A high-quality Seed dataset for Italian machine translation

Edoardo Ferrante
Council for Ligurian Linguistic Heritage
info@conseggio-ligure.org

Abstract

This paper describes the submission of a high-quality translation of the OLDI Seed dataset into Italian for the WMT 2024 Open Language Data Initiative shared task.

The base of this submission is a previous version of an Italian OLDI Seed dataset released by Haberland et al. (2024) via machine translation and partial post-editing. This data was subsequently reviewed in its entirety by two native speakers of Italian, who carried out extensive post-editing with particular attention to the idiomatic translation of named entities.

1 Language overview

This paper presents an Italian version of the OLDI Seed dataset (Maillard et al., 2023; NLLB Team et al., 2024).

Italian is a Romance language, recognised as an official language of the Italian Republic, the Republic of San Marino and the Canton of Ticino in Switzerland (Maiden, 2014). Modern Italian fundamentally represents cultured Florentine, as first attested by 14th century authors (Dante, Petrarch and Boccaccio) and later scholars (Coletti, 2022). Although it is a variety of Tuscan, standard Italian is purged of the more typical features of Tuscan, at a phonetic level represented above all by the so-called *gorgia* (i.e. the fricative pronunciation of certain occlusive consonants in intervocalic position) (Marotta, 2008).

The presence of a curated Italian version in the Seed dataset is of great importance for the regional languages of the Italian peninsula, six of which are already represented in the same dataset.[1] The creation of an Italian version enables the training of machine translation models for these languages to and from Italian, a direction which is more culturally relevant than English-centric MT, as the vast majority of speakers of such languages (or prospect learners) are also native Italian speakers (Haberland et al., 2024; Ramponi, 2024).

2 Data creation

The original source of the data was an initial Italian version of the Seed dataset released by Haberland et al. (2024). The authors created it by machine translating the original English version with an OpusMT bilingual English-Italian model (Tiedemann and Thottingal, 2020), combined with partial post-editing. Through personal correspondence with the authors we learned that their post-editing, which only affected a small percentage of the overall data, involved two steps:

1. A check of the length ratios of Italian and English sentences, followed by manual checking and post-editing of sentence pairs with outlier length ratios.

2. A spellchecker run using Hunspell (Ooms et al., 2017), followed by manual checking and post-editing of sentence pairs where spelling mistakes were found.

The submission described in this paper constitutes a further refinement of the dataset of Haberland et al. (2024), in order to bring it to a level that could be seen as comparable to that of translations produced by highly proficient bilingual individuals.

This project involved the participation of two annotators, henceforth A1 and A2, both native speakers of Italian with a university level of education. The refinement process followed these steps:

1. A manual, sequential review of the entire dataset by A1, followed by post-editing where necessary.

2. Following Haberland et al. (2024), a targeted review of sentence pairs with outlier length ratios, followed by post-editing where necessary.

[1] These are Friulian, Ligurian (Genoese), Lombard, Sicilian, Sardinian, Venetian (Maillard et al., 2023; NLLB Team et al., 2024).

Proceedings of the Ninth Conference on Machine Translation, pages 567–569
November 15-16, 2024 ©2024 Association for Computational Linguistics

3. A targeted review of sentences involving specific subsets of the corpus which were found to have a high incidence of mistranslated strings: date and time expressions, sentences about mathematics and sentences about the history of cinema.

4. A final targeted review of sentence pairs which were found to be of low-quality using a series of Quality Estimations approaches using LLMs, as described in Zhao et al. (2024).

Apart from the first item above, which was carried out by annotator A1 alone, the workload for all subsequent tasks was split equally between both annotators.

3 Experimental validation

In order to experimentally validate the quality of this Seed dataset, we replicate the baseline experiments of Haberland et al. (2024), by training an Italian-Ligurian machine translation model on a combination of the 6,193 paired Italian-Ligurian sentences from the Seed data and the same 1,520 paired Italian-Ligurian sentences from the Tatoeba project[2] used by the authors. The translation model is trained using Fairseq (Ott et al., 2019), with the exact same architecture and overall setup of Haberland et al. (2024).

Model	FLORES
NLLB-3.3B	13.9
Haberland et al. (2024)	14.5
Ours	**15.0**

Table 1: Italian-Ligurian translation performance measured with BLEU on FLORES `devtest`.

In Table 1 we compare the BLEU scores[3] obtained by three models on the FLORES (NLLB Team et al., 2024) `devtest` data. The first model, provided only for context, is the massively multilingual 3.3B version of NLLB (NLLB Team et al., 2024), which was trained on much larger amounts of data but without any direct Italian-Ligurian supervision. The second is the baseline model of Haberland et al. (2024). The final row reports the performance of the best of three training runs of our model, which is a re-training of Haberland et al.'s, the only difference being the use of the improved Seed data.

As can be observed in the results, our model achieves a performance of 15 BLEU points on the FLORES devtest set, 1.1 points higher compared to NLLB-3.3B (NLLB Team et al., 2024) and half a point higher compared to the baseline model of Haberland et al. (2024). The relatively small degree of improvement compared to the latter baseline can be attributed to the fact that, in general, machine translation for a high-resource language pair such as English-Italian is of high quality, so that manual post-editing (especially in a formal domain such as Wikipedia text) leads to only minor changes.

This result, although numerically marginal, confirms that our post-editing of the seed data for improved idiomaticity does not hurt the downstream performance of models trained on it but does, in fact, slightly improve it.

4 Data samples

We provide a selection of samples whose translations proved to be particularly hard for the OpusMT bilingual English-Italian model.

Acknowledgments

We thank Haberland et al. (2024) for the helpful discussions about post-editing and for helping us replicate their experiments.

Abstract

This paper describes the corrections made to the FLORES evaluation (dev and devtest) dataset for four African languages, namely Hausa, Northern Sotho (Sepedi), Xitsonga, and isiZulu. The original dataset, though groundbreaking in its coverage of low-resource languages, exhibited various inconsistencies and inaccuracies in the reviewed languages that could potentially hinder the integrity of the evaluation of downstream tasks in natural language processing (NLP), especially machine translation. Through a meticulous review process by native speakers, several corrections were identified and implemented, improving the overall quality and reliability of the dataset. For each language, we provide a concise summary of the errors encountered and corrected and also present some statistical analysis that measures the difference between the existing and corrected datasets. We believe that our corrections improve the linguistic accuracy and reliability of the data and, thereby, contribute to a more effective evaluation of NLP tasks involving the four African languages. Finally, we recommend that future translation efforts, particularly in low-resource languages, prioritize the active involvement of native speakers at every stage of the process to ensure linguistic accuracy and cultural relevance.

1 Introduction

Low-resource languages, especially from Africa, are greatly under-represented in the Natural Language Processing (NLP) landscape, and this is primarily due to the absence of sufficient resources for both training and evaluation (Adelani et al., 2022; Kreutzer et al., 2022). Various efforts have been made to create such resources and these include initiatives from organizations such as Lacuna[1] that fund new and qualitative open datasets, and communities such as Masakhane, HausaNLP, the University of Pretoria's Data Science for Social Impact (DSFSI) Research Group, and other individual initiatives (Abdulmumin et al., 2022; Parida et al., 2023). For machine translation evaluation, the FLORES dataset (Goyal et al., 2021; NLLB Team et al., 2022) is widely accepted as a benchmark for evaluation, especially because it was the first of its kind for many languages and enables many-to-many evaluation, making it easier to evaluate say a Hausa to Sepedi translation system without pivoting through a high resource language, e.g., English. Recently, the MAFAND dataset (Adelani et al., 2022) was created, but it only allows bilingual evaluation and is limited to the news domain.

While all these resources are being developed, it is imperative to review them for validation to ensure that they meet the expected standard of accuracy and representation. A revealing work by Kreutzer et al. (2022), albeit on mostly web-crawled datasets, found that many of the datasets that are being relied upon for low-resource languages are littered with significant errors such as misalignments, incorrect translations, and other issues. The significance of evaluation datasets make them even more deserving of such reviews especially by literate native speakers that know how these languages are written and spoken. This paper, therefore, presents a comprehensive review and correction of the public FLORES evaluation datasets for four African languages: Hausa, Northern Sotho, Xitsonga and isiZulu. We also provide the corrected datasets for future evaluation tasks[2].

2 The FLORES Evaluation Dataset

The FLORES evaluation dataset consists of the first FLORES-101 (Goyal et al., 2021) and the subsequent more expanded FLORES-200 (NLLB Team et al., 2022) that included more languages.

FLORES-101: This was the original evaluation data and was created by translating the English dataset collected from Wikipedia, consisting of several topics and domains, into 101 mostly low-resource languages. The dataset was the first available evaluation benchmark for several low-resource languages and it enabled the evaluation of many-to-many translation systems without pivoting through another high-resource language such as English. Several quality control mechanisms were put in place to ensure that the final dataset was of acceptable quality. To determine if translations are good enough for inclusion in FLORES-101, a 20% sample of the dataset were reviewed by language-specific evaluators who assess the quality using a Translation Quality Score (TQS) on a 0 to 100 scale, with a score of 90% deemed acceptable. Errors such as grammar, punctuation, spelling, and mistranslation were examined, and each was assigned a severity level of minor, major, or critical. Three of the four languages in this paper were included in this dataset–Hausa (hau), Northern Sotho (nso) and Zulu (zul).

FLORES-200: This dataset expanded FLORES-101 to over 200 languages, including our fourth target language–Xitsonga (tso). In this data, a more comprehensive process was developed to ensure the quality of the translations. Specifically, professional translators and reviewers aligned on language standards before the translators translated the sentences. Afterwards, automated checks were first conducted and then followed by manual checks by independent reviewers. Translations that were found lacking quality were sent back for post-editing. Similarly to FLORES-101, translations scoring above 90% TQS were included in the FLORES-200.

2.1 Problems Identified in FLORES

Prior to this work, we have not found any published work that carefully reviews and attempt to correct mistakes in the FLORES evaluation dataset. However, some issues have been raised on the FLORES' public GitHub repositories.[3] Some of these issues include near-identical translations in several dialects of Arabic: Mesopotamian (acm_arb), Ta'izzi-Adeni (acq_arb), Najdi (ars_arb), and Moroccan (ary_arb) Arabic dialects were found to be too similar to Standard Arabic (arb),[4,5] unspecifying the "orthography" and "variety" used in Lombard (lmo_latn) and Sardinian (srd_latn),[6,7] unmatched quotation marks,[8] and using Mandarin Chinese in Traditional Chinese Script (zho_Hant) for Cantonese (yue_Hant) translations.

3 Focus Languages and Evaluation

3.1 Languages Covered

In this work, the public[9] FLORES dev and devtest splits of Hausa, Northern Sotho (Sepedi), Xitsonga and isiZulu were reviewed and corrected by native speakers of the languages. A description of each language is presented in Appendix A.

3.2 Correction Guidelines

For reviewing and subsequently correcting the identified errors in the datasets, the participants were given the following guidelines.

Reviewing: At this stage, the participants identified sentences in both data splits that require reviewing.

- **Read the original text:** carefully read the original English text to understand the intended meaning and context.
- **Compare with translated text:** compare each sentence or phrase in the original English text with its corresponding translation. Pay attention to both the overall meaning and the nuances of the language.
- **Check for accuracy:** look for errors, inaccuracies, or deviations from the original meaning in the translation. This includes mistranslations, omissions, additions, and grammatical mistakes.
- **Evaluate clarity and cohesion:** assess whether the translated text is clear and coherent in the target language. Ensure that it flows naturally and is easy for a target language-speaking audience to understand.

[8] https://github.com/facebookresearch/flores/issues/36

[9] https://github.com/openlanguagedata/flores

Correcting the translations: To correct the translations, we followed the guidelines provided in the shared task description.[10] The participants were trained on and encouraged to follow these guidelines when correcting the identified incorrect translations.

3.3 The Annotators

The correction task was conducted by volunteer annotators that focused on their native languages. These annotators were a mix of university students and researchers holding first, second and third degrees in computing and linguistics.

3.4 Evaluating the Corrections

To determine the amounts of corrections and subsequent differences between the original and corrected data, we used the following metrics. The computations were conducted only on the instances that were corrected. We used the original dataset as the supposed predictions and for the reference translations, we used the corrected data. We used the Natural Language Toolkit (NLTK) (Bird and Loper, 2004) for all tokenization.

Token Difference: This is the difference between the number of all tokens in the original and corrected datasets.

Token Divergence: This was used to measure the difference or dissimilarity between two sets of tokens. Given T_o and T_c as the set of tokens in the original and corrected datasets respectively, the following formula was used:

$$\text{divergence} = \frac{|T_o - T_c| + |T_c - To|}{|T_o \cup T_c|} \tag{1}$$

The formula calculates the proportion of tokens that are different between the two sets relative to the total number of unique tokens across both texts. Higher divergence score indicates that the two texts are quite different, suggesting significant changes or corrections were made.

Translation Edit Rate: (Snover et al., 2006) is a metric used in machine translation and other natural language processing tasks to measure the number of edits required to change a system-generated translation into a reference translation, and is computed using the following formula.

$$\text{TER} = \frac{\#\text{ of edits}}{\#\text{ of words in ref. translation}} \tag{2}$$

The fewer the edits, the better the translation quality and a higher TER score indicates lower quality in the predicted translations.

BLEU: (Papineni et al., 2002) is an n-gram based metric that indicates the quality of generated machine translations. The BLEU is computed as follows:

$$\text{BLEU} = BP \times \exp\left(\sum_{n=1}^{N} w_n \log p_n\right) \tag{3}$$

where BP is the Brevity Penalty and is used to penalize instances where shorter translations are generated when the reference is comparably longer; p_n is the precision between the candidate translation and a set of ground truths; and w_n is the n-gram weights.

COMET: (Rei et al., 2020) is a metric that leverages pre-trained neural models and cross-lingual word embeddings to evaluate the quality of machine translation systems. We used the pre-trained models provided by Wang et al. (2024).

4 Error Analysis

Tables 1 and 2 present how similar, or different, the original sentences were to the corrections. Some of the errors found are analyzed below per language.

Hausa (hau) A significant part of the translations were suspected to have been automatically generated, as many of them appeared incoherent or unclear. To investigate this, we conducted a comparison with translations from the Hausa FLORES dataset and new translations generated by Google Translate. The comparison revealed that, although there were limited exact matches[11], several incorrect lexical choices in the dataset's translations aligned with those produced by Google Translate, supporting the suspicion that the translations may have been automatically generated. It is important to note that other translation tools may exist for Hausa that we did not evaluate. Furthermore, several sentence-level translations from Google Translate were found to be more qualitative and coherent

Table 2: Similarities between the original and corrected FLORES evaluation data on the four African languages – original as predictions; corrected as reference translations.

than those in the current dataset. For an illustration, we examine sentences from the dev and devtest sets, see Table 3.

In several instance, named entities were translated instead of reusing them as they are due to the lack of their equivalents in Hausa. This is illustrated in the first example provided in Table 3. Planned Parenthood appears as an organization that was not supposed to be translated (and may only be explained as *hukuma mai kula da tsarin iyali*). The words in the organization name were translated as *Iyayen Tsararru*, with their literal word translations (*iyaye* → parents, *tsararru* → planned) instead of the name of the organization as a named-entity. In the second example, the phrase "standard business attire" was translated as *Kaya masu kala ɗaya su ne cikakkun tufafin mu'amala* instead of *kayan sawa na aiki da aka saba dasu*. The first translation is at best an incorrect explanation of the English phrase. And these are just two examples of the many we found in the dataset.

In addition to these severe mistakes, the dataset was littered with a lot of inconsistencies especially in the use of the standardized Hausa alphabets. Special characters are often ommitted and instead replaced with their normalized equivalents, e.g., ɓ → b, ɗ → d, etc. In some few places, the special ƴ is written as 'y which is acceptable.

Northern Sotho (nso) Several key challenges and areas for improvement were identified and corrected, focusing on vocabulary consistency, syntax, spelling, and the accurate conveyance of technical terms. Most of the text was accurately translated and, for the text with problems, only small changes were required to make it more accurate. Some of the words like "*safatanaga* and *disafatanaga*" have generally maintained lexical consistency although they were wrongly translated. These have been corrected to "*sefatanaga* or *difatanaga* (plural)".

Although sometimes Sepedi uses borrowed words for many technical and scientific terms, things such as pavement do have a translation which could be "*tsela ya maoto or tselanathoko*". These could have been used instead of borrowing the pavement term to say *pabamente*. The use of a borrowed term could have been from the available corpus or from learned behaviour for borrowing unknown English terms. Another example is the word college which was translated to *colleje*, but Sepedi has a standard borrowed translation: "*kholetšhe*".

Addressing spelling errors and ensuring proper spacing between words are vital for readability and comprehension. For instance, the word "*tswarelo*" was corrected to "*tshwarelo*" to reflect the proper spelling. Similarly, "*patlaladitše*" was adjusted to "*phatlaladitše*", and "*bontša*" to "*bontšha*". Additionally, "*mephutso*" should be spelt as "*meputso*", and "*delo*" should be corrected to "*selo*". Spacing was required when using "*begona*" so that it is "*be gona*" and similar adjustments were made. These adjustments are crucial to maintain lexical consis-

Table 3: Some Hausa Examples of incorrect and inconsistent translations in FLORES dev and devtest.

tency and to ensure that translations are accurate and easily understood.

Some terms were left out, like "scientific" as "*tšа bo ramahlale*" when scientific tools were talked about, and this greatly affected the meaning of the sentence. Additionally, in another instance, a sentence describing the use of Caesarean section to give birth to Nadia was misleading. Incorrectly, it implied that Nadia was both the baby being born and the individual undergoing the operation. This was corrected to have the intended meaning.

Xitsonga (tso) Some of the problems identified in the Xitsonga translations included problems to do with vocabulary accuracy and the use of borrowed words. Among the errors that were identified is the translation of "Type 1 diabetes" to "*vuvabyi bya chukela bya Type 1*". The correct phrase should therefore be "*vuvabyi bya chukela bya muxaka wo sungula*", which captures the type of diabetes and avoid misunderstanding. Similar trends raise the importance of using proper terms that might fit local context as opposed to directly translating English words.

Another problem was that translations were mostly uniform, without contextual variations. Even here, the words "*xiyenge xa tlilinikhali na sayense*" (clinical and scientific division) were used wrongly. The word actually is "*xiyenge xa vutshila ni ntokoto bya sayense*" (clinical and scientific division), but this clearly passes on the intended meaning. Moreover, the use of pluralization of terms was arbitrary. While the singular form of the term "worker" is "*mutirhi*", the plural form should be "*vatirhi*", and the singular form of "methods" is "*maendlelo*", which should be in plural throughout instead of appearing in single forms.

Spelling problems and the usage of borrowed terms can have a substantial influence on the correctness of Xitsonga translations. One of the most illustrative examples of such incongruity of terms is that the English word "channel" has been translated as "*chanele*". Instead, the work should have used the original term "*nongonoko*" in order to ensure a perfect linguistic and connotative translation. To avoid generation of wrong impressions, the phrase borrowed from IsiZulu as used to mean "President" had to be replaced by the word "*murhangeri wa tiko*" from Xitsonga. Deficient spelling, as in the case of writing "*dokodela*" instead of "Dr", and examples of slang such as using "*mwana wa*" instead of the formal "*muongori*" indicate how borrowing and spelling mistakes reduced the quality of the translations. Fluency and correct spelling as well as using the native language correctly are a necessity to maintain the translated material's effectiveness.

isiZulu (zul) Similar to the errors identified in the other languages above, isiZulu translations displayed several common challenges. These included inconsistencies in vocabulary, syntax errors, and issues with the accurate expression of technical and scientific terms. The agglutinative nature of isiZulu and its conjunctive writing style further worsen these issues, leading to specific translation errors related to morphology and orthography.

A closer examination of these challenges reveals issues such as in the translation of "Around 11:29, the protest moved up Whitehall, ..." which was initially rendered as "*Ngawo-11:29 ababhikishi baya Odongeni Olumhlophe, ...*". This translation contains two key issues. First, "*Ngawo-11:29*" should have been "*Ngabo-11:29*" to correctly match the grammatical structure for time expressions in isiZulu. Second, the literal transliteration of "Whitehall" as "*Odongeni Olumhlophe*" failed to integrate properly into the sentence. The correct approach would involve incorporating the place name with the locative prefix "e-" to produce "e-Whitehall.". This prefix addition is required in conjunctive languages when using borrowed words or terms, but MT systems often fail to capture these variations. Additionally, another common issue was the unnecessary borrowing of words from English, despite the availability of standardized isiZulu terms. This was particularly evident with month names, scientific terms, and country names, where inconsistencies were frequent—one translation might use "January," another "*uJanuwari*," and yet another "*uMasingana*" Another example of this can be seen with the country name "Spain," which was inconsistently translated as both "Spain" and "*Speyini*" in different sections. Similar inconsistencies occurred with attempts to translate organizational names or acronyms, leading to partial translations that disrupted the linguistic flow.

To address the inconsistencies, standardized isiZulu terms were consistently applied throughout the translations. For instance, month names such as "*uMasingana*" replaced the inconsistent use of "January" and "*uJanuwari*" In dealing with organizational names and acronyms and countries' names, the approach was to fully translate these entities or retain their original form consistently, avoiding partial translations that could disrupt the flow.

In addition to the inconsistencies with terminology, other errors were also identified and addressed. These included issues with verb conjugation, where incorrect tenses or forms were initially used, and the improper handling of borrowed words that did not align with isiZulu's morphosyntactic rules. Minor spelling errors and incorrect use of prefixes or suffixes were also corrected to ensure that the translations were both grammatically accurate and easily understood.

5 Conclusion

In this work, we highlight the importance of qualitative evaluation datasets for low-resource languages and present our findings from a comprehensive review of the FLORES dataset for four African languages: Hausa, Northern Sotho, Xitsonga, and isiZulu. The original translations were marred by vocabulary inconsistencies, syntax errors, and inaccurate technical terms. After making necessary corrections, we measured the amount of edits and resulting difference between the improved datasets and the original using metrics like BLEU, TER, and COMET, which showed that significant improvements were made. The results presented highlight the need for ongoing refinement and human oversight in developing accurate translation datasets for underrepresented languages. For future work, we intend to expand the corrections to more African languages.

A Description of the Target Languages

Hausa (hau): Hausa is a widely spoken language across West Africa, particularly in Nigeria, Niger, Cameroon, and Ghana. It is spoken by approximately 77 million people worldwide, primarily in West Africa (Eberhard et al., 2022). Hausa ranks as the second most spoken language in Africa and 27th globally. The language belongs to the Chadic branch of the Afroasiatic language family, and it has a rich history of written communication. It was first written in Arabic script known as Ajami, reflecting the language's connection to Arabic, with many Hausa words borrowed from Arabic due to historical contact and influence. Today, the Boko script (also known as Roman script), which uses Latin characters, is the most common writing system for Hausa. This script excludes the letters p, q, v, and x, and includes additional consonants (ɓ, ɗ, ƙ, ƴ, kw, ƙw, gw, ky, ƙy, gy, sh, ts) and vowels (long a, i, o, u, e, and two diphthongs ai and au). Hausa follows a Subject-Verb-Object (SVO) sentence structure.

Northern Sotho (nso): Northern Sotho, also known as Sepedi or Sesotho sa Leboa, is one of the official languages of South Africa and is spoken primarily by the Bapedi people in Limpopo Province. It is a Bantu language that belongs to the Sotho-Tswana group and shares linguistic similarities with Sesotho (Southern Sotho) and Setswana. Sepedi is known for its rich oral tradition that includes folklore, proverbs, and praise poetry that have played a significant role in the preservation of cultural heritage (Nurse and Philippson, 2006). Sepedi is written using the Latin alphabet, with the standard 26 letters and a few additional characters such as the "š" which are adapted to its unique sounds. The language primarily follows a Subject-Verb-Object word order in sentence structure.

Xitsonga (tso): Xitsonga, or Tsonga, is a Bantu language that is mainly spoken in South Africa and more especially in the Limpopo province and parts of Mpumalanga province. The language is estimated to be spoken by about 2.3 million people in South Africa. Xitsonga belongs to the Niger-Congo language family, specifically the Tshwa-Ronga subgroup, and is characterized by the extensive use of prefixes and suffixes to convey meaning (Mabaso, 2018). This linguistic feature can impact the accuracy of translations, especially when dealing with technical and scientific concepts. It also feature a complex system of writing and syntax, which are prerequisites to clear and concise language usage. Xitsonga is currently used in education and media section in South Africa, thus is regarded as relevant in cultural linguistic practices. That is why, the language being mentioned as a part of the country's multiple languages system emphasizes its relevance and application in different phases of the people's activity.

Language	Sentence
English	I know them
Hausa	Na san su
Northern Sotho	Ndza va tiva
Xitsonga	Ke a ba tseba
isiZulu	Ngiyabazi

Table 4: The grammatical structure of different languages.

isiZulu (zul): Zulu or isiZulu (in Zulu) is one of the 12 official languages in South Africa, and it is considered to be the most widely spoken indigenous language in the country. It constitutes approximately a quarter of the population, with around 15.1 million speakers out of the population of 62 million people (StatsSA, 2022). IsiZulu is part of the Nguni language family, which is made up of a group of closely related Bantu languages belonging to a larger Niger-Congo language family, and they are widely spoken across Southern Africa (Mesham et al., 2021). These languages are particularly notable for their complex morphology, characterized by agglutinative morphology and conjunctive orthography. Agglutinative morphology means that words are typically formed by combining multiple small meaning-carrying units, known as morpheme. Conjunctive orthography means that the morphemes are glued together to form a word, rather than writing them with spaces in between, as seen in disjunctive orthography, commonly associated with the Sotho group, as well as Tshivenda and Xitsonga in South Africa indigenous languages (Taljard and Bosch, 2006). To illustrate this distinction, consider the example in Table 4 which examines the different grammatical structures of the phrase *I know them*.

Table 4 shows that while the phrase's meaning is consistent across languages, the writing systems vary: in disjunctive orthography, morphemes are separated by spaces, while in conjunctive orthography, as in isiZulu, they are joined into a single word. For example, in the phrase *I know them*, each morpheme serves a specific grammatical function– 'I' as the subject, 'know' as the verb, and 'them' as the object. In disjunctive orthography, these morphemes are written separately, making each unit distinct. In conjunctive orthography, they are combined into one continuous word, but the meaning remains intact. These orthographic variations pose challenges for machine translation systems, which must accurately process morphemes in different writing systems to produce accurate translations.

Expanding FLORES+ Benchmark for more Low-Resource Settings: Portuguese-Emakhuwa Machine Translation Evaluation

Abstract

As part of the Open Language Data Initiative shared tasks, we have expanded the FLORES+ evaluation set to include Emakhuwa, a low-resource language widely spoken in Mozambique. We translated the *dev* and *devtest* sets from Portuguese into Emakhuwa, and we detail the translation process and quality assurance measures used. Our methodology involved various quality checks, including post-editing and adequacy assessments. The resulting datasets consist of multiple reference sentences for each source. We present baseline results from training a Neural Machine Translation system and fine-tuning existing multilingual translation models. Our findings suggest that spelling inconsistencies remain a challenge in Emakhuwa. Additionally, the baseline models underperformed on this evaluation set, underscoring the necessity for further research to enhance machine translation quality for Emakhuwa. The data is publicly available at https://huggingface.co/datasets/LIACC/Emakhuwa-FLORES

1 Introduction

Evaluation datasets and benchmarks are essential for advancing Natural Language Processing (NLP) models. They provide the necessary tools for assessing model performance and guiding further enhancements. However, the scarcity of evaluation datasets and benchmarks for low-resource languages has significantly hindered the progress of NLP technologies in these languages. Recognizing this challenge, the FLORES+ evaluation set has emerged as a critical tool for the Machine Translation (MT) community, especially in low-resource languages. It promotes a more inclusive approach to language technology development across diverse linguistic landscapes. This work focuses on expanding the FLORES+ (NLLB Team et al., 2022) evaluation set to include Emakhuwa, a low-resource language spoken in Mozambique by approximately 9 million people. Our dataset consists of the *dev* and *devtest* sets managed by the Open Language Data Initiative[1](OLDI), which contain 997 sentences and 1012 sentences, respectively. Throughout our data collection process, we implemented robust quality assurance mechanisms, including thorough post-editing. The resulting dataset features multiple reference translations derived from these post-editing efforts.

2 Related Works

The Flores v1.0 MT evaluation set was introduced by Guzmán et al. (2019). This initial version focused on two language pairs: Nepali–English and Sinhala–English, with the data divided into *dev*, *test*, and *devtest* splits. After its release, the dataset was gradually expanded to include more languages. A significant expansion came with the work of Goyal et al. (2021), who introduced Flores-101, extending the evaluation set to support 101 languages. Further expansion was done with the release of Flores-200 by the NLLB team (NLLB Team et al., 2022) in 2022, which increased the language coverage to 204 languages. Additional contributions include Doumbouya et al. (2023), who added the Nko language, as well as AI4Bharat et al. (2023), who incorporated Bodo, Dogri, Meitei, Sindhi, and Goan Konkani into the dataset. These contributions have significantly broadened the opportunities for low-resource languages in MT, allowing researchers to track the progress of MT systems on these expanded evaluations. However, the coverage remains limited, especially considering that there are over 7,000 languages worldwide. One such language that remains underserved is Emakhuwa, which still lacks datasets for MT.

3 Emakhuwa

Emakhuwa, alternatively referred to as Makua, Macua, or Makhuwa, belongs to the Bantu language family and is predominantly spoken in the northern and central regions of Mozambique, specifically in the Nampula, Niassa, Cabo Delgado, and Zambezia provinces. There are eight variants of Emakhuwa, with Emakhuwa-Central (ISO 639-3 code *vmw*) being the standard variety (Ngunga and Faquir, 2014).

Emakhuwa follows the Subject-Verb-Object (SVO) structure, use a Latin scripts (ISO 15924 *Latn*), and is gender-neutral. Furthermore, similarly to other languages in the Bantu family, it is linguistically rich, with complex morphology featuring agglutinative and tonal attributes.

3.1 Challenges in Emakhuwa

Emakhuwa digital resources are scarce, and the spelling standards are still under development. While a fully standardized system is not yet in place, the existing guidelines (Ngunga and Faquir, 2014) offer a critical framework for contemporary written communication in Emakhuwa. One problem stressed in official standardization (Ngunga and Faquir, 2014) is the lack of guidance on tonal marking. Consequently, existing materials exhibit inconsistent spelling, particularly when marking tone, which is essential in Emakhuwa for disambiguation. To give an example, let us consider two words carrying distinct meanings: *omala* and *omaala* / *omàla*; *omala* means “to finish", while *omaala* / *omàla* means “to silence" or "to hush." In this case, the tonal marker *aa* / *à* clarifies the intended meaning.

Spelling variations are largely evident in existing Emkahuwa text corpora, where some use diacritics (e.g., *à*, *è*, *ì*, *ò*, *ù*) and consonantal sounds (e.g, *kh*, *nn*) for tonal marking, others use vowel lengthening (e.g., *aa*, *ee*, *ii*, *oo*, *uu*), and some even use a combination of methods. Emakhuwa's agglutinative nature with complex morphology further amplifies spelling discrepancies. Since tonal variations often occur at the morpheme level, different combinations of morphemes result in varied spellings of the same word.

These spelling inconsistencies create significant obstacles for language technology processes. They lead to data sparsity, as some spelling variants appear less frequently, which impairs the model's ability to learn the language's nuances effectively. This sparsity inflates the vocabulary size and can result in reduced performance of language technologies.

An additional challenge in Emakhuwa that contributes to inconsistencies is the adaptation of loanwords. Emakhuwa text corpora frequently contain Portuguese loanwords with inconsistent adaptations due to the absence of standardized guidelines for integrating borrowed terms (Ali et al., 2024). These loanwords are adapted in one of three ways: phonetically to match Portuguese pronunciation, in alignment with Emakhuwa phonotactics, or retained unchanged from Portuguese.

4 Methodology

We chose to translate the *devtest* and *dev* sets from Portuguese (*pt*) into Emakhuwa (*vmw*) because our translators were only proficient in these two languages. We focus specifically on the central variant of Emakhuwa, as it is the standard and established language variant.

The translators were selected based on their proficiency in these languages and their proven experience in Portuguese-Emakhuwa translation. In total, we collaborated with five experts: two were assigned the tasks of translation and revision, while the remaining collaborators were responsible for evaluating the translations (refer to Table 6 in the appendix for more details).

In general, we implemented the workflow as a peer review process, divided into three main steps: Data Preparation, Translation, and Validation. Below is a detailed description of each step (refer to Figure 1).

4.1 Data Preparation

We compile the sentences in *devtest* and *dev* sets as segments and then load them to the Matecat[2] CAT (Computer-Assisted Translation) tool. Before assigning translation tasks, we prepare a guideline and glossary. The guidelines were adapted from the Open Language Data Initiative guidelines[3], written in Portuguese and suggesting that the translated text should adhere to the latest orthography standards of the central variant of Emakhuwa. On the other hand, the glossary was built by digitizing existing bilingual dictionaries and the glossary of Political, Sports, and Social Concepts from Radio of Mozambique (Moçambique E.P., 2016). We con-

[2] https://www.matecat.com/

[3] https://oldi.org/guidelines

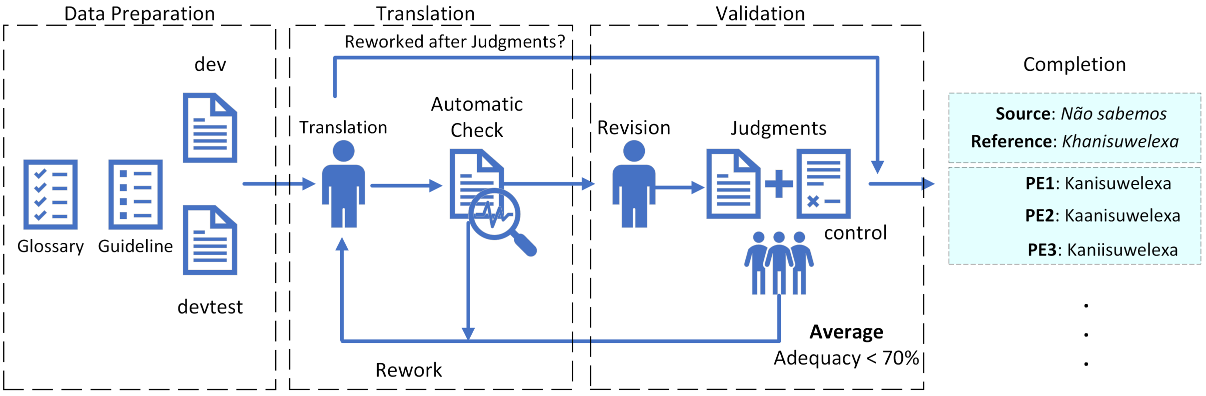

Figure 1: Workflow

ducted a small workshop to familiarize the team with the guidelines and gather feedback to improve them. The translation team found the glossary helpful, as it prevented using loanwords for existing Emakhuwa terms and ensured consistency in translations.

4.2 Translation

Translation tasks were subdivided between two translators: one worked on the *devtest* segments, and the other on the *dev* segments. Once all segments were translated, they were submitted to our spell checker system for an automatic check to identify potential misspellings (refer to Figure 10 in the appendix). We then provided feedback to the translators, asking them to review and refine their work if necessary.

4.3 Validation

The validation corresponds to two steps: revision and Judgments.

4.3.1 Revision

Following the translation step, we swapped the translated works between the two translators, asking them to post-edit each other's translations on the Matecat platform. Table 1 provides the Quality Report generated by Matecat, which includes various metrics used to evaluate the translation based on the revisions made. The report indicates that the reviewer working on *devtest* made more suggestions. A closer examination of the error categories on *devtest* (refer to Figure 9 in the appendix) reveals that most of the issues identified in the translation fell under the category of "Language Quality", meaning grammar, punctuation, and spelling errors. On the other hand, the reviewer of the *dev* set identified mostly errors related to "terminology and language consistency", suggesting that the translator was not consistently using the proper terms and maintaining uniformity throughout the text.

	dev	**devtest**

Quality score	23.31	54.22
Avg. Edit Distance	0.23 ± 1.77	7.09 ± 11.94

Table 1: Matecat's quality report post revision.

4.3.2 Judgments

Once all segments have been revised, we perform a second translation quality assessment using a Direct Assessment (DA) pipeline similar to the one described by Guzmán et al. 2019. Judgments were collected using our annotation tool (see Figure 7 in the appendix), and involve the following aspects.

Direct Assessment Three different raters evaluate the translation adequacy (i.e., the perceived translation quality) on a scale from 0 to 100. A score of 0 means that "no meaning was preserved in the translation". Scores from 1 to 34 - "the translation preserves some of the source meaning but loses significant parts", 35 and 67 - "the translation retains most of the source meaning", 68 to 99 - "the translation is consistent with the source text", and a score of 100 means "the translation is perfect". These quality intervals are inspired by the study of Wang et al. 2024.

Control To ensure raters' attentiveness and improve consistency during the evaluation, we included control instances with incorrect translation pairs. These incorrect pairs were generated using the Madland-400-3bt[4] model (Kudugunta et al., 2024), a multilingual MT system that supports the Emetto variant of Emakhuwa (ISO 639-3 *mgh*). While this model typically performs poorly when translating from Portuguese to Emakhuwa, it produces similar words that can mislead inattentive annotators. Based on these control translations, we provided feedback to the evaluators as they progressed in their tasks. We used emojis to give the feedback in our annotation tool: a ☺️ appeared if less than 25% of control translations were incorrectly rated (i.e. scores above 34 points), 😠 if 25%-50% are incorrectly rated, 😡 if 50%-75% are incorrectly rated, and 😭 if more than 75% of control translations are rated too highly.

Post Editing During the validation phase, we asked evaluators to post-edit translations with lower scores to enhance fluency and better align them with the source sentence's meaning. However, this task was made optional to prevent evaluators from inflating scores to avoid additional post-editing work.

Standard orthography To assess the perceived usage of standard orthography, raters also judged whether the translated text used standard orthography on a scale from 1 (not using standard orthography) to 5 (entirely written in standard orthography).

Finally, we calculate the average score for each segment. We then returned segments scoring below 70 to the translator for reworking. Figure 2 shows the histogram of the average translation scores.

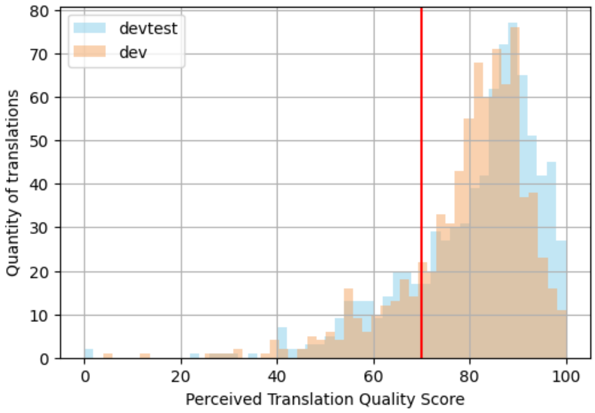

Figure 2: Averaged Translation Quality Score Histogram on both *dev* and *devtest* sets. Translations with an average score below 70 (indicated by the red line) were returned to the translator for rework.

4.4 Analysis

Figures 3 and 4 show the raw scores per annotator for Direct Assessments. Given the mean scores, in both the *test* and *devtest* sets, Annotator 1 and Annotator 2 gave higher quality scores, while Annotator 3 was more critical but still within the spectrum of acceptable translations. This suggests a generally positive perception of the translations produced. Figure 5 displays the Direct Assessment scores on the control set. Annotator 1 and Annotator 3 have median scores below the threshold of 34 points, suggesting that, as expected, they have generally assessed the control translations as low quality. Annotator 2, however, has a median score above the threshold, suggesting a trend to a more positive assessment compared to the other two annotators and was less attentive among the annotators.

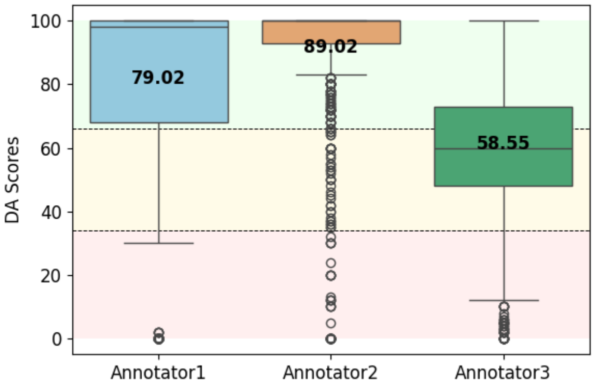

Figure 3: Direct Assessment adequacy scores per annotator on *dev* set

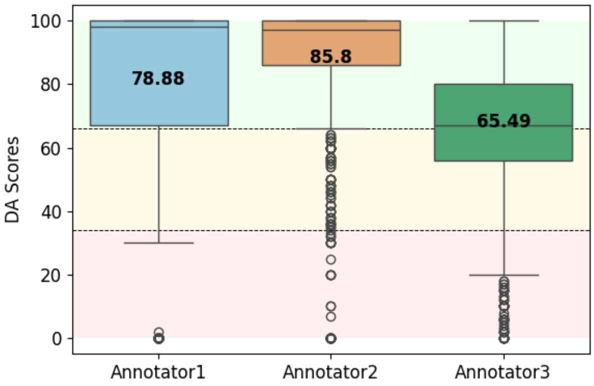

Figure 4: Direct Assessment adequacy scores per annotator on *devtest* set

Table 2 provides the reliability results for adequacy and standard orthography usage assessments. The inter-class correlation for adequacy is 0.67 for

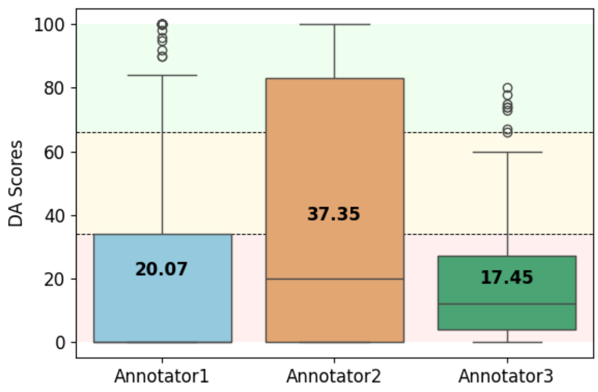

Figure 5: Direct Assessment adequacy scores per annotator on *control* set

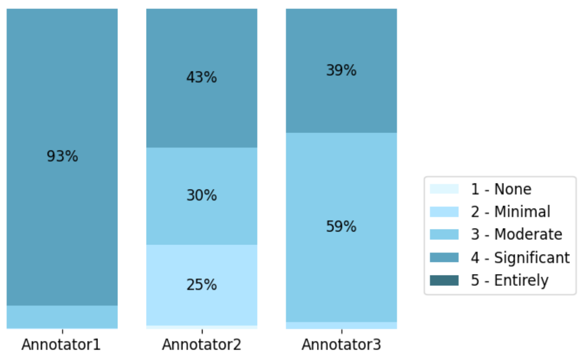

Figure 6: Assessment of standard orthography usage on the control set.

dev and 0.66 for *devtest*, suggesting moderate reliability. However, the inter-class correlations for standard orthography usage are lower, with values of 0.35 for *dev* and 0.27 for *devtest*, indicating considerable disagreement among annotators. This discrepancy highlights the ongoing lack of clarity regarding Emakhuwa spelling standards, as further illustrated in Figure 6, which depicts the varying assessments of standard orthography.

	Adequacy		**Orthography**	
	dev	devtest	dev	devtest
ICC	0.67	0.66	0.35	0.27
CI	[0.63, 0.71]	[0.62, 0.7]	[0.27, 0.42]	[0.18, 0.35]

Table 2: Intraclass Correlation Coefficient (ICC) and Confidence Interval (CI) Results for Adequacy and Orthography usage annotation.

4.5 Dataset Collected

Table 3 presents the statistics for the *devtest* and *dev* sets resulting from the completion of the translation tasks. The *dev* set comprises 997 sentence pairs, while the *devtest* set contains 1,012 sentence pairs. A sample of the dataset is displayed in Table 7 in the appendix.

5 Experiments

This section describes the experiment involving training neural MT models using the training sets described below. Then, we performed a comprehensive benchmark evaluation using the evaluation sets introduced in this study.

5.1 Training Data

To train the models, we used the data outlined below:

- Ali et al. (2021) dataset: This subset comprises parallel data in Portuguese and Emakhuwa from different sources, including online texts from the Jehovah's Witness, the African Story Book websites, and Optical Character Recognition (OCR) extracted texts. The corpus contains diverse writing styles, spelling styles, and genres.

- Parallel News: This subset consists of news articles translated from Portuguese into Emakhuwa.

The dataset includes around 63k training parallel sentences and 964 validation parallel sentences, spanning a range of topics (see Table 4), where a significant portion of the data comes from the religious domain, mainly consisting of translations of biblical texts.

5.2 Setup

We trained MT models in both directions, *pt-vmw* (Portuguese to Emakhuwa) and *vmw-pt* (Emakhuwa to Portuguese), using two approaches: training a vanilla transformer model and fine-tuning existing multilingual language models.

Training We adopt the transformer architecture (Vaswani et al., 2017), implemented through the OpenNMT toolkit (Klein et al., 2017). The model consists of an encoder and decoder comprising 6 layers, 8 heads, and 512 hidden units in the feed-forward network. We used an embedding size of 512 dimensions for both source and target words and a batch size of 32. We applied layer normalization and added dropout with a 0.1 probability to the embedding and transformer layers. Additionally, the Adam optimizer (Kingma and Ba, 2014) was used, and a learning rate of 0.0002. The checkpoints were saved every 1000 updates. We preprocess the input, applying the Byte Pair Encoding subword segmentation.

Fine-tuning Multilingual Models Multilingual language models are one of the most prominent approaches to low-resource languages nowadays since it enables knowledge transfer among related languages, making cross-lingual transfer and zero-shot learning possible.

In our experiments, we fine-tuned various multilingual language models that are well-established in the literature, namely: mT5 (Xue et al., 2021), byT5 (Xue et al., 2022), and the multilingual translation models M2M-100 (Fan et al., 2021) and NLLB (NLLBTeam et al., 2024). Specifically, we use mT5-base (580M parameters), byT5-base (580M parameters), M2M-100 (418M parameters), and NLLB-200's distilled variant (600M parameters). Additionally, we also fine-tuned the African-centric language models, namely, AfribyT5 (580M parameters) and AfrimT5 (580M parameters) by Adelani et al., 2022.

5.3 Evaluation

To assess the systems' performance, we used the SacreBLEU toolkit (Post, 2018) to compute the BLEU (Papineni et al., 2002) and ChrF scores (Popović, 2015).

6 Results and Discussion

Results are presented in Table 5. Our baseline results, derived from a vanilla transformer-base model, set a foundational performance benchmark. On the *devtest* set, the baseline model achieved a BLEU score of 2.93 and a ChrF score of 23.96 for the *vmw* → *pt* translation direction. These modest scores underscore the limitations of the vanilla transformer-base model in handling the complexities of translation tasks involving low-resource languages like Emakhuwa.

However, introducing multilingual language models enhanced translation performance, particularly in the *vmw* → *pt* direction. Among these, models based on byT5 demonstrated superior performance. For instance, the fine-tuned byT5 model achieved a BLEU score of 14.1 and a ChrF score of 37.75 on the *devtest* set, which marks a substantial improvement over the baseline. This highlights the advantage of leveraging tokenization-free approaches, which are better suited for handling the morphological richness and orthographic variations characteristic of Emakhuwa.

Across Table 5, our results show that while BLEU scores remained relatively low in the *pt* → *vmw* translation direction, ChrF were consistently higher. This discrepancy between BLEU and ChrF scores suggests that BLEU may be disproportionately penalizing spelling variations and minor orthographic differences, which are more prevalent in Emakhuwa translations. ChrF, on the other hand, being more sensitive to character-level n-grams, captures better the quality of translations. Nevertheless, further studies need to be done to assess the correlation of these automatic metrics with human evaluations.

Using multiple references Notably, using multiple references improved scores for both BLEU and ChrF across all models. Specifically, BLEU scores increased by +0.24 to +0.54 on the *dev* set and by +0.3 on the *devtest* set.

7 Conclusion

In conclusion, this study expanded the FLORES+ evaluation set to include Emakhuwa, a low-resource language spoken in Mozambique. By translating the *dev* and *devtest* sets from Portuguese to Emakhuwa. We discussed key challenges such as spelling inconsistencies and loanword adaptations, which are prevalent due to Emakhuwa's underdeveloped spelling standards. Our rigorous methodology, involving translation, post-editing, and validation, ensured high-quality datasets used to benchmark neural MT models. The results indicate that incorporating multiple reference translations can enhance translation quality, particularly in languages with underdeveloped orthographies such as Emakhuwa. The dataset is publicly available, providing a valuable resource for future research in low-resource language MT.

Abstract

FLORES is a benchmark dataset designed for evaluating machine translation systems, particularly for low-resource languages. This paper, conducted as a part of Open Language Data Initiative (OLDI) shared task, presents our contribution to expanding the FLORES dataset with high-quality translations from Russian to Tuvan, an endangered Turkic language. Our approach combined the linguistic expertise of native speakers to ensure both accuracy and cultural relevance in the translations. This project represents a significant step forward in supporting Tuvan as a low-resource language in the realm of natural language processing (NLP) and machine translation (MT).

1 Introduction

Tuvan is a Turkic language, written using the Cyrillic alphabet and spoken by approximately 258,000 people (as of 2020), according to Ethnologue (2024). It is one of two official languages, along with Russian, of the Republic of Tuva, which is located in South Central Siberia, Russia. Despite its historical and cultural significance, Tuvan is classified as vulnerable by UNESCO, making it a critical target for preservation and technological integration. The FLORES (Goyal et al., 2022), spearheaded by Meta, aims to enhance machine translation systems by providing high-quality, controlled datasets for under-resourced languages for evaluation purposes. This paper, as a part of OLDI shared task (Initiative, 2024b), details our efforts to contribute to this dataset by providing translations from Russian to Tuvan.

2 Related work

It is essential to provide a brief overview of the FLORES (Goyal et al., 2022) dataset for those unfamiliar with this resource. The FLORES dataset, introduced by Goyal et al. (2022), is a benchmark for evaluating machine translation models on low-resource languages, which was translated to over 200 languages. It is comprised of two sets: the dev set contains 997 sentences and the devtest set includes 1012 sentences, that were sampled from Wikinews, Wikijunior and Wikivoyage. FLORES dataset is crucial in advancing NLP for languages like Tuvan by providing benchmark specifically designed to evaluate machine translation systems across a wide variety of languages. The NLLB project (NLLB Team et al., 2022) further exemplifies efforts to scale human-centered machine translation across diverse languages.

3 Language overview

3.1 Handling dialectal differences

As the Republic of Tuva is a federal subject of Russia, the majority of the population is bilingual, speaking both Russian and Tuvan. For that reason, Tuvan translators relied on the FLORES dataset in Russian when developing one in Tuvan. During the translation process, any variations in interpretation due to dialectal differences were resolved by defaulting to the Central dialect's interpretation. This approach ensured uniformity and consistency across the dataset, which is crucial for training machine translation models that need to generalize well across different contexts.

The language is taught in schools optionally, but one can get a higher education in the Tuvan language and Literature in one of the universities of the Republic. Although the number of youth that speaks the language fluently decreases, it is still widely used both in cities and rural areas.

3.2 Linguistic challenges

Tuvan is characterized by its complex phonological and grammatical structures, including vowel harmony and extensive use of suffixes. These features posed challenges in translation, particularly in ensuring that the meaning and tone of the original Russian texts were accurately conveyed in Tuvan. However, since our work was limited to written form, we did not address challenges related to vocal translation or spoken dialects.

Proceedings of the Ninth Conference on Machine Translation, pages 593–599
November 15-16, 2024 ©2024 Association for Computational Linguistics

4 Data collection

4.1 Expertise of translators

Our translation team for the FLORES dataset was led by four native Tuvan speakers who are also proficient in Russian. The team included professional linguists and language enthusiasts with formal education in the Tuvan language. Although Tuvan language education is currently facultative, several of our translators had attended schools where Tuvan was the primary medium of instruction. This deep linguistic knowledge was crucial in ensuring that translations were not only accurate but also culturally relevant and sensitive. The following team of translators put their utmost effort to make the FLORES dataset available in Tuvan.

- Mongush Salim (Моңгуш Салим)
- Oorzhak Lyudmila (Ооржак Людмила)
- Ongai-ool Choduraa (Оңгай-оол Чодураа)
- Kuzhuget Ali (Кужугет Али)

4.2 Translation guidelines and training

Before beginning the translation tasks, all translators were provided with comprehensive guidelines, prepared in Russian, detailing the translation process. These guidelines, which are included in Appendix A, covered key aspects such as:

1. Maintaining the tone and style of the original text.
2. Handling idiomatic expressions and culturally specific references.
3. Ensuring pragmatic accuracy, including the correct use of pronouns and proper nouns.

Translators were instructed to adhere strictly to these guidelines in order to ensure a high level of consistency and quality across the entire dataset.

4.3 Managing the translation workflow

The translation process was managed using a Telegram group, where tasks were assigned, and progress was tracked using project management tools. This system allowed for effective coordination among the translators and ensured that the project stayed on schedule. It is worth pointing out that the workflow included multiple rounds of review and feedback among the translators to check one another and refine the translations further.

5 Experimental validation

5.1 Contribution to the evaluation of translation models

Our work makes a significant impact on the evaluation part of the Tuvan translation models by creating a reliable benchmark for this task. As for the current model of September 2024 developed by our team, it was trained on the existing Tuvan-Russian corpus, which consisted of approximately 200,000 pairs (Kuzhuget and Choigan, 2024) of translations sourced mainly from Wikipedia and other early Tuvan language projects (Kuzhuget et al., 2023). By contributing to the FLORES (Goyal et al., 2022) dataset, we have provided a more structured and high-quality resource, developed and checked by professionals, that is better suited for evaluating machine translation models.

The new dataset allowed us to run experiments to compare the quality of the existing translation models, available in Tuvan (Claude Sonnet 3.5, Google Translate v2 API, tyvan.ru). The results of these experiments are demonstrated on the Table 1.

Claude Sonnet 3.5 shows the highest performance overall, with BLEU scores of 35.65 and 33.04 for the Tyv-Rus translation in dev and devtest, respectively. The ChrF2++ scores are also the highest, reflecting good contextual understanding of this model. Google Translate v2 performs well, particularly with Tyv-Rus, achieving a BLEU score of around 28 in both datasets with ChrF2++ scores being also strong. The tyvan.ru model tends to have lower scores and lags behind the two above mentioned models.

Model	Dataset	Tyv-Rus		Rus-Tyv	
		BLEU	ChrF++	BLEU	ChrF++
tyvan.ru	dev	16.94	43.94	13.12	45.92
	devtest	16.41	43.09	13.35	46.11
Google Translate v2	dev	29.78	54.60	14.30	45.50
	devtest	27.16	52.87	15.58	46.18
Claude Sonnet 3.5	dev	35.65	59.65	16.67	48.45
	devtest	33.04	57.41	17.09	49.08

Table 1: Scores of Russian-Tuvan translation models on the FLORES dataset.

5.2 Manual evaluation of machine translation with the FLORES dataset

Objective

The objective of the manual evaluation on the FLORES dataset is to evaluate and compare the perceived translation adequacy of three translation services: Google Translate v2, Claude Sonnet 3.5, and tyvan.ru. For that purpose we asked five Tuvan native speakers (annotators) to assess the quality of the translations for adequacy by giving scores on a scale of 1 to 5, the higher the better.

Data

31 sentences were translated from Russian to Tuvan using the above mentioned services. The data was taken from two sets of FLORES dataset:

- dev set: First 16 sentences from the dev set
- devtest set: Last 15 sentences from the devtest set

Annotators were given a table with the first column containing sentences in Russian and three other columns containing translated sentences to Tuvan by the services, they had no information of the service that provided the translation to make the evaluation unbiased.

Results

Google Translate v2

- Median score: ~ 4
- Distribution: Skewed toward higher scores (4-5), with some variability and occasional lower ratings.

Claude Sonnet 3.5

- Median score: ~ 4
- Distribution: Consistently high (3-5), with some sentences receiving lower scores (down to 2).

tyvan.ru

- Median score: $\sim 3 - 4$
- Distribution: Most variability, with a wider range of scores (1-5). This service had the most mixed feedback, with some high and many low ratings.

Key Insights

Google Translate v2 and Claude Sonnet 3.5 performed relatively well, with consistent high scores. tyvan.ru showed more variability in performance, reflecting either inconsistent translation quality or differences in how annotators perceived adequacy.

Visuals

Box plots (Figure 1) were used to compare the distribution of scores across services in both dev and devtest sets. A histogram (Figure 2) illustrated the overall distribution of scores for each service, with distinct colors for easy comparison (yellow for Google Translate v2, blue for Claude Sonnet 3.5, red for tyvan.ru). This experiment highlights differences in translation quality as perceived by human annotators, showing that while Google Translate v2 and Claude Sonnet 3.5 generally perform well, tyvan.ru's performance was less consistent across annotators.

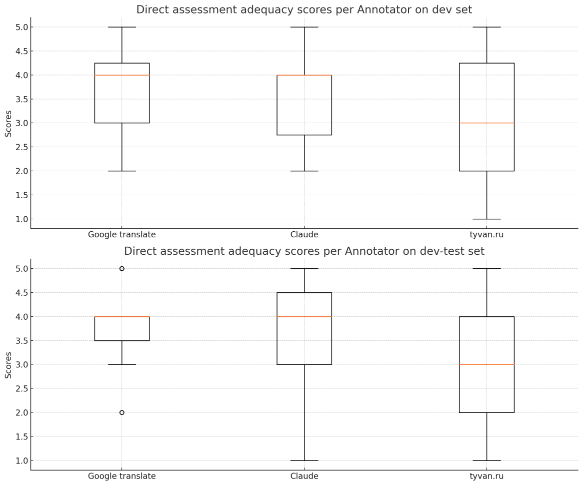

Figure 1: Direct assessment adequacy scores per Annotator

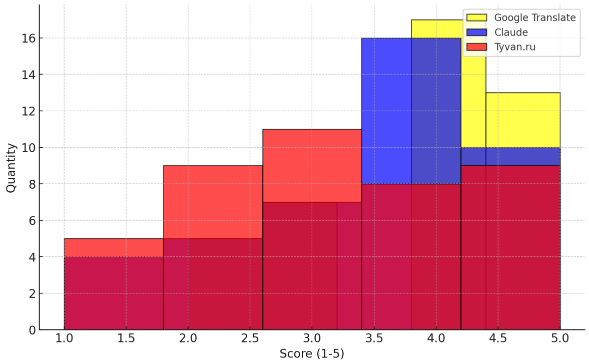

Figure 2: Perceived translation score distribution by Service

6 Data sample

As far as the the FLORES dataset in Tuvan is concerned, it has the following characteristics:

- dev set: 997 sentences, 18.26 average number of words in a sentence;
- devtest set: 1012 sentences, 18.44 average number of words in a sentence.

A table 2 showcases the examples of translated sentences from Russian to Tuvan. English translations were provided as examples so that English speakers could understand the general meaning of these sentences. But it is important to highlight that our translators were based only on the Russian

7 tyvan.ru and language preservation

The development of a Tuvan AI translator has been instrumental in preserving and revitalizing the Tuvan language, classified as endangered by UNESCO. Born out of a personal commitment to language preservation, the project began as a response to the lack of online translation resources for Tuvan. The initiative gained momentum with contributions from David Dale, who recognized the urgent need for language preservation during his work on the Erzya language (Dale, 2022), and Ali Kuzhuget, who has spent over a decade developing Tuvan language resources (Kuzhuget and Choigan, 2024), including dictionaries, keyboards, and translations of major platforms.

tyvan.ru serves as the online hub for these efforts, offering a range of Tuvan language tools, including the AI translator. Since its launch, the translator has been used by over 80,000 individuals, showcasing the growing interest in and need for Tuvan language resources. The project also extends its impact through the "One Code - Different Languages" volunteer initiative, which supports other vulnerable low-resource languages, such as Bashkir, Tatar, Chuvash, and Mari.

8 Limitations

The main challenge that occurs when dealing with low-resource languages like Tuvan is the small number of professionals, who could correctly translate to a low-resource language, abiding by all the grammar rules and nuances of the language. This results in a rather long translation process. Another project we are engaged in is the Seed (Maillard et al., 2023) project in Tuvan. One of the key limitations we faced in the second project is the lack of Tuvan speakers who are bilingual in any language other than Russian. Due to the historical context of Tuvans being part of the Soviet Union and Russia, Tuvan speakers typically only speak Russian in addition to Tuvan. Consequently, our extended research group is required to translate the Seed dataset from English to Russian first, and then from Russian to Tuvan. This two-step translation process introduces additional complexity and potential for translation inaccuracies, but it is a necessary approach given the linguistic resources available.

9 Conclusion

Our contribution to the FLORES dataset (Goyal et al., 2022) represents a significant step forward in supporting Tuvan as a low-resource language in the field of natural language processing. By focusing on the Central dialect and leveraging human expertise, we have created a high-quality resource that will aid in the development of more accurate and culturally sensitive machine translation systems.

In addition, we are currently in the process of translating the Seed (Maillard et al., 2023) dataset from English to Russian, and subsequently from Russian to Tuvan. This effort further enhances the resources available for Tuvan, contributing to the development of multilingual datasets and promoting the digital presence of the language.

This work not only enhances the digital presence of the Tuvan language but also contributes to its preservation and promotion.

10 Acknowledgments

We would like to express gratitude to the team of translators who implemented the FLORES dataset in Tuvan despite all limitations and difficulties. We also commend David Dale, author of the article on training a NLLB-200 model on Tuvan-Russian corpus Dale (2023), language enthusiast and a key figure in the Post-Soviet NLP community, whose insights and guidance were instrumental in refining our benchmarks and translation guidelines. David's commitment to advancing NLP for low-resource languages has greatly influenced our work, helping us achieve a higher standard of quality and relevance in our translations.

A.1 Важное примечание:

Ваши переводы будут использоваться для обучения или оценки движков машинного перевода. Поэтому этот проект требует человеческого перевода.

A.2 Общие рекомендации:

1. Контекст: Вы будете переводить предложения из разных источников. В некоторых случаях может быть предоставлена ссылка на исходный документ, чтобы дать вам больше контекста. Если она доступна, пожалуйста, обратитесь к ней.
2. Единицы измерения: Не переводите единицы измерения. Переводите их точно так, как указано в исходном содержании.
3. Сохранение тона: При переводе сохраняйте тон, используемый в исходном документе. Например, энциклопедический контент из источников вроде Википедии должен переводиться с использованием формального тона.
4. Плавность перевода: Предоставляйте плавные переводы, не отклоняясь слишком сильно от структуры исходного текста. Допускаются только необходимые изменения.
5. Точность: Не расширяйте или не заменяйте информацию по сравнению с тем, что присутствует в исходных документах. Не добавляйте никакой поясняющей или скобочной информации, определений и т.д.
6. Полнота перевода: Не игнорируйте любой значимый текст, который был в исходнике.
7. Выбор перевода: В случае нескольких возможных переводов, пожалуйста, выберите тот, который имеет наибольший смысл (например, для соответствия гендеру, культурной адаптации на целевом языке, уровня формальности и т.д.).

A.3 Именованные сущности:

Именованные сущности - это люди, места, организации и т.д., которые обычно упоминаются с использованием собственного имени. Этот раздел содержит рекомендации о том, как обращаться с именованными сущностями:

1. Общепринятые названия: Если в целевом языке существует общепринятое название для именованной сущности, используйте его.
2. Транслитерация: Если общепринятое название отсутствует, используйте транслитерацию оригинального термина, если это возможно. Если транслитерация не будет широко понята в контексте, вы можете сохранить оригинальный термин.

A.4 Идиоматические выражения:

Идиоматические выражения не должны переводиться дословно. Используйте эквивалентную идиому, если таковая существует. Если эквивалентная идиома отсутствует, используйте идиому схожего смысла. Если в целевом языке не существует похожих выражений, перефразируйте идиому так, чтобы значение было сохранено на целевом языке.

A.5 Неоднозначные местоимения:

Когда переводимое местоимение является неоднозначным (например, может быть интерпретировано как он/она или его/ее), выбирайте гендерно-нейтральные местоимения (такие как они), если таковые существуют на целевом языке. Однако, когда местоимение в исходном тексте четко обозначено по гендеру, вы должны следовать исходному материалу и сохранять гендерную маркировку.

Machine Translation Evaluation Benchmark for Wu Chinese: Workflow and Analysis

Abstract

Although the population of Wu speakers is the second largest among languages in China, it is a textually under-resourced language, creating significant challenges for building machine translation systems supporting Wu. In this paper, we describe our Wu Chinese contribution to the FLORES+[1] dataset to serve as a training corpus and evaluation benchmark for machine translation models and we demonstrate its orthographic compatibility with existing Wu data. Our contributions include: (1) an open-source, manually translated dataset, (2) full documentations on the process of dataset creation and validation experiments, (3) preliminary tools for Wu Chinese normalization and segmentation, and (4) benefits and limitations of our dataset, as well as implications for other under-resourced languages. The project codes are stored on Github.[2]

1 Introduction

Wu Chinese is a Sinitic language spoken in Shanghai, Zhejiang, parts of Jiangsu, Anhui, and Jiangxi of China. It represents a complex and internally divergent dialect group (Pan et al., 1991) with around 83 million speakers (Eberhard et al., 2024). Despite having a robust population of speakers, Wu Chinese has been facing a sharp decline in daily usage due to the promotion of Standard Chinese. Meanwhile, Wu Chinese lacks a widely-accepted writing system and is not commonly written by native speakers, which has relegated Wu to becoming under-resourced with respect to text data. In this data-scarce context, machine translation of Wu is an extremely challenging task.

To assist in the development of language models in Wu Chinese, we construct a FLORES+ benchmark dataset for Wu machine translation models and conduct evaluations that validate its utility via a language identification task. FLORES+ is an extension of the initial FLORES-101 project by NLLB Team et al. (2022), aiming at expanding the coverage to more languages worldwide. FLORES features fully aligned data directly translated from English Wikimedia and is consequently ideal for multilingual translation systems. Currently, the FLORES+ benchmark covers 3 language varieties written in Hanzi: Mandarin Chinese (Standard Beijing), Mandarin Chinese (Taiwanese), and Yue Chinese (Hong Kong Cantonese). The addition of Wu Chinese would facilitate machine translation across these similar varieties.

After translating and proofreading the new Wu Chinese dataset, we validated its consistency and generalizability with respect to existing Mandarin, Wu, and Yue Wikimedia resources. We also devised measures to normalize and segment Wu Wikimedia data in order to enhance their fidelity and provide a standardized dataset upon which to conduct our evaluations. Finally, we discuss the results of the experiments and suggest future work on Wu Chinese.

2 Language Overview

2.1 Wu Sounds and Wu Writings

Wu Chinese is mutually unintelligible with other Sinitic languages such as Mandarin and Yue (Cantonese), but shares a common set of *Hanzi* (Chinese characters) with these varieties. A significant feature of Wu Chinese that differentiates it from other Sinitic languages is its three-way VOT contrast in the syllable-initial position and its glottalization of

"checked tones" (Norman, 1988), inherited from Middle Chinese. A lot of Hanzi in Wu Chinese bear two ways of pronunciation: *Wendu* ("文读", literary reading) and *Baidu* ("白读", vernacular reading). Wendu is the borrowing of pronunciation from Northern and Jianghuai Mandarin dialects; Baidu is the indigenous pronunciation derived from antecedent tones. For instance, "学" reads [ɕɥæ] in Standard Mandarin; as for Wu, it reads [ɦoʔ] (Baidu) in "学堂" (the traditional word for "school") and [iɐʔ] (Wendu) in "学校" (the modern word for "school" borrowed from Mandarin). Although [ɕɥæ] and [iɐʔ] appear to be unrelated, the sound change is in fact systematically induced according to the phonotactic constraints of Wu Chinese. Wendu and Baidu can occur in one single word too, as "大学" ("university") reads [dɐ ɦoʔ] where [dɐ] is Wendu and [ɦoʔ] is Baidu.

With the above prerequisite knowledge, it is logical to believe that most syllabary utterances in Wu have had a Hanzi representation, since most Middle Chinese pronunciations have traceable documentations. However, through an evolution of sounds and lexicon over a thousand years, the *Benzi* ("本字", original character) of many sounds have been lost. To recover missing graphemes in Wu Chinese writings, 赵元任 (1956) proposed a guideline that for every Wu utterance:

1. If the Hanzi of the utterance is known, use that Hanzi;
2. Otherwise, use a known Hanzi of the same pronunciation in the target Wu variety.

This logic has constituted the overarching principle of modern Wu orthographies. In the second case where we have multiple Hanzi candidates, we adhere to the following rules based on 简明吴方言词典(闵家骥et al., 1986):

1. Use the Hanzi that historically appears in Ming-Qing literature;
2. When no historical usage is found, pick a Hanzi that best subscribes to the semantic meaning;
3. Otherwise, choose the Hanzi that most frequently appears in vulgar texts.

2.2 Dialectal Variations

In the past, the Suzhou dialect (a sub-dialect of Su-Hu-Jia within Northern Wu) has been the prestige form of Wu Chinese. Beginning from the late 20th century, the Shanghai dialect (spoken in the urban central area of Shanghai, also a sub-dialect of Su-Hu-Jia) has served as the lingua franca of the surrounding regions (Chen and Gussenhoven, 2015) because of the city's population and economic importance. There have also been recent attempts by the community to create "Standard Wu", which closely relates to Taizhou, Shanghai, and Ningbo dialects[3]. That being said, none of the Wu varieties is influential enough to profoundly alter the pronunciations or lexicons of others, considering the hegemonic impact of Standard Mandarin.

As a result of multiple factors, Wu dialects have developed vastly divergent readings of the same Hanzi. This becomes especially problematic when no Hanzi is registered to an utterance, i.e. finding a Hanzi of the same pronunciation in the local dialect is necessary. To illustrate how complex the spelling variations can become, below is an *incomplete* list of the pronunciations and corresponding common spellings of the location/time preposition in 33 Wu dialects transcribed by 钱乃荣 (1992):

"Prep. of loc./time"	[ləʔ]	"勒", "了"
	[lɐʔ]	"辣", "拉", "垃"
	[liʔ]	"立"
	[le], [læ]	"来"
	[kɛ]	"该"
	[tsɛ^{e}], [dʑɛ]	"在"

Inevitably, adopting one spelling standard means discarding the rest of equivalently common spellings. For instance, [lɐʔ lɐʔ] "辣辣" is the prevalent spelling of the location/time preposition (double syllable) in the Shanghai dialect, whereas [ləʔ lɐʔ] "勒拉" is commonly accepted in many other dialects and therefore more frequently encountered. We shall discuss the Chongming dialect which is the variety used in our dataset, and its corresponding orthography in the next section.

2.3 Relevant Resources

Before proceeding, we want to outline the resources available for natural language processing tasks related to Wu Chinese. The foundation of Wu Chinese studies was laid by 赵元任(Yuen Ren Chao) with his 现代吴语的研究(赵元任, 1956). Works by later scholars include 当代吴语研究(钱乃荣, 1992) and others. There is 简明吴方言词典(闵家骥et al., 1986), a dictionary that covers most Wu dialects with a light emphasis on the Shanghai dialect lexicon, as well as 上海话大词

[3] https://wuu.m.wikipedia.org/wiki/标准吴语/

典(钱乃荣, 2008) specifically for the Shanghai dialect. Thanks to community efforts, there is a Wu Wikipedia[4], a forum[5], and several online dictionaries[6][7] made by 吴语协会and 吴语学堂.

3 Methodology

The FLORES+ Wu dataset is directly translated from English into Wu Chinese. The target Wu variety is the Chongming dialect. The Chongming dialect (or more broadly the Shadi dialect) is a Wu dialect within the Su-Hu-Jia division, spoken in Chongming, Haimen and Qidong districts as well as in some areas of Zhangjiagang (张惠英, 2009). Although Chongming belongs to the Manucipality of Shanghai, the dialect is distinctive from the urban variety on many aspects and is known for preserving many rare characteristics of Middle Chinese. There is also a large dedicated Chongming dictionary (张惠英et al., 2014), which unfortunately was not accessible to us during our efforts.

While the Chongming dialect is not the most used or researched Wu dialect, it is a representative one of Northern Wu along the dialect continuum, because it spreads in between Shanghai and Suzhou, where the two prestige forms of Northern Wu are used. Besides, the lexicon of the Chongming dialect has a significant overlap with other dialects for its preservation of archaic features common to most Wu dialects. In contrast, the Shanghai dialect is less generalizable to other Wu dialects due to its integration with other Chinese languages. However, the overlap between the Chongming dialect and Southern Wu dialects might be less prominent. As a result, our dataset may be less effective for Southern Wu linguistic tasks.

Data were equally distributed and translated by 2 native speakers of the Chongming dialect who have earned or are pursuing a university degree in English. Both translators grew up in Chongming; one went to Putuo, Shanghai for high school and college, and the other went to Fengxian, Shanghai for college. They mainly speak Wu at home, but also speak it with peers on occasion. They are exposed to the Shanghai urban dialect as well as other local varieties. All translated data were checked by a third independent Wu speaker.

The translators worked collaboratively on the task. They mainly used 简明吴方言词典(闵家骥et al., 1986) and then 上海话大词典(钱乃荣, 2008) (see 2.3) if they were unable to recall the parallel Hanzi that represent the utterances. Despite the discrepancy between the Chongming and Shanghai lexicons, the dictionaries provided enough context to determine the appropriate orthography. For example, both "乃末" and "乃么" point to the same word [ne məʔ]; as both dictionaries only list "乃末", it was easy to make the choice. When the two dictionaries' orthographies diverged, 简明吴方言词典was prioritized. When there were phonetic distinctions between the Chongming and Shanghai dialect and the original character was indeterminable, we made sure that the selected Hanzi had aligned pronunciation. Noticeably, we did not use "勿" [vəʔ] but used "弗" [fəʔ] for the word of negation. We were also committed to maintaining a balanced language register, as the translated content is formal, though Wu Chinese is usually colloquial. We referred to the broadcasting-style Wu Chinese found in Shanghai and Suzhou to achieve the desired register. Beside the task of translation, the translators dedicated time to review Wu dictionary entries and online fora to grasp the overall construct of the written Wu landscape. During the proofreading process, when an alternative translation is suggested, the translator responsible for the line would ask for community guidance from the aforementioned fora. Proper wordings were selected according to the intuitive preferences of Wu native speakers from the community. In total, we have translated and verified the linguistic accuracy all 997 sentences in the dev set.

4 Data Samples

This sections lists the first 5 lines of translation along with their English counterparts.

   Local media reports an airport fire vehicle rolled over while responding.

5 Validation

5.1 Task

Language identification models have frequently been trained to corroborate translation datasets' correspondence with other texts in the target language. We train a language identification model on the FLORES+ Wu dataset to show its compatibility with other Wu Chinese text resources. The goal of our experimental setup is to train a model to correctly identify the language of an input sentence from among Mandarin, Wu, and Yue when prompted a sentence written in Hanzi.

Experiments are split into three parts. In each part, we trained three binary classification models: Mandarin-Wu, Mandarin-Yue, and Wu-Yue on their respective datasets, and a three-way classification model on all designated data. We recorded the performance of the models in terms of their accuracy on unseen data, collected separately by languages.

We broke down the experiments into distinct trials that reflect noteworthy characteristics of the training and evaluation data. In part 1, we conducted a 9:1 split on FLORES+ datasets to test their internal consistency. In part 2, we trained the model on Wikimedia data and tested on FLORES+ to showcase the compatibility of FLORES+ in its common use cases. In part 3, we reversed the training and testing data in part 2 to explore the extent of generalizability of FLORES+ given that it consists of small but parallel data.

5.2 Dataset Processing

We adopted two data sources, Wikimedia[8] and FLORES+.

We downloaded Wikimedia database XML dumps for Mandarin, Wu, and Yue. Since Mandarin and Yue dumps are significantly larger than Wu, only a portion of the data was extracted. After normalization, each dataset comprises $25,000$ lines of texts.

FLORES+ datasets in use include the existing two Mandarin dev sets and Yue dev set, as well as the newly built Wu dev set. As a result, there are 1994 lines of sentences in Mandarin, 997 in Wu and 997 in Yue.

