aligned pairs of chunks. This produced three similarity values for each essay pair. The final similarity value between the essay pair was computed as a weighted average of the three chunk-level similarity scores. Our similarity-based example ranking process is illustrated in Figure 2.

The motivation for splitting each candidate and target essay into three chunks is two-fold: First, entire essays would exceed the 128-token sequence length limit of the SBERT model used, which would subject them to truncation. Second, by taking a weighted average of chunk-level similarities, we could control the weight put on the similarity in specific areas of essays. For FDE-Arg essays, we assigned equal weight to all three chunks. For GerTE, in contrast, we assigned less weight to the similarity score of the top chunk pair since most essays in GerTE start by providing meta data on the source article. We considered similarity in this area to be less relevant.

We performed our experiments on both datasets using cross-validation, with $k \in \{1, 2, 4, 6, 8\}$ for GerTE and $k \in \{1, 2, 4, 6, 8, 10\}$ for FDE-Arg. If k is larger than the number of candidate examples available¹⁰, all candidates were selected and used.

4.4 Parameter-Efficient Fine-tuning

As an alternative to improving the prompt fed to the LLMs, we also experimented with parameter-efficient fine-tuning (PEFT) using QLoRA (Dettmers et al., 2023) with 4-bit quantization. Due to computational costs, this approach was only applied to the smaller model Llama-8B. We again divided our data into training and test partitions through 5-fold cross-validation and fine-tuned the model on the training partition. For either dataset, the model was fine-tuned on the zero-shot baseline prompt text, paired with the target output, which could be derived from the gold-standard zone labels in the datasets. The approach was implemented using the PEFT functionalities that are integrated into the Huggingface framework. All hyperparameters used are provided in the Appendix.

¹⁰This can happen if the training portion in a given fold does not contain sufficient essays on the same topic as the target essay.

5 Results

For both datasets, we adopted a regex-based method of extracting labels from the LLM’s output. Where the model’s output used made-up zone labels or where it did not produce the same number of labels as the number of input segments, we considered the output invalid and excluded it from evaluation.

Based on all test essays that yielded valid output, we evaluated model performance using standard multi-class classification metrics, viz. accuracy and average F1. For comparability, we follow Bai and Stede (2025) and used the *weighted* average F1 for GerTE; for FDE-Arg, we saw no justification for assigning frequency-dependent weights to the different content zones and therefore used the *macro* average F1.

Our experiment results are summarised in Table 4 for GerTE¹¹ and in Table 5 for FDE-Arg¹². Where cross-validation was used, the metrics are as averaged across all folds. The best-performance on either dataset by either model is printed in bold.

Our results reveal the following general trends: First, in line with expectations, the larger Llama model with 70 billion parameters consistently outperforms the smaller one. On GerTE, to which the larger model has not yet been applied, it achieves a weighted F1 of 0.79 under the best experimental condition (similarity-based six-shot prompting). This by far beats the hitherto highest F1 of 0.713, which is the performance of the best supervised model reported by Bai and Stede (2025), while requiring only six labelled essays. Moreover, with the same six-shot prompting scheme, the smaller Llama-8B model in fact also surpasses said supervised model, achieving an F1 of 0.73.

Second, confirming Bai et al. (2026)’s observations, zone extraction on FDE-Arg proves to be highly challenging, particularly for the smaller Llama-8B model. In fact, it produced invalid outputs for one-third to half of the test essays, and the labelling results on those that did receive valid outputs were consistently poor. Upon manual examination of the invalid outputs, we found that nearly all of them are cases of made-up labels that were simply not the ones that the model had been

¹¹Here, the results for the baselines using Llama-8B are taken from Bai and Stede (2025)’s original paper.

¹²Note that the baseline performance cannot be directly compared to the results in Bai et al. (2026) since their experiments only used 50 essays rather than our 100-sample FDE-Arg.

Figure 2: Ranking of candidate example essays for a given target essay based on semantic similarity.

	Llama-8B			Llama-70B		
	# invalid	Acc	F1 (w-avg)	# invalid	Acc	F1 (w-avg)
zero-shot (baseline)	12	0.654	0.641	1	0.736	0.731
zero + article (baseline)	8	0.673	0.661	0	0.755	0.745
one-shot (baseline)	10	0.661	0.649	0	0.751	0.743
zero + prompt addition (article + arguments)	8	0.686	0.672	0	0.776	0.77
one + prompt addition (article + arguments)	7	0.687	0.680	0	0.78	0.774
Similarity-based few-shot prompting						
$k = 1$	6	0.703	0.686	1	0.762	0.748
$k = 2$	7	0.707	0.691	0	0.766	0.751
$k = 4$	17	0.716	0.702	0	0.772	0.755
$k = 6$	9	0.742	0.73	0	0.8	0.79
$k = 8$	12	0.732	0.721	1	0.782	0.762
PEFT	2	0.635	0.638	-	-	-

Table 4: Content zone prediction results on GerTE in terms of accuracy (Acc) and weighted-average F1 (F1, w-avg). “# invalid” refers to the number of test essays which were excluded from evaluation due to invalid output.

instructed to use. The same behaviour of generating illegal labels is also observed with Llama-8B on GerTE, though much less frequently (see Table 4). Overall, the F1 scores achieved by Llama-8B should be interpreted with the number of invalid outputs in mind and are arguably less conclusive.

Finally, contrary to expectations, our fine-tuning experiments using QLoRA on Llama-8B did not bring about any improvements in terms of the chosen metrics. Our fine-tuned models performed near or even below the base models. We do observe, nonetheless, that on both datasets, the fine-tuning did lead the model to produce far fewer instances of invalid output. This is particularly true for FDE-Arg (see Table 5).

To illustrate common challenges in our task, Figure 3 shows the truth-normalised confusion matrices (values within rows add up to 1) for the best-performing model, which, for either dataset, is Llama-70B in a similarity-based few-shot prompt

scenario. The values are as averaged across all folds in cross-validation. For GerTE, “other” stands out as the most difficult class to recognise. As pointed out by Bai and Stede (2025), this is expected since it is both the least frequent label and a fuzzily defined fall-back class for all sentences that do not fit elsewhere. For FDE-Arg, confusion between “th1” and “th2” and, concurrently, between “pro” and “con” form the main challenges.

6 Discussion and Further Analysis

The focus of our experiments lies in exploring the three aforesaid strategies for improving LLM performance on the content zone prediction task. Based on our results, similarity-based few-shot prompting with approximately 6 to 8 labelled essays is particularly promising, showing the best prediction results on both datasets. This raises the question whether this success can be attributed to the sheer use of more example essays or to the

	Llama-8B			Llama-70B		
	# invalid	Acc	F1 (m-avg)	# invalid	Acc	F1 (m-avg)
zero-shot (baseline)	45	0.51	0.380	1	0.576	0.490

PEFT	6	0.547	0.408	-	-	-

Table 5: Content zone prediction results on FDE-Arg in terms of accuracy (Acc) and macro-average F1 (F1, m-avg). “# invalid” refers to the number of test essays which were excluded from evaluation due to invalid output.

Figure 3: Truth-normalised confusion matrices for the best-performing experimental setting on either dataset.

semantic similarity between example and target essays. To further examine this, we also experimented with k -shot prompting with *random* example selection. In this case, k examples are simply chosen at random from the set of candidate essays, viz. training essays that address the same topic as the target essay.

Appendix C provides the detailed F1 scores achieved by the models using randomly selected example essays, once again as averaged across all folds in cross-validation. Figure 4 graphically compares the F1 scores¹³ obtained in the similarity-based vs. the random few-shot prompting scheme. We have left out the performance of Llama-8B on FDE-Arg, where the large amounts of invalid outputs render the results inconclusive.

Overall, in both similarity-based and random few-shot prompting, an improvement of model performance can be observed with increasing numbers of examples k until it plateaus at approximately $k = 6$ or $k = 8$. While choosing examples based

on semantic similarity with target samples does not outperform choosing them randomly across all values for k , the similarity-based scheme is superior in the majority of the cases, especially with the application of Llama-70B to FDE-Arg. Moreover, across the board it is the similarity-based prompt setting that produces the best performance for a given model-dataset combination.

While not as effective as few-shot prompting, our experiments have also shown that adding task-relevant information to the prompt text can indeed benefit LLMs’ zone prediction performance. This is especially attractive since this strategy is highly cost-efficient, requiring neither significantly more computational resources (unlike PEFT) nor the availability of labelled training data. As shown by Table 4 and Table 5, in all of our experiments, the inclusion of our chosen additional information in the prompt text produced performance improvement compared to the baseline settings. The only exception here is that of Llama-8B on FDE-Arg, which, again, is less conclusive due to the abundance of invalid output. With respect to GerTE,

¹³Once again, *weighted-average* F1 for predictions on GerTE, *macro-average* F1 for those on FDE-Arg.

Figure 4: Graph representation of the F1 scores in the similarity-based (solid blue line) vs. the random (dashed orange line) k -shot prompting scheme.

the inclusion of our summary of the source article arguments primarily aims at improving the model’s performance on the classes “article_pro”, “article_con” and “own”. Similarly, the annotation guide-inspired additions to the prompt text for FDE-Arg have been designed to target correct prediction of the classes “cth”, “th1” and “th2”. Table 6 and Table 7 respectively show the class-specific F1 values as achieved by Llama-70B for the targeted classes in either dataset, contrasting the baselines with the settings including additional information in the prompt. It can be observed that the targeted classes have benefitted from the additions almost across the board.

Label	a_pro	a_con	own
zero (baseline)	0.788	0.701	0.766
zero + article + argument	0.869	0.777	0.772
one (baseline)	0.804	0.694	0.793
one + article + arguments	0.867	0.761	0.799

Label	cth	th1	th2
zero (baseline)	0.454	0.26	0.392
zero + “cth” clarification	0.496	0.27	0.444
zero + prediction steps	0.476	0.333	0.536
two (baseline)	0.561	0.522	0.618
two + “cth” clarification	0.554	0.532	0.639
two + prediction steps	0.576	0.557	0.657

Table 7: Llama-70B on FDE-Arg: Class-specific F1 for “cth”, “th1” and “th2” in selected experiment conditions.

Finally, as remarked in the previous section, fine-tuning using PEFT and QLoRA has not proved useful in our experiments. We do note, however, that both datasets we used are small for the purpose of model training, and that we have not performed any hyperparameter tuning. We therefore consider this result to be tentative and in need of further

experimentation.

7 Conclusion

We have introduced the novel German dataset FDE-Arg, which consists of 100 stand-alone argumentative essays by secondary school students and are annotated with a fine-grained set of argumentative content zones as developed by Bai et al. (2026). Using both FDE-Arg and source-dependent essays from the GerTE dataset, we applied two differently-sized Llama models to the task of predicting the argumentative content zones. While promising results could be obtained from the larger model, the smaller model struggled with the task, especially with the more challenging FDE-Arg dataset.

We further focused on three strategies for boosting model performance and found both the simple incorporation of additional, task-related information into the prompt text and few-shot prompting with approximately 6 to 8 labelled example instances to be effective. Moreover, choosing the examples based on semantic similarity with the target instance seems to be particularly promising. We could not observe any performance improvement through our current implementation of the fine-tuning approach using PEFT. However, FDE-Arg is gradually being expanded, and argumentative zone labels are being applied to a growing portion of the original FDE dataset. Therefore, we plan to revisit PEFT-based strategies in the future using significantly more labelled data and newer LLMs. Moreover, given the success of our similarity-based few-shot prompting scheme, we also plan to explore alternative ways to capture similarity between target and example instances in order to improve example selection for in-context learning.

Limitations

We acknowledge the following limitations in relation to our work: First, both datasets we used are rather small. GerTE contains 117 essays, while FDE-Arg contains 100. However, as mentioned in the main text, FDE-Arg is growing, and the original FDE dataset consists of 1,061 essays, which we plan to fully annotate with argumentative content zones within the next months. We are therefore confident that we will soon be able to elaborate on our experiments with more labelled data. Second, our experiments with PEFT have only been a first step, and we did not perform hyperparameter tuning. We plan to look more into fine-tuning-based approaches using LLMs once more training data from FDE-Arg are available. Finally, for now, with Llama 3 we have chosen a well-known but comparatively old LLM since our focus does not lie in comparisons between different LLMs. We do plan to repeat our experiments with more up-to-date LLMs in the future.

Acknowledgments

We thank the anonymous reviewers for their highly helpful comments and suggestions on the first draft of this paper. We are also grateful to Jun. Prof. Winnie-Karen Giera and her team for building the original FDE corpus and cooperating with us. Kemal Afzal and Dietmar Benndorf have made significant contributions to the annotation scheme for FDE-Arg. Part of the work reported here is funded by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) – 567969163.

A LLM Prompts

The following shows a baseline prompt used on FDE-Arg, featuring an authentic target essay from the dataset.

System prompt:

Du bist ein Deutschlehrer der 9. Klasse und analysierst argumentative Aufsätze deiner Schüler. Die Schüler schreiben den Aufsatz mit Bezug auf eine vorgegebene Streitfrage. Du überprüfst, wie der Aufsatz argumentativ aufgebaut ist.

User prompt:

Im Folgenden liegt ein Aufsatz vor. Der Aufsatz wurde in kleineren Einheiten wie Sätzen oder Phrasen unterteilt, die im folgenden zur Vereinfachung als 'Sätze' bezeichnet werden. Die Sätze sind nummeriert. Das Format dabei ist 'Satznummer: Satz'.
Entscheide zunächst, welche argumentative Gesamtkonstellation vorliegt:
'Entschieden' bedeutet: Der Aufsatz argumentiert für eine bestimmte Position des Autors.
'Unentschieden' bedeutet: Der Aufsatz bringt gleichberechtigt Argumente für beide Seiten der Streitfrage hervor. Der Autor entscheidet sich nicht für eine Position.
Analysiere die Funktionen der einzelnen Sätze. Dabei gilt eine grundlegende Unterscheidung zwischen der Funktion der These und der des Arguments: Eine These ist eine argumentative Position, die jemand einnehmen kann. Ein Argument ist ein Grund, der eine bestimmte These stützt oder angreift.
Jeder Satz im Aufsatz soll einer der folgenden 6 Funktionen zugeordnet werden:
'Zentrale_These' bedeutet: Der Satz beschreibt in einem entschiedenen Aufsatz die Kernposition

des Autors, oder er drückt in einem unentschiedenen Aufsatz explizit aus, dass der Autor sich nicht für eine Position entscheiden kann.

'These_1' bedeutet: Der Satz beschreibt in einem entschiedenen Aufsatz die Position, die mit der zentralen These übereinstimmt, oder er beschreibt in einem unentschiedenen Aufsatz die im Text erstgenannte Position.

'These_2' bedeutet: Der Satz beschreibt in einem entschiedenen Aufsatz die Position gegen die der zentralen These, oder er beschreibt in einem unentschiedenen Aufsatz die im Text später genannte Position.

'Pro_Argument' bedeutet: Der Satz beschreibt ein Argument, das These 1, also die Position des Autors in einem entschiedenen Aufsatz, stützt und bestärkt.

'Con_Argument' bedeutet: Der Satz beschreibt ein Argument, das These 2, also die Position gegen die des Autors in einem entschiedenen Aufsatz, stützt und bestärkt.

'Nicht_Argumentativ' bedeutet: Der Satz hat keine argumentative Funktion. Stattdessen gibt er zum Beispiel Hintergrundinformationen zum Thema, Anekdoten des Autors oder dient der Gliederung und der abschließenden Zusammenfassung des Aufsatzes.

Werte den Aufsatz aus und ordne jeden Satz einer der genannten 6 Funktionen zu. Das Format des Outputs soll ausschließlich wie folgt sein:

'Gesamtkonstellation

Satznummer: Funktion

Satznummer: Funktion'

, zum Beispiel

'Entschieden

1: Zentrale_These

2: Nicht_Argumentativ

3: Pro_Argument

4: These_1'.

Im Output sollen es neben der Gesamtkonstellation genauso viele Satznummer-Funktion-Paare geben wie es Sätze im Aufsatz gibt.

Schüleraufsatz

1: Was ist nun besser, Fast Food oder selbstgekochtes, gesundes Essen?

2: Immer öfter findet eine Diskussion zwischen den beiden Seiten statt, in der über die bessere Art von Essen debattiert, doch was ist nun besser?

3: Heutzutage konsumieren Kinder oder Teenager immer mehr Fast Food,

4: es ist schnell, günstig und lecker.

5: Dies stellt eine große Erleichterung für sie dar, wenn sie zum Beispiel nach einem stressigen Schultag schnell in ein Fast Food Restaurant gehen können und innerhalb kürzester Zeit ihr Essen vor sich stehen haben.

6: Jedoch kommen auch Argumente ans Licht die definitiv gegen eine solche Ernährung sprechen und eine gesündere Ernährung befürworten.

7: Aus diesem Anlass wird in dieser Erörterung über die positiven Seiten beider Essensarten, aber auch über ihre Probleme gesprochen.

8: Selbst gekochtes Essen ist viel gesünder

9: und besser als Fast Food,

10: da es eine bessere Essensqualität hat, das steht nicht zur Frage.

11: Man nimmt weniger Zusatzstoffe und Kalorien zu sich,

12: da man frische Sachen wie Gemüse verwendet.

13: Selbstkochen kann Spaß machen

14: und man findet vielleicht ein neues Hobby am Kochen,

15: doch auch Fast Food hat seine Vorteile.

16: Im Gegensatz zum selbstgekochten gesunden Essen, ist dieses günstiger und schneller,

17: fast immer schmeckt es einem

18: und nicht jeder hat noch Energie um nach einem anstrengendem Tag m Herd zustehen und zu kochen.

19: Fast Food findet man ja auch heutzutage überall, wenn man zum Beispiel in die Stadt geht um zu shoppen oder einkaufen zu gehen.

20: Alle Seiten haben ihre Vorteile aber auch Nachteile vorallem im Thema Gesundheit, wo frisch zubereitetes Essen auf jedenfall besser für den Körper ist doch man kann beide Seiten verstehen.

21: Zusammenfassend kan man sagen, dass Fast Food natürlich deutlich weniger Aufwand macht, zudem günstiger ist, aber auf eine gesunde Ernährung kann man nicht verzichten.

22: Meiner Meinung nach sollte man sich in der Mitte treffen.

23: Selbstgekochte, gesündere Sachen sind zwar besser und tragen zu einer guten Ernährung bei, aber man kann sich ab und zu einen Burger gönnen.

24: Doch übertreiben sollte man es nicht.

25: Zum Schluss lässt sich sagen, dass jeder das essen soll, was er/sie am besten für sich selber hält, aber eine gesunde Ernährung schaded nie.

The following shows a system prompt on GerTE with the added summary of source article arguments (see Section 4.2.1). The user prompt is the same as in the baseline prompt scenario.

Du bist ein Deutschlehrer der 9. Klasse und analysierst Aufsätze deiner Schüler. Du überprüfst dabei, ob die Aufsätze alle zu erwartenden Bestandteile enthält.

Hier ist der Lesetext, auf den der Aufsatz Bezug nimmt.

[FULL SOURCE ARTICLE TEXT]

Hier sind die Argumente, die im Lesetext vorkommen: Die Pro-Argumente sind folgende: Unterricht ist abwechslungsreicher.

Unterricht bleibt länger im Gedächtnis.

Nutzung von Twitter senkt die Hemmung vor aktiver Beteiligung am Unterricht.

Auch schüchterne Schüler:innen werden ermutigt, ihre Meinungen zu äußern.

Pädagogen raten zur Auseinandersetzung mit dem medialen Wandel.

Es gibt Erfolgsbeispiele für die Nutzung von Twitter im Unterricht, z.B. in den USA.

Angst vor Ablenkung ist nicht begründet, da auch Bücher ablenken können.

Laut Psychologen fördert das Internet die Gesprächskultur.

Die Con-Argumente sind folgende:

Schüler können leicht abgelenkt werden.

Viele Lehrer sind neuen Medienformen gegenüber skeptisch eingestellt.

The following shows the addition to the prompt text for FDE-Arg concerning the distinction between “cth” and “n-a” (see Section 4.2.2).

Manche Aufsätze enden mit einer knappen Zusammenfassung der Position des Autors, zum Teil etwas umformuliert. Sofern die zentrale These bereits woanders markiert wurde, wird dieser Abschlusssatz als Zusammenfassung des Aufsatzes gewertet und somit als “Nicht_Argumentativ” markiert. Gibt es hingegen an keiner anderen Stelle die zentrale These, so wird dieser Abschlusssatz als “Zentrale_These” markiert.

The following shows the addition to the FDE-Arg prompt text concerning the recommended prediction steps (see Section 4.2.2).

Bei der Zuordnung kannst du wie folgt vorgehen:

1. Finde die Kernaussage des Textes (“Zentrale_These”): Diese steht für sich selbst und kann prinzipiell an jeder Stelle des Textes stehen.
2. Finde weitere Thesen (“These_1” / “These_2”): Wenn der Text beide Positionen beleuchtet, unabhängig davon, ob der Autor sich letztendlich für eine Seite entscheidet, werden die beiden Positionen markiert.
3. Finde Argumente (“Pro_Argument” / “Con_Argument”): Argumente begründen die Thesen. Dabei können sie die Thesen direkt stützen oder ein anderes Argument und damit indirekt die Thesen stützen.
4. Markiere verbleibende Sätze (“Nicht_Argumentativ”): Alle Sätze, die zuvor nicht markiert wurden, haben keine argumentative Funktion.

B PEFT Hyperparameters

Hyperparameters for the PEFT-experiments on either dataset are given in Table 8. All parameters not mentioned in the table used the default values by HuggingFace.

C Few-Shot Prompting with Randomly Selected Examples

Table 9 and Table 10 give the experimental results on few-shot prompting using *randomly* selected example essays. All values are as averaged across all folds in cross-validation.

Multi-step Large Language Model for Fine-Grained Feedback in Stepwise Linear Equation Solutions

Imran Chamieh¹, Torsten Zesch², Klaus Giebertmann¹

¹Hochschule Ruhr West, Germany

²CATALPA, FernUniversität in Hagen, Germany

Abstract

This paper addresses the problem of fine-grained error classification in stepwise algebraic problem solving, with the objective of enabling precise and timely feedback in large-scale educational environments. Using authentic student data, we compare a carefully engineered rule-based baseline with large language models (LLMs) in zero-shot and few-shot configurations, as well as multi-step LLM-based approaches. We further consider hybrid architectures that combine symbolic computation with LLM-based reasoning. Our empirical results indicate that, although the baseline model delivers strong and reliable performance for narrowly defined error categories, the proposed multi-step LLM framework surpasses the rule-based model by achieving superior precision, F1 scores, and overall accuracy. These findings underscore the limitations of unstructured end-to-end prompting for error classification.

1 Introduction

Digital mathematics learning platforms routinely mark intermediate solution steps as correct or incorrect yet often fail to explain *why* a step is wrong. Whereas short feedback can lead the student to the correct solution. Consider the following example from Figure 1

$$\begin{aligned} S_2 : 6q - 4 &= 3 \\ S_3 : 6q &= 3 - 4 \end{aligned}$$

For a human instructor, it is readily apparent that the student made a sign error in the step S_3 by failing to change the sign of -4 when transposing it to the right-hand side of the equation. In conventional classroom settings, instructors typically identify such errors through detailed examination of students' solution processes and subsequently provide targeted, formative feedback. At a large scale, such

Figure 1: Example of binary error detection in an algebraic task. The system identifies incorrect steps but fails to provide explanatory feedback to the student.

as with intelligent tutoring systems (ITS), however, this process becomes increasingly difficult. ITS rely heavily on computer algebra systems (CAS) to verify whether a student's transformation is mathematically valid. While CAS reliably detects incorrect steps, it typically does not explain why a step is incorrect, so students receive binary correctness signals without diagnostic specificity, which lacks the useful feedback that allows students to self-correct their mistakes, as illustrated in 1. As a result, students may struggle to interpret their mistakes. In such cases, the educational value lies not in telling the student that the answer is wrong but in understanding *why*.

This paper examines the problem of fine-grained error classification in stepwise algebraic solutions, in contrast to the more conventional focus on assessing the correctness of complete solutions. We delineate a narrowly defined yet pedagogically meaningful error category that supports a direct mapping to targeted instructional feedback. Specifically, we address the detection of explicit algebraic sign errors ($+$ $\leftrightarrow$ $-$) in linear equations, using step-level interaction data collected from an intelligent tutoring system.

We formalize this construct as follows: given an initial algebraic equation S_i and the subsequent step S_{i+1} produced by a student, S_{i+1} is labeled True if and only if a sign inversion ($+ \leftrightarrow -$) is sufficient to render the transformation mathematically valid. In cases where multiple errors occur, the label is True if a sign inversion restores the mathematical validity of the affected term.

The central research question motivating this work is the following:

To what extent can different modeling paradigms reliably detect explicit algebraic sign errors at the step level in a manner that can be generalized to other error categories?

To address this question, we design an experimental framework that operationalizes the identification of explicit sign inversions in linear equations in accordance to the above definition. Within this framework, we compare three modeling approaches:

1. a **rule-based model** that explicitly enumerates valid algebraic transformations, matches them to student-generated steps, identifies the closest correct transformation, and then determines whether a sign error is present;
2. a **single-prompt LLM model** that frames sign-error detection as a zero-shot and few-shot classification task over (S_i, S_{i+1}) step pairs;
3. a **multi-step LLM pipeline** that decomposes the reasoning process into distinct stages (simplification, intent inference, and error classification), with each stage handled by a dedicated LLM or CAS component.