5.2.1 Normalization

The dumps were preprocessed with a simple filter removing Latin characters and template symbols. Because Mandarin and Yue Wikimedia were written in Traditional Chinese and Wu Wikimedia partially, we utilized OpenCC[9] which supports character-level and phrase-level conversion from Traditional to Simplified Chinese. OpenCC conversion was also applied to FLORES+ Taiwan Mandarin and Yue datasets.

For the lack of a standard orthography, Wu Wikimedia requires an additional step of normalization. For some characters and words that are often spelled differently, we replaced the constituents by our standard forms. However, the brute force method does not work for every character and word that need normalization. For example, "勒海" before normalization could be interpreted differently:

$$\text{勒海} \begin{cases} \text{勒嗨} & \text{"In there, over there"} \\ \text{勒海(浪)} & \text{"In the sea"} \end{cases}$$

The ambiguity of the language results in demands on more advanced normalization schemes, which are essential for language models to grasp semantic understandings.

5.2.2 Segmentation

Since Chinese languages do not depend on spaces to separate words, segmentation tools tailored to the respective languages are indispensable. For

[8] https://dumps.wikimedia.org/

	cmn	wuu	yue	total
cmn-wuu	0.995	0.990	-	0.993
cmn-yue	1.000	-	0.970	0.990
wuu-yue	-	0.990	0.990	0.990
c-w-y	0.995	0.990	0.979	0.990

Table 1: FastText classification precision rates by languages (k=1), trained with and evaluated on FLORES+ dev sets, 9:1 split. Rows represent in what languages the model is trained with; columns represent the language of the testing data. We use the ISO 639-3 codes for abbreviation: cmn (Mandarin), wuu (Wu), yue (Yue).

Mandarin, we used jieba[10], a popular open-source segmentation library with a prefix dictionary and a HMM-based model with Viterbi algorithm for unknown words; for Cantonese, we used cantoseg[11] which is built from jieba and reads in a merged corpus from jieba and PyCantonese (Lee et al., 2022).

As for Wu, We decided on adding an auxiliary dictionary to jieba for frequent words and phrases in Wu Chinese that are not present in Mandarin. We found this approach has also been used by Chen (2023). The entries in the auxiliary dictionary have been collected from 简明吴方言词典(闵家骥et al., 1986) for its wide coverage on Northern and Southern Wu dialects and 上海话大词典(钱乃荣, 2008) for its rich lexicon.

5.3 Model

We use fastText[12] text classification (Joulin et al., 2016) for all experiments. FastText is a CPU-based library for efficient learning of word representations and sentence classification. We tagged language labels to individual lines in every dataset and called the supervised command to train the models. When testing, fastText takes a k parameter and returns both precision and recall rates within the first k predicted labels. As only 2 or 3 distinct labels were present in each run, we used k=1 to compute the classification accuracy.

5.4 Results

In part 1, all four models demonstrate a high accuracy in classifying all languages. This validates the internal consistency of FLORES+ datasets including the new Wu Chinese addition.

	cmn	wuu	yue	total
cmn-wuu	0.896	0.999	-	0.930
cmn-yue	0.968	-	0.987	0.975
wuu-yue	-	0.996	0.986	0.991
c-w-y	0.868	0.997	0.971	0.926

Table 2: FastText classification precision rates by languages (k=1), evaluated on FLORES+ dev sets, trained with Wikimedia texts. Rows and columns are the same as Table 1.

	cmn	wuu	yue	total
cmn-wuu	0.944	0.639	-	0.792
cmn-yue	0.949	-	0.796	0.872
wuu-yue	-	0.815	0.884	0.849
c-w-y	0.929	0.615	0.735	0.759

Table 3: FastText classification precision rates by languages (k=1), evaluated on Wikimedia texts, trained with FLORES+ dev sets. Rows and columns are the same as Table 1.

In part 2, we can observe a total accuracy over 90% for all four models. However, a drop in accuracy for the Mandarin-Wu model on Mandarin texts indicates false positives of Mandarin texts mislabelled as Wu. Alternatively speaking, training on Mandarin and Wu Wikimedia data allows the model to capture features of Wu and thus correctly label Wu data, but is less effective for recognizing Mandarin features.

In part 3, due to insufficient training data, the models exhibit tendency to misclassify Wu and Yue data as Mandarin. There is a more significant contraction in testing accuracy on Wu data than Yue. Meanwhile, the accuracy of Mandarin-Yue and Wu-Yue models is maintained at a relatively stable level.

Some typical misclassifications are listed below. These input data are Mandarin but mislabeled as Wu, presented in the segmented format. The corresponding Wu translations are provided as well. "cmn" denotes Mandarin data (mislabeled as Wu) and "wuu" denotes Wu data (correctly labeled).

1. (cmn) 人类 的 手 比脚 短 ， 指 （ 趾 ） 骨 更 直 。
   (wuu) 人个 手比脚 短 ， 趾骨 更 直 。
2. (cmn) 看到 有人 愿意 支持 我 ， 我 很 高兴 。
   (wuu) 我蛮 高兴 有人 愿意 支持 我个 。
3. (cmn) 越来越 多 超市 开始 提供 更 多样化 的 即 食品 ， 部分 超市 甚至 提供

微波炉 或 其他 设备 以 食物 加热 。
(wuu) 超市 里个 现成 食品 种类 越来越 多 。 有眼 超市 甚至 提供 微波炉 或者 其他 方式 来 加热 食物 。

From these cases we can observe many common words in the two languages. There are nuanced differences in phrasing order and sentence structures but the presented orders and structures are generally acceptable in both languages and only subject to personal habits of the translators. Despite lexicon similarity, the model also seems to have difficulty in recognizing Wu constituents due to the relatively weak performance of the segmentation tool, evident in "我个" (1, 2), "我蛮” (2).

Overall, the FLORES+ Wu dataset is consistent and capable of evaluating models trained with common data after appropriate normalization and segmentation. However, its benchmarking quality might not be as good as the Mandarin and Yue dataset for several reasons.

The tokenization scheme could be further optimized with a better segmentation tool in use. The current manually configured word list for Wu in the auxiliary dictionary of `jieba` is relatively small compared to the pre-built Mandarin dictionary in `jieba` and the independently maintained Yue dictionary by Lee et al. (2022). As some syntactic structures of Wu have not been recognized by `jieba`, the models are unable to learn accurate representations of the constituents.

Although the spelling standard used in FLORES+ Wu dataset is relatively generalizable to other dialects, it fails to take account of many expressions in Southern Wu dialects which are a part of the Wikimedia data. Therefore, we suggest that the training and testing datasets should align in the range of dialects whenever possible.

Moreover, the tendency of Wu Chinese to be influenced by Mandarin poses problems, exemplified by our classifier mislabeling Wu data containing "了" as Mandarin, because this grammar particle is common in Mandarin but infrequent in older Wu data.

6 Conclusion

As for now, a contemporary, consistent, and organized corpus becomes crucial for high-quality Wu Chinese language models. Meanwhile, it is important for AI scientists and engineers to have an understanding in the linguistic properties of their training and testing data. We hope that our published dataset and code contributions provide a foundation for future efforts towards Wu Chinese machine translation and language modeling.

a.shopolatov@tahrirchi.uz

Abstract

This study presents several contributions for the Karakalpak language: a FLORES+ devtest dataset translated to Karakalpak, parallel corpora for Uzbek-Karakalpak, Russian-Karakalpak and English-Karakalpak of 100,000 pairs each and open-sourced fine-tuned neural models for translation across these languages. Our experiments compare different model variants and training approaches, demonstrating improvements over existing baselines. This work, conducted as part of the Open Language Data Initiative (OLDI) shared task, aims to advance machine translation capabilities for Karakalpak and contribute to expanding linguistic diversity in NLP technologies.

1 Introduction

The Karakalpak language, a member of the Turkic language family, is primarily spoken in the Republic of Karakalpakstan, an autonomous region within Uzbekistan, Central Asia. Current estimates suggest a native speaker population to be around 900,000 individuals (Ethnologue, 2024). Linguistically, Karakalpak is an agglutinative language which belongs to the Kipchak branch of the Turkic language family and shares close affinities with Kazakh and Nogai (Berdimuratov and Dáwletov, 1979).

As a low-resource language, Karakalpak presents significant challenges in the field of natural language processing, particularly in machine translation. Major translation platforms such as Google Translate (Google, 2024) currently do not offer support for this language as of the time of writing this paper, underscoring the need for dedicated research and development in this area.

This study, conducted as part of the Open Language Data Initiative (OLDI) shared task, presents fine-tuned neural models for Karakalpak translation, a fine-tuned version the No Language Left Behind (NLLB) model (NLLB Team et al., 2022). In line with OLDI's goals of expanding language resources, we release several key contributions:

1. A FLORES+ devtest dataset (NLLB Team et al., 2022) translated to Karakalpak
2. Parallel corpora for Uzbek-Karakalpak, Russian-Karakalpak and English-Karakalpak of 100,000 pairs each [1]
3. Open-sourced fine-tuned neural models for translation across Uzbek, Russian, English and Karakalpak languages [2]
4. Scripts for Latin-Cyrillic transliteration for Karakalpak

Our research aims to advance the state of machine translation for Karakalpak, contributing to the broader OLDI objective of improving natural language processing capabilities for low-resource languages. This work demonstrates how shared tasks like OLDI can drive progress in expanding linguistic diversity in NLP technologies.

2 Related work

The field of machine translation for low-resource languages has experienced significant advancement with the advent of the No Language Left Behind (NLLB) model families. These innovative models demonstrate the capability to facilitate translation across more than 200 languages, leveraging extensive collections of online corpora.

Another notable multilingual translation model is MADLAD-400 (Kudugunta et al., 2024), which extends the capabilities of large language models to cover 400 languages, including many low-resource languages and Karakalpak. This model represents a significant step forward in expanding the reach of

Table 1: Examples from the FLORES+ dataset for English-Karakalpak language pair

machine translation to a broader range of linguistic communities.

In the specific context of Karakalpak machine translation, several notable efforts have been made. A prominent example is the Apertium platform (Forcada et al., 2011), a rule-based machine translation system designed for low-resource languages. Utilizing finite-state algebra and rule-based methodologies, Apertium has developed morphological analyzers and spell-checking tools for Karakalpak[3]. Furthermore, it has produced machine translation systems for language pairs for Uzbek-Karakalpak, Kazakh-Karakalpak, and Tatar-Karakalpak.

A recent contribution to the Karakalpak translation comes from the Turkic Interlingua (TIL) team (Mirzakhalov, 2021), who introduced a model specifically trained on Turkic languages and corpora, with Karakalpak included in its linguistic scope. This initiative not only enhances the translation capabilities for Karakalpak but also contributes to the broader landscape of Turkic language processing. Additionally, the team has made significant strides in corpus development, introducing parallel corpora for numerous Turkic language pairs, including those involving Karakalpak.

Moreover, a proprietary online translation service for Karakalpak exists at https://from-to.uz/. To provide a comprehensive evaluation of Karakalpak machine translation capabilities, we will assess this tool's performance using its API, comparing it with our proposed models. This comparison will offer insights into both open-source and commercial solutions for low-resource language translation.

To our best knowledge, these developments collectively represent important steps towards improving machine translation capabilities for Karakalpak and other low-resource languages within the Turkic language family.

As an additional benchmark, we will include Claude-3.5-sonnet, a commercial large language model (LLM) with multilingual capabilities. While not specifically designed for Karakalpak translation, Claude-3.5-sonnet represents the current state of general-purpose language models and can provide valuable insights into how well such models perform on low-resource language tasks.

3 Datasets

3.1 FLORES+ Devtest Dataset

This study introduces the Karakalpak FLORES+ devtest dataset, which comprises 1012 sentences translated from English to Karakalpak. The FLORES+ datasets, derived from Wikimedia content, have been widely employed in the evaluation of foundational models within the NLLB family.

This dataset was developed under the auspices of the Open Language Data Initiative (OLDI). Two annotators were responsible for the translation of a devtest split, with subsequent cross-verification to ensure accuracy. The Karakalpak translations adhere to the most recent iteration of the Latin script orthography (see Table 1).

The Karakalpak orthography has experienced multiple changes recently. Both Latin and Cyrillic scripts are utilized, with the Latin script, introduced in 1995, undergoing several revisions. Notable modifications occurred in 2009 and 2016, with the latter replacing digraphs with diacritic letters to overcome previous limitations. Conversion scripts for Cyrillic and older Latin versions to the current system are available on GitHub[4].

3.2 Training data

The training dataset comprises diverse parallel corpora sourced from multiple domains, including news articles, literary works, lexicographic resources, and educational materials. Specifically, the corpus encompasses on average across three languages:

[3] https://github.com/apertium/apertium-uzb-kaa

[4] https://github.com/tahrirchi/kaa-scripts

- 23% sentences from news sources
- 34% sentences from books (novels, non-fiction)
- 24% sentences from bilingual dictionaries
- 19% sentences from school textbooks
- 4,000 English-Karakalpak pairs from Gatitos Project (Jones et al., 2023)

In total, the dataset consists of 100,000 sentence pairs for Uzbek-Karakalpak, Russian-Karakalpak, and English-Karakalpak each, making 300,000 pairs in total. Since there were too few bitexts with English, we decided to create English-Karakalpak dataset by translating Russian sentences from the Russian-Karakalpak dataset to English using Claude 3.5 Sonnet (See Appendix A). To promote further research and development in this field, we have made these corpora publicly available.

3.3 Data Mining Process

For mining parallel sentences, we apply only local mining, when we are sure that parallel sentences are to be mined from the translations of the same book, document or article. For alignment, we use LaBSE embeddings, although Karakalpak is not a supported language in LaBSE. We found that due to similarities of Karakalpak to already included Uzbek and Kazakh languages, LaBSE performed well for aligning sentences so we skipped this step.

The sentence alignment method we use is identical to the one applied for Erzya, as described by (Dale, 2022). We utilize LaBSE (Language-agnostic BERT Sentence Embedding) (Feng et al., 2020) to generate embeddings for each sentence pair. To calculate the alignment score, we first determine the cosine similarity between these embeddings. We then adjust this similarity by multiplying it with a length ratio - specifically, the length of the shorter sentence divided by the length of the longer sentence.

Using dynamic programming, we identify the sequence of sentence pairs that maximizes the total similarity score. Finally, we apply a threshold to filter out low-scoring alignments.

4 Translation Experiments

4.1 Model Training

For our experiments, we utilized the nllb-200-distilled-600M model, which is a transformer-based neural machine translation model with an encoder-decoder architecture. This model comprises 12 layers and employs the following approach: the source and target languages are indicated by the first tokens of the encoder and decoder inputs, respectively. This architecture allows the model to process and translate between numerous language pairs. The training process for our experiments consisted of several key steps:

4.1.1 Tokenizer Preparation

Initially, we trained a SentencePiece (Kudo and Richardson, 2018) tokenizer on an expanded mono-corpus of approximately 300,000 Karakalpak sentences with a total of 16,000 vocabulary length. We decided to train a separate tokenizer because we hypothesized that the intial vocabulary of the NLLB model was not suited for Karakalpak, as there were some non-ASCII characters in the writing system (see Table 2). We also provide an evaluation of a model without training a separate tokenizer and compare the model's performance with and without additional trained tokens.

Á á	Ǵ ǵ	Í ı	Ń ń	Ó ó	Ú ú

Table 2: Non-ASCII letters from Karakalpak Latin alphabet.

4.1.2 Vocabulary Expansion

Following tokenizer training, we augmented the model's vocabulary. This expansion resulted in a total of 269,399 tokens, representing an increase of 13,195 tokens from the original model configuration. We then resized the model's token embeddings and initialized the new embeddings by averaging the embeddings of their constituent subtokens from the original vocabulary.

4.1.3 Model Variants

We developed three distinct model variants to evaluate the impact of additional tokens and training data composition:

1. **dilmash-raw**[5]: This model was trained exclusively on a our own parallel corpus comprising 300,000 sentence pairs in Uzbek, Russian, and English on the original nllb-200-600M.

2. **dilmash**: Same as **dilmash-raw**, but it is a fine-tuned model with additional tokens which

Table 3: Evaluation of several models on sacreBLEU/chrF++ across various language pairs with Karakalpak on FLORES+ devtest set.

were trained on a bigger Karakalpak monocorpus.

3. **dilmash-TIL**: This variant was trained on the same dataset and tokenizer configuration as the **dilmash**, but supplemented with a strategically sampled subset from the TIL corpus. The sampling strategy was as follows:
   - 20% of parallel datasets containing Uzbek or Kazakh
   - 5% of all other datasets in the TIL corpus

To maintain balance with the Karakalpak dataset, we imposed an upper limit of 300,000 sentence pairs on the TIL corpus sample for the **dilmash-TIL**. This constraint ensured that the Karakalpak data was not overwhelmed by the additional multilingual data, while still allowing for potential improvements in cross-lingual transfer and overall model performance.

With a batch size of 1024 and using the AdaFactor (Shazeer and Stern, 2018) optimizer, we trained each model variant for 3 epochs. We employed a learning rate of 1e-4 with a linear warmup over the first 10% steps, followed by a constant learning rate schedule. Weight decay was set to 0.01 to help prevent overfitting.

To maximize computational efficiency and enable training on larger batch sizes, we utilized DeepSpeed ZeRO Stage 3 (Rasley et al., 2020) for model parallelism across 16 GPUs. This configuration allowed us to effectively distribute the model parameters and optimize memory usage, facilitating faster training times.

4.2 Evaluation Metrics

To evaluate the performance of our translation models, we employ two widely used metrics in machine translation:

- sacreBLEU (Post, 2018)
- chrF++ (Popović, 2017)

sacreBLEU, a standardized BLEU implementation, calculates the similarity between the machine-generated translation and one or more reference translations based on n-gram precision. It addresses inconsistencies in tokenization and BLEU computation across different implementations. chrF++, an extension of the character n-gram F-score, computes the F-score of character n-grams and word unigrams, which is particularly useful for morphologically rich languages, like Karakalpak or Uzbek.

5 Results and Discussion

Our evaluation on the FLORES+ Karakalpak devtest reveals several interesting insights into the performance of various translation models. The results, presented in Table 3, demonstrate the effectiveness of our proposed models, dilmash, dilmash-raw, and dilmash-TIL, in comparison to existing approaches.

Notably, the dilmash-raw model, which was trained on the original nllb-200-600M without additional tokens, outperforms the dilmash model with expanded vocabulary in most language pairs. This result suggests that the initialization of new token embeddings may have introduced some challenges. Our hypothesis is that the new token embeddings weren't initialized optimally, and before the model could learn good values for them, they may have affected other model parameters. The limited amount of Karakalpak data alone might not have been sufficient for the model to fully compensate for this initial distortion.

The dilmash-TIL model, which incorporates additional multilingual data from the TIL corpus, consistently outperforms both dilmash and dilmash-raw across all language pairs. This improvement is particularly notable in the ***-kaa** directions, with gains of up to 2.71 BLEU points (en-kaa) compared to dilmash. These results underscore two important points: first, the potential of using related Turkic language data to enhance translation quality for low-resource languages like Karakalpak; and second, that the additional training data and epochs may have allowed the model to better utilize the expanded vocabulary, overcoming the initial challenges faced by the dilmash model. To provide a more qualitative assessment of our models' performance, we have included translation examples in Appendix B.

While expanding the vocabulary can potentially improve model performance, careful consideration must be given to the initialization of new embeddings and the amount of training data available. The success of the dilmash-TIL model suggests that incorporating data from related languages and allowing for longer training periods can help overcome these challenges, ultimately leading to improved translation quality.

Interestingly, the Claude-3.5-sonnet model demonstrates superior performance in the **kaa-*** directions, surpassing our models by a significant margin. This suggests that large language models may have a particular advantage in understanding content in low-resource languages, possibly due to their extensive pretraining on diverse multilingual data.

The performance of other baseline models provides additional context. Google Translate when treating Karakalpak as Kazakh or Uzbek, achieves respectable results but falls short of our models and Claude-3.5-sonnet. The NLLB-200-600M model, despite not being originally trained on Karakalpak, shows some ability to transfer knowledge when treating Karakalpak as Uzbek rather than Kazakh. This aligns with linguistic expectations, given the closer relationship between Karakalpak and Uzbek (both in linguistic similarity and writing scripts).

6 Conclusion

Our key contributions in this work include:

1. Creation of a FLORES+ devtest dataset for Karakalpak.

2. Development of parallel corpora for Uzbek-Karakalpak, Russian-Karakalpak, and English-Karakalpak, each containing 100,000 sentence pairs.

3. Open-sourcing of fine-tuned neural models for translation across Uzbek, Russian, English, and Karakalpak languages.

4. Open-sourcing of scripts for Latin-Cyrillic transliteration for Karakalpak.

Looking ahead, we plan to explore data augmentation techniques to further enhance our models' performance. One promising approach is to leverage the capabilities of Claude-3.5-sonnet for back-translation, potentially expanding our training data with high-quality synthetic examples.

Additionally, we aim to expand our dataset by mining more data from a wider range of books and sources. This will not only increase the volume of our training data but also improve its diversity, potentially leading to more robust and versatile translation models.

7 Limitations

While our study presents some advancements in Karakalpak machine translation, several limitations should be noted. First, the relatively small size of our dataset, despite being substantial for a low-resource language, may limit the model's ability to generalize across diverse domains and linguistic contexts. Second, the reliance on machine translation for creating the English-Karakalpak dataset introduces potential biases and errors that could affect model performance. Additionally, our evaluation is primarily based on automatic metrics, which may not fully capture the nuances of translation quality, particularly for a morphologically rich language like Karakalpak. Future work should address these limitations through expanded data collection, human evaluation, and more diverse testing scenarios.

8 Acknowledgements

We thank David Dalé for his valuable insights and guidance throughout the project. Our heartfelt appreciation goes to Najimova Perizad and Nurlan Pirjanov for their expertise and assistance with the Karakalpak language. We are also grateful to Atabek Murtazaev and Nurniyazov Ajiniyaz for their support and contributions to this work. Their collective efforts and knowledge have been instrumental in improving the quality of this work.

Abstract

This paper introduces a translation of the FLORES+ dataset into the endangered Erzya language, with the goal of evaluating machine translation between this language and any of the other 200 languages already included into FLORES+. This translation was carried out as a part of the Open Language Data shared task at WMT24. We also present a benchmark of existing translation models bases on this dataset and a new translation model that achieves the state-of-the-art quality of translation into Erzya from Russian and English.

1 Introduction

The Erzya language is the language of Erzya, one of the indigenous peoples of Russia. Despite its official status in the Republic of Mordovia (along with Russian and Moksha), the use of the Erzya language is limited mainly to everyday topics, and its representation in the digital space remains low. On the one hand, this situation contributes to the reduced status of language in society and inhibits its development and intergenerational transfer, and is one of the factors that make the language endangered (UNESCO, 2010). On the other hand, this makes it more difficult to develop natural language processing (NLP) technologies for Erzya, such as machine translation (MT), the availability of which could help increase the prestige of the language. Development of MT technologies for Erzya, in turn, is hampered by the lack of a generally recognized dataset for evaluating the translation quality.

In this article, we aim to close this gap by publishing the Erzya version of the FLORES+ dataset. This dataset, created as part of the No Language Left Behind project (NLLB Team et al., 2022) and later transferred to the community-run Open Language Data Initiative[1], became the de facto standard for evaluating MT quality for low-resource languages. FLORES+ consists of two thousand sentences sampled from English texts of Wikimedia projects and translated into more than 200 languages. The emergence of the Erzya version of FLORES+ will allow researchers to evaluate the quality of MT between any of these languages and Erzya. This translation has been submitted to the Open Language Data shared task at the WMT24 conference[2].

The quality of the new FLORES+ translation has been validated by independent annotators (for a sample from the dataset) and with a set of automatic metrics of accuracy and fluency which were themselves validated against human judgements.

In addition, we present a new neural model for translating between Erzya and other languages (primarily English and Russian), created by fine-tuning an NLLB-200 model. It achieves a BLEU score of 22% for translation from Erzya to Russian and 17% in the opposite direction, which implies the translation quality suitable for practical applications. Along with our new model, we evaluated the translation quality of several other models that also support the Erzya language. The model from Yankovskaya et al. (2023), also based on NLLB, achieved the highest scores for translation from Erzya into Russian, and a Claude model (Anthropic, 2024), into English, whereas our model achieved the highest scores for translation into Erzya.

In total, the contributions[3] of this article are:

1. We release and describe the first complete translation of the FLORES+ dataset into the Erzya language and validate its quality.
2. We evaluate the performance of available MT systems for Erzya on this dataset.
3. We present a model for translation between Erzya and several high-resourced languages, a state-of-the-art for translating into Erzya.

2 Related work

2.1 The FLORES+ dataset

FLORES+ is the next stage in the evolution of the FLORES-200 dataset (NLLB Team et al., 2022), which, in turn, grew out of FLORES-101 (Goyal et al., 2022). The dataset is based on 3001 English sentences taken from three sources: Wikinews (international news), Wikijunior (non-fiction literature for children), and Wikivoyage (travel tips). It is divided into three roughly equal parts (dev, devtest, and test), of which the first two (2005 sentences) are included in FLORES+. The sentences were translated from English into 203 other languages by professional translators; among these languages are Russian and three Finno-Ugric ones (related to Erzya): Finnish, Estonian, and Hungarian.

A small subset of FLORES-200 (the first 250 sentences from the devtest subset, news domain) were translated by Yankovskaya et al. (2023) into 9 low-resource Finno-Ugric languages, including Erzya, and used to evaluate the quality of the machine translation system from this article.

As far as we know, no other multiway parallel datasets including the Erzya language have been published (one exception is the dataset of the Tatoeba project[4], however, it currently contains less than 100 Erzya sentences).

2.2 Erzya datasets

The available corpora of the Erzya language (especially parallel ones) are not numerous. Rueter and Tyers (2018) presented the Erzya corpus with morphosyntactic markup, including the translation of several hundred sentences into English and Finnish. Arkhangelskiy (2019) has compiled a web corpus of the Erzya language (available for download); there is also a corpus of the literary Erzya language, avaliable only for search[5]. Another corpus of the Erzya language, also searchable, is described by Rueter (2024a).

Medium-scale parallel datasets of Erzya with other languages have been considered only in recent papers on neural machine translation for Erzya: Dale (2022) and Yankovskaya et al. (2023).

2.3 Machine translation for Erzya

The Apertium platform implements a machine translation system between Erzya and related Moksha and Finnish languages[6], but this work gives an impression of being incomplete. In Dale (2022), one of the first machine translation systems for the Erzya language was created, based on a parallel Russian-Erzya corpus consisting of dictionaries and automatically aligned sentences from books and web publications (a total of 77K parallel pairs of sentences, words and phrases, as well as 333K sentences in Erzya without translation). Yankovskaya et al. (2023) collected parallel and monolingual datasets for 20 low-resource Finno-Ugric languages and trained a neural model for their translation, but the parallel part of their dataset remained unpublished. In both works, the new languages were added to the pre-trained multilingual translation models (mBART-50 (Tang et al., 2020) and NLLB-200 (NLLB Team et al., 2022), respectively) by adding new tokens to the model vocabulary and fine-tuning it with parallel and back-translated data.

The third known paper on neural machine translation for Erzya, Alnajjar et al. (2023), used the rule-based Apertium system to generate a synthetic Erzya-Moksha corpus, and also fine-tuned an NLLB-200 model on this data.

Finally, Mordovian State University announced the development of an Erzya-Russian MT system[7], but no publication on this topic has appeared yet.

2.4 Multilingual MT systems

In addition to MT systems explicitly trained with Erzya parallel data, some models might have learned this language from monolingual texts or parallel texts unintentionally found in web corpora. One could also hope that multilingual models can achieve some understanding of the Erzya language based on the grammar and vocabulary of other Finno-Ugric languages, as well as on the vocabulary borrowed by Erzya from Russian. Therefore, we are considering several public and proprietary systems that do not always explicitly include Erzya, but may still be suitable for its translation.

One of such systems is the NLLB-200 family of models, which is still the leader among open models in terms of the translation quality and language coverage trade-off. Their training data did not include the Erzya language (except perhaps a small number of web texts mistakenly classified as Russian), so the NLLB ability to translate Erzya is limited by the knowledge transferred from other languages. The

MADLAD-400 models (Kudugunta et al., 2024) were also not trained with Erzya parallel data, but used the monolingual web corpora collected in this paper (including Erzya) for unsupervised training and back-translation.

Finally, we consider three proprietary systems: Google Translate, which has recently added 110 new languages (Caswell, 2024) powered by the PALM-2 (Google, 2023) large language model (LLM), and the Claude (Anthropic, 2024) and GPT-4o (OpenAI, 2023) LLMs. All the three systems were trained with multilingual web data and with a large amount of parallel data (including, possibly, parallel texts for the Erzya language). Unfortunately, the technical reports for these systems give only very brief descriptions of their language coverage.

3 About the Erzya language

The Erzya language (myv) is one of the largest Finno-Ugric languages in the world and belongs to the Mordvinic branch of the Finno-Ugric group of the Uralic language family. Linguists distinguish five main dialects: Central, Western (Insar), northwestern (Alatyr), southeastern (Sura) and Shoksha (isolated in the northwestern regions). They differ mostly in their phonetic, and, to a lesser extent, morphological features. Our translation was based on the literary standard of the Erzya language (built primarily upon the Central dialect). Most modern Erzya is written using the Russian Cyrillic alphabet, although there are several Latin script proposals.[8]

Phonetically, the Erzya language contrasts palatalized and plain consonants and features vowel harmony. Grammatically, it is an agglutinative language with extensive systems of declension (including 12 noun cases, possesive suffixes and definitiveness marking) and conjugation (including 7 moods and marking the person and number of subject and object). The word order is SVO, and postpositions are widely used. Lexically, most words have Finno-Ugric origins,[9] with a significant number of Russian and Turkic loanwords.

In the XX century, the number of Erzya was approaching one million people (according to the 1970 census, 1,263 thousand people, along with Moksha). The dispersed settlement of the people led to accelerated assimilation and the decrease in the number of native speakers. Thus, the Republic of Mordovia, where Erzya and Moksha are the titular nation, and their languages are co-official with Russian, hosts only about 30% of all Erzya, with the rest settled in Samara, Orenburg, Nizhny Novgorod, Penza, Saratov regions and other regions of Russia.

The status of the official language allows Erzya to function in the public space: there are newspapers and magazines, TV shows, theater, and popular music in this language. In addition, being a state language, Erzya is studied for 1-2 hours per week as an elective or mandatory lesson in many schools in the Republic of Mordovia, and in the settlements with a predominantly Erzya population, even as the first language.

Nevertheless, the Erzya language is poorly represented in the digital space. A few areas where it nevertheless functions are mentioned below:

- Several documentaries and feature films, music videos and video blogs; [10]
- The Wikipedia in Erzya with 7877 articles;[11]
- The Erzya interface of vk.com;[12]
- A few websites, thematic groups, and channels on social networks and messengers.

The problem of transferring the Erzya language to the younger generation is pressing: most children only understand, but almost do not speak their native language. We hope that translation of FLORES into Erzya will facilitate the development of machine translation for this language, which, in turn, could spur other technologies, such as speech synthesis, text and image generation models, contributing to the preservation, popularization and development of the language.

4 Translation of FLORES+

We translated FLORES+ from from Russian into the Erzya language. The translation was carried out by two native speaker volunteers who are also teachers of the language and writers (one with a doctoral degree in philology). The 250 translated sentences from Yankovskaya et al. (2023) were also included, but only after a thorough revision. All 2009 translations were revised by one of the native translators and a linguist with a profound expertise in the language. In addition, the translations were

[8] Table 2 features an example of a sentence in Erzya alongside with its Latin transliteration and translation.

[9] There are numerous, but not always easily recognisable cognates with other Uralic languages, such as Finnish and Estonian: for example, “keď / käsi / käsi / hand”, “koto / kuusi / kuus / six”, or “ěräms / elää / elama / to live”.

Voyagers planning sex reassignment surgery abroad must ensure they're carrying valid **documents** for the return trip.
Инедавол (hurricane, from ине=great and давол=storm)	Раськень **инедаволонь** кунщкакуронть коряс те шкас Джерри а канды кодамояк зыян мода лангс. Согласно Национальному **ураганному** центру, на данный момент Джерри не представляет никакой угрозы на суше. The National **Hurricane** Center (NHC) says that at this point Jerry poses no threat to land.
Озавтозетне (inmates, "the imprisoned")	Чокшне ланга 10:00 ды 11:00 шканть ютксо пандонь шканть коряс **озавтозетне** тейсть кирвазтема вальмалост. Между 10:00 и 11:00 вечера по горному времени **заключенные** устроили пожар во дворе. Between 10:00-11:00 pm MDT, a fire was started by the **inmates** in the yard.
Кортницятне (negotiators, "talkers")	**Кортницятне** варчизь витемс тевенть, ансяк озавтозетнень вешемаст зть чарькодеве. **Переговорщики** попытались исправить ситуацию, но требования заключённых не ясны. **Negotiators** tried to rectify the situation, but the prisoners' demands are not clear.
Превмаксый (advisor, "intellect-giver")	1960 иетнестэ Бзежинский ульнесь Джон Ф. Кеннединь вакссо **превмаксыекс**, мейле Линдон Б.Джонсононь администрациясо. В 1960-х гг. Бжезинский занимал должность **советника** при Джоне Ф. Кеннеди, затем в администрации Линдона Б. Джонсона. Throughout 1960s, Brzezinski worked for John F. Kennedy as his **advisor** and then the Lyndon B. Johnson administration.

Table 1: Examples of lexical neologisms created according to the word-formation models of the Erzya language (the top 3) and semantic neologisms created by assigning a new meaning to already known words (the bottom 3).

scored with automatic quality metrics (Section 5), which helped identify several omissions and typos.

The successful translation of texts on topics that are uncommon for Erzya allows us to assess the capabilities of this language positively. However, we should note the difficulties in translating special terminology in various domains (such as science, politics, and sports). In such cases, we used lexical and semantic neologisms to solve the problem of insufficient vocabulary (see the examples in Table 1). For some sentences, to avoid distorting their meaning, we had to preserve the Russian terminology, (e.g. Table 2). In some cases, the neologisms are translations of one part of a complex word, for example, "пельсфинал/peĺsfinal" ("полуфинал" in Russian, "semi final" in English).

It would be difficult to directly evaluate how acceptable are these neologisms to the native speakers. But a human evaluation by two independent native speakers (Section 8) resulted in all sampled translations annotated as at least "acceptable", and the majority, as "good". This suggests that the new words are not perceived as serious problems to meaning preservation or fluency.

5 Automatic validation of data quality

To validate the quality of the newly translated Erzya FLORES dataset experimentally, we applied several automatic metrics of translation accuracy and fluency. To demonstrate the validity of the metrics themselves and to establish their baseline values, we needed human judgements of translation quality on some other dataset, and, fortunately, we had one.

Data. The baseline data consists of 1500 Erzya-Russian sentence pairs in the dev subset from Dale (2022), automatically aligned from various parallel documents. The sentence pairs were manually annotated by a proficient Erzya speaker for accuracy and fluency, with 0 standing for "unacceptable", 0.5 for "barely acceptable", and 1, for "good". The problems with meaning were mostly results of overly loose translations or incorrect alignment, whereas most of the fluency problems were caused by too literal translation from Russian (often by simply adding Erzya suffixes to the Russian words).

Our **simple metrics** are $\mathrm{rel\_sim}$ (computed as the edit distance between the source and the target, divided by the maximum of the length of the two and then subtracted from 1) and $\mathrm{len\_ratio}$ (the ratio

Examples in Erzya (Cyrillic), Erzya (transliterated to Latin), Russian and English
Докладсонть ули малав эрьва аспектэнь пшти критика малав неень исполнительной властень Ираконь коряс политиканть коряс ды виев тердема сеске полавтомс улиця курсонть.
Dokladsonť uli malav ěŕva aspektěń pšti kritika malav neeń ispolniteĺnoj vlasteń Irakoń koräs politikanť koräs dy viev terdema seske polavtoms ulicä kursonť.
В докладе содержится резкая критика почти каждого аспекта нынешней политики исполнительной власти в отношении Ирака и настоятельный призыв к незамедлительной смене курса.
The Report is highly critical of almost every aspect of the present policy of the Executive towards Iraq and it urges an immediate change of direction.

Table 2: An example of a translation with multiple loanwords from Russian (the loanwords are highlighted). Note that 4 out of these 6 words (aspektěń, kritika, politikanť, and kursonť), while being borrowed into Erzya from Russian, have ultimately Greek or Latin origins and are recognisable internationally.

of the character lengths of the source and target, the shortest of the two to the longest). We also include here the LID_rus metric: a probability, according to the GlotLID model (Kargaran et al., 2023), that the Erzya sentence is in fact Russian. We expect len_ratio to correlate with omissions; rel_sim and LID_rus are expected to correlate with fluency issues. The rest of the metrics, described below, target translation accuracy.

Dictionary-based metrics are computed by lemmatizing the words in a sentence pair and computing the proportion of words on the one side that has a counterpart on the other side that can be matched using a dictionary. WR_rus computes the proportion of Russian words whose translations can be found in the Erzya sentence, and WR_myv shows the opposite (they don't necessarily match because the Russian and Erzya sentences may have a different number of words).

Model-based metrics include two cosine similarities of sentence embeddings: LaBSE uses a LaBSE model (Feng et al., 2022) distilled for Erzya[13], and enc_sim uses the mean token embeddings from the encoder of the NLLB-based MT model described in Section 6. The latter model is also used for computing Ppl: the mean cross-entropy loss (perplexity) of the model for translating the Erzya sentence to Russian and in reverse. The Att metric is based on the encoder-decoder attention maps for this model: we average the cross-attentions to each encoder token over the layers and the heads, add up across the decoder tokens, and average across all the encoder tokens, except the first one (language code) and the last one (end of sentence), as they are expected to serve as "attention sinks". This metric is also averaged across two translation directions.

Correlations. To evaluate the quality of the metrics, we report their Spearman correlation with the quality annotation labels in the two last rows of Table 3. As we expected, rel_sim and LID_rus are predictive of fluency problems, and all dictionary- and model-based metrics correlate with accuracy.

Data comparison. The top two rows of Table 3 report the average values of our automatic metrics on our dev and devtest splits of FLORES. The next four rows report their values on the baseline data, depending on the presence or absence of fluency and meaning preservation problems. According to most metrics, the FLORES translations are similar or even better than the "good" (problem-free) subset of the baseline data. The only exception is WR_rus which for FLORES is slightly below the baseline; this might be explained by the difficulty of the FLORES domains, where many words are not yet covered by the Erzya dictionaries.

6 A new MT model for Erzya

Our preliminary exploration suggested that few existing models are capable of producing reliable Erzya sentences, so we tried training our own translation model, focused on translation into Erzya.

6.1 Datasets

"Natural" data. To train our model, we used the same monolingual Erzya and parallel Erzya-Russian datasets as Dale (2022). In addition, we collected and aligned some parallel news articles[14], and included several new translated books[15] and pairs of words and phrases from the Russian-Erzya dictionaries at Emerald (Rueter, 2024a,b) and Panlex (Kamholz et al., 2014). The books and articles have been aligned at the sentence level using the

Table 3: The average values of the automatic metrics on our FLORES translation (top 2 rows); their average values on the baseline data grouped by quality (next 4 rows), and their Spearman correlations with human quality labels on the baseline data (the last 2 rows).

algorithm from Dale (2022). We filtered out the pairs for which the Levenshtein distance was less than 20% of the text length, since their inclusion could lead to the model learning to copy the source words too often instead of translating them. We also dropped the pairs with more than 55% difference in length, as they were likely incorrect as translations. The volume of the cleaned Erzya-Russian dataset was 174460 pairs of sentences, phrases or words.[16]

Back-translation. To take advantage of the monolignual Erzya texts, we translated 200K Erzya sentences with the previous version of our model (trained only on "natural" data): 50% into Russian and 50% into 13 other languages previously represented in NLLB-200[17]. After filtering by string edit distances and length ratios, 176462 texts remained. To enhance the model's ability to translate from Erzya into languages other than Russian, we also translated 30K Russian sentences from the Erzya-Russian parallel dataset into the same 13 other languages using an NLLB-200-600M model.

During the training, the pairs of texts from one natural and two synthetic sources were randomly selected in the following proportion: 70% from the natural data (in both directions), 25% from the data translated from Erzya (only in the opposite direction, into Erzya), and 5% from the data translated from Russian to other languages (in both directions). We normalized 100% of the texts on the target side and 80% of the texts on the source side[18] using the algorithm from NLLB Team et al. (2022)[19].

6.2 Model training

When training the model, we followed an approach similar to Tars et al. (2022) and Dale (2022). As a basic model, we took NLLB-200 with 600 million parameters, enriched its dictionary with new tokens for the Erzya language, further trained embeddings for these tokens, and then further trained the entire model on parallel Russian-Erzya data, as well as on data obtained by reverse translation.

Vocabulary update. To better represent Erzya words in the model, we trained a new Sentencepiece tokenizer (Kudo and Richardson, 2018) on the Erzya side of the training dataset. Most of its tokens (6208 out of 8192) were missing from the NLLB vocabulary, so we added them there. The corresponding embeddings of each new token were initialized by the mean of the embeddings of the "old" tokens into which the new token could be decomposed. We also added a new language code to the tokenizer: myv_Cyrl.

Fine-tuning. Since the embeddings of the new tokens were initialized with a naive method, fine-tuning of the whole model with these parameters could introduce undesirable disturbances into other parameters. To avoid this, for the first 45K training steps, we updated only the embedding matrix, "freezing" the rest of the model parameters, and used an additional loss function (with a weight of 100): the mean squared error between the original and current embeddings of the "old" tokens. We used a single GPU, a batch of size 6, 4 gradient accumulation steps, and an Adafactor optimizer (Shazeer and Stern, 2018) with the learning rate that linearly warmed up from zero to 10^{-4} during the first 3000 steps and then stayed constant. After updating the token embeddings this way, we

[16] The collected parallel dataset (at least, its part that is free of copyright restrictions) will be made publicly available in our repository.

[17] Arabic, English, Estonian, Finnish, French, German, Kazakh, Mandarin, Mongolian, Spanish, Turkish, Ukrainian, and Uzbek. This choice was motivated by the international importance of the languages, by their connections to the post-Soviet region where most Erzya live, and by an attempt to represent diverse language families.

[18] We kept 20% of the source texts unnormalized to better prepare the model for potential downstream use cases when the input is not normalized.

[19] The normalization code was adopted from the SentenceSplitClean class in the Stopes repository.

continued training the whole model (with all the parameters unfrozen), for 220K more steps.

7 Comparing MT systems for Erzya

We used our FLORES+ translation (the dev subset) to evaluate the current quality of MT between Erzya on the one side and Russian and English on the other. We evaluated the translation quality with BLEU (Papineni et al., 2002).

7.1 The systems

Here we describe each of the systems that we tried including in our benchmark. For all models except the LLMs, we use beam search with the beam size of 5, and keep all other inference parameters at their default values, unless otherwise specified.

Ours. We used the model described in Section 6. For this model (and for NLLB), we normalized the input texts with the NLLB normalization algorithm.

SLONE (Dale, 2022). We use the myv-mul and mul-myv models from Dale (2022) to translate from and to Erzya, respectively. We use beam size of 5 and repetition penalty of 5, like in the original work (but we do not use reranking with the LID model).

SMUGRI (Yankovskaya et al., 2023). We used their latest model, also based on the NLLB-200 (with 1.3B parameters)[20], for translation in all 4 directions. We used the fairseq-interactive interface with beam size of 5, penalty of 100 for the unk token, and a maximum of 4 consecutive tokens repeating, and ran the model in the fp16 precision.

NLLB. We tried to use the NLLB-200-600M model to translate from Erzya into English and Russian. Since NLLB requires specifying the source language, and Erzya is not included in it, we indicated Estonian as the source language: it is genetically related to Erzya, and also, like Erzya, has experienced some lexical influence of Russian.

We used the MADLAD-400-3B-MT model (Kudugunta et al., 2024) in two configurations: as is (**MADLAD**), and fine-tuned with our Erzya-Russian dataset (without other languages) for 60K steps using a new Erzya token (**MADLAD-ft**). For both of them we used the HuggingFace package with beam size of 3.

System	ru-myv	en-myv	myv-ru	myv-en
NLLB	-	-	3.23	1.05
SLONE	8.11	4.99	15.12	11.70
SMUGRI	11.46	6.58	28.44	**21.12**
MADLAD	1.10	1.06	18.48	13.87
MADLAD-ft	15.50	-	25.50	-
Claude	14.13	7.09	**34.68**	20.18
GPT-4o	3.49	1.24	11.07	8.73
Ours	**17.09**	**7.35**	22.06	16.42

Table 4: BLEU scores for the evaluated MT systems on the dev subset of FLORES+.

Google Translate. We have tried several configurations of the Google Translate API: the general/nmt and general/translation-llm models in the Advanced v3 interface. Both models proved unable to translate from Erzya into Russian or English either when specifying related languages (Estonian, Finnish, Udmurt, Mari) as the source language, or when automatically detecting the language (most often it was defined as Udmurt, Mari, or Komi). In most cases, the models simply transliterated the Erzya text into the Latin alphabet, without trying to translate most of the words. Based on these results, we excluded Google Translate from the benchmark.

Claude (Anthropic, 2024) and **GPT-4**. We used the API of the Claude 3.5 Sonnet and GPT-4o models, respectively, to obtain the translations. For some texts, we obtained the necessary translations only after several iterations of inference without changing the prompt, because in the case of GPT, the prompt did not pass the jailbreak protection, and in the case of Claude, the prompt could produce empty translations, which were corrected upon retranslation. An example of our prompt is given in Appendix A.

7.2 Evaluation results

The results of MT evaluation with BLEU are in Table 4. As we had hoped, our model achieved the best quality of translation into Erzya from Russian and English. The Claude model won the first prize for translating from Erzya to Russian, and the model from Yankovskaya et al. (2023), from Erzya to English. In addition, the MADLAD model demonstrated promising results, with rather good understanding of Erzya even before fine-tuning.

8 Human validation of human and machine translation

While the BLEU scores reported above may help ranking translation systems, they cannot tell how good the translation is from the human point of

[20] The paper mentions M2M-100 as a base model. But the model that we used, https://huggingface.co/tartuNLP/smugri3_14-finno-ugric-nmt, is, apparently, a newer version, and it has the language code formats and the size of NLLB-200-1.3B. According to the model card, it is currently powering https://translate.ut.ee.

view. To shed some light on this, we engaged two new native Erzya speakers (not involved into the FLORES translation) to evaluate the translations of 30 randomly chosen FLORES sentences from Russian into Erzya. We showed them the human translations and machine translations by SLONE, Claude, and our new system, without displaying the system names and in a random order, to reduce the potential bias. The annotators were asked to rate each translation on a 1-5 point scale from Dale (2022), with the label 3 for "acceptable", 4 for "good", and 5 for "great" translations. Their full guidelines are given in Appendix B.

System	Annotator 1	Annotator 2	κ	ρ
Human	4.37(0.14)	4.33(0.12)	-0.03	-0.02
Claude	4.17(0.14)	4.1(0.13)	0.24	0.41
Our MT	3.9(0.19)	3.87(0.17)	0.29	0.54
SMUGRI	3.47(0.21)	3.57(0.21)	0.27	0.53

Table 5: Mean assigned scores (with standard errors in brackets), Cohen's kappa κ and Spearman correlation ρ of the two annotators' labels.

Table 5 reports the mean scores assigned by the annotators to each system, and their agreement scores. The inter-annotator agreement is fair for the MT systems, but there is none for human translations, indicating that more fine-grained annotation schemes might be needed in the future. Nevertheless, both annotators assign the highest (and similar) average scores to the human translations, reaffirming their quality.

Our MT system takes the third place in the human ranking, after the human translations and Claude. The reason for this low position is 3 "stupid" translation errors (out of the 30): two undertranslations and one cyclical hallucination. We hope that in the future, simple modifications of the decoding algorithm would help avoid such errors.

9 Conclusion

Although the *endangered* and *low-resourced* statuses for a language are by no means equivalent (Hämäläinen, 2021), they reinforce each other in a vicious circle. Lack of resources for a language lowers its prestige, which reduces the number of active speakers, which, in turn, disincentivises creation and maintenance of the language resources. As an example, the endangered Erzya language, with its few hundred thousand speakers and a modest Wikipedia community, did not make it to the FLORES-200 dataset and the NLLB-200 models — but if it did, it could have a positive impact at least on the Erzya Wikipedia.

Such projects as the Open Language Data Initiative shared task give one more chance to such languages. By releasing a FLORES+ translation into Erzya and using it to benchmark the few existing MT models that support it, we hope to help rolling the vicious circle in the opposite, virtuous direction. An Erzya version of FLORES might open a way to include this language into other NLP evaluation datasets, such as FLORES-based FLEURS (Conneau et al., 2023) for speech translation and Belebele (Bandarkar et al., 2024) for machine reading comprehension. And the presence of the language in such datasets, we hope, might motivate the researchers to include it in foundation models, which, in turn, might influence the development of practical applications, supporting the speakers of the language and increasing its status and chances of survival.

More directly, we are hoping that the emergency of the Erzya version of FLORES will facilitate improvements in machine translation research and applications for this language.

Some possible areas of future research based on the Erzya translation of FLORES+ include:

- Translating new MT training datasets, such as the Seed (Maillard et al., 2023)), into Erzya.
- Creating an automatic reference-free metric of translation quality for Erzya that would highly correlate with human judgments.
- Setting up a system of active learning that would help collect human translations for the sentences at which MT most likely fails.
- Creating an MT system suitable for translating content (such as books) into the Erzya language, minimizing the necessary revision and post-correction by human translators.

10 Acknowledgements

We express immense gratitude to our translators who accomplished the hardest work of this project and chose to stay anonymous. We are grateful to Jack Rueter for proofreading the translations, to Árpád Váldazs for providing the quality annotations used in Section 5, and to the volunteer annotators for helping us with the human evaluation in the last moment.

A Example prompts

We used the following prompt format for translating with Claude: *"You are an AI assistant responsible for translating phrases between Russian and Erzya-Mordvin. Your task is to translate a given sentence from Erzya-Mordvin into Russian. Ensure that the translation remains specific to Erzya-Mordvin, avoiding confusion with Komi, Moksha, or other Finno-Ugric languages to prevent false cognates. Verify that each word in the original Erzya-Mordvin sentence has a corresponding translated word in Russian, maintaining the accuracy and completeness of the content. The final translated sentence should retain a similar word count without omitting any parts of the original text. Output only the final translated result in Russian.*
{The source sentence}*. Output only the translated result."*. With GPT, we used a similar format, with the first paragraph fed as the system prompt, and the source sentence as the user prompt.

B Annotation guidelines

For human evaluation of human and machine translation in Section 8, we provided the annotators with a short guideline text in Russian. Below is its translation into English.

We ask you to rate the translations from Russian to Erzya on a scale of 1-5 points:

5 points - perfect translation (the meaning and style are fully preserved, the grammar and word choice are correct, the text looks natural);

4 points - good translation (the meaning is fully or almost completely preserved, the style and choice of words are acceptable for the target language);

3 points - acceptable translation (the core meaning is preserved; mistakes in word choice and grammar do not interfere with understanding; most of the text is fluent and in the target language);

2 points - poor translation (the text is mostly understandable and mostly in the target language, but there are serious errors in meaning preservation, grammar or word choice);

1 point - unsuitable translation (most of the text is in the wrong language, or nonsense, or has little in common with the original text).

If at least one word is incorrectly translated, the resulting score should not be 5; the choice between 1 and 4 is at your discretion.

If a word is an overly literary term or a neologism, but its meaning is clear, it does not lower the score. However, if the usage of an unusual word is unclear or it changes the original meaning, lower the score.

Spanish Corpus and Provenance with Computer-Aided Translation for the WMT24 OLDI Shared Task

Jose Cols
Department of Linguistics, University of Washington
jcols@uw.edu

Abstract

This paper presents the SEED-CAT submission to the WMT24 Open Language Data Initiative shared task. We detail our data collection method, which involves a computer-aided translation tool developed explicitly for translating SEED corpora. We release a professionally translated Spanish corpus and a provenance dataset documenting the translation process. The quality of the data was validated on the FLORES+ benchmark with English-Spanish neural machine translation models, achieving an average chrF++ score of 34.9.

1 Introduction

In recent years, the NLP community has made significant strides in reducing the data gap for hundreds of languages (Tiedemann, 2012; Bañón et al., 2020; Federmann et al., 2022; NLLB Team et al., 2022). Nonetheless, finding parallel corpora for machine translation and other NLP applications remains challenging for many language pairs (Haddow et al., 2022; Ranathunga et al., 2023). The WMT24 Open Language Data Initiative shared task aims to continue expanding language coverage with contributions from communities of native speakers.

This work describes our data collection method to expand the SEED dataset (NLLB Team et al., 2022; Maillard et al., 2023) with the Spanish language. Specifically, we focus on Latin American Spanish varieties to match the existing coverage of this language in the FLORES+ benchmark (NLLB Team et al., 2022). While the Spanish language benefits from the availability of multiple parallel corpora datasets (Aulamo et al., 2020), the majority of this corpora features other well-resourced languages such as English and French, and translation directions of regional significance to other languages like Asturian and Quechua remains a challenge (Oliver et al., 2023; Ahmed et al., 2023).

The multilingual alignment of the SEED dataset (Doumbouya et al., 2023) allows for the addition of a single corpus to enable dozens of translation directions into low-resource languages. Including Spanish represents an essential step toward incorporating other low-resource languages where finding English translators is challenging, as was the case for Ligurian, where half the data was translated from Italian (NLLB Team et al., 2022).

Considering the impact that high-quality parallel corpora can have on machine translation performance (Maillard et al., 2023), this work aims to facilitate extending the SEED dataset while supporting quality improvements in Spanish machine translation. Our main contributions are:

1. The expansion of the SEED dataset with professional translations of Latin American Spanish, created by native speakers, along with a neural machine translation baseline.
2. The open-source release of SEED-CAT, a web computer-aided translation tool explicitly designed to assist human translators in the translation of SEED files.
3. The automated generation and public release of a provenance dataset documenting the creation of each Spanish translation.

2 Background

Language overview According to a 2022 report from the Cervantes Institute,[1] there are more than 496 million native Spanish speakers in the world. Speakers are mainly concentrated in the Americas and the Iberian Peninsula, with Mexico having the largest population.

Spanish is an Ibero-Romance language that developed from Latin on the Iberian Peninsula. Thanks to its global expansion, this language has evolved into several dialectal variations. An example of this variation is the absence of the informal

[1] https://cvc.cervantes.es

Proceedings of the Ninth Conference on Machine Translation, pages 624–635
November 15-16, 2024 ©2024 Association for Computational Linguistics

second-person plural ‘vosotros’ in Latin American Spanish, where most varieties use the pronominal form ‘ustedes’ to address speakers in both formal and informal contexts (Hualde et al., 2012).

Although there are social, phonological, and lexical variations, Spanish retains a fundamental cohesiveness (Hualde et al., 2012). The Royal Spanish Academy and the Association of Academies of the Spanish Language collaborate to publish a unified set of orthography, dictionaries, and other language resources. The Spanish writing system is based on the Latin script, with the addition of the character ⟨ñ⟩ forming an alphabet of 27 letters (Hernández Gómez, 2015). This script is represented in our collected data.

Seed dataset The SEED dataset (NLLB Team et al., 2022; Maillard et al., 2023), currently managed by the Open Language Data Initiative (OLDI),[2] contains 6,193 parallel sentences in English along with professional translations into 40 low-resource languages. The English sentences were originally sampled from thousands of Wikipedia articles across various categories such as arts, history, mathematics, people, and technology, offering diverse content from notable topics (NLLB Team et al., 2022). In this work, we use the English corpus (eng_Latn) from the SEED dataset as the source text for the Spanish translations.

FLORES+ benchmark FLORES+ is an evaluation benchmark for machine translation with support for 212 languages based on the initial FLORES-101 dataset (Goyal et al., 2022) and its recent expansions (NLLB Team et al., 2022; Doumbouya et al., 2023). The collection of this data involved a rigorous and iterative quality assurance process with professional translators, pre-defined standards, post-editing, and automatic quality assessments. We rely on this benchmark to assess the quality of the Spanish translations.

Computer-aided translation CAT, or computer-aided translation, refers to software tools, such as word processing, translation memory (TM), and terminology management, used by human translators to assist the translation process (Bowker and Fisher, 2010). Studies have shown that these tools can enhance the productivity and translation quality of human translators (Federico et al., 2012; Koehn, 2009). While machine translation differs from other CAT tools, as it is the primary driver of the translation (Bowker and Fisher, 2010), modern CAT suites often include machine translation as a key feature. According to a user survey study involving 736 translators (Zaretskaya et al., 2017), machine translation ranked as the third most commonly used functionality, following translation memory and terminology management. CAT users from that study and other usability surveys (Alotaibi, 2020; Vargas-Sierra, 2019) also reported dissatisfaction with the ease of use and learnability of these systems, highlighting the importance of user-friendly interfaces for computer-assisted translation.

3 Data Collection

Seed-CAT Various commercial CAT solutions exist, with SDL Trados, Memsource, and Wordfast being recognized as popular options by different research (Alotaibi, 2020; Picton et al., 2017). Apart from requiring purchasing a license, these systems use custom file formats that may not be compatible with other tools, leading to interoperability issues in translation projects. Using general-purpose software can also result in unaligned parallel sentences due to translators re-ordering the files, a problem highlighted by Doumbouya et al. (2023) in their review of the original NLLB-SEED dataset (NLLB Team et al., 2022). Furthermore, commercial CAT systems often integrate machine translation models, such as Google Translate and DeepL, that restrict the use of their outputs for training other models.

Recognizing these challenges, we release SEED-CAT,[3] an open-source web application specifically designed to assist human translators in translating SEED dataset files. This application was at the center of our data collection efforts and was designed with the three core principles.

- The user interface and features are optimized for usability, device compatibility, and seamless integration with the SEED dataset. The list of languages and corpora is fetched at runtime from the dataset's repository, and metadata is displayed alongside each sentence (Figure 1).

- The system architecture facilitates application deployment, as it does not require configuring databases or user accounts. Data persistency is achieved via IndexedDB,[4] a transactional

[2] https://oldi.org/

[3] https://github.com/josecols/seed-cat

[4] https://www.w3.org/TR/IndexedDB/

database for object storage in web browsers.

- The application data model adheres to the W3C PROV-DM (Missier and Moreau, 2013) recommendation for data provenance, adding an additional layer of transparency to the translation creation process.

SEED-CAT integrates a focused set of features, such as machine translation and terminology consultation. Machine translation is supported for local[5] and remote inference, with the latter being recommended for broader device compatibility. The machine translation feature relies on the `facebook/nllb-200-distilled-600M` model (NLLB Team et al., 2022) to generate outputs. Likewise, terminology consultation in English is enabled by WordNet (Miller, 1995).

Users can also compare translations using text differencing (Myers, 2023), with word-based comparison for Latin-based languages and character-based comparison for other scripts. Additionally, part-of-speech color highlighting for English words can be toggled based on user preference. This feature relies on the Brill tagger (Brill, 1992) and a Treebank tokenizer (Marcus et al., 1993), both implemented using the `natural` library.[6]

Sourcing translators We recruited a team of ten freelance translators who were individually sourced through Fiverr, an online marketplace for digital services. We relied on the platform's reputation system and freelancer profiles to identify potential candidates. The final translators were selected based on specific criteria: native Latin American Spanish speakers, a minimum of two years of translation experience on the platform, at least 500 completed projects, and a brief English conversation assessment. The median translator had nine years of experience, 1,900 completed projects, and 779 reviews. In addition, we sourced an independent freelance translator with a degree in Applied Languages who underwent a similar vetting process. Additional background information on all translators is reported in Table 1.

Compensation Each translator determined their compensation separately based on the number of English words in their assigned task. The tasks were divided into two stages: *translation* and *review*, which had different compensation rates. The median compensation per translated word was 0.017 US dollars, with an average of 0.022, and the median compensation per reviewed word was 0.012 US dollars. Translators were also given a user guide to the SEED-CAT application, along with data samples and translation guidelines, to help them assess the complexity of the task when determining their rates.

Category	Detail	%
Education	Master's degree	9.1
	Bachelor's degree	54.5
	Course or certificate	27.3
	No formal training	9.1
Country	Argentina	9.1
	Chile	9.1
	Colombia	9.1
	Mexico	18.2
	Panama	9.1
	Venezuela	45.5

Table 1: Percentage distribution of participants by educational background in translation and country of origin.

Translation workflow The translation process was divided into two stages: first, translating all sentences from English to Spanish, and second, reviewing every sentence to ensure accuracy and quality. Both phases were carried out by the team of translators using the SEED-CAT application.

A team of ten translators completed the initial translation phase in 16 days. The translators worked on a contiguous set of segments for better contextual reference, with an average task size of 593 sentences. Each translator received a unique URL to access SEED-CAT, which automatically configured their browser with the target language file (`spa_Latn`), sentence range, and user identifier. Translators did not need to handle administrative tasks such as creating user accounts or managing assignments. When they opened the application URL, they were prompted to review and acknowledge the translation guidelines, and then they were directed to their first assigned segment for translation.

The review phase was carried out by three translators. Each reviewed segments that were initially translated by others, finishing the task in five days and proofreading an average of 2,064 sentences. The translators received a specific URL to open SEED-CAT in `review` mode. In this mode, the application automatically loads and deserializes the

Figure 1: SEED-CAT's user interface with two resizable panels to display the original sentence and the translation editor. Users can select different languages, track progress, review guidelines, or access other actions, such as importing/exporting provenance graphs using the top navigation bar. Translators can also open the source document and generate machine translations.

provenance information collected up to that point, enabling the consolidation of the translation and review history of a sentence into a single PROV-JSON file (Huynh et al., 2013). A total of 686 translations were copy-edited, with most corrections involving mistranslations, syntactic and lexical refinements, and grammatical issues such as verb agreement. Additionally, the decimal and thousand separators were standardized following established Spanish orthographic norms (Real Academia Española, 2010).

Dataset sample The final dataset contains 6,193 Spanish sentences (152,664 words) professionally translated by eleven native speakers from six countries in Latin America. Table 2 provides a brief excerpt of the parallel sentences.

Provenance dataset According to the World Wide Web Consortium (W3C) (Groth and Moreau, 2013), "provenance is information about entities, activities, and people involved in producing a piece of data or thing, which can be used to form assessments about its quality, reliability or trustworthiness."

During the translation process, the SEED-CAT application automatically recorded provenance information on how activities such as `EditTranslation`, `MachineTranslate`, and `QueryWordNet` were used to generate, invalidate, and revise translations. This information can be serialized into JSON files (Huynh et al., 2013), enabling data sharing with its complete history. Users can also import these files and modify the data entities while maintaining the provenance's integrity.

In the PROV data model (Missier and Moreau, 2013), entities, activities, and agents are linked through relations. These links can be used to create a directed graph to visualize dependencies and data interactions. Appendix E provides examples of these graphs from the Spanish dataset. This dataset containing 6,193 PROV-JSON files is released as part of our SEED contribution.

System usability scale The system usability scale (SUS) (Brooke, 1996) is a standardized 10-item questionnaire for assessing perceived usability. Users rate each statement of the survey on a scale from 1 to 5, enabling the calculation of the SUS score, which ranges from 0 to 100. Substantial research has found that this score is a reliable metric of perceived system usability (Lewis, 2018). We administered the SUS questionnaire to the eleven translators involved in the project to evaluate the SEED-CAT application, obtaining an SUS score of

#	English	Spanish
663	`For Gibbon, "The decline of Rome was the natural and inevitable effect of immoderate greatness.`	`Para Gibbon, "El declive de Roma fue el efecto natural e inevitable de la grandeza excesiva.`
2079	`By 1843 Richard Hoe developed the rotary press, and in 1844 Samuel Morse sent the first public telegraph message.`	`En 1843 Richard Hoe inventó la prensa rotativa, y en 1844 Samuel Morse envió el primer mensaje público por telégrafo.`
5500	`But mental ideas or judgments are true or false, so how then can mental states (ideas or judgments) be natural processes?`	`Pero las ideas o juicios mentales son verdaderos o falsos, entonces, ¿cómo pueden los estados mentales (ideas o juicios) ser procesos naturales?`

Table 2: Sample sentences from the `spa_Latn` dataset with English source text and corresponding translations.

82.95. Appendix C summarizes the participants' responses.

4 Experimental Validation

Following the shared task's recommendation for experimental validation, we trained four bilingual machine translation models on the 6,193 newly collected Spanish sentences and evaluated their performance on the FLORES+ benchmark.

4.1 Data

Italic experiments To validate our model training setup, we reproduced the bilingual results reported by Maillard et al. (2023) for bidirectional translations between English and three Italic languages: Friulan (`fur_Latn`), Venetian (`vec_Latn`), and Ligurian (`lij_Latn`). We focus on these languages due to their linguistic relation to Spanish and their complete data availability on the SEED dataset and the FLORES+ benchmark.

Spanish experiments For our bidirectional English and Spanish (`spa_Latn`) machine translation models, we divided the collected data described in Section 3 into two versions: one before and one after the translation review process. This allowed us to analyze the scoring effect of a more streamlined review process based solely on proofreading and copy-editing in contrast to the iterative quality assurance pipeline implemented in FLORES-200 (NLLB Team et al., 2022). Table 3 summarizes the employed corpora with their corresponding source, size, and split.

Language	Split	Lines	Source

`eng, fur`
`lij, vec`
	train	6193	Seed

	valid	997	FLORES+
	test	1012	FLORES+
`spa`	**train**	**6193**	**This work**
	valid	997	FLORES+
	test	1012	FLORES+

Table 3: Corpora used in model experiments. Our contribution is highlighted in bold font.

4.2 Tokenization

We trained a SentencePiece model (Kudo and Richardson, 2018) on the `train` split for each language pair using a joined vocabulary of 8k tokens and byte-pair encoding (BPE) (Sennrich et al., 2016) for subword segmentation. In total, we trained three tokenizers for the bilingual Italic experiments and two tokenizers for the Spanish experiments, one for each version of the translated dataset.

4.3 Models

The machine translation models in this work are implemented with the `fairseq` toolkit (Ott et al., 2019) using the `transformer` architecture (Vaswani et al., 2017). Modifications are also made to match the bilingual model configurations in Maillard et al. (2023) for comparison purposes. The resulting architecture consists of 8 attention heads, 6 encoder and decoder layers, each with 4096-dimensional feedforward networks. We trained each model with an inverse square root learning rate of 0.001 and 400 warm-up updates. Training is conducted on a cloud virtual machine with an

NVIDIA L4 24GB GPU and an image preloaded with Debian 11, Python 3.10, PyTorch 1.13, and CUDA 11.3. Data preparation, model training, and evaluation recipes are available.[7]

Italic models We train two models per language pair, one for each direction (eng_Latn ↔ xxx_Latn) between English and the three selected Italic languages from the Seed dataset. We use the dev split of the FLORES+ benchmark for validation and the highest BLEU score (Papineni et al., 2002) on this split as the checkpoint selection criterion. Training is stopped when the validation BLEU score fails to improve after 10,000 gradient updates, and the selected checkpoint is used to calculate the chrF++ scores (Popović, 2015) on the FLORES+ devtest split. These scores provide a baseline for guiding our training parameters until achieving performance on par with the results reported by Maillard et al. (2023). This enables comparing the metrics from our Spanish models and assessing the quality of our spa_Latn data contribution.

Spanish models Using only the newly collected Spanish data, we trained four models, two for each version of the spa_Latn dataset. Model training and architecture parameters were defined during the Italic experiments and remained constant for these models. For validation, we used the dev split from the FLORES+ dataset. Training was conducted for 2,000 epochs (averaging a total runtime of 12h 31m), with the best checkpoint selected based on the highest validation BLEU score.

4.4 Results

Italic experiments We evaluated all model hypotheses using the sacrebleu tool (Post, 2018) against the devtest split of the FLORES+ benchmark. Table 4 compares the original performance of bilingual machine translation models reported by Maillard et al. (2023) with our reproduction attempts, which employed a similar model architecture and training routine. Our reproduced models nearly match the average chrF++ score for the English-to-Italic direction, falling short by 0.2 points while showing an improvement of 2.8 chrF++ points for the Italic-to-English direction.

Language	Original		Reproduction	
	eng→	→eng	eng→	→eng
fur_Latn	35.4	35.6	35.7	36.8
lij_Latn	34.1	32.1	33.4	36.0
vec_Latn	33.5	32.3	33.2	35.5
Average	34.3	33.3	34.1	36.1

Table 4: Performance comparison (chrF++) between original (Maillard et al., 2023) and our reproduced bilingual models for three Italic languages (fur_Latn, lij_Latn, vec_Latn).

Spanish experiments We achieved a chrF++ score of 35.0 for English-to-Spanish translation and 34.7 for the reverse direction by training exclusively on the collected spa_Latn data. The average score of 34.9 is comparable to the 35.1 mean obtained by the Italic models trained on existing SEED corpora. This result suggests that the new Spanish training data is representative of the spa_Latn data in the FLORES+ benchmark.

Analyzing the effect of the translation review process, we observed an average improvement of 0.3 chrF++ points. Specifically, the English-to-Spanish model trained on the reviewed data improved from 34.5 to 35.0, while the reverse direction decreased slightly from 34.8 to 34.7. Figure 2 breaks down the performance of the four bilingual Spanish models.

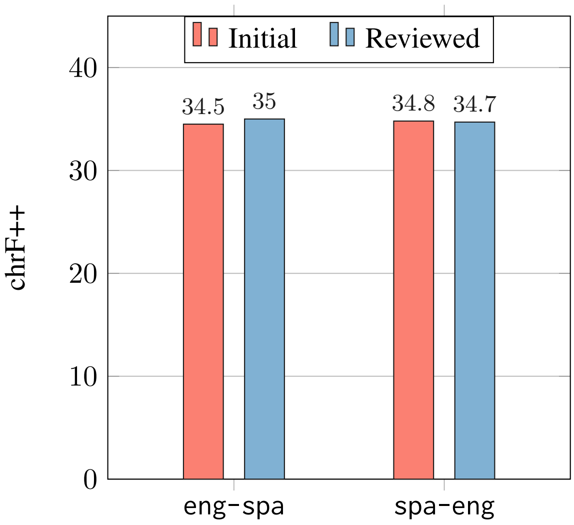

Figure 2: Performance (chrF++) of the eng_Latn↔ spa_Latn bilingual models trained on two versions of Spanish data: before (*Initial*) and after the translation review process (*Reviewed*).

5 Discussions

Seed English corpus Each line in the English corpus is an excerpt from a Wikipedia article,

[7] https://github.com/josecols/seed-cat/tree/main/nmt

which may consist of complete sentences or fragments. Translators identified two primary challenges when working with this data: incomplete sentences and a lack of context due to changes in the original article. For example, segment 5540, “`By way of example, they provide two proofs of the irrationality of .`” is missing an object at the end. Translations of such sentences inevitably reflect the original issues.

Furthermore, Wikipedia articles support versioning,[8] so including the date of compilation in the metadata or augmenting the dataset with provenance information could enable the correct context retrieval at the time of translation.

Seed-CAT The SEED-CAT application facilitated the translation of the English corpus, the review of translations, and the generation of the provenance dataset. Translators rated its usability highly, with an “A” grade based on the Sauro–Lewis curved grading scale (Lewis and Sauro, 2018). Notably, the system’s perceived learnability, identified in Alotaibi (2020) and Zaretskaya et al. (2017) as a key area for improvement in other CAT systems, scored the highest in our study, with an average of 93.2. This result underscores our efforts in user-centered design to make participation by language communities more accessible.

Translation workflow During the review phase, translators proofread and copy-edited the entire `spa_Latn` dataset, modifying 686 sentences and 1,815 words. Although the cost of this phase was lower than the initial translation, they were still comparable. Given the marginal improvement in the post-review model’s metric and the significant impact of high-quality parallel sentences on machine translation performance (Maillard et al., 2023), teams should consider allocating review resources toward generating more translations. In our case, this approach could have generated 3,498 additional translations of similar average length.

6 Conclusions

This work presented the SEED-CAT application and its role in expanding the SEED dataset with a professionally translated Spanish corpus. By integrating a provenance data model and its serialization in SEED-CAT, we automatically obtained a JSON dataset detailing the origin of each translation. Our experimental machine translation validation on the FLORES+ benchmark demonstrates that the collected Spanish data is of high quality, achieving on-par performance with other established language pairs in the SEED dataset. The excellent grade from the system usability scale survey suggests that the SEED-CAT application has the potential to facilitate the inclusion of additional languages in future efforts.

Limitations

To effectively support the expansion of the SEED dataset, localizing the SEED-CAT user interface is essential. Future translation projects may involve translators who work in languages other than English. Identifying these relevant languages and implementing the UI localization requires further work. Similarly, the machine translation feature is constrained by the availability of open models and their supported translation directions.

While the provenance dataset includes timestamps for when activities are performed, this information is not a reliable source for measuring the time taken to translate a sentence or other similar metrics. Users may experience interruptions, and the system does not track user engagement or attention.

Latin American Spanish varieties exhibit dialectal divisions that affect morphosyntactic features such as word order and verb tense (Hualde et al., 2012). Our data collection methodology does not distinguish between these variations. However, the specific variety spoken by each translator who participated in the project is detailed in Appendix D.

Acknowledgements

We thank the anonymous reviewers for their comments and suggestions, as well as the dedicated team of translators for their expertise and dedication in producing translations for this work.

A Performance of bilingual models

Table 5 summarizes the performance on the FLORES+ benchmark of the bilingual machine translation models using both BLEU and chrF++ metrics.

B Machine translation examples

Table 6 presents three sample machine translations generated by the `eng-spa` model trained solely on the 6,193 reviewed translations of the `spa_Latn` data.

C System usability scale

Table 7 details the responses of each translator to the system usability scale (SUS) survey. The columns correspond to each numbered statement as they appear in the standard questionnaire (Brooke, 1996), while the rows represent the translators in no particular order. The table also summarizes the average score per participant, the score per question, and the total SUS score.

Model	BLEU		chrF++
	valid	test	test
eng→fur	10.3	10.4	35.7
eng←fur	10.8	10.0	36.8
eng→lij	7.5	8.0	33.4
eng←lij	9.6	9.3	36.0
eng→vec	7.0	6.3	33.2
eng←vec	9.9	9.4	35.5
Average	9.2	8.9	35.1
spa←eng	8.4	8.1	35.0
spa→eng	7.2	7.2	34.7
Average	7.8	7.7	34.9

Table 5: Performance of the bilingual models evaluated using automatic metrics on the valid and test splits.

D Spanish varieties

Table 8 relates each translator identifier in the provenance dataset with their specific Latin American Spanish variety.

E Provenance graphs

Figures 3 and 4 depict the provenance graphs of two translations. The translation process for each sentence can vary significantly, leading to graphs of different complexity. These graphs were generated using the Python prov package.[9]

[9] https://github.com/trungdong/prov

Efficient Terminology Integration for LLM-based Translation in Specialized Domains

Sejoon Kim, Mingi Sung, Jeonghwan Lee, Hyunkuk Lim, Jorge Froilan Gimenez Perez
PwC Korea GenAI Team, Seoul, South Korea
{sejoon.s.kim, mingi.sung, jeonghwan.lee, hyunkuk.lim, gimenez.jorge}@pwc.com

Abstract

Traditional machine translation methods typically involve training models directly on large parallel corpora, with limited emphasis on specialized terminology. However, In specialized fields such as patent, finance, or biomedical domains, terminology is crucial for translation, with many terms that needs to be translated following agreed-upon conventions. In this paper we introduce a methodology that efficiently trains models with a smaller amount of data while preserving the accuracy of terminology translation. We achieve this through a systematic process of term extraction and glossary creation using the Trie Tree algorithm, followed by data reconstruction to teach the LLM how to integrate these specialized terms. This methodology enhances the model's ability to handle specialized terminology and ensures high-quality translations, particularly in fields where term consistency is crucial. Our approach has demonstrated exceptional performance, achieving the highest translation score among participants in the WMT patent task to date, showcasing its effectiveness and broad applicability in specialized translation domains where general methods often fall short.

1 Introduction

Conventional approaches to machine translation typically rely on training models using extensive parallel corpora, with little focus on specialized vocabulary. While this can be an effective approach in general, it demands large amounts of data and may lead to inconsistent translations of technical or domain-specific terminology. This challenge is particularly acute in specialized fields, where precise terminology usage is crucial and high-quality training data is often scarce (Skianis et al., 2020; Ghazvininejad et al., 2023; Zhang et al., 2023). Datasets for training models in these specialized domains are usually limited, and even when they exist, many are private due to security concerns. Consequently, certain industries lag behind in the advancement of deep learning-based translation. This disparity is even more pronounced for less commonly spoken languages, where specialized translation capabilities are significantly underdeveloped, resulting in an unequal distribution of progress in neural machine translation.

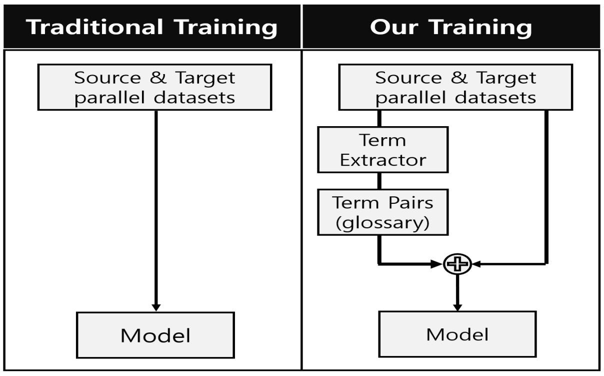

Figure 1: Training method in terminology-based LLM translation

Numerous approaches have been explored to integrate terminology constraints into Neural Machine Translation (NMT) systems, aiming to improve domain-specific translation quality. Recent research on terminology-based machine translation has shifted towards incorporating constraints during the training phase, which eliminates the computational overhead during inference and enhances translation quality. Dinu et al. (2019) introduced a method where NMT models are trained with augmented datasets that include terminology constraints as inline annotations, allowing the model to learn the appropriate use of these terms during training. Building on this, Ailem et al. (2021) proposed further enhancements by using token masking and a modified cross-entropy loss function, which biases the model towards generating constraint terms more effectively. Additionally, the use of large language models for post-translation re-

Proceedings of the Ninth Conference on Machine Translation, pages 636–642
November 15-16, 2024 ©2024 Association for Computational Linguistics

finement has been explored to improve terminology recall, demonstrating the evolving nature of terminology integration in NMT (Bogoychev and Chen, 2023; Ghazvininejad et al., 2023; Moslem et al., 2023). These training-based approaches have demonstrated significant improvements in both BLEU scores and terminology usage rates compared to decoding-time methods, indicating their effectiveness in satisfying lexical constraints without compromising translation quality.

In this paper, we propose a fine-tuning approach to resolve the domain-specific terminology mismatch problem using only a small dataset. Our approach focuses on extracting a glossary from the existing training datasets and fine-tuning the model to integrate these terms effectively into translations. First, we train a terminology extraction model to generate a glossary from existing training datasets, which we integrate into our trie data structure (Bodon and Rónyai, 2003). We then extract domain-specific terms from the source sentences using the tree structure and pass them along with the source texts to instruct our Large Language Model (LLM) to effectively incorporate specialized terminology into translations. This approach ensures high-quality and consistent results in specialized fields. Figure 1 illustrates how our approach differs from traditional fine-tuning methods. This targeted refinement process enhances the model's capacity to manage specialized terminology, thereby maximizing the utility of the original training data and significantly improving translation accuracy and consistency. Our methodology has proven to be exceptionally effective, particularly in specialized translation tasks, where general translation methods often struggle to maintain accuracy and consistency. Notably, our approach achieved the highest translation score among all participants in the WMT patent task, underscoring its superior performance and broad applicability across various specialized translation domains. Through this systematic and targeted strategy, we ensure that our translations are not only accurate but also contextually relevant, thereby providing a reliable solution for specialized translation needs.

2 Methodology

In this section, we describe the methodology employed in developing a domain-specific terminology-based LLM translation system, focusing on three key processes: (1) the creation of a terminology glossary, (2) the identification of terms within the source text, and (3) the application of these terms during the translation process using LLM prompts and sLLM fine-tuning.

2.1 Construction of the Terminology Glossary: Terminology Aligner

System Message:
I will now show you source sentences in Japanese and target sentences in Korean. Your task is to extract and pair key terms from both the original and translation texts. Maintain the exact form of the terms without modification.
Please follow these instructions for extracting term pairs:

- Extract term pairs that are closely related to patents.
- Only extract nouns.
- The extracted term pairs will be used to create a Japanese-Korean glossary.
- Return the results in the form of a Python dictionary, as shown in the example.
- However, if the exact same term appears more than once include it only once.

Example 1:

```
src_sentence = それぞれについて官能評を行った結果を表４２に示す。

tgt_sentence = 각각에 대하여 관능 평가를 행한 결과를 표 42에 나타낸다。

result = {"官能評": "관능 평가"}
```

Example 2:

```
src_sentence = 各種の特許や技術標準化にする問題が討された。

tgt_sentence = 각종 특허권과 기술 표준화에 관한 문제가 검토되었다。

result = {"特許": "특허권", "技術標準化": "기술 표준화"}
```

Figure 2: Instructions for Term Extraction

To enable the translation model to produce accurate translations that incorporate specialized terminology, we first construct a "Terminology Pair Dictionary," aligning key terms between the source and target languages. We achieve this by fine-tuning the Mistral Nemo model, creating a Terminology Aligner model whose primary objective is to extract pairs of key terms from both the original and translated texts.

For our training data, we leverage the GPT-3.5 API to generate synthetic data by crafting prompts that instruct the API to extract key term pairs from existing Japanese-Korean translation pairs in our dataset, along with the system prompt shown in Figure 2. From the 1,000,000 training samples provided by the organizers, we randomly select 1,000 examples to fine-tune Mistral Nemo for a single epoch. We adopt this conservative approach, recognizing that Mistral Nemo already possesses a robust grasp of both Korean and Japanese and is capable of performing various tasks, including the one at hand. Our goal is to specialize the model for our particular task without compromising its broader capabilities or confusing it with unrelated tasks.

Furthermore, when the entire dataset was used for fine-tuning, the model frequently extracts non-essential term pairs or entire sentences as pairs, indicating overfitting. By carefully selecting the amount of data and limiting the number of training epochs, we ensure that it extracts only the most relevant, domain-specific term pairs and effectively fine-tune the Terminology Aligner model.

2.2 Term Identification in the Source Text: Trie-Tree Algorithm

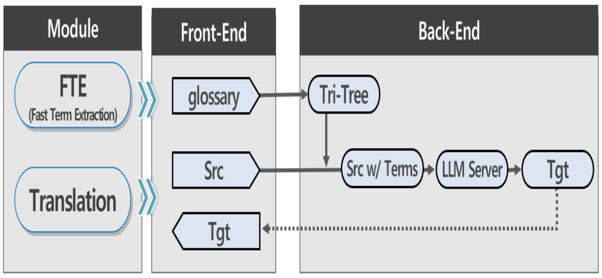

Figure 3: Overall process of term extraction to translation

The next step in our methodology involves identifying and extracting specialized terms from the source text that must be accurately translated using the glossary we constructed. To account for industries where there is often a high volume of technical terms and the need for efficient text scanning, we implement the Trie Tree data structure to extract the domain-specific terms.

The Trie Tree is particularly well-suited for this task due to its efficiency in string searching and matching. The algorithm operates by placing a cursor at the first Unicode character of the text, while another cursor points to the root of the tree. As the text cursor advances through each character, the tree cursor checks for corresponding child nodes. If a match is found, the tree cursor moves to the next node; if not, it resets to the root. When the cursor reaches a node marked as a 'term,' the term is identified, and its position is recorded. This allows us to quickly retrieve the term's translation and include it in the LLM prompt, ensuring that all relevant terms in the text are accurately and efficiently identified. The process is visually illustrated in Figure 3, which describes the step-by-step progression of the Trie Tree algorithm from text scanning to term retrieval and integration into the LLM prompt.

2.3 Application of Terms in Translation: LLM Prompting and sLLM Fine-Tuning

System Message:
You are a professional translator. You are especially familiar with specialized patent knowledge and terms in chemistry, electricity, mechanical engineering, and physics, as well as general everyday terms. Translate the following Japanese source text into Korean.

- Refer to the word pairs in the glossary when you translate.
- Do not translate the glossary itself.
- Do not include anything but translation result only.
- If a term in the glossary has multiple possible translations separated by '|', choose the most appropriate one.
- The translation result must be written in a single line. There must be no newline character at the end.

Glossary:
{セレノール化合物 ： 셀레놀 화합물,
端部 ： 끝부분 | 단부 | 모서리 ,
絶膜 ： 절연막,
送信回路 ： 송신 회로 | 전송 회로}

Figure 4: Instructions for Term Extraction

The final phase of our methodology involves the use of the extracted terminology during the translation process. To do this, we first extract term pairs from all translation pairs in our dataset using the created tree structure. These extracted term pairs are then combined with each original translation pair and the system message in Figure 4 to create an instruction-based training dataset to fine-tune our translation model.

Similar to our fine-tuning process with the Terminology Aligner, we observed that both the amount of data and the number of training epochs significantly influence the quality of the translation output, particularly in terms of how natural the translations sound. Interestingly, when working with smaller datasets, the model tends to produce more natural, conversational translations. However, as the dataset size increases, the model increasingly adheres to the original sentence structure, resulting in a more formal and literal style of translation.

To balance these tendencies, we use approximately 1,000 data points for training and limit the training to three epochs, with a temperature setting of 0.1. This configuration allows the model to generate translations that were both accurate and natural, making an effective use of the specialized terminology while maintaining a high level of fluency and readability.

3 Experimental Results and Application

	Team	BLEU (mecab)	RIBES
1	GenAI	**70.60**	**0.939073**
2	Chatgpt (w/ glossary)	69.00	0.929945
3	sakura	68.00	0.926839
4	Bering Lab	66.25	0.925226
5	ryan	65.74	0.922837
6	goku20	64.30	0.922486
7	ORGANIZER	62.43	0.915266
8	tpt_wat	61.00	0.918436
9	Chatgpt (w/o glossary)	59.90	0.908637

Table 1: BLEU (mecab) and RIBES scores for the Japanese-to-Korean translation task

Our proposed methodology has been rigorously tested and evaluated within the framework of the WMT patent task, where it achieves the highest translation score to date among all participants. This success demonstrates the effectiveness of our approach in handling domain-specific translations, particularly in maintaining consistency in terminology.

In addition to the translation results generated by our model, we submitted two additional translations using ChatGPT. The first result, labeled 'ChatGPT (w/ glossary)' in Tables 1 and 2, was obtained by replacing our model with ChatGPT while keeping the system prompt and glossary identical to our methodology. The second result was generated using ChatGPT alone without any additional inputs.

Several interesting findings emerged: for the Japanese-to-Korean translation task, ChatGPT without the glossary scores lower than other models in the patent translation domain. However, the score significantly improves when our glossary is provided. This demonstrates that the integration of a terminology glossary substantially enhances translation performance, regardless of the underlying model's capabilities. By comparing ChatGPT with and without the glossary, it becomes evident that our system effectively boosts translation quality through efficient terminology integration. Our specialized language model, trained specifically to use the glossary, outperforms ChatGPT even with the glossary. Upon reviewing the outputs, we notice that ChatGPT sometimes fails to correctly apply terms inside the glossay and occasionally uses Japanese terms instead of their Korean equivalents in the Japanese-to-Korean translation.

These findings highlight that our model can be effectively trained with a small dataset, achieving high-quality translations while remaining a smaller, more efficient model. Beyond patent translation, our methodology can be extended to specialized fields such as legal and financial translation where accurate term alignment is critical, providing a robust solution where general translation methods may fall short.

4 Discussion

4.1 Advantages of Our Methodology Over Traditional Approaches

The effectiveness of our methodology is further underscored by several key advantages it holds over traditional approaches:

4.1.1 Focused Learning on Domain-Specific Terms

Traditional models typically assign equal importance to all words in the training data, which can result in inconsistent translations of specialized terms

Table 2: BLEU and RIBES scores for the Korean-to-Japanese translation task

across different contexts. Our methodology addresses this by prioritizing domain-specific terms, ensuring they are recognized and used consistently in relevant translations.

4.1.2 Efficient Data Utilization through Terminology Extraction

Traditional methods often require large volumes of data to achieve satisfactory performance, particularly in specialized domains. Our method optimizes the use of training data by focusing on key term pairs and creating a dedicated glossary, enabling more efficient learning even with a smaller dataset.

4.1.3 Enhanced Translation Consistency and Accuracy

A common challenge with traditional translation methods is inconsistency in translating specialized terms, especially when these terms have multiple possible translations depending on context. Our approach mitigates this by ensuring the model is trained with a consistent set of term translations derived from the glossary.

4.1.4 Improved Model Generalization

Traditional models trained on large corpora may overfit to specific sentence structures or styles present in the training data, leading to poor generalization to new texts. Our approach incorporates the glossary into training, acting as a regularizing factor that improves generalization to new texts within the same domain.

4.1.5 Customizability for Different Domains

Our methodology allows for greater flexibility in adapting the model to different specialized fields. By updating the glossary with new terms relevant to a particular domain, the model can be quickly tailored to perform well without extensive retraining.

5 Conclusion

Our terminology-based LLM translation methodology represents a significant advancement in the field of machine translation, particularly for specialized domains requiring precise and consistent term usage. By constructing a terminology glossary using the Terminology Aligner, implementing an efficient term identification process with a Trie Tree algorithm, and fine-tuning the translation process using LLM prompts, we present a system that not only improves translation accuracy but also maintains a high level of naturalness in the output. Our approach has proven successful in terms of performance, operational cost, and training data efficiency, showing great promise for a wide range of professional translation applications.

A Appendix

In this appendix, we provide additional details on the training procedures, model configurations, and methodologies employed in our approach for efficient terminology integration in LLM-based translation within specialized domains.

A.1 Training Details and Additional Information

For both the translation task and the terminology extraction task, we used the **Mistral-Nemo-Instruct-2407** model as our base language model. This model was selected due to its strong capability in following instructions, including tasks such as translation and terminology extraction.

A.1.1 Training Details

Model Configuration and Training Parameters

Base Model	mistralai/Mistral-Nemo-Instruct-2407
LoRA Adapter Settings	
Alpha	8
Rank	8
Dropout Rate	0.1
Target Modules	`["q_proj", "k_proj", "v_proj", "o_proj", "gate_proj", "down_proj", "up_proj"]`
Learning Rate	1e-5
Optimizer	AdamW
Learning Rate Scheduler	Linear
Warmup Ratio	0.01
Epochs	1
Batch Size	4
Gradient Checkpointing	Enabled

LoRA was applied to mitigate GPU memory limitations and prevent catastrophic forgetting.

A.2 Fine-Tuning Challenges and Considerations

Our preliminary experiments indicated that using smaller datasets for fine-tuning resulted in more effective performance for both the terminology aligner and the translation model. Based on these observations, we concluded that a smaller dataset was sufficient to format the model's outputs appropriately and guide it to produce task-specific responses without deviating from the desired content.

The Mistral-Nemo model already exhibited strong abilities in instruction following, including translation and terminology extraction. Therefore, extensive fine-tuning was unnecessary and could potentially degrade performance. Training with larger datasets led to overfitting, where the model's training loss decreased, but the actual translation quality did not improve. In some cases, the model exhibited issues like repetitive outputs. We attempted to mitigate overfitting by increasing dropout rates and weight decay. However, these adjustments did not yield significant improvements in our experiments.

Rakuten's Participation in WMT 2024 Patent Translation Task

Ohnmar Htun and **Alberto Poncelas**
Rakuten Institute of Technology
Rakuten Group, Inc.

Abstract

This paper introduces our machine translation system (team *sakura*), developed for the 2024 WMT Patent Translation Task. Our system focuses on translations between Japanese-English, Japanese-Korean, and Japanese-Chinese. As large language models have shown good results for various natural language processing tasks, we have adopted the *RakutenAI-7B-chat* model, which has demonstrated effectiveness in English and Japanese. We fine-tune this model with patent-domain parallel texts and translate using multiple prompts.

1 Introduction

Machine Translation (MT) systems are becoming increasingly important in the translation industry. While generic MT models are good at translating common phrases into everyday language, they often struggle with specialized domains unless they have been specifically tuned for those areas. Patent documents are an example of this specialized content.

The patent translation shared task[1] at Conference on Machine Translation (WMT) 2024 aims to bring together Natural Language Processing (NLP) researchers to assess and explore innovative methods for translating patents, specifically between Japanese (Ja) and English (En), Korean (Ko) or Chinese (Zh), and vice versa.

Recently, significant advancements have been made in the field of NLP due to the development of Large Language Models (LLMs). Unlike encoder-decoder models, which are typically created to perform a single task such as machine translation, LLMs are designed for multiple NLP purposes. As a result, LLMs are often pre-trained on larger and more diverse texts, which helps improve the model's language understanding. In our work, we propose using an LLM fine-tuned with parallel data to perform accurate translations in the patent domain.

An LLM that has been specifically adapted to multiple NLP tasks in both English and Japanese is the *RakutenAI-7B* (Rakuten Group, Inc. et al., 2024) model. It has been pre-trained on a large volume of data, and its tokenizer has been optimized for the character-per-token rate in Japanese, making it ideal for complex tasks such as Japanese translation.

We participated in the patent translation (*sakura* team) shared task. In our proposal, we fine-tune the LLM with patent-domain bilingual data to build a multilingual model that achieves high-quality translations in multiple language directions. In addition, we produce translations using multiple prompts to further boost performance.

2 Related Work

LLM has been explored in the patent industry for tasks such as claim generation (Jiang et al., 2024), Question-Answer, or Classification (Bai et al., 2024).

Regarding the patent translation, previous participants in the JPO shared task have explored various methodologies, including training encoder-decoder models as suggested by Park and Lee (2021), utilizing Transformer-based NMT model (Vaswani et al., 2017) with ensemble decoding (Susanto et al., 2019) and adapting pre-trained models such as BART (Lewis et al., 2020) mBART (Liu et al., 2020) with patent-specific data (Wang and Htun, 2020; Kim and Komachi, 2021).

3 Task Description

The shared task consists of translating a set of sentences from patent publications in the En ↔ Ja, Ko ↔ Ja and Zh ↔ Ja language directions. The

[1] https://www2.statmt.org/wmt24/patent-task.html

Proceedings of the Ninth Conference on Machine Translation, pages 643–646
November 15-16, 2024 ©2024 Association for Computational Linguistics

text belongs to the domains of Chemistry, Electricity, Mechanical Engineering or Physics.

These sentences, are organized as different test set according to the year the patents were published:

- *test-n1*: Published between 2011 and 2013 (same test sets used in the past years).
- *test-n2*: Published between 2016 and 2017 (not available for Ko-Ja).
- *test-n3*: Published between 2016 and 2017 (but target sentences were manually created by translating source sentences).
- *test-n4*: Published between 2019 and 2020.
- *test-2022*: The union of the previous n1 to n4 sets.

The *test-n1* to *test-n4* vary in size from 2K to 5K sentences depending on the language. The only exception is *test-n3*, which was created manually and contains between 200 and 700 sentences. The total size of these tests, i.e. *test-2022*, ranges from 7K to 10K sentences.

3.1 Evaluation

In order to determine the performance of our model, we submit the translation of the test sets mentioned above. The results of the different tasks are published in https://lotus.kuee.kyoto-u.ac.jp/WAT/evaluation/index.html.

The translations are tokenized using Juman (Kurohashi and Kawahara, 2009), KyTea[2], Mecab (Kudo, 2005) or Moses tokenizer[3]. The website presents multiple evaluation metrics for evaluating the translation. In this paper we present only the BLEU (Papineni et al., 2002) scores. The other metrics are correlated with BLEU. We refer to their website for the rest of the metrics.

3.2 Training Data

The organizers of the shared task also provide the JPO Patent Corpus (JPC) for training. This is a dataset built by the Japan Patent Office[4] consisting of sets of 1M parallel sentences for each language pair (English-Japanese, Chinese-Japanese and Korean-Japanese).

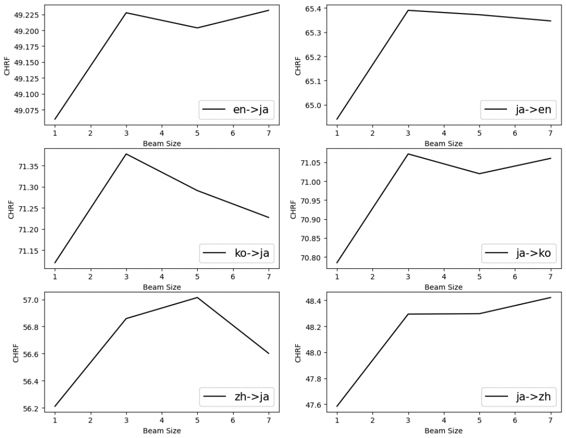

Figure 1: Performance of the fine-tuned model on the dev set using different beam sizes for decoding.

The data also include a dev set in the same domain with around 2K sentences each.

4 Experimental Settings

For our experiments, we fine-tune the *RakutenAI-7B-chat*[5] model, which has been optimized for the English and Japanese languages. However, it has not been explicitly adapted for other languages such as Korean and Chinese.

We use the JPO data described in Section 3.2 for this fine-tuning and do not incorporate any additional data other than what has been provided by the shared task organizers. The training process involves 200K steps with a batch size of 8. We fine-tune the model using the prompt "*Translate the following English text to Japanese:*" appending the sentence to be translated and replacing the source and target languages as needed for each language direction.

4.1 Influence of Beam Size

For decoding, we chose a beam size of three. While larger beam sizes involve considering more candidate translations, this does not always result in better performance. We tested our fine-tuned model with beam sizes of 1, 3, 5, and 7 on the development set. The results, measured using CHRF (Popović, 2015) metric, are shown in Figure 1. Although there is no single optimal beam size, our findings indicate that increasing the beam size beyond three does not lead to significant improvements and in some cases it may even degrade performance.

Test	Direction	BLEU	Δ
test-2022	En → Ja	53.4	+4.5
	Ja → En	50.1	+5.6
test-n1	En → Ja	51.1	+5.8
	Ja → En	49.3	+5.2
test-n2	En → Ja	46.3	+5.7
	Ja → En	43.9	+6.2
test-n3	En → Ja	54.9	+7.4
	Ja → En	43.1	+8.1
test-n4	En → Ja	62.1	+1.6
	Ja → En	59.7	+4.8

Table 1: BLEU scores for Japanese-English translation (using Moses tokenizer for Ja → En and kytea for En → Ja). The column Δ indicates the difference between the scores of our model and those of the organizers.

4.2 Influence of the Prompt

At decoding time, we perform multiple translations using different variations of the prompt. The prompts are the following:

- *Translate the following English text to Japanese* (same as training data)
- *Translate the following English sentence to Japanese:* (replace "text" with "sentence")
- *Translate the following text to Japanese:* (omit the source language)
- *Translate the text to Japanese:* (above prompt rephrased)
- *Translate the following English patent text to Japanese:* (explicitly indicate that is a patent text)

We use LASER (Heffernan et al., 2022) scores compared to the source to retrieve the best translation. Although all of them are similar, there are small nuances that can increase the quality by around 0.5-1 BLEU points.

5 Results

In this section we present the translation performance achieve by our model on the different language directions.

5.1 Japanese-English

First, Table 1 illustrates the performance of our model on English-Japanese translation. We observe that our model achieves the best results for this language pair compared to the model of the organizers, with an average improvement of 5 BLEU points for English-to-Japanese and 6 BLEU points for Japanese-to-English. Furthermore, it shows greater improvements in this pair compared to the other language pairs. This success can be attributed to the fact that our model was pre-trained on these two languages, benefiting from higher exposure.

Test	Direction	BLEU	Δ

	Ja → Zh	58.7	+1.2

Table 2: BLEU scores for Japanese-Chinese translation (using Kytea tokenizer). The column Δ indicates the difference between the scores of our model and those of the organizers.

Test	Direction	BLEU	Δ
test-2022	Ko → Ja	74.3	+0.4
	Ja → Ko	75.4	+2.6
test-n1	Ko → Ja	73.3	+1.6
	Ja → Ko	72.9	+2.2
test-n3	Ko → Ja	52.3	+0.3
	Ja → Ko	68.0	+5.6
test-n4	Ko → Ja	77.3	+0.2
	Ja → Ko	78.4	+3.7

Table 3: BLEU scores for Japanese-Korean translation (using Mecab tokenizer). The column Δ indicates the difference between the scores of our model and those of the organizers.

5.2 Japanese-Chinese

Table 2 presents the results for Chinese-Japanese translation. Although improvements are observed across all test sets, there is a notable disparity between the language directions. While Zh → Ja shows an improvement of 5 BLEU points, for the reverse direction there is an improvement of 1.5 BLEU points.

5.3 Japanese-Korean

Lastly, in Table 3 we show the performance of the Japanese-Korean translation. For this language pair we achieve smaller improvements when compared to the baseline of the organizers.

6 Conclusion

In this paper, we described our MT model developed for the 2024 WMT Patent Translation Task, specifically for English-Japanese, Japanese-Korean, and Japanese-Chinese translations. The ranking system has evaluated participating teams every year from 2016 to 2024. Our model achieved first place in 20 out of the 28 tasks without using external data. Our approach involves fine-tuning the "*RakutenAI-7B-chat*" model using sentences from the patent domain and decoding with multiple prompts. Although this model was originally pre-trained only on English and Japanese data, fine-tuning with Korean and Chinese text has led to good translation performance, surpassing the models submitted in previous years for the same task.

Abstract

This paper presents SETU-ADAPT’s submissions to the WMT 2024 Biomedical Shared Task, where we participated for the language pairs English-to-French and English-to-German. Our approach focused on fine-tuning Large Language Models (LLMs), using in-domain and synthetic data, employing different data retrieval strategies. We introduce a novel MT framework, involving three autonomous agents: a Translator Agent, an Evaluator Agent and a Reviewer Agent. We present our findings and report the quality of the outputs.

1 Introduction

Translating texts in the biomedical domain presents unique challenges that sets it apart from general domain translation tasks. The domain is characterised by the use of specialised terminology, fixed expressions and relative data scarcity. In recent times, LLMs (Brown et al., 2020; Przystupa and Abdul-Mageed, 2019) have become the go-to systems for building Machine Translation (MT) systems, due to their impressive performance in generating accurate translations across diverse domains. Precisely, the ability to fine-tune these models on new data, adapting them to the specialised terminology used in the biomedical domains, makes them particularly suitable for our task.

In our experiments, we built our MT systems using Llama-3 (Dubey et al., 2024) and No Language Left Behind (NLLB) (Costa-jussà et al., 2022), based on the high performance reported in their relevant publications. We further design and develop strategies to address data scarcity and improve the quality of the outputs. Our first approach involves back-translation (Xu et al., 2019), where we leverage monolingual data and translate them back into the source language, thus generating synthetic data to be combined with the original dataset. This approach is widely recognized as an effective method to overcome the challenges caused by the translation of low-resource languages and specific domains. Another data augmentation method that we adopt is based on terminology-aware mining (Haque et al., 2020), where we extract a terminology list from our training data and use it to mine semantically similar sentences from the general domain corpus. We further experimented using few-shot prompting, where we provided the model with a few translation samples retrieved through semantic search based on the source sentence. Finally, we propose an innovative MT system powered by `GPT-4o` (OpenAI et al., 2024) that employs an agentic workflow (Wang et al., 2024). This system follows a collaborative framework, where three LLM-based agents work together autonomously to produce translations.

The paper is organised as follows. We present an overview of our proposed systems in Section 3. We describe our datasets and our data augmentation strategies in Section 4 and Section 5. We introduce our last system, involving LLM-based autonomous agents in Section 6. We present the results of our evaluation in Section 7 and draw our conclusions in Section 8.

2 Related Work

The main difficulties found in biomedical MT have been the highly specialised domain, the lack of relevant data, and the importance of using the correct terminology. To address the issues caused by

[*] Both authors are equal contributors to this work.

Proceedings of the Ninth Conference on Machine Translation, pages 647–653
November 15-16, 2024 ©2024 Association for Computational Linguistics

domain-specific terminology, Choi et al. (2022) adopted a soft-constrained translation approach, where terminology constraints retrieved from the training corpus are provided to the MT system as a suggestion rather than a hard constraint. Soft-constrained decoding appears to be a promising solution to drive the systems to include the necessary terminology in the output while preserving the model's fluency and flexibility in the translation.

Ballier et al. (2022) trained different systems on a selection of texts from WMT, Khresmoi (Dušek et al., 2017) and UFAL (Bojar et al., 2017) datasets, comparing the results. Interestingly, they find that `mBART-50` (Tang et al., 2021), despite producing fluent grammatical sentences, fails at translating consistently domain-specific terminology. Their study suggests that this well-known model may not be adequate for the task of biomedical translation, especially in the context of translating biomedical abstracts where its small context window may cause inaccurate translations.

Manchanda and Bhagwat (2022) confirms previous studies that showed how fine-tuning any model from a general domain to a specialised one, as is the case with clinical and biomedical texts, improves the translation quality in most cases. Their study introduces a novel approach, based on combining general-purpose and domain-specific datasets for fine-tuning while applying a higher learning rate to the general domain data. Their experiments demonstrate how this combined fine-tuning approach may improve translation quality in both domains.

In the last few years, we have seen a general surge of LLMs applied to MT (Hendy et al., 2023; He et al., 2024). Several studies have been conducted with a high degree of success on the application of LLMs for the translation of biomedical texts. The first study of this sort was published by Han et al. (2022), where they compare MT models of different sizes to investigate the applicability of Kaplan's scaling laws (Kaplan et al., 2020) in biomedical translation. Their findings confirmed that larger general-purpose models consistently outperform smaller models, even when the latter are fine-tuned on domain-specific data. Interestingly, the performance gap narrows significantly when the training data for smaller models is meticulously curated, bringing their efficacy close to that of the NLLB model. The efficacy of LLMs in translating biomedical data is further confirmed by several recent studies (Jahan et al., 2024; Keles et al., 2024; García-Ferrero et al., 2024).

Finally, we underline one of the latest research directions in the study of LLMs: multi-agentic workflows. Agents are instances of LLMs, each with a tailored system prompt that defines their behaviour, adhering to specific criteria and output requirements. Usually, agents also have access to external features, such as memory mechanism (Zhang et al., 2024), retrieval-augmented generation (Gao et al., 2024), and tool use (Qu et al., 2024). In the experiment conducted by Liang et al. (2024), the authors exemplify this approach with a novel translation framework called Multi-Agent Debate (MAD). Their system is based on a guided interaction between multiple agents who engage in a debate to determine the most effective translation for a given source text. A designated judge agent oversees this process and ultimately decides on the final solution. This iterative strategy allows successive agents to refine the initial translation hypothesis, progressively improving translation quality. They achieve good performance with the models `gpt-3.5-turbo` and `gpt-4` (Brown et al., 2020).

3 Systems Overview

We submit five MT systems for evaluation, each employing different approaches to biomedical translation. These systems range from traditional fine-tuning on in-domain data to various data augmentation approaches and the use of LLMs, prompt engineering, and multi-agent workflows.

Table 1 provides an overview of the five systems submitted for evaluation. System 1 utilizes the NLLB model fine-tuned with terminology mining techniques, applied in both directions (see §5.1). System 2 also uses NLLB, but we fine-tune it on both in-domain and synthetic data. For this system, we augmented the training data with an additional 5,000 backtranslated sentences to address data scarcity (see §5.2). System 3 uses a combination of agents powered by NLLB and GPT, who are tasked with post-editing and refining the NLLB outputs to make them more fluent and effective. For System 4, we select the smallest checkpoint of the most recent models developed by Meta AI, called `LLama-3-8B` (Dubey et al., 2024). This system uses parameter-efficient fine-tuning on the in-domain data, and the output is improved with three fuzzy matches prepended to the prompt. Finally, our last submission, System 5 uses a multi-agent crew powered by `GPT4-o` (OpenAI et al., 2024).

System	Model	In-Domain FT	Backtranslation	Terminology Mining	Agents	FSP
1	NLLB	✓		✓		
2	NLLB	✓	✓			
3	NLLB	✓			✓	
4	LLama-3	✓				✓
5	GPT-4o				✓	✓

Table 1: Overview of our submitted systems. The checkmark (✓) indicates the presence of a feature. FSP stands for Few-Shot Prompting.

The multi-agents workflow is described in depth in the relevant section (see §6).

4 Dataset Selection

In this section, we describe the composition of the datasets used for our experiments. We curated a selection of parallel sentences from the corpora provided by the shared task organisers, including part of the Biomedical Translation repository and the UFAL Medical[1] corpus. This resulted in two datasets: 11,190 parallel sentences for English-German and 13,032 for English-French. We investigated synthetically increasing the training data by employing different data augmentation techniques for the English-to-German language pair. We provide an overview of the dataset selection in Table 2.

Dataset	EN-DE	EN-FR
Original	11,190	13,032
+ Term. Mining	14,583	NA
+ Backtranslation	16,190	NA

Table 2: Overview of datasets.

5 Data Augmentation

In this section, we describe the different approaches we have used to augment the datasets used for our MT systems. We adopt back-translation, terminology mining, and fuzzy matches.

5.1 Terminology Mining

We perform terminology mining on English-to-German language pairs. We extract biomedical terms from the training data using the pre-trained named entity recognition (NER) model `d4data/biomedical-ner-all`. This model is designed to identify biomedical entities within the text, such as diseases, disorders, and therapeutic procedures, providing a confidence score and the specific unit being identified. The implementation utilises the pipeline function from the Hugging Face Transformers[2] library (Wolf et al., 2020), configured for the task of token classification.

First, the NER model iterates over every term in the dataset, obtaining a list of identified entities. We then filter them, collecting only those labeled as *B-Disease-disorder* or *B-Therapeutic-procedure*, provided that the model's confidence score for the entity exceeds 0.98 and the length of the identified word is greater than five characters. Entities meeting these criteria are then printed for verification and appended to the list of extracted terms. This approach ensures that only relevant biomedical terms are extracted from the dataset, focusing specifically on diseases, disorders, and therapeutic procedures. The terminology mining process yielded a total of 14 biomedical terms, that we used to collect 3,393 sentences containing at least one biomedical term.

5.2 Backtranslation

We adopt back-translation for the English-German language pair, to address data scarcity with semantically similar sentences, extracted with a pre-trained sentence embedding model, and then backtranslated with NLLB. We initially filter the EMEA monolingual dataset (Calzolari et al., 2012), selecting only sentences that exceed 100 characters in length, and further limit our selection to the first 1,000 entries for easier processing. We encode the text data using the pre-trained sentence embedding model `multi-qa-mpnet-base-dot-v1` from the Sentence-Transformers library. The sentence embeddings are stored as a new column in the dataset, on which we perform semantic search, using FAISS index (Douze et al., 2024) for more efficient computation. The index is then queried to retrieve the top 5 most similar samples from the original dataset. We collect a total of 5,000 sentences, aggregated

[1] https://ufal.mff.cuni.cz/ufal_medical_corpus

[2] https://github.com/huggingface/transformers

and sorted by similarity scores in descending order.

This methodology enables the efficient retrieval of contextually relevant sentences from large datasets. We make use of the resulting sentences, backtranslating them to English using the baseline NLLB-200-600M and leading to the creation of a synthetic dataset, that is in the same domain. The synthetic dataset is added to the original dataset to fine-tune the baseline model.

5.3 Fuzzy Matches

Fuzzy matches are human translated segments, stored in parallel datasets. Drawing on findings from Moslem et al. (2023), we incorporate semantically-similar fuzzy matches in a three-shot prompting scenario. This approach leverages the model's in-context learning ability (Brown et al., 2020) to further improve the quality of the MT outputs. A wide range of academic literature has demonstrated that incorporating fuzzy matches in a few-shot scenario may improve the model's understanding of domain-specific terminology and fixed expressions (Castaldo and Monti, 2024; Moslem et al., 2022; Knowles et al., 2018).

To extract fuzzy matches, we employ semantic search on sentence embeddings generated by the all-MiniLM-L6-v2 model. The embeddings are stored in a flat index created with the FAISS[3] library, from which we retrieve the three most similar sentences. After extracting the fuzzy matches for our input sentence, we prepend them to a minimalist prompt that directly maps the source language to the target language. We incorporate fuzzy matches in System 4 and 5, achieving substantial improvements over the zero-shot baseline. We present an overview of the prompt templates used in this study in Table 3, with the following annotations: ♦ shows the presence of a line break, [src] stands for source language, [tgt] stands for target language, and [input] stands for the text to be translated.

Prompt Type	Template
Zero-Shot	[src]: [input] ♦ [tgt]:
Few-Shots	[src]: [source$_1$] ♦ [tgt]: [target$_1$] ♦ ... [src]: [source$_k$] ♦ [tgt]: [target$_k$] ♦ [src]: [input] ♦ [tgt]:

Table 3: Overview of the prompt templates used in this study.

6 Multi-Agents Workflow

We design a team composed of three autonomous agents that collaborate to simulate a translation agency with the goal of refining an initial translation hypothesis from multiple perspectives. The process begins with the creation of our agent crew, using the CrewAI library[4].

The first agent, the Translator Agent, is tasked with translating a given sentence. Following this, the Evaluator Agent assesses the translation based on fluency and accuracy. This assessment is quantified with a numerical quality metric that ranges from 0 to 100, where 100 signifies a translation that is both perfectly fluent and accurate.

If the translation receives a score below 80, the Reviewer Agent intervenes to review the initial hypothesis, aiming to improve its accuracy. This iterative process repeats until the Evaluator Agent awards a quality score greater than 80, indicating a successful translation. We provide the reference code used for this experiment in the relevant GitHub repository.[5]

7 Evaluation

This section discusses the results that we obtained from our experiments. Table 4 shows the results obtained by evaluating our models on the validation set, using BLEU (Papineni et al., 2002), ChrF (Popović, 2015) and the COMET model wmt22-comet-da (Rei et al., 2022a). Our quality estimation is based on the reference-free COMET model wmt22-cometkiwi-da (Rei et al., 2022b). Our systems achieve good results for both language pairs, and the data augmentation approaches visibly improve the translation outputs, as documented in the evaluation of Systems 1, 2 and 3. Terminology mining seems particularly effective, improving the BLEU score of our first system significantly above the others.

In order to confirm the results of our automatic evaluation and to allow for a more precise comparison of the different systems used for the primary language pair of our study, we include a manual evaluation on a small sample of translations, conducted by two professional translators in the EN-DE language pair, for which we adopt the MQM-DQF framework (Burchardt, 2013; Lommel and

[3] https://github.com/facebookresearch/faiss

[4] https://github.com/crewAIInc/crewAI

[5] https://github.com/Ancastal/biomedical-wmt-agents

Melby, 2018).

The results of the MQM evaluation reveal that System 5 produces the fewest overall errors, with the majority of these errors falling under the Fluency category. In contrast, the other systems exhibit a higher concentration of errors in the Accuracy category. In System 1, where Terminology Mining was applied, fewer terminology-related errors were detected, further confirming the effectiveness of this strategy. Additionally, we find that in System 3 the involvement of `GPT-4o` agents in post-editing led to a reduction in accuracy-related errors.

System	BLEU	ChrF	COMET	QE
English-to-German				
Baseline	2.97	26.01	70.09	0.62
System 1	25.29	60.13	79.50	0.58
System 2	23.80	58.89	78.33	0.56
System 3	23.97	59.22	78.93	0.63
System 4	22.95	58.90	84.32	0.73
System 5	25.24	63.01	86.13	0.77
English-to-French				
System 3	29.18	57.01	75.70	0.65

Table 4: Experiment Results for Different Systems

8 Conclusions

This study presents the approaches we have adopted to address the challenges caused by biomedical translation, specifically the need for consistent translation of domain-specific terminology and the lack of in-domain parallel data.

By adopting data augmentation techniques, we found that our models improved consistently in translating biomedical terminology, achieving better results in our evaluation. Terminology mining proved particularly effective, resulting in our best overall submission. We also explored the use of backtranslation, but we found that its effectiveness may be limited in fine-tuning LLMs. We speculate that it may require a different ratio of original to synthetic data used during training, or a different weighting. Our experiments with fuzzy matches demonstrated the potential to use in-context learning to improve MT quality and adapt LLMs to domain-specific terminology.

Finally, we introduced a novel MT workflow based on the collaboration of three autonomous LLM-based agents. This approach offers an innovative way to refine an initial translation hypothesis from multiple perspectives, potentially leading to more accurate outputs.

9 Limitations

We acknowledge that several aspects of our study have room for improvement. First, the evaluation was conducted on a relatively small dataset of 50 biomedical abstracts, limiting the objectivity of the results. Second, while data augmentation helped improve performance, the training data could be expanded by incorporating larger corpora and potentially leading to better quality. Additionally, the models employed in this study may not represent the best performing MT systems by the time of publication, requiring further experiments with more recent models to validate our findings. Finally, manual evaluation was only conducted for a single language pair, limiting the scope of our analysis.

Abstract

This paper presents the results of the low-resource Indic language translation task, organized in conjunction with the Ninth Conference on Machine Translation (WMT) 2024. In this edition, participants were challenged to develop machine translation models for four distinct language pairs: English–Assamese, English-Mizo, English-Khasi, and English-Manipuri. The task utilized the enriched IndicNE-Corp1.0 dataset, which includes an extensive collection of parallel and monolingual corpora for northeastern Indic languages. The evaluation was conducted through a comprehensive suite of automatic metrics—BLEU, TER, RIBES, METEOR, and ChrF—supplemented by meticulous human assessment to measure the translation systems' performance and accuracy. This initiative aims to drive advancements in low-resource machine translation and make a substantial contribution to the growing body of knowledge in this dynamic field.

1 Introduction

The low-resource Indic language translation field has witnessed significant advancements, particularly marked by the success of last year's Indic MT Shared Task. This initiative, organized alongside the Eighth Conference on Machine Translation (WMT) 2023[1] (Pal et al., 2023), demonstrated the potential and necessity of focusing on low-resourced languages. Building on the momentum and achievements of last year's task, we are pleased to continue our efforts with the Indic MT Shared Task for the Ninth Conference on Machine Translation (WMT) 2024[2].

Low-resource Indic languages represent a vast and diverse array of languages spoken across India. Despite their deep cultural and linguistic heritage, these languages face significant challenges due to limited resources and institutional support. The obstacles are multifaceted, including smaller speaker populations, minimal governmental backing, insufficient documentation, and restricted access to modern technological tools.

India is celebrated for its linguistic diversity, with many languages spoken throughout the subcontinent. The Eighth Schedule of the Indian Constitution officially recognizes 22 languages, granting them substantial governmental support and resources. However, numerous other languages, particularly those spoken by indigenous and minority communities, often remain marginalized and under-supported. These low-resource languages encounter additional barriers, such as the absence of standardized scripts, limited lexical resources, and a dearth of linguistic research. These factors, combined with the lack of formal educational resources and declining inter-generational transmission, threaten their preservation and vitality. As a result, many of these languages risk becoming endangered, underscoring the urgent need for targeted efforts to document, revitalize, and sustain them in the face of ongoing challenges.

Given these challenges, our initiative is dedicated to documenting, revitalizing, and supporting low-resource Indic languages through innovative technological solutions. The previous year's Indic MT Shared Task concentrated on four language pairs: English–Assamese, English–Mizo, English–Khasi, and English–Manipuri — utilizing the enriched IndicNE-Corp1.0 dataset (Pal et al., 2023). The success of this task highlighted the critical need for sustained efforts in this domain. Our ongoing objective is to foster advancements in machine translation and natural language processing tailored to these languages.

The evaluation of this task employs a comprehensive set of metrics, incorporating both automatic measures—such as BLEU (Papineni et al., 2002),

TER (Snover et al., 2006), RIBES (Isozaki et al., 2010), METEOR (Banerjee and Lavie, 2005), and ChrF (Popović, 2015)—and rigorous human assessments. This dual approach ensures a thorough evaluation of the translation systems' performance, accuracy, and cultural fidelity.

Through this ongoing initiative, we aim to make a significant contribution to the preservation of linguistic diversity and cultural heritage, thereby supporting the rights and identities of minority language communities in India. By leveraging cutting-edge technologies, we strive to create a lasting impact and propel the field of low-resource language translation forward, ensuring these languages not only survive but thrive in the digital age.

2 Languages

2.1 Khasi Language and Its Dialects

Khasi belongs to the Austro-Asiatic family of languages spoken in the central and eastern regions of Meghalaya. Before 1813, the Khasi lacked its own script. During the period from 1813 to 1814, the Bengali script was employed to translate the Bible into Khasi, owing to the widespread literacy in Bengali at that time. By 1816, some translated versions of the Gospel of Matthew had been printed and distributed among Khasi speakers who were literate in Bengali. However, it was not until 1841, with the arrival of a Welsh missionary, that the Roman script was introduced, and translations were subsequently made into the standard dialect, specifically the Sohra variety.

Khasi exhibits significant dialectal diversity. Grierson (1904) identified four dialects of Khasi: Standard Khasi, Pnar or Synteng, Lyngngam, and War. Acharya (1971) reaffirmed Grierson's classification and noted the existence of additional sub-dialects, such as Bhoi, spoken in the northern open lands of Meghalaya. Bareh (1977) offers a more comprehensive list of Khasi dialects, primarily based on their geographical distribution:

- Amwi in the southern Jaiñtia hills,
- Shella in the southern Khasi hills,
- Warding in the south of the Khasi hills,
- Myriaw, Nongkhlaw, Nongspung, Maram, and Mawiang in the mid-western area of the Khasi hills,
- Cherra in the mid-southern hills,
- Mylliem, Laitlyngkot, Nongkrem, and Lyniong-Khasi in the central parts,
- Jowai in the central Jaintia hills,
- Bhoi in the north-east Khasi hills,
- Manar, Nongwah, and Jirang in the north Khasi hills,
- Khatarblang (Mawpran) in the mid-southern region, and
- Nongstoin and Langrin in the west Khasi region.

Bareh further adds that several sub-dialects exhibit variations within each group, particularly in phonology. Among these, Amwi is considered the most typical dialect. Compared to other dialects, Amwi appears to be the most rudimentary and is generally not intelligible to speakers of neighbouring dialects such as Jowai or Khad ar Blang. Amwi is said to be more agglutinative in form, potentially preserving its Mon-Khmer heritage. While its grammar resembles Jowai's, notable differences exist in morphology and phonology. Despite these distinctions, the Amwi speakers are familiar with their neighbouring dialects and can adopt them for communication.

Bareh (1977) categorizes the aforementioned dialects into three major branches:

1. **Eastern dialects**:
   - Jowai (Central Highlands),
   - Amwi and the War dialects (in the south), and
   - Bhoi Synteng in the north.
2. **Central dialects**:
   - Nongphlang or Nonglum, Cherra, and related dialects such as Nongkrem, Mylliem, Nongkhlaw, Nongspung, Rambrai, Mawsynram, Maram, Laitlyngkot, Mawphlang, etc.,
   - Bhoi East (in the north), consisting of Mawrong, Bhoi Lymbong, etc., and
   - Bhoi West (in the north), consisting of Manar, etc.,
   - War Shala (in the south), and
   - Warding (in the south).
3. **Western dialects**:

- Nongstoin
- Lyngam
- Langrin

Addressing the abovementioned dialects, Bareh notes that numerous sub-dialects exhibit phonological variations within each group. Daladier (2007:341), cited in Sidwell (2009), comments on the Mon-Khmer language group, which includes Khasi, noting that it comprises three main branches. Although now standardized and formalized through written use, Khasi retains conservative unwritten dialects, particularly in the War region. Other notable dialects include Pnar and War, with War further subdivided into four sub-dialect groups: Nongtalang, Amvi, Tremblang, and Shella. The subclassification of Pnar dialects remains largely unexplored. Additionally, Pnar-War and War-Khasi dialects are spoken in several Jaintia villages. The War dialects of Khasi are divided into two groups: War-Khasi and War-Jaintia, spoken in the southeast corners of the Khasi and Jaintia Hills districts, respectively. Grierson (1904) also discusses the War dialects.

For the shared task, we have utilized the Sohra (Cherra) dialect of Khasi as the standard form for translation purposes. This dialect, recognized for its historical significance and broad usage in educational and religious contexts, has been established as the standardized variant of Khasi following its formalization through the introduction of the Roman script in 1841. By employing the Sohra dialect, we ensure consistency and accessibility for participants, reflecting the widely accepted linguistic norm within the Khasi-speaking community.

2.2 Introduction: About the Manipuri Language

Manipuri, also known as Meiteilon, is a Sino-Tibetan language predominantly spoken in the northeastern Indian state of Manipur. It is recognized as one of the 22 scheduled languages of India and serves as the lingua franca among various ethnic communities in the region, fostering communication and cultural exchange.

The language boasts a rich literary heritage, with a history of written texts dating back to ancient times. Manipuri uses the Meitei script, also known as Meitei Mayek, alongside the Bengali script for writing purposes. Despite its cultural significance, Manipuri faces linguistic preservation and modernization challenges, particularly in the digital era. There is a pressing need for computational resources and tools to support the language, which is vital for its continued use and growth.

In recent years, there has been growing interest in developing natural language processing (NLP)(Allen, 2003) tools and resources for under-resourced languages like Manipuri. However, several challenges persist in this area for the Manipuri language (Gyanendro Singh et al., 2016). One of the primary issues is the limited availability of annotated corpora and linguistic resources, which are essential for training robust machine learning models. This scarcity hinders the development of accurate NLP applications such as machine translation (Pal et al., 2023), sentiment analysis (Singh and Singh, 2017), and speech recognition (Gyanendro Singh et al., 2016).

Another significant challenge is the complexity of the Manipuri script and its morphological structure. The language exhibits rich inflectional morphology, making it difficult to apply standard NLP techniques that are typically designed for resource-rich languages like English. Moreover, the lack of standardization in digital representation further complicates computational processing, as existing tools often struggle with script conversion and text normalization.

Current research efforts are focused on addressing these challenges by creating linguistic resources, developing language-specific algorithms, and adapting existing NLP frameworks to better accommodate the unique characteristics of Manipuri. However, much work remains to be done to bridge the gap between Manipuri and other well-resourced languages in the digital domain.

2.3 Introduction: About the Assamese Language

Assamese, an Indo-Aryan language, is predominantly spoken in the northeastern Indian state of Assam. It serves as the official language of Assam and plays a crucial role as a lingua franca among various ethnic groups in the region, facilitating communication and cultural exchange. Assamese is also one of the 22 scheduled languages of India, underscoring its significance in the country's linguistic landscape.

The Assamese language has a rich literary tradition, with its roots extending back to the early medieval period. The script used for Assamese is derived from the ancient Brahmi script, and over time, it evolved into its current form. Despite its historical and cultural importance, Assamese faces challenges in the modern era, particularly in the field of language technology. The development of computational tools and resources for Assamese is critical for its preservation and growth, especially in an increasingly digital world.

2.4 Introduction: About the Mizo Language

Mizo, a member of the Tibeto-Burman language family, is predominantly spoken in the northeastern Indian state of Mizoram. It serves as the primary language of communication among the Mizo people and is also spoken by various ethnic groups in neighbouring states and regions, including Manipur, Tripura, Assam, and even parts of Myanmar and Bangladesh. Mizo is recognized for its tonal nature and distinct phonological features, which make it a unique language in the Tibeto-Burman group.

The language has a rich oral tradition, encompassing folktales, songs, and cultural narratives that reflect the heritage of the Mizo people. The development of the written form of Mizo began in the late 19th century with the introduction of the Roman script by Christian missionaries, which facilitated the transcription of the language and the creation of written literature. Today, Mizo has a well-established literary tradition, with a substantial body of work ranging from poetry to modern prose. Despite its cultural significance, Mizo faces linguistic preservation and development challenges, particularly in the context of modern technological advancements and digital communication.

3 Low-Resource Indic Language Translation 2024 Shared Task

3.1 Overview and Task Description

Building upon the resounding success of the "Shared Task: Low-Resource Indic Language Translation" at WMT 2023, which witnessed enthusiastic participation from around the globe, we are excited to announce the continuation of this initiative at the Ninth Conference on Machine Translation (WMT 2024). The advances in machine translation (MT) have significantly enhanced the performance of translation systems, especially with the adoption of techniques such as multilingual translation and transfer learning. Despite these advancements, extending coverage to diverse low-resource languages remains a formidable challenge due to the scarcity of parallel data needed to train robust MT systems.

The WMT 2024 Indic Machine Translation Shared Task addresses this challenge by focusing on low-resource Indic languages from diverse language families. This year, the task emphasizes the following language pairs: English-Assamese, English-Mizo, English-Khasi, and English-Manipuri. Additionally, there was an intended focus on English-Nyishi; however, this category was cancelled due to issues with training data. Similarly, other planned language pairs under the category with very limited training data, such as English-Bodo, English-Mising, and English-Kokborok, were also cancelled for this year.

3.2 Categories

This year's task features two main categories based on the availability of training data:

3.2.1 Category 1: Moderate Training Data Available

- English ⇔ Assamese (en-as)
- English ⇔ Mizo (en-lus)
- English ⇔ Khasi (en-kha)
- English ⇔ Manipuri (en-mni)

3.3 Goal

The central objective of this shared task is to develop machine translation systems that produce high-quality translations despite the constraints posed by limited data availability. Participants are encouraged to explore several innovative strategies, including:

- **Monolingual Data Utilization**: Effectively leveraging monolingual data to enhance translation quality.
- **Multilingual Approaches**: Investigating the benefits of cross-lingual transfer for low-resource language pairs.
- **Transfer Learning**: Adapting models trained on resource-rich language pairs to target low-resource languages.
- **Innovative Techniques**: Experimenting with novel methods specifically tailored to low-resource settings.

3.4 Data

3.4.1 Training

The datasets used for this task include parallel and monolingual corpora for Assamese, Khasi, Mizo, and Manipuri, drawn from the IndicNE-Corp1.0 dataset. While the dataset for Nyishi was planned, it remains unavailable this year due to data quality issues.

3.4.2 Testing

For the testing section, we have created 1000 language pair sentences for each of the following language pairs:

- English ⇔ Assamese (en-as)
- English ⇔ Mizo (en-lus)
- English ⇔ Khasi (en-kha)
- English ⇔ Manipuri (en-mni)

The first 500 sentences are provided in English to be translated into the specific target language, and the last 500 sentences are provided in the target language to be translated into English.

3.5 Evaluation

The evaluation will be conducted using both automatic and human evaluation methods to ensure a comprehensive assessment of the translation systems. Automatic evaluation metrics include BLEU, TER, RIBES, METEOR, and ChrF. In addition, native speakers will perform human evaluations to assess the quality of the translation more rigorously.

4 Dataset

4.1 Training

The dataset for the WMT 2024 Shared Task on Low-Resource Indic Language Translation is primarily based on the IndicNE-Corp1.0 dataset [3]. This corpus was built by aggregating datasets from previous research, including significant contributions from (Laskar et al., 2020) (Laskar et al., 2022), (Khenglawt et al., 2022), and (Laitonjam and Ranbir Singh, 2021). The compiled datasets encompass both parallel and monolingual corpora across four languages: Assamese, Mizo, Khasi, and Manipuri.

In earlier studies, we focused on developing parallel and monolingual corpora for English ⇔ Assamese (en-asm) (Laskar et al., 2020, 2022), English ⇔ Mizo (en-lus) (Khenglawt et al., 2022), English ⇔ Khasi (en-kha) (Laskar et al., 2021), and English ⇔ Manipuri (en-mni) (Laitonjam and Ranbir Singh, 2021). The data was sourced from a variety of online platforms including the Bible, multilingual dictionaries (such as Xobdo and Glosbe), multilingual question papers, PMIndia (Haddow and Kirefu, 2020), web pages, blogs, and online newspapers.

Table 1 shows the detailed statistics of the parallel datasets used for training and validation for each language pair.

Type	Sentences	Tokens (eng)	Tokens (target)
Assamese	50,000	969,623	825,063
Mizo	50,000	981,468	1,062,414
Khasi	24,000	729,930	875,545
Manipuri	21,687	390,730	330,319

Table 1: Parallel data statistics for train and validation.

In addition to the parallel corpora, we also made monolingual data available for each language, which is presented in Table 2.

Language	Size (MB)	Sentences	Tokens
Assamese	805	2,624,715	49,232,154
Mizo	145	1,909,823	27,936,225
Khasi	104	182,737	22,140,361
Manipuri	716	2,144,897	36,514,693

Table 2: Monolingual data statistics for Assamese, Mizo, Khasi, and Manipuri languages.

4.2 Testing

The testing dataset for the 2024 shared task was meticulously curated to present a substantial challenge beyond previous years' datasets. It comprised 1000 samples for each language pair, spanning four distinct and diverse domains: News, Travel, Sports, Entertainment, and Business. This domain-specific distribution aimed to comprehensively evaluate models' performance across varied and complex linguistic contexts, reflecting real-world translation demands. A collaborative approach was employed to create these testing samples, involving four specialized teams, each dedicated to one domain. These teams were provided 1000 English sentences, which they translated into their assigned target languages. The translation teams were instructed to maintain high fidelity to the source mate-

[3] https://data.statmt.org/wmt23/indic-mt/

Language Pair	Domain	Source Sentences	Target Sentences	Task
en-as	Sports and Travel	500	500	English to Assamese
en-lus	Sports and Travel	500	500	English to Mizo
en-kha	Sports and Travel	500	500	English to Khasi
en-mni	Sports and Travel	500	500	English to Manipuri
en-as	Entertainment and Business	500	500	Assamese to English
en-lus	Entertainment and Business	500	500	Mizo to English
en-kha	Entertainment and Business	500	500	Khasi to English
en-mni	Entertainment and Business	500	500	Manipuri to English

Table 3: Domain-specific distribution of the test dataset for each language pair.

rial while ensuring the translations were idiomatic and contextually appropriate for each domain.

The test set release process was intentionally staged to introduce additional complexity and rigour. In the first phase, 500 English sentences were released, requiring participants to translate these into the target languages. This forward translation task required participants to demonstrate their models' proficiency in capturing nuances and domain-specific terminology in the target languages. In the second phase, 500 sentences in the target languages were provided, requiring translation back into English. This reverse translation task assessed the models' ability to accurately render the meaning, tone, and subtleties of the original sentences in English, thus testing bidirectional translation capability. The combined forward and reverse tasks aimed to evaluate the accuracy, fluency, and idiomatic correctness of the translations. The careful selection of diverse domains and the structured release of the test set was intended to challenge the generalization capabilities of the participating models. The goal was to ensure that only the most robust models, capable of handling a wide range of real-world scenarios, would excel.

This approach ensures a rigorous and multi-faceted evaluation, capturing the subtleties of each language pair's translation performance across different domains.

5 Participants and System Descriptions

In this shared task, total of 12 teams registered and contributed, as indicated in table 8, the released dataset have been distributed among participants. In table 7, we have compiled the system outputs submitted by participants, encompassing both primary and contrastive submission types.

DLUT-NLP (Ju et al., 2024)**:** The participant for low-resource translation tasks involving English-Assamese, English-Mizo, English-Khasi, and English-Manipuri language pairs. It utilized a transformer-based model, with monolingual data for pre-training and parallel data for fine-tuning. Enhancements included back-translation, oversampling, and model averaging, along with knn-mt technology during inference, supported by a datastore created from parallel data.

Language Pair	Submissions
English - Assamese	11 (primary), 6 (contrastive)
English-Mizo	10 (primary), 5 (contrastive)
English-Khasi	10 (primary), 6 (contrastive)
English-Manipuri	10 (primary), 6 (contrastive)

Table 4: Number of participants in the low-resource Indic language translations

A3-108 (Yadav et al., 2024)**:** The team tackled low-resource machine translation by implementing control mechanisms in transformer-based NMT models. They encoded the target sentence length as a control token in the source sentence for eight language pairs: English-Assamese, Manipuri, Khasi, and Mizo. Four variations of this encoding were tested against baseline models. Two systems were submitted for each language pair: a primary system using control tokens based on the target-to-source token length ratio, and a contrastive baseline system without control tokens. All models were trained on the provided dataset.

SRIB-NMT (Patil et al., 2024)**:** The team participated in the WMT-24 challenge for translating English to four low-resource Indic languages. They used transformer models for both their primary and contrastive systems. The primary system involved pre-training language models on large amounts of text data before fine-tuning them for translation. The contrastive system improved upon this by further fine-tuning a pre-trained translation model using a technique called LoRA, resulting in better translation quality.

YES-MT (Bhaskar and Krishnamurthy, 2024)**:**

The team participated, focusing on four language pairs: English to Assamese, Khasi, Manipuri, and Mizo. Their primary systems used Transformer models trained from scratch. In contrast, contrastive systems applied transfer learning with fine-tuning techniques like LoRA and Supervised Fine-Tuning (SFT) on pre-trained models such as IndicTrans2 and LLaMA 3. Their experiments explored the effectiveness of these approaches, including quantization, in enhancing translation quality for low-resource languages.

HW-TSC (Wei et al., 2024)**:** The team participated in the WMT-24 challenge for translating English to four low-resource Indic languages. They used transformer models for both their primary and contrastive systems. The primary system involved pre-training language models on large amounts of text data before fine-tuning them for translation. The contrastive system improved upon this by further fine-tuning a pre-trained translation model using a technique called LoRA, resulting in better translation quality.

CycleL (Sören Dréano, 2024)**:** The team developed a novel self-supervised Neural Machine Translation (NMT) model called CycleGN. Unlike traditional NMT models, CycleGN doesn't require parallel data. It utilizes Cycle Consistency Loss (CCL) and Masked Language Modeling (MLM) for training. The model was tested on low-resource language pairs Spanish-Aragonese and Spanish-Asturian using PILAR datasets as part of the WMT24 Shared Task. Despite computational challenges and early training termination, the results demonstrated the potential of self-supervised learning for low-resource translation scenarios.

NLIP_Lab-IIITH (Sahoo et al., 2024)**:** The participated team aiming to improve Manipuri and Khasi translations. They utilized mBART and IndicTrans2 models as baselines, incorporating data augmentation techniques like backtranslation and data filtering with fine-tuned LaBSE. Despite limited data, iterative fine-tuning on enhanced datasets led to significant improvements in translation quality, as measured by BLEU, chrF, and TER metrics.

MTNLP-IIITH (P M et al., 2024)**:** The team tackled the WMT24 Low-Resource Indic NMT challenge for Manipuri and Khasi, employing mBART and IndicTrans2 models. To overcome data scarcity, they implemented backtranslation and LaBSE-based data filtering. Despite computational constraints, iterative fine-tuning on the processed data yielded substantial enhancements in translation quality as assessed by BLEU, chrF, and TER metrics.

SPRING-IITM (Sayed et al., 2024)**:** The team developed a robust translation model for four low-resource Indic languages: Khasi, Mizo, Manipuri, and Assamese. They expanded their training corpus using back translation on monolingual datasets and fine-tuned the pre-trained NLLB 3.3B model for Assamese, Mizo, and Manipuri, achieving superior performance over the baseline. For Khasi, they introduced special tokens and trained the model on a custom Khasi corpus, demonstrating significant improvements in translation quality for all four languages.

JUNLP: The participant focused on developing a translation system for four low-resource Indic languages: Assamese, Manipuri, Mizo, and Khasi, which are widely spoken in India's North Eastern zone. They combined all language data into a single system using Transformer architecture, enabling translation from English to any of these languages within the same framework. Their approach addresses the challenges posed by the scarcity of data for these languages.

SRPH-LIT (Roquea et al., 2024)**:** The team from Samsung R&D Institute Philippines joined the WMT 2024 Low-Resource Indic Language Translation task, focusing on the translation of the following pairs: English ⇔ Assamese, English ⇔ Mizo, English ⇔ Khasi, and English ⇔ Manipuri. In both directions, they adopt the standard sequence-to-sequence Transformer model for translation. The following techniques are data augmentation by back-translation, noisy channel reranking, and checking a multilingual model, which is trained on all the combined language pairs.

ADAPT-MT (Gajakos et al., 2024)**:** The ADAPT-MT team participated in the WMT 2024 Low-Resource Indic Language Translation task, focusing on Assamese-to-English and English-to-Assamese. They leveraged Large Language Models (LLMs) as their base systems, employing strategies like fine-tuning with WMT data, few-shot prompting, and efficient data extraction techniques to enhance translation quality. Their approaches were evaluated using BLEU, ChrF, WER, and COMET metrics, showing effective improvements in translating low-resource languages.

Table 5: The following table provides an overview of the teams registered for the low-resource Indic language translation task at WMT24 and the datasets provided to them. Participation varied across different language pairs, and only 12 teams in bold completed submissions of both system outputs and system descriptions.

6 Results and Discussion

Results for both directions of the four language pairs in WMT 2024 are detailed as follows: English-Assamese in Table 6, English-Mizo in Table 10, English-Khasi in Table 12, and English-Manipuri in Table 8. This section provides the evaluation scores for teams that submitted system outputs and corresponding papers.

Quantitative results are evaluated using established metrics: BLEU, TER, RIBES, ChrF, and METER. BLEU measures the precision of n-grams in candidate translations relative to reference translations. TER quantifies the number of edits required to align the candidate translation with the reference. RIBES evaluates the correlation between the rank orders of words in candidate and

Table 8: Performance of teams in the WMT24 low-resource Indic language translation task for the English-Manipuri language pair, measured across multiple metrics.

reference translations. ChrF assesses the character n-gram F-score, and METER offers a learned metric for translation quality evaluation.

Furthermore, linguistic experts proficient in the target language pairs were engaged for manual evaluations. Twenty sample sentences from the primary submission type were randomly selected for each language pair. Human evaluators assessed the candidate translations based on three criteria: adequacy, fluency, and overall rating. Adequacy gauges how well the candidate translation captures the meaning of the reference. Fluency assesses whether the candidate translation constitutes a well-formed sentence in the target language, independent of its correspondence to the reference. Overall rating integrates both adequacy and fluency to comprehensively evaluate translation quality.

For example, if the reference translation is “The cat sat on the mat,” a candidate translation such as “The feline rested on the carpet” is deemed adequate as it preserves the meaning of the reference. In contrast, a candidate translation like “The cat ran across the street,” although fluent, is considered inadequate due to the introduction of new information not present in the reference.

The human evaluation parameters are rated on a scale of 0–5, with higher scores reflecting superior quality. The final adequacy, fluency, and overall rating scores are the average ratings assigned to individual test sentences.

Discussion

For the English-Assamese language pair team, SPRING-IITM achieved a high BLEU score, low TER and an overall rating of 4.6 in the human evaluation. They expanded their training corpus using back translation on monolingual datasets and fine-tuned the pre-trained NLLB 3.3B model. For the Assamese-English language pair team, HW-TSC reaches a higher BLEU score, which is even more than the en-as pair, lower TER and team ADAPT-MT gains a higher overall rating of 4.8 in human evaluation.

For the English-Manipuri language pair team, NLIP_Lab_IIITH achieved a higher BLUE score in automatic evaluation and overall rating in human evaluation compared to the other teams. They utilized mBART and In-dicTrans2 models as baselines, incorporating data augmentation techniques like back translation and data filtering with fine-

Table 13: Human evaluation results for teams in the WMT24 low-resource Indic language translation task for the English-Khasi language pair, based on Adequacy, Fluency, and Overall Quality scores.

tuned LaBSE.Team HW-TSC achieved higher BLEU score as well as overall rating in human evaluation for the Manipuri-Englishwhich is significantly higher when compared to the en-mni language pair. They employed a contrastive system which improved upon this by further fine-tuning a pre-trained translation model using a technique called LoRA, resulting in better translation quality.

For the English-Mizo language pair team, SPRING-IITM outperforms all the teams in both directions of the language pairs with higher BLEU and overall ratings in human evaluation. The team developed a robust translation model for four low-resource Indic languages: Khasi, Mizo, Manipuri, and Assamese. They expanded their training corpus using back translation on monolingual datasets and fine-tuned the pre-trained NLLB 3.3B model.

Team SPRING-IITM surpassed all the teams in for the both directions of the language pairs for English-Khasi in automatic and human evaluation. They expanded their training corpus using back translation on monolingual datasets and fine-tuned the pre-trained NLLB 3.3B model. For Khasi, they introduced special tokens and trained the model on a custom Khasi corpus.

Conclusion

The outcomes of the participating teams in the WMT 2024 translation task for four language pairs have been meticulously evaluated using both automated and human metrics. This year's shared task on low-resource Indic language translation utilised the IndicNE-Corp1.0 dataset from WMT 2023, while a newly developed test set was introduced, characterized by a higher difficulty level than the previous year. This enhanced test set aims to better assess the translation capabilities of the models across the participating languages.

The dataset features four under-resourced languages—Assamese, Mizo, Khasi, and Manipuri—from the northeastern region of India. Future initiatives will focus on expanding the dataset by adding more northeastern Indic languages and increasing the corpus size.

We will be incorporating additional languages in the next iteration of the shared task, including English ⇔ Nyishi (en-nshi), English ⇔ Bodo (en-bodo), English ⇔ Mising (en-mrp), and English ⇔ Kokborok (en-trp). This expansion aims to enhance the scope of linguistic diversity, allowing participants to engage with a broader range of low-resource languages.

Acknowledgements

Gratitude is extended to all participants for their active and enthusiastic engagement in this shared task. Appreciation is also expressed to the organisers and reviewers of the Ninth Conference on Machine Translation (WMT) 2024. We also appreciate the Center for Natural Language Processing (CNLP) & Artificial Intelligence (AI) laboratories resources and the research atmosphere at the Dept of CSE, NIT Silchar.

Abstract

This paper presents the findings of the WMT 2024's MultiIndic22MT Shared Task, focusing on Machine Translation (MT) of 22 Indian Languages. In this task, we challenged participants with building MT systems which could translate between any or all of 22 Indian languages in the 8th schedule of the Indian constitution and English. For evaluation, we focused on automatic metrics, namely, chrF, chrF++ and BLEU.

1 Introduction

India is a linguistically diverse region, with 1,369 distinct natively spoken languages which were identified in the census conducted in 2011. Among these native languages, 22 have been listed in the 8^{th} Schedule of the Constitution of India. Furthermore, about 97% of the population of India speaks one of these 22 languages as their first language in their daily lives. It is important to note that English is widely spoken and serves as the default medium of formal communication in many areas, particularly in business, education, government, and judiciary. However, the percentage of the population speaking English is approximately 10% and in the interest of smooth and clear communication, the importance in India of language translation for effective communication, social inclusion, equitable access, and national integrity cannot be over-emphasized.

Having established that Indian language MT is important, the only way to improve it is via active involvement from MT researchers and MT system developers to push the boundaries of translation quality. To this end, we offered the first of its kind shared task focusing on MT for all 22 scheduled Indian languages. Over half a decade ago, in the Workshop on Machine Translation 2018 (WAT 2018) (Nakazawa et al., 2018), the organizers introduced the IndicMT task for the first time spanning covering 7 Indic languages. Over the years they gradually added languages in WAT from 2018 to 2023 (Nakazawa et al., 2019, 2020, 2021, 2022, 2023), with WAT 2023 boasting 19 Indian languages. Over the years, with the increasing number of languages and datasets for Indian languages, these tasks have garnered growing attention, however the challenge still remains since Indian languages are still resource poor in comparison with European languages.

This year the multilingual Indian languages MT task, referred to as MultiIndic22MT, is hosted under the Ninth Conference on Machine Translation (WMT24) and for the first time ever, the task spans all 22 scheduled languages of India belonging to 4 language families and written in 12 scripts. The languages exhibit both genetic and contact relatedness (Kunchukuttan et al., 2018). Some of these languages are extremely low-resource. This diversity makes this language group ideal for studies in multilingual learning, language relatedness and low-resource MT. Our primary goal behind having this shared task was to attract both researchers and developers to identify effective practices for pushing the quality of Indian language Machine Translation, especially for the lower resourced languages. Our secondary goal was also to identify some interesting but yet unexplored practices, even if they do not lead to state-of-the-art MT performance.

2 MultiIndic22MT Shared Task

The task covered English and 22 Indic Languages, as follows:

1. Assamese
2. Bengali
3. Bodo
4. Dogri

Proceedings of the Ninth Conference on Machine Translation, pages 669–676
November 15-16, 2024 ©2024 Association for Computational Linguistics

5. Konkani
6. Gujarati
7. Hindi
8. Kannada
9. Kashmiri (Arabic script)
10. Maithili
11. Malayalam
12. Marathi
13. Manipuri (Meitei script)
14. Nepali
15. Oriya
16. Punjabi
17. Sanskrit
18. Santali
19. Sindhi (Devanagari script)
20. Tamil
21. Telugu
22. Urdu.

We evaluated user submissions on 44 translation directions (English-Indic and Indic-English). We also evaluate the performance of 5 Indic-Indic pairs: Bengali-Hindi, Tamil-Telugu, Hindi-Malayalam and Sindhi-Punjabi. We encouraged the use of multilingualism and transfer-learning by leveraging monolingual data, back-translation and (potentially) LLMs, to develop high quality systems. Although the intention is to have users develop multilingual systems and submit translations for all directions, we also welcomed submissions for specific language pairs. The link to the shared task page is here[1].

3 Datasets and Pre-trained Models

For this shared task, we prepared a fairly extensive list of resources for the participants to train their MT systems. We also describe the evaluation sets.

3.1 Datasets

We allowed participants to use existing mined as well as back-translated parallel data along with monolingual data.

Parallel Data: As a source of parallel corpora, we recommended using the Bharat Parallel Corpus Collection (BPCC) dataset[2] (Gala et al., 2023) which spans all 22 languages in the shared task. BPCC is a comprehensive and publicly available parallel corpus that includes both existing and new data for all 22 scheduled Indic languages. It comprises two parts: BPCC-Mined and BPCC-Human, totaling approximately 230 million bitext pairs. BPCC-Mined contains about 228 million pairs, with nearly 126 million pairs newly added as a part of this work. On the other hand, BPCC-Human consists of 2.2 million gold standard English-Indic pairs, with an additional 644K bitext pairs from English Wikipedia sentences (forming the BPCC-H-Wiki subset) and 139K sentences covering everyday use cases (forming the BPCC-H-Daily subset). It is worth highlighting that BPCC provides the first available datasets for 7 languages and significantly increases the available data for all languages covered. Note that one may pivot via English to obtain Indic-Indic parallel corpora.

Parallel Back-translated Data: Additionally, BPCC also contains back-translation data generated by intermediate checkpoints of IndicTrans2 (Gala et al., 2023) models for training purposes. This data consists of English original sentences translated to 22 Indic languages for a total of 401.9M back-translated sentences and Indian language original sentences translated to English for a total of 400.9M back-translated sentences. The mined, human curated and back-translated corpora represent an extensive training dataset which we expect will be sufficient for training MT systems of reasonable quality.

Monolingual Data: We also recommended the use of monolingual data from Varta[3] (Aralikatte et al., 2023), IndicCorp v2[4] (Doddapaneni et al., 2023) and Sangraha[5] (Khan et al., 2024) corpora. Sangraha subsumes IndicCorp v2 but does not explicitly include Varta. Sangraha covers 22 languages, containing a total of 251B tokens, of which con-

tains verified[6] (64B), unverified[7] (24B), and synthetic[8] (162B) tokens. On the other hand, Varta spans only 9B tokens and belongs to the NEWS domain, whereas Sangraha spans multiple domains. Our evaluation sets, which we will describe later, are multi-domain (including news) and hence we expected Sangaraha to be a better source but could not neglect Varta due to its domain specificity and high quality.

3.2 Pre-trained Models

In addition to datasets, following recently followed trends in shared tasks, we encouraged participants to leverage one or all of the following publicly available models for fine-tuning or synthetic data generation:

IndicTrans2 (Gala et al., 2023): This consists of the 3 IndicTrans2 models, one-to-many, many-to-one, and many-to-many, for English to Indic, Indic to English and Indic to Indic translation. These are the current state-of-the-art open-source MT systems, and we encouraged participants to build on top of these models to improve performance, especially for the lower resourced languages like Santali, Sindhi, Bodo, Dogri, Konkani, Kashmiri, Maithili and Manipuri.

mT5 (Xue et al., 2021): mT5 is a well known pre-trained model which supports half of the Indian languages in this shared task. However, it is only pre-trained and not fine-tuned for MT and is more suitable for focused domain specific fine-tuning investigations.

IndicBART (Dabre et al., 2022): IndicBART is a small pre-trained model for 11 Indic languages and English which, when fine-tuned, is known to outperform mBART (Liu et al., 2020) and give comparable performance as a mT5, despite both models being twice its size.

VartaT5 (Aralikatte et al., 2023): This is a T5 model specific for Indic languages and is analogous to IndicBART.

BLOOM (Workshop et al., 2023): BLOOM is a family of decoder only pre-trained models supporting 44 languages, some of them being a subset of the Indian languages we focus on in this shared task. Model sizes range from 500 million parameters to 176 billion parameters. However, BLOOM is known to be an under-trained model, and thus we expected participants to focus more on using Gemma.