The final approach is structurally analogous to chain-of-thought reasoning in that it decomposes a complex decision into a sequence of specialized subtasks, thereby reducing the cognitive and computational burden on any single model invocation. Consequently, we refer to this configuration as a multi-step LLM pipeline composed of multiple specialized components, rather than a single monolithic prompt.

Our contributions are threefold:

1. We introduce a step-level dataset of annotated linear-equation transformations that specifically targets explicit sign errors¹.

2. We conduct a controlled comparison between symbolic (rule-based) and LLM-based methods for fine-grained algebraic error detection.
3. We propose a compositional, multi-step LLM framework designed to mitigate over-generalization and enhance diagnostic precision.

2 Related Work

Beyond the binary verification provided by standard CAS, the field has long pursued the automation of fine-grained diagnostic feedback through multiple technical paradigms. Early approaches focused on model tracing and symbolic reasoning, which depend on explicitly defined domain models to map student deviations against an “expert” path (Anderson et al., 1995). In contrast to generic computer algebra verification, these systems use expert-defined rules to infer which specific algebraic transformation a student likely attempted. Although such rule-based classifiers can attain high precision under controlled conditions (McTavish and Larusson, 2014), they are commonly constrained by a pronounced “authoring bottleneck” (Bent et al., 2019). Systematically encoding the full space of student misconceptions as rigid symbolic rules is highly labor-intensive and does not scale with increasing problem complexity or heterogeneity in student behavior.

With the advent of data-driven methodologies, researchers address the limitations of manual rule engineering by adopting supervised learning-based classifiers trained on labeled student solutions. Recent work ranges from statistical diagnostic models for algebra misconceptions, like McNichols et al. (2023) works, to neural architectures that categorize fine-grained algebraic error types from stepwise solutions or written responses (Gomes and Jaques, 2020; Russell et al., 2009; Kirve et al., 2025). While these models reduce the inflexibility associated with rule-based systems, they function as “black-box” predictors and require substantial quantities of labeled training data. This requirement poses a significant limitation in contexts involving rare or highly specialized mathematical misconceptions, for which annotated corpora are typically scarce.

Recent advancements in LLMs have introduced a new paradigm, offering a balance between the structured reasoning capabilities traditionally associated with symbolic systems and the flexibility

¹<https://github.com/Imrancham/Step-Level-Error-Detection-in-Linear-Equations>

ID	S_i	S_{i+1}	Sign Error
1	$6q - 4 = 3$	$6q = 3 - 4$	True
2	$6q - 4 = 3$	$6q = -1$	False
3	$5x + 5 = x - 1$	$4x = 4$	False
4	$y + x = -x + 2$	$y = 2$	False
5	$q(h - y) = 0$	$qh + qh = 0$	True
6	$2a + 4 = 0$	$2x = -4$	False
7	$-3(x - 1) = 0$	$-3x = 3$	True
8	$x + 2 = 3$	$x = 5$	False

Table 1: Sample of equation pairs (S_i, S_{i+1}) that have different error types.

of data-driven models, while reducing the need for the huge datasets typically required by purely data-driven systems. McNichols et al. (2024) investigated the zero-shot diagnostic capabilities of LLMs such as GPT-4 in educational contexts. A recurring observation in this literature is the presence of a “precision gap” namely, the tendency of LLMs to overgeneralize when fine-grained diagnostic specificity is needed (Chamieh et al., 2024). Our work addresses this by moving away from unstructured, end-to-end prompting toward a multi-step framework that reintroduces symbolic-like rigor into the multi-step LLM process.

3 Dataset

The dataset described in this study was collected from a digital mathematics learning platform used in undergraduate engineering courses at Hochschule Ruhr West (Ruhr West University of Applied Sciences). Approximately 144 first- and second-semester students used the platform as part of mandatory mathematics courses. The platform generates individualized exercises using parameterized mathematical templates and records student solutions at the step level. Whenever a submitted step does not follow validly from the preceding one, the system stores a record comprising the previous equation (S_i) and the student’s produced next step (S_{i+1}). Although the platform detects the occurrence of an error, it does not provide a classification of the underlying error type and, hence, no targeted feedback.

3.1 Data Filtering and Annotation

Since the winter semester of 2022/23, 49,661 incorrect solution steps have been collected. These range from basic arithmetic slips to complex conceptual errors in trigonometry or calculus. For the purposes of the present study, we restrict our focus to linear equations. We filtered the raw logs to exclude entries containing non-linear terms (e.g.,

higher-degree polynomials, square roots, or variables in denominators), resulting in a subset of 4,024 equation pairs.

Each pair (S_i, S_{i+1}) was manually annotated by a domain expert actively involved in teaching the corresponding courses, with a binary label indicating the presence (True) or absence (False) of an **explicit sign error**.

Note that, according to our definition of sign error in the introduction, we exclude arithmetic mistakes in which a student carries out a numerical computation incorrectly while otherwise maintaining valid algebraic reasoning. For instance, in the second example in Table 1, the step $S_{i+1} : 6q = -1$ is not classified as a sign error, because no single modification of a sign would convert the transformation into a correct one, even though the incorrect result stems from an erroneous evaluation of $3 - 4$, in which the term -4 appears with an incorrect sign. In contrast, in the first example in Table 1, the step yielding $S_{i+1} : 6q = 3 - 4$ is categorized as an explicit sign error, since changing the minus in -4 to a plus would render the equation correct. Overall, there are 780 of the annotated instances that exhibit such explicit sign errors, which makes approximately 19%.

3.2 Dataset statistics

Figure 2 provides a visualized distribution of the dataset. We observe that student-produced equations S_{i+1} are, on average, shorter than the source equation S_i , reflecting term aggregation during manipulation. A slight increase in the number of distinct variables is observed in S_{i+1} , can be seen in the Figure 2 on the right, primarily due to handwriting-recognition artifacts (e.g., confusion between α and a , ω and w , or 0 and o).

4 Experimental Setup

This section describes the models and configurations used to identify explicit sign errors in step-wise linear equation transformations. Figure 3 provides an overview of the processing pipeline shared across approaches.

Models Evaluated To ensure our findings generalize across different architectures, we evaluate both commercial and open-weight large language models across all single-step and multi-step configurations. We consider the following models: gemini-2.5-flash, gpt-5-mini, mistral-large-latest, and Llama-3-70b.

Figure 2: Distributional statistics for the dataset

Models are accessed via their respective APIs using default decoding parameters (temperature and sampling). Llama-3-70b is additionally evaluated locally on a machine equipped with 8 NVIDIA Quadro RTX 8000 GPUs, using the same generation settings to mirror the API configuration. To mitigate run-to-run variability inherent in generative models and to ensure stable performance estimates, all LLM-based experiments are repeated five times, and we report the mean and standard deviation performance across these runs.

4.1 Rule-Based Baseline

We implement a rule-based model as a high-precision and fully interpretable baseline for sign error detection. Rule-based systems allow explicit control over error definitions and decision criteria, which is particularly important in educational feedback settings where false positives can negatively affect student trust. This model also serves as a reference point for evaluating the behavior of LLM-based approaches. The pipeline consists of three steps.

Transformation Enumeration Given an initial equation S_i , we construct a transformation tree that enumerates all possible subsequent algebraic operations, including term transposition, coefficient normalization via division, distribution, and progressive variable isolation. Each node in this tree corresponds to an equation that is algebraically equivalent to S_i ; see Figure 4. This procedure establishes the foundation for inferring student intent by enabling the identification, in a subsequent stage, of the equation that is most similar to the

student’s produced step.

Similarity Matching. To approximate the student’s intended transformation, we compute a similarity score between the student’s equation S_{i+1} and each equation in the transformations tree. Prior to comparison, equations are represented in two normalized forms: (i) a structural form derived from SymPy’s internal expression representation and (ii) a canonical string form obtained by rewriting equations into a normalized representation (e.g., $a = b \rightarrow a - b = 0$). For each representation, similarity is computed using Python’s SequenceMatcher, based on the Ratcliff–Obershelp algorithm [Ratcliff et al. \(1988\)](#), which estimates the degree of overlap between two string representations by identifying matching subsequences. The final similarity score is obtained as a weighted combination of the similarity scores computed over the structural and canonical representations. These weights are fixed across all experiments. The candidate transformation with the highest combined similarity score is selected as the reference equation.

Sign Error Detection Finally, we compare S_{i+1} against the selected reference equation term by term. Matching terms are removed, and remaining terms are inspected for sign inversion. If a term in S_{i+1} differs from its counterpart in the reference equation only by the sign attached to that term, and flipping this sign would make the step valid, the pair (S_i, S_{i+1}) is classified as containing an explicit sign error.

Figure 3: Comparative architecture of three diagnostic approaches—rule-based, multi-agent LLM, and prompt-based LLM—designed to identify sign errors by evaluating student input S_1 against the preceding step.

Figure 4: Tree-structured graph depicting the sequence of derived equation transformations, with the corresponding operations explicitly annotated at each transformation step.

4.2 Single-Step LLM

In the single-step paradigm, we evaluate the models as direct sign error classifiers under two distinct settings: zero-shot and few-shot. Each model receives the equation pair (S_i, S_{i+1}) along with a prompt defining explicit versus implicit sign errors in accordance with our annotation scheme. The models are instructed to output a binary decision (True or False) indicating the presence of an explicit sign error.

Prompt Engineering We experiment with multiple prompt variants that describe the task and define the notion of the explicit sign error, including different numbers of labeled examples. These prompt variants are evaluated on a subset of 200 examples of the data for each model, and we select a single best-performing prompt that is then used for all

reported results.

Output Normalization LLMs occasionally produce explanatory text, despite being instructed to output only True or False. We therefore post-process outputs using simple regular expressions to extract the final binary decision.

4.3 Multi-Step LLM

To address the precision limitations and overgeneralization observed in the single-step paradigm, we hypothesize that decomposing sign-error detection into a sequence of focused subtasks improves diagnostic reliability. Rather than relying on a single model invocation to simultaneously perform mathematical simplification, intent inference, and error classification, we distribute these operations across distinct components with structured input–output contracts. We evaluate three variations of this multi-step architecture:

1. Three-Step Pure LLM Pipeline This configuration relies entirely on LLMs for all operations:

- **Step 1 (Canonical Simplification):** An LLM agent simplifies both the original equation S_i and the student equation S_{i+1} into canonical forms by combining similar terms. Where applicable, it also computes the correct final solution for S_i .
- **Step 2 (Intent Inference and Correct Transformation):** A second LLM receives the raw and simplified forms of both equations. It infers the student’s intended algebraic operation

(e.g., transposing a term) and applies it correctly to S_i to generate a “gold” intermediate equation. It also flags cases where the student’s canonical form deviates substantially from expectations, signaling non-sign-related errors (e.g., summation errors).

- **Step 3 (Sign-Error Classification):** A final LLM agent compares the student’s raw equation with the “gold” intermediate equation from Step 2, determining if the discrepancy is strictly a single-term sign flip.

2. Hybrid CAS-LLM Pipeline To evaluate the benefit of integrating deterministic mathematical tools, this variant replaces the generative simplification step with a CAS tool. We utilize SymPy to programmatically simplify S_i and S_{i+1} and compute the correct final solution. The CAS-generated symbolic representations are then fed directly into the second step for Intent Inference and Classification in step 3, functioning exactly as described in the pure LLM pipeline.

3. Two-Step LLM Pipeline To determine whether canonical simplification is strictly necessary for accurate classification, this ablation omits Step 1 entirely. The raw equations (S_i, S_{i+1}) are passed directly to an LLM for Intent Inference to generate the “gold” intermediate step, followed immediately by the Sign-Error Classification step.

4.4 Evaluation Metrics

All models are evaluated using standard binary classification metrics, including precision (P), recall (R), F1-score (F1), and accuracy (Acc). Following common practice in educational error diagnosis, we place particular emphasis on precision, since incorrectly flagging correct solution steps or providing wrong feedback is undesirable in instructional settings. For all non-deterministic models (LLMs), reported metrics correspond to the mean over five independent runs.

5 Results and Discussion

Table 2 summarizes the performance of the rule-based baseline, the single-step LLM configurations (zero-shot and few-shot), and the proposed multi-step LLM framework for detecting explicit sign errors.

Overall Performance. The rule-based system constitutes a strong and well-balanced baseline

Table 2: Performance comparison of rule-based, prompt-based, and multi-agent models for sign error detection.

($P = 0.84$, $R = 0.82$, $F1 = 0.83$, $Acc = 0.93$), demonstrating that symbolic approaches remain highly effective when the target error category is narrowly specified and closely aligned with a fixed set of transformation rules.

Among all evaluated approaches, the highest-performing models are the **three-step LLM configurations**, in particular GPT and Gemini, which achieve performance comparable to, and in some cases marginally surpassing, the rule-based system. Gemini attains the highest overall scores ($P = 0.93$, $F1 = 0.85$, $Acc = 0.95$), while GPT exhibits similarly strong performance ($P = 0.85$, $F1 = 0.83$, $Acc = 0.94$). These findings suggest that decomposing the task into structured intermediate steps substantially enhances LLM performance relative to single-pass inference.

Zero-shot, Few-shot, and Multi-Step LLMs:

Across all models, zero-shot and few-shot prompting display a consistent precision-recall trade-off, characterized by high recall but comparatively low precision. This pattern indicates that LLMs tend to over-predict sign errors when guided solely by

prompt-based conditioning, pointing to a misalignment between natural language-based reasoning and the formal definition of explicit sign errors.

The introduction of structure via multi-step decomposition fundamentally alters this behavior. Although two-stage pipelines remain unstable, three-step architectures systematically enhance the balance between precision and recall. This pattern indicates that an explicit factorization of the overall task into sub-components—such as simplification, intent inference, and classification—is crucial for aligning model predictions with well-defined formal error categories.

Importantly, augmenting the pipeline with a CAS component does not yield consistent performance gains, suggesting that the primary bottlenecks are not computational in nature but instead arise from difficulties in interpreting and propagating intermediate representations. Collectively, these results indicate that *structured reasoning, rather than the provision of additional training examples or external computational resources, constitutes the principal driver of the observed performance improvements.*

Comparison with Rule-Based Approach:

While the rule-based system remains a strong baseline, the proposed multi-step LLM framework exhibits several distinct advantages. First, it attains comparable or marginally superior peak performance without dependence on manually crafted transformation rules. Second, it exhibits more robust generalization to a broader spectrum of transformation patterns, including those not encountered during development, whereas the rule-based system is intrinsically constrained by its fixed, predefined transformation hierarchy.

Crucially, the multi-step framework mitigates the systematic over-prediction characteristic of single-step LLMs by imposing intermediate structural constraints, thereby yielding more accurate and calibrated classifications. This finding indicates that explicit structured reasoning—rather than model scale alone—is a key factor in aligning LLM outputs with formally specified error taxonomies.

5.1 Error Analysis

Misclassifications across all approaches can be attributed to three primary sources: structural mismatch, intent ambiguity, and output-format inconsistency.

For the **rule-based system**, errors arise when the

Figure 5: F1 scores across different equation length bins (Short, Medium, and Long).

similarity function fails to align a student’s transformation with any rule present in the transformation tree. For instance, consider the transition,

$$\begin{aligned} S_i : \quad -4t &= 1 - 5y \\ S_{i+1} : \quad t &= (5y + 1)/4 \end{aligned}$$

which is erroneously matched to,

$$best_match : y = (4t + 1)/5,$$

thereby resulting in an incorrect classification.

In the **multi-step architecture**, errors are primarily driven by difficulties in reliably inferring the student’s underlying intent, particularly when the observed transformations deviate substantially from expected intermediate forms or involve several implicit operations. For instance:

$$\begin{aligned} S_i : \quad z &= -10(x - 2) + 11(y + 1) - 21 \\ S_{i+1} \quad 10 &= -10x + 11y \end{aligned}$$

In this case, the model assigns a coarse-grained intent category (distribution and simplification) but fails to correctly classify the step due to the omission of the variable z and the substantial structural divergence between the two expressions.

For **single-step LLMs**, the dominant source of error is a discrepancy between the model’s internal reasoning and the strict operational definition of explicit sign errors. The models frequently produce correct mathematical interpretations but fail

to assign the corresponding label. For example:

$$\begin{array}{ll} S_i : & -2p - 2 = 10 \\ S_{i+1} : & p = 6 \end{array}$$

GPT response: *"No — explicit sign error: False. Reason: The correct solution is $p = -6$, and the student wrote $p = 6$. That is a wrong final sign but no incorrect sign operation is shown in the student's work."*

Although the model correctly infers that the mathematically valid solution is $p = -6$, it classifies the step as not containing an explicit sign error because no explicit sign manipulation is syntactically present in the student's work.

Open-Weight vs. Commercial Models: Open-weight models like Mistral and LLaMA often struggle to follow strict output formats, tending to produce free-form explanations instead of schema-compliant labels. This makes automatic parsing harder, complicates integration with downstream components, and can hurt overall pipeline performance. For instance, a typical LLaMA reply might say: *"The student's final simplified value has a sign error compared to the correct final value..."*. Although this is semantically correct, its unstructured form makes it difficult to automatically extract the underlying error category (e.g., a sign error). In contrast, commercial systems such as GPT and Gemini more reliably follow predefined schemas and generate structured, machine-interpretable outputs, which simplifies parsing and limits error propagation throughout the pipeline.

Impact of Equation Length: Equation length exerts a systematic negative effect on performance: all models do very well on short equations, begin to diverge on equations of medium length, and drop sharply on long equations (Figure 5). Rule-based methods and multi-step LLM approaches maintain relatively high accuracy on equations of medium length; however, all models struggle with long equations, where their performance converges and single-step LLMs are particularly impaired. These findings suggest that the increased compositional complexity associated with longer equations poses a specific challenge for single-step inference. Although multi-step reasoning strategies mitigate this effect to some extent, they do not fully resolve the underlying difficulty.

5.2 Summary

The results show that structured multi-step LLM systems can combine rule-based reasoning with generative flexibility to achieve higher precision and better performance by breaking tasks into sub-tasks and enforcing explicit structure on outputs. However, they still struggle with complex transformations, clarifying ambiguous student intent, and consistently following strict output formats, especially for open-weight models.

6 Conclusion and Future Work

In this study, we investigate the application of LLMs in various configurations for the detection of explicit sign errors in linear equation solving, with the objective of enabling accurate and timely feedback in large-scale educational environments. Using authentic student response data, we compare a carefully engineered rule-based baseline against zero-shot, few-shot, two-step, and three-step LLM-based pipelines, as well as hybrid variants augmented with CAS.

Our findings indicate that although the rule-based system constitutes a strong baseline, structured multi-step LLM approaches improve performance relative to single-step methods. In particular, three-step pipelines achieve the highest overall effectiveness, yielding a favorable balance between precision and recall and matching or surpassing the performance of the rule-based approach. In contrast, two-step pipelines exhibit instability, underscoring the importance of sufficient task decomposition. The integration of CAS results in only modest performance gains, suggesting that the primary challenges are rooted in reasoning and representation rather than in symbolic computation.

Future research will aim to generalize the proposed framework to encompass a wider spectrum of algebraic error categories and to address more structurally complex mathematical domains. Furthermore, we intend to systematically investigate hybrid architectures that more tightly integrate symbolic verification mechanisms with LLM-based inferential processes, with particular emphasis on enhancing the robustness and faithfulness of intermediate representations and mitigating error propagation across successive stages of the computational pipeline.

7 Limitations

This study is restricted to the detection of explicit algebraic sign errors occurring during transformations of linear equations, which limits the generalizability of our findings to other procedural errors commonly observed in student work, as well as to the treatment of more complex algebraic expressions that do not share the structural simplicity of linear equations. Extending the framework to additional error types would require corresponding modifications to the proposed multi-step architecture to handle a broader range of algebraic transformations. From a technical standpoint, we employed an identical prompt across all models while acknowledging that each model possesses distinct characteristics and prompt-sensitivity profiles. These model-specific properties may have influenced their respective outputs and, consequently, could have impacted the comparability of the results.

8 Ethics

This study utilizes screenshots of student solution steps, specifically those containing errors, collected from a digital mathematics learning platform. All data were fully anonymized prior to analysis, and no personally identifiable information was accessible to the authors at any stage of the study. All participating students provided informed consent via the platform's data usage agreement, permitting the use of their anonymized solution data for research purposes.

9.2 Prompt Examples

Prompt 1:

Detect whether there is an EXPLICIT sign error.
Explicit = wrong +/- is written.
Other = No Explicit sign error appears.
Original: {t0}
Student: {t1}
Explicit Sign Error: True/False

Prompt 2:

You are an expert at detecting sign errors in algebra.
A sign error is TRUE only if an incorrect sign (+ or -) is explicitly written.
Examples:
Original: $x + 5 = 15$
Student: $x = 15 + 5$
Explicit Sign Error: True
Original: $x + 5 = 15$
Student: $x = 20$
Explicit Sign Error: False
Now evaluate:
Original: {t0}
Student: {t1}
Explicit Sign Error: True or False

Prompt 3:

You are an expert at detecting sign errors in mathematical expressions.
Affirm whether there is a sign error in the student's work or not.
A sign error is TRUE only when the student's written work shows an incorrect sign for a variable or numeric (+ instead of -, or vice versa).

EXPLICIT vs IMPLICIT:

- EXPLICIT (TRUE): Original " $x + 1 = 2$ " Student writes " $x = 2 + 1$ " when it should be " $x = 2 - 1$ " → wrong sign is visible
→ sign error: TRUE
- IMPLICIT (FALSE): Original " $x + 1 = 2$ " Student writes → " $x = 3$ " when answer is 1 → might be sign error mentally, but no sign is shown → sign error: FALSE Example:

Original: $x + 5 = 15$
Student: $x = 15 + 5$
Explicit Sign Error: True
Implicit Sign Error: False

Original: $x + 5 = 15$
Student: $x = 20$
Explicit Sign Error: False
Implicit Sign Error: True

Original: $-(3x + 4) = 12$
Student: $-3x - 4 = 12$
Explicit Sign Error: False
Implicit Sign Error: False Does the following transformation contain an explicit sign error?

Original: t0
Student: t1

Prompt 4:

You are an expert at detecting sign errors in mathematical expressions. Affirm whether there is a sign error in the student's work or not. A sign error is TRUE only when the student's written work shows an incorrect sign for a variable or numeric (+ instead of -, or vice versa).

EXPLICIT vs IMPLICIT:

- EXPLICIT (TRUE): Original " $x + 1 = 2$ " Student writes " $x = 2 + 1$ " when it should be " $x = 2 - 1$ " → wrong sign is visible
→ sign error: TRUE

- IMPLICIT (FALSE): Original " $x + 1 = 2$ " Student writes → " $x = 3$ " when answer is 1 → might be sign error mentally, but no sign is shown → sign error: FALSE

Example:

Original: $x + 8 = 15$

Student: $x = 15 + 8$

Explicit Sign Error: True

Probability of an Explicit Sign Error: 100

Original: $-(3x - 4) = 12$

Student: $-3x - 4 = 12$

Sign Error: True

Probability of an Explicit Sign Error: 100

Original: $-(3x + 4) = 12$

Student: $-3x - 4 = 12$

Sign Error: False

Probability of an Explicit Sign Error: 1

Does the following transformation contain an explicit sign error?

Original: $\{t0\}$

Student: $\{t1\}$

9.3 Multi-Step Prompts

Step 1:

You are a math simplification agent. Your task is to mathematically simplify and canonicalize two equations.

ORIGINAL_EQUATION: "{original_eq}" STUDENT_EQUATION: "{student_eq}"

1. Combine all like terms (variables and constants) in the ORIGINAL_EQUATION to produce a canonical form.

2. Do the same for the STUDENT_EQUATION.

3. If the ORIGINAL_EQUATION can be fully solved, calculate the correct final value.

Respond with JSON in this exact format:

```
{ { "original_simplified": "canonical form of original", "student_simplified": "canonical form of student",  
  "original_final_value": "final value if solvable, or 'unsolvable'" }
```

Step 2:

You are an equation transformation agent. Your task is to infer the single logical step the student was attempting.

ORIGINAL_EQUATION: "{original_eq}"

STUDENT_EQUATION: "{student_eq}"

1. INFER INTENT: Describe the single major step (e.g., 'Transposing $3x$ to the RHS', 'Distributing -5 ').

2. PERFORM CORRECT TRANSFORMATION: Apply the inferred intent correctly to the ORIGINAL_EQUATION.

3. CHECK FOR PRE-EXISTING ERRORS: Compare canonical forms:

- Original Simplified: '{simplified_data.original_simplified}'

- Student Simplified: '{simplified_data.student_simplified}'

If the student's canonical form is radically different (indicating severe error like incorrect summation), set 'pre_existing_summation_error' to true.

Respond with JSON in this exact format:

```
{ { "student_intent": "description of intended operation",  
  "correct_intermediate_eq": "correct result of that operation",  
  "pre_existing_summation_error": true or false }
```

Step 3:

You are the final error classification agent. Isolate a single explicit sign error by comparing the correct transformation result with the student's actual result.

1. CORRECT INTERMEDIATE EQUATION (Target): "{correct_intermediate_eq}"
2. STUDENT'S RAW EQUATION: "{student_eq_raw}"
3. STUDENT'S SIMPLIFIED EQUATION: "{simplified_data.student_simplified}"
4. CORRECT FINAL VALUE: "{simplified_data.original_final_value}"
5. PRE-EXISTING SUMMATION ERROR: {transform_data.pre_existing_summation_error}

Classification Logic:

****Single Sign Flip Check:****

- Check if STUDENT'S RAW EQUATION could be made identical to CORRECT INTERMEDIATE EQUATION by flipping the sign of ONLY ONE TERM. Set 'is_single_flip_correction_possible' accordingly.

****Rule 1: Implicit/Summation Errors**** - IF PRE-EXISTING SUMMATION ERROR is True OR

is_single_flip_correction_possible is False:

- Set error_type='Summation_Error'

- Set is_error_in_intermediate_step=True

- Set error_found=False

****Rule 2: Explicit Sign Errors****

- ELSE (Single flip is True AND No pre-existing summation error):

- Set error_found=True

- Find the single sign-flipped term

- Determine if error was due to Transposition (moving term across '=') or Distribution (expanding parentheses)

- Set is_error_in_intermediate_step=False

****Rule 3: Arithmetic Simplification**** - If not Transposition/Distribution/Summation, check if student's final simplified value has a sign error compared to correct final value and classify as 'Arithmetic_Simplification'.

Respond with JSON in this exact format:

```
{ { "error_found": true or false,
  "error_type": "Transposition" or "Distribution" or "Arithmetic_Simplification" or "Summation_Error" or "None",
  "is_single_flip_correction_possible": true or false,
  "is_error_in_intermediate_step": true or false,
  "original_term": "term that was handled incorrectly",
  "correct_sign": "sign it should have",
  "student_sign": "sign student used",
  "reasoning": "explanation of classification"
}
```

Quality-Conditioned Agreement in Automated Short Answer Scoring: Mid-Range Degradation and the Impact of Task-Specific Adaptation

Abstract

Automated short answer scoring (ASAS) is shifting from discriminative, fine-tuned models to large language models (LLMs) used in few-shot settings. This paradigm leverages LLMs' broad world knowledge and ease of deployment, but limited task-specific data may reduce alignment on complex scoring tasks. In particular, its impact on scoring partially correct responses that require nuanced interpretation remains underexplored. We investigate the relationship between the degree of task-specific adaptation of different models and quality-conditioned scoring agreement. We compare three LLMs (GPT-5.2, GPT-4o, Claude Opus 4.5) in few-shot mode, a fine-tuned BERT-based encoder, and a human expert on two open-ended biology items, using several hundred student responses and ground truth scores provided by a biology education expert. The results show that human-human agreement is highest and stable across the full quality spectrum. All AI models perform well on fully correct and fully incorrect responses, but exhibit substantial degradation on mid-range responses. This mid-range degradation is conditioned on task-specific adaptation: It is most severe in few-shot LLMs with few examples and decreases as task-specific data increases, with fine-tuned encoder models performing best. This mid-range degradation may lead to inequitable evaluation of responses produced by students with developing understanding. Our findings highlight the importance of quality-conditioned fairness, with particular attention to mid-range responses.

1 Introduction

Automated short answer scoring (ASAS) of open-ended responses is a central application of natural language processing (NLP) in education (Bonthu et al., 2021; Haller et al., 2022). ASAS approaches can be classified into reference-based – scoring based on similarity to reference graded responses –

and example-based, where the model learns to map student responses to rubric scores using task-specific labeled data. The fundamental trade-off is that reference-based approaches require only a few scored examples but their accuracy is typically very limited (Bexte et al., 2023), while example-based ones can reliably learn to mimic expert grading but require ample training data (Gurin Schleifer et al., 2023) and are still prone to gaming (Ding et al., 2020).

Early example-based systems relied on hand-crafted linguistic features and machine learning models to approximate human scoring (Haller et al., 2022). More recent work has leveraged neural machine learning that can capture deeper semantic relationships in student responses. Such neural-based automated assessment systems primarily relied on discriminative machine learning implemented on top of encoders that transferred raw responses into vectorized embeddings (Condor, 2020; Li et al., 2021; Gurin Schleifer et al., 2023).

The emergence of generative LLMs introduced a new paradigm for ASAS. Decoder-based language models can evaluate student responses based on their extensive pretraining and general world knowledge, relying on instructions to guide in-context interpretation (e.g., according to given rubrics), rather than on adapting their parameters using task-specific datasets (Lin et al., 2023).

However, because generative models are not explicitly trained on the application of a specific assessment framework to student responses, their scoring may be less aligned with expert grading, particularly in assessment contexts that have domain-specific standards and require subtle interpretation (Wu et al., 2025; Yacobson et al., 2025). Few-shot prompting, which is a prompting strategy that provides a few labeled examples, was developed to help the model align its interpretation with that of experts (Lin et al., 2023). This raises the question of the amount of task-specific data that

various types of architectures require to align with expert grading.

The alignment of automated scoring systems with human grading is typically evaluated using metrics like κ or Pearson's correlation between model predictions and human raters (Beigman Klebanov and Madnani, 2022; Williamson et al., 2012). That said, it is also recognized that overall scoring accuracy may not be sufficient for validating an automated scoring system, as its performance can vary systematically across student sub-populations, raising fairness concerns (Williamson et al., 2012). While the psychometric theory discusses sub-populations to be examined quite generally, e.g., as “identifiable and relevant” subgroups (Xi, 2010), much of the literature on fairness in educational AI tends to focus on demographics-based sub-groups (Loukina et al., 2019; Madaio et al., 2022) and on high-stakes, large-scale assessment (Johnson and McCaffrey, 2023). Discussing fairness in the formative classroom assessment specifically, Camilli (2006) noted that the use of the assessment is generally “to ‘locate’ the presenting proficiencies of students in order to guide instruction along the contours of their strengths and weaknesses”, and help instructors “see if there is anything that, if not addressed, sets certain students up to fail or otherwise miss significant opportunities to learn” (p. 248). To help provide the right learning opportunities for learners at different current states of knowledge, these states of knowledge need to be detected accurately and equitably, as otherwise students whose knowledge state tends to be mis-recognized would be in danger of being provided inappropriate learning support.

In the recent literature on automated analysis of student responses, there are indications that states of partial knowledge may be harder to detect automatically than completely correct knowledge states (Gurin Schleifer et al., 2025; Kortemeyer, 2023) or than both completely correct and completely incorrect ones (Grévisse, 2024). In such cases, students demonstrating partial mastery of a concept (mid-range responses) may receive less reliable evaluation than those whose responses are clearly correct or clearly incorrect. We refer as “quality-conditioned fairness” to the requirement that ASAS system performs equally well across the entire range of response quality.

Due to the nuanced interpretation required for mid-range responses, we expect that task-specific labeled data will be particularly important for AI

grading systems when grading such answers, and that its quantity will be associated with the systems' accuracy on these responses.

However, little is known about agreement patterns across the response quality spectrum, and how this relates to model architectures – encoder-based discriminative models and decoder-based generative ones – and across different levels of task-specific adaptation (few-shot with varying levels of ‘few’, and fine-tuning). Thus, our research is guided by the following research question:

RQ: *What is the association between response quality and inter-rater agreement for human-human vs human-AI pairings for different levels of task-specific adaptation of the AI models? (few-shot with different numbers of examples vs fine-tuned)?*

The data used for this study included responses from about 800 high-school students to two open questions in biology requiring students to provide scientific explanations in the domain of cellular respiration. The responses were graded according to an analytic grading rubric by two biology education experts. To answer the RQs, we compared three generative decoder-based models in a variety of few-shot modes, a discriminative fine-tuned encoder model and a human grader in terms of their agreement with the expert human grader overall and across different levels of response quality.

Previewing the results, we show that disagreements between human and AI raters concentrate among mid-quality responses, while agreement remains high at the extremes of the quality spectrum. They also demonstrate a consistent pattern of **mid-range degradation of AI scoring accuracy**, meaning that AI graders, but not the second human expert grader, tended to be less aligned with the expert on the mid-range responses, and that this tendency was partially mitigated as the AI system received more task-specific data.

These findings highlight the importance of task-specific adaptation for accurately evaluating partially correct responses and suggest that evaluation frameworks for AI-assisted assessment should explicitly consider quality-conditioned, and specifically mid-range, assessment fairness.

2 Related Work

Fine-tuning the parameters of the model on task-specific data is a common technique for adapting encoder-based pre-trained language models such

as BERT (Devlin et al., 2019) to the given task. The more recent models, while still utilizing the Transformer architecture, use orders of magnitude more parameters (hence their designation as *large* language models, or LLMs), and demonstrate in-context learning, namely, the ability to perform well on tasks that the model has not been trained for with only a small number of examples (few-shot). While larger models generally demonstrate stronger in-context learning, empirical studies suggest that parameters other than size, such as the design of the prompt, the model architecture, the diversity of the training data, and the selection of the few-shot examples can impact the model's in-context learning ability (Berti et al., 2025).

A number of studies compared the performance of fine-tuned encoders and few-shot LLMs on ASAS. Chamieh et al. (2024) evaluated ASAS performance on datasets from various domains, including mathematics, science, and English language arts. They found that fine-tuned models generally performed better, especially for tasks that require more complicated reasoning or domain-specific knowledge. Kortemeyer (2024) compared the performance of GPT-4, BERT, and RoBERTa-large (Liu et al., 2019) on ASAS datasets in varied science domains. They found that the fine-tuned BERT and RoBERTa-large outperform the general-purpose GPT-4 LLM. Henkel et al. (2024) found that few-shot models outperformed zero-shot ones in the context of ASAS, suggesting that more task-specific information may help improve scoring performance. Ferreira Mello et al. (2025) studied ASAS in English in the context of undergraduate computer science and in Brazilian Portuguese in 8th grade biology and found that fine-tuned BERT models outperformed few-shot GPT-4o on both datasets. Across these studies, the evaluation of performance was done using overall summary measures, such as RMSE, F1, Pearson's correlation, or kappa-family metrics. In particular, it remains unclear *what kinds of responses* were easier or harder for the different models to score.

There are indications in the literature on automated scoring of constructed responses that point towards a specific weakness of LLM-based scoring, namely, the tendency of these models to over-score low quality responses. Chang and Ginter (2024) examined the quality of GPT-4 scoring, in zero-shot and one-shot setting, of short answers in a variety of undergraduate courses in Finnish. They found that the models were too lenient, both in

binary pass/fail scoring and in scoring on a scale: Too few responses were marked as fail, and too few responses were assigned to the bottom half of the scale. Kortemeyer (2023) reported similar results for scoring short answers in introductory physics – GPT-4 was a more lenient rater. The author noted that agreement between human and AI scores was stronger at the high end of the response quality spectrum. In the context of medical undergraduate courses, Grévisse (2024) observed that different LLMs were more or less severe than human raters on data from different courses. They further observed that there was stronger agreement between the LLM and human ratings for the completely incorrect and completely correct answers than for partially correct answers and noted GPT-4's especially high precision on detecting the fully correct answers. These findings suggest that automated scoring should be examined from the point of view of response quality, as there is evidence that the scoring accuracy may be uneven across the score distribution. However, it is not clear whether few-shot LLM scoring is more or less susceptible to uneven performance than the more extensive task adaptation through fine-tuning. It is also not clear whether any unevenness in AI scoring may have to do with inherent difficulty of discriminating between scores at certain levels, namely, whether human scoring exhibits a similar pattern. Our contribution is a systematic examination of multiple scoring mechanisms – human, fine-tuned pre-trained language models, and few-shot LLMs – in terms of the relationship between scoring accuracy and response quality, in the context of ASAS.

3 Methodology

3.1 Assessment Items and Scoring Rubric

We analyzed student responses to two open-ended items in biology. The items deal with cellular respiration, and specifically, the effect of smoking and anemia on physical exercise. The items are conceptually similar and differ in context and surface features, and students' explanations are expected to have the same structure, and use similar argumentative flow. They are similar to questions that frequently appear on the biology national matriculation exam. They were administered in Hebrew and their translation is presented below.

Smoking (Item 1): Cigarette smoke contains harmful substances, including CO, which binds haemoglobin more strongly than oxygen. Explain

how high CO levels impair exercise ability.

Anemia (Item 2): A man with low red blood cell levels (anaemia) reports weakness and difficulty exercising. Explain how reduced red blood cells make exercise difficult.

Due to their conceptual similarity, the items share the same grading rubric. It is an analytic grading rubric that decomposes a student’s scientific explanation into a collection of 10 binary categories, each representing an essential property that the student response should include. The items and the rubric were developed by the 2nd author of this paper. The full description of the grading rubric can be found in [Ariely et al. \(2025\)](#).

3.1.1 Data Collection, Scoring, and Partitioning

Student responses were collected in two cycles conducted in two different academic years, with a two-year gap between the cycles. In the first cycle, student responses to an instrument that contained both items were collected from 669 students in grades 10-12 attending 25 high schools across the country. For each category in the rubric, a student’s response was graded as ‘1’ if that category was addressed in the text, and ‘0’ otherwise. Approximately 5% of the 669 responses were annotated jointly by two human raters – Rater1 (the second author) and Rater2. Then, an additional 20% of the 669 responses were annotated independently by both raters establishing inter-rater agreement on $n = 130$ responses (κ ranged between 0.89 and 0.98 across categories). Last, Rater1 coded the remaining responses; see [Ariely et al. \(2023\)](#) for more details on the annotation process. The data was used as **training data** for the models, namely, for fine-tuning the BERT-based models and for picking the few-shot examples for the LLM-based grading.

In the second cycle, responses to the same instrument were collected from 152 students (in total, 304 responses) of similar demographics, and scored by Rater1 (the 2nd author of this paper). We refer to this scoring as the ground truth labels. These responses were used as **test data** for all the experiments described below. A second human rating was obtained for the test items as part of the current study of human vs AI raters and will be described in more detail in section 3.3.2.

3.2 Evaluation Metric for Scoring Differences

The scoring of each response is represented as a 10-dimensional binary vector, where each dimension corresponds to a category, with ‘1’ indicating a correct response on that category. As noted above, we referred to the scoring of Rater1 as the ground truth labels. The overall score of a response is thus defined as the number of categories (i.e., bins) that Rater1 marked as correct, which ranges from 0 to 10, meaning that higher scores indicate higher response quality.

3.2.1 Manhattan Distance for Scoring Differences

For a student response s , we denote the gold labels of s by: $l_s^G = (l_1^G, \dots, l_{10}^G)$, and the labels assigned by Rater2 (Human or AI-based) – by: $l_s^{R_2} = (l_1^{R_2}, \dots, l_{10}^{R_2})$. l_s^G and $l_s^{R_2}$ are binary 10-dimensional vectors. We measure the absolute difference between the two scorings by the Manhattan-distance (also called the L_1 -distance) ([Chen and Ng, 2004](#)) between l_s^G and $l_s^{R_2}$:

$$\|l_s^G - l_s^{R_2}\|_1 = |l_1^G - l_1^{R_2}| + \dots + |l_{10}^G - l_{10}^{R_2}|, \quad (1)$$

which equals the number of categories scored differently by Rater2 compared to the gold labels.

3.3 Experimental Set-Up

3.3.1 The Raters and the Scoring Task

The experimental set-up included comparing the alignment to the ground truth labels of the following scoring mechanisms: (i) a second human expert, (ii) a fine-tuned BERT-based model, and (iii) three LLMs – GPT-5.2 ([Singh et al., 2025](#)), GPT-4o ([OpenAI, 2023](#)), and Claude-opus-4.5 ([Anthropic, 2025](#)). At the time of writing, GPT-5.2 and Claude-opus-4.5 are the frontier models of OpenAI and Anthropic, while GPT-4o represents OpenAI’s previous generation model, which is the current workhorse for many LLM tasks due to its good combination of capabilities, speed, and cost.

The task of the graders was to score each response of the test set (152 responses for each item) according to each of the categories of the rubric, producing a 10-dimensional binary vector per response. For the LLMs we took the majority result: Each LLM was invoked three times for every category on every response; the result that appeared most of the time is considered the final LLM score.

We then computed the Manhattan distance, per response and rater, between the Rater2’s scoring

vector and the ground truth vector, as described in Section 3.2.1. Below, we provide more details about the scoring procedure.

3.3.2 Scoring Procedures by Scoring Mechanism

Below we describe how the scoring of the test set was implemented for each scoring mechanism.

1. **Human:** The test set was labeled according to the rubric by a second biology education expert who scored part of the 1st cycle dataset (that was used as training data in this study) a few years ago, after a short recap with Rater1 on the rubric and its implementation.
2. **Fine-tuned BERT-based Classifier:** The BERT-based model DictaBERT (Shmidman et al., 2023) was fine-tuned on the training data ($n = 669$). A separate binary classifier was trained for each item and category, meaning that overall, 20 classifiers were fitted. More details can be found in Ariely et al. (2025).
3. **Few-shot LLMs:** The generative models – GPT-4o, GPT-5.2, and Claude Opus 4.5 – were prompted with assessment instructions. Each category in the rubric had its own prompt for each item, overall $2 \times 10 = 20$ prompts. The prompts followed a straightforward few-shot ASAS strategy and their general structure was: role definition, task definition, per-category scoring instructions, and few-shot examples, split equally between positive and negative examples. An example of a prompt for one of the items and categories is provided in Appendix A. We acknowledge that there are various prompting strategies for ASAS. Our approach was to rely on established prompting strategy developed and tested in previous ASAS research. Thus, we adopted the prompts of Ariely et al. (2025), which were initially developed for a GPT-4o grader. We note that Ariely et al. (2025) tried several combinations of few-shot examples, specifically 2/4/6/8/10-shot (with an equal split between positive and negative examples). **Determining the Number of Few-Shot Examples for the Frontier Models.** Prior to experimenting with the costly models (GPT-5.2 and Claude Opus 4.5), we analyzed the results of running the 2/4/6/8/10-shot prompts with GPT-4o. The results showed that 10-shot prompting achieved better results, both in terms of overall (average) agreement and in terms of mid-range fairness, as can be seen in Figure 1.

Thus, for the costly models, we ran only the 10-shot version. For the few-shot examples, we randomly chose five positive and five negative examples from the training set. The total cost of running the ten 10-shot prompts on the test set for each item for each of the two LLMs (40 prompts in total) was around \$1,000.

4 Results

Table 1 shows the average L1 distance between the gold labels and the scoring of the second human rater (H2) and the AI models, per score level (number of correct categories – #CC – in the gold labels), for each of the two items. Figure 1 shows the same information visually, including standard deviations shown in the relevant background color.

Let us first consider the overall performance of the different models on the two items. On average and across score levels, H2 had the highest agreement with the expert, followed by the fine-tuned BERT-based models, followed by the LLMs in few-shot mode. Among the GPT models, we did not observe an advantage for GPT5.2 over the prior generation GPT4o model with the same number of few-shot examples (10). For GPT4o – the only model that was tested with several numbers of few-shot examples – providing 6-10 examples resulted in approximately similar performance, while providing only four examples resulted in performance degradation on Item 2, and providing only two examples resulted in a substantial degradation in the middle range of the scores – difference of 3 categories or more, on average, for scores with 4-6 correct categories out of 10 – for both items.

Analyzing the results by score level (number of correct categories out of 10), we observe excellent AI-model performance on the extremes – best and worst quality responses – regardless of model-type and amount of task-specific data. In contrast, there is a degradation for partially correct responses, especially for the few-shot models.

While on average fine-tuned models performed better than few-shot ones, the GPT models in all few-shot scenarios – including those with only two examples – performed very well on fully or almost fully correct answers (score 9-10), showing average distance of less than one category from the gold score. On the fully correct responses, the GPT models outperformed the fine-tuned models on both items. The exceptionally strong performance of few-shot models on the best responses

aligns with some similar reports in the literature (e.g., Grévisse (2024); Kortemeyer (2023)).

Next, we observe that all GPT models perform well on the lowest end of the scale – score levels 0 and 1. With the exception of two-shot GPT4o on Item 2, in all other cases the average distance from the gold label is less than one category. Although fine-tuned models do better, with average distance of at most 0.5 category from the gold label for score 0 and 1 across the two items, few-shot models are also fairly accurate.

Table 1 shows that all few-shot models suffer a substantial degradation in performance in the middle range of the scores. For all six GPT models, for each of the four score levels 4-7, for both items, all but one of the $6 \times 4 \times 2 = 48$ results show average distance of more than two categories from the gold label. Fine-tuned models also perform worse in this middle range than in the extremes, but the degradation is not as severe – the maximum average distances from the gold scores is 1.5 categories. In contrast, the human rater H2 does not show a clear pattern of degradation in agreement with the gold labels in the middle of the score range.

Our final observation is that of the erratic behavior of the Claude model. While the overall and the score-level-dependent patterns of errors are highly consistent across the two items for H2, fine-tuned, and GPT family models, Claude’s performance oscillates dramatically – it is the best few-shot model for Item 1 but is by far the worst model for Item 2.

5 Discussion & Conclusions

Quality-conditioned agreement. The findings show that agreement is strongly conditioned by response quality and that this relationship differs considerably between human-human and human-AI pairings. Human raters exhibit the highest agreement, which is also stable across the response quality range and shows no mid-range degradation, suggesting that human experts are relatively consistent in interpreting partially correct responses. In contrast, the AI models showed a U-shaped pattern:¹ Agreement is highest at the extremes (fully correct or incorrect responses) and substantially lower in the middle range, indicating that model-human agreement is not uniform across the scoring range. This mid-range degradation pattern complements a recent ASAS study showing that criterion-level

agreement declines as cognitive complexity increases (Emirtekin and Özarslan, 2026), and a similar trend found in project-based learning (Usher and Faraon, 2025).

Task Specific Adaptation. The results also showed that task-specific adaptation emerged as a key factor in improving agreement. The fine-tuned model, which had access to the highest amount of task specific data, outperformed scoring based on LLMs with few-shot examples across both items, most notably on mid-range responses. In line with this, the initial experiment on the number of few-shot examples on GPT-4o demonstrated a similar pattern, with the U-shape disagreement curve having a larger ‘belly’ for lower numbers of few-shot examples (see Figure 1). While the advantage of fine-tuned models on LLMs in few-shot mode on ASAS tasks was shown previously on the aggregated level (Kortemeyer, 2024; Henkel et al., 2024; Ferreira Mello et al., 2025), the present work suggests that this advantage may be mostly concentrated in the mid-range examples. In fact, for the fully correct/incorrect responses, LLMs performed well with very little task-specific data.

Possible explanations for the observed pattern. In trying to explain these results, it may be that extreme responses (fully correct or incorrect) provide clearer signals that are easier to classify, while mid-quality responses require nuanced judgment and interpretation of rubric criteria. Experienced human experts may be better at applying such nuanced educational judgment (Yacobson et al., 2025), and encoder models can learn to distinguish between them using labeled data that changes their internal representation in a way that can separate between them. LLMs, when provided with a rubric and few-shot examples, utilize in-context pattern matching to identify semantic and structural alignments between the criteria, the examples, and the student’s input. Our empirical results that show that LLMs are less good than fine-tuned encoders on ASAS tasks are in line with previous findings (e.g., Ferreira Mello et al. (2025)).

Implication for automated scoring in practice. The great promise of few-shot automated scoring is fast deployment of the automated scoring model, thus saving instructors valuable time through automated evaluation of student responses without having to wait until sufficient human-scored data is available for fine-tuning. Our results suggest that such scoring may be inequitable, with substantially inaccurate scores concentrating on the partially in-

¹Specifically, the graphs in Figure 1 show an inverted U-shape since they show discrepancy rather than agreement.

correct responses. However, the high agreement on fully correct and fully incorrect responses, even for LLM models with very few examples, suggests that automated scoring as a first pass can identify these responses and handle them without human intervention, while responses predicted to be in the middle range would be routed to the human rater for scoring. Gradually, as more human-scored data is accumulated and fine-tuning becomes feasible, the scoring can be automated more fully.

Implications for fairness. Bias is a well-recognized hazard in automated scoring of constructed responses (Madnani et al., 2017; Loukina et al., 2019; Gorgun and Yildirim-Erbasli, 2026). Much of the existing literature has focused on demographic-group-based biases, where students

from different groups (e.g., by socioeconomic status (Chinta et al., 2024; Baker and Hawn, 2022) gender (Madnani et al., 2017), or linguistic background (Loukina et al., 2019)) receive systematically different scores despite comparable skill levels. However, bias can also arise at the individual level, where similarly skilled students are treated differently due to consistent features of their responses – for example, students who write in a more concise style may be systematically scored differently (Madnani et al., 2017; Beigman Klebanov and Madnani, 2022). In addition, statistical biases may emerge from properties of the data, for instance, if examples that include certain properties, such as specific misconceptions, are not represented enough in the data for the models to learn

Figure 1: Human-Model Agreement With Respect To Student's Response Quality For All The Models

their linguistic signature.

Statistical bias can also take the form of a representation bias. For example, Gurin Schleifer et al. (2025) identified what they termed an ‘Anna Karenina principle’, showing that as responses become more incorrect, their representations in the embedding space become more spread, making it harder to automatically cluster together responses of the same error type. This creates a differential measurement error that disproportionately affects lower-quality responses, and may constitute a fairness problem if such clusters are used to design feedback targeted at each knowledge group, as proposed by Ariely et al. (2024). In this case, low-quality responses may receive unsuitable feedback.