Gemma (Team et al., 2024): Is another family of decoder only models with 2 and 7 billion parameters. Gemma is theoretically capable of tokenizing all 22 Indian languages of this task but its primary support is more in favor of the higher resource languages like Hindi, Marathi, Bengali, etc. We expected that participants would explore some prompting approaches on top of Gemma to determine its viability for Indian language translation.

4 Submission Criteria

We expected two types of submissions: Constrained and Unconstrained. Constrained submissions were those which used the data and models stipulated by the organizers explicitly. Unconstrained submissions were those where any other data or models were used without confirmation from the organizers. Furthermore, we encouraged primary and contrastive submissions, where participants could submit one Primary (ranked) and one Contrastive (unranked, optional).

5 Evaluation Sets and Metrics

Evaluation Sets: We provide participants with a validation set and 3 test sets. The validation set is an extension of FLORES-200 for the 22 Indian languages[9], as described in Gala et al. (2023) and consists of 997 23-way sentences. As for the test sets, 2 out of 3 are publicly available and one is a hidden test set. The publicly available sets are In22-Conv[10] and In22-Gen[11] spanning 1,503 and 1,024 23-way parallel sentences, for the conversational and general styles, respectively. The hidden test set was originally described in Chitale et al. (2024) and is an Indic language original test set where Indic sentences were translated into English by linguists. This is different from all other test sets which are English original and were translated into Indic languages. This hidden test set was released to the participants 2 weeks before the deadline and unlike In22-Conv and In22-Gen, the references

[6] The URLs of webpages from which the corpora were crawled were manually verified by linguists.

[7] The urls of webpages from which the corpora were crawled were unverifiable.

[8] These were obtained by translating English documents into Indian languages.

[9] https://indictrans2-public.objectstore.e2enetworks.net/flores-22_dev.zip

[10] https://huggingface.co/datasets/ai4bharat/IN22-Conv

[11] https://huggingface.co/datasets/ai4bharat/IN22-Gen

were kept hidden. This test set covered only 13 of the 22 Indic languages namely, Assamese, Bengali, Bodo, Gujarati, Hindi, Kashmiri, Malayalam, Nepali, Santali, Sanskrit, Sindhi, Telugu and Urdu. While we asked participants to work on translation to and from English for In22-Conv and In22-Gen, for the hidden test set, only translation from Indic to English direction was possible in order to keep the test set hidden[12].

Evaluation Metrics: We asked participants to submit their translations to us which we would then evaluate using BLEU (Papineni et al., 2002), chrF (Popović, 2015) and chrF++ (Popović, 2017) using sacreBLEU[13] (Post, 2018). We follow the appropriate tokenization of Indic languages as done by Gala et al. (2023) before computing scores.

6 Participants and Submissions

Although 32 teams had registered initially, only 4 teams ended up submitting systems and 3 submitted system description papers (1 withdrew). The teams and their submitted systems are as follows:

6.1 BV-SLP Team

The BV-SLP team (Joshi et al., 2024), short for the Banasthali Vidyapith Speech and Language Processing Lab, focused on Sindhi to English translation and only submitted translations for the hidden test set. Their approach focuses on special handling of named entities. They first extract named entities from the source Sindhi sentence and translate it first using a knowledge base of Sindhi-English named entity pairs. This intermediate output is then translated using a NMT system, which is trained to retain the translated named entities and only translate the Sindhi part. To develop the NMT system itself, they converted the existing Sindhi-English parallel corpus into a form where the Sindhi sentences had their named entities replaced with their English translations. This pre-translation approach is well known to work well for handling named entities. They used two approaches for translation itself, one (Primary) where Sindhi is directly translated into English and one (Contrastive) where Sindhi is first translated into Hindi and then into English.

6.2 NITS-CNLP Team

The NITS-CNLP team (Singh et al., 2024), short for the National Institute of Technology Silchar's Centre for Natural Language Processing, focused on English to Manipuri translation and submitted a primary and a contrastive system. Their approach was rather straightforward, where they used the English-Manipuri data from BPCC (Gala et al., 2023) and trained a transformer model. They submitted results for the In22-Conv and In22-Gen test sets. They also performed some manual evaluations.

6.3 NLIP-Lab Team

The NLIP-Lab (Brahma et al., 2024), short for the Natural Language and Information Processing Lab, was the only team that went all out and submitted translations for all translation directions and test sets. The NLIP-Lab team use an approach based on pre-training models using codemixed data which was synthetically created. Specifically, they take BPCC parallel data and replace words in English sentences with semantically similar words of the target Indic language sentences. They then pre-train a model with both the original and code-mixed data. They further refine their pre-trained model with original and code-mixed data obtained only from the high quality BPCC-seed datasets. Finally, they fine-tune their models only on the seed datasets without the code-mixed counterparts. They hypothesized that this leads to fairly strong MT systems.

7 Results and Findings

Overall, the NLIP-Lab team got 1st rank for all language pairs, directions and test sets, including In22-Conv, In22-Gen and the hidden test set for Indic to English translation.

7.1 Sindhi to English Translation

NLIP-Lab had a contender in the form of BV-SLP team for Sindhi to English translation but where the primary system of BV-SLP got BLEU, chrF and chrF++ scores of 19.4, 44.6 and 43.0, respectively. NLIP-Lab translations scored BLEU, chrF and chrF++ scores of 21.2, 47.1 and 45.5, respectively. This showed that NLIP-Lab's RASP pre-training and fine-tuning approach was definitely better than the named entity handling approach. The likely explanation was that NLIP-Lab used a

[12] Asking for English to Indic translation meant that we would have to release English sentences too and this would lead to the test set references being exposed.

[13] https://github.com/mjpost/sacrebleu

lot more parallel data and trained a larger model than their competitior.

7.2 English to Manipuri Translation

Once again, NLIP-Lab's contender for the English to Manipuri task was the NITS-CNLP lab. This was for the In22-Conv and In22-Gen test sets. NITS-CNLP got BLEU, chrF and chrF++ scores of 6.4, 28.6 and 26.6 for In22-Conv and 8.1, 32.1 and 29.4 for In22-Gen. However, NLIP-Lab got better scores of 15.2, 43.6 and 41.1 for In22-Conv and 18.2, 48.0 and 45.0 for In22-Gen. This shows that NLIP-Lab's systems are substantially better. However, this is to be expected given that NITS-CNLP did not train massively multilingual models and the latter did.

7.3 Did NLIP-Lab Beat IndicTrans2?

Unfortunately, NLIP-Lab's systems did not beat IndicTrans2. For the Indic to English directions, IndicTrans2 was almost 10 BLEU better on In22-Gen and almost 4 BLEU better on In22-Conv. For the English to Indic directions, however, the gap narrowed down to about 2 BLEU. This implies that despite IndicTrans2 being trained on significantly larger data (mostly backtranslated) and in multiple stages, its performance can still be approached by systems not leveraging massive amounts of data. This highlights then need for investigating better approaches for translating into Indic languages. As a side note, these same observations hold for Indic to Indic translation.

8 Conclusion

In this report we present the findings of the MultiIndic22MT shared task for machine translation involving 22 Indian languages. Despite the initial enthusiasm shown by participants during task registration, only 3 out of 32 teams submitted their translations and system description papers. Of these 3, only NLIP-Lab submitted translations for all directions and got first rank for all their submissions. Approaches explored varied from named entity replacement, pivot language translation (using Hindi as a pivot), code-mixed pretraining and training from scratch. Overall, code-mixed pre-training stood tall and led to the best systems. However, none of the systems could still beat IndicTrans2, indicating that there is much effort needed for pushing the state of the art for translation involving Indian languages. Given the advent of LLMs and the focus on decoder-only architectures which are well suited for document level MT, we expect that the next batch of innovations will be focused on the same. However, most LLMs dont support Indic languages that well and thus participants may have to resort to using approaches like transliteration to bridge the gap or even reduce it between the type of scripts that LLMs have seen and those that they have not (J et al., 2024; Dabre et al., 2020, 2022; Gala et al., 2023). We hope that more people will participate in another iteration of this task with interesting approaches.

Abstract

This paper presents the results of the English-to-Low Resource Multimodal Translation shared tasks from the Ninth Conference on Machine Translation (WMT2024). This year, 7 teams submitted their translation results for the automatic and human evaluation.

1 Introduction

The Ninth Conference on Machine Translation (WMT24), held in conjunction with EMNLP 2024, hosted a number of shared tasks covering various aspects of machine translation (MT). This conference builds on 17 previous editions of WMT as a workshop or a conference. This year, Workshop on Asian Translation (WAT), the most recognized shared task campaign on Asian languages, merged with WMT, adding many new shared tasks to the venue.

Multi-modal translation, which involves incorporating non-text sources alongside text input for machine translation, has gained attention in the past years (Specia et al., 2016; Elliott et al., 2016). However, research in this area has focused on European languages such as English, German, French, Czech, and mainly used two datasets: Flickr30k (Young et al., 2014) and MS-COCO (Lin et al., 2014), where the text caption corresponds to the content of the associated image.

We organized the WMT2024 English-to-LowRes Multimodal Shared Task for Low-Resource Asian and African languages. One important difference is that in our setting, the text caption is attached to a rectangular region of the picture and not the picture as a whole. This approach provides an interesting opportunity to consider not only the broader image but also the localized visual context surrounding the described region, which may provide additional cues for more accurate translation.

2 Task and Datasets

In this task, participants were provided with corpora from the Visual Genome dataset in four target language: Hindi, Bengali, Malayalam, and Hausa. The specific datasets are: Hindi Visual Genome 1.1 (HVG, Parida et al., 2019)[1] for Hindi; Bengali Visual Genome (BVG, Sen et al., 2022)[2] for Bengali; Malayalam Visual Genome (MVG, Parida and Bojar, 2021)[3] for Malayalam; and Hausa Visual Genome (HaVG, Abdulmumin et al., 2022)[4] for Hausa. The datasets are split into train, test, dev and challenge test in a parallel fashion. The number of sentences in each split is provided in Table 1. Each split contains items consisting of an image, a highlighted rectangular region within the image ($x, y, width, height$), the original English caption for this region, and the reference translation in the respective target language. These components are illustrated in Figure 1. Depending on the task track, some of these components serve as the source, while others act as references or competing candidate solutions. The specific tracks for this task are listed below.

2.1 Text-Only Translation

Labeled "TEXT" in WAT official tables, participants translate short English captions into the target language without using visual information. Additional textual resources are allowed but must be documented in the system description paper.

2.2 Captioning

Labeled with the target language code, e.g., "HI," "BN," "ML," "HA", participants generate captions

Figure 1: Example of a Data Point (Image Id, Region Detail, Source, and Target Languages

in the target language for the highlighted rectangular region in the input image.

2.3 Multi-Modal Translation

Labeled "MM", given an image, a rectangular region within it, and an English caption for that region, participants translate the caption into the target language. Both textual and visual information are available for this task.

3 Evaluation Methods

3.1 Automatic Evaluation

We evaluated translation results by two metrics: BLEU (Papineni et al., 2002), and RIBES (Isozaki et al., 2010). BLEU scores were calculated using SacreBLEU (Post, 2018). RIBES scores were calculated using `RIBES.py` version 1.02.4.[5] All scores for each task were calculated automatically using the corresponding reference translations by the evaluation system through which the participants make their submissions.

Automatic Evaluation System The automatic evaluation system receives translation results by participants and automatically gives evaluation scores to the uploaded results. As shown in Figure 2, the system requires participants to provide the following information for each submission:

- Human Evaluation: whether or not they submit the results for human evaluation;
- Publish the results of the evaluation: whether or not they permit to publish automatic evaluation scores on the WAT2024 web page;
- Task: the task to which the results belong;
- Used Other Resources: whether or not they used additional resources; and
- Method: the type of the method including SMT, RBMT, SMT and RBMT, EBMT, NMT and Other.

Evaluation scores of translation results that participants permit to be published are disclosed via the WAT2024 evaluation web page. Participants can also submit the results for human evaluation using the same web interface. This automatic evaluation system will remain available even after WMT-WAT2024.

3.2 Human Evaluation

In WMT2024, we conducted **JPO adequacy evaluation**.

JPO adequacy evaluation The evaluation was carried out by translation experts based on the JPO adequacy evaluation criterion, which was originally defined by Japan Patent Office to assess the quality of translated patent documents.

Sentence selection and evaluation For the JPO adequacy evaluation, the 200 test sentences were randomly selected from the test sentences. For each test sentence, input source sentence, translation by participants' system, and reference translation were shown to the annotators. To guarantee the quality of the evaluation, each sentence was evaluated by two annotators. Note that the selected sentences are basically the same as those used in the previous workshop.

Evaluation Criterion Table 2 shows the JPO adequacy criterion from 5 to 1. The evaluation is performed subjectively. "Important information" represents the technical factors and their relationships. The degree of importance of each element is also considered in evaluating. The percentages

Table 2: The JPO adequacy criterion

in each grade are rough indications for the transmission degree of the source sentence meanings. The detailed criterion is described in the JPO document (in Japanese).[6]

4 Baseline Systems

Human evaluations were conducted as pairwise comparisons between the translation results for a specific baseline system and translation results for each participant's system. That is, the specific baseline system served as the standard for human evaluation.

At WMT2024, we adopted some of neural machine translation (NMT) as baseline systems. The NMT baseline systems consisted of publicly available software, and the procedures for building the systems and for translating using the systems were published on the WAT web page.

Tokenization The shared task datasets come untokenized and we did not use or recommend any specific external tokenizer. The standard OpenNMT-py sub-word segmentation was used for pre/post-processing for the baseline system and each participant used what they wanted.

NMT Methods We used the NMT models for all tasks. For the English→Hindi, English→Malayalam, and English→Bengali Multimodal tasks we used the Transformer model (Vaswani et al., 2018) as implemented in OpenNMT-py (Klein et al., 2017) and used the "base" model with default parameters for the multimodal task baseline. We have generated the vocabulary of 32k sub-word types jointly for both the source and target languages. The vocabulary is shared between the encoder and decoder.

5 Participating Teams and Results

We describe the teams' profiles and submissions as described in their respective description papers. Table 3 shows the team IDs, their respective organizations, and countries.

5.1 Systems' Descriptions

DCU_NMT participated in the English-to-Hindi track only, developing both text-only and multimodal neural machine translation (NMT) systems. They trained the text-only models from scratch on constrained data and further enhanced them with back-translated data. For the multimodal approach, they used a context-aware transformer to integrate visual features by first encoding the image captions with a BERT model and then concatenating them with the textual input. They reported that while the back-translated text-only model achieved the best performance overall, the multimodal systems, despite lacking back-translated data, outperformed the text-only baseline, indicating the potential of visual context. However, their findings revealed that the impact of visual features was inconsistent, showing less effectiveness on the challenge set, highlighting the need for further exploration into effective multimodal integration.

ODIAGEN participated in and reported results for all the tracks, including both text-only and multimodal translation. For text-only translation, they trained the Mistral-7B (Jiang et al., 2023) model to handle English to multiple low-resource languages: Hindi, Bengali, Malayalam, and Hausa. In the multimodal English-to-Hindi task, they employed the PaliGemma-3B (Beyer et al., 2024) model, integrating both image and text inputs. However, their findings revealed that the multimodal systems were suboptimal due to improper normalization of location coordinates, which hindered the models ability to map these coordinates accurately to the provided images. While the PaliGemma-3B model demonstrated strong performance in text translation tasks, it struggled to leverage visual context effectively, underscoring the importance of refining multimodal techniques for better accuracy.

Arewa_NLP participated in the English-Hausa text-only translation task, fine-tuning the OPUS-MT-en-ha transformer model. While the system performed well on standard test set, it struggled with the more complex content in the Challenge Test, suggesting a need for further training.

v036 participated in the English-to-Indic tracks only with the help of visual context. They utilized InternVL2 (Chen et al., 2023) to extract features from the marked image region, which was then passed into a Rapid Automatic Keyword Extraction (RAKE) algorithm to generate keywords for use as hash-tags to provide context to the source text. They then used an LLM (Llama 405B) to generate chain-of-thoughts prompts, consisting the original source and target sentences, extracted keywords as hash-tags and some reasoning why that translation was generated, that serve as training data. Finally, they fine-tuned Llama 8b Instruct model, one for each language, on the generated prompts. They reported that although their predictions were mostly correct, the model failed to generate similar translations as the ground truth, indicating the need for human evaluation as the best method to assess the quality of the translations.

Brotherhood participated in all the tracks, leveraging LLMs such as GPT-4o and Claude 3.5 Sonnet to enhance cross-lingual image captioning without traditional training or fine-tuning (Betala and Chokshi, 2024). They used instruction-tuned prompting to generate contextual conversations around cropped images, incorporating the original English captions as context, and translated these conversations into target languages. They employed weighted prompting strategy to balance the original captions with the translated conversations for more descriptive outputs. They reported that their training-free approach minimizes error propagation from flawed datasets while offering flexibility in balancing source fidelity with descriptiveness, demonstrating promise for improving low-resource language datasets. However, they identified challenges such as dependence on LLM APIs, hallucination risks, computational demands, and the limitations of traditional metrics like BLEU for evaluating enriched descriptions, highlighting the need for more comprehensive evaluation methods.

UNLP participated in the English-to-Hindi, Malayalam, Bengali, and Hausa tracks. They used visual context to improve translation accuracy, employing a gated fusion mechanism to integrate visual information with textual data, combining the outputs of visual and textual encoders to create context-aware translations. For each language,

Team ID	Organization	Country

Arewa_NLP	FUTB, BUK, and Arewa Data Science Academy	Nigeria
v036	SCB DataX, Walmart Global Tech	Thailand, India
Brotherhood	Indian Institute of Technology Madras	India
UNLP	University of Galway, and Lua Health, Galway	Ireland
00-7	Krutrim AI	India

Table 3: List of participants who submitted translations for the WMT2024 English-to-LowRes Multimodal Translation Task

they fine-tuned their multimodal model on this combined input, ensuring a nuanced understanding of both linguistic and visual cues. The team reported that while their multimodal model consistently outperformed text-only baselines across BLEU, ChrF2, and TER metrics, some discrepancies with the ground truth translations highlight the importance of incorporating human evaluation for a more reliable assessment of translation quality.

00-7 competed in three tracks—Image Captioning, Text-only, and Multimodal Translation—for Indic languages, developing a multimodal model that integrates a multilingual LLM with a vision module for improved translation. Their method employs a ViT image encoder to extract visual token embeddings, which are projected into the LLM space through an adapter layer, generating translations autoregressively. They achieved state-of-the-art results for Hindi on the Challenge set, while remaining competitive for other languages. Despite the models success, they observed limited impact of the vision modality on translation quality.

5.2 Results

Automatic evaluation results Tables 4 to 8 present the automatic evaluation results of the submitted systems, indicating that the systems performed competitively against each other. Despite these promising results, participants expressed a need for human evaluations, as shown in subsequent tables. This reflects a common concern among participants who suspect that their systems may outperform the scores they received, underscoring the importance of qualitative assessments in conjunction with automatic metrics.

6 Conclusion and Future Directions

This paper presents an overview of the English-to-Low Resource Multimodal Translation shared tasks at WMT2024. The task attracted strong participation from numerous teams. Out of these, 7 teams submitted system description papers detailing their approaches and results. In the future, we aim to expand the range of low-resource languages, with a particular focus on multimodal translation, and encourage greater participation from more teams.

Abstract

This paper presents the results of the Ninth Conference on Machine Translation (WMT24) Shared Task "Translation into Low-Resource Languages of Spain". The task focused on the development of machine translation systems for three language pairs: Spanish–Aragonese, Spanish–Aranese, and Spanish–Asturian. 17 teams participated in the shared task with a total of 87 submissions. The baseline system for all language pairs was Apertium, a rule-based machine translation system that still performs competitively well, even in an era dominated by more advanced non-symbolic approaches. We report and discuss the results of the submitted systems, highlighting the strengths of both neural and rule-based approaches.

1 Introduction

In Spain, a diverse linguistic landscape exists, including, beyond the widely recognized Spanish, other languages such as Basque, Catalan, and Galician. Although Spanish is obviously at the forefront in terms of the volume of resources available for training data-driven machine translation (MT) systems, the capabilities and richness of the other languages should not be underestimated. Basque, Catalan, and Galician, which might have been considered limited in resources in the past, actually possess a significant amount of data that facilitate their integration into modern MT technologies. In fact, these three languages have been recently included among the list of up to 100 languages in well-known multilingual systems such as mBERT[1] (Devlin et al., 2019), XLM-R (Conneau et al., 2020), mBART (Liu et al., 2020), mT5 (Xue et al., 2021) or NLLB-200 (Costa-jussà et al., 2024). However, Spain is home to additional languages with much fewer resources, especially in the form of bilingual data. This task focuses on three of them, namely, Aragonese, Aranese, and Asturian, all of them Romance languages. In particular, participants were asked to submit MT systems from Spanish into any of these three languages.

An interesting fact about our three low-resource languages is that they have open rule-based MT systems available for the Apertium framework. Apertium (Forcada et al., 2011) is a free/open-source rule-based architecture for MT that consists of a pipeline of modules performing morphological analysis, part-of-speech tagging, lexical transfer, lexical selection, chunk-level or recursive structural transfer, and morphological generation.

Another important aspect is that the target languages of the shared task have undergone various orthographic conventions and standards, and the datasets, as well as the MT systems, available may not necessarily adhere to the current conventions adopted by the language academies and used in the test sets.

Submission platform. We utilized the open-source OCELoT platform[2] to collect translation submissions. The platform offers anonymized public leaderboards and has been employed in several previous WMT tasks. Submission privileges were restricted to registered and verified teams with accurate contact information, and each team was limited to a maximum of seven submissions per test set.

Main goals. The primary objectives of this shared task can be summarized as follows:

- To push the boundaries of MT system development when the amount of resources is extremely scarce.

- To explore the transferability among low-resource Romance languages when translating from Spanish.

[1] `https://huggingface.co/google-bert/bert-base-multilingual-cased`

[2] `https://github.com/AppraiseDev/OCELoT`

Proceedings of the Ninth Conference on Machine Translation, pages 684–698
November 15-16, 2024 ©2024 Association for Computational Linguistics

- To find the best way to use pre-trained models of any kind for the translation between Spanish and low-resource Romance languages.

- To create publicly available corpora for MT development and evaluation.

Main findings. The main conclusions of the shared task and insights gained are outlined next:

- The best systems result in automatic evaluation scores that are statistically significantly higher than the baseline system, namely, the Apertium rule-based system.

- However, the absolute differences in BLEU and chrF2 scores are not very large (up to 2 BLEU and 1 chrF2 points) in the case of Aragonese and Aranese, which suggests that the rule-based system may still play a role in the translation of these languages, given the fact that they are considerably less resource-hungry than the neural counterparts.

- In the case of Asturian, while the best systems generally maintain a similar range of differences with Apertium, there is one standout system that extends the gap significantly, achieving up to 5 BLEU and more than 3 chrF2 points higher. It is worth noting that this winning system primarily leverages a commercial large language model (LLM) through few-shot learning, sampling a new output if the LLM generates a translation that is unexpectedly short or long compared to the source. This underscores the increasing potential of cutting-edge LLMs and the implications for smaller, specialized systems, which may soon be outpaced by new models, even for low-resource languages like Asturian.

The structure of the paper is as follows. Sec. 2 provides an overview of the three target languages. Sec. 3 then outlines the different submission categories based on the resources used, whereas Sec. 4 describes the training data and resources provided to participants, as well as the development and test data used. Sec. 5 briefly describe the systems submitted within each category. The automatic evaluation results are then reported and discussed in Sec. 6. Finally, Sec. 7 concludes the paper with summarizing remarks.

2 Languages

Aragonese (Glottocode[3] `arag1245`), a Romance language mainly spoken in the Pyrenees valleys of Aragón, is primarily used in rural communities and among older generations; intergenerational transmission is severely at risk. It has around 25 000 speakers (Reyes et al., 2017, Table 5).[4] Although recognized as cultural heritage, it does not hold official status, which hampers its broader use and preservation. Despite these challenges, efforts to revitalize the language continue, supported by educational initiatives and cultural programs.

Aranese (Glottocode `aran1260`) is a variety of the Occitan language spoken in the Val d'Aran, Catalonia, where it holds official status alongside Catalan and Spanish. It is spoken by approximately 4 500 people (Generalitat de Catalunya, 2019, page 4), though its use has been declining due to the dominance of Spanish and Catalan in the region. Despite its small number of speakers, Aranese remains protected by local laws, and efforts to promote its use in education and public life are ongoing.

Asturian (Glottocode `astu1246`), another Romance language, is spoken by around 250 000 people (Llera Ramo, 2018, Figure 6) in Asturias, though it lacks official status. Like the other languages, Asturian is recognized and protected as cultural heritage, and there are efforts to increase its presence in schools and public life. Many speakers have a passive understanding of the language, and there is a strong cultural identity linked to it.

3 Submission Categories

Participants could submit their work in one of three categories,[5] depending on the corpora used, the models employed, and the reproducibility of the results: *constrained*, *open*, and *closed*.

Constrained submissions. These submissions are limited to using only the resources (corpora, dictionaries, Apertium-based systems or data, and orthographic conventions) listed in Section 4.1. Participants may also use publicly available pre-trained language or translation models, as long as their size does not exceed 1 billion parameters (1B),

[3] `https://glottolog.org`

[4] Here and in the following figures, we provide the data for the number of people who can speak the language, including those with even a basic level of proficiency.

[5] The organizers reserved the right to assign submissions to the appropriate category if there was any uncertainty.

as specified in their model cards.[6] This size restriction also applies to neural systems used for auxiliary purposes, such as generating synthetic data. The developed systems could be either bilingual or multilingual, and do not necessarily needed to cover all the target languages.

Open submissions. Submissions in this category can utilize any resources (corpora, pre-trained models, etc.) in any language, with no size restrictions, as long as the resources are publicly available under open-source licenses to ensure reproducibility. MT systems or large language models available online also fall into this category, provided that the resulting outputs are made available to the public.

Closed submissions. Closed submissions face no restrictions on the availability of resources (corpora, pre-trained models, etc.) used for training.

4 Data and Resources

This section describes the training corpora and resources provided to the participants for the *constrained* submissions (Sec. 4.1), as well as the development and test corpora used for all submission categories (Sec. 4.2).

4.1 Training Corpora and Resources

Training data. The shared task included a *constrained* submission category that restricted the resources participants could use to develop their systems, as outlined in Sec. 3. In addition to the FLORES+ dev set (see Sec. 4.2), which could be used for training or validation, participants in this category were provided with the following resources:

- Any resource from OPUS, particularly the largely uncurated resources available for Spanish–Aragonese,[7] Spanish–Occitan,[8] and Spanish–Asturian.[9] Using data from OPUS included monolingual data on the source or target sides or any other bilingual corpus.

- Data from the PILAR dataset (Galiano-Jiménez et al., 2024b), a collection of low-resource language corpora from the Iberian Peninsula. PILAR contains monolingual and parallel resources for research and development in Romance languages, with data for Aragonese (monolingual web crawled and literary texts), Aranese (bilingual Spanish–Aranese legal provisions from the Diari Oficial de la Generalitat de Catalunya, web crawled texts, and classic literary works), and Asturian (literary and popular science writings).

Systems submitted to the other categories (open and closed) could use the resources listed above, but they were not restricted to them.

Language identification. Participants also had access to tools such as Idiomata Cognitor (Galiano-Jiménez et al., 2024a), a highly accurate language identifier for the target languages and other Romance languages.[10]

Apertium data. For participants interested in integrating linguistic data into their systems or generating synthetic data, links were provided to Apertium's resources for Aragonese,[11] Spanish–Aragonese,[12] Aragonese–Catalan,[13] Spanish–Asturian,[14] Asturian,[15] Occitan–Spanish,[16] and Occitan–Catalan.[17]

Other MT systems. In addition to Apertium-based MT systems, participants were informed of other available MT systems, which could also follow different orthographic conventions to those used in the test sets: the *traduze*[18] system for Aragonese–Spanish; the *Softcatalà*[19] neural Aranese–Catalan system; and the *eslema*[20] MT system for Asturian–Spanish.

Dictionaries. Dictionaries, whether monolingual or bilingual, could serve as valuable complementary resources for participants. The following dictionaries were suggested as potential sources:

[6] For example, NLLB-200-600M, among others, meets this requirement: https://huggingface.co/facebook/nllb-200-distilled-600M.

Diccionari der aranés[21] by Institut d'Estudis Aranesi;[22] and the *Diccionariu de la Llingua Asturiana*, available online[23] with a limit of 500 query results.

Orthographic standards. Participants were informed that the target languages have exhibited various orthographic conventions over time. The evaluation and test sets adhere to contemporary standards, as supported by their respective language academies. The following documents reflect these standards: *Normes ortogràfiques*[24] by the Academia de la Llingua Asturiana; *Ortografía de l'aragonés*[25] by the Academia Aragonesa de la Lengua; and *Gramatica der occitan aranés*[26] published by the Institut d'Estudis Aranesi.

4.2 Development and Test Data

Ad-hoc versions of the FLORES+ datasets were purposefully created for the three languages in the shared task. FLORES+ is a multilingual translation benchmark that began with a limited set of languages (Guzmán et al., 2019), was later expanded to 101 languages (Goyal et al., 2022), and most recently to 200 languages (Costa-jussà et al., 2024). In late 2023, the Open Language Data Initiative[27] (OLDI) took over leadership in extending the dataset to new languages and renamed it FLORES+. Specifically, OLDI proposed a shared task[28] to extend FLORES+ to more languages for the Ninth Conference on Machine Translation (WMT24). The Aragonese, Aranese and Asturian versions of FLORES+ used in this shared task were submitted to the OLDI's task as well.

The sentences in FLORES+ are translations of English sentences sampled equally from Wikinews (an international news source), Wikijunior (a collection of age-appropriate non-fiction books), and Wikivoyage (a travel guide). The dataset consists of a development set (dev) of 997 sentences and a development test set (devtest) of 1012 sentences.

Participants in this shared task were initially provided with the FLORES+ dev set in March 2024 and encouraged to use it for system development, as it closely mirrors the test set in terms of orthographic, grammatical, and domain aspects. Participants had a deadline of July 12, 2024, to submit translations of the Spanish side of the devtest set. Only after that deadline, was the devtest set for Aragonese, Aranese, and Asturian publicly released.

The following provides a brief overview of the FLORES+ datasets for each language, whereas a more detailed explanation of the creation process is available in the paper by Pérez-Ortiz et al. (2024).

For the Aragonese and Aranese datasets, a first draft of the dev and devtest sets were initially generated using the Spanish–Aragonese and Catalan–Aranese Apertium (Forcada et al., 2011) rule-based system. These machine translations were post-edited by language experts and then reviewed by native speakers, including members of the Academia Aragonesa de la Lengua[29] and the Institut d'Estudis Aranesi.[30] The post-editing step is justified by three factors: the lack of resources to hire qualified translators for a from-scratch translation, the common practice of post-editing for these languages, and the high degree of similarity between Spanish and these languages, which makes Apertium translations reliable and less prone to unnatural *translationese*. In the case of Asturian, professional translations originally included in FLORES-101 were reviewed twice by native speakers, including members of the Academia de la Llingua Asturiana.[31]

Pérez-Ortiz et al. (2024, Table 2) report the extent of changes made to the dev and devtest sets after both the initial and final revisions by the language academies. The data reveal significant modifications to the output of Apertium, with a TER score[32] of approximately 26% for Aragonese, 64% for Aranese, and 7% for Asturian, after the two rounds of revision.

[32] The translation error rate (TER) metric (Snover et al., 2006) is employed here to quantify the number of edits needed to transform the sentences from the initial versions into their corresponding counterparts in the final corpus.

5 Teams Participating in the Shared Task

We received a total of 87 submissions from 17 different teams. Table 1 lists the teams that participated in the shared task, along with the language pairs they worked on and the reference, if available, to their system description paper.

Along with their translations of the test set, participants submitted an extended abstract describing their systems and the resources used. Based on that information, we provide a brief overview of the systems developed by each of the participants.

CUNI-GA. The CUNI-GA team's contribution (Hrabal et al., 2024) for the three language pairs in the shared task involved the QLoRA fine-tuning of two open-source large language models (LLMs): Aya-23-8B and Command-R 35B. They used a small back-translated dataset, specifically the literary section of the PILAR corpus (Galiano-Jiménez et al., 2024b), which was back-translated using Apertium. Both LLMs were fine-tuned with a single joint model covering all the languages.

CycleL. The Dublin City University presented two systems (Spanish–Aragonese and Spanish–Asturian) to the constrained task (Dréano et al., 2024). They employed CycleGN, a fully self-supervised NMT framework that does not rely on parallel data. For this shared task, they exclusively used the PILAR corpus, applying sentence permutations to ensure the dataset remained non-parallel.

Helsinki-NLP. This team submitted models (de Gibert et al., 2024) exclusively to the unconstrained open track. Alongside the data provided in the task, such as PILAR, they utilized additional monolingual resources like Wikipedia dumps and dictionary definitions. To enhance their training data, they generated synthetic parallel data through back-translation using an OPUS-MT model. Their data filtering process incorporated language identification using the Idiomata Cognitor tool, as well as the OpusCleaner (Bogoychev et al., 2023) and OpusFilter (Aulamo et al., 2021) tools, to clean and refine their datasets.

For their models, Helsinki-NLP considered various initial systems, including OPUS-MT models (Tiedemann et al., 2024) and different sizes of NLLB-200 models, ranging from 600M to 3.3B parameters. They ultimately chose a multilingual OPUS-MT model based on the transformer-big architecture and produced an ensemble model after fine-tuning. Their other submissions used sequence-level distillation to train smaller student models that integrated rule-based translation. This was done by translating parallel sentences using both their neural best system and Apertium, selecting the output with the best chrF score relative to the reference, and training smaller transformer-based models on the distilled data. The sizes of distilled models ranged from the transformer *base* architecture to even smaller models obtained via the OpusDistillery tool.[33] Their different models showed statistically significant differences in most cases, except for Asturian, with the distilled models providing competitive translation performance.

HW-TSC. The Huawei Translation Service Center participated in the *constrained category* by submitting three systems, one for each of the target languages. Their submissions (Luo et al., 2024) were based on a transformer-big architecture with an expanded number of encoder layers (25). They started by training multilingual systems on sampled training data to obtain both one-to-many and many-to-one pre-trained models, which were then further trained on the original bilingual data to create translation models between Spanish and Aragonese, Aranese, and Asturian in both directions. Additionally, they utilized synthetic corpora generated via Apertium (forward translation) and through back-translation using the aforementioned multilingual models. LaBSE (Feng et al., 2022) denoising was applied to filter out noisy parallel sentences from both the provided training data and the generated synthetic data. Finally, transductive ensemble learning was employed to aggregate multiple models for inference.

ILENIA-MT. For the constrained submission (Sant et al., 2024), the team leveraged synthetic corpus generation through Apertium, primarily using data from OPUS and PILAR. Synthetic data was generated by translating from Spanish to Aragonese and Aranese (pivoting through Catalan in this case) using Apertium, while for Asturian, the team directly used NLLB-200-600M. Additional monolingual data was sourced from orthography dictionaries as supplementary resources. A comprehensive data filtering process was applied, involving the removal of noisy sentences using LABSE-based

Table 1: Participants in the WMT24 Shared Task "Translation into Low-Resource Languages of Spain". Apertium has its own row, but it is not an actual participant; it rather serves as the baseline system.

embeddings (Feng et al., 2022), sentence length filtering, and language recognition with the Idiomata Cognitor tool. The NLLB-200-600M model was then fine-tuned with all the resulting parallel and synthetic data. To handle unsupported languages in NLLB, new language tags were added for Aragonese and Aranese, initialized with embeddings from Spanish and Occitan, respectively.

For the open submission (Sant et al., 2024), ILENIA-MT used Apertium to generate a large amount of synthetic data, translating 30 million sentences sourced from Spanish monolingual corpora. A transformer model was then trained from scratch. This approach resulted in slightly lower scores than the constrained submission.

imaxin software. This team presented an improved version of the Apertium system for the Spanish–Asturian language pair (González, 2024). The team has enhanced Apertium both in terms of syntax, by developing new constraint grammar and transfer rules, and in the lexical domain, by expanding the dictionaries.

LCT-LAP. The University of the Basque Country submitted three systems to the *constrained category* (Bär et al., 2024). These systems were obtained by fine-tuning OPUS-MT pre-trained models for two high-resource Romance languages: Spanish–Galician was used as the starting point for Spanish–Asturian, and Spanish–Catalan was used for Spanish–Aragonese and Spanish–Aranese. The fine-tuning was conducted on OPUS corpora, with noisy parallel sentences removed from the provided training data, and on synthetic corpora generated with Apertium by translating monolingual corpora in PILAR. Before utilizing the OPUS corpora, Idiomata Cognitor was employed to remove parallel sentences not in the desired language, and Apertium was then employed to translate one side of the parallel corpus, followed by BLEU scoring to filter out low-quality parallel sentences.

Mora translate. This team participated in the Spanish–Asturian language pair with a constrained submission (Menan et al., 2024). Their main contribution is a dual-stage data filtering system that combines statistical methods for both bilingual and monolingual data, along with a filtering method based on Jensen-Shannon divergence (Lin, 1991). They used the filtered CCMatrix and Wikimedia corpora, and utilized the PILAR corpus for Asturian and the Spanish portion of the English–Spanish Wikimedia corpus as monolingual data. Training was conducted in two phases: (1) training the entire model using the filtered Spanish–Asturian CCMatrix, and (2) fine-tuning the best model by unfreezing only the decoder. For fine-tuning, several datasets were combined, including monolingual data translated with NLLB-200-600M.

SJTU-MT. The systems submitted by this team (Hu et al., 2024) are based on strategies that differ significantly from traditional methods. The submissions covered all three target languages with notable variations in approach for each language pair.

For Aragonese and Aranese, the team generated a pseudo-parallel corpus using Apertium. They sampled one million Spanish sentences from the NLLB Spanish corpus in OPUS, then translated these into Aragonese and Aranese using Apertium to create a synthetic parallel corpus. Both models used a small LLM, Qwen2-0.5B,[34] which was first fine-tuned on this synthetic corpus.

For Aragonese, the model underwent an additional step of few-shot fine-tuning. This involved assembling five-shot examples using sentences from the FLORES+ dev set, providing these as context before training the model to translate sentences. At inference time, when a new sentence is inputted for translation, they use the BM25 ranking function (Robertson and Zaragoza, 2009) to identify the five most relevant examples from the FLORES+ dev set to replicate the same few-shot format introduced during training.[35]

For Aranese, after supervised fine-tuning of Qwen2 on the pseudo-corpus, an additional step involved applying the recently proposed *contrastive preference optimization* (CPO) algorithm (Xu et al., 2024). This method, which moves beyond standard training that replicates a reference translation, employs reinforcement learning loss functions to push models towards preferred translations while steering away from suboptimal ones. In order to apply CPO to their model, the team used Apertium translations as the least preferred and the target references from FLORES+ as the most preferred. Despite discouraging Apertium-like translations at times during training, this process improved the system's performance for Aranese.[36]

For Aragonese and Aranese, if the generated translations were significantly shorter or longer than the input, they were replaced with Apertium translations.

For Asturian, the team employed a completely different approach and participated in the open track. They used the large language model Claude 3.5 Sonnet,[37] utilizing a simple prompting strategy: when translating a new FLORES+ devtest sentence, they retrieved the 20 most similar examples from the FLORES+ dev set using the BM25 ranking function, providing these as suggestions to the model. If the translations produced were significantly shorter or longer than the input, rather than relying on Apertium as before, they simply resampled the model's output until achieving a translation within an acceptable length range.

SRPH-LIT. Samsung R&D Institute Philippines submitted three translation systems to the *constrained category* (Velasco et al., 2024), each addressing one of the three language pairs with a standard sequence-to-sequence transformer architecture. For each language pair, three systems were trained and combined using a noisy-channel reranking strategy to enhance output selection during decoding. The training data included filtered OPUS corpora —using ratio-based and LaBSE-based embedding methods— as well as synthetic data generated through back-translation with Apertium. Due to limited direct translation support in Apertium, translations for Aragonese–Spanish followed the path Aragonese–Catalan, Catalan–Interlingua, Interlingua–Spanish, while Aranese–Spanish followed the path Aranese–Catalan, Catalan–Spanish.

Stevens The Stevens Institute of Technology participated with a *constrained* model for Spanish–Aragonese. They leveraged NLLB-200 via a multi-stage fine-tuning process applied to both Aragonese–Spanish and Spanish–Aragonese translations. To supplement the limited available parallel data, they developed a back-translation system, generating synthetic parallel data and refining it by selecting the top 20% based on L2 cosine similarity. This iterative process enhanced both the back-translation model and the final forward translation system. The final system was an ensemble, created by averaging the weights of the two best-performing models on the development corpus.

[34] https://github.com/QwenLM/Qwen

[35] Notably, this approach leveraged the dev set not only during training but also during inference, as opposed to many other systems.

[36] This confirms that the use of post-editing of Apertium translations as an initial step in obtaining the FLORES+ data for our target languages did not overly bias the translations toward an Apertium-like style.

[37] https://www.anthropic.com/news/claude-3-5-sonnet

TAN-IBE. The TAN-IBE team (Oliver, 2024) presented systems for all language pairs in the shared task. To address the lack of resources and the low quality of existing corpora, the team: (a) cleaned the existing corpora; (b) created new corpora from Wikipedia; (c) experimented with back-translation and synthetic corpora; and (d) explored multilingual systems. All training was conducted using a transformer Marian-NMT model. For the Spanish–Asturian pair, they submitted an open system using a cleaned version of the NLLB corpus and the newly created Wikipedia corpus. For Spanish–Aragonese and Spanish–Aranese, they submitted constrained systems, using the cleaned existing corpora, the new Wikipedia corpus, and synthetic corpora generated with Apertium.

TIM-UNIGE. This team started by generating synthetic data for both forward and back-translation (Mutal and Ormaechea, 2024). They employed a two-phase synthetic data generation strategy using the BLOOMZ-560M model (Muennighoff et al., 2023) to fit within the constraints of the task. In the first phase, they fine-tuned BLOOMZ[38] on monolingual data from the target and related languages, using the task of predicting the next token. The FLORES+ dataset served as the validation set. This approach allowed the model to generate additional monolingual text, which they obtained by sampling various prefix lengths from the FLORES+ sentences and completing them through the model.

This synthetic monolingual text was then passed through Apertium to create additional parallel data, which was used to train their models. The training involved either building a transformer from scratch, using a pretrained Helsinki model (72M parameters), or the NLLB-200-600M model. A curriculum learning strategy was employed during training, where multiple phases gradually incorporated smaller subsets of higher-quality data, reduced the learning rate, and shortened the training steps. The final step involved fine-tuning exclusively on the FLORES+ dataset.

TRIBBLE. Universitat Pompeu Fabra and the Polish Academy of Science jointly submitted a model in the *constrained category* for translating into the three languages addressed in the shared task (Kuzmin et al., 2024). Their system, built on the NLLB-200-600M model, was trained on corpora sampled from OPUS and PILAR, along with synthetic data generated using Apertium. They further refined the data by utilizing Idiomata Cognitor and fastText to filter out sentence pairs in undesired languages. To reduce noise in the parallel corpus, they translated the Spanish side into the target language using Apertium and computed similarity scores based on the Levenshtein distance, discarding low-similarity bilingual sentence pairs.

UAlacant. The models submitted by Universitat d'Alacant (Galiano-Jiménez et al., 2024) use both parallel and monolingual corpora, supplemented by synthetic corpora, in the three translation directions of this task. The systems use corpora from OPUS and PILAR, together with synthetic data generated by Apertium. All submissions are classified as open due to the use of the NLLB-200-1.3B model, which exceeds the 1B parameter limit. For each translation direction, they submitted three models by fine-tuning NLLB-200.

The first approach combines parallel corpora for translation with monolingual data used in a denoising task, helping the system to learn from target language corpora even in the absence of sufficient bilingual data. A second approach introduces synthetic data, including both back-translation, where monolingual target language texts are translated into Spanish, and synthetic corpora generated by translating Spanish texts into the target languages. The third approach trains on multiple language pairs simultaneously, including Spanish, Aragonese, Asturian, Aranese and related Romance languages, such as Catalan, Galician and Valencian, using their linguistic similarities to enhance knowledge transfer and improve performance across languages. This results in a multilingual system capable of translating between all the languages.

Vicomtech. This team submitted systems for both the *constrained* and *open categories* (Ponce et al., 2024). For the *constrained category*, they exploited synthetic data generation using Apertium, like many other participants, combining it with the available parallel data. A filtering process that included language identification using Idiomata Cognitor, cross-lingual embeddings, and sentence length ratios was considered to clean the training data. Their neural translation models were built using transformer-base architectures (6 layers in the encoder and 6 in the decoder), alongside the NLLB-

[38] BLOOMZ has the characteristic of having been exposed to the FLORES datasets during its training.

Table 3: BLEU scores computed over the FLORES+ devtest set for Spanish–Aranese.

200-600M model, finding the non-pretrained neural models to work slightly better.

For the *open category*, a key highlight of their approach, as emphasized by the authors, was the use of the Llama3-8B LLM (Dubey, 2024) to generate synthetic data in the reverse direction, i.e., from the target low-resource languages into Spanish. This approach allowed their MT systems to exploit whatever knowledge of the target languages the LLMs might have, even if this knowledge is likely limited due to exposure to only small amounts of text. Their *open category* models combined data from Apertium, other NMT systems, and LLM-generated data, resulting in slightly better scores for Asturian over the constrained models.

Z-AGI Labs. This team participated in all language pairs of the shared task. They fine-tuned the NLLB and Helsinki-NLP/OpusMT models using the OPUS dataset provided on the shared task website.

6 Results and Discussion

We measured the translation quality of the different systems submitted to the shared task when translating the FLORES+ devtest dataset by means of

BLEU (Papineni et al., 2002)[39] and chrF2 (Popović, 2015).[40]. We did not use neural-based metrics, such as COMET (Rei et al., 2020), as they are not available for the target languages. Neither did we conduct a manual evaluation because of the lack of resources to hire qualified translators.

Table 4: BLEU scores computed over the FLORES+ devtest set for Spanish–Asturian.

As already mentioned in the introduction, the three language pairs have an Apertium MT system available; we therefore include Apertium among the systems evalauted in this section. The specific versions of Apertium used for each language are: Spanish–Aragonese 0.6.0,[41] Spanish–Aranese 1.0.8,[42] Spanish–Asturian 1.1.1.[43]

Tables 2, 3 and 4 show the BLEU scores attained by each system for Aragonese, Aranese and Asturian, respectively. Similarly, tables 5, 6 and 7 show the results obtained with chrF2. Each table reports, in addition to the BLEU or chrF2 scores, a ranking of the systems from best (#1) to worse. This ranking was derived using a statistical significance test conducted through paired approximate randomization (Riezler and Maxwell, 2005) with SacreBLEU.[44] Systems within the same rank do not exhibit statistically significant differences.

The ranking process involved an iterative approach. We began by selecting the best system for each metric as the control translation. The translations provided by other systems were then compared to this control to determine if the differences were statistically significant. Systems whose output did not differ significantly from the control were associated with it and removed from the pool of translations. The next best system then became the new control translation, and the process was repeated. This iterative process continued until no system remained in the pool.

In the **Spanish–Aragonese** translation task (Tables 2 and 5), the *open* submission results show the ILENIA-MT team achieving the highest BLEU score of 62.7. Notably, ILENIA-MT's performance is consistent, as their second submission scores nearly identical at 62.6. The Apertium baseline and the submission by Vicomtech closely follow, with BLEU scores of 61.1 and 61.0, respectively. UAlacant's entries, which rank 3rd and 4th with scores of 60.2 and 59.8, demonstrate strong competitiveness as well, outperforming the submissions from Helsinki-NLP, which rank lower.

In the *constrained* submission category, SJTU-MT and HW-TSC lead with BLEU scores of 63.2 and 63.0, respectively, surpassing the top scores from the *open* submissions —a difference that is statistically significant—. SJTU-MT's approach

Table 6: chrF2 computed over the FLORES+ devtest set for Spanish–Aranese.

stands out as one of the most innovative in the task, employing strategies that diverge significantly from traditional methods, whereas HW-TSC used the largest number of layers in the encoder (25) of all the submissions. ILENIA-MT continues to perform strongly, with their top entry scoring 62.3, closely followed by TIM-UNIGE, Apertium and Vicomtech.

For the **Spanish–Aranese** pair (Tables 3 and 6), the *open* submission category presents a narrower range of BLEU scores compared to Aragonese. Apertium and Vicomtech share the top position with a BLEU score of 28.8, closely followed by UAlacant with 28.5.

In the *constrained submission* category, SJTU-MT once again leads, achieving a BLEU score of 30.4. This time, several other teams — TIM-UNIGE, ILENIA-MT, and Vicomtech— join SJTU-MT at the top, all with scores outperforming the *open* submissions by a statistically significant margin.

The lower BLEU scores for the **Spanish–Asturian** language pair (Tables 4 and 7), are likely due to the way the FLORES+ dev and devtest datasets were constructed, with translations originating from English rather than Spanish. In

Table 7: chrF2 computed over the FLORES+ devtest set for Spanish–Asturian.

the *open* submission category, SJTU-MT leads with a score of 23.2, significantly outperforming the second-best system, Helsinki-NLP, by 5 BLEU points, with the latter's scores clustering around 18.0.

The *constrained* submission results show HW-TSC leading with a BLEU score of 19.8, followed by ILENIA-MT at 18.4. Despite the constrained environment, HW-TSC's results indicate that their extensive use of encoder layers and synthetic data generation proved beneficial.

7 Conclusions

This paper has presented the outcomes of the Ninth Conference on Machine Translation (WMT24) Shared Task on Translation into Low-Resource Languages of Spain. The challenge centred on building MT systems for three Romance language pairs: Spanish–Aragonese, Spanish–Aranese, and Spanish–Asturian. In total, 17 teams took part in this shared task.

Across all three language pairs, there is some variability in performance both between and within the categories (open, constrained, and closed). Top-performing teams such as SJTU-MT, ILENIA-MT, and HW-TSC consistently achieved high rankings across multiple pairs. The results also underscore the challenges posed by low-resource languages, where factors such as data availability and the choice of methods —e.g., synthetic data generation, fine-tuning strategies, or transformer model size— significantly affect performance. Notably, most of the best-performing systems utilized the Apertium rule-based system to generate synthetic data, highlighting the ongoing relevance of these approaches in complementing neural methods.

Acknowledgements

This task would have not been possible without the support and help in data acquisition and in the translation of the FLORES+ sentences from Academia Aragonesa de la Lengua (Instituto de l'Aragonés), Academia de la Llingua Asturiana and Institut d'Estudis Aranesi.

This shared task is part of the R+D+i projects PID2021-127999NB-I00 (*LiLowLa: Lightweight neural translation technologies for low-resource languages*) and PID2021-124663OB-I00 (*TAN-IBE: Neural Machine Translation for the Romance Languages of the Iberian Peninsula*), founded by MCIN /AEI /10.13039/501100011033 / FEDER, UE.

Findings of the WMT 2024 Shared Task on Discourse-Level Literary Translation

vincentwang0229@gmail.com

Abstract

Following last year's WMT, we (Tencent AI Lab and China Literature Ltd.) have continued to host literary translation shared task (Wang et al., 2023) this year, the second edition of the *Discourse-Level Literary Translation*.

First, we (Tencent AI Lab and China Literature Ltd.) release a copyrighted and document-level Chinese-English web novel corpus. Furthermore, we put forth an industry-endorsed criteria to guide human evaluation process. This year, we totally received 10 submissions from 5 academia and industry teams. We employ both automatic and human evaluations to measure the performance of the submitted systems. The official ranking of the systems is based on the overall human judgments. In addition, our extensive analysis reveals a series of interesting findings on literary and discourse-aware MT. We release data, system outputs, and leaderboard at `https://www2.statmt.org/wmt24/literary-translation-task.html`.

1 Introduction

With the swift progression of MT and the notable advancements in Large Language Models (LLM) (**??**), our curiosity is piqued regarding the efficacy of MT and LLM in the realm of literary translation. We aim to explore the extent to which these technologies can aid in addressing the intricate challenges of translating literary works. Therefore, we hold the first edition of the *Discourse-Level Literary Translation* in WMT 2023. Literary texts encompass a wide range of forms, including novels, short stories, poetry, plays, essays, and more. Among these, *web novels*, also known as online or internet novels, represent a unique and rapidly growing subset of literature. Their popularity, accessibility, and diverse genres set them apart. As they provide not only an extensive volume of text but also exhibit distinctive linguistic features, cultural phenomena, and simulations of societies, web novels can serve as valuable resources and challenging for MT research.

Limitations

We discuss the potential limitations of this edition of the shared task as follows:

- *Language Pair*. This year, we only focus on Chinese→English direction. However, we have a long-term plan to continuously organize this task, and will extend the copyrighted dataset into Chinese-Russian and Chinese-German language pairs next year.
- *Literary Genre*. This year, we mainly used the Web Fiction Corpus which is only one type of literary text. We use Web Fiction for two reasons: (1) its literariness is less complicated than others (e.g. poetry, masterpiece); (2) such bilingual data are numerous and continuously increased. We will consider to extend more literary genres such as poetic translation in the next year.
- *Discourse Benchmark*. We have accumulated some discourse- and context-aware benchmarks (**???**). These benchmarks are pivotal for assessing the proficiency of LLMs in handling complex language structures and contextual nuances. As participation of LLM-based systems in our shared tasks increases, we anticipate integrating these benchmarks more comprehensively into our future evaluations to better measure and understand the evolution of LLM capabilities in linguistic context and discourse comprehension.

Abstract

This paper presents the findings from the third edition of the Chat Translation Shared Task. As with previous editions, the task involved translating bilingual customer support conversations, specifically focusing on the impact of conversation context in translation quality and evaluation. We also include two new language pairs: English↔Korean and English↔Dutch, in addition to the set of language pairs from previous editions: English↔German, English↔French, and English↔Brazilian Portuguese.

We received 22 primary submissions and 32 contrastive submissions from eight teams, with each language pair having participation from at least three teams. We evaluated the systems comprehensively using both automatic metrics and human judgments via a direct assessment framework. The official rankings for each language pair were determined based on human evaluation scores, considering performance in both translation directions—agent and customer. Our analysis shows that while the systems excelled at translating individual turns, there is room for improvement in overall conversation-level translation quality.

1 Introduction

Translating conversational text, in particular customer support chats, is an important and challenging application for machine translation (MT) technology. According to a 2020 survey from CSA Research, 75% of shoppers are more likely to make another purchase if customer support is offered in their native language, making it appealing for businesses to invest in multilingual support.[1] However, there are several key challenges to translating chats: customer support chats typically feature short text exchanges between agents and customers (see Table 1), leading to fragmented sentences and omission of information (implied by the context). This makes it difficult for MT systems to produce coherent translations that maintain the intended meaning of the text (Farajian et al., 2020). Furthermore, chats often use colloquial language and are characterized by informality and grammatical inaccuracies (Gonçalves et al., 2022). Consequently, translating such content poses a dual challenge: not only must a system accurately translate between languages, but it should also effectively model the nuances and ambiguity in a dialogue.

While recent advancements in MT systems, driven by LLMs, have proven effective in various tasks, bilingual chat translation remains underexplored. The **Chat Translation Shared Task** aims to bridge this gap by promoting research and development of MT systems designed specifically for conversational translation. This year's edition places special emphasis on the role of conversation context, encouraging teams to examine how context influences translation in the inherently ambiguous and dynamic nature of chat interactions. Following the success of the previous two editions of the Chat Translation Shared Task (Farajian et al., 2020; Farinha et al., 2022), this year we organized the third edition of the task with the following improvements:

- We expanded the set of language pairs to include English↔Korean (EN-KO) and English↔Dutch (EN-NL), in addition to languages from previous editions: English↔German (EN-DE), English↔French (EN-FR), and English↔Brazilian Portuguese (EN-PT).
- We carefully curated the evaluation sets to enable the evaluation of effective context utilization on systems' performance.
- We conducted a comprehensive evaluation of all systems using: a) automatic metrics (both neural and lexical) that assess translation quality and the accuracy of modeling discourse phenomena

👤 customer	ich habe die Frage daher nicht verstanden so I did not understand the question
🎧 agent	Could you please elaborate on your query? Könnten Sie bitte Ihre Anfrage näher erläutern?

Table 1: An example of a EN-DE conversation between a *customer* (👤) and an *agent* (🎧) from MAIA dataset.

using MuDA (Fernandes et al., 2023b), b) human direct assessments by professional linguists, and c) LLM-based fine-grained error analysis following the MQM framework.

We received a total of 22 primary submissions, 6 submissions for en↔de, 5 for en↔fr, 4 for en↔nl, 4 for en↔pt-br, and 3 for en↔ko. Six out of the eight teams used large language models (LLMs) as their base translation model, implementing various strategies such as finetuning on shared task data, augmenting training data with synthetic datasets, prompting strategies, quality-aware decoding, and several ways of leveraging conversational context to improve translation quality. With these multifaceted solutions explored by several teams, this year's shared task yields valuable insights into the effectiveness of LLMs in translating conversational texts. We summarize the key findings from the shared task below:

- Incorporating contextual information from previous turns almost always improved translation quality. However, the optimal method for introducing context (whether through summary, graph, or raw context) still requires further investigation.

- Human evaluation showed that turn-level translation quality was consistently high across all participating systems and language pairs. Nonetheless, there is room for improvement in translating texts from later turns and at the conversation level as a whole.

- The UNBABEL-IT submission achieved the best results across most language pairs and evaluation criteria, except on the EN-DE and EN-FR tasks according to automatic metrics.

These findings suggest that future editions of the shared task could benefit from a) designing evaluation frameworks, both automatic and human, that specifically target dialogue-specific criteria to better understand system limitations (Yeh et al., 2021; A, 2022; Deriu et al., 2021); b) expanding the datasets to include more challenging domains (e.g. patient-physician conversation or everyday dialogues) and contexts (e.g. multimodal chats) for a more thorough evaluation of MT systems.

2 Task Description

As in previous editions of the task, we evaluate the effectiveness of a translation layer in translating text from the customer's language to the agent's language (e.g., English) and vice versa. We provide real bilingual customer support data for five different language pairs and encourage the participants to use conversation context. They are asked to submit translations for both directions (agent and customer). We detail the shared task dataset provided to the participants and evaluation in § 2.1 and § 2.2 respectively.

2.1 Data: The MAIA 2.0 Corpus

The MAIA 2.0 corpus builds upon the dataset released in the previous edition (Farinha et al., 2022) and includes two additional language pairs: Dutch and Korean. Furthermore, we expanded the sizes of the existing language pairs, ensuring that each language pair contained approximately 20k segments. The dataset encompasses dialogues across diverse

Table 2: Dataset statistics with the number of segments (#seg), number of conversations (#conv), average conversation length (#length), and average number of words per turn (#words) in each split. Note that for KO customer parts, we considered the English reference translation to calculate the number of words.

topics, including account registration issues, payment and delivery clarifications, and after-sale services in various industries such as retail and gaming. The new dataset was automatically anonymized using Unbabel's proprietary anonymization tool, followed by a manual validation performed by expert linguists, to comply with the General Data Protection Regulation (GDPR). The corpus is released under the CC-BY-NC-4.0 license and can be freely used for research purposes only. Please note that, as the license states, no commercial uses are permitted for this corpus.

Training and Evaluation Datasets. We provide both training and evaluation (development and test) sets that participants can use to build their systems. Table 2 presents each data splits' statistics, including the number of segments, conversations, and average conversation length. We construct the development and test sets by selecting conversations that exhibit the highest counts of context-dependent discourse phenomena tags, as extracted using Multilingual Discourse Aware (MuDA) tagger (Fernandes et al., 2023b).

2.2 Evaluation

We perform a comprehensive evaluation of all submitted systems, using both automatic and human evaluation. Official rankings are determined based on the human assessment scores for both customer and agent translations. We outline the various evaluations conducted below:

2.2.1 Automatic Evaluation

We use COMET (Rei et al., 2022) as our primary evaluation metric for assessing translation quality of the submitted systems.[2] Additionally, we report lexical metrics: BLEU and CHRF using the SacreBLEU library (Post, 2018). We also include CONTEXTCOMETQE (Agrawal et al., 2024), a reference-free metric that uses bilingual context (previous two turns) to assess the translation quality of the current turn. As efficient discourse handling is not directly reflected in standard MT metrics (both lexical and neural), we report the F1 accuracy on the MuDA-tagged discourse phenomena. We considered 4 context-dependent discourse phenomena in our analysis:

- **Lexical cohesion:** Entities may have multiple possible translations in the target language, but the same entity should be referred to by the same word in a conversation.
- **Formality:** Korean uses honorifics to indicate formality, which are special titles or words expressing courtesy or respect for position. In other languages, speakers use second-person pronouns to refer to someone more formally or informally, depending on their relationship with the addressee. Formality should be consistent throughout a conversation.
- **Pronoun resolution:** Some highly inflected languages use gendered pronouns based on semantic or morphological rules. To assign the correct pronoun, it is therefore necessary to use the conversation's context to distinguish the grammatical gender of the pronoun's antecedent.
- **Verb forms:** Verbs must be translated consistently using the form that reflects the tone, and mood of both parties in the conversation.

2.2.2 Manual Evaluation

We use the DA+SQM (Direct Assessment + Scalar Quality Metric) evaluation framework, following the campaigns conducted by the WMT General Translation track over the past years, implemented via the Appraise framework (Federmann, 2018) to collect human assessments of translation quality

EN-PT	28	41	5	4700
EN-DE	31	36	7	6629
EN-KO	48	24	4	3648
EN-FR	33	37	6	6324

Table 3: Statistics of the conversations and instances sampled for the human evaluation step.

for the submitted systems. We ask professional linguists hired via the UpWork[3] platform to evaluate each turn in a conversation within the full context and provide a conversation-level quality score on a continuous scale from 0 to 100. They were instructed to pay special attention to conversation-level properties such as the consistency of style, selection of terms, formality, etc in addition to the correctness criteria. The quality scale includes seven labeled tick marks representing various quality levels based on both accuracy and grammatical correctness (Figure 1).

Data Selection For the human evaluation, we retain conversations with up to a given number of turns to make the evaluation manageable. The number of turns for each language pair is specified in Table 3 (“Threshold”), together with the number of conversations and instances retained.

Measure We generate turn-level and conversation-level system rankings for each language pair by aggregating the direct assessment scores provided by the linguists at the turn level and the conversation level respectively.

2.2.3 LLM-based Error Assessments

LLM-based evaluation has garnered a lot of interest from the community for conducting human-like evaluations. This shift is largely driven by the increasing complexity and scale of language models, making them capable of capturing nuanced understanding and performance of models in real-world tasks. For MT, LLM-based metrics are used to provide fine-grained error assessments over the nature, type, and severity of the errors following the MQM framework (Fernandes et al., 2023a; Lu et al., 2024; Kocmi and Federmann, 2023). Recently, Agrawal et al. (2024) show that context-aware prompting for deriving MQM assessment using LLMs can achieve better correlation with human judgments than the standard MQM prompt for chat translation evaluation, even surpassing COMET.

Hence, we complement our evaluation with an LLM-based fine-grained assessment of MT outputs derived using CONTEXTMQM (Agrawal et al., 2024). The prompt includes the past eight bilingual source sentences as context and one in-domain in-context example with MQM assessment to elicit MQM-like evaluation from GPT-4o-mini[4] for all systems submitted for the EN-DE track.[5] Like MQM, we compute the segment-level *error* score aggregating the number of minor, major, and critical errors, weighted by factors of 10, 5, and 1, respectively.

[3] upwork.com

[4] `gpt-4o-mini-2024-07-18` accessed on 10-2-2024.

[5] Due to budget constraints, we conduct this evaluation only on EN-DE, which had the highest number (eight) of participating teams.

3 Participants

This section provides a brief description of each participant's systems (§ 3.1). Table 4 summarizes details about the team's institutions and the language directions they participated in. Participants were asked to submit up to three systems per language direction: one primary (explicitly marked) and up to two contrastive systems. Next, we discuss the commonalities and differences between the different submissions § 3.2.

3.1 Systems

3.1.1 NLLB-3.3B (Baseline)

For our baseline model, we used the NLLB-3.3B multilingual machine translation model (Costa-jussà et al., 2022) based on an encoder-decoder Transformer architecture (Vaswani et al., 2017). NLLB-3.3B is trained to support over 200 languages, including those of interest in this shared task: English, German, French, Dutch, Brazilian Portuguese, and Korean. We opted for a sentence-level baseline that does not incorporate additional context and used a beam size of 4 for generating translation hypotheses.

3.1.2 UNBABEL-IT

The joint submission of Unbabel and IT includes one primary submission and two contrastive submissions per language pair. The systems are based on Tower-7B models and are trained on the chat datasets released by the shared task. Their primary system uses contextual MBR re-ranking over a set of 50 candidates to get the best hypothesis. Additionally, the first contrastive submission is a 70B variant of the Tower model specialized to have general purpose translation capabilities and the second one uses greedy decoding with the 7B model finetuned on chat datasets.

3.1.3 DEEPTEXT LAB

DEEPTEXT LAB participated in the English-Korean language pair with a single primary system. Their submission leverages Google's Gemma-2-27B model [6], using the most recent two turns and summaries of previous turns as context, all within the same document. The turn summaries are generated using the GPT-4o-mini model. Their system was trained solely using the training data provided by the shared task.

TEAM	INSTITUTION	DIRECTIONS
DeepText Lab	Yonsei University	EN-KO
HW-TSC	Huawei Translation Service Center	EN-DE
Multitan-GML	Université Paris Cité	EN-FR
SETU-ADAPT	ADAPT research centre & Dublin City University	EN-DE, EN-FR
SheffieldGATE	University of Sheffield	EN-DE, EN-NL, EN-PT
CLTeam	Vrije Universiteit Amsterdam	EN-DE, EN-NL, EN-FR, EN-PT
DCUGenNLP	Dublin City University	ALL
Unbabel-IT	Unbabel & Instituto de Telecomunicações	ALL
Baseline	Organizers	ALL

Table 4: The participating teams, their affiliations, and the language directions that they participated.

3.1.4 HW-TSC

Huawei Translation Service Center (HW-TSC) team submitted a primary and two contrastive systems for English↔German language pair. Their system is a 25-6 transformer encoder-decoder model with a feed-forward dimension of 4096 and 16 self-attention layers. Their primary submission uses a model from the previous edition of the shared task as a baseline, finetuned on this edition's training data, followed by a second finetuning on the validation data. Next, they use MBR reranking to select the optimal candidate with COMET as the utility function using outputs generated from a diverse set of models. Their system then undergoes a self-training step on the MBR output. The contrastive submissions include models trained with different finetuning strategies (e.g. excluding the finetuning on the dev set).

3.1.5 SHEFFIELDGATE

The SHEFFIELDGATE team participated in English↔German, English↔Dutch, and English↔Brazilian Portuguese, with one primary system per language pair. Their system performs low-rank (Hu et al., 2022) instruction-tuning with the training and validation datasets provided by the shared task on the Llama-3-8B-Instruct [7] model. To incorporate contextual information and dependencies between chat messages, they introduce a context-aware sliding window approach that incorporates translations generated at each turn into the prompt.

Baseline	NLLB-3.3B	✗	✗	✓	✗	Beam (4)

Table 5: Summary of approaches for all primary submissions. NR: Not reported.

3.1.6 SETU-ADAPT

SETU-ADAPT team submitted 3 (one primary and two contrastive) systems based on different pre-trained models: NLLB[8], MBART-50[9] and Llama-3-8B[10]. Their primary system for EN-DE uses a Llama-3-8B backbone finetuned on the in-domain chat and a synthetic dataset generated by back-translating domain-specific monolingual sentences. For EN-FR, they finetune an NLLB-600M model. During inference, with the LLM-based models, they perform few-shot prompting using examples retrieved via similarity search from the training dataset. Their contrastive systems are based on the encoder-decoder models but use the same datasets for training.

3.1.7 MULTITAN-GML

MULTITAN-GML's primary system finetunes a "Dialog" in-domain specialized model hosted on the Model Studio Lite server [11] with 2022 Chat Task (train, valid, test) and 2024 Chat Task (valid) datasets. Their two contrastive submissions use outputs from NLLB-3.3B model and the Deep_translator API respectively. All outputs are post-edited using GPT-4o.

3.1.8 DCUGENNLP

DCUGENNLP team submitted a total of 15 systems (one primary and two contrastive) for all the five language pairs. Their primary system finetunes a Llama-3.1-8B model on a mix of the chat task's training data and datasets from other WMT tracks. They also include synthetically generated customer-service data generated using one of their contrastive submission. Other contrastive submissions use Mistral-7B as base models with optional prompt tuning or finetuning of adapter layers.

3.1.9 CLTEAM

CLTEAM submitted one primary and one contrastive systems for each of the English↔German, English↔French, English↔Dutch, and English↔Brazilian Portuguese language pairs. Their system uses TowerInstruct-7B-v0.2 [12] model as the base LLM. For their primary submission, they prompt the model with both the dialogue history represented using a graph and the source sequence to be translated. To generate the graph, they prompt GPT-4o to extract entities and relationships from the dialogue data, creating triples from these elements. For the contrastive submission, they prompt the model with only the source sequence to be translated.

3.2 Discussion

Table 5 presents a summary of approaches used by all the submitted systems. We highlight some key aspects below:

Model Architecture Most teams except CLTEAM and HW-TSC finetuned general-purpose pre-trained LLMs. Where CLTEAM used an off-the-shelf translation-finetuned LLM, HW-TSC opted for a custom bilingual encoder-decoder model for their participation.

Training Data All teams used the provided training and development data, sourced from the current and previous versions of the task. HW-TSC went a step further by generating a synthetic parallel corpus. They did this by forward translating source-side monolingual data into target-side text and backtranslating target-side monolingual into source-side texts. SETU-ADAPT similarly used

back translation to generate more in-domain data for their EN-FR submission.

Inference Both Unbabel-IT and HW-TSC leveraged a quality-aware decoding (QAD) approach (Fernandes et al., 2022) for further improving the quality of outputs during inference. While HW-TSC optimized for Comet, Unbabel-IT used a context-aware Comet metric as a utility for selecting the best candidate. HW-TSC also used MBR outputs to further finetune the model.

Context Usage Different strategies were employed to incorporate conversation context into the translation process. Unbabel-IT, SheffieldGATE, and Multitan-GML utilized the previous turns of the conversation as context to maintain continuity and coherence in translations. DeepText Lab used both the previous two turns as well as the summary of all the previous conversation turns except the last two, generated by GPT-4o-mini. This allowed the model to focus on the essential part of the previous content without being overwhelmed by excessive details. On the other hand, CLTeam used a graph representation of the conversation's history as context, capturing the connectivity between various concepts thus serving as a compressed memory of the dialogue context. SETU-ADAPT used few shot examples extracted from the training data using sentence-embedding similarity.

All teams that participated for more than one language pair opted for a multilingual system except for SETU-ADAPT team who submitted two different systems for each language pair they participated in (EN-DE, EN-FR).

4 Overall Results

We present the results of the automatic evaluation for all participating systems for all language pairs

System	EN-DE		EN-FR		EN-NL		EN-PT		EN-KO

in § 4.1. We then discuss findings from human evaluation in § 4.2, followed by an LLM-based error assessment of submitted systems for the EN-DE task in § 4.3.

4.1 Automatic Evaluation

Tables 6-9 show the results of automatic evaluations on the official test set using COMET, CHRF CONTEXTCOMETQE and BLEU respectively -– most participant systems improve the translation quality according to both neural (COMET, CONTEXTCOMETQE) and lexical (CHRF, BLEU) metrics over the NLLB-3.3B model, except the SETU-ADAPT system for EN-FR. This can be explained by the fact that SETU-ADAPT finetunes an NLLB-600M model for EN-FR, which, albeit from the same family of models as our baseline (NLLB-3.3B), is significantly smaller in size.

The UNBABEL-IT submission consistently outperforms all other systems, except the EN-DE translation task, where the winning submission according to COMET, BLEU, and CHRF is HW-TSC. Similarly, MULTITAN-GML scores the best on BLEU and CHRF when translating French into English. Interestingly both systems (UNBABEL-IT and HW-TSC) use MBR decoding with CONTEXTCOMET and COMET respectively, suggesting that inference optimization techniques like quality-aware decoding methods (Fernandes et al., 2022) can be useful in pushing the translation quality of strong MT systems. However, as we will see in §4.2, this difference is not reflected in human assessments and in automatic metrics (CONTEXTMQM and CONTEXTCOMETQE), with different methods scoring the two systems differently. This highlights the importance of carefully selecting the optimized metrics and the evaluation criteria, as over-optimizing certain metrics may lead to mixed or misleading outcomes (Fernandes et al., 2022).

UNBABEL-IT's submission also achieves the highest scores across all settings according to CONTEXTCOMETQE. However, we observe that the range of quality scores produced by the CONTEXTCOMETQE model, when aggregated at the system level, significantly deviates from the typical range of this metric.[13] While Agrawal et al. (2024) demonstrate its effectiveness as a segment-level

[13] System-level scores are higher when the context is not considered.

metric with improved correlation to human judgments, further investigation is necessary to understand how these system-level scores should be interpreted. For instance, MULTITAN-GML, which performs well on lexical metrics such as BLEU and CHRF, receives a notably lower score with CONTEXTCOMETQE.

System	Precision	Recall	F1
HW-TSC	76.7	86.2	81.2

Unbabel-IT	75.4	66.2	70.5
NLLB-3.3B	74.3	84.6	79.1

Table 10: MUDA scores for EN-DE pronouns.

Discourse Phenomena Analysis Figure 2 shows the F1 accuracy for all systems in correctly using the discourse markers across multiple phenomena for all language pairs. The baseline system (NLLB-3.3B) has competitive accuracy with submitted systems on higher resource language pairs (EN→DE and EN→FR). For all settings except "pronouns" for German and "formality" for German and French, UNBABEL-IT achieves the highest accuracy across the board. Surprisingly, the MUDA F1 score for correctly generating German pronouns is worse for UNBABEL-IT relative to the baseline. A qualitative analysis shows that this is due to pronouns being under-generated in UNBABEL-IT's translations resulting in high precision but low recall scores as shown in Table 10.

To validate the observations and findings derived from automatic metrics, we now turn to human evaluation of the submitted systems for a more reliable assessment of translation quality.

4.2 Human Evaluation

We present the human evaluation results at both turn and conversation levels in Tables 11 and 12 respectively.

Overall results. UNBABEL-IT outperforms all systems on both turn-level and conversation-level evaluation, surpassing the HW-TSC system that achieved the highest COMET scores on EN-DE translation pair.[14] The translation quality according

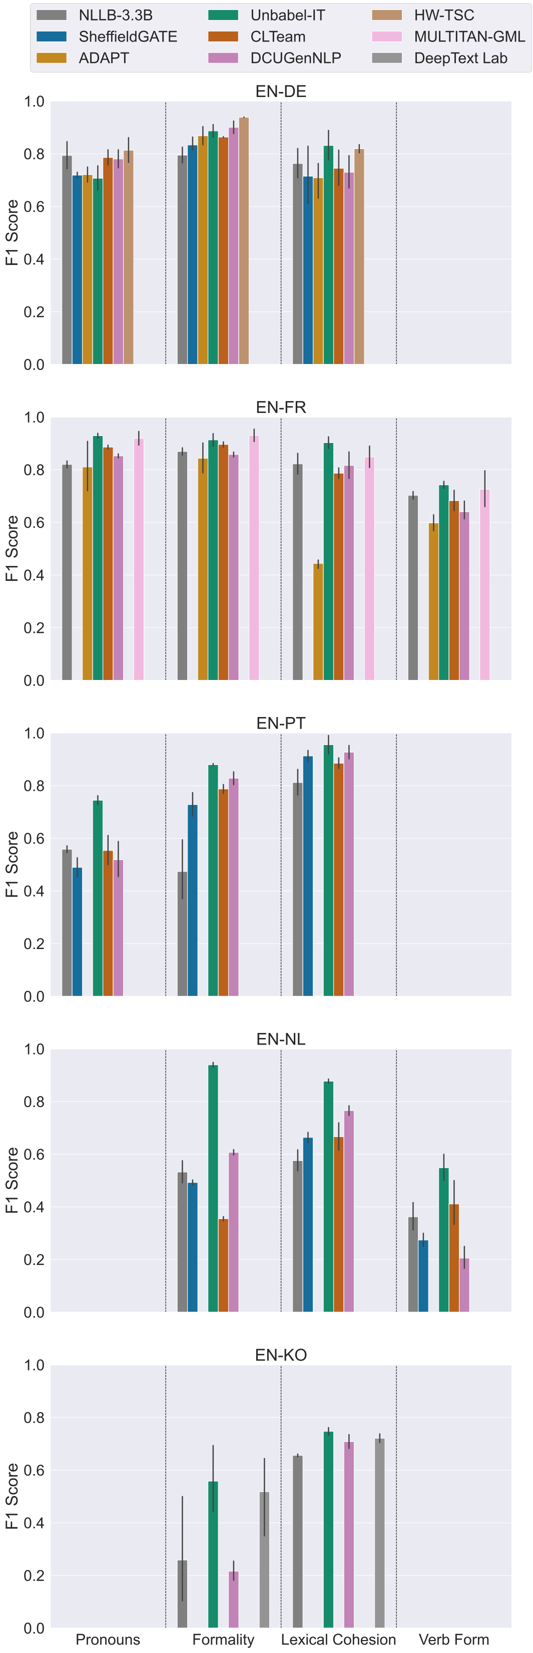

Figure 2: MUDA F1 scores across all settings.