Our results contribute to this line of research by identifying a form of measurement bias that appears in ASAS. We observe a U-shaped pattern in which scoring errors concentrate in mid-range responses. These responses are typically produced by students whose knowledge is still developing. Such students may benefit the most from formative feedback, as they are often better able to use feedback to refine their understanding than lower-performing students (Roll et al., 2014; Shute, 2008). Additionally, because mid-range responses contain both correct and incorrect elements, scoring errors – especially misjudging correct components – may be particularly confusing. As a result, reduced accuracy in this range may hinder learning at a critical stage, making this a fairness concern.

We define quality-conditioned fairness as the requirement that automated scoring systems maintain consistent accuracy across the full spectrum of response quality. As we showed, this form of fairness is closely tied to the availability of task-specific data, with greater adaptation reducing mid-range errors. By identifying and characterizing this

pattern, we turn it from an “unknown bias” into a “known bias,” which is a necessary step toward improving fairness in educational AI systems in general (Baker and Hawn, 2022).

Future work. To better understand the phenomenon of mid-range degradation, it would be useful to extend this research to additional instruments and domains, and to examine the direction of misalignment, as prior work suggests that LLMs may tend to over-score incorrect responses. To improve mid-range alignment, it would be valuable to investigate whether including more mid-quality examples in few-shot prompts can reduce the observed degradation in scoring. A more human-in-the-loop approach worth investigating is whether task-specific prompts can achieve higher alignment, and how to train domain experts or teachers to develop and validate them within their local context.

Contribution. This work identifies mid-range scoring degradation in ASAS and shows that it is strongly governed by the degree of task-specific adaptation. A key takeaway is that LLM-based ASAS systems must be evaluated for quality-conditioned agreement, with particular attention to mid-range responses.

Limitations

The prompting approach used for the LLM-based scoring mechanisms followed a common few-shot strategy drawn from prior work. However, these prompts were originally designed and validated for GPT-4o. It is possible that alternative prompting strategies, or prompts tailored to each specific model, could yield different performance patterns. Additionally, the assessment used in this study consisted of two items in biology. Although these items were selected to represent common question types found in standard assessments on the topic,

they still constitute a limited sample of possible tasks. Thus, the generalizability of the findings to other items and domains remains to be established.

This research does not employ standard evaluation metrics such as Quadratic Weighted Kappa (QWK) or Pearson’s correlation, which may hinder direct comparison with existing ASAS benchmarks. Incorporating standard quality-conditioned agreement metrics should be considered in future work.

Ethics statement

We acknowledge that this work complies with the ACL Code of Ethics. The research and its data collection procedures were approved by the Institutional Review Board and the Ministry of Education.

Acknowledgments

The authors thank Cipy Hofman for her contribution to the research. This work was supported by the Knell Family Institute for Artificial Intelligence, Israel.

A Prompt Example

The general prompt structure is taken from [Ariely et al. \(2025\)](#). The scoring instructions are tuned per category. Each category-specific prompt is then followed by randomly chosen few-shot positive and negative examples.

1. Role definition:

'You are an expert in education and assessment in biology.'

2. Task definition and general instructions:

'You are required to assign a score to category in a student's response titled: "Changes in the rate or amount of energy Production." Note that although the overall context of the response is important, you should focus solely on the students' reference to changes in the rate or amount of energy or ATP production. Anything else mentioned around this category may be significant for the response, but irrelevant for evaluating this specific category.'

3. Instructions for scoring:

'If the category is present in the response, score 1. If not, score 0.'

Using LLMs for Item Creation: Validating the Potential of Automatically Generated Sentence Repetition Test Items for Language Assessment

Abstract

Various aspects of the Elicited Imitation Test (EIT), a sentence repetition task for language assessment, can be automated, for example in terms of test administration or automatic scoring. It is potentially also possible to generate test items with Large Language Models (LLMs). This study investigates the potential of GPT-4o for item creation in the context of EIT, creating a parallel form to two popular and validated tests. We analysed the tests in terms of their linguistic and psychometric properties. While the items created by the LLM show some difference in grammatical structures when compared to human-written items, linguistic complexity results did not differ significantly between tests. Psychometric properties showed only minor differences. These findings lend support to the potential of Automatic Item Generation with LLMs in the context of sentence repetition tasks and might support the process of standardisation in SLA research and testing by enabling parallel test creation.

1 Introduction

Creating items for language tests places a particular kind of strain on the test developer: it requires resources such as personnel and time as well as expertise, making it a complex and labourious process. In the realm of language assessment, recent advancements have made possible the automation of this task. For example, [Settles et al. \(2020\)](#) used machine learning techniques for the automatic creation of proficiency assessments for adaptive testing. Likewise, [Attali et al. \(2022\)](#) utilised a transformers-based approach for generating reading comprehension assessments. As these examples make apparent, generating items automatically can accelerate the process of test creation and reduce the amount of labour typically associated

with this task. Indeed, Automatic Item Generation (AIG) can be found in many contexts nowadays, from generating reading comprehension questions ([Huang and He, 2016](#); [Sayin and Gierl, 2024](#)) to multiple choice items ([Gierl et al., 2012](#)). Another test format that lends itself well to automation and therefore AIG is the Elicited Imitation Test (EIT). While AIG is a promising and efficient approach, questions remain about construct representation and validity.

Traditionally, item creation for the EIT has been manual, relying on test creators for writing their own items and tests. Since EIT is a sentence repetition task, the sentences need to be carefully controlled in terms of length and linguistic complexity. Automating this process would reduce the amount of work related to item creation and increase the possibility of adaptive testing in the context of EIT. Furthermore, AIG has the potential to tackle another problem: the lack of standardisation in EITs and in language research generally ([Isbell and Son, 2022](#)), which becomes problematic when researchers want to compare a construct, e.g. language proficiency, across studies or when the need for repeated assessment arises. Parallel and comparable forms are a solution to this issue, provided they demonstrate comparable psychometric properties.

As suggested in recent literature, pre-trained LLMs and prompting are increasingly used for engineering test items ([Song et al., 2025](#)). One clear advantage of this approach is that using pre-trained LLMs is an accessible option for most people without a strong computational background that is otherwise needed to engineer systems for automatic item generation. However, questions remain about the quality and linguistic properties of these generated items, particularly in the context of validity in

(language) testing.

The aims of this study are to (1) investigate the linguistic properties of automatically generated items with LLMs in the context of a parallel form of an EIT, and (2) to examine if these test items display validity evidence in order to support the development of standardised and comparable EIT forms.

2 Theoretical background

2.1 Elicited Imitation

The Elicited Imitation Test (EIT) is a sentence repetition task, commonly used as a measure of general language proficiency. The test is also used in Second Language Acquisition (SLA) research, for example, to measure implicit grammatical knowledge of a second language (Erlam, 2006). Furthermore, the EIT can also be used as a placement test (Yan et al., 2020) or as a diagnostic tool for language acquisition in children (Klem et al., 2015).

The procedure of an EIT is as follows: The test taker hears sentences one by one, which they have to repeat verbatim. There is usually a short pause between the stimulus and the repetition to avoid over-reliance on working memory. The rationale behind sentence repetition is that the test taker reconstructs the meaning of the sentence based on their own grammatical knowledge.

Various design implementations can be employed when designing an EIT, for example using sentences of varying length (Ortega et al., 2002), including a distractor instead of a pause (Erlam, 2006), including ungrammatical sentences, or including only items that target a specific construct such as the passive-form (Spada et al., 2015).

So far, most of the test creation in the context of the EIT has been manual. Items have been written by researchers or test developers, which is a labour-intensive and complex task. Furthermore, it makes scaling of the test for parallel testing or testing on a larger scale difficult. This can cause problems as comparable testing and standardisation are two things that are currently lacking in SLA research (Isbell and Son, 2022). This difficulty could be tackled by automating EI test generation and administration to increase its scalability.

Research efforts have concentrated on automating the EIT using various technologies (McGuire and Larson-Hall, 2025; Isbell et al., 2023; Kim et al., 2024). For instance, Isbell et al. (2023) used Automatic Speech Recognition (ASR) and string

matching to automate the scoring of the Korean EIT, achieving very high correlations ($> .90$) between human and automated scores. Automatic scoring has also been implemented for written EITs (Chiffigarov et al., 2025). Furthermore, the EIT can be digitised and taken on the web, yielding results highly similar to lab-based approaches (Kim et al., 2024). In addition to these two areas, researchers have also investigated item creation for EITs (Christensen et al., 2010). Unlike delivery and scoring, EIT item creation has largely been manual.

2.2 Item Creation Approaches in EIT

Items used in existing EITs have traditionally been hand-crafted. For example, the most well-known EIT by Ortega et al. (2002) used hand-crafted items, as do the parallel forms in several languages. In order to create parallel English versions for comparability, Wu et al. (2022) also hand-crafted items based on the original Ortega EIT. Using appropriate items in the context of EIT is important, since the purpose of the test can vary from testing advanced learners (Solon et al., 2019) by including more complex items to testing specific grammatical target structures, e.g., *passives*, (Godfroid and Kim, 2021; Spada et al., 2015) to see if learners have acquired those structures.

To our knowledge, the first study using a corpus-based item bank in the context of EIT was carried out by Christensen et al. (2010). In this study, the authors used an annotated corpus for flexible item selection and then compared an existing EIT, using human-written items, with an EIT created with their automatic item selection tool. Interestingly, the automatically created version of their EIT had even higher correlation scores with an external measurement used in their study, the Spoken Language Achievement Test (SLAT), than the manually created EIT. While this is promising for the generation of items, the finding might also hint at different behaviour or validity characteristics of the two forms.

Using a corpus in the context of creating EIT items holds advantages: sentences from a corpus can be more authentic than items written for EIT use and, additionally, choosing sentences from a corpus is also less work than hand-crafting EIT items. However, this approach can also introduce a substantial amount of noise and effort: sentences can be out of context or inappropriate. Furthermore, items might be too long or overly complicated and require manual adaptation. A corpus might also be limited to a specific domain only,

which might be unfamiliar to some population of learners. Another difficulty is having control over potential target structures in the corpus sentences, which requires additional annotation of the corpus. A corpus-based item bank in the context of EIT therefore also places demands on test creators and does not entirely simplify the item creation process.

In summary, previous approaches in EIT relied on manual creation or corpus-based retrieval of items. Corpus-based methods are a step towards automation, however, they only offer a partial solution to the problems of scalability, effort, structural control and standardisation. These limitations encourage the exploration of alternative approaches, such as Automatic Item Generation (AIG).

2.3 Automatic Item Generation

AIG refers to the creation of (test) items using automated approaches such as machine learning and carries several advantages, among them more time- and resource-efficient item creation (Circi et al., 2023).

This approach finds application in several fields and contexts, for example, the creation of multiple choice items in a medical context (Gierl et al., 2012) or for generating reading comprehension questions (Huang and He, 2016; Sayin and Gierl, 2024). For generating items, cognitive models are employed, which model the domain knowledge, content, or skills needed to develop items (Gierl et al., 2012). Recent advancements in Large Language Models (LLMs) have created new approaches in AIG. While AIG usually involves the complex task of incorporating cognitive models in item creation, LLMs have enabled a less technically complex approach, involving few- or zero-shot prompting (Attali et al., 2022) and allowing for more flexibility and fewer constraints in the item creation process, for example by allowing the creation of a variety of item types in various subject domains (Tan et al., 2024). Generally, using prompt engineering with pre-trained models is a growing trend in the field (Song et al., 2025) and is additionally a feasible method for automatic item creation for people without a computational background, for example teachers and educators.

Beyond the generation of items, an equally important aspect in AIG is the evaluation and validation of test items. In the context of AIG with LLMs, item and measurement properties are often not reported or evaluated (Tan et al., 2024). Especially in the context of high-stakes tests, validation

and testing of items is crucial to make sure that the test actually tests what it is supposed to test. This is also important in the case of the EIT, as generated items may differ in linguistic structures or lengths when compared to established test items, potentially altering cognitive load for the participant and item difficulty.

Tests are often evaluated in terms of validity. Broadly speaking, validity can be defined as the "meaning of test scores" (Messick, 1995, p. 5), referring to the overall concept as describing whether a test measures what it intends to measure. Validity can be measured in several ways. An example is construct validity, an aspect of validity that tests if a test indeed measures the underlying construct it is trying to measure, or criterion validity, that measures how related test results are to another test (El-Hamamsy et al., 2022).

For the evaluation of AIG items, recent work has focused on automated approaches, but using a human-in-the-loop evaluation of items, for example, on the rating of the quality of generated items (Kim et al., 2025; Ma et al., 2025). Another possibility for assessing the suitability of items are psychometric methods such as Item Response Theory (IRT), which can inform about validity and quality in the context of AIG (Falcão et al., 2023).

Using AIG in the context of Elicited Imitation Tests certainly holds potential: it enables parallel testing, the generation of a large item bank, and supports the labour-intensive process of crafting items. While an earlier approach (Christensen et al., 2010) used corpora and annotation to find suitable items, LLMs can simplify this process by responding flexibly to certain demands, e.g. the presence of specific constructs or topics. This allows for more control than a corpus-based setup.

3 Present Study

Taken together, AIG seems to be promising in the context of EITs, allowing for flexibility and opening potential for the creation of parallel forms, which in turn can help with the process of standardisation. However, automatically generated items would need to be validated in order to make claims about their potential to be used in language assessment. To date, no study has systematically investigated whether LLM-generated items can be used as valid EIT items. To research this, we use an LLM-generated EIT, employing GPT-4o. We opted for GPT as it is the most widely adopted tool in ed-

ucation (Bhullar et al., 2024), accessible through a web interface and frequently used in AIG (Tan et al., 2024; Chan et al., 2025), which helps with comparability of the findings. This way, our findings are directly relevant to educators and students in practice. For comparability, we will concentrate on parallel forms in particular. Since grammatical structures and complexity are of specific interest to EIT items, we will investigate item properties and measurement properties in two ways: evaluating items and tests in terms of their linguistic and psychometric properties. The research questions are as follows:

1. To what extent do the properties of GPT-generated test items differ from those of established test items? More specifically,
 - (a) Are they different in terms of linguistic complexity?
 - (b) Are they different in terms of grammatical structures used?
2. How do the automatically generated tests compare to established tests in terms of validity?

4 Method

4.1 Materials

Three EITs were used in this study: (1) An established EIT by Ortega et al. (2002), (2) the parallel version by Wu et al. (2022) and (3) an EIT generated by GPT-4o. The items of the GPT-generated EIT can be found in Appendix A.

Our automatic item generation approach was as follows: we prompted GPT-4o to create an EIT with 30 items, varying in length, starting at 7 syllables. We employed few-shot prompting for automatic item generation, including the items of the original EIT by Ortega et al. (2002) as well as their syllable count as examples. The model output, 30 items, was used for the resulting GPT-generated EIT. The prompt can be found in Appendix C.

The tests were all uploaded to ILAP (Löber et al., 2024), an assessment platform, where participants could take the tests on their own devices via a web browser. All EIT tests used the same procedure: The participants saw instructions about the test, followed by three practice items that were not counted towards the final score. Then, a notification about the start of the test followed. The test then began. After each sentence, there was a beep followed by a four-second pause. Participants then had eight seconds to repeat the sentence they had just heard.

Audio stimuli for all items on the three EITs were created with the Amazon AWS text-to-speech service, which had been integrated into the platform.

Furthermore, we administered questionnaires about participants' demographic background and a C-Test as a measure for general English language proficiency taken from Ishihara et al. (2003). The C-Test was programmed with jsPsych (De Leeuw, 2015) in JavaScript and integrated into the platform used for EIT data collection. The test consisted of three text passages with half of every fifth or sixth word removed. The maximum score on the C-test was 50 points (15 points for each of the first 2 passages and 20 points for the last passage).

The EITs were scored automatically, using the ASR and string matching approach by Isbell et al. (2023). We used accuracy based on Mean Error Rate (MER) - $(100 - \text{MER})$ - as the scoring metric (McGuire and Larson-Hall, 2025). We then mapped our continuous scores to ordinal scores for better comparability with the ordinal scoring scheme by Ortega et al. (2002), encompassing scores from 0-4. We followed the approach taken by Isbell et al. (2023) for mapping the scores, which can be found below in Table 1. For total scores, we took the sum of all item scores. The maximum score on the EITs was 120.

Ordinal score	Continuous score
4	91 - 100
3	71 - 90
2	41 - 70
1	21 - 40
0	20 or below

Table 1: The ordinal scoring scheme, mapping continuous scores to ordinal scores

The C-Test was also automatically scored, assigning binary scores (1 or 0) to each gap. This was done by employing string matching between the participants' response to the expected response for each gap. We then used the sum of all answers as the total score. The maximum score on the C-Test was 50.

4.2 Study Design

The study ran for four weeks. Each week, a teacher administered an EIT to a class in a randomised order, e.g. class 1 completing EIT 1 in week 1, EIT 2 in week 2 and EIT 3 in week 3 while class 2

completed EIT 2 in week 1, EIT 3 in week 2 and EIT 1 in week 3, etc.

Students created an individual accounts on the platform used for testing. The EITs were implemented into the platform by the researchers, where they could be administered to the students with an access code. Before being able to access any test, students were shown a consent form where they could indicate whether they consented or not to their data being used for study purposes. Furthermore, we also implemented the questionnaire and C-Test on the platform. These could be taken by students at any time during the course of the 4-week study.

4.3 Participants

Participants were 73 undergraduate students from a university in China, majoring in English. 60 of the students were female and the mean age was 20.1 years (SD = 1.55), ranging from 18 to 25 years of age. All students reported Chinese as their native language and the majority (72%) reported English as their second language. Students' self-reported English proficiency was intermediate to upper intermediate.

4.4 Analysis

Data were analysed with R (version 4.5.0), using the packages stringr (Wickham, 2019), lme4 (Bates et al., 2015), lavaan (Rosseel, 2012), mirt (Chalmers, 2012) and koRpus (Michalke et al., 2021). We also analysed all test items in terms of the grammatical structures and corresponding learner levels with the rule-based annotation tool POLKE (Sagirov and Chen, 2025). POLKE annotates text with grammatical structures and their corresponding Common European Framework of References (CEFR) (Council of Europe, 2001) learner levels (A1-C2) and is based on the English Grammar Profile (O'Keeffe and Mark, 2017). In addition to the grammatical structures and learner levels, the tool also supplies super-categories of structures (e.g. nouns, verbs, adjectives) as well as sub-categories (e.g. types, linking, phrasal).

In addition, we analysed the EIT items in terms of their linguistic complexity, using the tool CTAP (Chen and Meurers, 2016) as well as the stringr and koRpus packages in R. For measure selection, we followed Bulté et al. (2025)'s summary of core and noncore measures of complexity, selecting six measures. We also analysed word frequency, using the SUBTLEXus log-10 frequency of all tokens.

The full overview of complexity measures used can be found in Appendix B.

Furthermore, we employed Item Response Theory (IRT) and Confirmatory Factor Analysis (CFA) as well as correlations to analyse the test properties of the 3 EITs.

5 Results

5.1 Descriptive Results

Not all participants completed every measure. Specifically, 68 participants finished the background questionnaire, 62 the C-Test, 63 EIT 1, 61 EIT 2 and 62 EIT 3, with 53 participants completing all 3 EITs. We analysed all data available to us, which meant that for example, the correlation analyses were conducted with only participants who completed all measures included in the analysis.

The mean score on the C-Test was 38.96 (SD = 11.01). Mean scores on the EITs were similar: EIT 1 (59.6, SD = 34.50) and EIT 3 (57.82, SD = 31.20) displayed highly similar scores, whereas EIT 2 (51.58, SD = 35.78) showed a slightly lower mean score. EIT scores showed a high range, 11-113 for EIT 1, 5-112 for EIT 2 and 5-113 for EIT 3. The tests themselves displayed high levels of similarity: The mean syllable length was between 10.4 and 10.97 syllables for all three tests and the mean sentence length was between 14.93 and 15.2 for all three tests. Descriptive statistics for the scores on the three tests, including standard deviations (SD), can be found in Table 2 and 3 below.

Test	n	Mean score	SD
Ortega (2002)	63	59.58	34.50
Wu et al. (2022)	61	51.58	35.78
GPT-4o	62	57.82	31.20

Table 2: Number of participants, mean score and standard deviation (SD) for the three tests.

Test	Mean SL	SD	Mean SC	SD
Ortega (2002)	10.83	2.59	14.93	3.34
Wu et al. (2022)	10.97	2.62	15.03	3.78
GPT-4o	10.40	2.62	15.20	3.89

Table 3: Descriptive statistics for test properties. SL = sentence length, SC = syllable count.

5.2 Items

We first analysed the POLKE annotations in terms of the distribution of super-categories. We excluded

categories with counts < 5 in order to meet the assumptions of chi-square tests. These were the categories future, passives, questions and reported speech. The distribution of the remaining categories differed significantly between tests, $\chi^2(22) = 39.839$, $p = 0.011$. Following this, we inspected the residuals of the chi-square test. The GPT-generated tests produced fewer structures belonging to the adverbs and present category and more structures belonging to the preposition category than EIT 1 and EIT 2. Figure 1 shows the distribution of super-categories.

Figure 1: The distribution of super-categories for all three tests.

After that, we analysed whether there were differences in the distribution of CEFR learner levels within the POLKE-annotated grammar structures between the tests. The distribution of learner levels did not significantly differ between the tests, $\chi^2(10) = 9.8922$, $p = 0.45$. Figure 2 shows this distribution.

We then divided the complexity measures into sub-measures of syntactic (Table 4) and lexical complexity (Table 5). The results for each can be found in the tables below.

Prior to statistical testing, we used Shapiro-Wilk Tests to check for the distribution of data. If the tests were significant, we rejected the assumption of normality and used non-parametric tests. We first ran Kruskal-Wallis tests on the syntactic complexity measures. Three measures did not differ significantly between conditions: mean words per phrase ($p = 0.09$), mean phrases per clause ($p = 0.70$) and mean clauses per T-Unit ($p = 0.09$). One

Figure 2: The distribution of learner levels associated with grammatical structures for all three tests, in percentages.

difference was significant: the normalised rate of occurrence of dependent clauses differed significantly between the tests, $H(2) = 6.09$, $p = 0.048$. We used Dunn's post hoc test with Bonferroni corrections to assess which groups differed. However, after adjusting, there was no significant difference between the Ortega et al. (2002) test and the GPT-generated form ($p = 0.177$) or between the Wu et al. (2022) form and the GPT-generated form ($p = 0.062$).

For lexical complexity, a Kruskal-Wallis test showed that the mean word length did not vary significantly between tests, $H(2) = 2.93$, $p = 0.231$. Word frequency also did not differ significantly between tests ($p = 0.178$).

Test	MW phrase	MP clause
Ortega (2002)	1.47	4.17
Wu et al. (2022)	1.59	3.98
GPT-4o	1.68	4.20
Test	MC T-Unit	N. ROC
Ortega (2002)	1.73	0.44
Wu et al. (2022)	1.76	0.47
GPT-4o	1.42	0.27

Table 4: Syntactic complexity mean scores for all three tests. MW = mean words, MP = mean phrases, MC = mean clauses, N. ROC = Normalised rate of occurrence of dependent clauses.

Test	Mean WL	MATTR	WF
Ortega (2002)	3.95	0.92	4.71
Wu et al. (2022)	4.01	0.91	4.60
GPT-4o	4.35	0.92	4.55

Table 5: Lexical complexity mean scores for the three tests. MATTR = moving-average type-token ratio, WL = word length, WF = word frequency.

5.3 Validity

All three tests displayed very high internal consistency, $\alpha = 0.98$.

We first calculated Spearman correlations of the scores between tests. EIT 1 and 3 showed a correlation coefficient of $\rho = 0.80$ (shared variance: 0.64), EIT 1 and 2 showed a correlation coefficient of $\rho = 0.76$ (shared variance: 0.58), and EIT 2 and 3 correlated with a correlation coefficient of $\rho = 0.76$ (shared variance: 0.58).

Using IRT, we then fitted a 1PL graded response model to the 3 EITs and used common-person linking to obtain discrimination values for the items. All items showed acceptable discrimination values higher than 0.39 (Popham, 2000). We compared the discrimination values between tests, which differed significantly, $H(2) = 6.61$, $p = 0.037$. Dunn’s post hoc test with Bonferroni corrections showed that the discrimination values differed only between the Wu et al. (2022) and GPT-generated form, $p = 0.038$, with the GPT-generated form showing higher discrimination values, but not between the Ortega et al. (2002) and GPT-generated form ($p = 0.22$) or the Ortega et al. (2002) and Wu et al. (2022) form ($p = 1$).

Focusing on the test level next, we employed confirmatory factor analysis (CFA) to obtain standardised factor loadings for the tests. We created a one-factor CFA model, using Full Information Maximum Likelihood (FIML) for missing data, with all three tests loading on the same latent variable, namely proficiency. The model was just-identified ($df = 0$), so we could not assess model fit. We then compared the standardised factor loadings of the tests. All tests displayed strong and significant factor loadings, indicating that they are connected in a highly similar way to the construct proficiency. The factor loadings can be found in table 6.

To obtain a measure of criterion validity, we correlated participants’ final scores on the EIT with their final scores on the C-Test using Spearman correlation. All EITs showed a weak to moderate

Test	Factor loadings
Ortega (2002)	0.89
Wu et al. (2022)	0.85
GPT-4o	0.93

Table 6: Standardised factor loadings per test.

correlation with the C-Test, $\rho = 0.26$ for EIT 1, $\rho = 0.35$ for EIT 2, and $\rho = 0.29$ for EIT 3. Using Fisher’s r-to-z transformation, we tested if the correlations differed between tests. There was no significant difference between EIT 1 and EIT 2 ($p = 0.55$), EIT 2 and 3 ($p = 0.72$) or EIT 1 and 3 ($p = 0.81$).