[14] We note that the human evaluation for EN-DE, like other LPs, was conducted on a subset of the dataset (limited to a maximum of 30 turns per conversation).

Table 12: Human Evaluation results aggregated at the conversation level on the official test set.

to direct assessment scores of all systems evaluated across all language pairs is high (> 65) at both conversation and turn levels. This could be because of the nature of the chat dataset which contains very short texts (the number of words per turn across language pairs is less than 8, see Table 2).

Conversation-level results. Figure 3 shows the distribution of scores assigned at the conversation level for all systems and language pairs. Confirming the automatic results, NLLB-3.3B scores the lowest and with the highest standard deviation for EN-KO, EN-NL and EN-PT. We also observe that EN-NL generally exhibits the largest standard deviation. After analyzing the outputs, we found that EN-NL has the highest number of segments (and conversations) receiving either a score of 0 (when hallucinating or copying source text verbatim) or 100, indicating a significant variation in translation quality for this language pair. Although there are sentences with mid-range scores, the dominance of segments with extremely high or low scores greatly influences the overall results, substantially raising the standard deviation.

Turn-level results. Figure 4 illustrates DA scores with the increase in the number of turns. For most systems and language pairs, translation quality deteriorates over successive turns, indicating a decline in the systems' ability to maintain consistency and accuracy in prolonged dialogues. This decline is particularly evident in the baseline sys-

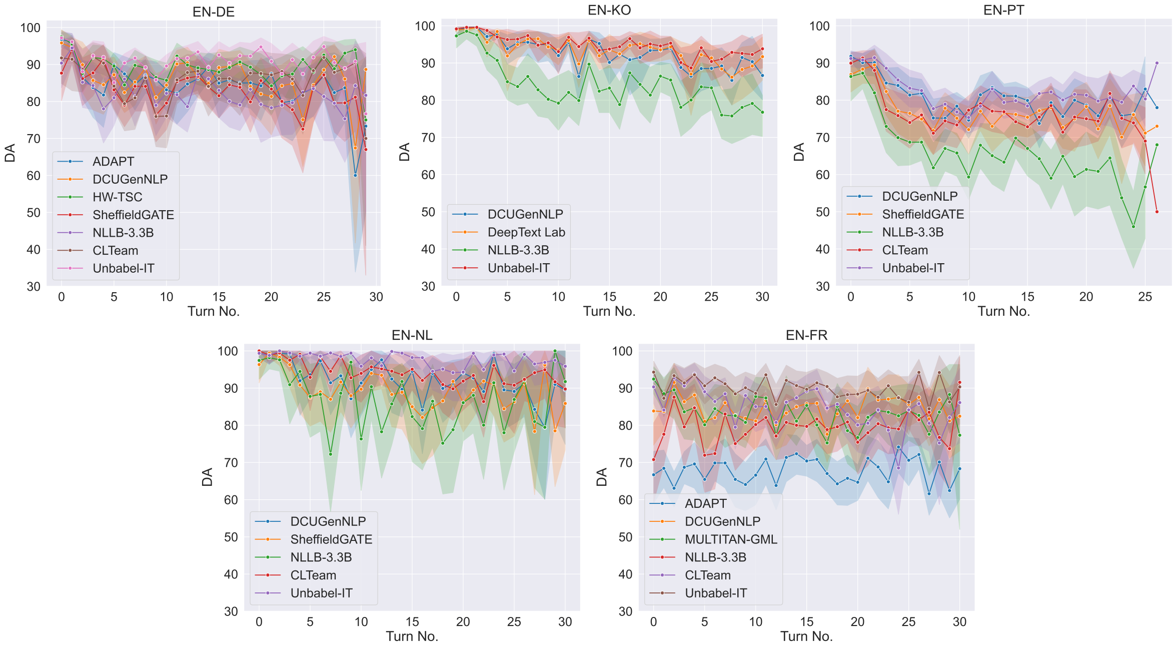

Figure 4: Turn-level DA score across different language pairs through a chat.

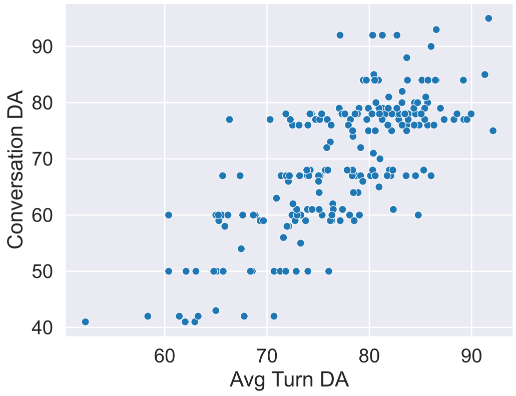

Figure 5: Turn avg. vs conversation-level DA scores.

tem, which does not leverage contextual information from previous turns to generate translations. Interestingly, however, despite not using contextual information, HW-TSC's system maintains translation quality across successive turns. This can likely be attributed to rigorous training on in-domain data, both authentic and synthetically generated.

Turn Vs. Conversation Quality results. Overall, **conversation-level quality is lower than turn-level scores** suggesting that there are aspects beyond translation accuracy that might impact the overall translation quality and user experience. This is corroborated by the observation that the Spearman correlation between the average turn-level score and conversation-level DA score, though high, is 0.722. For future evaluations, it might be worth investigating dialogue-oriented human assessment (Mendonca et al., 2023) to understand how turn-level scores impact conversation-level quality.

While direct assessments from experts provide a reliable measure of translation quality, DA scores fall short in offering insights into when and how errors occur, as well as their types and nature. Therefore, to assess the severity of errors generated by these systems, we now turn to LLM-based fine-grained error assessment of translation outputs.

4.3 LLM-based Evaluation

System	% Perfect	# Minor	# Major	# Critical	Avg. Score
HW-TSC	89.12	100	88	59	-0.554
SETU-ADAPT	82.61	158	139	99	-0.903
SheffieldGATE	77.95	220	178	95	-1.009
CLTeam	86.28	139	82	79	-0.656
DCUGenNLP	83.10	143	158	80	-0.849
Unbabel-IT	**94.41**	**51**	**47**	**18**	**-0.228**
NLLB-3.3B	80.50	161	143	117	-1.002

Table 13: CONTEXTMQM scores for EN-DE.

Table 13 shows the results from using LLM-based error assessments via CONTEXTMQM. UNBABEL-IT leads the pack with 94.41% perfect translations. It also has the lowest number of errors in each category (minor, major, and critical), with an average error score of -0.228 (less than 1 minor error), the best among all systems. All systems, however, manage to achieve over 77% perfect translations, meaning the overall quality across the board is strong.

Despite the positive results, there are notable differences in error distribution. For example, both the SHEFFIELDGATE and SETU-ADAPT models, while maintaining a reasonable percentage of perfect translations (82.61% and 77.95%, respectively), suffer from a significantly higher number of errors across all categories—minor, major, and critical. This suggests that when these systems do make errors, they tend to be more frequent and more serious, dragging down their overall performance compared to other systems. Interestingly, contrary to human evaluation but in line with other automatic measures, DCUGENNLP scores worse than CLTEAM submission, highlighting limitations of existing evaluation methods to discern systems with close translation quality.

5 Conclusions

This paper presents the findings of the Chat Translation Shared Task 2024. This year, we expanded the set of language pairs to include two additional languages (EN-KO and EN-NL). We created the evaluation sets with a focus on context usage when assessing system performance. We also employed a range of complementary evaluation methods to assess all systems, including automatic metrics that focus on translation quality, as well as fine-grained error assessments and analysis of specific discourse phenomena.

We find that the best systems finetune strong pretrained LLMs using multilingual in-domain data and use contextual information (such as graphs, summaries or raw context) during training and inference. Additionally, using synthetic data during training improved translation quality. Furthermore, QAD strategies were effective in aligning translations with quality expectations.

As future work, a possible direction is to leverage reference-free discourse quality metrics that can give complementary insights to the translation evaluation approaches we tried this year. It might also be worth investigating human and automatic evaluation frameworks that assess specific dimensions relevant to chat (e.g. fluidity, coherence, consistency, etc).

Limitations

Due to budget constraints, we conducted human evaluations using DA on a subset of the test set, which limited the number of turns evaluated for each language pair. For similar cost-related reasons, we ran CONTEXTMQM on a single language pair that received the highest number of submissions. Additionally, we note that our analysis of discourse-specific phenomena is constrained by the quality of taggers, which only annotate specific properties based on predefined rules and may not fully capture all levels of ambiguity present in chat datasets.

Ethics Statement

Data released. MAIA 2.0 corpus includes conversations from clients who gave written consent to use this data for research purposes as long as it follows the General Data Protection Regulation (GDPR). The original segments of customers and agents are translated via the MTPE (Machine Translation followed by a Post-Editing) process by experienced translators of the Unbabel Community. To make the data publicly available, the corpus was first anonymized automatically by using the Unbabel proprietary anonymization tool and then went through manual verification.

Human evaluation. Human direct assessment of system outputs was performed by professional translators hired via the UpWork platform and paid at professional rates.

Reproducibility. For LLM-based error assessment, the continual updates of closed commercial models present challenges to the reproducibility of research. We have included the exact version of the model we used, along with the precise date of evaluation.

Abstract

The repetition of words in an English sentence can create a monotonous or awkward impression. In such cases, repetition should be avoided appropriately. To evaluate the performance of machine translation (MT) systems in avoiding such repetition and outputting more polished translations, we presented the shared task of controlling the lexical choice of MT systems. From Japanese–English parallel news articles, we collected several hundred sentence pairs in which the source sentences containing repeated words were translated in a style that avoided repetition. Participants were required to encourage the MT system to output tokens in a *non-repetitive* manner while maintaining translation quality. We conducted human and automatic evaluations of systems submitted by two teams based on an encoder-decoder Transformer and a large language model, respectively. From the experimental results and analysis, we report a series of findings on this task.

Ja: . . . 入学予定者７人が教育方針や私立小への入学などを理由に入学を辞退した。

En(trans): ..., seven students scheduled to enroll withdrew their enrollment due to reasons such as the educational policy and enrolling in a private school.

En: ..., seven children dropped plans to enter the school, with parents citing disagreements with its education policy, decisions to join private schools or other reasons, ...

Figure 1: Motivating example from a Japanese–English parallel news article along with a consistent translation ("En(trans)") for comparison. Repeated words and their counterparts are highlighted. "入学" is intentionally removed (*reduction*), probably because it is contextually obvious. In this paper, we distinguish this type of removal from undertranslation. Additionally, "入学" and "入学" are translated differently as "join" and "enter," respectively (*substitution*).

1 Introduction

The development of neural models has improved the performance of machine translation (MT) significantly (Sutskever et al., 2014; Bahdanau et al., 2015; Vaswani et al., 2017). MT systems are now used in a variety of real-world scenarios; however, challenges remain for such systems that assist human writers. Specifically, the MT output must not only be *adequate* and *fluent* but also follow the writing style of the target domain. For example, it is advisable for an application in the English news domain to follow rules such as the use of active rather than passive voice, the use of the affirmative rather than the negative, and the avoidance of redundant phrases (Block, 1994; Cappon, 2019; Papper, 2021). Among these writing style rules, we focus on the rule regarding the repetition of words in the English news domain. Generally, common words repeated in a sentence can create a monotonous or awkward impression, and in such cases, repetition should be avoided appropriately (Burstein and Wolska, 2003). Typical workarounds are (1) the removal of redundant terms, if possible (Strunk and White, 1999) or (2) the use of alternative words, such as synonyms, as substitutes.[1] In this paper, we refer to translation techniques (1) and (2) as *reduction* and *substitution*, respectively, and call the translation style using these techniques a *non-repetitive style*. Figure 1 shows an example of a non-repetitive style translation from a Japanese–English parallel news article. We observe that human writers in the English news domain often translate Japanese text with such reduction and substitution.[2] These translation techniques arise from the difference between the styles of the source and

[1] https://effectiviology.com/writing-tips-from-the-elements-of-style/#Avoid_repetition

[2] Other examples are listed in Appendix A.

Proceedings of the Ninth Conference on Machine Translation, pages 715–727
November 15-16, 2024 ©2024 Association for Computational Linguistics

target languages; that is, an article in the source language was originally produced by a writer who attached importance to conveying content without the reader misunderstanding it by using the same expressions consistently, and then it was translated into the target language by a writer who was encouraged to (or preferred to) translate it in a more diverse or concise way. The assumption in this task is that sentences translated in a simple word-by-word manner cannot be suited to the target domain. We could thus associate these translation techniques with a type of rewriting. Although this task focuses on the news domain, the monotony or awkwardness arising from the repetition of words in English is also a common problem in other domains.

Given this motivation, we presented a shared task for non-repetitive translation. To configure appropriate settings, we limited the task to one-to-one or two-to-two translations. We hypothesized that the closer the distance between repeated words, the greater the need to translate using reduction or substitution. Additionally, we targeted the repetition of common words because such words tend to be substituted according to the findings of Guillou (2013). We qualitatively categorized several patterns of non-repetitive style translations, and then collected several hundred instances in which some words were repeated in the source sentence and translated using reduction or substitution, which we used as development and test data. In the remainder of this paper, we first explain the research background of this task (§2). Next, we describe the task definition (§3), dataset we prepared (§4), evaluation methods (§5), and submitted systems (§6). Finally, we present the results and some analysis (§7).

2 Related Work

Contrast with Consistent Translation In the context of MT research, lexically consistent translation (in this paper, we also refer to this as *repetitive style translation*) has been studied actively (Pu et al., 2017; Kuang et al., 2018; Tu et al., 2018; Lyu et al., 2021, 2022). A representative study is the hypothesis of "one translation per discourse," which was advocated by Carpuat (2009). The motivation for these studies is the assumption that translating text in a consistent style should be encouraged because this style is unambiguous and accurate for readers. Moreover, from the viewpoint of experimental evaluation, many researchers have reported that BLEU scores improved as a result of encouraging consistent translation (Lyu et al., 2021, 2022). However, it is debatable whether all words should be translated consistently. Translation consistency can depend on several factors, such as the target domain, type of words, and translation direction (Guillou, 2013). For example, it is indisputable that technical terms in the patent domain should be translated consistently. By contrast, Guillou (2013) reported that high-frequency verbs are often translated in diverse ways in English–French translation. While improving document-level consistency based on the postprocess approach, Zhang et al. (2023) also mentioned the side effect of the loss of translation diversity. From another point of view, consistent translation has the risk of leading to a robotic wording and giving a monotonous or awkward impression to readers, as shown in Figure 1. By contrast, Cappon (2019) claimed that excessive substitution may obscure the meaning of the sentence. In monolingual writing, this phenomenon is derided as *the elegant variation*.[3] To summarize, there is a trade-off between ambiguity and monotony. This task particularly focuses on the latter aspect, which has not often been addressed in previous studies. To the best of our knowledge, no test sets exist for directly evaluating such a translation style.

Reduction and Substitution Although several studies have been conducted related to non-repetitive translation, the scope of our research is different. First, several researchers have addressed the problem of controlling the output length of MT systems (Lakew et al., 2019; Schioppa et al., 2021). Typically, special tokens representing the output length at several discrete levels are inserted into source sentences. Although this approach is associated with reduction, our task requires a more meticulous omission of specific words in sentences. Regarding substitutions, MT systems are sometimes required to select infrequent words from the vocabulary. However, researchers have reported that MT systems are biased toward outputting high-frequency target words (Ott et al., 2018; Gu et al., 2020) and tend to produce lexically poorer translations than humans (Vanmassenhove et al., 2019, 2021). Gu et al. (2020) designed the objective function so that low-frequency target tokens were more likely to be output. However, they conducted

[3] https://en.wikipedia.org/wiki/Elegant_variation

the experiment using regular corpora and did not present a perspective on in what scenarios low-frequency words should be output. By contrast, we set up a more specific scenario.

This task is also related to research outside of translation technique. Neural models have the traditional problem of not outputting the end-of-sequence token while generating the same tokens endlessly. To alleviate this problem, several approaches including learning-based methods (Welleck et al., 2020) and decoding-based methods (Keskar et al., 2019), have been proposed. Although the goal is different, these studies are also relevant to our task in the sense that word repetition should be avoided.

3 Task Definition

Our task focused on lexical choice in MT, particularly choice regarding repeated words in a source sentence. The translation direction was Japanese to English. Participants were required to control an MT system using reduction or substitution so that it did not output the same words for certain repeated words in a source sentence. Simultaneously, participants also needed to maintain translation quality as much as possible.

The challenges underlying this task included the following:

- Maintaining the balance between translation quality and controlling the output: Translation quality can be degraded when the non-repetitive style is enforced inappropriately.

- Avoiding bias toward high-frequency bilingual word pairs: Generally, for a given source word, high-frequency target words associated with it are more likely to be output. This can make it difficult to determine appropriate substitutions for some words.

- Predicting which words can be reduced or substituted: It is not easy to make an appropriate prediction because it depends on the context within the sentence.

- Mining training instances: Translations with reduction can be particularly difficult to identify in noisy corpora because of the challenge of discriminating them from undertranslations.

4 Dataset

We prepared the training, development, and test data for this task. They were all sourced from Japanese–English news articles published by Jiji Press LTD., a Japanese news agency. We annotated the development and test data for this task, whereas the training data comprised a regular MT corpus.

4.1 Development and Test Data

We provided development and test sets for this task, which we refer to as Jiji 2023 data and Jiji 2024 data, respectively. These data included 162 and 479 instances, respectively. The Jiji 2023 data were originally built for the Non-Repetitive Translation Task in WAT 2023 (Nakazawa et al., 2023). We reviewed the data and filtered out some instances this year. By contrast, the Jiji 2024 data were newly created in this year. In both datasets, all Japanese sentences contained some repeated words that were translated into English with reduction or substitution. From Japanese–English news articles, we first automatically created sentence pairs based on lexical similarities using the method of (Utiyama and Isahara, 2007) and then manually selected appropriate instances. To reduce the negative effects of imbalanced content in the source and target sentences, the Japanese sentences in the Jiji 2023 and 2024 data were manually translated from English by professional translators while preserving as much of the vocabulary of the original Japanese sentences as possible. Both the released development and test sets contained raw and tagged parallel data. In the tagged data, we marked repeated words in the source sentence and their counterparts in the target sentence with tags, which indicated that these words were evaluation targets. Examples are shown in Table 1. The respective attributes inside the tags indicate the following:

id: This indicates the IDs of repeated words. In the example, two tagged repeated words are included, that is, “機能” (“id=0”) and “製品” (“id=1”). The number of instances including multiple tagged repeated words, such as this example, are limited. Additionally, the number of types of repeated words in one instance is one or two.

ref: This indicates the IDs of pairs of source words and their counterparts, such as (“製品,” “models”) (i.e., “id=1” and “ref=0”) and (“製品,” “products”) (i.e., “id=1” and “ref=1”).

Ja	JEMAの担当者は白物家電について、「<target id=0 ref=0 type=s>機能<\target>を絞った低価格<target id=1 ref=0 type=s>製品<\target>、高価格な高<target id=0 ref=1 type=s>機能<\target><target id=1 ref=1 type=s>製品<\target>とも好調だ」と述べている。
En	“Shipments have been robust for both low-priced <target id=1 ref=0 type=s>models<\target> with reduced <target id=0 ref=0 type=s>functions<\target> and expensive <target id=0 ref=1 type=s>high-spec<\target> <target id=1 ref=1 type=s>products<\target>,” a JEMA official said.

Table 1: Examples of tagged instances in the development and test data. The tags are highlighted.

Split	# Parallel sentences
train	200K
dev	479
test	1851

Table 2: Statistics of the Jiji 2020 data. Note that “dev” and “test” in the table are different from the Jiji 2023 and 2024 data.

type: This indicates whether tagged source words are substituted (“s”) or reduced (“r”).

Note that not all words repeated in the source sentence were evaluation targets. This is because some words, such as proper nouns and technical terms, should be translated consistently, even if they were repeated in the sentence. We provided the tagged development data to help to tune the model during training. However, participants could not use the tagged test data when submitting the system results. In this task, the systems had to detect repeated words that could be reduced or substituted on their own.

4.2 Training Data

Regarding the training data, we provided all the data from the WAT 2020 Newswire tasks (Nakazawa et al., 2020), which were also constructed from Jiji news articles and have been continuously used in WAT since 2020 (Nakazawa et al., 2020, 2021, 2022, 2023). For simplicity, we refer to these data as Jiji 2020 data. The main files in the Jiji 2020 data are shown in Table 2. These data are a regular parallel corpus. They were not annotated specifically for this task but were in exactly the same domain as the Jiji 2023 and 2024 data. Although the development and test sets in the Jiji 2020 data, which are described as “dev” and “test” in Table 2, were not directly related to the evaluation of this task, they could be used to measure basic translation performance during training. Unfortunately, the number of parallel sentences in the Jiji 2020 data was limited. Thus, we allowed participants to use any other corpora for training.

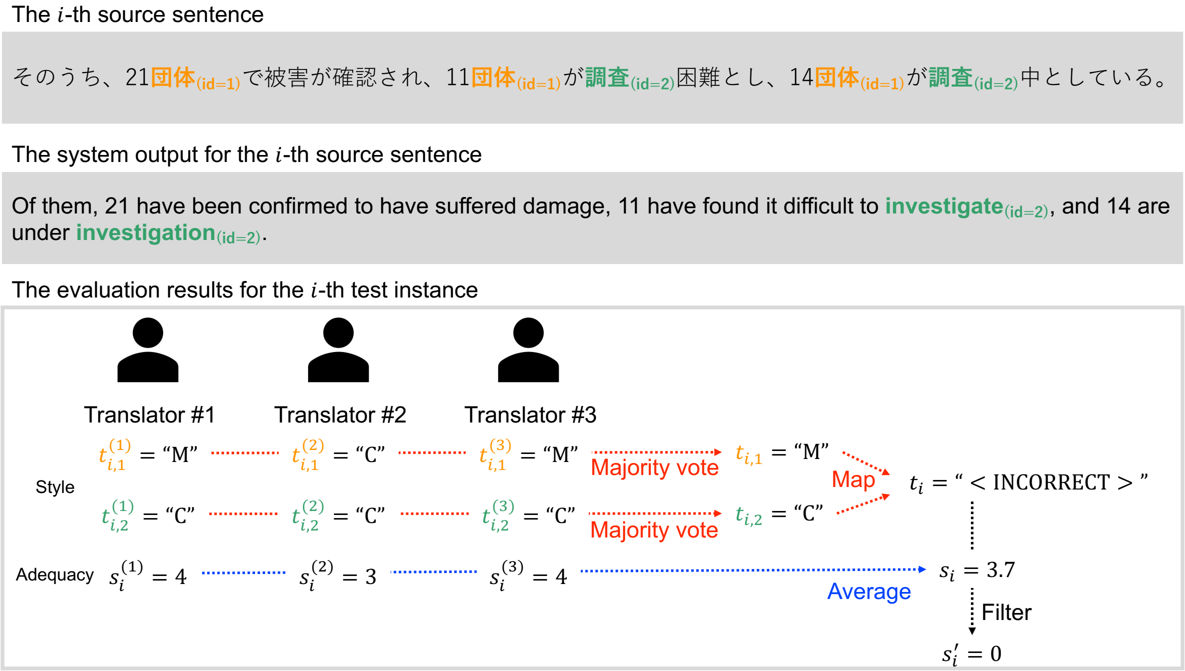
5 Evaluation

We conducted both human and automatic evaluation. We based the main results of this task on the human evaluation and prepared the automatic evaluation as secondary metrics. Again, the goal of this task was to control an MT system to output translations in a non-repetitive style while maintaining translation quality.

5.1 Human Evaluation

We evaluated system performance using the total number of outputs that met both acceptable translation adequacy and appropriate lexical choice. Both aspects were checked by three human translators, who were assigned by the authors.

Translation Style Regarding the evaluation for lexical choice, the human translators checked whether the translations for the tagged source words were correctly written in a non-repetitive style. Whether untagged repeated words were translated in a repetitive or non-repetitive way did not affect this evaluation. Moreover, the technique (i.e., reduction or substitution) did not have to be consistent with that of the reference translation. In our preliminary investigations, we qualitatively studied the lexical choices of several translators, and observed cases in which one translator chose substitution, and another chose reduction. Additionally, the systems did not have to choose the same words used in the reference, provided the meaning was appropriate. The determination of substitution or repetition was essentially based on the word stem. For example, conversions between voice (e.g., “attack” and “be attacked”), tense (e.g., “study” and “studied”), and parts of speech (e.g., “problematic” and “problem”) were not considered to be substitutions. Conversions to idioms (e.g., “visit” and “pay a visit”) were an exception and handled as substitutions. This evaluation is not trivial. For example, it is difficult to establish uniform guidelines for determining the correctness of synonyms in substitution and whether they are appropriate reductions



The i-th source sentence

そのうち、21団体(id=1)で被害が確認され、11団体(id=1)が調査(id=2)困難とし、14団体(id=1)が調査(id=2)中としている。

The system output for the i-th source sentence

Of them, 21 have been confirmed to have suffered damage, 11 have found it difficult to investigate(id=2), and 14 are under investigation(id=2).

The evaluation results for the i-th test instance

Figure 2: Example of human evaluation for the i-th test instance. "団体" (id=1) is undertranslated (at least one counterpart should appear in the output in this case) (the label is thus "M"), and "調査" (id=2) is translated in a repetitive style (the label is thus "C"). For simplicity, 1-indexed IDs are used for the repeated words.

or inappropriate omissions. Thus, we adopted a majority vote by the three human translators in this evaluation process.

Next, we explain the evaluation procedure for the i-th test instance, which is also illustrated in Figure 2. Other test instances were also evaluated in the same manner and all results were finally aggregated. First, each translator labeled the translations for the tagged source words in the i-th test instance as "S" (substitution), "R" (reduction), "C" (consistent, i.e., repetitive), or "M" (mistranslation or undertranslation). Note that "S," "R," and "C" implicitly indicate that the meaning of the translation is correct. Let the label for the j-th evaluation target in the i-th test instance given by the k-th translator be $t_{i,j}^{(k)}$. Next, the three labels $t_{i,j}^{(1)}$, $t_{i,j}^{(2)}$, and $t_{i,j}^{(3)}$ were reduced to one by a majority vote, which we denote by $t_{i,j}$. Because the number of types of labels was more than two, three labels could all be different. Although we assumed that such a case was limited, we introduced an additional heuristic rule to determine the label as follows:

- If the label set was equal to {"C,""R,""S"}, "S" was assigned to $t_{i,j}$: Because two translators thought it was correctly translated in a non-repetitive style, the label should be "R" or "S." Next, because two translators thought the word was not reduced, the label was determined to be "S."
- If the label set was equal to {"M,""R,""S"}, "R" was assigned to $t_{i,j}$: Because two translators thought it was correctly translated in a non-repetitive style, the label should be "R" or "S." Next, the label "M" was assigned probably because that translator thought some necessary word was omitted. Thus, the label was determined to be "S."
- If the label set was equal to {"M,""C,""S"}, "S" was assigned to $t_{i,j}$: Because two translators thought the meaning of the translation was correct, the label should be "C" or "S." Next, the label "M" was assigned probably because that translator thought some word had a slightly different nuance. Thus, the label was determined to be "S."
- If the label set was equal to {"M,""C,""R"}, "R" was assigned to $t_{i,j}$: Because two translators thought the meaning of the translation was correct, the label should be "C" or "S." Next, the label "M" was assigned probably because that translator thought some necessary word was omitted. Thus, the label was determined to be "R."

Finally, one representative label was assigned to the i-th test instance, which we denote by t_i. Representative labels were chosen from "<NON-REP>," "<REP>," and "<INCORRECT>." For test instances including only one target, the representative label t_i was simply mapped from $t_{i,1}$ as follows:

- If $t_{i,1}$ was "R" or "S," "<NON-REP>" was assigned to t_i.
- If $t_{i,1}$ was "M," "<INCORRECT>" was assigned to t_i.
- If $t_{i,1}$ was "C," "<REP>" was assigned to t_i.

For test instances including two targets, the representative label t_i was determined as follows:

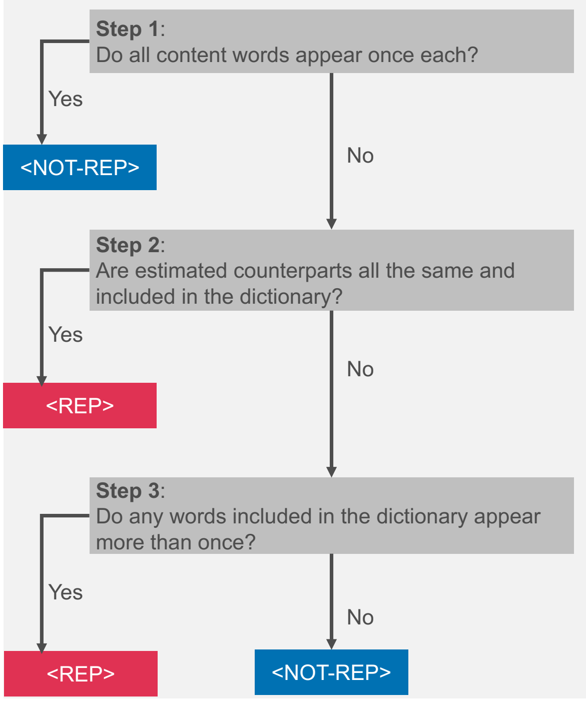
- If $t_{i,1}$ was "R" or "S," and $t_{i,2}$ was "R" or "S," "<NON-REP>" was assigned to t_i.
- If $t_{i,1}$ was "M" or $t_{i,2}$ was "M," "<INCORRECT>" was assigned to t_i.
- Otherwise, "<REP>" was assigned to t_i.

Translation Accuracy In this task, the content of the system output may be omitted incorrectly or obscured if reduction or substitution is enforced inappropriately. Thus, we measured translation adequacy for system outputs. The evaluation framework was based on Japanese Patent Office (JPO) adequacy.[4] This criterion is well established and has also been used in domains other than patents.

Specifically, the k-th translator assigned a five-level discrete score $s_i^{(k)} \in \{1, 2, 3, 4, 5\}$ to the i-th system output. Next, we averaged $s_i^{(1)}$, $s_i^{(2)}$, and $s_i^{(3)}$ to s_i. Additionally, to view the balance between translation style and adequacy, we reflected the style label t_i in the adequacy score s_i. If the translation style was not "<NON-REP>," we reduced the adequacy score s_i to 0. We refer to this metric as *filtered adequacy* and denote it by s'_i.

5.2 Automatic Evaluation

We also automatically predicted whether the target word was translated in a repetitive style. Note that "<NON-REP>" and "<INCORRECT>" could not be discriminated in this process. Thus, we introduced one more label "<NOT-REP>," which indicated "<NON-REP>" or "<INCORRECT>."



Step 1:
Do all content words appear once each?
Yes
No
<NOT-REP>
Step 2:
Are estimated counterparts all the same and included in the dictionary?
Yes
No
<REP>
Step 3:
Do any words included in the dictionary appear more than once?
Yes
No
<REP>
<NOT-REP>

Figure 3: Yes/no flowchart for predicting translation styles.

As a preprocess, we built a bilingual dictionary from the Jiji 2020 data and JParaCrawl v3.0 (Morishita et al., 2022). We aggregated translations of evaluation target words in the Jiji 2024 data by running the AWESOME aligner (Dou and Neubig, 2021) on the above corpora. Let the j-th evaluation target word in the i-th source sentence be $w_{i,j}$. Based on the alignment results, we obtained a set of possible counterparts of $w_{i,j}$, which we denoted by $S_{w_{i,j}}$. We then removed low-frequency counterparts from $S_{w_{i,j}}$ to limit the maximum dictionary size $|S_{w_{i,j}}|$ to 10. We predicted a style label by applying several simple binary classifications in order of reliability confidence as follows:

(1) *Do all tokens appear once each?*: If all content words appear once each in the i-th system translation, this output is classified as "<NOT-REP>."

(2) *Are estimated counterparts all the same and included in the dictionary?*: First, we estimate counterparts of $w_{i,j}$ using the word aligner. If these counterparts are all the same and exist in $S_{w_{i,j}}$, this output is classified as "<REP>."

(3) *Do any tokens in the dictionary appear more than once?*: If any word in S_{w_x} appears more than once, this output is classified as a repetitive style; otherwise, the output is classified

[4] https://www.jpo.go.jp/system/laws/sesaku/kikaihonyaku/tokkyohonyaku_hyouka.html (in Japanese)

as “<NOT-REP>.”

We designed the third block to mitigate misclassification caused by alignment errors in (2). The above procedures are illustrated in Figure 3. Finally, we calculated the percentage of instances labeled as “<REP>” in the test set. We refer to this metric as *repetition rate*.

To measure translation quality, we also computed BLUE scores (Papineni et al., 2002) using SacreBleu (Post, 2018).[5]

6 Systems

In this shared task, two teams submitted the system and description paper. In this section, we provide an overview of the submitted systems and the baseline system that we built. For comparison, resources used by each system are listed in Table 3.

6.1 Baseline

As a baseline, we built an MT system using fairseq (Ott et al., 2019). We adopted Transformer (big) (Vaswani et al., 2017) as the architecture, and used the Jiji 2020 and JParaCrawl v3.0 (Morishita et al., 2022) as training data. We based the method on the tagging approach (Sennrich et al., 2016; Lakew et al., 2019; Johnson et al., 2017; Schioppa et al., 2021). Specifically, we introduced style and domain tags, and combined them. First, from the Jiji 2020 data and JParaCrawl v3.0, we mined sentence pairs in which some content words were repeated in the source sentence and no content words were repeated in the target sentence. We detected content words in Japanese and English sentences using GiNZA[6] and spaCy,[7] respectively. To avoid selecting noisy instances, we excluded parallel sentences with lexical similarity scores less than 0.7 from the tagging. Specifically, we prepended the style tag “<NON-REP>” and all repeated words to the source sentences as follows:

Src: <NON-REP> <文書> 米国立公文書館が文書を保管していた。

Second, we also attached the domain tag “<JIJI>” to training instances from the Jiji 2020 data. Similarly, we did not tag sentence pairs with lexical similarity scores less than 0.7. We prepended the domain tag to the source sentences as follows:

Src: <JIJI> <NON-REP> <文書> 米国立公文書館が文書を保管していた。

System	Resource
Baseline	JParaCrawl v3.0, Jiji 2020
SYSTRAN	all Ja–En data from OPUS, Jiji 2020
Waseda Riko	Claude 3.5 Sonnet, examples from the task website[8]

Table 3: Comparison of resources used by each system. Although the Waseda Riko system did not explicitly use the data on which Claude 3.5 Sonnet was built, they are also listed as “Claude 3.5 Sonnet” in the table.

For inference, we prepended the style and domain tags to all the test source sentences. In this system, we adopted the same hyperparameter settings as Morishita et al. (2022).

6.2 SYSTRAN (Avila and Crego, 2024)

The team introduced a *repetition penalty* in the fine-tuning phase. The method was inspired by label smoothing (Szegedy et al., 2015). For training instances including word repetition in the target sentence, the ground-truth score corresponding to the repeated word was decreased from 1. The team automatically detected such instances using the spaCy tokenizer[9] and GIZA++ toolkit (Och and Ney, 2003). Specifically, the repetition penalty was combined with label smoothing, and is formulated as follows:

$$q'_t = (1-\epsilon)(1-\alpha_t)q_t + \frac{\epsilon}{V},$$

where q_t indicates a one-hot vector used as the ground-truth label at the t-th time step, at which a repeated word appears, ϵ is a hyperparameter for label smoothing and V is the vocabulary size. α_t is also a hyperparameter used to control the degree to which word repetition is discouraged. The team first trained a Transformer encoder-decoder model on parallel sentences from OPUS[10] and then fine-tuned the model on parallel sentences from the Jiji 2020 data using the above technique. To avoid feeding noisy instances into the model, the team used back-translated sentences instead of the original sentence pairs in the fine-tuning stage.

6.3 Waseda Riko (Wang et al., 2024)

The team built a large language model (LLM)-based pipeline. The procedure was composed of

System	BLEU (%) (↑)	Translation Style		Repetition Rate (%) (↓)
		# <NOT-REP>	# <REP>	
Waseda Riko	24.4	413	57	**12.1**
SYSTRAN	28.9	214	256	54.5
Baseline	**29.1**	332	138	29.4

Table 5: Automatic evaluation results.

the following four steps:

(1) Preprocess: Detect repeated words from the source sentence using the MeCab tokenizer (Kudo et al., 2004) and tag these possible repeated words.

(2) Translation: Instruct the LLM to translate the tagged source sentence in a non-repetitive manner using a few-shot prompt (Brown et al., 2020).

(3) Proofreading: Instruct the LLM to review the output in the previous step and rewrite the translation as needed to enhance the result.

(4) Postprocess: Tag the counterparts in the target sentence.[11]

The team used Claude 3.5 Sonnet[12] and designed a prompt suited for this task. Specifically, they instructed the LLM to output translations along with the estimated counterparts and translation labels in JSON format. Because of this structured output design, the following processes were performed successfully.

7 Results and Discussion

7.1 Human Evaluation

We summarize the human evaluation scores of all systems in Table 4.[13] The Waseda Riko system achieved the best results in both translation adequacy and style control. Focusing on the drop from the adequacy score to the filtered adequacy score, the baseline system lost 1.8 points, whereas the Waseda Riko system only decreased by 0.5 points. This difference highlights that the Waseda Riko team successfully controlled the translation style without compromising translation quality. The SYSTRAN system achieved an adequacy score competitive with that of the baseline system, but passed more source sentences in a repetitive style. By contrast, the baseline system was the worst in terms of the percentage of incorrect instances. Considering the difference between the SYSTRAN and baseline systems, a trade-off existed between style control and translation adequacy.

The basic idea of the Waseda Riko system is similar to that of the baseline system: possible repeated words in the source sentence were automatically detected using a third-party tokenizer and the model was explicitly informed about them. (Wang et al. (2024) also reported that it was still difficult for LLMs to consistently identify repeated words in the input sentence.) Although the baseline system was trained on parallel sentences that were (possibly) translated in a non-repetitive style, the percentage of test instances in the desired style was 50%. Although the results of the Waseda Riko team were also supported by the high performance of the commercial LLM, their proposed prompt design and pipeline configuration were equally important. The key was how to provide the instruction to "translate in a non-repetitive style," which is (probably) new and complex for many LLMs. We attempted to instruct GPT-3.5 turbo[14] to solve this task using a simple prompt, such as *"Translate the following Japanese news text into English using as few of the same content words as possible,"* in our preliminary experiments, but this did not work well.

[11] Human evaluation was performed on untagged translations; thus, it was not necessary to tag the system output.

[13] Detailed statistics are listed in Appendix B.

[14] https://azure.microsoft.com/en-us/products/ai-services/openai-service

7.2 Automatic Evaluation

We also summarize the automatic evaluation scores of all systems in Table 5. In contrast to the human evaluation, the baseline and SYSTRAN systems achieved a better BLEU score than the Waseda Riko system. This gap depended on whether the systems used the Jiji 2020 data for training. Although the Waseda Riko team analyzed these data and then built the heuristic rules to detect repeated words (Wang et al., 2024), the team did not fully train the LLM on these data. The LLM learned the several translations from the Jiji data using the few-shot prompt, whereas the baseline and SYSTRAN models adapted the output translations more directly to the target domain. Although we configured the primary results of this task based on the human evaluation, the motivation for this task was to adapt the lexical choice of MT systems to the target domain; thus, it should be noted that BLEU scores were also important metrics in our task.

Regarding the repetition rate, the trend was coincident with the human evaluation results. Specifically, the accuracy as a binary classifier (i.e., "<REP>" or not) between automatic and human evaluations was 93.4% in the baseline system, 92.1% in the SYSTRAN system, and 93.0% in the Waseda Riko system. Importantly, this metric had a certain degree of reliability independent of the success rate of style control and the degree of matching with the target domain.

8 Conclusion and Future Work

In this paper, we presented an overview of the WMT2024 Shared Task on non-repetitive translation. Particularly, the experimental results revealed the effectiveness of the LLM in controlling translation. We believe that our task will encourage further research on controlling MT systems. In the future, we will address several limitations in the current task settings. First, the test instances were limited to a comparatively short content. It would be an interesting challenge to address repetition observed in longer documents. Second, we will make both human and automatic evaluations more established. Currently, (1) evaluation relies heavily on human evaluation, and (2) the human evaluation is prone to variance. Regarding (2), specifically, although the percentage of test instances where the three translators voted for all different labels was limited, that of the test instances where the three translators voted for the same label was approximately 69%. These were partially because of (1) the difficulty of automatically detecting mistranslations and undertranslations, and (2) the difficulty of defining the correct answer for a translation output using substitution or reduction, respectively. Thus, we will develop more reliable evaluation guidelines in collaboration with translators. It would also be interesting to introduce automatic evaluation using LLMs.

Acknowledgments

We would like to thank the organizers of the WMT2024 for giving us the opportunity to present this task, the reviewers for their time and effort, and all the teams for their active participation in our task. We are also deeply grateful to Hidehiro Asaka and Takayuki Kawakami for providing the valuable data used in this research.

These research results were obtained from the commissioned research (No. 225) by National Institute of Information and Communications Technology (NICT), Japan.

A Examples of Non-Repetitive Trasnlations

Table 6 shows examples of non-repetitive translations from the task website.[15]

Reduction	Ja	耐震化を済ませていない４９４団体に今後の対応を尋ねたところ、改修するのは７０団体、建て替えは２６５団体、移転が１１団体だった。
	En(trans)	When the 494 organizations that had not yet completed earthquake proofing were asked about their future measures, 70 organizations opted for retrofitting, 265 chose rebuilding, and 11 selected relocation.
	En	Of the 494 unprepared municipalities, 70 are set to carry out repairs, 265 will construct new buildings and 11 are planning relocation.
	Note	In the original English sentence, a noun ellipsis occurs, e.g., “70 municipalities” is expressed as “70.”
Reduction	Ja	開発費を参加国間で分担できるため、国産開発に比べて費用を安く抑えることが可能となる。
	En(trans)	Since development expenses can be shared among participating countries, it will be possible to keep costs lower than domestic development.
	En	It will allow the government to cut spending compared with full domestic development by sharing costs with partner countries.
	Note	“Costs” is used instead of “development costs” in the original English sentence probably because it is contextually inferable.
Reduction	Ja	同社はニューヨーク州のヨンカース工場と中西部ネブラスカ州のリンカーン工場で車両の製造や試験を行う。
	En(trans)	The company will manufacture and test vehicles at its Yonkers, New York, factory and its Lincoln, Nebraska, factory in the Midwest.
	En	Kawasaki Rail Car will build and test the subway cars at its facilities in Yonkers and in Lincoln, Nebraska.
	Note	The two nouns (“facility”) are merged into one and the noun head is shared by the two prepositional phrases. Although strictly they are not reduced, we also consider these examples to be a type of reduction.
Substitution	Ja	農作物への影響が心配されるが、農林水産省は「（首都圏などでは）積雪が長引かなかったので大きな影響はない」（園芸作物課）とみている。
	En(trans)	There are concerns about the impact on crops, but an official at the Horticultural Crops Division of the Ministry of Agriculture, Forestry and Fisheries (MAFF) said, “the snowfall (in the Tokyo metropolitan area and other regions) was not prolonged, so there will be no major impact.”
	En	Although many people are worried about the effects of harsh cold on crops, an official of Japan’s agricultural ministry predicted that there will be no significant impact, as the snow did not stay for long in areas such as the Tokyo metropolitan area.
	Note	Words with similar meaning such as synonyms and hypernyms are typically used for substitution.
Substitution	Ja	物質を構成する素粒子の振る舞いは「標準理論」で説明されるが、宇宙の全質量の４分の１を占める「暗黒物質」など説明できない部分もある。
	En(trans)	The Standard theory explains the behavior of elementary particles, which make up matter, but it cannot explain some things, such as dark matter, which makes up one quarter of the mass of the universe.
	En	The so-called Standard Model explains the behavior of elementary particles, the fundamental building blocks of matter. But the theory leaves some mysteries, such as dark matter which is thought to make up about a quarter of the mass of the universe.
	Note	Repeated words are sometimes translated in a non-literal manner.
Substitution	Ja	当時、テニス部の生徒６人とコーチがコートで練習をしており、生徒の１人がボールを拾おうとしたところ、隣のコートにパラシュート状の物があることに気付いたという。
	En(trans)	At the time, six students and the coach from the tennis club were reportedly practicing on the court when one of the students went to pick up a ball and noticed a parachute-like object on the adjacent court.
	En	At the time, the student was practicing tennis with five other students and one coach at another court next to the one where the parachute was found.
	Note	Repeated words are sometimes substituted with pronouns or pro-verbs, such as “it” and “do so.”

Table 6: Examples of non-repetitive translations from Jiji Japanese–English news articles. “Ja” and “En” indicate the original parallel sentences from the articles. “En(trans)” indicates consistent translations by humans, which are listed for comparison.

Abstract

Translating for languages with limited resources poses a persistent challenge due to the scarcity of high-quality training data. To enhance translation accuracy, we explored controlled generation mechanisms, focusing on the importance of control tokens. In our experiments, while training, we encoded the target sentence length as a control token to the source sentence, treating it as an additional feature for the source sentence. We developed various NMT models using transformer architecture and conducted experiments across 8 language directions (English $\Longleftrightarrow$ Assamese, Manipuri, Khasi, and Mizo), exploring four variations of length encoding mechanisms. Through comparative analysis against the baseline model, we submitted two systems for each language direction. We report our findings for the same in this work.

1 Introduction

Developing Machine Translation solutions for low-resource language pairs is one of the most interesting areas under the umbrella of Machine Translation. There have been many ways of adapting Machine Translation for low-resource language pairs, like,

- Using statistical models instead of neural-based ones to build a system. (Koehn and Knowles, 2017)
- Using multiple combinations of word segmentation to tackle data sparsity in this setting. (Sennrich et al., 2016b; Mujadia and Sharma, 2021; Yadav and Shrivastava, 2021)
- Using monolingual data to create synthetic bitext and train an improved system. (Sennrich et al., 2016a; Burchell et al., 2022; Fadaee et al., 2017)
- Using a pivot language as a bridge between high and low resource language pairs. (Kunchukuttan et al., 2017)
- Using transfer learning (Zoph et al., 2016) by transferring the knowledge from a high language pair setting to a related low language pair setting.
- Multilingual NMT extended on transfer learning by sharing learning space between multiple languages, with the goal of low-resource pair learning from the high-resource pair in a system with decent success. (Johnson et al., 2017)

For low-resource languages, the scarcity of high-quality, extensive datasets necessitates carefully utilising available resources. To maximize the extraction of information from these limited data, we plan to append the target length at the end of the source sentences. This approach draws inspiration from previous research, where incorporating the target length significantly enhanced performance in subtitle generation (Lakew et al., 2019) and current work is adapted from Fan et al. (2018) work on summarization.

In the current work, we consider target token length, length of target sentence **after** subword segmentation, as an additional feature for the source sentence. Intuition is that the system will learn to produce translations subjected to target length. There is an issue of accurately predicting the number of target language tokens in test cases or real-world scenarios. To predict target length, we used multiple methods,

- Neural network to predict target length given source sentence.

Proceedings of the Ninth Conference on Machine Translation, pages 728–734
November 15-16, 2024 ©2024 Association for Computational Linguistics

- Mean token length ratio of target to source sentence from validation set (Lakew et al., 2019) to predict target length given a source sentence.
- Sampling from a normal distribution, where the mean and standard deviation are calculated based on the ratios observed in the validation dataset.
- And for comparison, we also used the actual target length from the test set provided in Pal et al. (2023).

Systems for translating between English and the languages Assamese, Manipuri, Khasi, and Mizo (collectively referred to as IL in the rest of the paper) were developed in this study. It was observed that utilizing the average ratio of target-to-source token lengths from the validation set proved to be an effective method for obtaining control tokens for translation in a low-resource context.

We summarize the contribution of our work as follows.

- Using the number of tokens as a controlling token to improve system performance in a low-resource environment.
- Viable strategy to get control tokens for unseen data.

2 Related Work

Lakew et al. (2019) biased the output length with a transformer architecture using i) target-source length ratio and ii) enriching the transformer positional embedding with length information.

Fan et al. (2018) added the number of tokens to be generated in abstract summarization during training and observed an improvement in the ROUGE score. However, replicating the same for machine translation has been challenging. As Stahlberg (2020) noted, length information can be provided as additional input to the decoder network (Fan et al., 2018; Liu et al., 2018) at each time step as the number of remaining tokens (Kikuchi et al., 2016), or by modifying Transformer positional embeddings (Takase and Okazaki, 2019). Nonetheless, these methods are not directly applicable to machine translation due to the difficulty in accurately predicting translation length.

Additionally, Lakew et al. (2019) biased the output length with a transformer architecture using i) the target-source length ratio and ii) enriching the transformer positional embedding with length information.

3 Approach

This section describes our strategies for computing the control token number, datasets used for training and testing, model architecture, evaluation and systems submitted in shared task.

3.1 Control Tokens

Predicting target length accurately in machine translation remains a complex task, influenced by various factors such as language pair characteristics, sentence structure, and context. To address this challenge, we use a few straightforward heuristics to leverage insights from training and validation data to estimate control tokens effectively. These heuristics aim to give additional information about output length for generation to MT systems. Control tokens (CT) were generated using the following methods (Figure 1):

- **Actual Control Token** refers to the exact count of tokens in the target sentence, derived from a reference or gold standard.
- **Predicted Control Token** is obtained by training a transformer model to predict the number of target tokens given source sentences, where the model learns to estimate the length of the target sentence based on the features extracted from the source sentence. We did this to leverage the self-attention mechanism of the transformer to capture contextual dependencies effectively, making it suitable for tasks requiring an understanding of sentence structure and length prediction.

$$\text{Attention}(Q, K, V) = \text{softmax}(\frac{QK^T}{\sqrt{d_k}})V \tag{1}$$

- **Ratio Control Token** is the target-to-source token length ratio of the validation dataset for each language pair. Here, we utilize the relationship between the

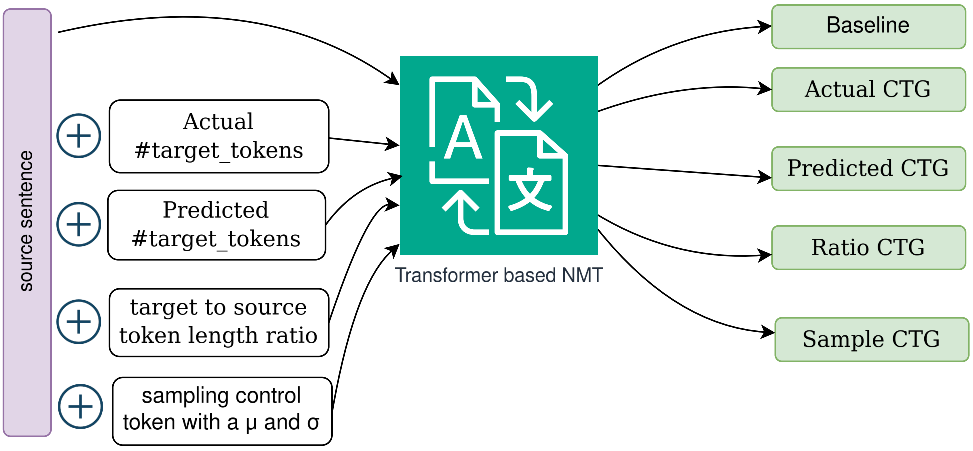

Figure 1: Illustration of our Control Token Generation (CTG) approach

lengths of target sentences and their corresponding source sentences from the validation dataset. For i^{th} source sentence, the control token (CT) is,

$$CT = R_{avg} * len_{source_i} \tag{2}$$

where $R_{avg} = \frac{\sum_{\forall j} len_{target_j} / len_{source_j}}{\text{number of sentence pairs}}$ and, len_{sent} is length of token length of *sent*.

- **Sampled Control Token** is achieved by sampling from a normal distribution where the mean and standard deviation are derived from the ratios observed in the validation dataset.

$$CT = \mathcal{N}(R_{avg}, \sigma^2) * len_{source_i} \tag{3}$$

where $R_{avg} = \frac{\sum_{\forall j} len_{target_j} / len_{source_j}}{\text{number of sentence pairs}}$, σ^2 is standard deviation in ratios and, len_{sent} is token length of sentence *sent*.

3.2 Datasets

We used the Dataset from Pal et al. (2023), Pakray et al. (2024) for English $\iff$ Assamese, Manipuri, Khasi, and Mizo. Table 1 gives the statistics for each language pair and merge operations (mergeOps) used for the Byte Pair Encoding model of both source and target sentences (Sennrich et al., 2016b).

Figure 2 gives the distribution of IL sentence length with English sentence length ratio for all language pairs. Some sentences in training data have very high ratios compared to validation or test sets. This is where our method can induce learning correspondence between the number of tokens generated and the Control token.

Language Pair	Train	Validation	Test	mergeOps
English Assamese	50 K	2000	2000	16K
English Mizo	50K	2000	1500	16K
English Khasi	24K	1000	1000	4K
English Manipuri	21K	1000	1000	16K

Table 1: Dataset with merge operation for respective language pair

3.3 Architecture

For all the models, we trained machine translation models with the Transformers architecture(Vaswani et al., 2017) using fairseq(Ott et al., 2019) tool[1]. During the training, each source sentence was appended with a ‘control token number’, the count of target tokens.

4 Experiments

To select the systems as primary and contrastive output, we carried out experiments for English $\iff$ Assamese, Khasi, Manipuri and Mizo and evaluated the translations of the test set from Pal et al. (2023) using lexical-based metrics, CHRF++ (Popović, 2017).

4.1 Results and Analysis

Table 2 summarises the performance of translation systems for EN-IL and IL-EN using CHRF++. We found statistically significant improvement in translation performance by adding a control token as an additional feature. We observed that,

- In most of the cases, scores improve when the Actual CT is added to the source.

[1] We used basic configuration of transformer architecture

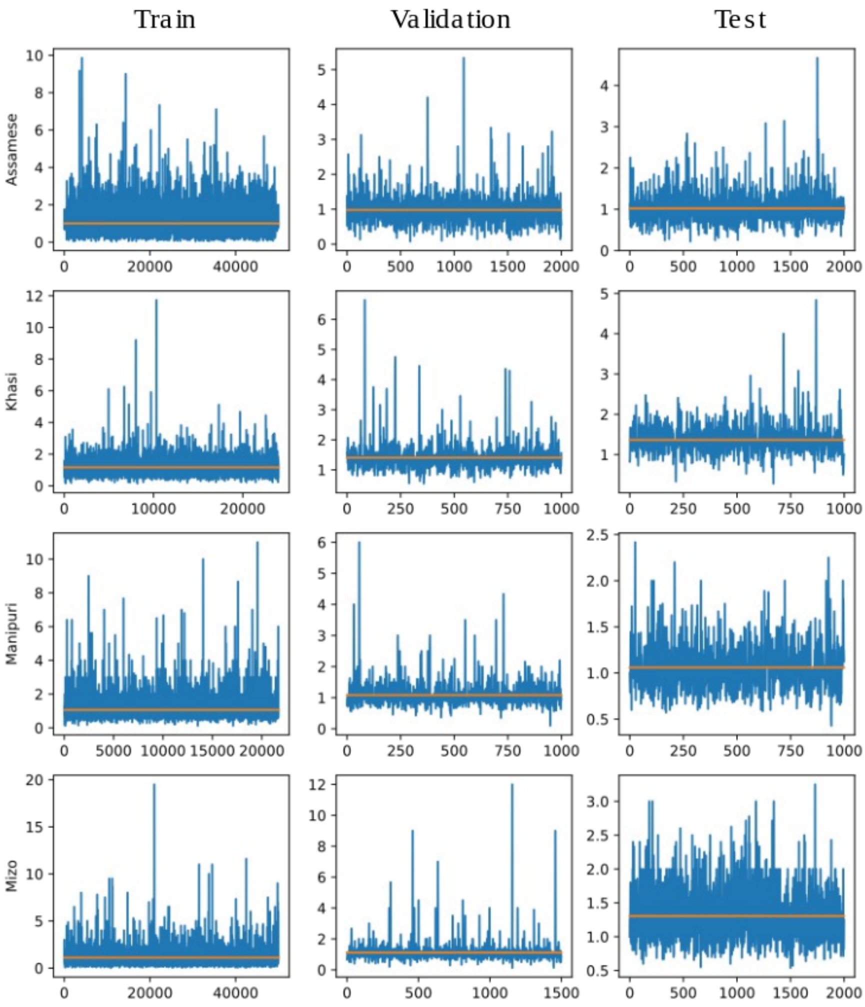

Figure 2: Distribution of Sentence Length Ratio (IL/English) across Train, Validation, and Test Datasets. The orange line denotes the average ratio. The X-axis indicates the number of sentences, and the Y-axis depicts the Sentence Length Ratio (IL/English).

This is expected since it is a gold reference, ensuring the number of target tokens is precise.

- Predicting CT is a challenging problem, as mentioned earlier. While there were improvements in systems, there is also a significant drop in CHRF++ scores for English to Mizo and English to Khasi.

- Utilizing the ratio from validation to determine CT appears to be an optimal choice, which becomes more apparent when examining the distribution of sentence length ratios of Validation and Test in Figure 2. Here, a clear similarity is observed between the two distributions regarding the range of sentence ratios. The inclusion of Ratio CT led to improved performance for English to IL, and vice-versa following actual CT.

- Sampled CT demonstrated strong performance for English to IL, but it did not exhibit the same level of effectiveness for

Language Direction	Baseline	Actual CTG	Predicted CTG	Ratio CTG	Sampling CTG
EN-MZ	**38.11**	37.72	31.44	36.37	37.23
EN-MN	30.47	**32.27**	**31.96**	**32.21**	**32.11**
EN-KH	31.69	**35.35**	26.07	**34.28**	**35.53**
EN-AS	18.44	18.62	18.63	17.67	17.49
MZ-EN	31.03	**32.77**	29.25	**31.5**	**32.68**
MN-EN	**35**	34.24	32.62	34.03	34.45
KH-EN	26.23	**27.58**	26.42	**27.09**	**27.39**
AS-EN	22.76	**24.12**	**23.76**	**23.98**	22.79

Table 2: CHRF++ scores of EN-IL and IL-EN Translation system. Scores in Bold are statistically significant improvements compared to the baseline scores with p<0.05.

IL to English. Despite this, it performed comparably well to Ratio CTG in the English to IL direction.

We further analyzed the target-to-source length ratio for EN-IL direction for all 4 language pairs in Figure 3. Examining the average sentence length ratio between Train (●) and baseline systems (■) in comparison to the reference length ratio (▲), sheds light on the behaviour of baseline systems and highlights the advantage of employing CT. In the case of English to Manipuri and Khasi, where significant improvements in CHRF++ scores were noted, the length ratio for baseline systems fell short of the test set. Conversely, when considering the Ratio CTG (◆), we observe their proximity to the Reference Ratio. This supports the idea of using control tokens as an additional feature in the source sentence. It also explains the impact of a poorer prediction system; as seen in the English-to-Mizo ratio, which overshoots by a large margin, there is also a significant drop in translation performance.

Based on these observations, we conclude that if the target sentence length is predictable, leveraging it as an additional feature with the source sentence proves to be a great choice for training a translation model in a low-resource setting.

4.2 Submission

For Translation submission, we preprocessed unseen testset shared by Organizers and submitted translations from the following two systems,

- Primary System: is a model trained using transformer architecture with source sentence and target output length predicted using average **Ratio** of source and target sentences in the validation dataset.
- Contrastive System: is a model trained using transformer architecture without adding CT (Baseline).

Language Direction	**System**	**TER**	**RIBES**	**METEOR**	**ChrF**
English to Assamese	Baseline	100.46	0.0347	0.0587	0.1817
	Ratio	99.79	0.0243	0.05134	0.1773
English to Manipuri	Baseline	101.73	0.0084	0.0179	0.1401
	Ratio	101.55	0.0072	0.0166	0.1415
English to Mizo	Baseline	92.32	0.0406	0.0978	0.18
	Ratio	92.84	0.0328	0.0906	0.173
English to Khasi	Baseline	92.92	0.087	0.1209	0.1905
	Ratio	87.69	0.0873	0.1589	0.2296
Assamese to English	Baseline	96.44	0.0378	0.0677	0.1803
	Ratio	96.19	0.0322	0.0671	0.1883
Manipuri to English	Baseline	96.45	0.029	0.0615	0.1865
	Ratio	96.5	0.0271	0.0635	0.1889
Mizo to English	Baseline	97.75	0.0195	0.0544	0.1633
	Ratio	96.18	0.0181	0.0587	0.1826
Khasi to English	Baseline	105.76	0.0094	0.0403	0.1358
	Ratio	107.7	0.0071	0.0359	0.1348

Table 3: Performance on Unseen Testset

5 Performance on Unseen Testset

Despite the promising results in test sets with training datasets, on the Unseen test set (3) provided by the shared task organizer (Pakray et al., 2024), our approach only gave a slight increase in score compared to the baseline in English to Manipuri, English to Khasi, Assamese to English, Manipuri to English and Mizo to English.

6 Conclusion and Future Work

We address the challenge of translating languages with limited resources by enhancing translation accuracy using target sentence length as an additional feature in the source sentence. We experimented using transformer architecture across 8 language directions (English $\Longleftrightarrow$ Assamese, Manipuri, Khasi, and Mizo). Evaluation against baseline models on a shared test set revealed that our approach significantly improves translation quality in some language directions, demonstrating its effectiveness in improving translation for low-resource languages. However, for the unseen dataset, even though there was an improvement, it wasn't that huge. Overall, we also found that the baseline systems themselves were not promising. Hence, we would be repli-

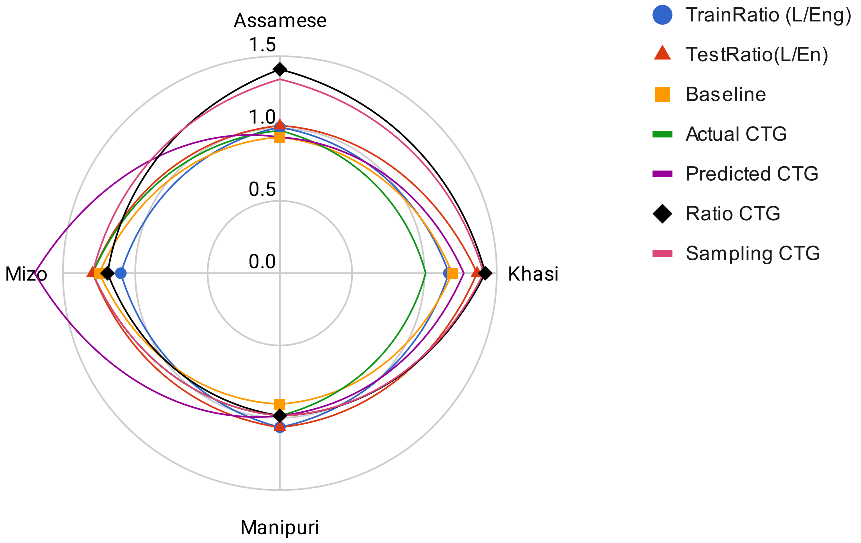

Figure 3: Distribution of Average Sentence length Ratio (IL/English) for Train, Validation and Test Dataset for all language pairs in English to IL direction.

cating this work with other datasets and language pairs to check the validity of this outcome.

Abstract

This paper presents the methodology developed by the Samsung R&D Institute Philippines (SRPH) Language Intelligence Team (LIT) for the WMT 2024 Shared Task on Low-Resource Indic Language Translation. We trained standard sequence-to-sequence Transformer models from scratch for both English-to-Indic and Indic-to-English translation directions. Additionally, we explored data augmentation through backtranslation and the application of noisy channel reranking to improve translation quality. A multilingual model trained across all language pairs was also investigated. Our results demonstrate the effectiveness of the multilingual model, with significant performance improvements observed in most language pairs, highlighting the potential of shared language representations in low-resource translation scenarios.

1 Introduction

This paper details our primary submission for the WMT 2024 Shared Task on Low-Resource Indic Language Translation. Our submission covers the following language pairs: English ↔ Assamese (en-as), English ↔ Mizo (en-mz), English ↔ Khasi (en-kh), and English ↔ Manipuri (en-mn). Our approach builds upon the methodology used in Samsung R&D Philippines' WMT23 entry (Cruz, 2023). We employed a standard sequence-to-sequence Transformer architecture (Vaswani et al., 2023), combined with data augmentation through backtranslation (Sennrich et al., 2016), noisy channel reranking (Yee et al., 2019), and additionally experiment with a multilingual model trained on all language pairs.

2 Methodology

2.1 Environment

For preprocessing, training, and generation, we utilized PyTorch 2.0 and fairseq 0.12.2. All training was conducted on NVIDIA P100 GPUs.

2.2 Data Analysis

We used the Indic dataset provided from WMT 2023 for all language pairs. First, we conducted an exploratory data analysis for all the languages to see if there were noteworthy patterns that could guide us in our translation in the Indic and English languages. We used various methods in this data analysis such as finding N-most common words, generating N-grams, and histograms of lengths of sentences.

An interesting pattern emerged when generating the histograms of sentence lengths as seen in Figure 1. For the English-Mizo pair, the distributions almost completely overlap. However, for the English-Assamese, English-Khasi, and English-Manipuri pairs, the Indic languages generally exhibit slightly longer sequences. We hypothesize that these longer sequences may cause translation errors in the Indic to English language directions. The models might be driven to provide translations that are driven more by length alignment, and so may attempt to fill in additional tokens to produce longer sequences even if it may not necessarily be semantically accurate.

2.3 Data Preprocessing

We exclusively used the task dataset for all language pairs. For the parallel data, we first removed exact duplicates, then detokenized the text to correct spacing around punctuation. The statistics of parallel data are summarized in Table 1. Following this, we trained a BPE tokenizer (Sennrich et al., 2015), applied BPE tokenization, and binarized the data for use with fairseq. Each language pair

has a shared vocabulary between English and the respective Indic language. The preprocessed parallel data was used to train our translation models. The same preprocessing steps were applied to the monolingual data for training the language models. As no monolingual data was provided for English, we used the combined English sides of the parallel data to train the English language model.

2.4 Augmenting Data with Backtranslation

Due to time and data constraints, data augmentation via backtranslation was applied only in the English-to-Indic direction. Backtranslated data was generated by translating the monolingual Indic data into English using the trained Indic-to-English models. After generating the backtranslations, we applied ratio-based filters (Cruz, 2023) to remove low-quality parallel data, filtering based on sentence length, token length, character-to-token ratio, pair token ratio, and pair length ratio. For more details, please refer to the original paper. The dataset statistics for the backtranslated data are presented in Table 2.

2.5 Model Training

For each of the four language pairs, we trained four models: two **Translation Models**, one for each translation direction, and two **Language Models**, one for each language. The specifics of these models are described in the following subsections. Three of these four models were combined for noisy channel reranking in one direction, as detailed in Section 2.7. Additionally, we experimented with a **Multilingual Model** using the same architecture as our translation models, but trained across all language pairs.

2.5.1 Translation Models

For the translation models (English→Indic, Indic→English), we trained encoder-decoder Transformer architectures (Vaswani et al., 2023) from scratch using parallel data. Separate models were trained for each language pair and for each translation direction. We used the large variant of the Transformer model with 213M parameters, training for 100,000 steps, with the first 10,000 being warmup steps (Gotmare et al., 2018), with a maximum of 8,000 tokens per step. The learning rates varied across language directions, as follows: en→as (9e-5), en→kh (5e-4), en→mizo (9e-5), en→mn (9e-5), as→en (5e-4), kh→en (5e-4), mizo→en (5e-4), and mn→en (5e-4). All other hyperparameters are detailed in Table 3.

These translation models were not only used as direct translation models but also served as channel translation models for noisy channel reranking, further discussed in Section 2.7.

2.5.2 Language Models

We trained monolingual language models for each language from scratch using the decoder-only component of the original Transformer architecture, as described by (Vaswani et al., 2023). We used the base variant of the Transformer, which contains 65M parameters. For the Indic language models (Assamese, Mizo, Khasi, Manipuri), we trained on the provided monolingual data. For the English language model, we concatenated the English side of the parallel data for training.

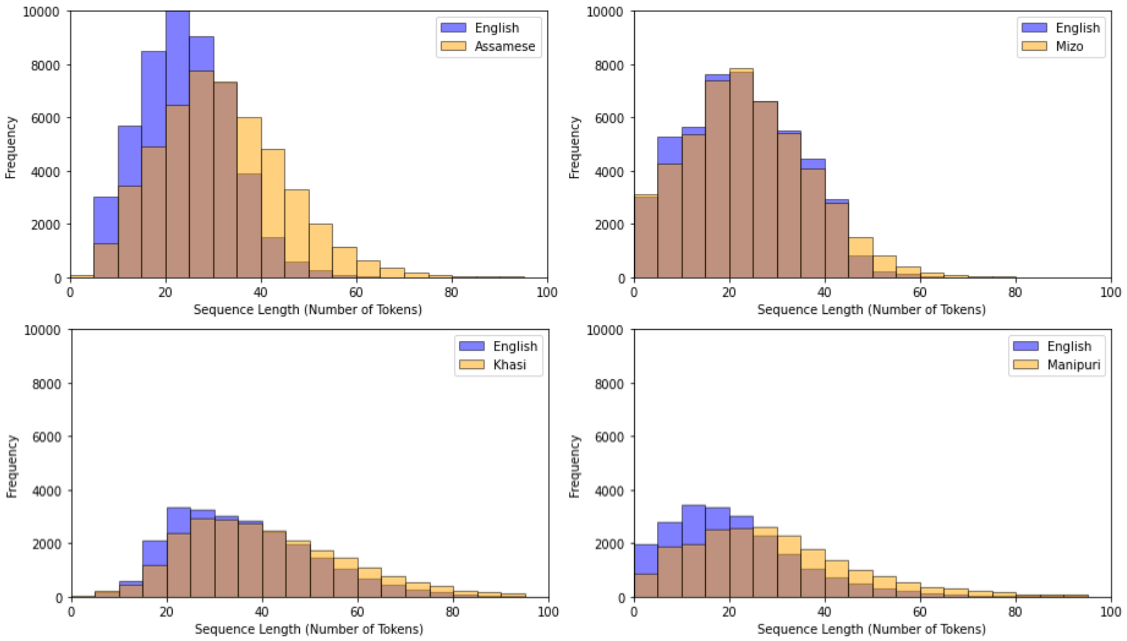

Figure 1: Histogram of Sentence Lengths

All models were trained using the Adam optimizer (Kingma and Ba, 2017) with $\beta_1 = 0.90$ and $\beta_2 = 0.98$. Training was conducted for a maximum of 100,000 steps, with the first 10,000 steps as a warmup (Gotmare et al., 2018). The learning rate started at 1e-7, peaked at 5e-4, and decayed following an inverse square root learning rate schedule. The batch size was set to 32,000 tokens, and a dropout rate of 0.1 was applied. These models were later used in noisy channel reranking, as detailed in Section 2.7.

2.6 Multilingual Model

We trained a large variant of the Transformer model with 213M parameters on all four language pairs, in both the English-to-Indic and Indic-to-English directions, following the approach of last year's entries (Zhang, 2023). Given the low-resource nature of each individual pair, we aimed to enable the language pairs to leverage cross-linguistic knowledge (Aharoni et al., 2019). The training process spanned 50,000 steps, with the first 5,000 steps serving as warmup (Gotmare et al., 2018; Neubig and Hu, 2018). We used 8 P100 GPUs for a maximum of 51,200 tokens per step and a learning rate of 1e-4. The remaining hyperparameters were consistent with those used in the other translation models as shown in Table 3.

Curriculum learning has been shown to improve generalization by introducing tasks progressively, allowing the model to build on prior knowledge (Wang et al., 2019). For our multilingual translation model, we aimed to apply a form of curriculum learning by training on different language pairs one at a time. We prepended source and target language tokens and trained the model sequentially on one language pair at a time. This structured training approach, inspired by Bengio et al. (2009), could help the model learn each language faster and transfer learned knowledge across language pairs. Similar to the benefits seen in multi-task learning by Niehues and Cho (2017), we hypothesized that this sequential training will enhance the model's ability to share representations across languages, ultimately leading to improved performance.

2.7 Noisy-Channel Reranking (NCR)

We experimented with Noisy Channel Reranking (Yee et al., 2019) to reevaluate and improve the translations. For brevity, we refer to this as NCR. This method utilizes three different models: a direct translation model (source→target), a channel model (target→source), and a monolingual language model (target only). These models are combined to rescore each candidate translation token during beam search decoding. The score for a candidate token $\hat{y}_i^{(T)}$ at timestep T is recomputed using the linear combination of the outputs from all three models:

Training Hyperparameters	
Vocab Size	31,960
Tied Weights	Yes
Dropout	0.3
Attention Dropout	0.1
Weight Decay	0.0
Label Smoothing	0.1
Optimizer	Adam
Adam Betas	β_1=0.90, β_2=0.98
Adam ϵ	ϵ=1e-6
LR Schedule	Inverse Sqrt
Batch Size	8,000 tokens

Table 3: Fixed hyperparameters for direct translation models.

$$\begin{aligned} P(\hat{y}_i^{(T)}|x;\hat{y}^{(T-1)})' = \frac{1}{t}log(P(y|\hat{x}^{(T-1)}) \\ +\frac{1}{s}[\delta_{ch}log(P(x|\hat{y}^{(T-1)}) \\ +\delta_{lm}log(P(\hat{y}^{(T-1)}))] \end{aligned} \tag{1}$$

Here, t represents the length of the target sentence y, and s represents the length of the source sentence x, both of which serve as debiasing terms. The weights δ_{ch} and δ_{lm} control the influence of the channel model and the language model, respectively, on the final score.

2.8 Decoding and Noisy-channel Reranking Hyperparameter Tuning

We determined the optimal length penalty values by sweeping across four values: 0.5, 1.0, 1.5, and 2.0. This was done for each language direction, and the length penalty that resulted in the highest BLEU score on the provided test data was selected. The optimal length penalties for each direction are as follows: en→as (1.5), en→kh (2.0), en→mizo (1.0), en→mn (1.5), as→en (2.0), kh→en (1.5), mizo→en (0.5), and mn→en (2.0). These values were then used to tune the channel and language model weights for NCR.

We applied a similar approach to find the optimal values for the channel weight, δ_{ch}, and the language model weight, δ_{lm}. For the English-to-Indic models, we fixed δ_{ch} at 0.1 and varied δ_{lm} across 0.1, 0.2, 0.3, 0.4, 0.5, and 0.6. For the Indic-to-English models, we reversed the setup by fixing δ_{lm} at 0.1 and varying δ_{ch} across the same values.

These configurations were chosen due to time constraints, which limited our ability to perform more exhaustive evaluations of various combinations of δ_{lm} and δ_{ch}. Additionally, based on our initial evaluation of the translation models, the English-to-Indic models exhibited stronger performance, so we focused on evaluating their impact as channel models in NCR. Conversely, the Indic language models were trained on significantly more data than the English language model, making it essential to assess their influence in the reranking process.

3 Results and Discussion

In this section, we present the results of our experiments and provide an in-depth discussion of our findings. Tables 4 and 5 summarize the BLEU and chrF scores for each model and method on last year's test set, respectively. Table 6 summarizes the hyperparameters used for training the models.