5.4 Scores

To find out if participants’ final test scores differed significantly between tests, we ran a mixed linear model, modeling participants as random effects to account for individual differences between users. The resulting linear mixed model with users as random effects showed a significant main effect of test between EIT 1 and EIT 2 scores ($p = 0.021$), and no difference between EIT 1 and EIT 3 ($p = 0.66$). Participants therefore had a significantly lower score on EIT 2 than on EIT 1.

6 Discussion and Conclusion

In this study, we explored the potential for automatic item generation for parallel forms with GPT-generated items in the context of Elicited Imitation. Our results are promising: the GPT-generated test behaved very similarly to the original Ortega et al. (2002) form as well as the parallel form (Wu et al., 2022), displaying highly similar linguistic properties, high internal reliability as well as similar factor loadings and construct validity.

There were slight differences between the tests (human-written vs GPT-generated) when it came to the grammatical constructs used: The GPT-generated test displayed a lower number of adverbs and present (tense) and higher numbers of prepositions than the other two tests. However, there was no difference between the three tests in the learner levels associated with the grammatical constructs, potentially an indicator for the non-significant difference in the difficulty of items between the tests. In other words, the differences found in the use of grammatical structures did not seem to contribute to the difficulty of the tests. We should also add that we did not specifically prompt for following

the grammatical constructs used closely. Interestingly, the different grammatical structures do not seem to influence item or test difficulty.

The complexity analysis showed that all three tests score very similarly on all measures. The only significantly different measure, normalised rate of occurrence of dependent clauses, turned out to be non-significant in the post hoc tests.

In summary, the GPT-generated test deviates from the original EIT and the human-written parallel form on a few grammatical structures and not on complexity measures, but the deviations on grammatical structures do not seem to add to overall test difficulty of the GPT-generated form or interfere with form equivalence. This finding should be further investigated in future studies, focusing on item and test difficulty on EITs. While some studies have already investigated this topic (Hendrickson et al., 2010; Campfield, 2017) and found effects depending on the sentence length or lexical complexity, future studies might want to explore that topic further.

A slightly different picture emerged when looking at our psychometric analysis. While the Ortega et al. (2002) and GPT-generated form seem highly similar, the Wu et al. (2022) form displayed some deviations from both forms: the IRT analysis showed lower item discrimination scores than for the GPT-generated form. In terms of scores, the parallel form from Wu et al. (2022) showed a lower mean score. This is in line with the findings from the parallel forms study (Wu et al., 2022), where the authors found an 8% score difference between the parallel form and the Ortega et al. (2002) form. Between those two tests, we found a score difference of 14%. Interestingly, the TTS voice used in our tests was the same across tests, pointing to no added difficulty introduced by speaker variability as Wu et al. (2022) suspected as one of the culprits for enhanced test difficulty. The lower score on this test must therefore be for reasons beyond speaker variability and the complexity measures employed in this study. We also reported less shared variance between the tests than in Wu et al. (2022). This finding might be due to the different population used in this study.

An unexpected finding also emerged from our data: the correlation of the C-Test with performance on the EIT was quite low (weak correlation of $\rho = 0.26$ and $\rho = 0.29$ on EIT 1 and EIT 3, respectively, and moderate ($\rho = 0.35$) on EIT 2), which is contrary to what other studies found

($r = 0.69$ in Davis and Norris, 2021, $r = 0.50$ in Spada et al., 2015). A C-Test counts as a measure of holistic proficiency, but due to the nature of the C-Test, which is more geared towards writing and reading, it can be argued that the sub-skills of listening and speaking are not included, which is what the EIT taps into. These two sub-skills might have been developed less strongly when compared to writing and reading for our participants, which might explain the weak correlation. In our case, the mean scores on the C-Test and the EITs also point to C-Tests being easier for our participants than the EIT.

Taken together, our findings show that an LLM-generated test holds potential in creating valid EIT items in a parallel forms context. This finding could enable the scaling of tests, making it possible to create more parallel forms with LLM-generated items. Furthermore, this can potentially help to tackle the problem of standardisation in language research (Isbell and Son, 2022), by enabling the creation – at least in the case of EIT – of comparable forms to existing EITs. For future studies, it would be interesting to see if our findings would be applicable across language contexts. While we only concentrated on English in this study, performance of LLMs might be less consistent beyond that and it is unclear if the performance of GPT can be carried over to other languages. Since all the available parallel and comparable EIT forms across languages are created manually (e.g. Wu and Ortega, 2013; Bowden, 2016), studies could shed more light on the performance of automatically generated items across languages.

7 Limitations

A few limitations of this research should be mentioned. First of all, the number of participants ($n = 73$) was quite low, leading to less generalisable results. Due to this low number of participants, we were not able to carry out more sophisticated analyses, e.g. Differential Item Functioning and our IRT analysis should be taken as preliminary. Having more participants at hand, and possibly a more heterogeneous group of participants, would undoubtedly shed more light on validity and parallel form equivalence.

Furthermore, due to the nature of our online experiment, we experienced a number of dropout cases and missing data from the background questionnaire.

As already pointed out in the previous section, we also did not compare performance across different LLMs. GPT is one of the most readily available options and widely used in the context of education (Doughty et al., 2024; Vanzo et al., 2025) and is also relevant to educators, teachers and test creators. However, the performance of other models would also be of interest for this strand of research.

We also only tested 30 LLM-generated sentences. While our results seem promising for parallel test creation, future research should test a larger number of items to evaluate if our findings are generalisable to different contexts, e.g. repeated or adaptive testing.

Lastly, we did not take the ability of models to produce certain grammatical constructs on demand into account. While we found that the GPT-generated test mostly showed strong similarities to the two human-written forms in terms of super-categories, we didn't explicitly prompt for it. Further research could concentrate on this ability of LLMs, as this is central to some EITs targeting specific grammatical constructs and can shed light on large language models' abilities to produce grammatical constructs.

A Appendix A

GPT-generated EIT test items

1. She is buying a new jacket.
2. The blue car is parked outside.
3. The store closes early on Sundays.
4. He usually takes the bus to work.
5. I don’t know why she left so suddenly.
6. We had a great time at the beach yesterday.
7. The restaurant downtown serves excellent seafood.
8. She was excited to finally start her new job.
9. The dog that lives next door barks all the time.
10. I hope to visit my grandmother this weekend.
11. The weather in this city changes very quickly.
12. She spent the whole afternoon reading a good book.
13. My neighbor’s cat always sits by the window and watches birds.
14. The teacher gave us an interesting assignment about history.
15. The bakery on the corner sells delicious chocolate cake.
16. I wish I could have stayed longer at the party last night.
17. He told me that he would help me move to my new apartment.
18. The little girl with curly hair is playing in the garden.
19. We decided to take a road trip through the mountains next week.
20. If I had known about the meeting, I would have arrived earlier.
21. She was surprised to see her childhood friend after so many years.
22. The scientist explained how the new discovery could change medicine.

23. He was looking for his wallet but couldn't remember where he left it.
24. The old library downtown has a huge collection of rare books.
25. I didn't expect the movie to be so emotional and thought-provoking.
26. The woman who just moved in next door seems very friendly and kind.
27. We were planning to go hiking, but the weather turned out terrible.
28. The students who studied all night found the exam easier than expected.
29. If I had known how difficult this course would be, I might have chosen another.
30. The train that was supposed to arrive at noon has been delayed due to bad weather.

B Appendix B

Complexity measures employed in this study

- Mean word length
- MATTR of lemmas
- Mean words per phrase
- Mean phrases per clause
- Mean clauses per T-Unit
- Normalised rate of occurrence of dependent clauses
- SUBTLEXus log-10 mean frequency of all tokens

C Appendix C

Could you create an Elicited Imitation Test? Please create 30 items, varying in length, start with the shortest one, then gradually generate longer items. Start at 7 syllables.

Below, you will find an example of an existing EIT (in brackets are the amount of syllables of the sentences).

Please only respond with your generated items.
{examples}

Comparative Evaluation of AI-Generated vs. Expert-written Answer Explanations for a Medical Education Self-Assessment

Yiyun Zhou, Francis O'Donnell, and Victoria Yaneva
National Board of Medical Examiners, Philadelphia, USA
{YYZhou, FODonnell, VYaneva}@nbme.org

Abstract

Answer explanations for medical multiple-choice questions (MCQs) are a valuable learning tool, but producing them is resource-intensive. Writing high-quality explanations requires specialized medical expertise and careful alignment with the keyed answer, distractors, and the clinical vignette. This paper evaluates whether a template-aware, retrieval-guided large language model (LLM) workflow can support this production task in a real formative assessment setting. Using a 50-item medical education self-assessment, we compared AI-generated and expert-written MCQ explanations in a blinded study involving eight medical faculty and sixteen medical students. Each participant rated 25 of 50 paired explanations on clarity, amount of information, and structure. The clearest empirical difference was in amount of information: AI-generated explanations were rated significantly higher than expert-written explanations in a cumulative link mixed model analysis (OR = 1.99, 95% CI [1.33, 2.99], $p = 0.001$). Ratings of clarity and structure did not differ significantly between conditions. Based on faculty ratings, a smaller proportion of AI-generated explanations were judged to require correction (20%) compared with expert-written explanations (38%). These findings suggest that AI can reduce first-draft authoring effort in explanation writing while still requiring expert review to ensure content accuracy.

1 Introduction

Multiple-choice questions (MCQs) are a central component of clinical education and assessment, yet their instructional potential often extends beyond the selection of a correct answer. In many clinical learning tools, MCQs are accompanied by narrative explanations that justify why the correct option is appropriate and why the alternative options are incorrect (see Appendix A for an example

MCQ and explanation). These explanations typically outline the relevant clinical concepts, diagnostic reasoning, or guideline-based considerations that underlie the item, making the expert reasoning process more transparent to learners. By explicitly articulating the logic behind answer choices, answer explanations can help students connect factual knowledge with clinical decision-making, reinforce key principles, and clarify common misconceptions. As a result, they have the potential to transform MCQs from purely evaluative instruments into powerful learning tools that support the development of clinical reasoning.

While valuable as learning support instruments, writing answer explanations for medical self-assessment questions is resource-intensive, which limits the availability of such materials. This is largely due to the strict criteria these explanations must satisfy to be pedagogically useful. Each explanation must justify the correct answer, explain why distractors are incorrect, remain faithful to the clinical vignette, and conform to an editorial style that supports instruction (Ch'en et al., 2025). In practice, therefore, producing high-quality explanations involves more than clinical expertise alone; it also requires careful editing and review to ensure clarity, accuracy, and consistency.

Large language models (LLMs) offer a possible way to reduce this drafting burden. Prior work has shown strong LLM performance on medical question answering and medical explanation tasks (Singhal et al., 2023, 2025). However, most of this literature has focused on answer accuracy and explanation correctness on benchmark datasets rather than the production of pedagogically valuable explanation drafts in real assessment workflows (Kim et al., 2024; Alonso et al., 2024; Chen et al., 2025). That gap matters because educational explanation writing requires not only domain reasoning, but also adherence to instructional goals, editorial conventions, formatting requirements, and expert qual-

ity control; it is also a workflow task shaped by editorial and quality control procedures.

This paper makes two main contributions. First, we develop a pipeline for generating answer explanations for clinical MCQs using AI. The pipeline is designed to produce explanations that address both the correct answer and the distractors while adhering to instructional conventions used in medical education materials. Second, we evaluate the quality of the generated explanations in a comparative study with expert-written explanations. Using blinded evaluations from 8 clinical faculty members and 16 medical students, we find that AI-generated explanations perform comparably to or better than expert-written explanations on clarity, amount of information, and structure.

2 Related Work

Prior work shows that LLMs can perform strongly on medical question answering (QA) benchmarks and that domain adaptation and prompting can further improve performance on medical QA and long-form medical responses, but this literature has largely emphasized answer accuracy rather than the quality, reliability, or educational usefulness of the accompanying explanations (Jin et al., 2021; Singhal et al., 2023, 2025; Chen et al., 2025). This motivates our focus on evaluating explanation quality directly rather than treating the explanations as a by-product of answer prediction.

Our method is also related to work on retrieval-augmented generation, in-context example retrieval, and post-generation refinement and verification. Retrieval can improve knowledge-intensive generation, and the choice of in-context examples can substantially affect downstream LLM performance (Lewis et al., 2020; Wang et al., 2024). Our expert-guided prompt iteration and post-generation checks are also informed by work on automatic prompt optimization, self-refinement, and verification-based decoding (Pryzant et al., 2023; Madaan et al., 2023; Dhuliawala et al., 2024). However, prior work does not directly address the question studied here: whether a retrieval- and prompt-based LLM workflow can generate answer explanations for real medical self-assessment items that are acceptable under expert review and comparable to expert-written explanations.

3 Dataset

The study used two data sets, each consisting of 50 MCQs, from a self-assessment program for medical students in the clinical stage of their training.

Set 1 served as the reference set and included MCQs with corresponding explanations that were used in the system prompts. Set 2 was the experimental set. Although it also contained expert-written explanations, these were not used during AI generation; instead, they were reserved for the later human evaluation, where AI-generated explanations were compared with the expert-written explanations for Set 2.

In addition to the two sets of items and explanations, two internally developed explanation templates reflecting existing editorial standards were provided – a *General* template for areas like basic science and biostatistics, and a *Clinical* template for areas that focus on patient management workflows. These templates guided the expected organization and level of detail in the generated explanations.

Each item within the sets included three distinct metadata tags: *Content Area* - the specific medical topic, coded hierarchically, e.g., Multi: acid-base disorders; *Competency Group* - the targeted physician competency, e.g., B2 Laboratory/diagnostic studies; and *Template Type* - the explanation template structure as either General or Clinical, determined by an LLM. There were 49 content areas and 13 competency groups represented in the dataset.

4 Methodology

When creating answer explanations for MCQs, we face three main challenges.

First, different explanations need to follow different templates depending on their content, as explained in the previous section. Therefore, one of our first tasks given a new item is to perform a binary classification step to correctly classify it into the template most appropriate for its content. Our approach to this task is described in section 4.1. Next, we need to determine the most appropriate items from our reference set that can be used for few-shot prompting. This task is challenging, because the items in the reference set cover multiple topics, content areas and tasks, and relevance can be determined across multiple dimensions. Our approach to this task is described in section 4.2. Finally, the generation is performed using an agentic

structure with *Expert-in-the-Loop* (EITL) calibration, as described in Section 4.3.

Figure 1 provides an overview of the approach and the following sections describe each step.

Figure 1: The workflow Architecture. Input items are routed via a classifier to retrieve context, which is then fed alongside the original input into the generator.

4.1 Dataset Stratification and Template Classification

To optimize the generation process for domain specificity, we employ a schema-aware preprocessing strategy that segments the reference corpus (Set 1), $\mathcal{D}_{ref}$, into distinct reasoning templates - *Clinical* template and *General* template. Correctly routing input items to these templates is critical for correctly organizing the information in the explanations. We implement a hybrid classification pipeline that processes each target item q to assign a template category $T \in \{T_{clinical}, T_{general}\}$. The primary classification is performed by a large language model (GPT-5) which analyzes the semantic content and the metadata tags of the item. To reduce misclassification, we also used a deterministic keyword-based fallback for items with uncertain template assignments, like in domains such as biostatistics and epidemiology. This hybrid approach significantly reduces noise in specialized domains where purely semantic vector matching may struggle to distinguish between subtle sub-competencies.

4.2 Hierarchical Dynamic Few-Shot Retrieval

Because LLMs outputs can be sensitive to the choice of in-context examples, fixed few-shot prompts may be poorly aligned when a query item differs in subdomain, competency, or explanation format. Prior work has shown that retrieval and example selection can substantially affect downstream LLM performance. To address this, we dynamically retrieve a small set of exemplars for each query item q from a reference pool $\mathcal{D}_{ref}$. Rather

than relying only on semantic similarity, we rank candidates using a hierarchical relevance scheme that first prioritizes metadata alignment and then uses textual overlap as a secondary signal.

Specifically, the ranking favors exact matches on the full Content Area code, then broader partial matches on the Content Area prefix, followed by matches on Competency Group and Template type. Lexical overlap between the query and candidate item is used to refine the ordering among otherwise suitable examples. This strategy encourages the retrieved exemplars to match not only the topic of the item but also its instructional framing and expected explanation style. We then insert the top- k examples (with $k = 3$) into the prompt, yielding a query-specific few-shot context that is more stable and better aligned than a static prompt.

4.3 Iterative Optimization and Generation

The generation phase employs GPT-5 as the backbone reasoning engine. Prior to large-scale inference, we perform an Expert-in-the-Loop calibration phase to align the model’s output with the specific pedagogical voice of the assessment. This process treats prompt engineering as a discrete optimization problem (Pryzant et al., 2023), where the objective function is the satisfaction score of a human Subject Matter Expert (SME). In our case, the SME was an editor expert with no clinical background but with experience in editing MCQ explanations for clarity and consistency. In each iteration t , the system generates a batch of explanations R_t using prompt P_t . The SME evaluates these outputs for consistency, format, style guidelines, and presentation logic, providing unstructured natural language feedback F_t . We utilize a meta-prompting strategy to inject this feedback into the prompt instructions, deriving a refined prompt P_{t+1} . This iterative cycle continues until the SME confirms that the outputs consistently meets the required standard without further intervention, ensuring the instructions generalize well to unseen data (Shah, 2025). Following prompt calibration, the system executes the inference pipeline. To mitigate the risk of hallucinations—a critical failure mode in medical QA—we implement a deterministic self-correction loop. The system parses the generated output to verify that every distractor option is explicitly addressed and logically refuted. If the parser detects missing components or structural inconsistencies, an automated “nudge” prompt triggers a regeneration pass. This iterative refinement

helps make the final output more structurally complete and better aligned with the target explanation style (Madaan et al., 2023). Medical consistency was assessed separately through expert review and the blinded comparative study.

5 Study Design and Findings

We evaluated the 50 AI-generated explanations through an external rating study by comparing them to the 50 existing expert-written explanations for corresponding MCQs in Set 2.

The study used a balanced incomplete block design implemented in Qualtrics. For each Set 2 MCQ, participants evaluated two explanations: one AI-generated explanation and one expert-written explanation. The source of each explanation was blinded. Each participant rated explanations for 25 of the 50 MCQs. Participants included 8 medical faculty members and 16 third-year medical students. In the faculty group, each MCQ was evaluated by four faculty members; in the student group, each MCQ was evaluated by seven to nine students.

After reading an explanation, participants rated its *clarity*, *amount of information*, and *structure* on a three-point scale (Poor, Fair, Good). Faculty also indicated whether an explanation needed correction, and both groups could provide optional open-ended comments. For inferential analysis, we fit separate cumulative link mixed models for the three rated dimensions with fixed effects for explanation type, rater group, and their interaction, plus random intercepts for rater and question.

Table 1 shows that average ratings were high for both sources, especially for clarity and structure, where scores clustered near the upper end of the three-point scale. This ceiling effect helps explain why source differences on those dimensions remained small. Even so, AI explanations received slightly higher mean ratings than expert-written explanations in all six source-by-group comparisons. Median-based summaries pointed in the same direction (see Table 2).

The clearest advantage for AI appeared in the *amount-of-information* dimension. A cumulative link mixed model estimated that AI explanations were nearly twice as likely as expert-written explanations to receive a higher rating (OR = 1.99, 95% CI [1.33, 2.99], $p = 0.001$). Neither rater group nor the interaction between rater group and explanation type was statistically significant, suggesting

that faculty and students did not differ systematically in their rating patterns and that the relative advantage of AI explanations was similar across both groups.

Lastly, faculty flagged fewer AI explanations than expert-written explanations for needing corrections: 10 of 50 AI explanations (20%) versus 19 of 50 expert-written explanations (38%). Most flagged cases were identified by only one reviewer, suggesting subjectivity.

6 Conclusion

This study demonstrates that a retrieval-guided LLM pipeline can generate explanations for MCQs that are comparable to expert-authored explanations under blinded human evaluation. Across both faculty and student raters, AI explanations matched expert explanations on clarity and structure and were rated significantly higher on the amount-of-information dimension. These results suggest that LLM-assisted workflows can meaningfully support the production of MCQ explanations in medicine. A strength of this study is its inclusion of both clinical faculty and medical students, allowing explanation quality to be assessed from the perspectives of expert reviewers and intended learners.

However, even highly rated AI explanations occasionally included verbosity, stylistic inconsistencies, or unsupported clinical details, necessitating expert review. Rather than investing effort in drafting explanations from scratch, experts can focus on review, calibration, and targeted revision to ensure clinical accuracy and pedagogical quality. More broadly, these results point to a practical role for AI in assessment development pipelines: accelerating the generation of high-quality first drafts while preserving expert oversight as the central mechanism for maintaining reliability and trust.

7 Limitations and Ethical Considerations

This study has several limitations. First, the evaluation was conducted on a single set of medical self-assessment explanations from one assessment context and therefore reflects one content domain and one editorial style rather than a fuller range of medical assessment materials. Second, the external review sample was modest (8 faculty and 16 third-year medical students, all U.S.-based), and each participant rated only a subset of explanation pairs under a balanced incomplete block design. Third, the three-point Poor/Fair/Good scale reduced re-

Dimension	Students		Faculty

Amount of information	2 (1)	3 (1)	2 (1)	3 (1)
Structure	3 (0)	3 (0)	3 (0)	3 (0)

Table 2: Median and interquartile range of medians across explanations.

spondent burden for a lengthy rating task, but it also compressed variation and likely contributed to ceiling effects on clarity and structure.

From an ethical and operational perspective, we frame this work as AI-assisted content generation within a human-reviewed editorial process, not as replacement of human expertise. In this study, generated explanations remained subject to editor screening and expert review for clarity, alignment with the vignette, medical consistency, and bias. The need for this oversight is underscored by observed issues such as redundancy, imprecise wording, and occasional content misrepresentation in generated outputs. Because the study involves proprietary assessment materials and externally authored comparison explanations, we intentionally abstract some operational details and refer to external contributors generically. More broadly, the goal of this work is not to suggest that explanation authoring can be fully automated, but to evaluate whether retrieval-guided generation can support a more efficient and responsible human-centered authoring workflow for educational content.

Bias is another important reason for human oversight. Language models trained on large corpora may reflect biases related to patient demographics, disease prevalence, or clinical assumptions. If such biases appear in explanations, they could reinforce stereotypes or present an unbalanced view of clinical practice. Systematic evaluation for bias and careful editorial review are therefore necessary components of responsible deployment.

Transparency and accountability are also important in assessment contexts. Organizations using AI-assisted workflows must determine how to communicate the role of AI in content development and ensure that responsibility for the final content remains clearly assigned to human experts. More

broadly, AI systems should be positioned as tools that support expert authorship rather than replace it, helping to reduce drafting effort while preserving expert oversight and responsibility for educational quality.

A Sample Item and Explanation

A.1 Item

A 58-year-old woman is brought to the emergency department 4 hours after the sudden onset of left-sided facial, arm, and leg weakness. She has hypertension treated with a diuretic. She reports the sensation of a fluttering heart for 1 week. Her pulse is 125/min and irregular, and blood pressure is 135/80 mm Hg. Physical examination shows a left-sided facial droop. There is flaccid weakness of the left upper and lower extremities. An ECG shows a rapid, irregular ventricular rate with no discernible P waves. Which of the following therapies would best improve function of the weakened muscles over the next 3 hours?

- A. Acetylcholine agonist
- B. Acetylcholine antagonist
- C. Antifibrinolytic
- D. Fibrinolytic
- E. Procoagulant

Correct Answer. D.

A.2 Explanation

This patient with a likely thromboembolic cerebral infarction (stroke) from atrial fibrillation would benefit from fibrinolytic therapy. Strokes occur due to ischemic or hemorrhagic loss of blood supply to the brain and manifest as focal neurological deficits related to the dysfunction of the affected brain region. Approximately 80–85% of strokes are ischemic, commonly arising from thromboembolic disease, for which atrial fibrillation is a major risk factor. Atrial fibrillation typically presents with palpitations, fatigue, lightheadedness, and mild dyspnea if symptomatic. On ECG, atrial fibrillation demonstrates irregularly irregular RR intervals without discernible P waves. Prolonged atrial fibrillation leads to left atrial hemostasis and increases the risk of thrombosis. A thrombus from this patient's left atrium likely embolized to the right internal carotid artery supplying the right precentral gyrus, resulting in left-sided hemiparesis. Alteplase (tissue plasminogen activator) is a fibrinolytic medication utilized in ischemic strokes that binds to fibrin clots and converts plasminogen to plasmin, which lyses clots. If given early (generally within 3–4.5 hours after onset of the event), alteplase may promote neurological recovery.

Incorrect Answers: A, B, C, and E.

Acetylcholine agonists (Choice A) and antagonists (Choice B) are unlikely to be helpful in lysing this patient's thromboembolic clot, as the interaction of acetylcholine with the coagulation cascade is poorly defined. Acetylcholine agonists (eg, bethanechol) may improve cognition in patients with dementia, decrease heart rate, improve gut peristalsis, increase bladder contraction, and increase exocrine gland secretions. Acetylcholine antagonists (eg, benztropine) typically increase heart rate, decrease gut and bladder activity, and worsen cognitive function. They also act on muscle at the motor end-plate; however, this patient's weakness results from central nervous system dysfunction without pathology at the muscle fiber itself.

Antifibrinolytic (Choice C) therapy (eg, tranexamic acid) displaces plasminogen from fibrin clots to promote hemostasis during intraoperative bleeding, heavy menstrual bleeding, and traumatic hemorrhage. Procoagulant (Choice E) therapy (eg, protamine, coagulation factors) increases activation of the coagulation cascade. Both antifibrinolytic and procoagulant therapy would not lyse this patient's clot and may lead to further thrombosis.

Educational Objective. Patients with atrial fibrillation are at risk for thromboembolism due to left atrial hemostasis, which may result in ischemic strokes. Strokes manifest as focal neurological deficits related to the dysfunction of the affected brain region. Ischemic strokes are treated with fibrinolytic therapy, which promotes neurological recovery.

Abstract

Russian grammar correction models can improve on aggregate benchmarks while getting worse at specific grammar rules. We show this through per-rule evaluation on a diagnostic benchmark of 48 prescriptive rules: finetuning on synthetic data improves overall $F_{0.5}$ while driving subordinate-clause comma accuracy from 14% to 1%. The suppression is invisible under corpus-level metrics and undetectable with existing coarse, corpus-specific tagsets; it is recoverable only when diagnosed at rule granularity. To enable this analysis, we develop a 98-category error taxonomy grounded in Rozental’s reference grammar and SyntErr, an open-source synthetic data generator whose per-rule distribution is an explicit parameter, designed to support arbitrary rule sets and languages. Finetuning eight open models (0.8B–12B) on 39K synthetic examples yields up to 75.3 $F_{0.5}$, approaching frontier API models with models small enough to run on device. We release the taxonomy, generator, per-rule evaluation data, and all training artifacts.

1 Introduction

Russian grammatical error correction remains a small field with limited resources: the largest annotated corpus contains fewer than 15K sentences, and each of the handful of existing benchmarks defines its own error categories and tagset. These tagsets serve different purposes: RLC (Kosakin et al., 2024) classifies errors by their likely cause in the writer (e.g., case-government errors after a verb or preposition; transfer from the writer’s first language, L1), which is useful for second-language (L2) pedagogy; RULEC-GEC and GERA use POS-based categories suited to automatic annotation. But neither approach identifies which prescriptive rule was violated.

Recent work has shown that generative LLMs are increasingly competitive with sequence label-

ing models for GEC, but they are still evaluated with the same aggregate metrics. This is problematic because the failure modes differ. Sequence-labeling models make one wrong prediction at a time, on individual tokens, which is easy to inspect. Generative models can systematically fail to apply a rule that was underrepresented in their training data, a failure that no aggregate score will reveal. Diagnosing the latter requires mapping errors to specific grammar rules.

We cross-reference three Russian GEC corpora against Rozental’s reference grammar (Rozental’, 1997), the most widely used prescriptive handbook for Russian writing norms¹, covering orthography, punctuation, and morphology/stylistics across 213 paragraphs. Coverage is sparse: the best corpus covers 65% of paragraphs, and 47 paragraphs have no attestation in any corpus.

A deeper problem is the data itself. RULEC-GEC and RU-Lang8, both L2 corpora, remain the primary training resources for Russian GEC, so current systems are optimized for learner errors. But L1 and L2 error distributions barely overlap outside of spelling: L2 corpora contain virtually no prescriptive rule violations, and some L2 errors superficially resemble L1 errors without sharing the same underlying cause. It has been shown (Sorokin and Nasyrova, 2025) that training on L2 data actively degrades performance on L1 rule-specific correction.

Our central argument is that GEC for morphologically rich languages suffers from three entangled problems that current approaches fail to decompose: (1) the sequence labeling formulation conflates rule identity, corpus frequency, and the specific replacement word into a single classification decision; (2) training on L2 corpora actively

¹For orthography and punctuation alone, the RAS-endorsed handbook by Lopatin et al. has greater institutional authority, but does not cover morphological norms, government, or stylistics, which are all essential for GEC.

* Corresponding author.

suppresses L1 prescriptive rules because the two error populations are largely disjoint; (3) aggregate evaluation hides rule-level damage, making both problems invisible. We address all three through rule-grounded synthetic data (SyntErr), per-rule evaluation anchored in Rozental’s reference grammar, and per-rule diagnostics that reveal training-data-induced suppression.

Our contributions are:

- **Taxonomy and cross-reference.** A three-level error taxonomy (8 categories / 29 sub-categories / 98 fine-grained tags) grounded in Rozental’s 213 paragraphs. We cross-reference three corpora (GERA, RULEC-GEC, LORuGEC) against this taxonomy and provide an empirical classification of 4,682 of GERA’s 5,988 errors into our categories via LLM-assisted classification (Claude Sonnet 4.6), revealing per-corpus coverage gaps (§3).
- **SyntErr.** An open-source rule-based error generator that ties each synthetic error to a specific Rozental paragraph, with configurable per-rule error rates. The current release covers the 48 rules tested by LORuGEC (Sorokin and Nasyrova, 2025), a subset of our 98 categories that future work can extend.
- **Experimental evidence.** Fine-tuning eight open models (0.8B–12B) from three families on 39K SyntErr examples plus 348 LORuGEC examples reaches 75.3 $F_{0.5}$, approaching frontier APIs with on-device-sized models (§5).

2 Related Work

We review existing Russian GEC corpora (§2.1), synthetic data generation methods (§2.2), and position our approach relative to both.

2.1 Corpora

Table 1 summarizes the publicly available Russian GEC corpora. Tag-set granularity varies by more than an order of magnitude, from 4 coarse edit labels in RU-Lang8 to 57 cause-oriented tags in RLC-GEC. Most are L2 (learner) corpora; only GERA, LORuGEC, and CoRST contain L1 errors, and LORuGEC is the only one annotated at the level of individual grammar rules. Two of the larger resources (RLC, CoRST) are accessible only through

a query interface rather than as bulk downloads. No corpus is annotated against a reference grammar.

RULEC-GEC (Rozovskaya and Roth, 2019), the main Russian GEC benchmark, contains 12.5K L2/heritage sentences annotated with 23 morphosyntactic tags. RU-Lang8 adds L2 author diversity but uses only four coarse edit labels. RLC-GEC (Kosakin et al., 2024) is a fully annotated subset of the Russian Learner Corpus with 57 cause-oriented tags. LORuGEC (Sorokin and Nasyrova, 2025) is the first Russian corpus annotated at the level of individual grammar rules (48 rules, 960 sentences).

Beyond error-annotated corpora, RuBLiMP (Taktasheva et al., 2024) provides 45K minimal pairs isolating 45 grammatical phenomena, showing that even large LMs fail on negation, reflexivity, tense, and aspect. RuCoLA (Mikhailov et al., 2022) offers 9.8K sentences for binary acceptability judgments. We use both as supplementary evaluation (§5).

2.2 Synthetic Data and Rule-Based Evaluation

Tagged corruption models (Stahlberg and Kumar, 2021, 2024) train a neural network to introduce errors guided by error type labels, but for Russian the only available labels come from 5K RULEC-GEC sentences with a coarse 20-tag set, so the generator reproduces L2 patterns and cannot generate L1 rule violations absent from its training data. Rule-based generation sidesteps this: GECTurk (Kara et al., 2023) (Turkish), Ma et al. (2022) (native Chinese GEC, closest to ours in motivation), Palma Gomez et al. (2023) (Ukrainian), and Náplava and Straka (2019); Náplava et al. (2022) (Czech) all define language-specific heuristics. Two recent studies anchor evaluation in reference grammars: Li et al. (2026) probe LLMs against 673 points from a Luxembourgish grammar book, finding that translation quality does not predict grammatical competence; Banno et al. (2026) use the English Grammar Profile to detect constructs in L2 writing. Sorokin and Nasyrova (2025) improve Russian GEC via retrieval-augmented prompting (41.0 $\rightarrow$ 56.1 $F_{0.5}$ on LORuGEC).

Across these resources and methods, three gaps recur. No Russian GEC corpus annotates errors against a reference grammar, so coverage of prescriptive rules is unknown. No Russian generator offers explicit per-rule control over the error distribution it produces; existing generators inherit their

Table 1: GEC corpora with natural Russian-language data

Corpus	Year	Size (annotated / full)	Source	Tag set size	Format
RLC-GEC	2024	31,519	L2	57	CSV
RLC	2013	~90,000 / 193,189	L2/HL	46+	Query interface
RULEC-GEC	2019	12,480	L2/HL	23	M2
GERA	2024	6,681	L1, schoolchildren	31	M2
LORuGEC	2025	960	L1 grammar resources	48	M2
CoRST	2013	~20,000 / ~175,000	L1, students	39	Query interface
RU-Lang8	2021	4,412 / 51,575	L2	4	M2

distribution from the L2 corpora they were trained on. And evaluation reports single aggregate metrics that cannot separate gains in frequent rules from losses in rare ones. The rest of the paper takes up these three gaps in turn.

3 Analysis

3.1 Taxonomy

We anchor our error taxonomy in Rozental’s Справочник по правописанию и стилистике (Rozental’, 1997) (Handbook on Spelling and Style), the most widely used prescriptive handbook for Russian. It comprises three parts (orthography §§ 1–74, punctuation §§ 75–138, morphology/stylistics §§ 139–213) and consists of 213 paragraphs. We define a three-level taxonomy: 8 coarse categories (e.g., SPELL, PUNCT), 29 sub-categories, and 98 fine-grained tags. Each fine-grained tag maps to one or more Rozental paragraphs and carries an applicability rating (full, partial, or L1-only). Parts I–II describe hard rules violated by both L1 and L2 writers. Part III is different: it covers morphological variants (e.g., § 198: в отпуске vs. the colloquial в отпуску), verbal government, agreement subtleties, and stylistic norms — prescriptive preferences that L2 learners rarely encounter. Of our 98 fine-grained tags, 55 are fully applicable to L2 writers, 28 partially, and 15 are L1-only. This makes the same taxonomy usable for evaluating both native-speaker and learner GEC systems.

3.2 Coverage Analysis

Existing corpora follow a corpus-driven error-set approach: tags are derived from errors already present in the data. The resulting tagsets are coarse. GERA’s single PUNCT tag spans 16 distinct punctuation rules in our taxonomy; S:ORTH covers 24 spelling subcategories (Table 3). A model that corrects only doubled consonants but fails on root

vowel alternations is indistinguishable under these tags. Prescriptive rules, by contrast, are explicit, reproducible, and citable: when a model fails on Rozental § 87 (comma in compound sentences), the failure traces to a specific norm. A full cross-reference (supplementary materials) confirms the scale of the mismatch: 77 of our 98 fine-grained tags fall under just 20 RULEC tags, and 95 fall under just 27 GERA tags.

To assess coverage at the level of individual rules, we built a per-paragraph evidence table² for three corpora: two L1 (GERA, LORuGEC) and one L2 (RULEC). The pipeline uses the Claude Sonnet 4.6 API: for each Rozental paragraph it searches the corpus for candidate error examples, classifies them to the specific sub-rule, and records the result. For GERA (5,988 errors) we additionally classified each error into our fine-grained tags, grouping errors by their original GERA tag so each classification request covered one tag at a time (Table 3). 4,682 errors received a fine-grained tag; the remaining 1,306 fell outside the 48 currently-implemented rules or the LLM declined to classify them. All assignments were reviewed by a single annotator (a native Russian speaker); approximately 12% of the model’s initial assignments were corrected during review.

Table 2 shows that coverage is incomplete even at the paragraph level. Within each paragraph the situation is worse. A single Rozental paragraph may contain up to twenty sub-rules (the general rule, its exceptions, and special cases), but corpora typically attest only one of them, and sometimes only an exception rather than the general rule it modifies. The mapping is not clean in either direction: one correction can correspond to several rules, and one sentence can contain several distinct errors. RULEC has no punctuation coverage at all,

III. Morph. (75 §§)	39	41	7	58
Total (213)	139	95	42	166

Table 2: Evidence coverage: Rozental paragraphs with at least one verified error example per corpus. RULEC has zero punctuation coverage. 47 paragraphs are untested in any corpus. Condensed by Rozental chapter; the full per-paragraph table (213 rows) is in the supplementary materials.

GERA tag	N	N _{tags}	Top categories
PUNCT	2542	16	subordinate cl. (668), parenthetical (263), isolation (239)
S:ORTH	975	24	checked root (145), unchecked root (124), conjunction sp. (101)
G:NOUN:CASE	303	10	double gov. (110), prep. case (63)
S:LETTER:CASE	244	4	proper nouns (117), titles (63)
L:OTHER	233	3	paronyms (212)
L:REP	286	2	pleonasm (249)

Table 3: GERA error reclassification. Each GERA tag maps to multiple fine-grained categories in our 98-tag Rozental-grounded taxonomy. Automated classification by Claude Sonnet 4.6 with errors grouped by their original GERA tag so each request covered one tag at a time; results manually verified. N_{tags}: number of distinct fine-grained tags per GERA tag. GERA’s single PUNCT tag spans 16 distinct punctuation rules; S:ORTH spans 24 spelling subcategories. Full distribution available at <https://synterr-nlp.github.io/papers/bea-2026/>.

and across all three corpora 47 paragraphs (about a fifth of Rozental) have no attestation.

The gaps are not random. Learner corpora (RULEC, RU-Lang8) systematically miss the L1-only rules, which is why training on L2 data has been shown to degrade L1 correction performance (Sorokin and Nasyrova, 2025). These gaps propagate directly into training data: a model trained on a corpus that lacks punctuation examples will not learn punctuation rules, regardless of architecture. With the shift toward LLM-based GEC this bottleneck becomes addressable. LLMs already command Russian grammar from pretraining; what they need is a rule-level training signal, not token rewrites, to improve on specific prescriptive norms.

3.3 Why Generative Models?

The sequence labeling formulation of GEC (classifying each token as KEEP, DELETE, REPLACE, or APPEND (Omelianchuk et al., 2020)) has been the dominant paradigm for six years: it guarantees minimal edits by construction, producing corrections that preserve the author’s text rather than rewriting it. For English, where most corrections are single-token edits on a language with minimal inflection, the label vocabulary stays manageable.

For morphologically rich languages like Russian, the formulation entangles three things: the linguistic rule being violated, the frequency of that violation in the training corpus, and the specific replacement word. For example, the same case error gets a different label when it appears on книга than on стол: GECToR-style labels are concrete output forms (e.g., \$REPLACE_книгу), not abstract operations like “put in the genitive,” so each word × case combination demands its own label. GECToR-style models pick each token’s correction from a fixed vocabulary of 5–20K discrete labels. This vocabulary grows combinatorially with case, number, gender, and animacy, and cannot generalize to rule–word combinations absent from training.

This class imbalance is severe: in both RULEC-GEC and GERA, 94% of source tokens are already correct and receive the KEEP label during training. A rule that appears in a handful of training examples can’t compete with this signal: the model defaults to copying rather than correcting. This explains the finding of Sorokin and Nasyrova (2025) that fine-tuning on general GEC data is detrimental for rule-specific errors.

Generative models sacrifice the structural guarantee of minimal edits. In exchange, no single decision has to do all three jobs at once. The rule itself comes from pretraining. Which rules to train on comes from SyntErr, not from how often they appear in natural data. The editing behavior (*be precise, be minimal, do not rewrite*) comes from the prompt and training format, which makes it a soft constraint rather than an architectural one. Without careful prompt and data design, this softness leads to paraphrase; our overcorrection analysis (§6) quantifies this failure mode and how to mitigate it. In exchange, because the output is free text, any rule that SyntErr can generate becomes a training example with no change to the model.

4 SyntErr

We present SyntErr: an open-source error generation tool for GEC. SyntErr accepts any error taxonomy and any target distribution, extensible to new languages and rule sets. Given clean text, it introduces errors whose type, frequency, and direction are explicit YAML configuration parameters, not artifacts of corpus collection. Labels are correct by construction: each error is tagged with the rule that generated it.

Every step of the pipeline exploits linguistic information from stanza (Qi et al., 2020): POS tags and morphological features determine which tokens are valid corruption targets, dependency parses identify syntactic positions (clause boundaries for punctuation, amod arcs for agreement, obl/nmod for government targets), and pymorphy3 generates correctly inflected corrupt forms preserving all non-target features. The result is structurally realistic errors, not random noise. Concurrently, Qiu et al. (2025) reimplemented ERRANT using stanza for multilingual GEC annotation across five languages, validating stanza as the tool of choice for morphologically aware GEC pipelines.

Each example is a (src, tgt, rule) pair with one or several errors, depending on configuration. SyntErr’s minimal-pair mode (one error per sentence) is what we use for supervised fine-tuning in this paper. The current release implements all 48 rules tested by LORuGEC (Sorokin and Nasyrova, 2025), generates 10K examples in under 2 minutes on CPU, and requires no GPU or annotated data as input.

Pipeline. The generation pipeline operates in four steps. (1) An error-type distribution is specified via YAML configuration, or set to uniform (default). (2) Clean source sentences are analyzed by stanza (Qi et al., 2020), which provides both morphological tags (contextual POS, case, gender, number, e.g., стали = noun.Gen or verb.Past) and a full dependency parse tree. The parse tree is critical: it tells the generator *which* tokens stand in a syntactic relation that a given rule can target. (3) An error type is selected according to the distribution; the dependency tree is queried for applicable positions (e.g., all amod arcs for adjective–noun agreement, all clause boundaries for comma rules), and one is chosen at random. (4) The corruption is applied using pymorphy3 for morphological inflection. The output is a {src, tgt, rule} triple. The pipeline diagram is shown in Figure 2.

Figure 1: Dependency-driven error generation. Each arc family targets different syntactic relations: agreement (blue) uses amod/nsubj, punctuation (green) uses clause boundaries, government (red) uses obl/nmod. Corrupted forms shown below.

Most error types are not applied at random positions but at positions identified through dependency parsing: punctuation rules inspect clause boundaries and conjunction scopes, agreement rules traverse amod and nsubj arcs, and government rules use obl/nmod arcs to corrupt case frames (Figure 1). Spelling rules use dictionary lookup and Zaliznyak’s stress dictionary (Zaliznyak, 2010); inflection uses pymorphy3. Detailed rule descriptions are in Appendix D.

5 Evaluation

5.1 Experimental Setup

Models. We evaluate models in three settings: (1) frontier API models: Claude Sonnet 4.6, Claude Opus 4.5/4.6, GPT-5.4, and GigaChat-2-Max (zero-shot only); (2) eight open models fine-tuned with LoRA: Qwen 3.5 (0.8B, 4B, 9B), Qwen 2.5-7B, Gemma 3 (1B, 4B, 12B), and Apertus-8B; (3) GigaChat-3.1-Lightning (10B MoE, 1.8B active; zero-shot only). All evaluations use greedy decoding.

Data. We generated 39,209 training examples across the 48 LORuGEC evaluation rules. Source text is drawn from the RuBLiMP source pool (Taktasheva et al., 2024) (38%), Taiga (Shavrina and Shapovalova, 2017) and news corpora (Fedorov, 2019) (25%), and targeted mining for forms required by underrepresented rules (e.g., rare conjunctions, diminutive suffixes, compound adjectives; 37%). The target distribution is approximately uniform; some rules are limited by source sentence availability. All RuBLiMP benchmark sentences are excluded. Punctuation corrections are skewed 3.6:1 toward comma insertion over deletion, reflecting the natural L1 tendency to omit

required commas rather than insert spurious ones.

Fine-tuning. We fine-tune with LoRA (Hu et al., 2022) ($r=16$, $\alpha=32$, all attention and MLP projections), effective batch size 32, learning rate 10^{-4} , bf16 precision.

LORuGEC provides 348 validation and 612 test sentences. All reported scores are on the 612-sentence test set. For each model, we train three settings: (1) *SyntErr only* (39K synthetic examples), with early stopping on LORuGEC val loss (patience 5); (2) *LORuGEC only* (348 sentences — the LORuGEC val split, repurposed as training data), trained for 3 epochs; (3) *SyntErr then LORuGEC* (two-stage: first SyntErr with early stopping on val, then continued on the 348 examples for 3 epochs). Conditions (2) and (3) train on the LORuGEC val split; with 348 examples at effective batch size 32, training completes in ~ 33 steps, too few to trigger intermediate evaluation. We additionally train a clean-text control where source equals target (no errors introduced), to verify that gains come from error patterns rather than task-format exposure.

Prompt. All training and evaluation use the system prompt proposed by Sorokin and Nasyrova (2025) for LORuGEC evaluation (“Дорогая языковая модель. . .”; full text in Appendix A). This prompt instructs the model to minimally correct the input text. We adopt it to ensure fair comparison with published baselines, but note that prompt sensitivity varies substantially across model families (Table 7). We additionally evaluate frontier models with a strict prompt that explicitly forbids word substitution (“НЕ МЕНЯЙ СЛОВА” — ‘don’t change words’; full text in Appendix A). The strict prompt is used only for the prompt-sensitivity ablation (Table 7), not for the main results in Table 4: it deliberately disallows lexical substitution, which is appropriate for spelling and punctuation rules but not for morphological or stylistic ones. The baseline prompt asks for minimal correction but does so in indirect, deferential language; some models interpret this as license to paraphrase. The strict prompt constrains the model to targeted edits only. The gap reaches 16.7 $F_{0.5}$ on GigaChat-2-Max (Table 7), confirming that prompt design is a major confound in GEC evaluation (Li et al., 2026).

Benchmarks. *LORuGEC test*: 612 test sentences, 48 prescriptive rules. *GERA*: 1,314 test sentences from school texts, OOD for synthetic data. *RuCoLA*: 1,804 OOD dev sentences for gram-

maticity judgment (Matthews Correlation Coefficient; 0 = chance, 1 = perfect). All GEC scores use M2scorer $F_{0.5}$.

We normalize $\ddot{e} \rightarrow e$ and dash variants before scoring (details in Appendix E).

5.2 Results

Fine-tuning on SyntErr improves LORuGEC scores across all models (Table 4). Fine-tuning on SyntErr improves LORuGEC $F_{0.5}$ over zero-shot for every model tested. Qwen3.5-0.8B jumps from 13.7 to 45.2 (+31.5), Qwen3.5-4B from 47.6 to 67.0 (+19.4), and Apertus-8B from 48.7 to 69.4 (+20.7). Continuation on 348 real LORuGEC examples adds further gains: Qwen3.5-4B reaches 75.3 and Apertus-8B 72.4, approaching Claude Opus 4.6 zero-shot (81.8, Table 5) with far fewer parameters. For Qwen3.5-9B, SyntErr-only (57.3) still improves over zero-shot (49.2) but underperforms lorugec-only (61.2), likely due to the 3.6:1 comma insertion skew in training data; continuation training recovers to 70.9.

Clean-text control. To test whether SyntErr’s gains come from learning error patterns or simply from exposure to the prompt-and-response format, we train on clean text where the source and target are identical, following the no-corruption baseline of Kiyono et al. (2019). This collapses performance: Qwen2.5-7B drops to 2.0 on LORuGEC (from 39.5 zero-shot), Qwen3.5-0.8B to 0.0, confirming that the gains require actual error examples.

Per-rule analysis. LORuGEC’s 48 rules allow fine-grained evaluation. On Qwen3.5-4B, SyntErr→LORuGEC continuation improves 39 of 48 rules over zero-shot, degrades 5, and leaves 4 unchanged. Table 6 shows the extremes. Gains concentrate on fused/split spelling rules that SyntErr generates by construction; regressions concentrate on government and lexical rules that require semantic judgment. Notably, subordinate clause comma deletion drops from 10% to 0% under SyntErr-only: the 3.6:1 insertion skew in training data teaches the model to preserve commas rather than remove them. Continuation on 348 real examples recovers this to 50%. Full per-rule results (48 rules $\times$ 35 settings) are available at <https://synterr-nlp.github.io/papers/bea-2026/>.

Does GEC finetuning break general language understanding? Training a model to correct specific grammar rules could in principle make it reject

sentences that native speakers find perfectly acceptable. To check this, we evaluate all models on RuCoLA (Mikhailov et al., 2022), a benchmark where the model judges whether Russian sentences are grammatically acceptable or not. For models ≥4B parameters, MCC remains stable across all training settings (Table 9). Smaller models (0.8B, 1B) show some degradation under SyntErr, reflecting the narrower capacity trade-off at that scale.

6 Discussion

GERA degradation. SyntErr’s source text is formal, edited prose (news, encyclopedias); GERA contains school essays by children. Qwen models show GERA degradation after SyntErr training (Qwen3.5-4B: 56.5 → 47.9), but Gemma models do not (46.3 → 48.9). The pattern is consistent across model sizes within each family, suggesting an architecture- or pretraining-level difference rather than a capacity issue. On Qwen3.5-4B, SyntErr increases the share of unchanged outputs (*copy*

Rule	ZS	+s→l	Δ
<i>Top 5 improvements</i>			
зато (spelling)	16.7	91.7	+75.0

in Table 8) on GERA from 7.7% to 22.5%: the model learns to be conservative from minimal-pair training and under-applies this to the noisier school-essay domain. Gemma, which starts with a lower zero-shot baseline, has less to lose from increased conservatism. Continuation on LORuGEC recovers GERA in all cases.

Prompt sensitivity. Replacing the baseline prompt with a strict variant yields up to +16.7 F_{0.5} on GigaChat-2-Max (Table 7).