3.1 Baseline

Our baseline consists of standard Transformer models trained from scratch for each language pair, without any backtranslation, length penalty tuning, noisy channel reranking, or multilingual setup. These models were trained using the parallel data provided, with a shared BPE vocabulary between English and each respective Indic language.

For the English-Khasi pair in particular, we set the target vocabulary size to 10,000, while for the other three language pairs, we retained a target of 32,000. Initially, we aimed for a 32,000 vocabulary size across all language pairs, but English-Khasi's vocabulary only reached approximately 20,000. Given that this was our worst-performing pair, we reduced the target size to 10,000, resulting in a BLEU score improvement of about 3 points.

As shown in Table 4, the baseline models performed adequately for most language pairs, with BLEU scores ranging from 4.2 (Khasi→English) to 34.1 (English→Manipuri). Notably, the English-to-Indic models generally outperformed the Indic-to-English models across all language pairs.

3.2 Data Augmentation Using Backtranslation

The number of pairs in the backtranslated data, as shown in Table 2, was greatly reduced after filtering. This reduction most likely stems from the poor performance of the Indic-to-English models used for backtranslation. These models may have produced low-quality translations, leading to a substantial number of backtranslated pairs being dis-

source→target	**BLEU Scores**

mn→en	35.3	-	34.2	34.7	**44.2**

Table 5: chrF Scores from the WMT2023 Indic MT test data. The use of **BT Data** (training on backtranslated data) showed a decline in performance. The **tuned lenpen** (length penalty) and **NCR** (Noisy Channel Reranking) was tuned for the BLEU scores and yielded mixed results for chrF. The multilingual setting outperformed all other settings in all language pairs except en→as, where the baseline was best.

carded during the filtering process. The pairs that remained after filtering likely were still not of the best quality, which diminished the overall quality of the training. As a result, the models trained on this backtranslated data performed worse, as reflected in their BLEU scores in Table 4 and their chrF scores in Table 5.

3.3 Length Penalty

Our tuning of the length penalty, as shown in Table 6, revealed that most language directions, with the exception of English-to-Mizo and Mizo-to-English, preferred shorter translation sequences. As shown in Figure 1, the distribution of sentence lengths across the language pairs indicates a reasonable amount of overlap, though the Indic languages tend to have slightly longer sequences.

This preference for shorter sequences coincides with a known issue in Neural Machine Translation (NMT) models when handling long input sequences. NMT models typically rely on absolute positional encodings, which use fixed sine and cosine functions to assign vector positions. This approach tends to struggle with longer sequences due to the limitations of these fixed encodings, resulting in less precise representations as sentence length increases (Neishi and Yoshinaga, 2019). This is likely contributing to the models' difficulty in generating coherent longer translations, particularly for underperforming language pairs like English-Assamese and English-Khasi. As sequence length increases, the models are more prone to generating irrelevant or erroneous tokens, leading to a degradation in translation quality.

It is interesting to note that despite the Indic languages generally having longer sequences, a length penalty greater than one was found to be optimal for both directions, even in English-to-Indic translation. This indicates that the models may be biased

source→target	Hyperparameters		
	lenpen	ch_wt	lm_wt
en→as	1.5	0.1	0.2
as→en	2.0	0.6	0.1
en→mz	1.0	0.1	0.1
mz→en	0.5	0.4	0.1
en→kh	2.0	0.1	0.1
kh→en	1.5	0.2	0.1
en→mn	1.5	0.1	0.1
mn→en	2.0	0.3	0.1

Table 6: Final length penalty (lenpen), channel model weight (ch_wt), and language model weight (lm_wt).

towards shorter outputs across most language pairs, potentially as a safeguard against these positional encoding limitations. While this behavior aligns with our expectations for the English-Assamese pair based on its performance, the similar tendencies in the English-Khasi pair were more surprising, given the closer alignment of sentence lengths between these languages.

3.4 Noisy Channel Reranking

The BLEU scores obtained with NCR, as shown in Table 4, yielded mixed results. After tuning the length penalty, we observed that NCR improved performance for only one model out of eight, specifically English-to-Khasi. The chrF scores, as shown in Table 5, also indicate slightly improved performance with NCR solely for the English-to-Khasi pair. For all other language pairs, there was either no change in BLEU and chrF scores or a slight decrease. It is crucial to highlight that these results reflect the best combination of hyperparameters we identified; alternative hyperparameter settings would have resulted in even more pronounced variations in scores.

One notable finding is that the optimal language model weight was consistently around 0.1 across most language pairs. This suggests that the language model contributed minimally to improving translation quality. This issue may stem from either data quality or data quantity limitations. Investigating data quality issues would be valuable, but addressing them poses a significant challenge due to the already low-resource nature of the Indic languages. Further filtering could exacerbate data scarcity, making it difficult to maintain sufficient training data.

Conversely, the channel model weights were found to be more effective, with optimal values varying by language pair but generally falling in the mid-range. For the best-performing Indic-to-English pairs with NCR, specifically Mizo-to-English and Manipuri-to-English, the channel model weights were 0.4 and 0.3, respectively. These language pairs also had the best direct translation models and channel models, suggesting a stronger alignment between model quality and channel model effectiveness for these particular languages.

3.5 Multilingual Model

The multilingual model trained on all language pairs demonstrated considerable improvements over the baseline models, achieving the best performance in 6 out of the 8 language pairs. We attribute this success to the model's ability to learn from a broader context across all five languages, allowing for the creation of shared language representations. This approach is especially beneficial given the small size of the training datasets, as the multilingual model can leverage cross-linguistic knowledge to enhance translation quality.

However, due to time constraints, we were unable to explore the potential of using the multilingual model as a channel model within NCR. This remains a promising avenue for future research. Further studies could also investigate pre-training on the available monolingual data before fine-tuning for translation tasks. Additionally, fine-tuning the multilingual model for language modeling could further improve its utility in NCR, potentially acting out all three functions in NCR, leveraging shared linguistic knowledge on all languages and tasks, enhancing performance in low-resource language pairs.

4 Conclusion

In this paper, we presented our approach to the WMT 2024 Shared Task on Low-Resource Indic Language Translation. Our experiments demonstrated that the multilingual model trained across all language pairs performed exceptionally well, particularly in comparison to the baseline models, achieving the highest BLEU scores in 6 out of 8 language pairs and the highest chrF scores in 7 out of 8 language pairs. This indicates that leveraging shared language representations, especially when dealing with small datasets, can significantly enhance translation performance by utilizing cross-linguistic knowledge.

Despite some success, our attempts to improve results through data augmentation using backtranslation and noisy channel reranking yielded mixed outcomes. The poor quality of the Indic-to-English backtranslated data led to performance degradation, emphasizing the importance of both data quality and quantity in low-resource scenarios. Additionally, while noisy channel reranking provided benefits in isolated cases, its overall impact was limited, potentially due to suboptimal language model and channel model contributions.

The promising performance of our multilingual model suggests that further research could explore its integration within noisy channel reranking, possibly utilizing it as both a translation and a channel model. Additionally, future work should focus on enhancing the quality of backtranslated data and investigating pre-training strategies on monolingual data to boost the performance of low-resource language pairs.

Abstract

This paper describes the submission systems of DLUT-NLP team for the WMT24 low-resource Indic language translation shared task. We participated in the translation task of four language pairs, including en↔as, en↔mz, en↔kha, en↔mni. We used a transformer-based neural network architecture to train the model. Our system used the following methods: First, data processing was performed, and then we used monolingual data for pre-training. Next, we used parallel data for fine-tuning to obtain a multilingual translation model, and then we used this model for back-translation. We merged the back-translated data with the official parallel data and used the upsampling method to train a multilingual translation model from scratch. In order to improve the translation ability of the model for each translation direction, we fine-tuned the model for each language pair and used model averaging to obtain the best model for each language pair. Finally, we used kNN-MT and established a datastore using the official parallel data to assist translation in the inference stage. Experimental results show that our method greatly improves the BLEU scores for translation of these four language pairs.

1 Introduction

This paper introduces our system for WMT24 low-resource Indic language translation shared task. We participated in 4 language pairs, including English↔Assamese (en↔as), English↔Mizo (en↔mz), English↔Khasi (en↔kha) and English↔Manipuri (en↔mni).

The main methods used by our system are denoising language model pre-training (Lampple and Conneau, 2019; Song et al., 2019; Lewis et al., 2020), back-translation (Sennrich et al., 2016a) and kNN-MT (Khandelwal et al., 2020). Neural machine translation is the first choice for machine translation systems nowadays, but it requires a large amount of parallel data. Therefore, low-resource translation is a major challenge due to its lack of data. In this task, the organizers provided a large amount of monolingual data in addition to a small amount of parallel data. So we considered using some pre-training methods to improve the performance of the model. At the same time, back-translation is a commonly used method in the field of machine translation, which is effective in many scenarios. Therefore, we used the back translation method to obtain pseudo-parallel data to train a strong baseline model. To obtain the best model for each translation direction, we fine-tuned the baseline model for each language pair using the official parallel data. During this process, we used model averaging technology to improve the translation quality of the model. In addition to parametric methods, a large number of non-parametric methods have recently emerged to help models generate translations. We adopted the kNN-MT method and built a datastore for each translation direction to assist the model in the inference phase.

The rest of the paper is organized as follows: In Section 2 we describe our data processing methods; In Section 3 we describe the implementation process of our translation systems; In Section 4, we describe the experimental settings; In Section 5, we discuss about the results; Finally, in Section 6, the conclusion is drawn.

2 Data

For bilingual data, we only used official bilingual data. For monolingual data, in addition to the official monolingual data for Assamese, Mizo, Khasi and Manipuri (Pal et al., 2023; Pakray et al., 2024), we obtained English monolingual data from the WMT24 general task. Specifically, we used the English side of bilingual data (English↔German) in the WMT24 general task as English monolingual data.The statistics of the dataset is shown in Table 1.

test	2k	1k	1k	2k	-

Table 1: The number of sentences in the training, dev and test sets.

Since the quality of official data is relatively high, we did not perform additional preprocessing. For the English monolingual data, we performed some additional preprocessing steps. During preprocessing, we deleted sentences that were too long or repeated. And then we filtered out sentences in other languages by applying language identification. Finally we used an n-gram language model trained with KenLM (Heafield, 2011)[1] to calculate the perplexity of English monolingual data and removed sentences with high perplexity (>7,000). We used the Sentencepiece (Kudo and Richardson, 2018) tool to train a multilingual BPE (Sennrich et al., 2016b) model for subword segmentation. The training data includes all the parallel training data and monolingual data. The vocabulary size is set to 32,000.

3 System Overview

3.1 Pre-training

Using monolingual data for pre-training tasks is an effective solution for low-resource situations (Raffel et al., 2020). To this end, we first performed BART-style pre-training (Lewis et al., 2020) with all the available monolingual data and then fine-tuned the pretrained model with bilingual data. Following Lewis et al. (2020), we masked words with a probability of 0.15 and we randomly swapped words in the input sentences with a probability of 0.5.

After pre-training, we used all the bilingual data to fine-tune the pre-trained model. The bilingual data contains 4 language pairs in 8 translation directions.

3.2 Back-translation

To improve our translation pipeline, we explored the integration of back-translation as a potential enhancement. Back-translation involves using a trained model to translate from the target language back to the source language, effectively creating a synthetic parallel dataset. We used the approach inspired by Sennrich et al. (2016a) to generate pseudo-parallel corpus.

Specifically, we used the model fine-tuned in the pre-training phase. We used this model to translate all non-English monolingual data into English as pseudo-parallel data. Then we mixed all the pseudo-parallel data with the official bilingual data. We used this data to train a multilingual translation model from scratch. During training, we used upsampling method and the official parallel data was upsampled until it reached to a ratio of 1:1 with the synthetic data.

3.3 Language-specific Fine-tuning

Although multilingual translation models have made great progress, there is still the problem of inconsistent convergence of different language pairs in joint training (Wu et al., 2021; Huang et al., 2022). That is, different language pairs reach convergence in various training stages. We hope to get the best model for each language pair. Due to the low quality of pseudo-parallel data, we used the official bilingual data of each language pair to fine-tune the model trained using pseudo-parallel data.

During fine-tuning, we used the model averaging technology. Through model averaging, we combined the advantages of various models into a unified translation model. This process can not only improve the stability of the translation output, but also help improve the overall translation quality. We kept the three models with the lowest loss on the validation set for each language pair. We then used these three models to get the best model for each language pair.

3.4 kNN-MT

Non-parametric, k-nearest-neighbor algorithms have recently made inroads to assist generative models such as language models and machine translation decoders. Khandelwal et al. (2020) introduced k-nearest-neighbor machine translation

[1] https://github.com/kpu/kenlm

(kNN-MT): a simple non-parametric method for machine translation via nearest-neighbor retrievals was proposed and has been verified its effectiveness. According to his method, we constructed a datastore to store the translation examples to be accessed during decoding with the official parallel data. When decoding, we used the current translation context to retrieve the k-nearest-neighbors in the datastore. Let $\boldsymbol{x} = \left(x_1, \ldots, x_{|\boldsymbol{x}|}\right) \in \mathcal{V}_X^{|\boldsymbol{x}|}$ and $\boldsymbol{y} = \left(y_1, \ldots, y_{|\boldsymbol{y}|}\right) \in \mathcal{V}_Y^{|\boldsymbol{y}|}$ denote a source sentence and target sentence, respectively, where $|\cdot|$ represents the length of the sentence, and $\mathcal{V}_X$ and $\mathcal{V}_Y$ are the vocabularies of the source language and target language, respectively. Each target token y_t from the translation examples is stored in the datastore with a d-dimensional key ($\in \mathbb{R}^d$), which is the representation of the translation context $(\boldsymbol{x}, \boldsymbol{y}_{<t})$ obtained from the decoder of the pre-trained NMT model. The datastore $\mathcal{M} \subseteq \mathbb{R}^d \times \mathcal{V}_Y$ is formally defined as a set of tuples as follows:

$$\mathcal{M} = \{(f\left(\boldsymbol{x}, \boldsymbol{y}_{<t}\right), y_t) | (\boldsymbol{x}, \boldsymbol{y}) \in \mathcal{D}, 1 \leq t \leq |\boldsymbol{y}|\} \tag{1}$$

The size of the datastore for each translation direction is shown in Table 2. During decoding, kNN-MT retrieves the k-nearest-neighbor key–value pairs $\{(\boldsymbol{k}_i, v_i)\}_{i=1}^{k} \subseteq \mathbb{R}^d \times \mathcal{V}_Y$ from the datastore $\mathcal{M}$ using the query vector $f\left(\boldsymbol{x}, \boldsymbol{y}_{<t}\right)$ at timestep t. $f : \mathcal{V}_X^{|x|} \times \mathcal{V}_Y^{t-1} \rightarrow \mathbb{R}^d$ represents the intermediate representation of the final decoder layer from the source sentence and prefix target tokens. In our system, the value of k is set to 32 for all translation directions. In order to speed up the retrieval during translation, we used FAISS (Johnson et al., 2019). We then obtained the output probability for each token by interpolating the kNN-MT probability and the probability from the translation model. The formula for calculating the kNN-MT probability is:

$$\begin{aligned} & p_{k\mathrm{NN}}\left(y_t \mid \boldsymbol{x}, \boldsymbol{y}_{<t}\right) \\ & \propto \textstyle\sum_{i=1}^{k} \mathbb{1}_{y_t = v_i} \exp \frac{-\left\|\boldsymbol{k}_i - f\left(\boldsymbol{x}, \boldsymbol{y}_{<t}\right)\right\|_2^2}{\tau} \end{aligned} \tag{2}$$

The formula for calculating the output probability is as follows:

$$\begin{aligned} & P\left(y_t \mid \boldsymbol{x}, \boldsymbol{y}_{<t}\right) \\ & = \lambda p_{k\mathrm{NN}}\left(y_t \mid \boldsymbol{x}, \boldsymbol{y}_{<t}\right) + (1-\lambda) p_{\mathrm{NMT}}(y_t \mid \boldsymbol{x}, \boldsymbol{y}_{<t}). \end{aligned} \tag{3}$$

For all translation directions, we set λ = 0.3 and τ = 100 in the kNN-MT decoding.

4 Experiments

All of our translation models were implemented based on fairseq (Ott et al., 2019) and trained on 8 NVIDIA 3090 GPUs. All models use the same structure of 12 transformer layers (Vaswani et al., 2017). During training, we used the Adam (Kingma, 2014) optimizer with β_1 = 0.9, β_2 = 0.98, the learning rate scheduling strategy of inverse sqrt, the number of warmup step set to 4000, the maximum learning rate set to 0.0005 and FP16 to accelerate the training process. We trained our models till convergence with early stopping criteria with a patience of 5. The dropout ratio is set to 0.5. We used a fixed beam size of 4 and a length penalty of 0.8 when doing back-translation.

All experiments were evaluated using the sacrebleu (Post, 2018) tool to calculate BLEU (Papineni et al., 2002) scores on the official validation sets.

5 Results

As shown in Table 3, each method can bring certain improvements to the model. However, pre-training and back-translation did not bring much improvement. For example, pre-training leads to an improvement of 0.82 BLEU on average, while back-translation brings BLEU improvements of 0.41. In particular, back-translation has caused some damage to the performance of the model on some translation directions. The BLEU in en→mni direction dropped from 25.17 to 24.04. This may be caused by the low quality of pseudo-parallel data. We believe that fine-tuning the model separately using the data of each language pair is necessary for a multilingual translation model. And it achieves 1.03 BLEU improvement on average. Doing so can alleviate the problem of inconsistent convergence of different language pairs in joint training, although it does not benefit all translation directions. It can be seen that all translation directions

System	en→as	en→kha	en→mz	en→mni	as→en	kha→en	mz→en	mni→en

kNN-MT	**12.82**	**18.78**	**29.39**	**28.99**	**19.69**	13.82	**31.27**	**39.02**

Table 3: BLEU scores of all translation direction on validation sets

are further improved with kNN-MT (+2.33 BLEU). The four translation directions of the two language pairs en↔mni and en↔mz can even get an average improvement of 4.05 BLEU. This shows the great potential of kNN-MT in improving data utilization efficiency, inspiring more research on kNN-MT in low-resource scenarios. Finally, from the overall perspective, some translation directions do not benefit much from our methods. The translation performance of the model in these translation directions may be most limited by the size of the data. However, the results in most translation directions still achieve significant improvements over the baseline, which demonstrates the effectiveness of our approach for low-resource machine translation.

6 Conclusion

In this paper, we describe DLUT-NLP's submission to the WMT24 low-resource Indic language translation shared task. We participated in four subtasks with a total of eight translation directions. We leveraged methods ranging from pre-training, back-translation, language-specific fine-tuning and kNN-MT. Experimental results show that we achieved large improvements in all directions.

Limitations

We found that our system still has the following limitations:

- We did not perform effective filtering on the pseudo-parallel corpus, and we did not perform iterative back-translation. This may be the reason why our back-translation did not achieve the expected results.
- We believe that we have not made enough use of monolingual data. Next, we need to explore other ways to use monolingual data, such as using other pre-training tasks.
- We did not leverage any existing LLMs because we were not sure whether they were trained on languages other than English included in the task. This will also be a future exploration mission.

Abstract

In the context of the Indic Low Resource Machine Translation (MT) challenge at WMT-24 ((Pakray et al., 2024)), we participated in four language pairs: English-Assamese (en-as), English-Mizo (en-mz), English-Khasi (en-kh), and English-Manipuri (en-mn). To address these tasks, we employed a transformer-based sequence-to-sequence architecture (Vaswani et al., 2017). In the PRIMARY system, which did not utilize external data, we first pretrained language models (low resource languages) using available monolingual data before finetuning them on small parallel datasets for translation. For the CONTRASTIVE submission approach, we utilized pretrained translation models like Indic Trans2 (Gala et al., 2023) and applied LoRA Fine-tuning (Hu et al., 2021) to adapt them to smaller, low-resource languages, aiming to leverage cross-lingual language transfer capabilities (CONNEAU and Lample, 2019). These approaches resulted in significant improvements in SacreBLEU scores(Post, 2018) for low-resource languages.

1 Introduction

With increasing digital connectivity there is huge demand for good translations systems for people to access wide array of digital information in their native local languages. This gives people flexibility and ease of access. For any machine learning task, the quality and quantity of data is of paramount importance. There are multiple languages which have either negligible or zero digital footprint. On top of that presence of good quality parallel/ bitext data is even more rare event.

Due to increased demand and intangible benefits from translation systems there has been lot of research in the field of machine translation. One such area is the low resource machine translation system. In the above statement "resource" refers to data resource. We are working on handling translations for languages which have very less data available (both monolingual and parallel).

Some major works for multilingual Machine translation (approx 200*200 languages) is NLLB (Costa-jussà et al., 2022). Here the authors use Mixture of Experts (MoE) to train single large multilingual model capable of handling approx 200+ languages as source(src) and target(tgt) languages. One of the objectives behind NLLB is handling low resource languages.

The details of WMT23 Indic MT findings can be found here (Pal et al., 2023). For our PRIMARY approach (no additional data apart from what was shared), we pretrained language model (using monolingual data). We explored 2 pretraining objectives namely Causal Language Modeling (Radford et al., 2019) and denoising (Lewis et al., 2020). Using these Pretrained Language Models as initial model weights we finetuned for tranlstaion task using available parallel corpus.

For the CONTRASTIVE submission approach, we utilized pretrained translation models like Indic Trans2 (Gala et al., 2023) and applied LoRA Finetuning (Hu et al., 2021) to adapt them to smaller, low-resource languages, aiming to leverage cross-lingual language transfer capabilities (CONNEAU and Lample, 2019).

2 Related Work

Our submissions use the concepts like transfer learning, denoising pretraining (Lewis et al., 2020), Causal Language Modeling (Radford et al., 2019). We use denoising pretraining and causal language modeling as pretraining tasks. Using transfer learning we use the pretrained model for new task like translation. We use pretrained indic translation model like Indic Trans2 (Gala et al., 2023) for contrastive submission and adapted them to low resource languages using LoRA Fine-tuning (Hu et al., 2021). We aim to take advantage of cross-lingual language transfer capabilities (CONNEAU and Lample, 2019) and hence used IndicTrans2

machine translation model.

3 System Description

We have submitted in 2 categories i) PRIMARY ii) CONTRASTIVE

3.1 PRIMARY System

For PRIMARY System we trained the model from scratch using only the shared data as part of workshop. We trained separate model for each direction.

3.1.1 Tokenizer

First we need to train tokenizer for each english <-> language pair (ie:- one of Assamese, Manipuri, Mizo, Khasi). We use sentence piece[1] tokenizer library to train joint dictionary (combined vocab) for each of english <-> (Assamese, Manipuri, Mizo, Khasi) language pairs. We use mono data(each from as,mn,kh,mz languages) + almost equal amount of english data to train sentence piece tokenizer (subset choosen from AI4Bharat Samanantaar dataset (Ramesh et al., 2022)).

3.1.2 Pretraining

We Pretrain the model using monolingual data. We explored 2 subtasks for the same

1. Causal Language Modeling (Radford et al., 2019) - Here we train decoder only model for causal language modeling ie:- predicting the next word using context words. The pretrained decoder from this task is utilized to initialize the decoder component of our seq2seq architecture employed for the translation task.

2. Denoising Task (Lewis et al., 2020) - We integrate a seq2seq transformer model that takes a noisy version of the input (such as perturbed mono data, added tokens, or shuffled data) and expects the output from the decoder to be the original, unperturbed input. By utilizing this denoising objective task, we aim for the model to understand language patterns and structures. The pretrained model from this task can be used for translation task.

Both of the above pretraining tasks are explored independently and we used each tasks pretrained checkpoints for finetuning separately.

3.1.3 Finetuning

Using the pretrained checkpoint we finetune the models for translation task (with small amount of parallel data). Pretraining helps the model to understand the language nuances and leads to faster converging of models for translation tasks.

3.2 CONTRASTIVE System

For CONTRASTIVE Submission (where external data etc is allowed). We use translation model of other languages eg:- IndicTrans2 (Gala et al., 2023). As the 4 low resource languages ie:- Mizo, Manipuri, Khasi and Assamese are near to Indic Languages supported by (Gala et al., 2023) we believe the the model will benefit from shared parameters, vocabs and hence map Cross Lingual language references (CONNEAU and Lample, 2019). We use the same tokenizer as used by IndicTrans2 Model.

LoRA (Hu et al., 2021) adaptation is a lightweight and resource-friendly technique for customizing pretrained models. It involves adding small adapter weights (to certain layers) alongside the existing model weights. During training, the original model weights remain unchanged while only the adapter weights are updated. At test time, the adapter weights and the original model weights are combined to generate predictions. This approach allows for efficient customization without requiring extensive modifications to the original model. Since only a small number of parameters are updated during training, the overall training time is reduced. Additionally, this approach helps mitigate the issue of catastrophic forgetting to some degree.

Table 3: CONTRASTIVE Submission Model details

4 Experiments

4.1 Implementation

4.1.1 PRIMARY Submission

For Primary submission we use fairseq[2] framework for both pretraining and finetuning stage. The model architecture details can be found in Table 2. We experimented with lesser #encoder, #decoder layers as compared to standard (6 encoder and 6 decoder layers) to reduce model complexity and hence training time.

4.1.2 CONTRASTIVE Submission

For CONTRASTIVE submission we use IndicTrans2(Gala et al., 2023) and use huggingface peft library for LoRA finetuning. The model details can be found in Table 3

5 Results

The results as shared by conference committee are attached below. PRIMARY submission results Table 4 and CONTRASTIVE submission results in Table 5.

We use SacreBLEU (Post, 2018) for validation evaluation. The validation scores (development set) reported during training for Primary system are attached in Table 6

Direction	BLEU	TER	RIBES	METEOR	ChrF
en -> as	1.32	101.83	7.1	7.44	22.15
en -> mn	0	101.83	1.91	3.07	18.89
en -> mz	0	102.98	3.61	6.20	16.46
en -> kh	0.54	103.72	8.21	9.69	17.78

Table 4: PRIMARY Submission Scores on test suite

Direction	BLEU	TER	RIBES	METEOR	ChrF
as -> en	29.59	34.92	35.05	74.09	64.88

mz -> en	11.27	64.94	20.26	47.84	44.82
kh -> en	4.2	80.89	12.05	32.83	31.8

Table 5: CONTRASTIVE Submission Scores on test suite

5.1 Learnings

Following are the learnings from our Experiments

1. Transfer Learning benefits translation task. We saw it in PRIMARY submissions in which language models are pretrained on denoising/ causal language modeling(CLM) task and then transferred for translation task. Especially its evident from initial bleu score and loss. We saw denoising task led to faster converging of models (lower initial loss) relative to CLM task objective.

2. Languages that share a common linguistic ancestor or follow similar word order patterns (such as SVO or SOV) can benefit from using the same vocabulary and sharing parameters during initialization. This allows for more efficient training and better performance across related languages.

3. Using Translation for related language benefits from cross lingual language reference.(Bleu scores of CONTRASTIVE submission)

4. LoRA finetuning is effective for adapting a translation model to new low resource language (lesser training time and resources).

Direction	SacreBLEU
en -> as	8
en -> mn	16.9
en -> mz	22.3
en -> kh	11.1

Table 6: PRIMARY Submission Scores on development suite shared along with training data

[2] https://github.com/facebookresearch/fairseq

5.2 Conclusion

The adpatation of another language translation model to similar but low resource language is benefitted by sharing params, vocabs etc across languages (due to cross lingual language learning). LoRA finetuning leds to quicker converging for low resource languages (18-19 hours on A100 GPU with 40GB of RAM).

We have described our submission to WMT2024 Indic Translation Task, leveraging various concepts like Denoising task(Lewis et al., 2020), Cross Lingual Transfer Learning(CONNEAU and Lample, 2019), IndicTrans2 Model(Gala et al., 2023), LoRA adaptation(Hu et al., 2021) etc.

Limitations

1. Exploring impact of Iterative Backtranslation(Hoang et al., 2018) benefits using intermediate models in PRIMARY setting.

2. Exploring more pretraining task objectives for PRIMARY System.

3. Exploring multi task learning impact for PRIMARY systems.

4. Exploring the difference in scores, training resources for full precision finetuning vs LoRA finetuning.

Abstract

Machine Translation for low-resource languages poses significant challenges, primarily due to the limited availability of data.The WMT24 Low-Resource Indic Neural Machine Translation task challenges us to employ innovative techniques to improve machine translation for low-resource Indian languages. Our proposed solution leverages advancements in neural machine translation, focusing on methodologies such as back-translation and fine-tuning. By fine-tuning pretrained models like mBART, we achieved significant progress in translating languages such as Manipuri and Khasi. The best score was achieved for the English-to-Khasi (en-kh) primary model, with the highest BLEU score of 0.0492, chrF score of 0.3316, and METEOR score of 0.2589 (on scale of 0 to 1) and comparable scores for other language pairs.

1 Introduction

Machine translation is a sub-field of computational linguistics that focuses on developing systems capable of automatically translating text or speech from one language to another. The WMT24 task enables us to perform machine translation on those languages which are considered low-resource that is with limited data availability due to their lesser prevalence or documentation. Our work focuses on translating the 'En-X' language pair in both directions, where 'En' stands for English and 'X' includes Manipuri, a Tibeto-Burman language, and Khasi, which belongs to the Austroasiatic language family.

In recent years, Neural Machine Translation (NMT) has emerged as a powerful approach within machine translation, leveraging deep learning to achieve state-of-the-art results. Although, the NMT models being the data-hungry lead to peformance degradation when it comes to low resource languages. To tackle this problem, we employed fine-tuning and utilised the mBART (mbart-large-50-many-to-many-mmt) (Tang et al., 2020) experimenting with different configurations and settings for both preprocessing and training. mBART (Liu et al., 2020) is a multilingual sequence-to-sequence model trained on extensive monolingual datasets using a denoising autoencoder approach. It builds on the BART framework (Lewis et al., 2019) by combining a bidirectional encoder with a left-to-right autoregressive decoder, making it suitable for various translation tasks across multiple languages. Even if most of our final systems did not reach a satisfactory or competitive performance, we argue that our experiments brought up some interesting points that deserve more attention.

2 Related Work

In a comprehensive study, (Gaikwad et al., 2023) examined fine-tuning-based techniques to improve translation capabilities for low-resource languages by harnessing the multilingual IndicTrans2 model and achieved significant results.

In 2023, (Suman et al., 2023) utilized IndicBART (Dabre et al., 2022) and mBART-large-50, adapting them to specific language pairs and this method led to substantial performance gains for the Assamese and Manipuri languages.

Another 2023 study, (Jha et al., 2023), proposed and evaluated a multilingual neural machine translation system for Indian languages using the mT5 transformer. This system, trained on the modified Asian Language Treebank (ALT) dataset, demonstrated strong performance in translations between English, Hindi, and Bengali, achieving BLEU scores above 20 for five out of the six language pairs.

(Saini and Vidhyarthi, 2023) evaluated various pretrained models for English-to-Marathi translation, developing a bidirectional system. The

[0]* These authors contributed equally to this work.

Proceedings of the Ninth Conference on Machine Translation, pages 751–755
November 15-16, 2024 ©2024 Association for Computational Linguistics

findings indicated that fine-tuning significantly enhanced the mBART model's performance.

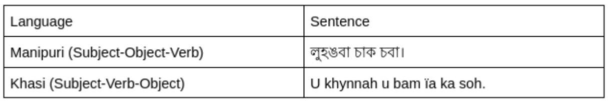
(Signoroni and Rychly, 2023) addressed the challenges of neural machine translation (NMT) for low-resource language pairs by using supervised NMT systems. They experimented with different configurations and settings for both preprocessing and training, delving into the complexities of translating these languages.

3 Dataset

3.1 Languages

Manipuri, also known as Meitei or Meiteilon, is predominantly spoken in the northeastern Indian state of Manipur and is one of India's 22 scheduled languages having about 1.8 million native speakers (Signoroni and Rychly, 2023). It is distinguished by its rich morphological features, including a complex phonological system with tones, an agglutinative structure, and a Subject-Object-Verb (SOV) word order, as shown in Figure1. As a tonal language, Manipuri uses various tones and pronunciations to convey meaning and employs primarily two scripts: Meitei and Bengali. Despite being a scheduled language, Manipuri is often considered a low-resource language in natural language processing, presenting valuable opportunities for transfer learning and the development of multilingual models.

Khasi primarily spoken in the northeastern Indian state of Meghalaya by the Khasi people, is one of the major languages of the region spoken by over 1 million individuals (Signoroni and Rychly, 2023). Belonging to the Austroasiatic language family, Khasi is more commonly written using the Latin alphabet. Structurally, Khasi typically follows a subject-verb-object (SVO) order, similar to English, but differs from most Indian languages, which generally use a subject-object-verb (SOV) order, as shown in Figure 1.



Language	Sentence
Manipuri (Subject-Object-Verb)	লুহঙবা চাক চবা।
Khasi (Subject-Verb-Object)	U khynnah u bam ïa ka soh.

Figure 1: Translations of "The boy eats an apple" showing word order in Manipuri and Khasi.

3.2 Composition

In this study, we used WMT 2024 (Pal et al., 2023) (Kakum et al., 2023) to fine-tune which includes both bilingual and monolingual data. For the bilingual data, we used the language pairs English-Khasi (en ↔ kh) and English-Manipuri (en ↔ mn). The compositions of these datasets are presented in Table 1 and 2.

Lang. Pair	Train	Test	Validation	Monolingual
en ↔ kh	24,000	1000	1000	182,737
en ↔ mn	21,687	1000	1000	2,144,897

Table 1: Number of lines in the dataset for the language pairs used in the task. The Monolingual column refers to the size of the non-English side.

Lang. Pair	Type:Token Ratio	Avg. Sentence Length
en ↔ kh	0.019 (en) 0.0093 (kh)	30.41 tokens (en) 36.48 tokens (kh)
en ↔ mn	0.0573 (en) 0.0083 (mn)	18.02 tokens (en) 15.23 tokens(mn)

Table 2: Training Dataset Statistics for Language Pairs: Type-Token Ratio and Average Sentence Length

4 System Overview

4.1 Initial Fine-Tuning

We begin by fine-tuning the mBART model (mbart-large-50-many-to-many-mmt) for the language pairs: English to Khasi (en → kh), Khasi to English (kh → en), English to Manipuri (en → mn), and Manipuri to English (mn → en). To ensure the quality and consistency of the bilingual data, we perform several preprocessing steps, including the removal of HTML tags, invisible characters, newline tabs, and duplicate entries.

For machine translation preparation, we tokenize both the input and the target texts. Truncating techniques are applied to standardize the texts by setting the maximum length of the tokenized sequences to 512 tokens. This ensures uniformity across all the examples in the dataset. This serves as our baseline model.

4.2 Data Augmentation

4.2.1 Backtranslation

A back-translation strategy (Sennrich et al., 2016) is employed to augment the training dataset with more data. Specifically, we back-translate 100,000 monolingual Khasi and Manipuri sentences into English using the baseline model. However, it is likely that the backtranslated data contains a significant portion of low-quality translations. To remove

Lang. Pair	Filtered Data
kh ↔ en	534
mn ↔ en	662

Table 3: Count of high-quality sentence pairs after cosine similarity filtering (threshold 0.84) for Khasi-English (kh ↔ en) and Manipuri-English (mn ↔ en).

low-quality data and ensure high-quality translation pairs, we employ a filtering process using the LaBSE model and cosine similarity.

4.2.2 Data Filtering

LaBSE Fine-tuning The Language-agnostic BERT Sentence Embedding (LaBSE) model (Feng et al., 2022) is not originally trained in the Khasi or Manipuri languages. Therefore, to generate accurate sentence embeddings for these language pairs, we fine-tune the LaBSE model specifically for en ↔ kh and en ↔ mn pairs, despite the limited size of available bilingual data. This fine-tuned model is then employed to produce sentence embeddings for the back-translated Khasi-English and Manipuri-English pairs.

Embedding and Similarity Calculation To ensure the accuracy of the back-translated data, we use cosine similarity, a metric that measures the cosine of the angle between two vectors in multidimensional space, to compare sentence embeddings. We apply a threshold of 0.84, effectively filtering out low-quality translations, and retaining only those pairs that meet our quality standards. Consequently, only a small portion of the original 100,000 back-translated sentences remain after filtering using this threshold. The data retained after filtering are presented in Table 3.

4.2.3 Further Filtering and cleaning

Despite filtering, some sentences with continuous symbols or non-English characters remain. To address this, we conduct an additional data cleaning round, removing sentences with continuous symbols and residual Manipuri or Khasi words in the English translations. The cleaned data is then combined with the original training set to create the augmented dataset as the final dataset.

4.3 Training with Augmented Data

Subsequently, we fine-tune the mBART model (mbart-large-50-many-to-many-mmt) using the augmented dataset, which includes both the original training data and the filtered back-translated data. The same data-preprocessing steps are employed for the augmented dataset as applied for the baseline model to maintain uniformity. The fine-tuning process incorporates this augmented data to enhance the model's performance and robustness.

5 Results and Analysis

Table 4 shows WMT24 evaluation results, highlighting a more challenging test set compared to last year. The low average semantic similarity score of 0.0253 as found using the (Reimers and Gurevych, 2019) sentence-transformer model that maps sentences to a 384 dimensional dense vector space to calculate semantic similarity between train and test data indicating reduced model performance too.

Among the primary models, the English-to-Khasi (en → kh) model, trained on both original and filtered back-translated data, performed the best across most metrics. It achieved the highest BLEU score of 0.0492, a chrF score of 0.3316, and a METEOR score of 0.2589, indicating strong performance for this language pair. The high chrF score shows effective capture of character-level nuances, while the lowest TER score of 84.79 reflects fewer required edits to match reference translations.

It is important to note that the Khasi-to-English (kh-en) primary model is excluded from this evaluation because of issues encountered during the evaluation process. Meanwhile, the English-to-Manipuri (en → mn) model shows a BLEU score of 0, highlighting the difficulty in translating from English to Manipuri. This may be partly due to the smaller size of the training data for this pair compared to the en-kh pair. Despite some fluctuations, the overall performance of both models is comparable in the test data.

When considering all metrics, the primary model shows slight improvements over the baseline model, indicating that the additional filtered back-translated data enhanced translation quality. However, the baseline model also performs competitively. The filtered back-translated data includes only 534 sentences for the kh ↔ en pair and 662 for the mn ↔ en pair (Table 3), with the small dataset likely due to stringent filtering.

Table 5 shows that the primary model slightly outperforms the baseline model in BLEU, chrF, and TER metrics for the English-to-Khasi (en → kh) and English-to-Manipuri (en → mn) models, sug-

Lang. Pair	BLEU (↑)	chrF (↑)	TER (↓)	METEOR (↑)	RIBES (↑)
Baseline					
en-kh	0.0359	0.2333	103.49	0.1649	0.1106
kh-en	0.0060	0.1731	106.60	0.1020	0.0487
en-mn	0.0064	0.3191	96.46	0.0724	0.0628
mn-en	0.0484	0.2662	101.76	0.1940	0.1087
Primary					
en-kh	0.0492	0.3316	84.79	0.2589	0.1595
en-mn	0.0000	0.3325	94.77	0.0822	0.0737
mn-en	0.0362	0.2777	94.79	0.1873	0.1136

Table 4: Results of Primary and Baseline models evaluated on WMT24 evaluation test data (scores calculated on the scale from 0 to 1)

Lang. Pair	BLEU (↑)	chrF (↑)	TER (↓)
Baseline			
en-kh	0.1748	0.3964	0.75699
kh-en	0.1274	0.3566	0.8791
en-mn	0.2089	0.5676	0.6537
mn-en	0.3265	0.5709	0.6522
Primary			
en-kh	0.1867	0.4126	0.7275
kh-en	0.1234	0.3570	0.8845
en-mn	0.2097	0.5726	0.6495
mn-en	0.3224	0.5698	0.6483

Table 5: Results of Baseline and Primary models evaluated on WMT23 validation data (scores calculated on the scale from 0 to 1)

gesting that filtered back-translated data improves translation quality. However, for the Khasi-to-English (kh → en) and Manipuri-to-English (mn → en) models, the primary model experiences a slight performance drop. This decrease is likely due to the filtered back-translated English sentences lacking coherence and contextual appropriateness, which affects the model's effectiveness. Despite these variations, the primary model still performs slightly better than the baseline model when considering all metrics.

6 Conclusion

Improving machine translation for low-resource languages remains a critical focus in the field. In this paper, we develop a system for translating low-resource Indic languages, specifically Manipuri and Khasi, in both English-to-Indic and Indic-to-English language pairs. We use back-translation and then apply cosine similarity for data filtering. While effective, their success depends on the quality of the back-translation and fine-tuned LaBSE models.

The morphological complexity of the Indic languages along with inability of capturing cultural and context specific meanings also poses as a challenge which the model could not solve. We further encounter challenges including data scarcity and high computational requirements which we believe can help produce better results.

7 Future Work

For future work, we aim to focus on enhancing machine translation for low-resource languages by leveraging language-specific properties such as part-of-speech (POS) tags and dependency parsing. By integrating POS tagging one can enable the model to better understand the syntactic roles of words, leading to more accurate and contextually appropriate translations. Dependency parsing can also capture the grammatical structure and relationships between words, allowing the model to manage complex sentence structures more effectively. Additionally, the use of more filtered backtranslated data can provide a richer training dataset, further improving translation quality. Combining these linguistic techniques with extensive backtranslation, so that we can capture the nuances of the individual low-resource languages, we can significantly address the current challenges in machine translation.

Abstract

CycleGN is a Neural Machine Translation framework relying on the Transformer architecture. Its approach is similar to a Discriminator-less CycleGAN, specifically tailored for non-parallel text datasets.

The foundational concept of our research posits that in an ideal scenario, retro-translations of generated translations should revert to the original source sentences. Consequently, a pair of models can be trained using a Cycle Consistency Loss only, with one model translating in one direction and the second model in the opposite direction.

One of the main advantages of such an approach is that it makes it possible to learn with non-parallel datasets, which are by definition rare and short for low-resource languages. In order to verify this hypothesis and as a contribution to the WMT24 challenge, CycleGN models were trained for both the "Translation into Low-Resource Languages of Spain" and "Low-Resource Indic Language Translation" tasks. These submissions fall under the "constrained" category, as no pre-trained translation model was used, and the models were trained using the provided datasets.

Given that the CycleGN architecture demonstrated its capacity to learn from non-parallel datasets, the authors anticipated that it would similarly be effective in learning from low-resource languages. However, preliminary results indicate that, for most low-resource language pairs, the models did not exhibit significant learning ability. This study explores this lack of learning.

1 Introduction

The introduction of the Transformer architecture (Vaswani et al., 2017) marked a significant advancement in Machine Translation, rapidly gaining widespread adoption. Its parallelized structure enhanced computational efficiency, allowing for the integration of a larger number of parameters.

Neural Machine Translation (NMT) relies on extensive text corpora, structured as aligned pairs, where sentences of equivalent meaning are available in at least two different languages. This alignment is crucial for initiating model training to establish linguistic connections. Ongoing efforts, such as OPUS (Tiedemann and Thottingal, 2020) and Tatoeba (Tiedemann, 2012), focus on providing public access to these datasets. However, parallel datasets represent only a small fraction of the total data available in monolingual datasets.

While large parallel corpora exist for many language pairs, the ability to utilize monolingual datasets alone would greatly increase the available training data. This approach is particularly advantageous for low-resource languages, with limited parallel text corpora.

Back-translation (Sennrich et al., 2016) is a technique that enhances training data by using a pre-trained machine translation (MT) model to translate sentences from a monolingual dataset, creating synthetic parallel pairs. This method allows for the generation of additional training examples in situations where parallel corpora are scarce.

This research builds on the concept that translating a sentence from a source language to a target language, and then back-translating it to the source language, provides a means to evaluate the effectiveness of the translation models. By comparing the original sentence with the machine-generated back-translation, the discrepancy is then quantified using a Cycle Consistency Loss, which serves as a metric for model performance and guides the backpropagation of gradients within the neural networks. This approach is analogous to techniques used in Image-to-Image Translation, such as the CycleGAN framework proposed by Zhu et al. (2017).

2 Previous work

The TextCycleGAN model (Lorandi et al., 2023), although not based on the Transformer architecture

Proceedings of the Ninth Conference on Machine Translation, pages 756–761
November 15-16, 2024 ©2024 Association for Computational Linguistics

or focused on Machine Translation (MT), introduced a novel approach for text style transfer. This method applied a CycleGAN to the Yelp dataset, enabling the model to learn mappings between positive and negative textual styles without the need for paired examples.

Shen et al. (2017) demonstrated the potential of training two encoder-decoder networks in an unsupervised manner, allowing for the sharing of a latent space and facilitating style transfer. Similarly, Lample et al. (2018) extended this technique to the MT domain, proving that effective translation can be achieved without relying on parallel datasets.

3 Definitions

Machine Translation models are most commonly trained using "parallel" datasets, which are structured collections of text pairs. Each pair comprises a segment of text in a source language and its translation in the target language. A non-parallel dataset on the other hand does not consist in pairs of text segments, consequently the source and target sentences do not share any explicit correspondence.

In the context of this study, the datasets are "permuted". A permuted dataset is defined as a parallel dataset wherein the sentences of one language have been systematically rearranged. Consequently, this results in a non-parallel corpus where it is guaranteed that each sentence has a corresponding translation located at an unspecified index within the dataset.

4 Datasets

The PILAR dataset (Galiano-Jiménez et al., 2024) has been used exclusively for the low-resource languages of Spain. Using a parallel curated dataset as a starting point ensures that the dataset is non-parallel by permuting the sentences. For each Iberian language, both a literary and a crawled versions were available in the PILAR datasets and have been merged for training. The development sets of the PILAR dataset are translations of the development sets of the FLORES dataset (NLLB Team et al., 2022), which is an evaluation benchmark for multilingual machine translation.

The Low-Resource Indic Language Translation task was also part of the WMT23 (Pal et al., 2023). The datasets were kept the same between the two editions.

Table 1 references the number of sentences used for each language-pair.

Language Pair	Number of lines	Number of epochs
Spanish-Aragonese	84,703	10
Spanish-Asturian	38,869	10
English-Assamese	2,624,715	1
English-Khasi	182,737	3
English-Manipuri	2,144,897	1
English-Mizo	1,909,823	1

Table 1: Number of sentences for each language pair and number of epochs during training

5 Training

For clarity and consistency, the mathematical notations from the original CycleGAN framework will be adopted in this study. The objective is to develop two Neural Machine Translation (NMT) models for two languages, $\mathcal{X}$ and $\mathcal{Y}$, using their respective datasets. Specifically, we aim to construct models $\mathcal{G} : \mathcal{X} \mapsto \mathcal{Y}$ and $\mathcal{F} : \mathcal{Y} \mapsto \mathcal{X}$ such that, in the ideal scenario of perfect translation, the relationships $\mathcal{G}(\mathcal{F}(y)) = y$ and $\mathcal{F}(\mathcal{G}(x)) = x$, with $x \in \mathcal{X}$ and for $y \in \mathcal{Y}$.

To achieve this, the Cross-Entropy Loss (CEL) (Zhang and Sabuncu, 2018) is utilised as the Cycle Consistency Loss (CCL), which measures the distance between the original sentence and its doubly translated counterpart, thereby guiding the computation of gradients.

Furthermore, similar to the original CycleGAN implementation, our study also incorporates an Identity Loss (IL) to enhance training stability. This loss, also based on CEL, ensures that when the model $\mathcal{G}$, which maps $\mathcal{X} \mapsto \mathcal{Y}$, receives an input $y \in \mathcal{Y}$, the output remains unchanged, i.e., $\mathcal{G}(y) = y$. The same loss function is applied to $\mathcal{F}$, ensuring that $\mathcal{F}(x)$ remains equal to x, as illustrated in Figure 1.

Further details of the training process, including the specific methodologies, vocabulary organization and pretraining, are comprehensively discussed in the CycleGN submission for the WMT24 main translation task. Readers interested in the full technical details are encouraged to refer to that publication for a more complete understanding of the training framework.

5.1 Model architecture

The architecture used for both models, $\mathcal{G}$ and $\mathcal{F}$, is the Marian framework (Junczys-Dowmunt et al., 2018) implemented by Huggingface's Transformers library (Wolf et al., 2020), which is licensed under the Apache Licence. While most parameters

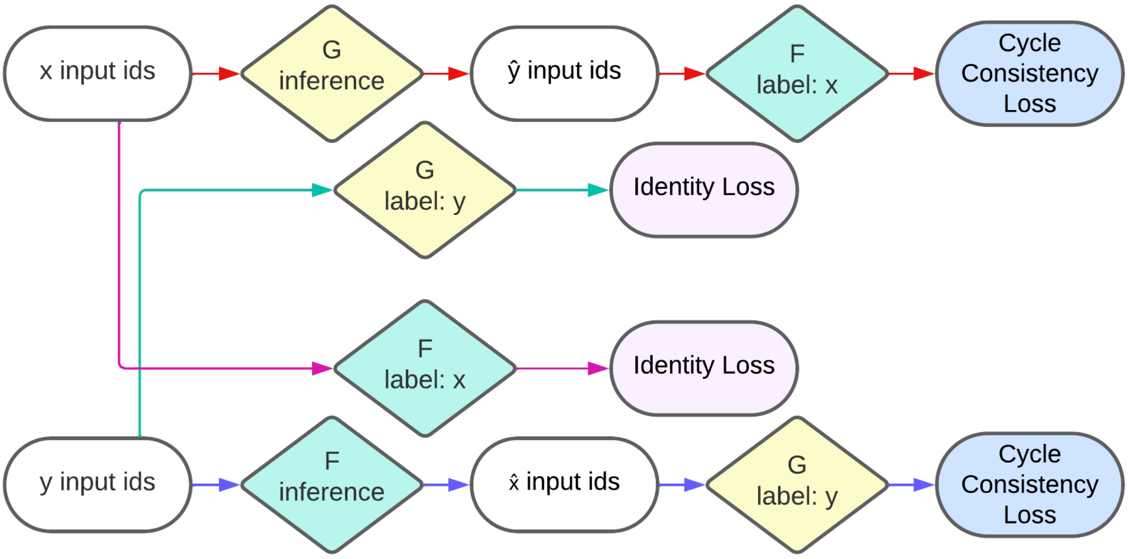

Figure 1: CycleGN training process

follow the default configuration, Table 2 references the changes that were made in order to reduce the computational cost of the architecture.

Parameter	Huggingface	Current work
Vocabulary size	58,101	32,000
Encoder layers	12	6
Decoder layers	12	6
Encoder attention heads	16	8
Decoder attention heads	16	8
Encoder feed-forward	4096	2048
Decoder feed-forward	4096	2048
Position embeddings	1024	128
Activation function	GELU	ReLU

Table 2: Non-default parameters in the configuration of Marian Transformer models

6 Results

Even if tracking the CCL is an inexpensive manner to estimate the progress of the training of the CycleGN architecture, a low loss value can also hide an absence of translation. Indeed, as there is no Discriminator to ensure that $\hat{x}$ belongs to $\mathcal{X}$ and $\hat{y}$ belongs to $\mathcal{Y}$, $\mathcal{G}$ and $\mathcal{F}$ will converge towards $x = \hat{y} = \hat{\hat{x}}$ and $y = \hat{x} = \hat{\hat{y}}$, as this approach achieves an optimal outcome on the CCL function, registering a value of zero. This is why an evaluation metric such as COMET is crucial to assess the progression of the CycleGN framework. To measure the performances of CycleGN, every 1,000th batch the CCL was averaged.

6.1 Indic Languages

Tracking the evolution of the CDC clearly shows the absence of learning in the four language pairs examined. The evolution of the CCL is particularly chaotic, which is partly due to an imbalance of class. Table 3 displays the average number of tokens in the Indic datasets depending on the language. In 3 of the 4 cases, the difference is large, i.e. sentences where the difference in the number of tokens is more than 10%.

Language pair	Length of source	Length of target
English-Assamese	33.10	22.81
Encoder layers	24.09	75.27
English-Manipuri	24.09	26.07
English-Mizo	32.05	17.55

Table 3: Average number of tokens in sentences

Figures 2, 3, 4 and 5 display the respective evolution of the Cycle Consistency Loss during the training of the language-pairs English-Assamese, English-Khasi, English-Manipuri and English-Mizo.

Contrary to what the authors had hoped for on the basis of previous results obtained for the main task of the WMT24 challenge, no model followed the expected learning curve, i.e. G and F models with a close and slowly decreasing Cycle Consistency Loss.

To reduce this imbalance of class, it may be necessary to manually adjust the size of the sentences.

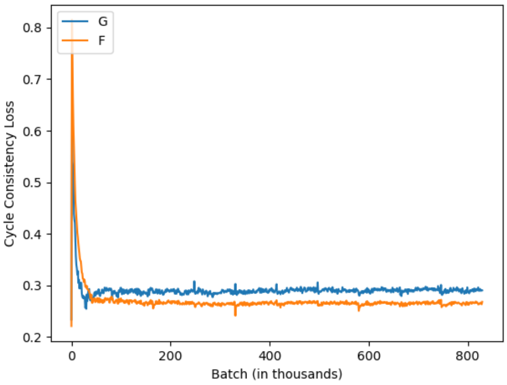

Figure 2: Evolution of the Cycle Consistency Loss during the training of the English-Assamese model

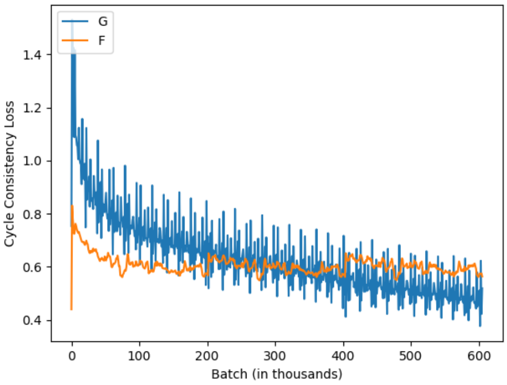

Figure 3: Evolution of the Cycle Consistency Loss during the training of the English-Khasi model

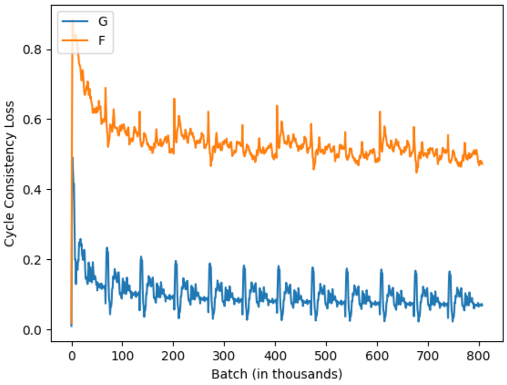

Figure 4: Evolution of the Cycle Consistency Loss during the training of the English-Manipuri model

This can be done by choosing another tokenization method, selectively choosing phrases to keep only those of a similar size, or by trimming sentences to lengthen or shorten them as required.

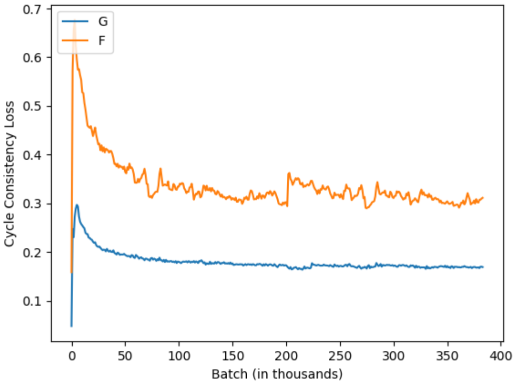

Figure 5: Evolution of the Cycle Consistency Loss during the training of the English-Mizo model

6.2 Iberian Languages

As with Indic Languages, CycleGN was unable to learn from the datasets provided. However, it was not due to an imbalance of classes in this case, but rather because the classes were too close together, as the Iberian languages are very close to the source language, Spanish.

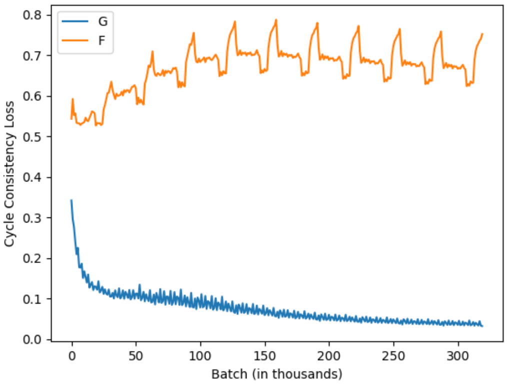

Figure 6: Evolution of the Cycle Consistency Loss during the training of the Spanish-Aragonese model

Rather than translating directly from Spanish into Aranese or Asturian, it is possible that translation can be achieved by using a different intermediate language such as English. Thus, two CycleGN models would have to be trained, the first to translate from Aranese or Asturian into English, and the second from English into Spanish. This would double the training time for an already expensive framework.

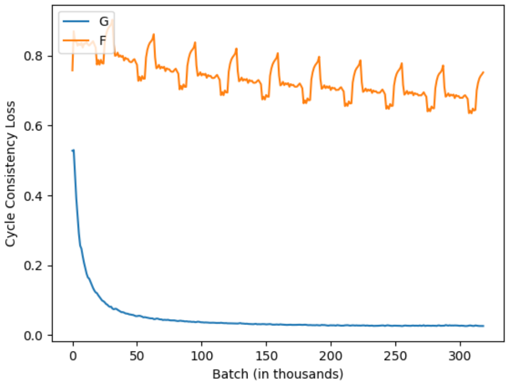

Figure 7: Evolution of the Cycle Consistency Loss during the training of the Spanish-Asturian model

7 Conclusion

In conclusion, while the training process demonstrated significant progress and effective translation capabilities in the main study, the results presented in this paper reveal several challenges that prevented similar success. The issues identified, particularly in relation to both class imbalance and class proximity, indicate that further refinement and investigation are necessary. Future research should focus on addressing these challenges, with the aim of optimizing the training process and overcoming the outlined issues. Resolving these problems is crucial for realizing the full potential of the framework within the context discussed in this paper.

8 Future Work

Further investigations will benefit from the incorporation of a more extensive dataset and an exploration of larger model architectures. Future work also include methods discussed in Section 6 to allow translation training.

8.1 Largert dataset

The current work has been trained on a small dataset compared to MT standards. Future work should try to see how convergence progresses with more iterations. Further computational optimizations are probably necessary to shorten the training time required.

8.2 Larger models

The current architecture relies on a total of 158,769,152 parameters, which is only about a third of the size of the default in the Huggingface library.

9 Source Code

The source code of CycleGN is available at https://github.com/SorenDreano/CycleGN.

Limitations

The investigation acknowledges certain inherent limitations which may impact the generalizability and applicability of the findings.

Language diversity

Another issue that arises from the computing cost of CycleGN is the lack in language diversity. Indeed, our current work only used the English-German and Chinese-English language pairs. Consequently, it cannot be certain that the approach presented can be applied to other languages and all alphabets. This is why CycleGN is taking part in WMT24, to explore the framework's performance on a wide range of language pairs.

Training limitations

Due to time constraints and the fact that CycleGN is a computationally expensive architecture, it was not possible to train the Spanish-Aranese pair. Similarly, the training of all models was stopped early, before reaching performance stagnation.

Ethics Statement

This study, focusing on the training of NMT models using non-parallel datasets, adheres to the highest ethical standards in research. We recognize the critical importance of ethical considerations in computational linguistics and machine learning, especially as they pertain to data sourcing, model development, and potential impacts on various linguistic communities.

Our research utilizes publicly available, non-parallel linguistic datasets. We ensure that all data is sourced following legal and ethical guidelines, respecting intellectual property rights and privacy concerns.

In our commitment to scientific integrity, we maintain transparency in our research methodologies, model development, and findings. We aim to make our results reproducible and accessible to the scientific community, contributing positively to the field of machine translation.

Abstract

This paper presents the SETU-ADAPT's submissions to the WMT 2024 Low-Resource Indic Language Translation task. We participated in the unconstrained segment of the task, focusing on the Assamese-to-English and English-to-Assamese language pairs. Our approach involves leveraging Large Language Models (LLMs) as the baseline systems for all our MT tasks. Furthermore, we applied various strategies to improve the baseline systems. In our first approach, we fine-tuned LLMs using all the data provided by the task organisers. Our second approach explores in-context learning with few-shot prompting. In our final approach we explore an efficient data extraction technique based on a fuzzy match-based similarity measure for fine-tuning. We evaluated our systems using BLEU, chrF, WER, and COMET. The experimental results showed that our strategies can effectively improve the quality of translations in low-resource scenarios.

1 Introduction

Advances in deep learning have led to major improvements in present-day MT systems. However, developing reasonable-quality MT systems for low-resource languages, especially those from the Indic language family, remains a challenge (Pal et al., 2023). India, home to numerous ancient and morphologically rich languages, presents unique obstacles for MT development due to the intricate morphology, syntax, and scarcity of parallel data for many regional languages (Suman et al., 2023; Ahmed et al., 2023). This motivated us to participate in the WMT 2024 Low-Resource Indic Language Translation task and contribute to the advancements in indic MT systems.

Large-pre-trained models are becoming the norm in MT due to their accuracy, scalability, and usage flexibility. Hence, for our experiments we chose LLMs as our baseline MT systems. More specifically, we used IndicTrans2[1] as the baseline for building all our MT systems. We carried out our experiments for Assamese-to-English and English-to-Assamese language pairs.

We conducted experiments applying different methodologies for improving the performance of our MT systems. Our primary approach involves fine-tuning LLMs using all the available data. However, Assamese is a very low-resource language, and obtaining good quality data is challenging. Since there is limited availability of domain-specific parallel data, in our second approach we generated synthetic data by retrieving a large corpus of monolingual data from OPUS[2]. We then performed similarity search in order to identify domain-specific sentences of target language from the generic data and back-translated them into the source language. Our third approach involves investigating in-context learning using few-shot prompting. We augmented the prompt with samples whose source-side is similar to the source sentence to be translated.

The rest of the paper is organised as follows: we discuss related works in Section 2. We detail the data sets used in Section 3. Our models and experimental setups are described in Sections 4 and 5. The results are reported and findings are discussed in Section 6. Section 7 concludes this work and discusses avenues for future work.

2 Related Work

In this section, we discuss the papers that are related to our work. Burchell et al. (2022) introduced a framework that differentiates between lexical and syntactic diversity in back translation. Their research highlights that while both types of diversity improve Neural MT (NMT) performance, lexical diversity is more critical. They also demonstrated that nucleus sampling, a method that balances diversity with adequacy, provides superior results for low-resource and mid-resource language pairs.

Ahmed and Buys (2024) introduced the concept of "Synthetic Pivoting" to address the limitations of traditional pivot-based methods, which often face challenges due to structural mismatches between the pivot and low-resource languages. Synthetic Pivoting generates synthetic pivot sentences that better align with the structure of both the source and target languages, resulting in more accurate translations. This method has substantially improved translation quality, particularly for Southern African languages, by simplifying the translation process and effectively utilising high-quality synthetic data.

Suman et al. (2023) focused on improving the translation quality for low-resource Indic languages: Manipuri and Assamese. They leveraged linguistic and scriptural similarities between these languages and Bengali to improve translation outcomes. By utilising pre-trained models on Bengali and incorporating transliteration techniques, they were able to overcome the challenges posed by the limited resources available for Manipuri and Assamese. Their experiments showed that their approaches were effective in improving translation.

Moslem et al. (2023) explored using LLMs for adaptive translation. Their research demonstrated that in-context learning with LLMs enables real-time adaptation to specific terminology and stylistic preferences during inference. They showed that this eliminated the need for extensive fine-tuning. They found that few-shot in-context learning, especially when combined with fuzzy matches from translation memories, can outperform traditional encoder-decoder models regarding translation quality, particularly for high-resource language pairs.

Zhang et al. (2023) investigated the potential of fine-tuning LLMs for MT, focusing on decoder-based models that had not been extensively studied before. They evaluated 15 publicly available LLMs using methodologies such as zero-shot prompting, few-shot learning, and fine-tuning, with a particular emphasis on the QLoRA (Dettmers et al. (2023)) fine-tuning method. QLoRA proved a highly effective technique, reducing memory usage by quantising the model to 4-bit precision and limiting the number of trainable parameters. Their findings showed that fine-tuning LLMs, especially using QLoRA, significantly outperformed zero-shot and few-shot approaches, particularly in document-level translation tasks.

3 Data

We utilised the data provided by WMT organisers for our experiments. The data statistics are detailed in Table 1.

Assamese ↔ English	
Files	Sentences
Train	50,000
Valid	2,000
Test (2023)	2,000
Test (2024) - Blind Test	500

Table 1: *Statistics of the datasets used.*

4 Models used

4.1 IndicTrans2

We used IndicTrans2, a Transformer-based (Vaswani et al., 2023) Multilingual NMT model trained on the BPCC dataset,[3] as our baseline MT system. We used the `ai4bharat/indictrans2-indic-en-1B` and `ai4bharat/indictrans2-en-indic-1B` checkpoints for our systems. For building our MT systems we set the following hyperparameters:

- the data was tokenised to a fixed length of 128 tokens, where sequences longer than 128 tokens were truncated and shorter ones were padded to ensure uniform length across batches,
- the learning rate: 2×10^{-5},
- the batch size: 16,
- the training ran for 3 epochs satisfying our stopping criterion,
- a weight decay of 0.01 for improving the model's generalisation capabilities.

[3] https://ai4bharat.iitm.ac.in/bpcc/

We fine-tuned the model in order to adapt it to the domain and styles of data of Assamese-to-English translation task.

4.2 GPT-4o

GPT-4o (OpenAI et al., 2024) is a language model from OpenAI based on Transformer, which serves as the foundation for many language models today. It comprises multiple layers of self-attention mechanisms and feed-forward neural networks, enabling the model to efficiently process and generate text sequences. The model has been trained on a diverse and extensive dataset, allowing it to capture various linguistic patterns and contextual knowledge. We used GPT-4o for our in-context learning strategy. We used the following set of hyper-parameters for our experiment: (i) the temperature was set to 0.2, which controls the randomness of the output, ensuring more deterministic responses, and (ii) all other hyperparameters were not explicitly set and were set to the default values.

5 Experiments

In this Section we discuss our experiments. As discussed in Section 4, we used IndicTrans2 as our baseline model. We selected this model as the baseline due to its superiority as far as translation performance on low-resource Indian languages like Assamese is concerned (cf. Figure 1). We evaluated our MT models using the test data described in Section 3. We used BLEU (Papineni et al. (2002)), chrF (Popović (2015)), WER, and COMET[4] (Rei et al. (2020)) metrics for evaluation. The following subsections describes our MT systems.

5.1 Assamese-to-English

5.1.1 Primary

Our primary MT system for the Assamese-to-English translation task is the fine-tuned IndicTrans2 model (cf. Section 4). In other words, we fine-tuned the baseline model on the domain data provided by the organisers. Our data sets were detailed in Section 3. We used the same set of hyperparameters that we described in Section 4.

5.1.2 Contrastive System One

as for our second system, we implemented an in-context few-shot learning approach, using which we generated English translations of Assamese sentences using `OpenAI's GPT-4o`. More specifically, for few-shot learning we create prompts for the model with a few samples of translation pairs (source and target) whose source-side is similar to the source sentence we want to translate. We will now explain how we obtained training instances, whose source-side is similar to the sentence to be translated. We first convert all the Assamese training set sentences into dense vector embeddings using `sentence-transformers/all-MiniLM-L6-v2` [5]. The resulting embeddings were then indexed using FAISS,[6] enabling efficient similarity searches to retrieve the most relevant examples.

Furthermore, for each Assamese sentence of the test set, we used FAISS to retrieve the top five closest sentences from the training data based on the cosine similarity of their embeddings. Then, we constructed a detailed prompt for the GPT-4o model using the sentence-pairs that were retrieved from the training set. In Figure 2, we show an example of prompt used for in-context learning.

5.1.3 Contrastive system two

For building our second Contrastive system we used our primary MT model (see Section 5.1.1) as our baseline. We adapted this MT system by fine-tuning it with a synthetic data. In order to create the synthetic data, we used a large English corpus comprising 5,000K sentences from the OPUS repository's NLLB project. We took 500k sentences for that large corpus for our experiment. We further filtered the sentences to include only those whose lengths are of 100 to 500 characters. With this, we omitted very short and excessively long sentences.

To extract domain-similar sentences from the now filtered corpus, we performed a semantic search on it using the validation set. All the corpus sentences were first converted to 768-dimensional dense vector embeddings using the `sentence-transformers-qa-mpnet-base-dot-v1` [7] model. We chose the `qa-mpnet-base-dot-v1` model over the `all-MiniLM-L6-v2` model used in 5.1.2 because it can store more detailed information about a sentence and capture semantic relationships across a wide range of contexts,

[4] COMET version 3.19.1 supports Assamese language.

Negative chrF++ values indicate poor translation quality or situations where the translation system fails to generate meaningful or accurate translations. Adapted from (Gala et al., 2023)*

essential for extracting accurate and richer sentence representations from OPUS. These sentence embeddings were then indexed using FAISS. Later, we performed similarity searches by querying the FAISS index with embeddings of the validation sentences. We retrieved the top five nearest neighbours from the corpus for each validation sentence based on cosine similarity. We then removed sentences with similarity scores below 0.2. This process ensured that only the most relevant and contextually similar sentences were selected.

The final fuzzy matching English sentences were then back-translated into Assamese using our primary checkpoint. These new English-Assamese sentence pairs were used to create a new checkpoint by fine-tuning the primary system checkpoint and translation capabilities.

5.2 English to Assamese

5.2.1 Primary

We build out primary systems using an MT approach similar to the one we used in Constrative system one (5.1.2) of the Assamese-to-English translation section, where we utilised `OpenAI's GPT-4o` model. The primary difference lies in the prompt structure. In Figure 3, we show the sample prompt that was modified to treat English sentences as inputs and Assamese sentences as outputs.

6 Results

This section presents the evaluation results of the MT systems for both the Assamese-to-English and English-to-Assamese tasks. We performed the initial evaluation using the test pairs from the WMT 2023 dataset. Additionally, we present the results of our evaluation of the blind test set provided by the organisers. The results are reported in terms of BLEU, chrF, WER, and COMET metrics.

To ensure the reliability of our findings using the 2023 dataset, we conducted a statistical evaluation across pairs of models. This involved using bootstrap resampling (Koehn, 2004), calculating BLEU scores, and performing paired t-tests. For each test, we generated 100 bootstrap samples, each containing 100 randomly selected sentences from the dataset without repetition. This method maintains the original dataset's integrity while ensuring diversity in each sample. The results of these statistical analyses are also presented in this section. In all comparisons, we tested the null hypothesis that there is no difference in performance between the systems by calculating p-values. A low p-value (less than 0.05) indicates that we can reject the

```
Give only the final English
   sentence in a single line.
Context:
Assamese 1: <Assamese sentence 1>
Translation in English 1: <
   English translation 1>
Assamese 2: <Assamese sentence 2>
Translation in English 2: <
   English translation 2>
...
Assamese 5: <Assamese sentence 5>
Translation in English 5: <
   English translation 5>

What is the English translation
   for Assamese: <input sentence
   >?
```

Figure 2: *Prompt structure for GPT-4o model: Assamese-to-English*

null hypothesis, suggesting that the observed differences are statistically significant and not due to random variation.

Four models were evaluated for the Assamese-to-English translation task: the baseline, primary, contrastive model one and contrastive model two. The evaluation results are summarised in Table 2.

Model	BLEU ↑	chrF ↑	WER ↓	COMET ↑
B	0.2946	0.5646	0.7000	0.8064
P	0.3418	0.5748	0.6455	0.8086
C1	0.3110	0.5690	0.7035	0.8157
C2	0.3221	0.5724	0.6556	0.8075

Table 2: *Evaluation Results for Assamese-to-English Translation using WMT2023 test pair.*
***B** = Baseline, **P** = Primary (5.1.1), **C1** = Contrastive 1 (5.1.2), **C2** = Contrastive 2 (5.1.3). ↑ indicates higher is better, and ↓ indicates lower is better.*

As shown in Table 2, the primary model (P) outperforms the baseline (B) in all metrics except COMET, where Contrastive system one (C1) achieves slightly higher scores than Contrastive system two (C2) . The BLEU and WER improvements suggest that the primary MT model provides more accurate and fluent translations compared to those by the baseline and contrastive models.

The statistical analysis further supports these findings. When comparing model **B** and **P**, the BLEU score of **P** (0.3418) was higher than that of **B** (0.2946), with a t-statistic of -10.71 and a p-value of 1.72e-09. Similarly, when comparing **P** to **C1** (0.3110), the t-statistic was -10.17 with a p-value of 7.70e-20. In the comparison with **C2** (0.3221), the t-statistic was -8.64, and the p-value was 5.25e-08. Across all comparisons, the null hypothesis was rejected, indicating that **p** consistently performed better than the other models.

```
Give only the final Assamese
   sentence in a single line.
Context:
English 1: <English sentence 1>

English 5: <English sentence 5>
Translation in Assamese 5: <
   Assamese translation 5>

What is the Assamese translation
   for English: <input sentence>?
```

Figure 3: *Prompt structure for GPT-4o model: English to Assamese*

For the English-to-Assamese translation task, two models were evaluated: the baseline and the primary model. The results are summarised in Table 3.

Model	BLEU ↑	chrF ↑	WER ↓	COMET ↑
B	0.1432	0.4948	0.8105	0.8263
P	0.1768	0.4815	0.7457	0.8220

Table 3: *Evaluation Results for English-to-Assamese Translation using WMT2023 test pair.*
***B** = Baseline, **P** = Primary (5.2.1). ↑ indicates higher is better, and ↓ indicates lower is better.*

In Table 3, the primary model shows a noticeable improvement over the baseline in BLEU and WER, indicating better translation accuracy and reduced word errors. However, the chrF and COMET scores are slightly lower than those of the baseline.

The statistical significance tests compares Baseline and Primary (BLEU scores of 0.1432 for the Baseline and BLEU scores of 0.1768 for the Primary) with a t-statistic of -53.11 and a p-value of 1.45e-74. These results clearly indicate that Primary produces better translations than those by the Baseline. The null hypothesis, which assumes no difference in performance between the two systems, was rejected, confirming that the Primary system outperforms the Baseline.

We now present our results on the blind test set provided by the WMT organisers. The results for Assamese-to-English translation in WMT24 Low-Resource Indic Language Translation Task are summarised in Table 4. We observe that contrastive system two generally achieves the best results, leading to 0.3227 BLEU, 0.7563 METEOR, and 0.6573 chrF points, indicating better overall translation quality and semantic accuracy. The primary system closely follows the best-performing system (contrastive system two), performing slightly better in TER (33.56 points) and RIBES (0.3778 points), suggesting that translations require fewer edits, though it falls slightly behind contrastive system two on other metrics (0.3180 BLEU, 0.7537 METEOR, and 0.6551 chrF points). Contrastive system one consistently underperforms the other two systems, with lower scores across all metrics, particularly 39.03 TER and 0.7219 METEOR points.

Model	BLEU ↑	TER ↓	RIBES ↑	METEOR ↑	chrF ↑
P	0.3180	33.56	0.3778	0.7537	0.6551
C1	0.2981	39.03	0.3713	0.7219	0.6437
C2	0.3227	33.63	0.3720	0.7563	0.6573

Table 4: *Evaluation Results for Assamese-to-English Translation (2024).*
***P** = Primary (5.1.1), **C1** = Contrastive 1 (5.1.2), **C2** = Contrastive 2 (5.1.3). ↑ indicates higher is better, and ↓ indicates lower is better.*

The results for English-to-Assamese translation in WMT24 Low-Resource Indic Language Translation Task are summarised in Table 5. We only had one system for this direction, where we obtained 0.1612 BLEU, 65.96 TER, 0.2641 RIBES, 0.3927 METEOR, and 0.5673 chrF points on the test set.

Model	BLEU ↑	TER ↓	RIBES ↑	METEOR ↑	chrF ↑
P	0.1612	65.96	0.2641	0.3927	0.5673

Table 5: *Evaluation Results for English-to-Assamese. **P** = Primary (5.2.1). ↑ indicates higher is better, and ↓ indicates lower is better.*

7 Conclusion

In this work, we presented our MT models developed for the WMT 2024 Low Resource Indic Translation Task, focusing on the Assamese-to-English and English-to-Assamese language pairs. We conducted a comparative analysis using experimental setups to explore strategies such as fine-tuning, back translation, and in-context learning with few-shot prompting. All of these methods demonstrated significant performance improvements in translation.

For our future work, we intend to investigate synthetic pivoting methods for Indic languages and implement QLoRA technique to improve our current in-context learning approach, both discussed in Section 2. We believe that these techniques hold the potential to address the challenges associated with low-resource language translation and further improve the performance of our models.