Reasoning hurts. Enabling thinking mode on Qwen3.5-9B drops LORuGEC F_{0.5} from 49.2 to 23.4. The model cites Rozental by name in 165

	LORuGEC		GERA	
	Base	Strict	Base	Strict
GC-2-Max	48.4	65.1 +16.7	37.5	58.7 +21.2
GPT-5.4	73.7	77.4 +3.7	59.4	66.1 +6.7
Claude 4.6	76.7	78.2 +1.5	65.9	71.5 +5.6

Table 7: Prompt sensitivity (M2 F_{0.5}). Base = baseline prompt (Appendix A); Strict = explicit “do not change words.”

of 612 examples, but states the rule incorrectly 91% of the time. On *и так, и эдак (no comma per § 154), it finds the correct answer (“*sometimes written without commas as a fixed idiom*”) but frames it as optional and copies the input. The minimize-changes instruction interacts adversarially with the reasoning process: the model uses it to justify rejecting every correction it considers (“*since the prompt says ‘don’t change correct punctuation,’ I should not remove them*”). On rare words the model cannot recognize, reasoning produces empty output: up to 167 self-correction loops (“Wait, let me reconsider...”) consuming 14K tokens without committing to an answer. These loops are a reasoning pattern trained via reinforcement learning on math and code (DeepSeek-AI, 2025), where backtracking enables error recovery; for GEC, they amplify uncertainty rather than resolving it. The model’s prescriptive knowledge is too shallow to support productive chain-of-thought decomposition (Wei et al., 2022). The degradation is not category-specific either: under thinking, exact-match accuracy drops in every L0 category we measured (spelling −21.5, punctuation −22.4, agreement −25.6, morphology −20.0, government −56.2, lexical −10.7, averaged across the 35 LORuGEC rules mappable to our taxonomy). Mechanical categories where reasoning is plausibly unnecessary (spelling, punctuation) suffer at the same magnitude as semantic ones, ruling out the reading that thinking helps complex rules while hurting simple ones. Scaling does not help either: Qwen3.5-35B-A3B (MoE, 9B active) drops from 58.9 to 29.3 under the same conditions, confirming that reasoning-mode degradation is not a capacity issue.

The overcorrection problem. Sorokin and Nasyrova (2025) argue that generative models rewrite for fluency rather than minimally fixing errors. We quantify this directly (Table 8). On LORuGEC, zero-shot Qwen3.5-4B produces wrong edits 40.5%

	LORuGEC			GERA		
	Copy	Exact	Over	Copy	Exact	Over
ZS	31.2	28.3	40.5	7.7	40.5	51.8
+lor	5.1	23.5	71.4	3.1	13.0	83.9
+syn	38.4	38.4	23.2	22.5	55.0	22.5
+s→l	24.8	54.4	20.8	16.1	60.3	23.7

Table 8: Prediction behavior (%; Qwen3.5-4B). *Copy*: pred = source. *Exact*: pred = gold. *Over*: pred ≠ source ≠ gold. LORuGEC-only (+lor) produces 71–84% overcorrection.

of the time (overcorrection) and copies the input unchanged 31.2% (undercorrection). SyntErr finetuning halves overcorrection to 23.2% and doubles exact match from 28.3% to 38.4%. The second training stage (continuation on real LORuGEC examples) teaches the model when *not* to edit: overcorrection drops to 20.8%, exact match reaches 54.4%. LORuGEC-only finetuning (348 examples) fails badly: 71.4% overcorrection, showing the model learns to edit everything but not *what* to edit.

Per-rule analysis reveals the mechanism: on rules SyntErr covers well, overcorrection is near zero (0–6%); on rules requiring lexical judgment, it remains 43–78% as the model normalizes register rather than correcting grammar.

Aggregate scores hide rule-level damage. Averaged across all eight models, SyntErr finetuning suppresses subordinate clause comma deletion from 14% to 1%: because SyntErr generates comma *insertion* errors 3.6× more often than *deletion* errors, the model learns to preserve commas rather than remove them. Meanwhile, compound-word spelling (e.g., OTTOFO vs. OT TORO) improves from 28% to 85%. Aggregate F_{0.5} rises because the spelling gains outweigh the punctuation losses, but the punctuation rules are silently suppressed, invisible under aggregate evaluation. Continuation on 348 real examples recovers the affected rules (1% → 69%): the suppression is reversible once diagnosed. This is only possible with per-rule evaluation grounded in a reference grammar.

L1 transfer without L1 training data. Training exclusively on SyntErr (synthetic L1) and 348 LORuGEC examples transfers to GERA without any GERA-specific training: Qwen3.5-4B reaches 62.8 F_{0.5}, within 4.3 points of Sorokin and Nasyrova’s Qwen2.5-7B finetuned on GERA data (67.1). SyntErr teaches which errors to fix; LORuGEC

continuation teaches when not to edit.

7 Conclusion

We have presented three contributions toward rule-grounded GEC for morphologically rich languages. First, a 98-category taxonomy anchored in Rozenal’s reference grammar, revealing that existing corpora cover at most 65% of its paragraphs and that their coarse tagsets mask critical gaps. Second, SyntErr, an error generator whose per-rule distribution is an explicit parameter, not an artifact of corpus collection; the current release covers 48 of the taxonomy’s 98 categories and is open to extension. Third, experimental evidence across eight models from three families that 39K synthetic examples plus 348 real examples yield up to 75.3 $F_{0.5}$ on LORuGEC, approaching frontier models with 0.8B–12B open models.

Per-rule evaluation, enabled by the taxonomy, reveals what aggregate scores hide: training data can suppress specific rules (subordinate clause commas: 14% $\rightarrow$ 1%, averaged across models) while improving others (3aTo spelling: 17% $\rightarrow$ 92%), and continuation training on a small diagnostic set recovers the suppressed rules. This is the practical payoff of grounding GEC evaluation in a reference grammar.

A natural next direction is reinforcement learning rather than supervised fine-tuning. SFT remains the dominant recipe, but our results suggest it can distort the model’s edit distribution: the model learns the marginal of the synthetic data (“edit something on every sentence”) even where the input is already correct, which is exactly the overcorrection pattern we measure. A reward that captures minimal-edit behavior at the rule level should let the model retain pretrained linguistic knowledge while still picking up rule-specific corrections, without acquiring the SFT-induced bias toward editing.

We release the taxonomy with cross-reference tables, SyntErr, all training configurations and adapter weights, and per-rule evaluation data³.

Limitations

Scope. We evaluate on Russian only. We do not evaluate on L2 (learner) benchmarks or at the document level, and we use a single prompt regime in the main results (§6 reports a separate

prompt-sensitivity analysis but not a fully orthogonal sweep).

Coverage. Our taxonomy defines 98 fine-grained tags across 213 paragraphs; the current SyntErr implementation covers 48 (those tested by LORuGEC). The remaining 50 tags are implementable but not evaluated here. Punctuation generation is also directionally skewed (3.6:1 toward comma insertion; §5), which biases the kinds of punctuation errors the model ever sees during fine-tuning.

Single seed and training-stack sensitivity. We report single-seed numbers throughout and did not re-run training across multiple seeds. A small exploratory multi-seed run on two of the 4B configurations turned out to be inconclusive: the absolute scores depended substantially on the training stack (quantization, optimizer, kernel choices), and the cross-stack swing was larger than any plausible seed-to-seed variance, in a model-family-dependent way. LoRA fine-tuning at this scale is known to be sensitive to these choices, and disentangling stack effects from seed effects is beyond the scope of this paper. The absolute numbers in this paper should therefore be read with that envelope of uncertainty, even though the rule-level patterns we describe (suppression of specific rules under fine-tuning, recovery via continuation on a small diagnostic set) were consistent across all configurations we tried.

Stage order. Our two-stage models train on SyntErr first and then continue on LORuGEC. We did not test the reverse order or a randomly mixed schedule; stage order plausibly matters and is left to future work.

Validation as stopping signal. Our SyntErr-only models use the LORuGEC validation split as the early-stopping signal. This split is also used as training data in the +LORuGEC and SyntErr $\rightarrow$ LORuGEC settings, so the val-as-stop and val-as-train roles are entangled; SyntErr-only numbers may be slightly optimistic relative to a fully held-out criterion.

Single-annotator categorization. The per-paragraph mapping between Rozenal and the three corpora reflects one careful annotator’s judgment; we do not report an inter-annotator agreement score. The cross-reference should be

³All artifacts are available at <https://synterr-nlp.github.io/papers/bea-2026/>.

read as a high-effort survey rather than a validated annotation.

Strict prompt is an ablation. The *strict* prompt (§6) restricts the model to orthography and punctuation and disallows lexical substitution by design. We use it to isolate prompt sensitivity and not as a competitive system; its scope is narrower than the full GEC task.

Ethics Statement

Our taxonomy encodes prescriptive norms as a reproducible evaluation tool, not as a claim about how Russian should be written. SyntErr uses no personally identifiable data; all evaluation corpora are publicly available.

Acknowledgments

We thank the anonymous reviewers for their feedback. We thank Simon Scheidegger (HEC Lausanne) for providing access to the DGX Spark used for training and evaluation. Claude (Anthropic) was used for English prose drafting, SyntErr and evaluation pipeline development, and LLM-assisted error classification. All generated text and code were manually verified by the authors.

A Prompts

All finetuned models and baseline zero-shot evaluations use the system prompt proposed for LORuGEC evaluation:

Дорогая языковая модель, после «Исходное предложение» тебе будет дано предложение на русском языке, которое может содержать орфографические, пунктуационные, грамматические и речевые ошибки. Выведи, пожалуйста, только корректный вариант данного предложения, не давая

никаких комментариев и не выделяя никаких символов. Твоя задача — минимально изменить текст, не меняй слова и знаки препинания, которые и так правильные.

The user message template is: Исходное предложение: {src}

Strict prompt. For the prompt sensitivity experiment (Table 7), we use the following system prompt:

Исправь только знаки препинания и орфографию. Верни то же самое предложение, изменив только ошибочные запятые, тире, точки, дефисы или буквы, или их отсутствие. НЕ МЕНЯЙ СЛОВА. Каждое слово в ответе должно присутствовать в исходном предложении. Выведи только результат.

With bare {src} as the user message (no prefix).

B Training Details

Hardware. Small models ($\leq 7B$) were trained on 4× RTX 5090 (vast.ai). Large models (8–12B) were trained on a single RTX 6000 Ada (vast.ai). Evaluation was performed on a DGX Spark (GB10 Blackwell, 128GB unified memory).

LoRA configuration. All models use LoRA with $r=16$, $\alpha=32$, dropout 0, targeting all attention projections (q, k, v, o) and MLP projections ($gate, up, down$). Training uses Unsloth (Unsloth AI, 2024) with full 16-bit base weights (LoRA, not QLoRA), effective batch size 32 (per-device $4 \times$ gradient accumulation 8), learning rate 10^{-4} with cosine schedule. Early stopping monitors evaluation loss on LORuGEC validation (348 examples) with patience 5 epochs. Base training uses seed 42; continuation training uses seed 43.

Data. SyntErr training set: 39,209 examples across 48 LORuGEC rules (59 generation rules including bidirectional variants). Source text composition: 37% scarce-rule-enriched sentences (mined to boost underrepresented rules), 38% RuBLiMP scoring pool (Taktasheva et al., 2024), 25% news articles. LORuGEC training split: 348 examples (validation set of LORuGEC).

Models. Qwen3.5 (0.8B, 4B, 9B) (Qwen Team, 2025), Qwen2.5-7B (Yang et al., 2024), Gemma 3 (1B, 4B, 12B) (Gemma Team et al., 2025), Apertus-8B (Swiss AI, 2025), GigaChat-3.1-Lightning (Sber AI, 2026) (zero-shot only).

Inference. All local inference uses vLLM (Kwon et al., 2023) with bf16 precision, prefix caching enabled, and max-model-len 4096. Gemma 3 and Qwen 3.5 models require the -language-model-only flag (multimodal backbone with text-only inference). GigaChat-3.1-Lightning (Sber AI, 2026) uses the MLA attention backend with unquantized MoE routing. Frontier API models (GigaChat-2-Max, GPT-5.4, Claude Sonnet 4.6) were evaluated via their respective APIs. All models are evaluated in non-reasoning mode (-no-think): the model produces the corrected sentence directly, with no chain-of-thought or reasoning tokens.

Merge and deployment. LoRA adapters are merged into full-precision checkpoints using PEFT (Hugging Face, 2023) before evaluation. Qwen 3.5 models require AutoModelForImageTextToText for correct merging (multimodal architecture); Gemma 3 requires removal of rope_parameters from nested config levels for vLLM compatibility.

Reproducibility. All training and evaluation code, adapter checkpoints, configuration files, the SyntErr data generation pipeline, and the 39K-example SyntErr training set itself are released at <https://synterr-nlp.github.io/papers/bea-2026/>. The SyntErr source repository is at <https://github.com/synterr-nlp/synterr>. Training is deterministic given the seed, hardware, and library versions.

C Full Results

Table 10 reports full precision, recall, and $F_{0.5}$ for all models and settings on LORuGEC and GERA. Table 9 reports RuCoLA grammaticality judgment (MCC).

D SyntErr Generation Details

Architecture. SyntErr is built around three core abstractions: ErrorHandler (a protocol from which all rule-specific error generators inherit), Analyzer (the morphological/syntactic backend), and ErrorPipeline (which orchestrates distribution sampling, candidate selection, and corruption). Rules are classified as *length-preserving* (e.g., vowel alternations, suffix errors, paronym substitution) or *length-changing* (e.g., function word insertion/deletion, compound-form splitting/merging). After any length-changing rule fires, ErrorPipeline recalculates all downstream token indices to keep the alignment between source and target consistent. The full pipeline is shown in Figure 2.

Rule examples. Consider, for example, the algorithm for introducing a "paronym" type error. First, the word is looked up in a paronym dictionary. If the word is found, it is replaced with one of its paronyms, selected at random. The new word is then inflected using pymorphy3 to preserve the original grammatical categories.

Among native speakers of Russian, spelling er-

rors involving the use of **н** and **nn** in suffixes are quite common. To simulate the error of writing **н** instead of **nn**, we utilize a morpheme dictionary to verify that **nn** constitutes part of the suffix rather than belonging to the root or appearing at a morpheme boundary. We then delete one **н**. Conversely, to generate the opposite error, we verify that **н** belongs to one of the suffixes that take a single **н** (such as **-ан-**, **-ян-**, **-ин-**) and that the target word is not among the exceptions, after which we add an additional **н**.

A more complex example involves comma placement errors (insertion of an extraneous comma). According to the rules outlined in Rozental’s reference guide, an extra comma is inserted in the following cases where it is not required:

1. A comma before the conjunction **как** when it means **в качестве** (*as*) or is part of idiom. Uses dep-tree: only targets **как** with **dep_rel=case/fixed/flat** (adjunct/apposition sense), NOT **advcl/ccomp/mark** (subordinate clause).
2. A comma within a phraseological unit containing repeated conjunctions (e.g. **ни слуху**

ни духу).

3. A comma between adjacent conjunctions at clause boundaries. Only fires when a то/так/но correlative follows the subordinate clause.
4. A comma within indivisible expressions (e.g. как ни в чём ни бывало, куда глаза глядят).

Examples of sentences with errors of these types generated using SyntErr are presented in Table 11.

Performance. SyntErr generates 10K examples in under 2 minutes on CPU; a GPU is not required but significantly accelerates stanza, especially when using depparse.

We measured generation time on a laptop (AMD Ryzen 5 7535HS, 6 cores; NVIDIA RTX 4050 6GB; 16GB RAM; Ubuntu 24.04 LTS) using a mixed source dataset compiled from RuBLiMP (Taktasheva et al., 2024), Taiga (Shavrina and Shapovalova, 2017), Russian Wikipedia,⁴ and news articles.⁵ Benchmark presets use error probability 1.0 and max one error per sentence; profile_* presets isolate handler categories.

Table 12 compares backends and depparse overhead. Natasha is fastest but lacks dependency parsing, limiting it to spelling and morphological rules. Stanza is roughly 5× slower on CPU than on GPU (Table 12); GPU throughput is roughly independent of batch size above 64 (Table 14). Per-category timings (Table 13) show uniform throughput across error types.

Rule coverage. The 48 LORuGEC rules expand to 59 generation rules (bidirectional variants for split/merge and comma insertion/deletion). Each generation rule was assigned a uniform target of 847 examples; 40 rules reached this target, and the remaining 19 are limited by source sentence availability. Punctuation rules are directionally skewed toward comma insertion (3.6:1 comma insertion skew).

Dependency-driven error generation. The key design choice is that most error types are applied at positions identified through dependency parsing, not at random. Three families of errors rely on the parse tree:

Punctuation (§§77–138): comma errors inspect clause boundaries, conjunction scopes, and modifier attachment. For compound sentences (§87), SyntErr finds the conj arc between predicates joined by и/а/но and deletes the required comma. Spurious insertion follows the same logic in reverse: inserting commas where they are *not* required (before как in non-comparative contexts, inside phraseological expressions, between adjacent conjunctions).

Agreement (§§191–197): adjective-noun errors traverse amod arcs; subject-verb errors use nsubj arcs.

Government (§§196–210): prepositional government errors corrupt case via obl/nmod arcs.

Rules not requiring syntax — spelling (§§1–34), paronym substitution, compound splitting — use morphological tags and dictionary lookup. Inflection uses pymorphy3; stress-sensitive rules use Zaliznyak’s dictionary (Zaliznyak, 2010).

Source text filtering. Before generating errors, source sentences are filtered to keep those between 10 and 50 tokens (long enough to host a target rule, short enough to validate by hand). They are then deduplicated to avoid repetition, and any sentence appearing in the RuBLiMP benchmark is removed to prevent evaluation-time leakage.

Table 11: Examples of SyntErr-generated errors

Backend	Dep.	500	1K	2K	10K
<i>stanza (GPU)</i>					
+ depparse	yes	11.4	14.4	20.7	71.6
no depparse	no	9.9	12.1	16.4	51.1
<i>stanza (CPU)</i>					
+ depparse	yes	28.9	45.9	77.1	348
no depparse	no	15.9	28.2	44.4	190
natasha	no	3.4	5.4	8.7	37.3
spaCy	no	7.0	9.2	14.0	50.9

Table 12: SyntErr generation time in seconds (balanced preset; mean over 5 runs, measured with hyperfine (Peters, 2023)). lorugc preset within 5% of balanced.

Table 13: Preset performance (2K sentences, stanza GPU+depparse). S/s = sentences per second.

Preset	Time (s)	S/s	Notes
profile_spell	19.6 ± 0.2	102	no inflection
profile_morph	19.6 ± 0.1	102	pymorphy3
profile_punct	19.8 ± 0.0	101	dep traversal
profile_struct	19.5 ± 0.1	102	ins/del tokens
balanced	20.4 ± 0.7	98	reference

Table 14: Batch size vs. throughput (2K sentences). S/s = sentences per second.

Batch	Time (s)	S/s	GPU MiB
32	22.0 ± 0.1	91	1059
64	20.6 ± 0.3	97	1443
128	20.0 ± 0.1	100	1975
256	19.8 ± 0.1	101	3443
512	19.4 ± 0.2	103	3541

In force-apply mode (all 48 rules, bidirectional), stanza GPU processes 10K sentences in 79 s. Peak memory: 1.8 GB (stanza GPU+depparse), 0.4 GB (natasha), 1.1 GB (spaCy).

Figure 2: SyntErr error generation pipeline. Clean sentences are parsed by Stanza into analyzed tokens; a per-rule error-type distribution (from a reference corpus or a config file) drives an applicability check that selects a matched rule; the rule is then applied to produce a (src, tgt, rule) triple.

E Scoring Normalization

Before scoring, we apply two normalizations. First, `ë` is mapped to `e`: LORuGEC targets use `e` consistently, but models frequently produce the formally correct `ë`. Second, Unicode dash variants (FIGURE DASH U+2012, EN DASH U+2013) are mapped to EM DASH U+2014; the gold data uses these inconsistently (56 em-dash vs. 6 en-dash in LORuGEC). Hyphen-minus is not normalized, as it is semantically distinct. We do not normalize quotation marks: Russian prescriptive typography requires angle quotes («ёлочки»), but some gold examples use straight quotes. Models producing the correct form are penalized; we accept this small bias rather than erase a genuine distinction.

FinnGEC: Benchmarking Grammatical Error Correction for Finnish

Abstract

Grammatical error correction (GEC) is a natural language processing task critical for improving language quality, supporting communication efficacy, and for language learning and teaching. To date, most research in GEC has focused on major, resource-rich languages such as English, while lower-resource languages remain underexplored. In this paper, we focus on GEC for Finnish. We build a dataset based on data from real-world language learners. We explore various approaches to GEC, including fine-tuning transformer models and zero-shot LLM prompting. We also adapt ERRANT, a popular GEC evaluation tool, for the Finnish language, to evaluate the performance of the models. Our results indicate that the performance of GEC for Finnish is promising, but requires further research. To the best of our knowledge, this is the first in-depth exploration of GEC for Finnish; we provide benchmarks, datasets, and code for GEC for Finnish—by releasing our training and test data and the code for Finnish ERRANT—to support further research on this important task.

1 Introduction

Grammatical error correction (GEC) is important in many areas of natural language processing (NLP), including tools for improving language quality, supporting effective communication, and language learning and teaching. Writing is a fundamental skill in second-language (L2) learning. A common approach to support L2 learners and teachers is to employ GEC systems to provide feedback to learners on samples of their writing. The objective of GEC is to identify grammatical errors, spelling errors, punctuation errors, stylistic inaccuracies, and many other types of errors, and propose corrections for them (Bryant et al., 2023). Research on GEC is decades-old, and many approaches, models, and datasets have been proposed (Bryant et al., 2019; Rothe et al., 2021; Cao et al., 2025; Deng

et al., 2025; Park et al., 2025). However, most studies to date focus on major languages, such as English, because of their rich resources, while GEC for lower-resource languages is still underexplored.

In this paper, we focus on the GEC task for Finnish, which suffers from the scarcity of GEC data: high-quality annotated data for training and testing GEC models is difficult to collect for Finnish. This complicates the training and evaluation of GEC models in Finnish. To tackle this problem, we build GEC datasets based on language-learning data from real learners. We experiment with various approaches, including fine-tuning transformer models and prompt-based methods. We adapt ERRANT (Bryant et al., 2017)—a GEC performance metric widely used, e.g., for English—to the Finnish language, and evaluate the performance of various models with our datasets. To the best of our knowledge, this is the first work that provides benchmarks for the GEC task for Finnish.

The main contributions of this paper are as follows:

- We build a Finnish GEC dataset based on real language-learning data. The dataset is based on actual errors made by real-world learners of Finnish as L2. We release this dataset to facilitate future research on GEC.
- We experiment with a number of approaches to GEC for Finnish. This provides benchmarks for future research on this task.
- We adapt ERRANT to the Finnish language and use it to evaluate model performance on our datasets. We also release the Finnish ERRANT to the research community.

The paper is organized as follows. We review related work in Section 2. We describe the sources of our data and the pre-processing steps in Section 3. We discuss our GEC methodology in Section 4. We present our experimental setup and analyze the

results in Section 5. We conclude and outline directions for future work in Section 6.

2 Related Work

GEC is typically approached as a monolingual sequence-to-sequence task, where an incorrect sentence is rewritten into its corrected version. This formulation enables the application of recurrent neural architectures, including machine translation (MT) models (Ji et al., 2017; Junczys-Dowmunt et al., 2018; Zhao et al., 2019; Rothe et al., 2021). Since the emergence of transformer models, multilingual encoder-decoder models pre-trained at scale, such as mT5 (Xue et al., 2021), have become the dominant backbone for both monolingual and multilingual GEC (Rothe et al., 2021). Given the data-intensive nature of these methods, the models are commonly pre-trained on *synthetic* datasets generated through various data-augmentation strategies, i.e., random word perturbations, Wikipedia edits, back-translation, and error-pattern imitation (Kiyono et al., 2019; Grundkiewicz et al., 2019; Takahashi et al., 2020). More recently, Wang et al. (2024) proposed contextual data augmentation to ensure more consistent error distributions in the synthetic data.

An alternative line of work formulates GEC as a sequence *tagging* task, where sentences are annotated with token transformation labels and subsequently edited based on predicted transformations (Malmi et al., 2019; Stahlberg and Kumar, 2020; Omelianchuk et al., 2020; Tarnavskiy et al., 2022). Earlier work also explored adversarial training for GEC: Raheja and Alikaniotis (2020) used a Generative Adversarial Network (GAN)-based setup, where an MT-based generator corrects errors, while a discriminator evaluates correction quality. Parnow et al. (2021) combined a sequence labeler with an error detector in a similar fashion. Li and Wang (2024) showed that explicitly decoupling error detection and correction improves performance in general language models.

Large Language Models for GEC: The emergence of LLMs has significantly impacted GEC research. GPT-3 has been shown to effectively perform GEC, generating fluent corrections that often go beyond reference corrections (Loem et al., 2023). Yet LLMs are also prone to over-editing, which can vary across languages and cause semantic shift (Katinskaia and Yangarber, 2024). Alignment-enhanced methods have been proposed

to mitigate over-corrections in both sequence-to-sequence and decoder-only LLMs, for example by training models on both good and bad corrections to instruct the model to prefer the good ones (Yang and Quan, 2024; Liang et al., 2025).

Recent work has also explored LLM-based generation of synthetic data for GEC. Luhtaru et al. (2024) fine-tuned Llama 2 models for artificial error generation, producing synthetic errors that closely resemble human-made errors and achieving state-of-the-art results on German, Ukrainian and Estonian. Potter and Yuan (2024) extended this approach to code-switched text (text mixing multiple languages) generation, addressing the challenge of correcting errors in multilingual English as a Second Language (ESL) learner writing. Koo et al. (2024) proposed Knowledge-Augmented GEC (KAGEC), incorporating external knowledge retrieval to enhance LLMs’ context-aware generation capabilities, particularly for non-English languages, including Korean.

Low-Resource and Multilingual GEC: For low-resource scenarios, Korotkova et al. (2019) investigated zero-shot GEC using Transformer-based MT models. Cross-lingual transfer has emerged as a promising direction, leveraging multilingual pre-trained representations to transfer correction capabilities across languages (Yamashita et al., 2020; Sun et al., 2022). Palma Gomez and Rozovskaya (2025) recently proposed selective data augmentation with round-trip MT (translating text into an intermediate language and back), and demonstrated substantial improvements for Russian and Ukrainian GEC. The MultiGEC-2025 shared task (Masciolini and Volodina, 2025)¹ covered 12 languages, including Estonian, the closest relative of Finnish in the Uralic language family.

Finnish GEC remains a low-resource problem with limited dedicated infrastructure. The closest related language with established GEC support is Estonian, which has recently benefited from LLM-based error generation (Luhtaru et al., 2024). For Finnish, Creutz (2024) compared GPT-3.5, GPT-4, and Claude on authentic beginner-level learner texts, finding that GPT-4 achieves the best correction performance among these models.

Evaluation and Quality Control: Automatic evaluation of GEC systems relies on gold-standard reference-based metrics computed over *edits*—

¹<https://spraakbanken.gu.se/en/compsla/multigec-2025>

words or phrases that have been changed, added, or removed when comparing the model’s output and the reference. The M2 scorer (Dahlmeier and Ng, 2012) is an early standard. It first aligns the source sentence (to be corrected) with both the model’s output and the reference to identify which tokens were changed, inserted, or deleted, and then checks how many of the model’s edits match the reference edits. ERRANT (Bryant et al., 2017) extended this approach by automatically labeling each aligned edit with an *error type*, enabling fine-grained evaluation at the level of error types, and it has become a widely accepted framework for GEC evaluation. An alternative approach avoids the alignment step by computing an N-gram F-score directly between the hypothesis and the reference without pairwise alignment, making it computationally more efficient (Koyama et al., 2024).

Kobayashi et al. (2024) demonstrated that GPT-4 achieves state-of-the-art performance as a GEC evaluator, surpassing traditional automatic metrics in correlation with human judgments. A post-processing approach has also been explored, where a classifier judges whether each proposed correction is grammatically acceptable and filters out invalid ones (Cao et al., 2024). Goto et al. (2025b) proposed a ranking-based aggregation procedure that better aligns with human judgments across metric types. To support reproducible comparisons, Goto et al. (2025a) released *gec-metrics*, a unified library implementing a wide range of GEC evaluation metrics through a consistent interface.

3 Data

3.1 Corpus of Learner Errors

We begin by building a corpus of errors from data collected from learners of Finnish as L2, who use Revita, a language learning platform (Hou et al., 2025). The platform offers learners the possibility to practice with authentic real-world texts. The platform offers multiple-choice and “cloze” (fill-in-the-blank) exercises, where the base form—*lemma*—of a word is given to the learner, and serves as a hint in the context of 2–3 sentences. We refer to the complete exercise context as a “snippet.” The learner’s task is to produce the correct form of the word that best suits the context.

We build the *learner-error* corpus by collecting *actual observed* errors from learner data. This allows us to collect a dataset with two principal advantages. First, our dataset covers multiple contexts

and error types, including subject-verb agreement, tense, preposition, noun phrase agreement, government relations, etc. Errors may appear in any position in the sentence. This is in contrast to other existing GEC datasets, such as BLiMP (Warstadt et al., 2020), which has the following limitations:

- they target only certain error types, such as Subject-Verb Agreement (SVA);
- each instance can contain only one erroneous word, and the word is tagged with only one error type;
- this also means that some of the errors appear in a fixed role in a sentence: e.g., in SVA, only the predicate can contain an error.

This means that the set of errors observable in BLiMP is severely restricted by the rules used in their collection process.

Secondly, as different learners practice with the same lemma, they commit different mistakes, including spelling, grammatical, and syntactic errors. Further, a particular mistake made by a learner may contain multiple grammatical errors; e.g., it is quite common that a learner chooses an incorrect tense, person, and number all at the same time. We believe this is a more realistic scenario, and can better test the true performance of a GEC model.

We should note that our work on GEC is driven by its applications for language teaching and language learning (Katinskaia and Yangarber, 2021, 2023; Katinskaia et al., 2019). In L2 teaching, having robust GEC is crucial for several reasons. One is to support the generation of meaningful feedback for text (e.g., essays) produced by learners. When learners perform exercises, GEC is used to detect *alternative-correct* answers, also called multiple-admissible answers. Multiple admissibility occurs when more than one form of a word fits syntactically and semantically in a given context. In such situations, it is crucial that a model can **acknowledge** the correctness of alternative answers.

The learner-error corpus contains approximately 3.7K snippets. Each snippet contains one or more errors. Overall, there are approximately 23K distinct errors from 890 distinct texts in the dataset.

The exercise types from the learning platform are cloze and multiple-choice tasks. Therefore, the learner-error corpus contains primarily morphological substitution errors. However, since some exercises involve multi-word answer slots (e.g., compound verb forms), the dataset also contains a small number of insertion and deletion errors

# of errors	Proportion in (%)	
	learner data	Wiki data
0	52.6	50.0
1	19.2	18.1
2	13.8	18.4
3	6.1	9.7
4	3.0	2.0
5	1.8	1.2
≥ 6	3.5	0.7

Table 1: Training data: proportion of snippets with different numbers of errors.

arising from word count differences between the learner response and the reference.

3.2 From Learner Errors to Instances

We next describe the process of building the datasets of *instances* for training and testing models for GEC, from the learner-error corpus. Each instance is a “parallel” pair: a snippet (sequence of words and punctuation) containing some errors, paired with a *reference*—an error-free version of the same snippet. While a snippet with errors may be corrected in *multiple ways* in real life, we provide only a single error-free reference. The reference corresponds exactly to the correct snippet found in the original text with which the learners were practicing.

We split the snippets into three sets: approximately 1K snippets reserved for testing, and the remaining 2.7K snippets split into a training set (85%) and a validation set (15%)—at the snippet level: this means that *all instances* derived from a given snippet (see below) always fall into the same split, and are never distributed across more than one split. These three splits are randomly sampled from the error corpus. To ensure that there is no leakage across the splits, we filtered the validation and test sets to remove any snippets with identical references in the training set.

Each snippet contains one or more error *slots*—positions where some learner has made a mistake. Each error slot may have multiple distinct incorrect variants—committed by different learners at different times. We generate GEC instances by combining different error slots within each snippet. For example, a snippet with two error slots, each having 4 distinct learner-error variants, yields 25 instances in total: 16 two-error instances formed by pairing each variant from the first slot with each variant from the second slot ($4 \times 4 = 16$), 8 single-error instances formed by combining each variant

from one slot with the correct form of the other ($4 + 4 = 8$), and one “clean” instance where both slots are filled with the correct form (which constitutes a *negative* instance for GEC).

For the test set, we apply this combinatorial expansion fully, to maximize the coverage of error types. When applied to the 1K test snippets, this yields approximately 70K instances. We downsample the dataset to 9,981 instances using stratified sampling. The idea is to preserve the distribution of error density—the ratio of error slots to sentence length—while also limiting the number of instances assembled from the same source snippet. This prevents snippets with more error slots from dominating over snippets with fewer error slots, ensuring a more balanced representation across source texts. Lastly, we supplement the test set with zero-error instances sampled directly from texts in the language learning platform, to evaluate accurately the over-correction rate (OC). This results in a total of 17,854 instances in the test set.

For the training and validation sets, we apply a different expansion strategy to maximize the contextual diversity for each error pattern. We first scan a snippet by its sentence boundaries and segment the snippet into overlapping windows of different sentence sizes. A window may range from one standalone sentence to multiple contiguous sentences. For example, a 3-sentence snippet would yield six possible windows: three single-sentence windows, two two-sentence windows, and one full three-sentence window. We always include the full snippet window; we randomly select another 3 from the remaining windows, so each snippet contributes at most 4 training pairs. This allows us to generate training instances that vary in size and avoid high similarity due to overlapping contexts. Too much overlap in the training data would risk that the models would try to memorize the contexts.

For each window, we identify all error slots that fall within the window and apply a set of substitutions for each slot, but not necessarily for all slots. This means only a subset of the slots may be filled with their incorrect variants, while the others remain untouched. To maintain diversity of error combinations, the same error slot, even if it appears in multiple windows, will be substituted only once with an incorrect variant across all windows of the same snippet. We expect that this approach will serve to build a more robust model.

We also include an error-free instance from each snippet. The goal is to prevent the model from

Source	Training	Validation	Test
L2 learner data	10,668	1,372	17,854 [†]
Wikipedia data	1,850,000	150,000	—

Table 2: Dataset statistics after expansion and augmentation. [†]The test set includes 9,981 error-containing instances and additional zero-error instances drawn from the platform, used to evaluate the over-correction rate.

over-correcting: proposing corrections regardless of whether an error is present. Additionally, we supplement the training and validation sets with clean zero-error instances drawn directly from the platform—following the same approach used for the test set—resulting in approximately 52.6% zero-error instances in the training data, to reduce over-correction. In total, the training set contains 10,668 pairs and the validation set contains 1,372 pairs. The distribution of errors is shown in Table 1.

We note that error-correction pairs in our data are not one-to-one: the same erroneous form may map to different correct forms depending on the context, and vice versa. The model must therefore learn context-sensitive correction rather than memorizing fixed error pairs.

3.3 Augmentation with External Corpus

Although our dataset covers a diverse range of actual error types, composing instances by error combinations would introduce a bias into the training process: the same reference snippet may appear in multiple training pairs, causing the model to overfit to specific snippet contexts rather than learning generalizable correction patterns. To mitigate this, we augment the training data with an external corpus.

We augment the training data with sentences from Finnish Wikipedia (1.2M documents), split into snippets of 1–3 consecutive sentences (8–80 words). We retain only snippets that contain words or phrases for which real learner errors exist in the learner-error corpus. For each snippet, several such words or phrases are selected at random and replaced with incorrect variants drawn from that corpus, producing erroneous training pairs. We also include a large number of clean, error-free pairs to balance the dataset and discourage the model from over-correcting. This yields 1,850,000 training and 150,000 validation pairs (Table 2).

The actual error count distribution in training is shown in Table 1.

The distribution of errors in the validation set is nearly the same. This allows us to have much more

training data with diverse contexts and references.

4 Methodology

4.1 LLM Prompting

Recent advances in LLMs have shown very strong performance on various NLP tasks. Researchers have been exploring the potential of LLMs for GEC in particular (Staruch et al., 2025; Davis et al., 2024; Katinskaia and Yangarber, 2024). We consider the prompt-based approach to be a strong baseline for the GEC task. In this work, we focus on the zero-shot setting and prompt the LLMs with only one instance at a time. The prompt is presented in Appendix B. We focus the prompt on errors in morphology and agreement, as these constitute the dominant error types in our dataset, as described in Section 3. We plan to explore the few-shot setting in future work.

In this work, we use OpenAI GPT-5.4 and Claude Haiku 4.5 as prompt-based baselines, and evaluate their performance with the full balanced test set—17,854 instances.

4.2 Fine-tuning Encoder-Decoder and Decoder-Only Models

We experiment with two encoder-decoder transformer models. **FinT5** is a 260M-parameter monolingual T5 model² pretrained exclusively on Finnish text, giving it strong morphological knowledge of Finnish. **mBART** (Tang et al., 2020) is a 611M-parameter multilingual model pretrained on 50 languages, with Finnish accounting for only a small fraction of its pretraining data. We also experiment with **Poro2** (Zosa et al., 2025), a decoder-only model pretrained on Finnish and English with 8B parameters. More specifically, we experiment with Poro2-Instruct, created through supervised fine-tuning (SFT) and Direct Preference Optimization (DPO) of the Poro 2 8B Base model.

We adopt a two-stage training process for all models to mitigate overfitting caused by repeated error combinations in our L2 learner dataset:

1. Stage 1—Fine-tune with augmented data:

We fine-tune the models on synthetic Wikipedia data with artificially injected learner errors. This aims to teach the model to perform GEC across diverse contexts.

2. Stage 2—Fine-tune with L2 learner data:

We continue fine-tuning on the L2 learner

²Finnish-NLP/t5-small-nl24-finnish

Error type	Meaning	Examples (with description)
VERB:FORM	Verb Form	sanoa → sanon (infinitive vs. finite verb)
VERB:TENSE	Tense	menee → meni (present vs. past)
VERB:VOICE	Voice	sanon → sanotaan (active vs. passive)
VERB:MOOD	Mood	tulee → tulisi (indicative vs. conditional)
VERB:PART	Participle	juokseva → juossut (present vs. past)
PERSON	Person	sanon → sanot (1 person vs. 2 person)
DEGREE	Degree	iso → isompi (positive vs. comparative)
CASE	Case	kaupunki → kaupungin (nominative vs. genitive)
NUMBER	Number	koira → koirat (singular vs. plural)
NOUN_POSS	Possessive	koira → koirani ("dog" vs. "my dog")
CLITIC	Clitic	-kin, -kaan, -han, etc. (incorrect clitics)
AGR	Agreement	(Phrase-level agreement errors)
WO	Word Order	(Word order errors)
WORD_CHOICE	Word Choice	(same POS, different lemma)
CONJ	Conjunction	ja → mutta
PART	Particle	(Particle errors)
VOWEL_HARM	Vowel Harmony	talossa → talossä
COMPOUND	Compound	autotalli → auto talli (compound joined vs. split)
SPELL	Spelling	(Typos)
PUNCT	Punctuation	! → ?
INSERT	Insertion	(Missing words)
DELETE	Deletion	(Removed words)
OTHER	Other	—

Table 3: Error types for Finnish GEC.

dataset to adapt the model to the distribution of real Finnish learner errors in practice.

For FinT5 and mBART, both stages perform full parameter fine-tuning without layer freezing, while Poro2 is trained with LoRA adapters (Hu et al., 2022) on all linear layers. In Stage 1, each model is trained for up to 2 epochs on the augmented Wikipedia data, with the best checkpoint selected according to validation loss. In Stage 2, training continues from the Stage 1 final version and uses only the learner data. Stage 2 is configured to run up to 5 epochs, and to retain the best checkpoint according to validation loss. More detailed information about the hyperparameters is available in Appendix A.

4.3 Evaluation with Finnish ERRANT

ERROR ANnotation Toolkit (ERRANT) (Bryant et al., 2017) is widely used for evaluating GEC models. It requires reference corrections, and measures the performance in terms of an edit-based F-score. Besides computing scores for the overall performance, it also evaluates the different error types. The original ERRANT is designed for English and is developed with 25 English error types. In our work, we extend ERRANT according to the Finnish grammar and common error types. We

present our error types in Table 3. We apply the Stanza parser (Qi et al., 2020) to parse the sentences and extract information about the errors.

We adapt the Finnish ERRANT with multi-label annotation. Each edit can be tagged with multiple error types simultaneously, reflecting the compounding nature of Finnish morphological errors. It is common for a Finnish learner to make a mistake with multiple errors at the same time. For example, a learner can submit the answer *sanon* ("I say," indicative mood, present tense 1st person singular), while the correct answer is *sanoi-vat* ("they said," past tense 3rd person plural). In this case, we observe three errors within one edit: tense, person, and number. This adaptation treats the evaluation as a multi-label classification problem and avoids the information loss inherent in the single-label tagging scheme as in the native ERRANT.

Before the evaluation, all texts are normalized: Unicode NFC normalization, full-width character normalization, quote character normalization, and whitespace normalization. This avoids penalizing models for surface formatting differences unrelated to grammatical correctness.

We evaluate all models using precision (P), re-

Model	Architecture	Precision	Recall	$F_{0.5}$	OC %
FinT5 (260M)	encoder-decoder	33.89	17.44	28.52	23.4
mBART (611M)	encoder-decoder	50.46	9.71	27.44	3.6
Poro2 (8B)	decoder-only	36.52	24.30	33.18	13.0

Table 4: Stage-1 performance after fine-tuning with augmented Wikipedia data. OC—over-correction rate

Model	Architecture	Precision	Recall	$F_{0.5}$	OC %
OpenAI GPT-5.4	—	47.27	60.10	49.37	57.0
Claude Haiku 4.5	—	39.23	42.31	39.81	47.9
FinT5 (260M)	encoder-decoder	48.17	40.25	46.35	23.4
mBART (611M)	encoder-decoder	51.13	22.84	40.98	9.9
Poro2 (8B)	decoder-only	40.54	43.36	41.07	22.6

Table 5: Stage-2 Performance of prompt-based (top), and fine-tuned (bottom) models after fine-tuning on L2 learner data. OC—over-correction rate.

call (R), and $F_{0.5}$:

$$F_{\beta} = \frac{(1 + \beta^2) \cdot P \cdot R}{\beta^2 \cdot P + R} \quad (1)$$

with $\beta = 0.5$ to weight precision twice as heavily as recall, following standard GEC practice (Bryant et al., 2017). We also report the over-correction rate (OC), defined as the proportion of error-free input sentences for which the model attempts to modify something.

5 Experiments and Results

5.1 Fine-Tuning Performance

Table 4 presents the performance after Stage 1 fine-tuning on augmented Wikipedia data. Poro2 achieves the best $F_{0.5}$ of 33.18% at this stage. Among the encoder-decoder models, FinT5 achieves $F_{0.5}$ of 28.52% with an over-correction rate of 23.4%. mBART achieves the highest precision (50.46%) and the lowest over-correction rate (3.6%), suggesting it is more conservative in making corrections.

Table 5 presents the performance after Stage 2 fine-tuning on L2 learner data, alongside the prompt-based baselines. All fine-tuned models improve substantially over Stage 1. FinT5 achieves $F_{0.5}$ of 46.35% and mBART achieves 40.98%. Poro2 reaches 41.07%, slightly outperforming mBART.

Among the prompt-based approaches, GPT-5.4 achieves the best overall $F_{0.5}$ of 49.37%, outperforming all fine-tuned models, while Claude Haiku 4.5 reaches $F_{0.5}$ of 39.81%.

5.2 Error Analysis

Table 6 shows the full breakdown by $F_{0.5}$ for error types for all models. Vowel harmony errors (VOWEL:HARMONY) are the easiest to correct across all models, with all models scoring above 72%. Poro2 achieves the highest $F_{0.5}$ of 86.96%, followed by FinT5 at 83.80%. Claude Haiku has the lowest performance on the vowel harmony errors with 72.14% $F_{0.5}$.

Verb form errors (VERB:FORM) are also relatively easy to correct, with FinT5 achieving $F_{0.5}$ of 75.22% and Poro2 at 69.86%. mBART and Claude Haiku also perform competitively at 60.57% and 61.78%, suggesting that verb form correction is a tractable task for most models as it can be learned from local morphological patterns.

Case errors (CASE), on the other hand, require a deeper understanding of Finnish syntax.³ This is reflected by clear performance gaps between models. GPT-5.4 achieves the highest $F_{0.5}$ of 70.15% on case errors, followed by FinT5 at 63.09%. Claude Haiku and Poro2 both reach around 57%, while mBART reaches only 45.42%. This highlights the advantage of Finnish-specific pretraining. Both FinT5 (260M, Finnish-specific) and Poro2 (8B, Finnish and English) have clearly better performance than mBART (611M, 45.42%), the only multilingual model in the comparison, despite mBART being larger than FinT5.

Insertion, deletion, and punctuation errors (INSERT, DELETE, PUNCT) are the most challenging error types across all models, with most scoring very low on $F_{0.5}$. Unlike morphological er-

³We should note that Finnish has an extremely complex nominal case system, with at least 14 cases, possibly more, depending on the chosen theory.

Error Type	GPT-5.4	Claude Haiku	FinT5	mBART	Poro2
VOWEL:HARMONY	81.78	72.14	83.80	77.07	86.96
VERB:FORM	67.50	61.78	75.22	60.57	69.86
SPELL	69.56	60.04	48.71	55.65	54.63
CASE	70.15	57.22	63.09	45.42	57.14
DEGREE	72.89	70.75	41.79	15.12	44.03
VERB:VOICE	58.99	55.69	60.86	34.15	53.29

Table 6: $F_{0.5}$ by error type across all models.

rors, which can be corrected by modifying the word form, insertion and deletion errors require the model to determine whether a word is extraneous or missing in the context. This is also expected, as the cloze and multiple-choice exercise format produces primarily morphological substitutions, leaving the models with limited training signal for these error categories.

5.3 Manual FP Inspection

One known limitation of reference-based evaluation (Choshen et al., 2018) is that a correction is penalized if it differs from the reference, even if it is valid. As we are experimenting with a single-reference dataset, this limitation is even more pronounced. To mitigate this issue, we conducted a manual inspection of false positives (FPs) flagged by Finnish ERRANT. Due to resource constraints, we focus on four models: FinT5, mBART, Poro2, and GPT-5.4. We randomly sampled 100 instances from the intersection of FP instances produced by four models. Each FP instance may contain different edits from different models, but they all include false positives flagged by Finnish ERRANT. This reduces the workload but still allows us to inspect our model’s behavior comprehensively. A native Finnish expert then judged each instance at the sentence level, assigning either **Correct** (the model made a valid correction that ERRANT penalized) or **Wrong** (the model genuinely made an incorrect

correction).

Table 7 shows the results of the manual FP inspection. Our human evaluation shows that 51% (mBART), 61% (Poro2), 65% (FinT5), and 85% (GPT-5.4) of these flagged edits are in fact valid corrections, confirming that ERRANT underestimates true model precision.

The ranking of valid corrections reflects the overall $F_{0.5}$ ranking, suggesting that better-performing models also generate high-quality corrections even when they do not match the references. Furthermore, the large gap between GPT-5.4 (85%) and the best fine-tuned model FinT5 (65%) suggests that reference-based metrics systematically underestimate LLM performance more than fine-tuned model performance. Fine-tuned models are trained to reproduce the reference and tend to stay closer to it, while LLMs generate more diverse but potentially valid corrections.

6 Conclusion

In this paper, we present the first benchmarks for grammatical error correction for Finnish. We construct a dataset from L2 learner data. The dataset covers a diverse range of morphological and syntactic error types. We adapt ERRANT to Finnish to enable a systematic evaluation and benchmark a range of approaches spanning from prompt-based methods to fine-tuning transformer-based models.

Our results show that language-specific pre-

<i>Model</i>	<i>Valid</i>	<i>Invalid</i>
mBART (611M)	51	49
Poro2 (8B)	61	39
FinT5 (260M)	65	35
OpenAI GPT-5.4	85	15

Table 7: Manual inspection of 100 false positives flagged by ERRANT. *Valid*: the GEC model made a valid correction. *Invalid*: the GEC model made an incorrect correction.

training is a more impactful factor than model scale. FinT5 (260M parameters) outperforms the larger multilingual mBART model and outperforms Claude Haiku 4.5, a compact commercial LLM, particularly on morphologically complex error types such as case. Poro2, a decoder-only model fine-tuned under the same two-stage setup, achieves competitive results with mBART, demonstrating that decoder-only architectures can also be adapted effectively for Finnish GEC.

Finnish GEC remains an open challenge. For future research, we plan to use few-shot prompting techniques to reduce the over-correction problem and to further improve LLM-based GEC performance.

In terms of data preparation, expanding the training data to cover more error types, such as insertion, deletion, and punctuation, is an important direction. Our results show that the models currently receive insufficient training for these error categories. Scaling up training data through systematic synthetic error generation, either via LLM-based error injection or knowledge distillation from frontier models, is a potential direction for improving fine-tuned model performance.

In addition, we also plan to experiment with larger models. FinT5 already achieves competitive performance with compact commercial LLMs such as Claude Haiku 4.5 despite its small size, and experimenting with a larger Finnish-specific model may close the gap to frontier LLMs further.

This work was supported in part by the Research Council of Finland, Project “Know-AI” (Grant 1359285), and by Strategic Research Council Project “DALAI-Fin” (Grant 1373225).

Data Availability

The full training dataset, derived from learner data collected via Revita, is available upon request by

contacting the authors, subject to licensing constraints from the original data.

Limitations

Our dataset is sourced from a single language learning platform, which may limit generalization to other Finnish L2 learner populations. The raw L2 learner dataset is also relatively small, with 10,668 training, 1,372 validation, and 9,981 error-containing test pairs. Each instance provides only a single reference correction, though multiple valid corrections may exist for the same error. The dataset consists primarily of morphological substitution errors, as the cloze and multiple-choice exercise format produces mainly morphological substitutions; insertion, deletion, and punctuation errors are underrepresented, limiting the training signal available for these error categories.

Evaluation relies solely on Finnish ERRANT, an automatic metric adapted from English. For prompt-based approaches, only zero-shot prompting was evaluated, leaving few-shot settings for future work. Sequence-labeling approaches such as GECToR (Omelianchuk et al., 2020) are out of scope for this benchmark paper and left for future work.