Abstract

We develop a robust translation model for four low-resource Indic languages: Khasi, Mizo, Manipuri, and Assamese. Our approach includes a comprehensive pipeline from data collection and preprocessing to training and evaluation, leveraging data from WMT task datasets, BPCC, PMIndia, and OpenLanguageData. To address the scarcity of bilingual data, we use back-translation techniques on monolingual datasets for Mizo and Khasi, significantly expanding our training corpus. We fine-tune the pre-trained NLLB 3.3B model for Assamese, Mizo, and Manipuri, achieving improved performance over the baseline. For Khasi, which is not supported by the NLLB model, we introduce special tokens and train the model on our Khasi corpus. Our training involves masked language modelling, followed by fine-tuning for English-to-Indic and Indic-to-English translations.

1 Introduction

Translation of low-resource languages poses significant challenges in natural language processing. While substantial progress has been made in developing machine translation models for high-resource languages, low-resource languages often suffer from a lack of parallel corpora and digital resources (Haddow et al., 2022). Languages like Khasi, Mizo, Manipuri, and Assamese are representative of this challenge, where limited data and unique linguistic complexities hinder the development of robust translation systems.

In recent years, efforts to bridge this gap have gained momentum, driven by initiatives such as the Bharat Parallel Corpus Collection[1] (BPCC) (Gala et al., 2023) and government-supported projects like PMIndia (Haddow and Kirefu, 2020), which aim to provide bilingual data for Indic languages. Despite these efforts, translation models for low-resource Indic languages have yet to achieve performance levels comparable to their high-resource counterparts (Suman et al., 2023), necessitating innovative approaches to model training and data utilization.

In this work, we develop a robust translation model for four low-resource Indic languages: Khasi, Mizo, Manipuri, and Assamese. Our approach involves data collection, preprocessing, training, and evaluation. We utilize datasets from WMT, BPCC, PMIndia, and OpenLanguageData[2] (Maillard et al., 2023), and enhance bilingual data through back-translation (Edunov et al., 2018) techniques, especially for Mizo and Khasi, significantly expanding our training corpus.

We follow Meta's data preprocessing standards and use LoRA (Low-Rank Adaptation) (Hu et al., 2021) fine-tuning on the NLLB (et al., 2022) 3.3B model to improve efficiency and performance with fewer parameters. Our model initially focuses on one-way translation from English to the Indic languages, then on reverse translations (Dabre et al., 2019). The results show improved performance over the baseline, particularly for Khasi, where we address gaps in pre-trained model support.

2 Dataset

In this study, we focus on four low-resource Indic languages covered in the Low Resource Indic Languages Shared Task: Khasi, Mizo, Manipuri, and Assamese. This section highlights the significance of each language, including their role in their respective regions, their linguistic and cultural importance, and the details of the datasets used. Statistics regarding language speakers are according to the 2011 Indian Census[3].

Language	ISO-693-3	WMT Parallel	BPCC	PMIndia	OLD	Back-Translated	Total
Assamese	asm	50,000	35,354	9,732	0	0	95,086
Manipuri	mni	21,687	0	7,419	6,193	0	35,036
Khasi	kha	24,000	0	0	0	102,070	126,070
Mizo	lus	50,000	0	0	0	30,164	80,164

Table 1: Breakdown of data sources and volumes for each language. "OLD" refers to OpenLanguageData. The "Back-Translated" data was initially generated using Google Translate[4] for the first 500k characters from the monolingual WMT task data, with subsequent iterations increasing the data size using the trained model.

2.1 Languages

Assamese *(Asamiya)* is an Indo-Aryan language spoken primarily in the northeastern Indian state of Assam, where it serves as an official language and a regional lingua franca. With over 15 million native speakers, it is one of the most widely spoken languages in the region. Historically, Assamese was the court language of the Ahom kingdom. It is written in the Assamese script, an abugida system, known for its unique typographic ligatures.

Manipuri *(Meiteilon)* is a key Tibeto-Burman language spoken mainly in Manipur, India, where it is an official language and it is one of the constitutionally scheduled official languages of the Indian Republic. With 1.76 million speakers, it is the most widely spoken Tibeto-Burman language in India and holds the third place among the fastest-growing languages of India, following Hindi and Kashmiri. It is written in its own Meitei script as well as the Bengali script.

Khasi *(Ka Ktien Khasi)* is an Austroasiatic language primarily spoken by the Khasi people in Meghalaya, India, with approximately 1 million native speakers as of the 2011 census. The language holds an associate official status in certain districts of Meghalaya. Khasi is written in the Latin script. The closest relatives of Khasi are other languages in the Khasic group, such as Pnar and War.

Mizo *(Mizo ṭawng)* belonging to the Sino-Tibetan language family, is primarily spoken in the state of Mizoram, India, with around 800 thousand speakers. The Mizo language, also known as Lushai, has a rich oral history and was first written using the Latin script in the late 19th century. Mizo is recognized as the official language of Mizoram and is used in education, government, and media.

3 Methodology

This section covers the preprocessing steps and training methods used, including dataset preparation and the fine-tuning of Meta's multilingual NLLB 3.3B base pre-trained model. Detailed statistics on data distribution are presented in Table 1.

3.1 Preprocessing

In the preprocessing phase, we followed a series of steps to ensure the text data was clean and consistent before model training. We began by normalizing punctuation using Moses (Koehn et al., 2007), an open-source toolkit designed for preprocessing, training, and testing translation models. This step helps maintain consistency in text data, which is crucial for training robust models.

Non-printable characters, which often interfere with text processing, were replaced with a space. This choice ensures that any invisible or non-standard characters do not disrupt the tokenization process and ensures that the text is composed of standard printable characters.

We also applied Unicode normalization (NFKC) to transform characters into their canonical forms, making the text more uniform across different Unicode representations.

These preprocessing steps are aligned with those outlined by Meta for their multilingual models, and further details can be found on their GitHub[5]. This approach ensures that the text data used for training is clean, consistent, and compatible with the modelling requirements.

3.2 Training

For model training, we employed Meta's NLLB (No Language Left Behind) 3.3B parameter model,

[4] https://google.translate.com/

[5] https://github.com/facebookresearch/stopes/blob/main/stopes/pipelines/monolingual/monolingual_line_processor.py

a state-of-the-art multilingual machine translation model built to support over 200 languages, making it ideal for tasks involving low-resource languages (Tran et al., 2021; Yang et al., 2021). The NLLB 3.3B model is based on a Transformer (Vaswani et al., 2023) architecture with 3.3 billion parameters, featuring a dense encoder-decoder design. It includes the following hyperparameters:

Hyperparams	
embed size	2048
ffn size	8192
attn heads	16
enc/dec layers	48

Table 2: Hyperparameters for the baseline pre-trained model. 24 Encoder and 24 Decoder Layers.

To fine-tune the model, we employed LoRA, a technique that significantly reduces computational demands and training time by adapting only a small subset of the model's parameters. LoRA has been shown to match the performance of traditional fine-tuning methods while reducing the number of trainable parameters by a factor of 50 (Alves et al., 2023). This approach is especially effective for large-scale models like Meta's NLLB 3.3B, allowing efficient adaptation without significantly compromising on performance.

3.3 Parameters

The training process was conducted in three stages: first, the model was trained on masked language modelling (Devlin et al., 2019) to enhance its understanding of the target language by leveraging monolingual data. Next, it was fine-tuned for English-to-Indic translations, followed by further fine-tuning for Indic-to-English translations. In the case of Khasi, which was not natively supported by the NLLB model, special tokens were added to the tokenizer's vocabulary to accommodate the Khasi language. The model was subsequently trained on the Khasi corpus to ensure proper handling and integration of this language.

The training was performed across 4 Nvidia A6000 GPUs. These settings allowed us to optimize the model's performance while managing computational efficiency.

3.4 Inference

For inference, the trained adapter was loaded onto the NLLB 3.3B model. The model generated predictions using a beam search strategy with 10 beams and a repetition penalty of 2.5 to improve the diversity and quality of the translations. We experimented with various beam and penalty configurations, ultimately finding that this particular setup produced the most accurate and linguistically coherent outputs.

Training Args	
optimizer	adafactor
learning Rate	1e-5
epochs	8
precision	bf16
p_{mask}	0.15
peft type	lora
rank	128
lora alpha	256
lora dropout	0.1
target modules	all linear

Table 3: Training parameters and LoRA configuration used for fine-tuning the NLLB 3.3B model.

4 Results

The evaluation of our translation model across various language pairs and directions is shown in Table 4, with performance assessed using BLEU (Papineni et al., 2002), Translation Error Rate (Snover et al., 2006), RIBES (Isozaki et al., 2010), METEOR (Banerjee and Lavie, 2005), and chrF (Popović, 2015) metrics. We found that the scores in English-to-Manipuri and English-to-Mizo direction suffered from the poor quality of backtranslated data used in our training.

English-Assamese The model performed relatively well, with BLEU scores of 27.26 for English-to-Assamese and 26.69 for Assamese-to-English.

English-Manipuri The model showed lower BLEU scores for English-to-Manipuri (2.7) compared to Manipuri-to-English (20.88). The TER score was higher for English-to-Manipuri, reflecting greater translation errors in this direction.

English-Khasi For Khasi, the BLEU score was 12.12 for English-to-Khasi and 10.47 for Khasi-to-English.

English-Mizo The performance was mixed, with a BLEU score of 6.6 for English-to-Mizo and 18.49 for Mizo-to-English. The TER score indicates a higher error rate for English-to-Mizo, while the METEOR and ChrF scores were relatively balanced across both directions.

Language Pairs	Test Set	BLEU	TER	RIBES	METEOR	ChrF
English-Assamese	en_to_as_contrastive	27.26	52.79	0.3032	0.513	65.2
	as_to_en_contrastive	26.69	39.08	0.3308	0.7066	60.48
English-Manipuri	en_to_mn_contrastive	2.7	84.6	0.1185	0.1567	44.28
	mn_to_en_contrastive	20.88	48.77	0.3031	0.61	53.64
English-Khasi	en_to_kh_contrastive	12.12	63.31	0.1864	0.4453	44.55
	kh_to_en_contrastive	10.47	61.43	0.2172	0.5042	42.71
English-Mizo	en_to_mz_contrastive	6.6	66.06	0.1746	0.495	49.79
	mz_to_en_contrastive	18.49	53.19	0.2684	0.588	50.44

Table 4: Translation performance metrics of our MT System reported in the final evaluation.

5 Conclusion

In this work, we utilized Meta's NLLB 3.3B model, a large-scale multilingual transformer with 3.3 billion parameters, to enhance translation between low-resource Indic languages and English. The training process included masked language modelling, followed by English-to-Indic and Indic-to-English translations. Special tokens were added for Khasi, and LoRA (Low-Rank Adaptation) was employed to optimize computational efficiency and reduce training time.

Conducted on 4 NVIDIA A6000 GPUs, our approach demonstrates that large-scale multilingual models, when combined with LoRA, effectively capture diverse linguistic patterns and advance translation capabilities.

6 Limitations

In this study, we encountered several limitations that impacted the overall effectiveness of our translation system. One major challenge was the constrained size of our dataset due to computational resource limitations. The limited dataset size may have hindered the model's ability to generalize, particularly for low-resource languages where larger and more diverse datasets would have been advantageous.

Another issue we faced was the quality of back-translated data. The process of augmenting the dataset through machine translation often resulted in lower-quality data, which negatively influenced the model's performance. This highlights the need for more robust data generation techniques in future work.

We also observed a noticeable performance gap between translations where English was the target language and those where an Indic language was the target. This suggests that while the model may understand the morphological aspects of Indic languages, it struggles to generate accurate translations in these languages. This limitation underscores the need for further refinement in handling the complexities of Indic language generation.

Finally, the potential domain mismatch between our training data and real-world applications posed a significant challenge. The training data may not fully capture the linguistic and contextual nuances found in practical scenarios, leading to reduced performance in actual use cases. Addressing this issue in future work will be crucial for improving the model's real-world applicability.

Abstract

This paper introduces the submission by Huawei Translation Center (HW-TSC) to the WMT24 Indian Languages Machine Translation (MT) Shared Task. To develop a reliable machine translation system for low-resource Indian languages, we employed two distinct knowledge transfer strategies, taking into account the characteristics of the language scripts and the support available from existing open-source models for Indian languages. For Assamese(as) and Manipuri(mn), we fine-tuned the existing IndicTrans2(Gala et al., 2023) open-source model to enable bidirectional translation between English and these languages. For Khasi (kh) and Mizo (mz), We trained a multilingual model as a baseline using bilingual data from these four language pairs, along with an additional about 8kw English-Bengali bilingual data, all of which share certain linguistic features. This was followed by fine-tuning to achieve bidirectional translation between English and Khasi, as well as English and Mizo. Our transfer learning experiments produced impressive results: 23.5 BLEU for en→as, 31.8 BLEU for en→mn, 36.2 BLEU for as→en, and 47.9 BLEU for mn→en on their respective test sets. Similarly, the multilingual model transfer learning experiments yielded impressive outcomes, achieving 19.7 BLEU for en→kh, 32.8 BLEU for en→mz, 16.1 BLEU for kh→en, and 33.9 BLEU for mz→en on their respective test sets. These results not only highlight the effectiveness of transfer learning techniques for low-resource languages but also contribute to advancing machine translation capabilities for low-resource Indian languages.

1 Introduction

In the realm of machine translation, Neural Machine Translation (NMT) has become the dominant technology, as confirmed by previous research. However, training NMT models requires large amounts of data, which presents a significant challenge when dealing with low-resource languages. To tackle this challenge, we employed transfer learning, a well-established approach that enhances model performance by transferring knowledge gained from one task to other related tasks. To improve translation capabilities for low-resource languages, we faced the challenge of limited bilingual resources for Indian languages. To overcome this issue, we trained a multilingual model using not only all the bilingual data provided for the task but also additional Bengali data. Additionally, we examined the languages supported by the existing IndicTrans2(Gala et al., 2023) open-source model and conducted a comparative analysis. Based on our findings, we selected different baseline models for knowledge transfer depending on the language pair: for Assamese and Manipuri, we used the IndicTrans2 model as the baseline, while for Khasi and Mizo, we trained multilingual model by ourselves as the baseline. This approach enabled us to effectively leverage existing resources while addressing the specific challenges associated with each language pair.

IndicTrans2 is the first open-source transformer-based multilingual NMT model that supports high-quality translations across all the 22 scheduled Indic languages. It was trained on the extensive Bharat Parallel Corpus Collection (BPCC), a publicly accessible repository encompassing both pre-existing and freshly curated data for all 22 scheduled Indian languages, this model boasts a comprehensive understanding of the linguistic diversity within the Indian subcontinent. To enhance its linguistic prowess, IndicTrans2 has undergone auxiliary training utilizing the rich resource of back-translated monolingual data. The model was then trained on human-annotated data to achieve further improvements. We used this model in the first two subtasks and fine-tuned it on the training data provided by WMT24. By adopting this approach, we aim to capitalize on the acquired knowledge during training to significantly bolster the performance of the model in the specific translation task at hand. The fine-tuned IndicTrans2 achieves good scores, so we are using it for our final submission in the first two subtasks.

For the multilingual model, we first utilized resources from Bengali. The choice of Bengali was based on its belonging to the Indo-Aryan branch, its linguistic feature similarities with some of the target low-resource languages, and its relatively rich available data. By introducing Bengali data, we aimed to enable the model to learn features potentially shared with the target languages, thereby laying a foundation for processing other related languages. Next, we integrated all available bilingual data from Indic language MT track. This included parallel corpora between various Indian languages and English. Although the data for each language pair might be limited individually, the combined dataset offered diverse learning samples. We believe that this integration of multilingual data helps the model capture both the commonalities and differences among different Indian languages. Based on this carefully selected and integrated data, we trained a multilingual model. The design goal of this model was to handle translation tasks for multiple Indian languages simultaneously, using the commonalities between languages to compensate for the scarcity of data in any single language. Through this approach, we expect the model to learn more generalized language representations and translation knowledge under resource constraints, leading to improved performance on Khasi and Mizo translation tasks.

Ultimately, we adopted a differentiated strategy for knowledge transfer. This approach thoroughly considered the characteristics of each language to achieve optimal transfer effects. In Section 2, we will discuss the details of the data, the methods and processes used for data pre-processing. Section 3 will cover the overall architecture and training strategies of the NMT system, including a detailed account of the various optimization methods. In Section 4, we will present the experimental parameters, results, and their analysis. The final section will summarize the key findings of the paper.

2 Data

2.1 Data Details

We have fine-tuned the model using the WMT24 corpus. Additionally, we used 2M monolingual english dataset to do BT and FT. The amount of data we used is shown in Tables 1.

language pairs	bitext data	monolingual data
en-as	50K	en: 2M, as: 2.62M
en-mn	21K	en: 2M, mn: 2.14M
en-kh	24K	en: 2M, kh: 182K
en-mz	50K	en: 2M, mz: 1.9M

Table 1: Bilingual and monolingual used for training NMT models.

2.2 Data Pre-processing

Our data pre-processing methods for NMT include:

- Remove duplicate sentences or sentence pairs.
- Convert full-width symbols to half-width.
- Use fasttext[1] (Joulin et al., 2016) to filter other language sentences.
- Use mosesdecoder[2] (Koehn et al., 2007) to normalize English punctuation.
- Filter out sentences with more than 150 words.
- Use fast-align (Dyer et al., 2013) to filter sentence pairs with poor alignment.
- Sentencepiece[3] (SPM) (Kudo and Richardson, 2018) is used to perform subword segmentation, and the vocabulary size is set to 32K.

Since there may be some semantically dissimilar sentence pairs in bilingual data, we use LaBSE[4] (Feng et al., 2022) to calculate the semantic similarity of each bilingual sentence pair, and exclude bilingual sentence pairs with a similarity score lower than 0.75 from our training corpus.

3 NMT System

3.1 System Overview

We use Transformer (Vaswani, 2017) as our neural machine translation (NMT)(Bahdanau et al., 2014) model architecture. For the first two subtasks(en-as, en-mn), we use the IndicTrans2(Gala et al., 2023)

[2] https://github.com/moses-smt/mosesdecoder
[3] https://github.com/google/sentencepiece
[4] https://huggingface.co/sentence-transformers/LaBSE

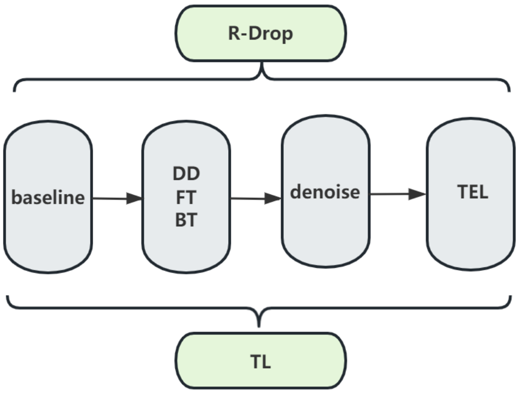

Figure 1: The overall training flow of NMT system.

model as our baseline model, which is a deep Transformer architecture with 18-layers encoder and 18-layers decoder. with the latter two subtasks(en-kh, en-mz), we trained a multilingual model as our baseline model, which is a deep Transformer architecture with 35-layers encoder and 3-layers decoder.

Fig. 1 shows the overall training flow of NMT system. Referred to previous work (Wei et al., 2021, 2022; Wu et al., 2023), We use training strategies such as regularized dropout (R-Drop) (Wu et al., 2021), data diversification (DD) (Nguyen et al., 2020), forward translation FT) (Abdulmumin, 2021), back translation (BT) (Sennrich et al., 2016), denoise, Transfer learning(TL) and transductive ensemble learning (TEL) (Wang et al., 2020) for training.

3.2 Regularized Dropout

Regularized Dropout (R-Drop)[5] (Wu et al., 2021) is a simple yet more effective alternative to regularize the training inconsistency induced by dropout (Srivastava et al., 2014). Concretely, in each mini-batch training, each data sample goes through the forward pass twice, and each pass is processed by a different sub model by randomly dropping out some hidden units. R-Drop forces the two distributions for the same data sample outputted by the two sub models to be consistent with each other, through minimizing the bidirectional Kullback-Leibler (KL) divergence (Van Erven and Harremos, 2014) between the two distributions. That is, R-Drop regularizes the outputs of two sub models randomly sampled from dropout for each data sample in training. In this way, the inconsistency between the training and inference stage can be alleviated.

3.3 Data Diversification

Data Diversification (DD) (Nguyen et al., 2020) is a data augmentation method to boost NMT performance. It diversifies the training data by using the predictions of multiple forward and backward models and then merging them with the original dataset which the final NMT model is trained on. DD is applicable to all NMT models. It does not require extra monolingual data, nor does it add more parameters. To conserve training resources, we only use one forward model and one backward model to diversify the training data.

3.4 Forward Translation

Forward translation (FT) (Abdulmumin, 2021), also known as self-training, is one of the most commonly used data augmentation methods. FT has proven effective for improving NMT performance by augmenting model training with synthetic parallel data. Generally, FT is performed in three steps: (1) randomly sample a subset from the large-scale source monolingual data; (2) use a "teacher" NMT model to translate the subset data into the target language to construct the synthetic parallel data; (3) combine the synthetic and authentic parallel data to train a "student" NMT model.

3.5 Back Translation

An effective method to improve NMT with target monolingual data is to augment the parallel training data with back translation (BT) (Sennrich et al., 2016; Wei et al., 2023). There are many published works that expand the understanding of BT and investigate methods for generating synthetic source sentences. Edunov et al. (2018) find that back translations obtained via sampling or noised beam outputs are more effective than back translations generated by beam or greedy search in most scenarios. Caswell et al. (2019) show that the main role of such noised beam outputs is not to diversify the source side, but simply to tell the model that the given source is synthetic. Therefore, they propose a simpler alternative strategy: Tagged BT. This method uses an extra token to mark back translated source sentences, which generally outperforms noised BT (Edunov et al., 2018). For better joint use with FT, we use sampling back translation (ST) (Edunov et al., 2018).

[5] https://github.com/dropreg/R-Drop

3.6 Denoise

In machine translation, denoising improves translation quality by removing noise from the training data, such as inaccurate translations, grammatical errors, or unnatural sentence structures, allowing the model to focus on high-quality data and produce more accurate and fluent translations. Additionally, denoising enhances the model's robustness by eliminating noisy data, which helps the model better learn the target language's patterns, reducing errors and leading to more stable and reliable performance across diverse inputs. It also optimizes training efficiency by decreasing the amount of data the model needs to process, particularly by filtering out low-quality data, which results in a cleaner and more consistent dataset and can shorten the overall training time. Moreover, denoising reduces error propagation by preventing the model from learning incorrect language patterns, thereby minimizing the accumulation and spread of errors in generated translations. Finally, it enhances the model's generalization ability, as denoised data is more representative, enabling the model to better adapt to different types of input sentences and improving its performance in real-world applications. Through denoising, machine translation models can more effectively utilize high-quality data, leading to superior translation outcomes and greater overall model stability.

3.7 Transductive Ensemble Learning

Ensemble learning (Garmash and Monz, 2016), which aggregates multiple diverse models for inference, is a common practice to improve the performance of machine learning models. However, it has been observed that the conventional ensemble methods only bring marginal improvement for NMT when individual models are strong or there are a large number of individual models. Transductive Ensemble Learning (TEL) (Zhang et al., 2019) studies how to effectively aggregate multiple NMT models under the transductive setting where the source sentences of the test set are known. TEL uses all individual models to translate the source test set into the target language space and then finetune a strong model on the translated synthetic data, which significantly boosts strong individual models and benefits a lot from more individual models.

3.8 Transfer Learning

Transfer learning(TL) is a machine learning technique where a model trained on one task is adapted for a second related task. Instead of starting the training of a new model from scratch, transfer learning leverages the knowledge learned from the first task to improve learning on the second task. For Assamese(as) and Manipuri(mn), We have used IndicTrans2(Gala et al., 2023), a powerful model that performs well for English-to-Indic and Indic-to English translation for 22 scheduled Indian languages. This knowledge can be used to translate other Indian languages to and from English. Our approach entailed the fine-tuning of this model, leveraging the parallel corpus provided by the WMT24 for the Indic MT task. This fine-tuning process equipped the model with the expertise required to proficiently translate Assamese and Manipuri to and from English, ultimately yielding the most outstanding results. Similarly, for Khasi and Mizo, we trained a multilingual model as the baseline. We also applied transfer learning techniques to enhance the baseline model using data specific to these language pairs. The results on both the test and dev sets were highly encouraging.

4 Experiment

4.1 Settings

We use Transformer architecture in all the subtasks. For the first two subtasks, we use IndicTrans2 (Gala et al., 2023) as our baseline model, which is a deep Transformer architecture with 18-layers encoder and 18-layers decoder. With the latter subtasks, the model is also a Transformer architecture with 35-layers encoder and 3-layers decoder. For the first two subtasks, our models apply Adam (Kingma and Ba, 2014) as optimizer to update the parameters with $\beta_1 = 0.9$ and $\beta_2 = 0.98$. We employ a warm-up learning rate of 10^{-7} for 2000 update steps and a learning rate of $3 * 10^{-5}$. For normalization, we use a dropout value of 0.2 and normalize the probabilities using smoothed label cross-entropy. We use GeLU activations (Hendrycks and Gimpel, 2016) for better learning. For the latter subtasks, parameter update frequency is 2, and learning rate is 5e-4. The number of warmup steps is 4000, and model is saved every 1000 steps. R-Drop (Wu et al., 2021) is used in model training for all subtasks, and we set λ to 5.

We use the scareBLEU library to calculate our BLEU (Papineni et al., 2002) and ChrF (Popović,

Language-pair	Training strategies	Bleu(test)	ChrF2(test)	Bleu(dev)	ChrF2(dev)

Table 3: The results of en-kh and en-mz language pairs on the test and dev set.

2015) scores with a word order of 2.

4.2 Results

Regarding this four language pair directions, we use Regularized Dropout, Bidirectional Training, Data Diversification, Forward Translation, Back Translation, Alternated Training, Curriculum Learning, and Transductive Ensemble Learning. The evaluation results of four language pair directions NMT system on WMT24 Indic MT test and dev set are shown in Tables 2 and Tables 3.

As shown in Table 2, IndicTrans2(Gala et al., 2023) provides a strong baseline. Fine-tuning the model with FT, BT, and bitext data leads to significant improvements, particularly in the en-mn direction, where the BLEU score increases by nearly 20 points over the baseline on the test and dev set. This improvement is largely attributed to Data Diversification. Table 3 further illustrates that FT and BT data contribute the most to model performance, especially in the en-mz direction, which sees an increase of nearly six BLEU points compared to the multilingual baseline. Even after enhancing the model with BT and FT data, adding filtered high-quality bilingual data results in an average gain of about one BLEU point, highlighting the critical role of data quality. Finally, we all use TEL technique to obtain a good result, the improvement is very small, almost less than one bleu score.

5 Conclusion

This paper presents the submission of HW-TSC to the WMT24 Indic MT Task. For the first two subtasks, we use IndicTrans2 as our baseline model to fine-tune it with corpus provided by WMT24 on the en-as and en-mn language pairs, which achieves remarkable performance. For the latter two subtasks, we train a multilingual model on the en-kh and en-mz language pairs, and then use training strategies such as R-Drop, DD, FT, BT, denoise and TEL to train the NMT model based on the deep Transformer-big architecture. By applying these training strategies, our submission achieved a competitive result in the final evaluation.

Abstract

In this paper, we describe our system for the WMT 24 shared task of Low-Resource Indic Language Translation. We consider eng ↔ {as, kha, lus, mni} as participating language pairs. In this shared task, we explore finetuning of a pre-trained machine translation model, where the pretraining objective includes alignment of embeddings of tokens from the 22 scheduled Indian languages by a carefully constructed alignment augmentation strategy (Lin et al., 2020). Our primary system[1] is based on language-specific finetuning on this pre-trained model. We achieve chrF2 scores of 50.6, 42.3, 54.9, and 66.3 on the official public test sets for eng→as, eng→kha, eng→lus, eng→mni respectively. We also explore multilingual training with/without language grouping and freezing of encoder and/or embedding layers.

1 Introduction

The WMT 2024 Shared Task on "Low-Resource Indic Language Translation" (Pakray et al., 2024) extends the efforts in this direction originally initiated in WMT 2023 (Pal et al., 2023), which garnered significant participation from the global community. Recent advancements in machine translation (MT), particularly through techniques like multilingual training and transfer learning, have expanded the scope of MT systems beyond high-resource languages (Johnson et al., 2017). However, low-resource languages continue to present substantial challenges due to the scarcity of parallel data required for effective training (Siddhant et al., 2020; Wang et al., 2022). The shared task focuses on low-resource Indic languages with limited data from diverse language families: Assamese (as), Mizo (lus), Khasi (kha), and Manipuri (mni). The task aims to improve translation quality for the English⇔Assamese, English⇔Mizo, English⇔Khasi, and English⇔Manipuri given the data provided in the constrained setting.

To address the challenges inherent in translating low-resource languages, participants are encouraged to explore several strategies. First, leveraging monolingual data is essential for enhancing translation quality, especially in the absence of sufficient parallel data. Second, multilingual approaches offer the potential for cross-lingual transfer, where knowledge from high-resource languages can be applied to low-resource pairs (Sen et al., 2019). Third, transfer learning provides a mechanism for adapting pre-trained models from high-resource languages to low-resource settings (Wang et al., 2020). Lastly, innovative techniques tailored to low-resource scenarios, such as data augmentation and language-specific fine-tuning, are crucial for improving performance.

In this paper, we describe our system for the WMT 2024 shared task, focusing on fine-tuning two pre-trained models developed by us: IndicRASP and IndicRASP-Seed[2]. IndicRASP model is pre-trained with the objective of aligning embeddings inspired by alignment augmentation (Lin et al., 2020) on 22 Indic languages. Our primary approach involves language-specific fine-tuning, leveraging multilingual training setups, language grouping, and layer freezing. We set up experiments in both bilingual and multilingual settings. We achieve BLEU scores of 20.1 for English→Assamese, 19.1 for English→Khasi, 30.0 for English→Mizo, and 35.6 for English→Manipuri on the public test set, demonstrating the effectiveness of our approach. Specifically, language-specific fine-tuning yielded significant improvements in translation quality, while multilingual setups provided balanced performance across all language pairs. Language grouping and layer freezing are effective techniques

for preserving pre-trained knowledge and mitigating the challenges of multilinguality. Our results highlight the importance of tailored fine-tuning strategies for low-resource languages and show the potential of using alignment-augmented pre-trained models to improve translation quality in low-resource settings.

2 Data

In this section, we present the details of the IndicNECorp1.0 dataset provided by the IndicMT shared task[3] organizers.

Language pair	Script	Dataset	#parallel sents
English-Assamese	Bengali	Training	50000
		Validation	2000
		Test	2000
English-Khasi	Latin	Training	24000
		Validation	1000
		Test	1000
English-Manipuri	Bengali	Training	21687
		Validation	1000
		Test	1000
English-Mizo	Latin	Training	50000
		Validation	1500
		Test	2000

Table 1: Parallel dataset details. Script refers to the writing script of the Indic language.

2.1 Monolingual Data

The official data also includes monolingual data for four languages. The dataset comprises approximately 2.6M sentences for Assamese, 0.1M for Khasi, 2M for Mizo, and 1M for Manipuri.

2.2 Parallel Data

The dataset includes four bilingual pairs between English and Indic languages[4]: English (en) - Assamese (as), English (en) - Khasi (kha), English (en) - Mizo (lus), and English (en) - Manipuri (mni). These languages are mainly spoken in the North-eastern part of India. The English-Assamese and English-Mizo training sets contain 50k parallel sentences each, while the English-Khasi and English-Manipuri training sets contain 24k and 21.6k parallel sentences, respectively. Dataset statistics are presented in Table 1.

3 Approach

In this section, we briefly describe our approaches. We explore transfer learning, language grouping, and layer-freezing techniques.

3.1 Transfer Learning

We explore transfer learning based on two pre-trained models IndicRASP and IndicRASP-Seed. IndicRASP-Seed is a fine-tuned model of IndicRASP on small and high-quality data. Particularly, the pre-trained model is trained on agreement-based objective (Lin et al., 2020; Yang et al., 2020) for Indic languages. Specifically, words from source sentences are randomly substituted by the semantically equivalent words from other languages. The model is pre-trained in 22 scheduled Indic languages using a subset of the Bharat Parallel Corpus Collection (BPCC) dataset (Gala et al., 2023). Out of these 22 languages, two of the shared task languages, Assamese and Manipuri, are part of the pre-training. Alignment augmentation is performed using bi-lingual dictionaries from MUSE[5] (Conneau et al., 2017) and GATITOS[6].

3.2 Language Grouping

We explore the effect of grouping languages based on script similarity in a multilingual setup. Although our primary focus is on bilingual models, for language grouping experiments, we utilize a multilingual approach where languages sharing similar scripts are trained together. This approach is motivated by the idea that joint training with similar languages can improve translation quality due to shared vocabulary and linguistic properties (Jiao et al., 2022; Gala et al., 2023).

- **Group 1** (Bengali script): Assamese and Manipuri
- **Group 2** (Latin script): Khasi and Mizo

3.3 Layer Freezing

We explored layer-freezing approaches to see the impact of freezing different layers of the architecture on final translation performance.

Frozen Encoder: In this approach, we freeze the encoder components during the fine-tuning process to preserve their pre-trained weights from the parent model while the embedding and decoder components are updated.

Frozen Embedding + Encoder: In this setup, we keep the embedding and encoder frozen during

[3] https://www2.statmt.org/wmt24/indic-mt-task.html

[4] Language code as per the dataset provided

[5] https://github.com/facebookresearch/MUSE#ground-truth-bilingual-dictionaries

[6] https://github.com/google-research/url-nlp/tree/main/gatitos

fine-tuning to preserve their pre-trained weights while updating only the parameters of the rest of the layers.

4 Experimental Setup

Settings: We fine-tune pre-trained checkpoints: IndicRASP and IndicRASP-Seed models on official parallel data using the Adam optimizer (Kingma and Ba, 2014) with β_1 set to 0.9 and β_2 set to 0.98. We set the initial warmup learning rate to 1e-07 and the learning rate to 3e-5, with a warmup step of 4000. We train the models with a dropout rate of 0.3 and a label smoothing rate of 0.1. All experiments are conducted on a single NVIDIA A100 GPU. We use a maximum token count of 512 per batch, accumulating gradients over two steps to simulate a larger batch size. The model is trained for up to 1,000,000 updates. We save checkpoints every 2500 updates. We employed a patience of 10 for early stopping.

Evaluation Metrics: We use the official dev and test sets of IndicNECorp1.0 for validation and evaluation. We evaluate using BLEU (Papineni et al., 2002), chrF (Popović, 2015), and chrF++ (Popović, 2017) metrics. We use the SacreBLEU toolkit (Post, 2018) to perform our evaluation[7] with a chrF word order of 2. Additionally, as per the evaluation metrics used by the organizers, we report results on TER (Snover et al., 2006), RIBES (Isozaki et al., 2010), and COMET (Rei et al., 2022) for our primary and contrastive submissions.

Models: We conducted our experiments in both bilingual and multilingual settings. In the bilingual setup, we fine-tuned the IndicTrans2 Distilled model (Gala et al., 2023), IndicRASP, and IndicRASP-Seed models for both English to Indic and Indic to English directions. The translation models are trained separately for each Indic language. In the multilingual setup, we fine-tuned pre-trained checkpoints of IndicRASP and IndicRASP-Seed for both directions. Inspired by Chiang et al. (2022), we initialized the bilingual model with a fine-tuned multilingual model for both English to Indic and Indic to English.

For experiments with layer freezing, we fine-tune pre-trained checkpoints of IndicTrans2 Distilled and IndicRASP-Seed models. Particularly, we perform experiments by freezing the embeddings and encoder and only the encoder component for both English to Indic and Indic to English directions. We conduct all layer-freezing experiments in a bilingual setup. For language grouping experiments, we fine-tune the IndicRASP and IndicRASP-Seed models based on script similarity in a multilingual setup.

5 Results and Discussions

In this section, we report our experimental results and describe our primary and contrastive submissions. The results for our primary and contrastive systems are shown in Table 4. Tables 2, 3, and 5 reports the chrF2, BLEU, and chrF++ scores respectively.

① **English → Indic:** Our primary English to Indic systems are language pair-specific (bilingual models) fine-tuned on pre-trained IndicRASP-Seed, achieving chrF2 scores of 50.6, 42.3, 54.9, and 66.3 for Assamese, Khasi, Mizo, and Manipuri respectively. For the contrastive systems, we consider a bilingual model fine-tuned on a pre-trained IndicRASP checkpoint. The contrastive system achieves chrF2 scores of 49.9, 42.2, 36.5, and 65.8 for Assamese, Khasi, Mizo, and Manipuri, respectively. The detailed primary and contrastive system results are reported in Table 4.

② **Indic → English:** Our primary Indic-to-English systems for Assamese and Manipuri are bilingual models fine-tuned on the pre-trained IndicRASP-Seed model, each achieving chrF2 scores of 52.8 and 67.9, respectively. Similarly, for Khasi and Mizo, our primary systems are bilingual models fine-tuned on a pre-trained IndicRASP checkpoint, achieving a chrF2 score of 36.1 and 49.4, respectively.

For the contrastive Indic-to-English system, we submit a multilingual system fine-tuned on the pre-trained checkpoint of the IndicRASP model, achieving chrF2 scores of 51.2, 36.0, 46.5, and 65.3 for Assamese, Khasi, Mizo, and Manipuri respectively. Table 4 shows the detailed scores in various metrics.

Bilingual vs. Multilingual: We observe IndicRASP-Seed outperforms the IndicRASP model for Assamese and Manipuri. This might be due to the fact that IndicRASP-Seed performs

Table 3: BLEU scores on IndicMT WMT24 shared task public test set.

an additional pre-training on a small, high-quality dataset over IndicRASP. However, when the original pre-training dataset did not contain the languages, like the case of Mizo and Khasi languages here, the comparison shows an opposite trend.

Bilingual models perform better than multilingual models, showing a +4.1 and +7.7 chrF2 score improvement for English to Manipuri and English to Khasi, respectively.

Bilingual models initialized with the weights from multilingual models show improvement over the standalone multilingual models, achieving a +7.8 chrF2 score for English to Khasi. This suggests that initializing bilingual models can be helpful in low-resource settings.

Language Grouping: We observe that script-based language grouping shows improvements over a standalone multilingual model with +1.6, +0.3, +3.3, and +1.4 for English to Assamese, Khasi, Mizo, and Manipuri, respectively. It suggests that grouping languages based on script similarity can be effective in addressing the curse of multilinguality.

Layer Freezing: We observe that freezing only the encoder yields better chrF2 scores compared to freezing both the embedding and the encoder. However, layer freezing underperforms compared to full parameter fine-tuned bilingual models.

6 Conclusion

In this paper, we describe NLIP Lab's Indic low-resource machine translation systems for the WMT24 shared task. We explore the translation capabilities of the alignment-augmented pre-trained model, IndicRASP and IndicRASP-Seed, to enhance translation quality for low-resource Indic languages. Experimentally, we found that the IndicRASP model performs better than the IndicTrans2 Distilled model. Additionally, we experiment with layer-freezing and language grouping techniques. In the future, we will focus on refining these techniques and utilizing monolingual data to enhance MT performance for low-resource Indic languages.

Limitations

The pre-trained models use bilingual dictionaries whose domains might differ from the shared task training corpus. Additionally, the considered pre-trained models cover only a limited number of shared task languages. Our submission does not utilize the provided monolingual data, which could further improve model performance through back-translation.

Acknowledgements

We express our gratitude to the reviewer for providing us with valuable feedback and suggestions for improving the readability of the paper. We also thank the Department of Artificial Intelligence and Department of Computer Science and Engineering, Indian Institute of Technology Hyderabad, for providing the necessary computing resources to conduct the experiments.

Abstract

This paper presents the systems submitted by the Yes-MT team for the Low-Resource Indic Language Translation Shared Task at WMT 2024 (Pakray et al., 2024), focusing on translating between English and the Assamese, Mizo, Khasi, and Manipuri languages. The experiments explored various approaches, including fine-tuning pre-trained models like mT5 (Xue et al., 2020) and IndicBart (Dabre et al., 2021) in both Multilingual and Monolingual settings, LoRA (Hu et al., 2021) finetune IndicTrans2 (Gala et al., 2023), zero-shot and few-shot prompting (Brown, 2020) with large language models (LLMs) like Llama 3 (Dubey et al., 2024) and Mixtral 8x7b (Jiang et al., 2024), LoRA Supervised Fine Tuning (Mecklenburg et al., 2024) Llama 3, and training Transformers (Vaswani, 2017) from scratch. The results were evaluated on the WMT23 Low-Resource Indic Language Translation Shared Task's test data using SacreBLEU (Post, 2018) and CHRF (Popović, 2015) highlighting the challenges of low-resource translation and show the potential of LLMs for these tasks, particularly with fine-tuning.

1 Introduction

Developing robust machine translation systems for India's diverse languages is crucial given the country's growing economic importance and the increasing availability of digital content. However, a significant challenge in developing effective translation tools arises from the limited availability of data for many Indian languages, particularly those spoken in the northeastern regions. This paper describes the Yes-MT team's efforts to address this challenge by participating in the WMT 2024 Low-Resource Indic Language Translation Shared Task, focusing on English to Assamese, Mizo, Khasi, and Manipuri translation. We explored techniques like fine-tuning pre-trained models (mT5, IndicBart) and utilizing large language models (LLMs) like Llama 3 and Mixtral for zero-shot and few-shot learning. Furthermore, we explored using the LoRA technique to fine-tune the IndicTrans2 model, and we also trained Transformer models from scratch. Our findings provide valuable insights into the strengths and weaknesses of different approaches, highlighting the potential of LLMs and fine-tuning techniques in overcoming the limitations of data scarcity.

2 Dataset

The dataset used in this study consists of parallel bilingual data provided by the WMT 2024 Low-Resource Indic Language Translation Shared Task organizers (Pal et al., 2023) & (Pakray et al., 2024). The training, validation, and test splits for each language pair are detailed in Table 1.

Language Pair	Train	Val	Test
Assamese (en-as)	50,000	2,000	2,000
Mizo (en-lus)	50,000	1,500	2,000
Khasi (en-kha)	24,000	1,000	1,000
Manipuri (en-mni)	21,000	1,000	1,000

Table 1: Number of Sentences in Train, Validation, and Test Sets

In addition to the bilingual data, we also had access to a significant amount of Monolingual data for each of the target languages, which included 2.60 million sentences in Assamese, 1.90 million sentences in Mizo, 0.18 million sentences in Khasi, and 2.10 million sentences in Manipuri. However, for the scope of this work, we focused exclusively on utilizing the provided bilingual data for training and evaluation, aiming to explore the capabilities of the models under truly low-resource conditions.

Limiting our study to the provided bilingual data allowed us to maintain a consistent and controlled experimental environment, ensuring the results reflected the performance of our approaches under

Proceedings of the Ninth Conference on Machine Translation, pages 788–792
November 15-16, 2024 ©2024 Association for Computational Linguistics

the typical constraints of low-resource language translation tasks. In the future, we may explore incorporating the available monolingual data, such as through back-translation, to further improve translation quality.

3 Experiments

This section details the experimental setup used for the various models and training strategies employed in our submission.

3.1 Primary Submission

Our primary submission involved training a Transformer model from scratch using the Fairseq framework (Ott et al., 2019). This model was trained for Multilingual translation, handling all four language directions (English to Assamese, Manipuri, Mizo, and Khasi) simultaneously. We utilized BPE tokenizer (Araabi et al., 2022) and Transformer architecture. The architectural details are shown in Table 2.

Parameter	Value
Embedding Dimension	512
FFN Dimension	1024
Attention Heads	4
Encoder Layers	6
Decoder Layers	6

Table 2: Transformer Architecture Details

3.2 Contrastive Submission

The contrastive submission explored fine-tuning pre-trained models in two settings: language-specific and Multilingual.

3.2.1 Multilingual Fine-tuning:

Both mT5 and IndicBart were fine-tuned in a Multilingual setting, where a single model was trained to handle all four language directions. To enable the models to distinguish between the target languages, we added language-specific tokens to their existing vocabularies, as suggested by previous work (Johnson et al., 2017). The language-specific tokens used are shown in Table 3. A single model was trained for one-to-many translation across all four language directions for each of the indicBart, mT5-small, and IndicTrans2 systems. The results are in Table 4. IndicBart and mT5-small were fine-tuned using Full Fine-Tuning (FFT), while IndicTrans2 was fine-tuned employing the LoRA (Low-Rank Adaptation) technique (Hu et al., 2021).

Language	Token
Assamese (asm)	‘<asm_Beng>‘
Manipuri (mni)	‘<mni_Beng>‘
Khasi (kha)	‘<kha_Latn>‘
Mizo (lus)	‘<lus_Latn>‘

Table 3: Language-Specific Tokens

3.2.2 Monolingual Fine-tuning:

We also trained separate models for each language pair, as these focused on a single translation direction and did not require language-specific tokens.

For each language direction, we trained four distinct models using mT5-Small and IndicBart with Full Fine-Tuning (FFT). The results are in Table 4.

3.3 Experiments with LLMs

Additionally, we explored the use of the Llama3 model in conjunction with the LoRA (Low-Rank Adaptation) technique.

Zero-Shot and Few-Shot Translation Evaluation We tested Zero Shot Translation capabilities of Llama 3-8B-8192, Llama 3-70B-8192, mixtral-8x7B-32768, Llama3-8B-instruct and Llama3.1-8B-instruct. We also tested the few-shot translation capabilities of Llama3.1-8B-instruct with 3-shot, 5-shot, and 10-shot prompting.

Supervised Fine-Tuning with LoRA We fine-tuned a 4-bit quantized (Liu et al., 2023) Llama3 model using the LoRA technique with Supervised Fine-Tuning (SFT), employing the LlamaFactory framework (Zheng et al., 2024). We used a prompt-based approach for translation, providing the model with a system prompt and a prompt template specifying the source and target languages.

The following template was used for fine-tuning the Large Language Models (LLMs):

```
System Prompt : You are a helpful assistant.
Prompt Template : Translate the following
English sentence to {target_language} in
{target_script} Script:\n{input_sent}
```

4 Results

4.1 Multilingual vs. Monolingual Performance

One key finding from our experiments was the performance comparison between the Multilingual and Monolingual training approaches for the mT5 and IndicBart models. As shown in Table 4, the

Model	Training Type	en-as	en-kha	en-mz	en-mni
Transformers	Multilingual	16.06	19.67	5.49	20.60
IndicBart	Monolingual	6.4	11.2	25.1	8.8
	Multilingual	6.5	11.4	25.3	9.1
mT5-small	Monolingual	14.3	12.9	31.4	19.2
	Multilingual	15.6	13.6	32.3	23.9
IndicTrans2-2B	ZeroShot	49.2	-	-	44.9
IndicTrans2-200M	ZeroShot	49.5	-	-	45.3
	Multilingual	47.27	-	-	49.12

Table 4: ChrF Scores for Monolingual : Models fine-tuned for one-to-one language translation
Multilingual : Models fine-tuned for one-to-many language translation

Multilingual versions of both mT5 and IndicBart consistently outperformed their Monolingual counterparts across the translation tasks.

- For mT5, the Multilingual model outperformed the Monolingual model across all language pairs, with ChrF score improvements ranging from 1.3 to 4.7 points. This suggests that mT5 benefits from the shared linguistic knowledge across different languages in a Multilingual setting, which enhances its ability to generalize to low-resource languages.
- Likewise, IndicBart demonstrated a slight performance boost in the Multilingual setting compared to the Monolingual models, suggesting that the Multilingual training approach provided a benefit.

The better performance of the Multilingual models is likely due to the shared linguistic knowledge they gained during training, which may have provided a richer context and improved their ability to generalize. This indicates that leveraging Multilingual data, even in limited-resource scenarios, can be a more effective approach than focusing on Monolingual training.

4.2 Expected Structured Output

A challenge observed during the experiments was the generation of structured output. Ideally, the output should directly provide the translated sentence without additional, unnecessary text. However, we noticed that the LLM models sometimes wrapped the translation in extraneous text, such as “The translation of the given sentence is: Translation”, followed by further analysis and explaination making it difficult to extract the translation. This adds noise to the output and complicates the process of extracting the actual translation.

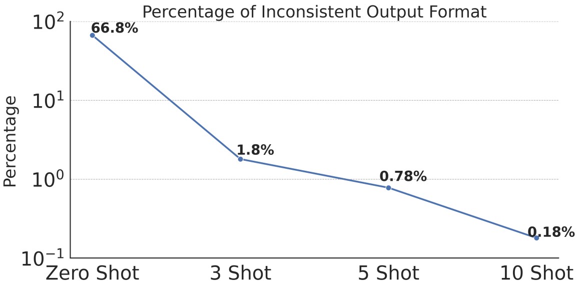

Figure 1: Inconsistent Output Format with Few Shot Prompting

We analyzed the percentage of outputs that were wrapped with unnecessary text across different settings:

This issue of unnecessary text in the output was more common in the zero-shot setting, where 66.% of the outputs included additional text. As the number of shots increased, the percentage of such outputs decreased significantly to 0.18% in 10 Shot Prompting, indicating that few-shot prompting can help guide the LLM to produce more structured and concise translations.

To improve the usability of LLM-based machine translation systems, it’s crucial to fine-tune the models or design prompts that consistently yield clean and structured outputs, particularly in low-resource settings where post-processing resources might be limited.

5 WMT 2024 Results

The performance of our models on the WMT 2024 Low-Resource Indic Language Translation Shared Task dataset is summarized in the following table, focusing on the ChrF (Popović, 2015) metrics:

For the primary submissions, we utilized Transformers trained from scratch without additional data. As indicated by the scores, the primary

Model	Inference	en-as	en-kha	en-mz	en-mni
Llama3-8B-8192	Zero Shot	18.56	14.92	15.57	13.45
Llama3-70B-8192	Zero Shot	27.54	18.57	20.62	15.53
mixtral-8x7B-32768	Zero Shot	6.79	15.45	16.57	2.65
Llama3-8B-instruct	Zero Shot	26.13	8.38	18.06	15.29
	1 Epoch	29.82	33.19	32.72	37.85
	2 Epoch	31.68	35.26	37.73	44.51
Llama3.1-8B-instruct	Zero Shot	22.93	12.03	15.23	14.47
	3 Shot	23.26	13.66	18.89	15.30
	5 Shot	23.48	15.11	18.77	15.29
	10 Shot	23.89	16.03	19.39	15.43

Table 5: ChrF Scores for Various Models, Shot Types, and Language Pairs

Language Pair	Submission Type	ChrF
Eng-Asm	primary	0.1123
	contrastive	0.6518
Eng-Mni	primary	0.1102
	contrastive	0.4438
Eng-Lus	primary	0.1282
	contrastive	0.4151
Eng-Kha	primary	0.1139
	contrastive	0.3541

Table 6: ChrF Scores for WMT 2024 Shared Task

systems struggled significantly, yielding very low ChrF values across all language pairs.

In contrast, the models fine-tuned for the contrastive submissions demonstrated noticeable improvements. For Assamese and Manipuri, we fine-tuned IndicTrans2, achieving the highest ChrF scores in these language pairs. For Mizo and Khasi, we fine-tuned Llama3, which also resulted in enhanced performance compared to the primary systems. These findings highlight the effectiveness of fine-tuning pre-trained models, even in low-resource settings.

6 Potential Test Set Bias

One of the noteworthy observations in this year (2024) WMT 2024 results is the significant difference in the performance of the primary Transformers trained from scratch when evaluated on this year's (2024) test set compared to last year's (2023) test set. Specifically, we observed that the models performed better on last year's test set despite using the same training data.

This discrepancy could be indicative of a translation bias present in last year's dataset, which might have inadvertently favored the models trained on that data. The primary systems, having been trained exclusively on the previous year's data, may have overfitted to patterns specific to that dataset, leading to better performance on the older test set but struggling on the newer one.

This implies that the primary models may have difficulty generalizing to entirely new data distributions, an important factor to consider in low-resource settings where the training data is limited and may not be representative of future data. It also underscores the importance of using diverse and varied datasets during training to help mitigate such biases and improve the overall robustness of the models.

7 Conclusion

This paper presented the systems and results of the Yes-MT team's participation in the WMT 2024 Low-Resource Indic Language Translation Shared Task. The experiments highlighted the potential of LLMs, especially when fine-tuned with techniques such as LoRA, in enhancing translation quality even under low-resource conditions. The contrastive submissions, which utilized fine-tuned LLMs, demonstrated significant improvements over the primary submissions that relied on training Transformers from scratch.

Our findings suggest that while training models from scratch can be challenging in low-resource settings due to data scarcity and generalization issues, fine-tuning pre-trained models can effectively bridge the gap, leveraging shared knowledge across languages to achieve better translation performance.

Future work could explore integrating monolingual data through back-translation or other data augmentation techniques, as well as further refining prompt engineering strategies to improve the structure and clarity of LLM outputs. Additionally, focusing on addressing potential biases in test data to help create more reliable translation systems.

Acknowledgments

We acknowledge the organizers of the WMT 2024 Low-Resource Indic Language Translation Shared Task for providing the valuable dataset and facilitating this research. We also thank the developers of the mT5, IndicBart, IndicTrans2, Llama 3, and Mixtral models for making their work publicly available.

Abstract

This paper presents our machine translation system that was developed for the WAT2024 MultiIndic MT shared task. We built our system for the Sindhi-English language pair. We developed two MT systems. The first system was our baseline system where Sindhi was translated into English. In the second system, we used Hindi as a pivot for the translation of text. In both the cases, we had identified the name entities and translated them into English as a preprocessing step. Once this was done, the standard NMT process was followed to train and generate MT outputs for the task. The systems were tested on the hidden dataset of the shared task

1 Introduction

This paper presents the system description of our neural machine translation system developed for the MultiIndic shared task organized at WMT 2024. We collected around two lac English-Hindi parallel corpus from Press Information Bureau's website[1] which had collection of news articles in English as well as in Hindi and then translated it into Sindhi (in Devanagari script). Thus, two NMT systems were trained on using this corpus. The first system was the baseline system which was trained using the Sindhi-English language pair. The second system had two NMT systems, Sindhi-Hindi and Hindi-English. This system used Hindi as the pivot language for translation.

2 System Overview

2.1 Preprocessing

Here, we did tokenization of text and also performed spelling correction. Then named entities from Sindhi text were extracted using the Bi-LSTM Sindhi POS tagger that was developed in-house (Nathani et al. 2023). The identified named entities were then classified into MUC-6 category (Grishman et al. 1996) through a rule-based approach. These tagged named entities were searched in a knowledge base which had translations of Sindhi/Hindi Organization and Location named entities in English. We extracted the named entities from the Sindhi/Hindi corpus using a rule-based NER system. Once the named entities were extracted, they were searched in a knowledge base that had translations of these named entities in English (Organization and Location names). If they were found then the same were replaced in the Sindhi/Hindi Corpus. In cases where the named entity translations were not present in the knowledge base, then they were transliterated and were replaced in Sindhi/Hindi corpus. This became our Named Entity Translation module which identified the named entities and accordingly translated/transliterated them into English (Sharma et al. 2023; Joshi & Katyayan 2023). The work of this module is shown in Figure 1.

2.2 Byte Pair Encoding

Here the source and the target corpus were divided into smaller units known as subwords. This task was performed to convert the words into smaller basic units which helped neural MT models in better handling of out of vocabulary (OOV) words.

2.3 Training of the Model

In training both systems we applied the same steps. For system 1 which was the baseline system, we had only one named entity translation module (Sindhi-English) while for the system 2 the named entity translation module performed Hindi-English translation/transliteration. The process followed

[1] https://pib.gov.in/

Proceedings of the Ninth Conference on Machine Translation, pages 793–796
November 15-16, 2024 ©2024 Association for Computational Linguistics

was; the POS tagging of Sindhi sentence was performed and NER was performed using a rule-based module. The identified named entities were translated as explained in the previous section. This produced an augmented corpus-based source sentence. For example, let us consider a Sindhi sentence, "**निशीथ जोशी नई दिल्ली जे इंदिरा गांधी अंतर्राष्ट्रीय हवाई अड्डे खां जयपुर जो सफर करे रहियो आहे।**" Here "**निशीथ जोशी** (Person)", "**नई दिल्ली** (location)", "**जयपुर** (location)", and "**इंदिरा गांधी अंतर्राष्ट्रीय हवाई अड्डे** (organization)" are named entities. Among these since "**निशीथ जोशी**" and "**जयपुर**" were not available in the knowledge base, so they were transliterated to "Nisheeth Joshi" and "Jaipur" respectively. The rest of the named entities had their categories in the knowledge base; thus, they were looked up in a sequential manner. "**नई दिल्ली**" was not found and was transliterated to "New Delhi", similarly "**इंदिरा गांधी अंतर्राष्ट्रीय हवाई अड्डे**" was translated to Indra Gandhi International Airport". The entire training corpus was augmented using this methodology. Figure 2 shows the working of the entire system.

The hyperparameters used in training both the systems are shown in table 1.

Parameter	Value
No. of Encoding Layers	6
No. of Decoding Layers	6
Early Stopping	
metric	bleu
min_improvement	0.2
steps	6
Optimizer	Adam
beta_1	0.8
beta_2	0.998

Minimum_learning_rate	0.00001
Max_steps	1000000

Tabel 1: Hyperparameters Used in Training NMT Models

3 Evaluation

We participated in the shared task using the hidden corpus and submitted the outputs for both the systems viz baseline and pivot MT systems. The results of the same are shown in table 2.

System	BLEU	chrF	chrF++
System 1	19.4	44.6	43
System 2	20	44.7	43.2

Tabel 2: Evaluation Results

The baseline system which translated Sindhi text into English had a BLEU score (Papineni et al. 2002) of 19.4, chrF score (Popović 2015) of 44.6 and chrF++ score (Popović 2017) of 43. From a human annotators perspective, this system produced fluent translations but in some cases lacked the desired quality. The second system which used Hindi as a pivot language (where Sindhi was translated into Hindi and then this Hindi translation was translated into English) produced slightly better results. Its BLEU score was 20, chrF score was 44.7 and chrF++ score was 43.2. This system generated translation which had improved adequacy and fluency scores.

Abstract

This paper presents a Transformer-based Neural Machine Translation (NMT) system developed by the Centre for Natural Language Processing and the Department of Computer Science and Engineering at the National Institute of Technology Silchar, India (NITS-CNLP) for the MultiIndic22MT 2024 Shared Task. The system focused on the English-Manipuri language pair for the WMT24 shared task. The proposed WMT system shows a BLEU score of 6.4, a chrF score of 28.6, and a chrF++ score of 26.6 on the public test set Indic-Conv dataset. Further, in the public test set Indic-Gen dataset, it achieved a BLEU score of 8.1, a chrF score of 32.1, and a chrF++ score of 29.4 on the English-to-Manipuri translation.

1 Introduction

The Centre for Natural Language Processing and the Department of Computer Science and Engineering at the National Institute of Technology Silchar, India (NITS-CNLP) participated in The MultiIndic22MT 2024 Shared Task (Dabre and Kunchukuttan, 2024) for English-Manipuri language pair in the WMT2024 shared task. The shared task involves developing Machine Translation (MT) for English and 22 Indic Languages (Assamese, Bengali, Bodo, Dogri, Konkani, Gujarati, Hindi, Kannada, Kashmiri (Arabic script), Maithili, Malayalam, Marathi, Manipuri (Meitei script), Nepali, Oriya, Punjabi, Sanskrit, Santali, Sindhi (Devanagari script), Tamil, Telugu, Urdu).

In recent years, there has been growing interest in developing effective machine translation systems for Manipuri (Singh et al., 2023a) (Singh and Singh, 2020) (Singh and Singh, 2022b) (Singh et al., 2023b), which is a language with a complex linguistic structure (Singh and Bandyopadhyay, 2010) and limited bitext. Various approaches have been explored to create models that can accurately translate between Manipuri and other languages(Singh and Singh, 2022a). These efforts include the development of translation models that handle different scripts, such as Bengali and Meitei Mayek, and the integration of linguistic (Singh and Bandyopadhyay, 2005) (Singh and Bandyopadhyay, 2010) and that are essential for producing high-quality translations.

1.1 Brief Description of Manipuri language

The Manipuri language can be written in: Bengali and Meitei Mayek. It is one of the 22 official languages of India included in the 8th schedule of the Indian constitution. Historically, computational linguistics research and translation efforts for Manipuri have predominantly focused on the Bengali script, due to its extensive availability of digital resources.

Most English-to-Manipuri translation models and linguistic resources have been developed using the Bengali script. Numerous projects have created bitext and bilingual dictionaries in this script, significantly advancing machine translation for Manipuri.

In contrast, the Meitei Mayek script, which holds cultural and historical significance for the Manipuri people, has not received similar attention. Although recent years have seen a revival of the Meitei Mayek script, highlighting the need for computational resources and tools to support its use in modern digital contexts, it still faces challenges due to the limited availability of textual data and digital resources.

Efforts to address this gap include digitizing ancient manuscripts and developing new textual resources in Meitei Mayek.

2 Our Approaches

2.1 Dataset and Preprocessing

The training dataset (Gala et al., 2023) provided by the WMT Shared Task 2024 consists of 42,740 bitext. After incorporating additional data from the

Proceedings of the Ninth Conference on Machine Translation, pages 797–803

Language	Sentence	Word
English-Training	63506	1093014
Manipuri-Training	63506	894411
English-Validation	997	30772
Manipuri-Validation	997	31799
English-Testing$_{\textbf{conv}}$	1502	14849
Manipuri-Testing $_{\textbf{conv}}$	1502	12621
English-Testing $_{\textbf{gen}}$	1023	25347
Manipuri-Testing $_{\textbf{gen}}$	1023	23421

Table 1: This table presents the BLEU, chrF, and chrF++ scores for the English-to-Manipuri machine translation system.

Ministry of Electronics and Information Technology (MeitY), we ensure that the dataset is properly aligned to each other to confirm that it consists of bitext, along with removing duplicates and noise. As a result, we obtain a clean training dataset of 63,506 bitext. The validation dataset, also provided by the WMT Shared Task 2024, contains 997 bitext. For testing, we use the test set from the WMT Shared Task 2024, which includes the Indic-Conv and Indic-Gen datasets, comprising 1,502 and 1,023 bitext, respectively.

2.2 Hyperparameter

2.2.1 Sentencepiece Model

We train a model (MT$_{sp}$) system based on a basic Transformer architecture (Vaswani et al., 2017), utilizing the OpenNMT toolkit (Klein et al., 2017)[1]. In this model, we employ the SentencePiece (Kudo, 2018)[2] tokenization technique with a vocabulary size of 8,000 for both English and Manipuri. The model consists of 6 encoder and 6 decoder layers, each with 8 attention heads. The MT$_{sp}$ system is trained for 200,000 steps, with validation conducted every 5,000 steps, and model checkpoints saved at 5,000-step intervals.

It utilizes a bucket size of 262,144 and a batch size of 2048, along with 8,000 warmup steps. Optimization is performed using the Adam optimizer (Kingma and Ba, 2014). The (MT$_{sp}$) is trained with a feed-forward layer size of 2048, a hidden size of 512, and a label smoothing of 0.1.

2.2.2 Proposed Subword Model

Our proposed model (WMT24$_{proposed}$) is also a transformer model trained using the OpenNMT toolkit. For tokenization, we employ the Byte Pair Encoding (BPE) method (Sennrich et al., 2016)[3] with the same vocab size 8000 for English and Manipuri. The proposed model shares the same hyperparameters as the (MT$_{sp}$), including training for 200,000 steps, with validation every 5,000 steps, and model checkpoints saved at 5,000-step intervals. It also uses the same bucket size of 262,144 and a batch size of 2048.

Both the (MT$_{sp}$) and (WMT24$_{proposed}$) models are configured with 8 attention heads, 6 encoder layers, 6 decoder layers, and a learning rate of 2, along with an attention dropout rate of 0.1. Optimization is performed using the Adam optimizer (Kingma and Ba, 2014), and the models share identical hyperparameters, including a feed-forward layer size of 2048, a hidden size of 512, and label smoothing of 0.1.

We train both the WMT24$_{proposed}$ and MT$_{sp}$ models using the complete set of 63,506 sentence pairs, which includes data from both the WMT Shared Task data and additional data provided by MeitY. We utilize the same validation sentences, and the testing data remains unchanged.

The performance of each model is evaluated using BLEU (Papineni et al., 2002), chrF (Popović, 2015), and chrF++ (Popović, 2017) metrics, utilizing the sacreBLEU tool (Post, 2018)[4] for score evaluation.

3 Results and Discussion

In this section, we discuss the experimental results and performance of the models. The reported BLEU, chrF, and chrF++ scores are calculated based on the de-tokenized text. The scores of the systems are given in Table 2. The English-to-Manipuri translation WMT24$_{proposed}$ model achieves a BLEU score of **6.4**, a chrF score of 28.6, and a chrF++ score of 26.6 on the Indic-Conv dataset. In contrast, the MT$_{sp}$ achieves a BLEU score of 5.1, a chrF score of 30.9, and a chrF++ score of 27.1 on the same dataset.

For the Indic-Gen dataset, the WMT24$_{proposed}$ achieves a BLEU score of **8.1**, a chrF score of 32.1, and a chrF++ score of 29.4, while the MT$_{sp}$ achieves a BLEU score of 6.8, a chrF score of 32.8, and a chrF++ score of 28.7. These results highlight the superior performance of the WMT24$_{proposed}$ compared to the MT$_{sp}$ model across all evaluation metrics.

MT_{sp}	gen	6.8	32.8	28.7

Table 2: This table presents the BLEU, chrF, and chrF++ scores for the English-to-Manipuri machine translation system.

3.1 Qualitative Analysis

In the table 3, sample 1, the word ꯍꯌꯦꯡ, meaning "tomorrow" is correctly translated in both models. The word "movie" has been translated to a more beautiful word in both translations as ꯃꯃꯤ ꯀꯨꯝꯍ, which we call movies in the early period, while in the reference, it is translated as cinema, which is not so accurate. While "Mom" has been translated as ꯍꯣꯝ in the reference but it is transliterated in MT_{sp} ꯃꯣꯝ. In the second sample, the phrase "school and I" is accurately translated; the reference ꯑꯩ ꯁ꯭ꯀꯨꯜ is correctly represented in the output as ꯑꯩꯅ ꯁ꯭ꯀꯨꯜ, but the overall meaning of the sentence is not conveyed as the reference text is "not to go" while both translations have translated it as "go". In the third sample, the word "holiday" is translated properly, with the reference being ꯁꯨꯇꯤꯅꯦ꯫, here both models show a better translation than the reference text. In the fourth sample, the phrase "14 April right" is accurately translated as ꯑꯦꯄ꯭ꯔꯤꯜ ꯱꯴, but in the $\text{WMT24}_{\text{proposed}}$, the word o.t.p ꯑꯣ.ꯇꯤ.ꯄꯤ has been included, which changes the overall meaning. In the fifth sample, the name "Lelina" is correctly translated as ꯂꯦꯂꯤꯅꯥ in the $\text{WMT24}_{\text{proposed}}$, but the meaning of the sentence cannot be conveyed as the phrase "thank you" has not been translated. The word "thank you" has been translated in the MT_{sp}. Still, the name "Lelina" is not translated. In the sixth sample, "Ambedkar Jayanti" is correctly translated as ꯑꯝꯕꯦꯗꯀꯔ ꯖꯌꯟꯇꯤ in the $\text{WMT24}_{\text{proposed}}$ model; however, the adequacy is hampered by the missing translation of "tomorrow" in the output, and the fluency is also affected by the ill-formed sentence structure. Meanwhile, in the MT_{sp} model, the word "Jayanti" is missing. In sample 7, the word "municipal" ꯃ꯭ꯌꯨꯅꯤꯁꯤꯄꯥꯜ has been translated in both models, while MT_{sp} performs better. Some keywords have been translated like the "senior citizen" ꯁꯤꯅꯤꯌꯔ ꯁꯤꯇꯤꯖꯦꯟꯁꯤꯡꯅ. In sample 8, the word "motorcycle" ꯊꯔꯦꯟꯁꯤꯡꯊꯤ is included in the $\text{WMT24}_{\text{proposed}}$, which is an extra word.

In the table 4, sample 1, the words "shoes," "clothes," "tie," "jewelry," "hairstyle," "make-up," "watch," "cosmetics," and "perfume" have been translated in both models. In the second sample, "dry" is translated as ꯑꯀꯪꯕ and "stone" as ꯅꯨꯡꯅ; in both samples, the overall meaning is conveyed. In sample 3, "chilli powder" ꯆꯤꯂꯤ ꯃꯀꯨꯄ has been translated correctly. In sample 4, the phrase "metro station" has been translated correctly in both models, but in this case, the MT_{sp} model performs better. In the sample 5, the word "Xeres" has not been translated, and the overall meaning of the sentence cannot be conveyed. In the last sample, while the output contains some keywords from the reference, it fails to translate the overall meaning of the sentence.

Four native speakers assessed the adequacy and fluency of the translations. The overall output of the sample has been shown in the figure 1. This evaluation indicates the quality of the sample outputs, reflecting how fluent and adequate the translations are in conveying the intended meaning.

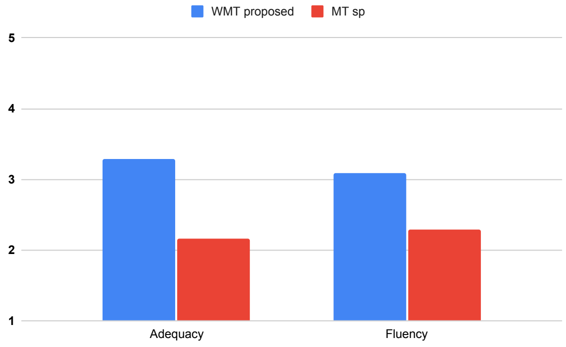

Figure 1: Adequacy and Fluency for the output samples

4 Conclusion

We develop and evaluate two Transformer-based machine translation (MT) systems tested on two different datasets (Indic-Conv and Indic-Gen) for translating English to Manipuri. One system (MT_{sp}) utilizes the OpenNMT toolkit with Senten-

cepiece tokenization for tokenization, while the proposed model (WMT24$_{\text{proposed}}$) employs the OpenNMT toolkit with Byte Pair Encoding (BPE). Both models are trained on a comprehensive dataset that includes data from WMT24 and MeitY.

The model is optimized with the Adam optimizer and is evaluated using BLEU, chrF, and chrF++ metrics. Additionally, the translations are assessed for both adequacy and fluency. The models successfully convey the overall meaning of the source sentences, but they often lack fluency, producing disjointed or grammatically incorrect outputs.

Overall, the WMT24$_{\text{proposed}}$ produces translations that are more syntactically correct, contextually appropriate, and idiomatically fluent, while MT$_{\text{sp}}$ offers more direct, simpler translations that sometimes lose nuance or complex structure.

Limitations

The proposed (WMT24$_{\text{proposed}}$) model translation conveys the main ideas of the reference sentence, despite certain errors and structural challenges. It captures some aspects of the overall meaning of the reference sentences. In the case of longer sentences, there is a large amount of adequacy. However, the fluency of these translations deteriorates as the length of the input sentences increases.

Acknowledgements

This study is funded by the Ministry of Electronics and Information Technology (MeitY), Government of India, under Ref. No. 11(1)/2022-HCC(TDIL)-Part(4). We would like to express our gratitude to the CNLP Lab and the Department of Computer Science and Engineering at NIT Silchar for their essential role in providing the computing resources used in this research.

Abstract

This paper describes NLIP Lab's multilingual machine translation system for the WAT24 shared task on multilingual Indic MT task for 22 scheduled languages belonging to 4 language families. We explore pre-training for Indic languages using alignment agreement objectives. We utilize bi-lingual dictionaries to substitute words from source sentences. Furthermore, we fine-tuned language direction-specific multilingual translation models using small and high-quality seed data. Our primary submission is a 243M parameters multilingual translation model covering 22 Indic languages. In the IN22-Gen benchmark, we achieved an average chrF++ score of 46.80 and 18.19 BLEU score for the En-Indic direction. In the Indic-En direction, we achieved an average chrF++ score of 56.34 and 30.82 BLEU score. In the In22-Conv benchmark, we achieved an average chrF++ score of 43.43 and BLEU score of 16.58 in the En-Indic direction, and in the Indic-En direction, we achieved an average of 52.44 and 29.77 for chrF++ and BLEU respectively. Our model[1] is competitive with IndicTransv1 (474M parameter model).

1 Introduction

Multilingual Neural Machine Translation (MNMT) has shown remarkable success in building translation systems for world languages in a single model (Johnson et al., 2017). These successes have led researchers to increase the model capacity catering to hundreds of world languages (Fan et al., 2020), (NLLB Team et al., 2022). It also led to multilingual translation models for particular languages under particular geographical groups such as Indic (Ramesh et al., 2022; Gala et al., 2023), African (Nekoto et al., 2020). Indic languages are interesting, with diverse languages belonging to various language families and written scripts.

This paper describes our system submission for the WAT 24 MultiIndic22MT task (Dabre and Kunchukuttan, 2024), which includes 22 scheduled Indian languages belonging to 4 language families across 12 written scripts. We participated in the constrained translation task. We explore an alignment agreement-based pre-training objective. Specifically, we substitute words from source sentences for equivalent words in a random language. The pre-training data consists of a sentence pair from the original data and code-switched augmented sentences. Our primary submission is a fine-tuned transformer-based multilingual model with 243M parameters. Experimental results show that our system achieves an average chrF++ score of 46.80 for the En-Indic direction in the IN22-Gen benchmark. We achieved an average chrF++ score of 46.80 and 18.19 BLEU score for the En-Indic direction. In the Indic-En direction, we achieved an average chrF++ score of 56.34 and 30.82 BLEU score. Compared with the IndicTransv2 model for Indic-Indic translation, our system lags most minor for pan_Guru-snd_Deva with 0.3 chrF++ scores. Due to computational constraints, we train our model on a reduced corpus.

2 Dataset

2.1 Pre-training data

In this section, we describe the dataset used for pre-training. We use the official Bharat Parallel Collection Corpus (BPCC) (Gala et al., 2023) but reduce the corpus size due to computational limitations. We also exclude sentences from the comparable directory. For languages with over 10 million parallel sentences, we reduce the no. of sentences by half. The corpus statistics are shown in Table 1. To handle skew data distribution and have good representation for low-resource languages, we use heuristic-based temperature sampling (Arivazhagan et al., 2019; Conneau et al., 2020) for data

[1] Our code and models are available at https://github.com/maharajbrahma/WAT2024-MultiIndicMT

Proceedings of the Ninth Conference on Machine Translation, pages 804–809
November 15-16, 2024 ©2024 Association for Computational Linguistics

sampling with temperature sampling (T = 5) shown in Figure 1. We utilize small, high-quality data from BPCC, namely ILCI, Massive, NLLB Seed, Daily, and Wiki, for direction-specific fine-tuning.

2.2 Alignment Augmentation

For alignment augmentation we English-centric bilingual dictionaries from MUSE[2] and GATITOS[3]. We use top 4000 words in dictionaries, replaced with a probability of 30% from the bi-lingual dictionary. We consider only replacing words in the languages that have dictionaries.

3 Methodology

Our pre-training approach is inspired by aligning embeddings (Lin et al., 2020; Yang et al., 2020) through substituting words from a bi-lingual dictionary. We pre-trained a universal model that covers En-Indic and Indic-En. We named this model **"IndicRASP"**. IndicRASP is fine-tuned into a language direction-specific model called **"IndicRASP-Seed"** using small and high-quality seed data.

IndicRASP (IR): IndicRASP is pre-trained on data from 22 Indic languages sourced from BPCC. During pre-training, we randomly substitute English words for corresponding Indic language words, resulting in code-switched augmented sentences. The alignment augmentation technique helps to bring semantically similar embeddings closer together. We get 56M sentences after alignment augmentation. We combined training sentences from the original En-Indic and Indic-En[4] and obtained 282M sentences for pre-training.

IndicRASP-Seed (IR Seed): To further enhance the performance of IndicRASP, we fine-tuned the model to be language-direction specific. We consider high-quality seed data from the BPCC corpus: ILCI, NLLB Seed, Massive, Daily, and Wiki. We sampled a total of 2.26M sentences and fine-tuned IndicRASP for both En-Indic and Indic-En directions.

4 Experiments

Setting: We use the standard sequence-to-sequence Transformer big model as our architecture for pre-training. It uses 6 encoder and 6 decoder layers, with an embedding size of 1024. The embeddings between the encoder and decoder are shared, with a feed-forward network size of 4096 and 16 attention heads.

Training: We pre-train the model with the Adam optimizer (Kingma and Ba, 2014) with β_1 set to 0.9 and β_2 set to 0.98. We set the warmup initial learning rate to 1e-07 and the learning rate to 5e-4, with a warmup step of 4000. We train the models with a dropout rate of 0.1 and a label smoothing rate of 0.1. During fine-tuning, we consider a learning rate of 3e-5 and a dropout rate of 0.2. All experiments are conducted on 8 NVIDIA A100 GPUs.

Baseline Models: We consider two baselines:

1. **IndicTransv1 (Ramesh et al., 2022)**: IndicTransv1 (IT1) is a multilingual transformer (Vaswani et al., 2017) translation model for 11 Indic languages trained. It is a 474M parameter trained on the 49.7M sentence pair on the Samanantar dataset.

2. **IndicTransv2 (Gala et al., 2023)**: IndicTransv2 (IT2) is a 1B parameter model trained on the BPCC corpus for 22 Scheduled Indian languages.

Language-Direction Specific Models: For our primary submission, we fine-tune IndicRASP with direction-specific small seed data for En-Indic and Indic-En. For the Indic-Indic model, we fine-tune the IndicRASP-Seed (En-Indic direction) on the Indic-Indic corpus extracted from the BPCC corpus.

Evaluation: We use the dev set of BPCC IN-Gen as our validation and evaluate our model on the test set of BPCC IN-Gen and IN-Conv. We report our results on lexical-based automatic metrics BLEU (Papineni et al., 2002), and chrF++ (Popović, 2017). We use the sacreBLEU library for evaluation, with a chrF word order of 2.

5 Results

We list the results of our model on the IN22-Gen in Table 3, 4 for chrF++ and BLEU, respectively. Similarly, Table 5 and 6 results for chrF++ and BLEU in IN22-Conv. Table 2 shows the performance of our primary submission on a hidden test set. Our findings described for IN22-Gen are:

- IndicRASP achieves an average chrF++ score of 45.50, and IndicRASP-Seed achieves 46.80 with an improvement of (+1.30) for the En-Indic direction. Similarly, IndicRASP

achieves an average BLEU score of 16.82 and 18.19 for the IndicRASP-Seed. It suggests that fine-tuning small, high-quality language directions improves the alignment augmented IndicRASP model. We can observe similar results for Indic-En.

- By comparing IT1 and IndicRASP-Seed, we find that IndicRASP-Seed has a chrF++ improvement of +1.30 for En-Indic; however, in the Indic-En direction, IndicRASP-Seed is lagging behind by 1.63.

- By comparing IT2 and IndicRASP-Seed, we find that IndicRASP-Seed lags behind by 1.74 chrF++ scores for En-Indic direction. In the Indic-En direction, the IndicRASP-Seed lags behind significantly by a 7.13 chrF++ score from IT2.

- For En-Indic languages highlighted in bold in Table 3, namely Manipuri, Oriya, and Santali, IndicRASP-Seed performs better than IndicTransv2 with chrF++ score difference of 0.5, 2.3, and 6.5 respectively.

- We observe that our setup performs better in the En-Indic direction than in Indic-En. This is possibly due to the reduction of the dataset.

In Table 7, we show the performance of IndicRASP-Seed for Indic-Indic direction in the IN22-Gen and IN22-Conv datasets. We observe that the IT2 is better than the IndicRASP-Seed in all language pairs, particularly for `mal_Mlym-hin_Deva`, IndicRASP-Seed lags highest behind by a 5.6 chrF++ score, and

6 Conclusion

This paper presents our system for the WAT24 shared task on the MultiIndic22MT 2024 Shared Task. We focus on a universal model using pretraining Indic languages with alignment augmentation and further obtaining direction-specific models using finetuning on small and high-quality seed data. We submit a competitive 243M parameter model covering 22 Indic languages that achieves a comparable performance with a 474M parameter model covering 11 languages.

Limitations

The present study particularly focuses on pre-training objectives on a parallel corpus. However, techniques such as utilizing monolingual corpus (Pan et al., 2021) along with alignment objective remain unexplored. Also, large language models can be potentially leveraged to generate datasets for low-resource Indic languages. Further, we restricted the alignment augmentation of substitute words from source sentences (English words). However, words from target sentences can also be substituted can explored.

Acknowledgements

We thank the reviewer for the valuable feedback. We are also grateful to the Department of Computer Science and Engineering, Indian Institute of Technology Hyderabad, for providing the necessary computing resources to conduct the experiments.

Abstract

This paper presents the system description of "DCU_NMT's" submission to the WMT-WAT24 English-to-Low-Resource Multimodal Translation Task. We participated in the English-to-Hindi track, developing both text-only and multimodal neural machine translation (NMT) systems. The text-only systems were trained from scratch on constrained data and augmented with back-translated data. For the multimodal approach, we implemented a context-aware transformer model that integrates visual features as additional contextual information. Specifically, image descriptions generated by an image captioning model were encoded using BERT and concatenated with the textual input.

The results indicate that our multimodal system, trained solely on limited data, showed improvements over the text-only baseline in both the challenge and evaluation sets, suggesting the potential benefits of incorporating visual information.

1 Introduction

The increasing prominence of multimodal content in the machine translation (MT) community highlights its potential to improve translation quality by incorporating visual context, which is otherwise inaccessible through textual information alone. This approach has significant implications for commercial applications, including the translation of image captions in online news articles and the translation of product descriptions in e-commerce platforms (Belz et al., 2017; Calixto et al., 2017; Lala et al., 2017; Zhou et al., 2018). By integrating visual information, multimodal MT systems can achieve more accurate and contextually appropriate translations.

Despite MT achieving near-human performance for many high-resource languages, significant challenges remain, particularly for low-resource languages (Popel et al., 2020; Costa-jussà et al., 2022). In recent years, the integration of additional modalities, such as images, into MT systems has gained prominence as a critical area of research (Sulubacak et al., 2020; Parida et al., 2021b,a). This multimodal approach seeks to address the limitations of traditional text-only MT by incorporating supplementary contextual information, thereby improving translation accuracy and expanding the applicability of MT across a broader spectrum of languages and specialised domains.

The WMT-WAT 2024 Shared Task[1] introduces the "English to Lowres Multi-Modal Translation Task," utilizing the Hindi, Bengali, Malayalam, and Hausa Visual Genome datasets. Participants are given an image, a specific rectangular region within it, and a short English caption describing the region. The task is to translate the caption into one of the target languages: Hindi, Bengali, Malayalam, or Hausa.

In this system description paper, we explain our approach for the tasks in which we participated in English (EN) to Hindi (HI) (i) Text only and (ii) Multimodal translation. We released the code and data produced during research through GitHub[2].

2 Dataset

We use the data sets provided by the organizers for the relevant tasks. The Visual Genome datasets for Hindi, Bengali, Malayalam, and Hausa include 29,000 training examples, 1,000 examples for development, and 1,600 examples for evaluation. These datasets are based on a shared set of images, with some variations due to independent sanity checks conducted for each language. For evaluation, the WMT-WAT 2024 Multimodal Shared Task utilises 1,600 examples from the evaluation set and 1,400 examples from the challenge

set. In this submission, we denote evaluation set as "EV" and challenge set as "CH" respectively. The statistics of the dataset are shown in Table 1. Due to time constrained, We only trained our systems for English-Hindi language pair.

		Tokens	
Set	Sentences	English	Hindi
Train	28930	143164	145448
D-Test	998	4922	4978
E-Test	1595	7853	7852
C-Test	1400	8186	8639

Table 1: Statistics of our data used in the English→Hindi Multimodal translation task.

3 Experimental Details

In this section, we present our experimental details for the tasks we participated in.

3.1 Text-only translation

For the EN-HI text-only translation task, we have two submissions: one restricted and the other using additional monolingual data.

Back-translation enables the effective use of monolingual data to improve the MT system, especially in a low-resource context (Sennrich et al., 2016; Ul Haq et al., 2020) where model struggles to learn reliable alignments from limited parallel data. For our experiments, we used backtranslated data generated from Flickr8k image captioning data set to enrich text-only data (Parida et al., 2022). For our text-only baseline, we trained the sentence-level transformer model from scratch using all training data until convergence.

3.2 Multimodal translation

For the EN-HI multimodal translation system, we employ a context-aware model, an extension of the Transformer architecture designed to incorporate additional contextual information during translation. Unlike traditional neural machine translation (NMT) models that translate sentences independently, context-aware NMT relaxes this assumption by conditioning the translation not only on the current source sentence but also on auxiliary information from within or outside the document. Given that the HVG data set is limited to the caption translation of specific image regions, we hypothesize that providing the model with additional context, such as a comprehensive description of the entire image, could enhance the accuracy of the generated translations. To take advantage of visual features, we extracted image captions from HVG image dataset and used them as additional context for translation. Additionally, we used pre-trained BERT as additional encoder to encode and aggregate contextual features (Wu et al., 2022).

We used BLIP[3], an image caption model, to generate a description of the HVG image dataset. As HVG contains short descriptions of specified regions of images in English and Hindi, we generate captions of entire image to be fed as additional information to multimodal context-aware model. Since our context-aware model expects context during the training and evaluation stage, we generated captions for the entire HVG dataset, including the evaluation (EV) and Challenge (CH) test sets. The overview of our multimodal translation system is depicted in Figure 1.

Two step training strategy is followed, we first train a strong sentence-level transformer model using all the training data until convergence, then the context-aware model is initialized from best checkpoint and fine-tuned on context-aware data. We select the best model on the validation data. Contextual features are encoded using pre-trained *bert-base* model released under transformers package [4].The model incorporates two special tokens: [CLS], which is added at the beginning of a sentence, and [SEP], which is employed to separate different sequences. The context is concatenated with sentences as follows:

> x_{ctx} = *[CLS] surfer on a surfboard riding a wave in the ocean [SEP] man surfing in ocean [SEP]*

Several techniques exist for context integration (Castilho et al., 2020; Wu et al., 2022; Haq et al., 2022), we used $1-fixed-sequence$ on the source and target side as context. In this approach, a single previous sentence or external sequence is considered context for current sentence being translated. After that Bert encoded features are extracted as defined in equation 1. Although the context-aware multi-encoder models are exposed to additional contextual information, the translation is still performed at sentence level.

$$C = BERT(x_{ctx}) \tag{1}$$

Figure 1: Overview of multimodal translation system.

Our translation models are based on transformer architecture with 6 encoder/decoder blocks, 512 embedding input, and 1024 FFN layer dimension size. Dropout rate is 0.3 for all tasks. We use the Adam optimizer and 5×10^{-4} learning rate schedule with 4000 warmup steps. Model training was conducted on two GPUs, with a batch size of 6000 tokens per GPU. Our Transformer implementation is based on the Fairseq (Ott et al., 2019) toolkit.

4 Results

Our results for EN-HI text-only and multimodal translation are presented in Table 2.

Modality	System	*BLEU*	
		EV	CH
text-only	Transformer	40.20	29.20
text-only	Transformer$_{bt}$	**42.70**	**35.90**
multimodal	Context-aware$_{src\_tgt}$	40.60	28.60
multimodal	Context-aware$_{src}$	40.60	**30.30**

Table 2: WMT_WAT2024 Automatic evaluation results for EN→HI on Evaluation (EV) and Challenge (CH) test sets. "Transformer$_{bt}$" denotes NMT model trained with back-translated data. For multimodal task, "src_tgt" represents context-aware model with visual contextual features used on both encoder and decoder side while src indicates context used only on the encoder side.

For text-only translation, the baseline system (Transformer) obtains BLEU scores of 40.20 on the evaluation set (EV) and 29.20 on the challenge test (CH). In contrast, the Transformer$_{bt}$ (Transformer with back-translated data) system demonstrates improved results, with BLEU scores of 42.70 for EV and 35.90 for CH. This improvement suggests that back-translation enhances translation quality by incorporating additional synthetic data, which is particularly advantageous for the challenge set (CH).

In multimodal translation, the context-aware$_{src\_tgt}$ approach achieves BLEU scores of 40.60 for EV and 28.60 for CH. Compared with a text-only restricted baseline, the EV score slightly exceeds that of the Transformer (40.20), the CH score is lower, indicating that while the multimodal context benefits the evaluation set, it does not consistently improve performance on the challenge set. Conversely, the context-aware$_{src}$ (source only context) method achieves BLEU scores of 40.60 for EV and 30.30 for CH, showing a modest improvement for the challenge set compared to the src_tgt and text-only methods (except Transformer$_{bt}$).

5 Discussion

The baseline Transformer model achieves BLEU scores of 40.20 for the evaluation set (EV) and 29.20 for the challenge test (CH). The Transformer$_{bt}$ model shows marked improvement, with BLEU scores of 42.70 for EV and 35.90 for CH, highlighting back-translation's effectiveness in enhancing performance, particularly in challenging scenarios.

In multimodal translation, the context-aware$_{src\_tgt}$ method, which utilises visual context on both the encoder and decoder sides, scores 40.60 for EV and 28.60 for CH. It slightly outperforms the baseline Transformer on EV but underperforms on CH, suggesting that while visual context can help in simpler cases, it may complicate results in more difficult scenarios.

The context-aware src only approach, using visual context only with the source text, achieves BLEU scores of 40.60 for EV and 30.30 for CH. It shows modest improvement over src_tgt for CH but does not surpass the Transformer + Back-translation in overall performance. This is obvious because multimodal translation systems are trained on constrained resources while Transfomer$_{bt}$ use 8k additional synthetic parallel sentences for training.

These findings underscore the value of back-translation in improving text-only translation, especially for more challenging tasks. For multimodal translation, while visual context can be beneficial, its effectiveness varies with context integration choice. The results suggest that different methods may be better suited to different types of translation challenge, indicating a need for further research to optimize the use of visual context.

6 Conclusion

Our results have showed that the Transformer with back-translated data consistently outperforms the text-only and multimodal systems in both evaluation tasks, demonstrating a significant benefit of back-translation, particularly for challenging scenarios. Our multimodal systems, despite not utilizing back-translated data, still outperformed the text-only baseline, highlighting the potential of visual context in improving translation accuracy. However, multimodal systems employing visual context on both the encoder and decoder sides do not exhibit a clear advantage over the text-only model or other multimodal approaches. Notably, the multimodal method shows diminished effectiveness for the challenge test (CH), suggesting that while additional visual context may enhance performance in certain cases, it can also introduce complexities that potentially undermine translation accuracy. These findings highlight the need for further investigation into optimizing the integration of visual context to improve translation outcomes across varying task difficulties.

Abstract

Multimodal machine translation leverages multiple data modalities to enhance translation quality, particularly for low-resourced languages. This paper uses a multimodal model that integrates visual information with textual data to improve translation accuracy from English to Hindi, Malayalam, Bengali, and Hausa. This approach employs a gated fusion mechanism to effectively combine the outputs of textual and visual encoders, enabling more nuanced translations that consider both language and contextual visual cues. The model's performance was evaluated against the text-only machine translation model based on BLEU, ChrF2 and TER. Experimental results demonstrate that the multimodal approach consistently outperforms the text-only baseline, highlighting the potential of integrating visual information in low-resourced language translation tasks.

1 Introduction

In recent years, neural network-based translation models have been widely used in translation tasks, demonstrating remarkable performance in terms of fluency and precision compared to previous generations of machine translation systems (Cho et al., 2014). The Transformer model, in particular, has shown significant improvements in machine translation tasks. A crucial component of the Transformer model is the cross-attention mechanism, which enhances the model's ability to capture semantic dependencies by combining self-attention—allowing source words to interact with one another—with attention mechanisms that involve target words (Vaswani et al., 2017).

Despite the broader context focus in text-only translation models, understanding the input text remains a challenge. In natural language, lexical ambiguity (Rios Gonzales et al., 2017) occurs when a single word has multiple meanings or interpretations, complicating text comprehension. For example, in the domain of finance and economics, the word "bank" almost always refers to a financial institution rather than the side of a river.

Multimodal Machine Translation (MMT), a subarea of NMT, has been introduced to utilise visual information from other modalities, such as images, to translate an aligned sentence in a source language into a target language. Recent studies (Yao and Wan, 2020; Zhao et al., 2022; Wang and Xiong, 2021) demonstrate the potential of leveraging multimodal information, alongside textual content, to enhance translation quality. Visual cues, as an additional source of information, can provide valuable insights that complement textual information, enabling MMT models to better understand and produce more accurate and contextually appropriate translations. The concept behind MMT is to integrate visual information to help disambiguate input words, detect the correct scenes in the source language, and select the appropriate translation in the target language (Hatami et al., 2022). MMT is particularly beneficial when dealing with low-resource languages where there is not sufficient parallel data to train the model.

This paper aims to explore the benefit of using visual information in translating English into four different low-resource languages, Hindi, Malayalam, Bengali and Hausa. We used a gated fusion approach to integrate textual and visual information in the encoder and generate the text in the target language on the decoder side. In the baseline, we train the model on the input text without considering the aligned image. For the multimodal model, we trained four different models for each language. We explain our methodology in Section 3, our experimental setup in Section 4, results in Section 5, and we conclude our findings in Section 6.

2 Related Work

There are various approaches proposed to integrate visual information with text-only translation models. These approaches typically utilise a visual

Proceedings of the Ninth Conference on Machine Translation, pages 815–822
November 15-16, 2024 ©2024 Association for Computational Linguistics

attention mechanism in either the decoder or encoder to capture the relationships between words in a sentence and image features. The common method involves extracting visual information by employing Convolutional Neural Networks (CNN) and then integrating this information with textual features.

Regarding visual features, existing studies on MMT employ two types of visual features: global and local visual features. Global features represent the entire image as a single vector without attention to the spatial layout of the image. On the other hand, local features describe an image as a sequence of equally sized patches (Calixto et al., 2017). Local features are extracted from multiple points in the image and are more robust to clutter than global features (Lisin et al., 2005). CNNs can be used to extract both global and local features from the image (Zheng et al., 2019).

Global image features are used in the encoder in addition to word sequences (Huang et al., 2016). Alternatively, they can be used to initialise the hidden parameters of the encoder and decoder of a RNN (Calixto and Liu, 2017). Element-wise multiplication was used to initialise the hidden states of the encoder/decoder in the attention-based model (Caglayan et al., 2017). Visual attention mechanism was employed to link visual and corresponding text semantically (Zhou et al., 2018).

Several approaches have been proposed to improve the quality of the visual modality in Multimodal Machine Translation (MMT). For instance, a multimodal Transformer-based self-attention mechanism was introduced to encode relevant information in images (Yao and Wan, 2020). A graph-based multimodal fusion encoder was developed to capture various relationships between modalities (Yin et al., 2020). Additionally, a translate-and-refine mechanism was implemented using images in a second-stage decoder to refine a text-only Neural Machine Translation (NMT) model, particularly for handling ambiguous words. A latent variable model was also employed to extract the multimodal relationships between image and text modalities (Calixto et al., 2019).

Recent methods aim to reduce noise in visual information and select visual features relevant to the text. For example, object-level visual modelling has been used to mask irrelevant objects and specific words in the source text to enhance visual feature learning (Wang and Xiong, 2021). Object detection in the image encoder has been employed to extract visual features from object regions within an image, which are then applied to a doubly-attentive decoder model (Zhao et al., 2022).

In this paper, we adopt the gated fusion MMT model (Wu et al., 2021), which integrates visual and textual representations through a gate mechanism. This gated fusion mechanism allows the model to adjust the amount of visual information that contributes to the translation process.

3 Methodology

The objective of our experiments is to evaluate the impact of visual features on translation quality in low-resource languages. Following Wu et al. (2021), we conduct experiments to assess both the text-only Transformer and the gated fusion multimodal Transformer (gated fusion MMT) using the shared task data for Hindi, Bengali, Malayalam, and Hausa. In this section, we provide descriptions of the model architectures mentioned above.

3.1 Text-only Machine Translation

For the text-only translation model, we use the training and development sets for Hindi, Bengali, Malayalam, and Hausa to train the Transformer-based model. This model serves as our baseline for evaluating the multimodal model. The text-only Transformer architecture was introduced by Vaswani et al. (2017). It consists of an encoder-decoder structure, where both the encoder and decoder are composed of stacked layers of self-attention, and feed-forward neural networks.

First, we tokenize the sentences into subwords in the training, development, and test sets. We then train four translation models on the tokenized sentences for these language pairs. Tokenization helps the model better learn the language and handle out-of-vocabulary words, especially in low-resource languages. During the inference step, we translate the tokenized test sentences from English into the four low-resource languages.

3.2 Multimodal Machine Translation

For the multimodal model, we use the gated fusion approach (Wu et al., 2021) to fuse both textual and visual information. Gated fusion MMT incorporates visual information into the translation process in a controlled and interpretable manner using a gating mechanism. The textual component is similar to the text-only model, with tokenized sentences

fed into the model. On the visual side, each sentence is paired with an image, and for each image, we have the coordinates of the rectangular region corresponding to the part of the image that relates to the sentence (see Figure 1).

For each language, we trained two models: one that considers the entire image and another that considers only the specific rectangular region. We use the pre-trained ResNet-101 CNN (He et al., 2016) to extract visual features from the images. In this study, we extract visual representations from both the whole image and the designated rectangular region, which is aligned with the text caption. The motivation for using the partial image (rather than the full image) is that objects outside the rectangular region may be irrelevant to the text caption and could potentially degrade translation model performance (Hatami et al., 2023).

Both the textual and visual representations are fed into the gated fusion model, allowing it to be trained based on both modalities. We then use these multimodal models to translate test sentences that are aligned with images. More detailed information about the multimodal models can be found in Section 4.2.2.

4 Experimental Setup

4.1 Dataset

The Hindi Visual Genome (HVG) (Parida et al., 2019), Bengali Visual Genome (BVG) (Sen et al., 2022), Malayalam Visual Genome (MVG) (Parida et al., 2019), and Hausa Visual Genome (HaVG) (Abdulmumin et al., 2022) datasets are multimodal datasets designed for English-to-Hindi, English-to-Bengali, English-to-Malayalam, and English-to-Hausa machine translation, respectively (Figure 1). These datasets, based on the original Visual Genome dataset, contain real-world images annotated with region-specific captions. The captions have been translated into the respective languages through a combination of automated translation and manual post-editing by native speakers to ensure contextual accuracy.

The MVG, HVG, BVG, and HaVG datasets are divided into training, development, evaluation, and challenge test sets, as outlined in Table 1.

Training Set: The training sets for Malayalam, Hindi, Bengali, and Hausa contain 29,000, 28,932, 28,930, and 28,930 image-caption pairs, respectively. Each pair consists of an image, a selected region in the image, and its corresponding English and Malayalam/Hindi/Bengali/Hausa captions. The captions have been manually refined to align with the visual context of the images.

Development Set (D-Test): The development sets contain 1,000 image-caption pairs in the Malayalam dataset and 998 pairs in the Hindi, Bengali, and Hausa datasets. These sets are used to validate and fine-tune model performance during the training process.

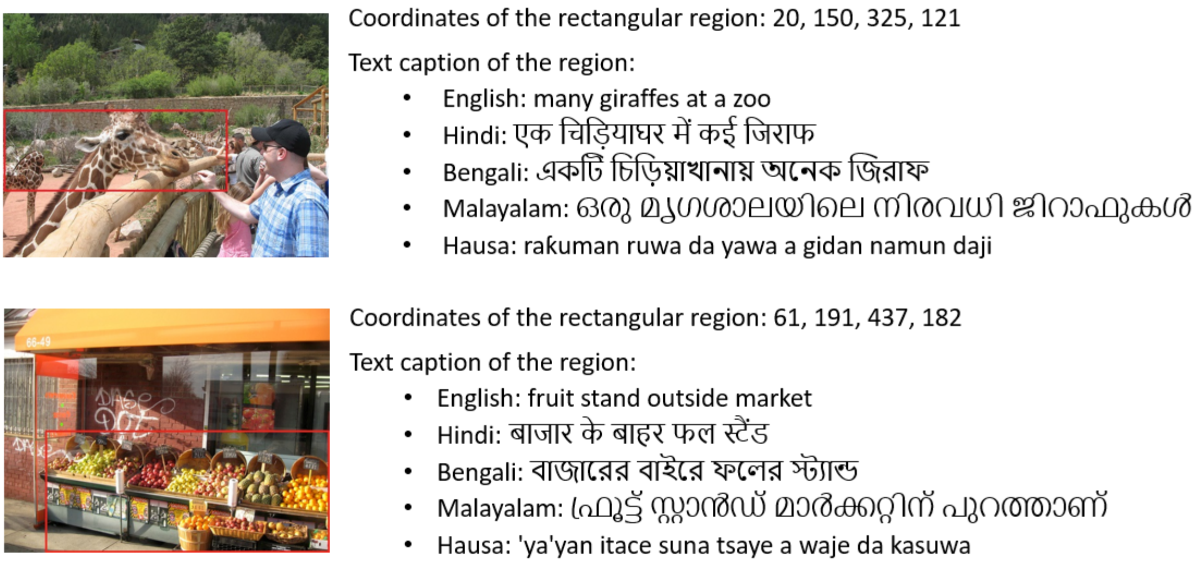
Evaluation Set (E-Test): The evaluation sets include 1,600 image-caption pairs in the Malayalam dataset and 1,595 pairs in the Hindi, Bengali, and Hausa datasets. These sets are used for evaluating model performance on unseen data, providing a benchmark for generalization capabilities.

Challenge Test Set (C-Test): The challenge test sets for all four languages consist of 1,400 image-caption pairs. These sets are designed to focus on ambiguous English words that require visual context to resolve their meaning in Malayalam, Hindi, Bengali, or Hausa. The ambiguous words were identified based on embedding similarity, and the corresponding images help disambiguate their meaning, providing a robust test for multimodal translation systems (Hatami et al., 2024).

4.2 Machine Translation Models

4.2.1 Text-only Translation Model

A text-only Transformer model serves as the baseline in our experiment, utilizing only the textual captions of images for translation. The model is trained using the OpenNMT toolkit (Klein et al., 2018) on the Visual Genome dataset for English-



Coordinates of the rectangular region: 20, 150, 325, 121

Text caption of the region:

- English: many giraffes at a zoo
- Hindi: एक चिड़ियाघर में कई जिराफ
- Bengali: একটি চিড়িয়াখানায় অনেক জিরাফ
- Malayalam: ഒരു മൃഗശാലയിലെ നിരവധി ജിറാഫുകൾ
- Hausa: raƙuman ruwa da yawa a gidan namun daji

Coordinates of the rectangular region: 61, 191, 437, 182

Text caption of the region:

- English: fruit stand outside market
- Hindi: बाजार के बाहर फल स्टैंड
- Bengali: বাজারের বাইরে ফলের স্ট্যান্ড
- Malayalam: ഫ്രൂട്ട് സ്റ്റാൻഡ് മാർക്കറ്റിന് പുറത്താണ്
- Hausa: 'ya'yan itace suna tsaye a waje da kasuwa

Figure 1: Examples from the Visual Genome dataset show English caption of the rectangular region (solid red line) with translation in Hindi, Bengali, Malayalam and Hausa.

to-Hindi, Bengali, Malayalam, and Hausa translations. It comprises a 6-layer Transformer architecture with attention mechanisms in both the encoder and decoder stages, trained for 50k steps.

The encoder processes a sequence of tokens (words or subword units) and generates context-aware representations for each token. The decoder generates the output sequence (e.g., translated text) by leveraging the encoded representations from the encoder along with the previously generated tokens. It employs multi-head self-attention and feed-forward layers, incorporating additional attention mechanisms to effectively focus on the encoded input. The core innovation of the Transformer is the **self-attention mechanism**, which computes attention scores across all tokens in the sequence, creating weighted representations that capture contextual relationships between tokens.

Since the Transformer model does not inherently process sequences in a fixed order, as recurrent neural networks (RNNs) do, it uses **positional encodings** to inject information about the position of tokens in the sequence. These positional encodings are added to the input embeddings, enabling the model to differentiate between tokens based on their positions within the sequence. To enhance its ability to capture different types of relationships between tokens, the Transformer employs **multi-head attention**. This involves splitting the self-attention process into multiple parallel attention heads, each learning a different set of attention weights. The outputs from all heads are then concatenated and linearly transformed to provide a richer, more comprehensive representation of the input sequence.

SentencePiece (Kudo and Richardson, 2018) is employed to segment words into subword units, offering a language-independent approach to tokenization without requiring pre-processing steps, thereby enhancing the model's adaptability and versatility in handling raw text.

4.2.2 Multimodal Machine Translation

In the MMT model, we adopt the gated fusion MMT model (Wu et al., 2021), which fuses visual and text representations by employing a gate mechanism. Gated fusion is a mechanism used to integrate visual information from images with textual information from source sentences during the translation process. The main idea behind gated fusion is to control the amount of visual information that is blended into the textual representation using a gating matrix.

The source sentence x is fed into a vanilla Transformer encoder to obtain a textual representation H_{text} of dimension $T{\times}d$ [1]. The image z is processed using a pre-trained ResNet-101 CNN (He et al., 2016), which has been trained on the ImageNet dataset (Russakovsky et al., 2014), to extract a 2048-dimensional average-pooled visual representation, denoted as $Embed_{image}(z)$. The visual representation $Embed_{image}(z)$ is projected to the

Multimodal MT (entire image)	**41.25***	**62.94***	**46.48***
Multimodal MT (partial image)	38.31	60.87	47.62

Table 2: BLEU, ChrF2 and TER scores for text-only and multimodal models for English to Hindi, Bengali, Malayalam and Hausa on the test set (* represents a statistically significant result compared to the baseline text-only model at a significance level of $p < 0.05$).

same dimension as H_{text} using a weight matrix W_z, denoted as:

$$\text{Embed}_{\text{image}}(z) = W_z \text{ResNet}_{\text{pool}}(z)$$

where W_z is a learned projection matrix.

To determine the amount of visual information to fuse with the textual representation, a gating matrix Λ of dimension $T{\times}d$ is generated ($[0,1]^{T\times d}$). This matrix is computed using a sigmoid function applied to both the projected visual representation and the textual representation:

$$\Lambda = \sigma\left(W_\Lambda \text{Embed}_{\text{image}}(z) + U_\Lambda H_{\text{text}}\right)$$

where W_Λ and U_Λ are learned parameters, and σ is the sigmoid function. The gating matrix Λ makes the fusion process interpretable, as it controls how much visual context is used in translation. A larger value in Λ indicates that the model is relying more on the visual context, while a smaller value indicates a stronger reliance on the textual representation alone.

The final representation H that combines both textual and visual information is given by:

$$H = H_{\text{text}} + \Lambda \text{Embed}_{\text{image}}(z)$$

This fused representation H is then passed into the Transformer decoder for generating the target translation.

4.3 Evaluation Metrics

We use three evaluation metrics: BLEU (Papineni et al., 2002), ChrF2 (Popović, 2015), and TER (Snover et al., 2006). BLEU assesses the precision of translation by comparing candidate translations to reference translations based on *n-grams*. ChrF2 evaluates the similarity between character *n-grams* in machine-generated and reference translations, particularly beneficial for languages with complex writing systems. TER quantifies the number of edits needed to align machine translations with human-generated references. We conduct statistical significance testing using the *sacreBLEU*[2] toolbox.

5 Results and Discussion

In this section, we present the results of our experiments, where we trained our models on the Visual Genome dataset and evaluated the translation quality using the BLEU, ChrF2, and TER metrics. We compare the translation quality of our proposed models with text-only baseline models, where the text-only NMT model was trained solely on text captions without images, across test sets for four languages.The MMT models were trained on both text captions and original images with entire images and just considering the coordinates of a part of the image related to the caption (partial image).

The results in Table 2 demonstrate the performance of both text-only and multimodal models across four language pairs: English to Hindi, Bengali, Malayalam, and Hausa. For English to Hindi, the MMT model that utilizes the entire image outperforms the text-only model, achieving a BLEU score of 39.65, ChrF2 score of 59.34, and TER score of 41.92. These improvements are statistically significant over the text-only MT model at $p < 0.05$, highlighting the benefit of incorporating visual context into the translation process. Similar trends are observed for English to Bengali, where the entire image-based MMT achieves a BLEU score of 41.92, a ChrF2 score of 65.96, and a TER score of 38.37, all of which are significantly better than the text-only model.

For English to Malayalam, the entire image-based multimodal model also shows clear advantages, with a BLEU score of 32.34, ChrF2 of 61.15, and TER of 53.94, outperforming the text-only model on all metrics. Finally, in the case of English to Hausa, the entire image-based multimodal MT model again demonstrates superior performance, achieving a BLEU score of 41.25, ChrF2 of 62.94, and TER of 46.48, compared to the text-only model. Across all language pairs, the partial image-based multimodal models do not consistently outperform the text-only models, suggesting that complete visual context is necessary for achieving the best translation quality.

6 Conclusion

This paper demonstrates the significant advantages of employing a multimodal machine translation approach that integrates visual information with textual data, especially in the case of low-resourced languages like Hindi, Malayalam, Bengali, and Hausa. The results indicate that the gated fusion MMT model enhances translation accuracy and provides a more nuanced understanding of context, leading to improved performance over traditional text-only models. By leveraging visual context, we can address the challenges faced in translating low-resourced languages, highlighting the importance of incorporating diverse data modalities to enrich the translation process.

Abstract

This paper covers the system description of the team "ODIAGEN's" submission to the 11th Workshop on Asian Translation (WAT 2024). We participated in the English-to-LowRes Multimodal Translation Task, in two of the tasks, i.e. Text-only Translation and Multi-modal Translation. For Text-only Translation, we trained the Mistral-7B model for English to Multi-lingual (Hindi, Bengali, Malayalam, Hausa). For Multi-modal Translation (using both image and text), we trained the PaliGemma-3B model for English to Hindi translation.

1 Introduction

Machine translation (MT) is a well-established area within Natural Language Processing (NLP), focusing on the development of software that can automatically translate text or speech between languages. While substantial progress has been made in achieving human-level translation for high-resource languages, significant challenges persist for low-resource languages (Popel et al., 2020) (Parida et al., 2023). Recent research has also investigated how to effectively incorporate other modalities, such as images, into the translation process.

Since 2013, the WAT (Workshop on Asian Translation) has been an open evaluation campaign centered on Asian languages (Nakazawa et al., 2021). The multimodal translation tasks in WAT2024 involve image caption translation, where the input includes a descriptive caption in the source language paired with the image it describes, and the output is a caption in the target language. This multimodal input leverages image context to clarify source words with multiple meanings.

The evaluation of these translation tasks is conducted using established metrics such as Bilingual Evaluation Understudy (BLEU) (Papineni et al., 2002) and Rank-based Intuitive Bilingual Evaluation Score (RIBES) (Isozaki et al., 2010). In this system description paper, we (team "ODIAGEN") outline our approach to the tasks and sub-tasks in which we participated.

- Task 1: English→Hindi (EN-HI) Multimodal Translation
  - EN-HI text-only translation
  - EN-HI multimodal translation
- Task 2: English→Malayalam (EN-ML) Text-only Translation
- Task 3: English→Bengali (EN-BN) Text-only Translation
- Task 4: English→Hausa (EN-HA) Text-only Translation

2 Datasets

We used only Hindi (Parida et al., 2019), Bengali (Sen et al., 2022), Malayala, and Hausa (Abdulmumin et al., 2022) Visual Genome datasets specified by the organizer for text-only and multi-modal translation without any additional synthetic data.

2.1 Pre-processing

2.1.1 For Text-only

A few Hindi samples were excluded due to identical Hindi and English text in the Hindi dataset, and one Malayalam sample was removed for similar reasons. Formatting issues in the Hindi dataset were corrected, and duplicate samples were excluded from all language datasets. Image metadata (image_id, X, Y, Width, Height) was excluded from the text-to-text translation task. The final dataset sentence/sample count is provided in Table 1.

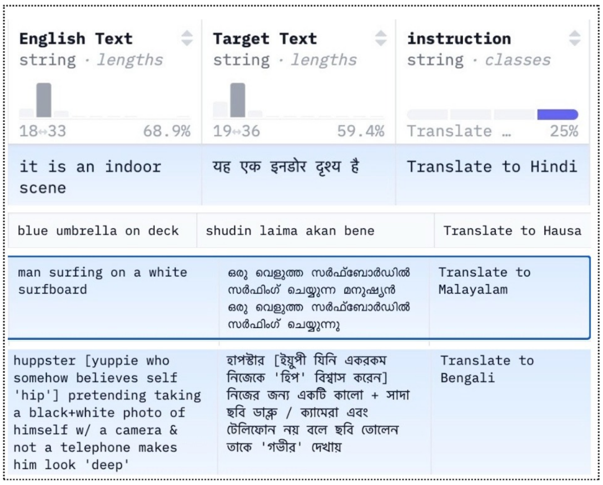
All four different language datasets were combined to make a common translation

Proceedings of the Ninth Conference on Machine Translation, pages 823–828
November 15-16, 2024 ©2024 Association for Computational Linguistics

Language	Sentence Count
Hindi	28,927
Bengali	28,927
Malayalam	28,922
Hausa	28,927

Table 1: Training Dataset Sentence Count

dataset with a single task of translating from English to instructed Target Language like Hindi, Bengali, Malayalam, and Hausa.



English Text	Target Text	instruction
string · *lengths*	string · *lengths*	string · *classes*
18↔33 68.9%	19↔36 59.4%	Translate … 25%
it is an indoor scene	यह एक इनडोर दृश्य है	Translate to Hindi
blue umbrella on deck	shudin laima akan bene	Translate to Hausa
man surfing on a white surfboard	ഒരു വെളുത്ത സർഫ്ബോർഡിൽ സർഫിംഗ് ചെയ്യുന്ന മനുഷ്യൻ ഒരു വെളുത്ത സർഫ്ബോർഡിൽ സർഫിംഗ് ചെയ്യുന്നു	Translate to Malayalam
huppster [yuppie who somehow believes self 'hip'] pretending taking a black+white photo of himself w/ a camera & not a telephone makes him look 'deep'	হাপস্টার [ইয়ুপী যিনি একরকম নিজেকে 'হিপ' বিশ্বাস করেন] নিজের জন্য একটি কালো + সাদা ছবি ডাক্লু / ক্যামেরা এবং টেলিফোন নয় বলে ছবি তোলেন তাকে 'গভীর' দেখায়	Translate to Bengali

Figure 1: Instruction set in different language

2.1.2 For Multimodal involving both Text and Image

The multimodal dataset comprises both text and images. The text portions of the dataset (train and test sets) are organized in simple tab-delimited plain text files. Each text file contains seven columns as follows:

- Column 1: imageid,
- Column 2: X,
- Column 3: Y,
- Column 4: Width,
- Column 5: Height,
- Column 6: English text,
- Column 7: Hindi Text.

The X, Y, Width, and Height columns define the rectangular region in the image described by the caption.

The `Mistral-7B` model (Beyer et al., 2024) requires data in the format $[xmin, ymin, xmax, ymax]$. We interpreted the provided X and Y coordinates as the center coordinates of the rectangular region and calculated $[xmin, ymin, xmax, ymax]$ as the coordinates of the bottom-left and top-right corners of the rectangular box.

2.2 Instruction Dataset

2.2.1 For Text-only

Alpaca prompt format was used to prepare instruction data sets for text-to-text translation for all languages. Sample prompt format is given below.

```
""" Below is an instruction that describes a
translation task, paired with an input that
provides context in Source Language. Write
a response that appropriately completes
translation to desired Target Language.

### Instruction:
{}

### Input:
{}

### Response:
{}"""
```

A raw training sample data for Hindi translation after prompt formatting is shown below, similar method was used for other language translations.

Below is an instruction that describes a translation task, paired with an input that provides context in the Source Language. Write a response that appropriately completes translation to desired Target Language.
Instruction: Translate to Hindi
Input: it is an indoor scene
Response: यह एक इनडोर दृश्य है

2.2.2 For Multi-modal involving both Image and Text

We passed the prompts in a CSV file with fields ‘image id’, and ‘message’. The prompt in the ”message” field is in the below format:
‘message’: [‘content’: ‘describe the image in Hindi <loc ymin><loc xmin><loc ymax><loc xmax>’, ‘role’: ‘user’,‘content’: English text, ‘role’:‘assistant’]

2.3 Tokenization

Both model `unsloth/mistral-7b-v0.3` and tokenizer were used from unsloth library, tok-

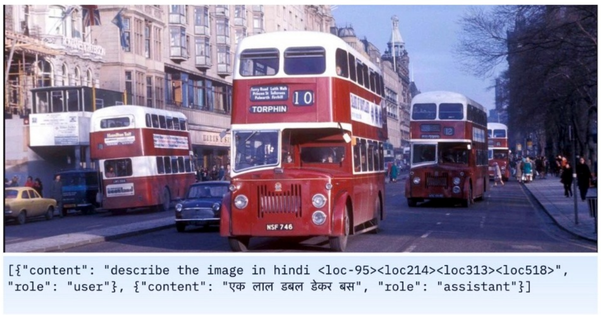
Set	Sentences	Tokens				
		English	Hindi	Malayalam	Bengali	Hausa
Train	28,927	143,164	145,448	107,126	113,978	113,978
D-Test	998	4,922	4,978	3,619	3,936	3,936
E-Test	1,595	7,853	7,852	5,689	6,408	6,408
C-Test	1,400	8,186	8,639	6,044	6,657	6,657

Table 2: Statistics of our data used in the English→Hindi, English→Malayalam, English→Bengali, and English→Hausa tasks: the number of sentences and tokens in text-text translation.

Set	Images	English Words	Hindi Words
Train	28,927	143,164	145,448
D-Test	998	4,922	4,978
E-Test	1,595	7,853	7,852
C-Test	1,400	8,186	8,639

Table 3: Statistics of our data used in the English→Hindi multi-modal translation.

enizer is based on SentencePiece with Byte-Pair Encoding (BPE). This is the standard approach for tokenization in many modern transformer-based language models, including those similar to Mistral.



```
[{"content": "describe the image in hindi <loc-95><loc214><loc313><loc518>",
"role": "user"}, {"content": "एक लाल डबल डेकर बस", "role": "assistant"}]
```

Figure 2: Instruction set in English-Hindi for multi-modal translation

3 Experimental Details

This section describes the complete pipeline used to produce the translation systems for the WAT English-to-Low Resource Multimodal shared task submission.

3.1 EN-HI, EN-ML, EN-BN, EN-HA Text-only Translation

For EN–HI, EN-BN, EN-ML, and EN–HA text-only (E-Test and C-Test) translation, the study fine-tunes the pre-trained Mistral-7B model (Jiang et al., 2023), which has been fine-tuned utilizing only HVG, BVG, MVG, and HaVG Datasets; aiming to develop a high-quality machine translation system.

The Mistral-7B model is a cutting-edge language model that has been fine-tuned specifically for developing high-quality machine translation systems. Leveraging its 7 billion parameters, Mistral-7B (Jiang et al., 2023) excels in capturing linguistic nuances and context, making it exceptionally adept at translating between languages with high accuracy. The fine-tuning process involves training the model on extensive and diverse datasets, allowing it to understand and generate translations that are not only precise but also contextually relevant.

3.2 EN-HI Multimodal Translation

This section discusses the multimodal translation pipeline for EN-HI. For EN-HI multimodal (E-Test and C-Test) translation, we used the object tags extracted from the HVG dataset images for image features and concatenated them with the text. The PaliGemma-3B model (Beyer et al., 2024) is finetuned on the Hindi-Visual-Genome dataset for English to Hindi Translation when a specific location is given in the input prompt as explained in Section 2.2.2. We used the script from LLaMa Factory (Zheng et al., 2024) with our configuration to fine-tune this model. During fine-tuning, we froze the vision tower and adjusted the parameters in the language model and projector layer. The hyperparameters are shown in Table 4.

4 Results

4.1 Text-only Translation

We present the official automatic evaluation results of our models for all the tasks we participated in Table 2, along with sample outputs in Table 3. After the fine-tuning process, these

Hyperparameter	Value
Train Batch Size	2
Eval Batch Size	8
Learning Rate	3×10^{-6}
Epochs	10
Warm-up Steps	50
LR Scheduler	Cosine
Gradient Accumulation Steps	8
Optimizer	"Adam"

Table 4: Training Hyperparameters.

models were used to generate translations for two distinct sets in each language: the evaluation set and the challenge set. The translation quality was assessed using the BLEU (Bilingual Evaluation Understudy) score and the RIBES (Ranking by Incremental Bilingual Evaluation System) score.

The English-to-Hindi model achieved a BLEU score of 41.60 on the evaluation set and 44.10 on the challenge set. Similarly, it attained a RIBES score of 0.82115 on the evaluation set and 0.8154 on the challenge set. These results underscore the model's robust performance and its ability to manage more complex or less typical translation tasks.

In the case of the English-to-Bengali model, a BLEU score of 43.70 was achieved on the evaluation set, with a slightly lower score of 35.60 on the challenge set. Similarly, it attained a RIBES score of 0.78975 on the evaluation set and 0.73534 on the challenge set. This indicates a robust overall performance and a commendable capability to handle nuanced translations specific to the Bengali language.

For the English-to-Malayalam model, the system achieved a BLEU score of 33.10 on the evaluation set and 18.10 on the challenge set. Similarly, it attained a RIBES score of 0.66837 on the evaluation set and 0.50594 on the challenge set. Despite a slightly lower score on the challenge set, the model still demonstrates a respectable performance in translating English to Malayalam.

Lastly, for the English-to-Hausa model, the system achieved a BLEU score of 49.80 on the evaluation set and 24.40 on the challenge set. Similarly, it attained a RIBES score of 0.81289 on the evaluation set and 0.66363 on the challenge set. This indicates a robust overall performance and a commendable capability to handle nuanced translations specific to the Hausa language.

4.2 Multi-modal Translation Involving both Image and Text

Contrary to our expectations, the PaliGemma-3B model showed very poor results on the mentioned dataset and we tried to investigate the factors behind it. By qualitative analysis, we figured out that the location coordinates that we normalized during pre-processing may not be the right approach required for PaliGemma-3B. We found that the normalized [xmin, ymin, xmax, ymax] coordinates provided in the input prompt did not perfectly align with the model-generated captions. Instead, they pointed to a neighboring location in the image with a significant overlap. However, this mismatch in location led to a very poor BLEU score for the predicted captions.

5 Availability

The text-to-text and multimodal datasets, as well as the models, are freely available for research and non-commercial use under a Creative Commons Attribution-NonCommercial-ShareAlike 4.0 License via Hugging Face.

We have also released our experimental code on GitHub.[1]

6 Conclusion

In this system description paper, we presented our approach for four tasks in WAT2024: (a) English→Hindi text-only and multimodal translation, (b) English→Malayalam text-only

[1] https://github.com/shantipriyap/ODIAGEN_WAT2024

Translation Model	Translation Type	BLEU Score (Evaluation Set)	BLEU Score (Challenge Set)
English to Hindi	Text-to-Text Multimodal	41.60 0.50	44.10 -
English to Bengali	Text-to-Text	43.70	35.60
English to Malayalam	Text-to-Text	33.10	18.10
English to Hausa	Text-to-Text	49.80	24.40

Table 5: Comparison of BLEU Scores for Different Translation Models and Types

Translation Model	Translation Type	RIBES Score (Evaluation Set)	RIBES Score (Challenge Set)
English to Hindi	Text-to-Text Multimodal	0.8212 0.1512	0.8155 -
English to Bengali	Text-to-Text	0.7898	0.7353
English to Malayalam	Text-to-Text	0.6684	0.5059
English to Hausa	Text-to-Text	0.8129	0.6636

Table 6: Comparison of RIBES Scores for Different Translation Models and Types

	MALAYALAM	HINDI	BENGALI	HAUSA
English-Sentence-1	silver car is parked	fine thin red hair	A stop light	A stop light
Target-Original	സിൽവർ കാർ പാർക്ക് ചെയ്തു	सूक्ष्म पतले लाल बाल	একটি স্টপ লাইট	Hasken tasha
Target-Translated	വെള്ളി കാർ പാർക്ക് ചെയ്തിരിക്കുന്നു	ठीक पतले लाल बाल	একটি স্টপ আলো	Hasken tasha
Gloss	Silver car has been parked	Correct thin red hair	A stop light	A stop light
Remarks (Comparison)	Translated version is more formal	Original version is better; ”Fine” mistranslated by our model.	Original version is more colloquial	Both are identical
English-Sentence-2	eye of the pumpkin	the cross is black	This is a person	three zebras in the wild
Target-Original	മത്തങ്ങയുടെ കണ്ണ്	क्रॉस काला है	এটি একজন ব্যক্তি	alfadarai uku a cikin daji
Target-Translated	പമ്മിക്കിന്റെ കണ്ണ്	क्रॉस काला है	এটি একজন ব্যক্তি	alfadarai uku a cikin daji
Gloss	Pumpkin’s eyes	The cross is black	This is a person	Three zebras in the wild
Remarks (Comparison)	Model doesn’t translate ”pumpkin,” which is colloquial	Both are identical	Both are identical	Both are identical
English-Sentence-3	pen on the paper	date and time of photo	the bird is black	a girl is standing.
Target-Original	പേപ്പറിൽ പേന	फोटो की तारीख और समय	পাখিটি কালো	yarinya tana tsaye
Target-Translated	പേപ്പറിൽ പേന	फोटो की तारीख और समय	পাখিটি কালো	yarinya tana tsaye
Gloss	Pen on the paper	Date and time of photo	The bird is black	A girl is standing
Remarks (Comparison)	Both are identical	Both are identical	Both are identical	Both are identical

Table 7: Comparison between original translations and our model’s translations for English-Malayalam, English-Hindi, and English-Bengali language pairs.

translation, (c) English→Bengali text-only translation, and (d) English→Hausa text-only translation. The results for the multimodal English→Hindi translation, which involves both image and text, were suboptimal due to improper normalization of the location coordinates for the `PaliGemma-3B` model. As a result, the model was unable to accurately map the provided coordinates in the prompt to the original image. We utilized the `PaliGemma-3B` model with a resolution of 448, which performed well in the translation tasks but failed to generate results relevant to the precise coordinates. Due to limitations in time and computing resources, addressing this issue has been deferred to future work. The code has been released on GitHub for use by other researchers.

Acknowledgments

We would like to express our gratitude to Silo AI in Helsinki, Finland, and Odia Generative AI in Bhubaneswar, India, for their support.

Abstract

This paper presents the work of our team, "ArewaNLP," for the WMT 2024 shared task. The paper describes the system submitted to the Ninth Conference on Machine Translation (WMT24). We participated in the English-Hausa text-only translation task. We fine-tuned the OPUS-MT-en-ha transformer model and our submission achieved competitive results in this task. We achieve a BLUE score of 27.76, 40.31 and 15.85 on the Development Test, Evaluation Test and Challenge Test respectively.

1 Introduction

Machine translation (MT) is widely regarded as one of the most successful applications of natural language processing (NLP). It has seen significant advancements, particularly in the accuracy of its results. While MT has achieved near-human performance for several language pairs, it still faces challenges when dealing with low-resource languages or when incorporating other modalities (such as images.(Parida et al., 2021).

In the broader field of machine learning and deep learning, multimodal processing involves training models using a combination of different information sources such as images, audio, text, or video. By incorporating multimodal data, models can learn features from various subsets of these sources (depending on the data modality), leading to improved prediction accuracy. Multimodal machine translation leverages information from multiple modalities, with the expectation that these additional modalities will offer valuable alternative perspectives on the input data. Despite machine translation's near-human performance for several language pairs, it still faces difficulties in translating low-resource languages and effectively utilizing other modalities. (Sen et al., 2022).

WMT is a workshop on Machine Translation. WMT24 features the English-to-Low-Resource Multimodal Translation Shared Task, which involves Bengali, Hausa, Hindi, and Malayalam datasets from the Visual Genome project. These datasets include both text and images, providing a rich resource for research in English-to-[Hindi, Bengali, Malayalam, Hausa] Machine Translation and Multimodal studies.(Parida et al., 2024; Scientist, 2024).

In this system description paper, we outline our approach to the English-Hausa text-only translation task.

2 Dataset

We utilized the Hausa Visual Genome (HaVG) dataset (Abdulmumin et al., 2022) provided by the organizers. This dataset comprises 32,923 images with corresponding descriptions, divided into training, development, test, and challenge-test sets. The training set includes 28,930 English and Hausa sentence pairs, while the development set contains 998 sentences, the evaluation test set has 1,595 sentences, and the challenge test set consists of 1,400 sentences. A summary of the sentence statistics is provided in Table 1.

3 Experimental Details

The experimental setup involved fine-tuning a pre-trained sequence-to-sequence language model, specifically the OPUS-MT-en-ha model, which was pre-trained on English-Hausa data. Fine-tuning was performed using PyTorch and Hugging Face Transformers. For the English-Hausa text-only translation task, we fine-tuned the OPUS-MT-en-ha model[1], a translation model pre-trained on English-Hausa data by the Language Technology Research Group at the University of Helsinki[2] .

Set	Sentences	Tokens	
		English	Hausa
Training set	28,930	147,219	144,864
Development test	998	5,068	4,978
Evaluation test	1,595	8,079	7,952
Challenge test	1,400	8,411	9,514
Total	32,923	-	-

Table 1: Statistics of data used in the English-Hausa text-only translation: the number of sentences and tokens.

3.1 Preprocessing

The Hausa Visual Genome dataset was prepared to train the translation model. The preprocessing phase involved preparing the Hausa Visual Genome (HaVG) dataset for training the translation model, The data was loaded using 'pandas' and converted into Hugging Face 'Dataset' objects for both English and Hausa texts. We employed the 'Helsinki-NLP/opus-mt-en-ha' tokenizer to tokenize the text, truncating or padding sequences to a maximum length of 128 tokens. The tokenized data was then formatted for PyTorch, including input IDs, attention masks, and labels, to ready it for training.

3.2 Model Fine-Tuning

Model fine-tuning is a crucial step in which the pre-trained model is adapted to the specific task of English-Hausa translation. We fine-tuned a pre-trained sequence-to-sequence language model using PyTorch and Hugging Face Transformers. The model was trained for 3 epochs with an AdamW[3] optimizer and a linear learning rate scheduler. Training was conducted on a GPU in batches of 8, with evaluation performed after each epoch. Upon completion, the fine-tuned model and tokenizer were saved. Fine-tuning not only enhanced the model's translation accuracy but also allowed it to perform well on different test sets, although it faced challenges with more difficult content as seen in the Challenge Test results.

This methodology enabled the model to achieve competitive BLEU scores on the various test sets, demonstrating its effectiveness in translating between English and Hausa, albeit with some room for improvement in handling more complex or less familiar content

4 Results

Table 4 presents the results of automatic evaluation of our model.

Development Test (D-Test BLEU: 27.76): The model scored 27.76 on the Development Test set. This is a solid result, indicating that the model produces translations that are reasonably accurate, though there's some room for improvement. This test set is typically used during the model's development phase to fine-tune its performance.

Evaluation Test (E-Test BLEU: 40.31): On the Evaluation Test set, the model achieved a BLEU score of 40.31, which is quite a bit higher than on the Development Test set. This suggests that the model is particularly good at translating the kinds of sentences found in this set, perhaps because they are similar to what the model has seen during training.

Challenge Test (C-Test BLEU: 15.85): The model scored 15.85 on the Challenge Test set, which is significantly lower than the other two scores. This suggests that the Challenge Test set contains more difficult or unfamiliar content, making it harder for the model to produce accurate translations.

Zero-shot vs. Finetuned Scenarios

The zero-shot evaluation BLEU scores (table 3) are very low compared to the fine-tuned results (table 4). This demonstrates that without prior exposure or training on this specific data, the model struggles to perform accurate translations. These low BLEU scores suggest that the model's ability to generalize to completely unseen data (zero-shot scenario) is limited.

The significant difference between fine-tuned and zero-shot BLEU scores across all sets illustrates the importance of HaVG data. Fine-tuning has allowed the model to learn the translation patterns within the datasets, leading to far superior performance compared to the zero-shot setting.

[3] https://keras.io/api/optimizers/adamw

English-Hausa Translation Examples

Table 2 presents sample English sentences alongside their Hausa translations, sourced from the challenge test set. Some examples are straightforward, where the model successfully translated simple, clear sentence structures. However, other examples are more challenging, showcasing the model's ability to handle complex or ambiguous translations. For instance, in examples 7 and 8, the word "cross" appears, which can refer to either a cruciform symbol or the act of crossing a street. The model accurately interpreted the context in both cases, delivering correct translations for each meaning. These more difficult examples illustrate the differences between the Dev, Eval, and Challenge sets, with the Challenge set specifically designed to test the model's performance by including context-dependent and nuanced sentences. The model's ability to navigate these complexities demonstrates its overall effectiveness.

S/N	English	Hausa Translation
1	A second pizza in a pan.	Pizza na biyu a cikin kwanon suya.
2	A girl on the tennis court is preparing to hit the ball.	Wata yarinya a filin wasan tanis tana shirin buga kwallon.
3	Knife block sitting on counter with knives in it.	Sandar wuka zaune akan kan tebur tare da wukake a ciki.
4	The players' socks are blue.	Yan wasan safa sune shui.
5	Balconies on the second story of the buildings.	Baranda akan bene na biyu na gine-ginen.
6	Beige stairway going to second level.	Matakala na beige zuwa bene na biyu.
7	The woman is waiting to cross the street.	Matar tana jira ta tsallaka titi.
8	A black cross on a vertical stabilizer.	Gicciye mai baar fata akan mai tsaye tsaye.
9	Man cross country skiing.	Mutum ya tsallaka kan asa a lokacin tsere.

Table 2: Sample of English to Hausa translations generated by our model.

D-Test BLEU	E-Test BLEU	C-Test BLEU
1.87	1.95	2.56

Table 3: Results of text-only translation task: Zero-shot

D-Test BLEU	E-Test BLEU	C-Test BLEU
27.76	40.31	15.85

Table 4: Results of text-only translation task: Fine-tuned model

5 Conclusion

This paper describes our system for English-to-Hausa text-only translation. The system performs well on more standard test sets (especially the Evaluation Test) but struggles with more challenging or unusual content, as seen in the Challenge Test results. This indicates that while the system is effective in many scenarios, it may need further training to handle more complex translation tasks. We plan to extend our work to include English-Hausa multimodal translation and image captioning tasks in the future.

Ethics Statement

In our work on the English-to-Hausa text-only translation task, we adhered to the highest standards of ethical research and data use. The datasets employed, including the Hausa Visual Genome dataset, were provided under appropriate licenses, and we ensured that all data used was handled in accordance with the terms specified by the providers. Our research also followed guidelines for responsible AI development, including fairness, transparency, and privacy considerations. We took particular care to avoid biases in our models that could negatively impact the communities whose languages we are working with. Additionally, we acknowledge the potential risks of deploying machine translation systems in sensitive contexts and emphasize the importance of human oversight in such applications.

Acknowledgements

We would like to express our gratitude to the organizers of WMT24 for their support and guidance throughout this project. Special thanks to Shantipriya Parida, Ondřej Bojar, Idris Abdulmumin, and Shamsuddeen Hassan Muhammad for providing the necessary datasets and for their insightful feedback. We also acknowledge the Language

Technology Research Group at the University of Helsinki for the OPUS-MT-en-ha model. Computational resources provided by our institutions were crucial for this research.

ashish3586@gmail.com

Abstract

This paper presents the approach and results of team v036 in the English-to-Low-Resource Multi-Modal Translation Task at the Ninth Conference on Machine Translation (WMT24). Our team tackled the challenge of translating English source text to low-resource Indic languages, specifically Hindi, Malayalam, and Bengali, while leveraging visual context provided alongside the text data. We used InternVL2 for extracting the image context along with Knowledge Distillation from bigger LLMs to train Small Language Model on the tranlsation task. During current shared task phase, we submitted best models (for this task), and overall we got rank 3 on Hindi, Bengali, and Malyalam datasets. We also open source our models on huggingface.[1]

1 Introduction

With the recent advances in text generative AI Achiam et al. (2023); Dubey et al. (2024); Yang et al. (2024) and Diffusion based Dhariwal and Nichol (2021); Nichol and Dhariwal (2021); Saharia et al. (2022); Ramesh et al. (2022) models, multimodal approaches have gained significant traction. The concept of a model to understand both text and visual contexts provides a unique advantage for these models to understand the real world. On the other end, Machine Translation has been one of the most important task in NLP world. Since its origin, the MT task has undergone large shifts from rule based Nirenburg (1989); Chen et al. (2007) to complex Neural network based approaches and recently Transformer Vaswani (2017); Yin and Read (2020); Xu et al. (2024) based approaches. In the recent days with the advancements in the field of NLP, Multimodal Machine Translation (MMT) has evolved as an important research field, wherein the Model utilizes both vision and text information to achieve the translation task. This would better equip the model with additional context information and thus reducing the issues due to polysemy or missing text context. MMT finds its application in various fields like Media, Retail, Automobile etc. In this work we explore the problem of English to Lowres Multimodal Translation for Hindi, Bengali and Malyalam languages. The task requires translating a short English caption of the rectangular region to one of these languages, given the image context. There are multiple approaches possible which can be largely classified into :

- Text-only translation (Source image not used)
- Image captioning (English source text not used)
- Multi-modal translation (uses both the image and the text)

We strongly feel that Multi-modal translation approach would best solve the problem due to more context information. In this paper, we propose a novel unconstrained approach to solve the Lowres MMT task for Hindi, Bengali and Malyalam languages. Our solution tries to merge the best of both text and language contexts. In particular, our key contributions are:

- Fusing Multimodal image context with improved language understanding : We provide a concise yet effective approach to combine context information from vision to text description
- Advanced Chain of Thought reasoning for language translation: Our approach to step by step reasoning ustilizing the COT, gives a whole new perspective to enhance the ability of the model to comprehend better.

- Custom finetuning : Our approach of custom finetuning on target languages on training samples, equips the model to better perform on the MMT task.

2 Data

Visual Genome introduced by Krishna et al. (2017) is a rich dataset to enable the modelling of complex cognitive interactions and relations between objects in an image. Based on this dataset, Parida et al. (2019) introduce the Hindi Visual Genome dataset, which is a multi-modal dataset consisting of text and images suitable for English-Hindi multimodal machine translation task. They select short English segments (captions) from Visual Genome along with the associated images and automatically translate them to Hindi with a careful manual post-editing(Parida et al. (2019)) The dataset takes into account ambiguous English words based on the embedding. similarity and manual selection of certain cases where image helps to resolve the ambiguity(Parida et al. (2019)). Hence this is a perfect dataset suited for the task. Similarly Sen et al. (2022) propose the Bengali Visual Genome Dataset which is manually labelled on HVG samples and Parida et al. (2019) curated the malyalam Visual Genome Dataset.

All three (Hindi, Bengali and Malyalam) dataset consists of 29k training samples, 1k dev set, 1.6k evaluation set and 1.4k challenge set.

The evaluation of the models were performed with BLEU metrics (Papineni et al. (2002)) on challenge and evaluation set independently. Along with these a manual labeller evaluation is also performed, subject to availability.

3 Related Work

MMT has gained increasing attention in recent years as a way to leverage visual information to improve translation quality. Several shared tasks and datasets have been introduced to advance research in this area, with a particular focus on low-resource languages. The Workshop on Asian Translation (WAT) has played a key role in promoting MMT research for Asian languages. Parida et al. (2019) introduced the first Hindi Visual Genome task at WAT 2019, using the Hindi Visual Genome 1.0 dataset (Parida et al. (2019)). This dataset contains English image captions paired with Hindi translations and associated image regions. The task evaluates systems on their ability to translate from English to Hindi while incorporating visual context. Subsequent iterations of WAT expanded the Hindi Visual Genome used an updated Hindi Visual Genome 1.1 dataset and introduced new evaluation tracks, including Hindi image captioning. The latest WAT 2021 (Nakazawa et al. (2021)) further refined the Hindi task and introduced a new English-Malayalam MMT task using the Malayalam Visual Genome dataset (Parida and Bojar, 2021). This represented the first multimodal translation dataset for Malayalam. For the Hindi task, recent approaches have focused on leveraging object tags extracted from images (Gupta et al. (2021)) and region-specific captioning (Parida et al. (2021)) to enhance translation quality. The introduction of the Malayalam task provides an opportunity to evaluate MMT techniques on a new low-resource language. While Hindi and Malayalam have been addressed in shared tasks, Bengali has seen less attention for MMT despite being widely spoken. The creation of a Bengali Visual Genome dataset, following the model of Hindi and Malayalam, would fill an important gap and enable MMT research for another major South Asian language. Overall, the development of these language-specific visual genome datasets has been crucial for advancing MMT for low-resource Indian languages. They provide much-needed benchmarks and drive innovation in incorporating visual context for translation. Expanding to additional languages like Bengali represents an important direction for broadening the scope of MMT research in the Indian context.

4 Approach

Our overall approach follow a three step process as seen in Figure 1.

4.1 Stage 1: Fusing Multimodal image context with improved language understanding

In this stage, we first extract context from cropped visual data using a powerful open-source Multimodal Large Language Model (MLLM)- InternVl2-8B (Chen et al. (2023, 2024)). This model demonstrates powerful capabilities in handling complex multimodal data and achieves state of art numbers on many open VQA tasks. Figure 2 shows a sample image and its description. We feed the output of segement description as an input into a Rapid Automatic Keyword Extraction (RAKE) algorithm (Rose et al. (2012)) which is an efficient keyword extraction algorithm. The top extracted key phrases

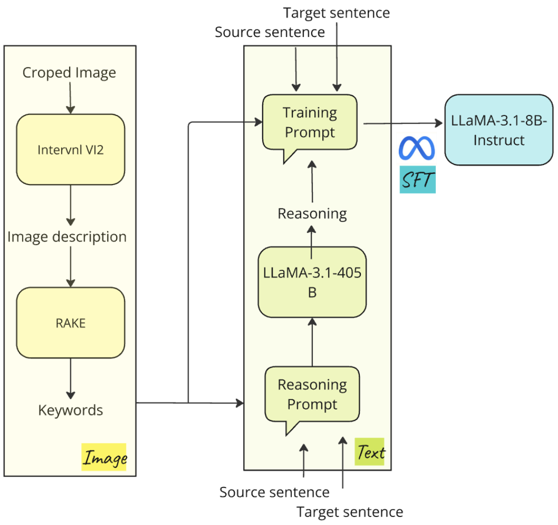

Figure 1: Overall Approach.

are selected and used as hastags to provide context to the source English text. This way we condense the full description into short and concise information for the next stage. This ensures that the further step do not completely rely on the image context also but rather use the original text but still use the relevant information from the image descriptors. This step is common for both train and evaluation process.

4.2 Stage 2: Advanced Chain of Thought reasoning for language translation

Chain-of-thought (CoT) (Wei et al. (2022)) prompting enables complex reasoning capabilities through intermediate reasoning steps. It is shown that the models ability is substantially improved by making them produce step by step reasoning. We employ this ability of Large Language model to solve the task in a more understandable and reasonable approach by decomposing the problem into multiple sub-problems. We use State of the Art LLaMa 405B (Dubey et al. (2024)) model to generate the CoTs for the training data. The model is provided with the English caption text that needs to be translated along, the hashtags generated in previous step, and the target language caption. The model is then asked to generate the step by step reasoning for converting the source caption text to target language text along with the condensed context information provided. Following prompt (Table 1) template is used to get the CoT from the bigger model.

Table 1: Prompt for CoT reasoning generation from bigger model (LLAMA 3.1 405B)

TASK:
ASSUMING YOU ARE A ENGLISH - HINDI translation expert, For given context of an image related to a original sentence, English sentence and translation of the sentence in hindi. Give reason on why this translation is the correct translation....ASsume that you secretly know the answer......DO NOT TRY TO FIX Translation...reason for whatever is given only.....reason SHOULD be proper Chain of Thought format in properly divided steps for the answer......give maximum 5 steps which are most important ones ....
Context: {RAKE HASTAGS}
English Sentence: {SOURCE TEXT}
Hindi Sentence: {TARGET TEXT}

Table 2: Prompt for SFT LLAMA 3.1 8B

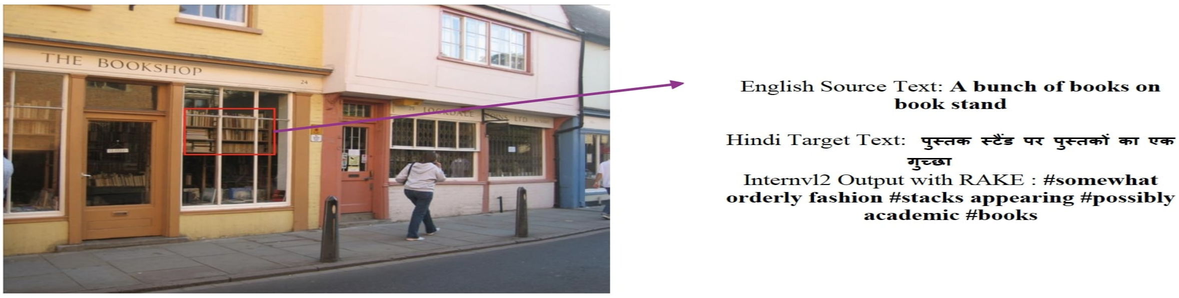
TASK:
ASSUME YOU ARE AN ENGLISH-HINDI translation expert. Given an image description in English, image context and reasoning/CoT in English, translate the image description in Hindi. Use the image context to solve ambiguity if required. Note: DO NOT USE the image context in translations, just use them for disambiguation.
IMAGE DESCRIPTION:
{SOURCE TEXT}
IMAGE CONTEXT:
{RAKE HASHTAGS}
REASONING:
{GENERATED CoT}
RESPONSE:
{TARGET TEXT}

4.3 Stage 3: Custom fine-tuning

In stage 3 we train a smaller model to perform the task of translation, we finetune a LLaMA 3.1-8B-Instruct model on training samples using data from previous stages. The model is trained by providing the English caption along with hashtag contexts, CoT reasoning and the final answer. A sample prompt is shown in Table 2. We use LORA finetuning with rank=64 and alpha=128. We use following template for the training data so that the CoT step is more aligned to as what humans think, that is first source, then CoT and finally the target text.

During **inference**, we provide the finetuned model with source English caption and context and ask it to come up with the Reasoning and the answer. We then use a post processor script to filter out the final answer from the model output.

These 3 fundamental steps are performed for all 3 languages and we curate one PEFT model for each language.



English Source Text: A bunch of books on book stand
Hindi Target Text: पुस्तक स्टैंड पर पुस्तकों का एक गुच्छा
Internvl2 Output with RAKE : #somewhat orderly fashion #stacks appearing #possibly academic #books

Figure 2: Sample Data with reference the image segment, its corresponding source and target text along with the key phrase extraction from Internvl2 descriptions

5 Experimental setup

In our experimental setup, we fine-tuned the LLaMA 3.1-8B-Instruct model for the translation task using Quantized Low-Rank Adaptation (QLoRA) (Hu et al. (2021); Dettmers et al. (2024)). The LoRA configuration was carefully selected to balance performance and computational efficiency. We set the rank (r) to 64 and the alpha parameter to 128, with a lora_alpha value of 0.05. Notably, we applied LoRA to all target modules in the model architecture, ensuring a comprehensive adaptation across the entire network.

For the optimization process, we employed a learning rate (lr) of 0.003, coupled with a cosine learning rate scheduler. This scheduling strategy allowed for dynamic adjustments to lr, potentially aiding in convergence and generalization. The model was trained for two epochs, striking a balance between sufficient learning and computational constraints.

The chosen LoRA hyperparameters strike a balance between model capacity and computational efficiency, with the rank of 64 providing sufficient expressiveness for the adaptation.

By leveraging Quantized LoRA and carefully selected training parameters, we aim to achieve high-quality translation performance while minimizing computational resources and training time. We used A100 40GB VRAM and 84GB RAM single node machine to fine tune our models.

6 Results

The results show that our Multimodal approach of using multistage image description extraction clubbed with CoT is an effective approach to solve this task leveraging the knowledge of Large language models. Table 3 shows the results for all 3 Indic languages on Evaluation and Challenge set. Our numbers are very close to SOTA numbers. The SOTA (baseline) approach is based on a fine-tuning of NLLB model on captions of Object tags of original along with synthetic images using DETR model. However, we do not use any additional image set in our process

Table 3: Results (BLEU Scores) on languages comparing to SOTA .

Language	Evaluation Set	Challenge Set
Hindi	0.446/**0.45**	0.432/**0.534**
Bengali	0.441/**0.506**	0.339/**0.487**
Malyalam	0.427/**0.519**	0.333/**0.422**

The data analysis of the final output revealed a set of cases where the output is technically correct, yet contains variations in tokens compared to the gold set. This suggests that human evaluation could potentially yield higher accuracy, and relying solely on the BLEU score for this task may not fully capture the quality of the output.

Limitations

Given that our approach heavily depends on multiple stages involving large language models, it may not be ideally suited for environments with limited resources. The complexity and computational demands of such models could pose challenges in settings where processing power, memory, or bandwidth are constrained. Additionally, this approach leverages the inherent knowledge embedded within the LLMs being used. The effectiveness of the method is closely tied to the pre-existing information and understanding that these models have acquired during training, which may be influenced by the data used for its training.

Ethics Statement

Our work proposes an innovative approach to addressing the challenge of translating low-resource English to Indic languages - Hindi, Bengali, and Malayalam. In conducting our research, we have carefully considered the ethical implications of data usage. As a result, we have chosen to exclusively rely on the data provided by the Task administrators for our experiments, refraining from incorporating any additional external data sources. This ensures that our approach remains transparent and aligns with the ethical standards expected in this field. However, while using this approach for real world application, data privacy and consent should be given careful considerations.

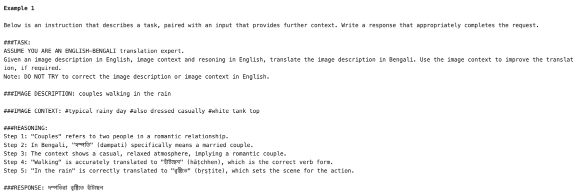
A Appendix

A sample example of COT generation is shown below:



Example 1

```
Below is an instruction that describes a task, paired with an input that provides further context. Write a response that appropriately completes the request.

###TASK:
ASSUME YOU ARE AN ENGLISH-BENGALI translation expert.
Given an image description in English, image context and resoning in English, translate the image description in Bengali. Use the image context to improve the translat
ion, if required.
Note: DO NOT TRY to correct the image description or image context in English.

###IMAGE DESCRIPTION: couples walking in the rain

###IMAGE CONTEXT: #typical rainy day #also dressed casually #white tank top

###REASONING:
Step 1: "Couples" refers to two people in a romantic relationship.
Step 2: In Bengali, "দম্পতি" (dampati) specifically means a married couple.
Step 3: The context shows a casual, relaxed atmosphere, implying a romantic couple.
Step 4: "Walking" is accurately translated to "হাঁটছেন" (hāṭchhen), which is the correct verb form.
Step 5: "In the rain" is correctly translated to "বৃষ্টিতে" (bṛṣṭite), which sets the scene for the action.

###RESPONSE: দম্পতিরা বৃষ্টিতে হাঁটছেন
```

Abstract

In this work, we provide the system description of our submission as part of the *English-to-Lowres Multimodal Translation Task* at the Workshop on Asian Translation (WAT2024). We introduce Chitranuvad, a multimodal model that effectively integrates Multilingual LLM and a vision module for Multimodal Translation. Our method uses a ViT image encoder to extract visual representations as visual token embeddings which are projected to the LLM space by an adapter layer and generates translation in an autoregressive fashion. We participated in all the three tracks (Image Captioning, Text-only and Multimodal translation tasks) for Indic languages (ie. English translation to Hindi, Bengali and Malyalam) and achieved SOTA results for Hindi in all of them on the Challenge set while remaining competitive for the other languages in the shared task.

1 Introduction

Recently, there has been an increased interest in Multimodal Machine Translation (MMT) task (Calixto and Liu, 2017; Delbrouck and Dupont, 2017; Elliott and Kádár, 2017; Yao and Wan, 2020) which involves translation between language pairs, incorporating other modalities (like images) as an auxiliary information. The visual cues act as 'symbol grounding' (Fodor, 1975; Harnad, 1990, 2003, 2005), helping to resolve ambiguities in language (Rainie et al., 2012; Hu et al., 2014; Specia et al., 2016; van Miltenburg et al., 2019; Caglayan et al., 2020) by learning to connect language and perception (Mooney, 2008; Bisk et al., 2020). For example, in order to correctly translate the word *court* in Figure 1, the model has to infer from the image that the statement is about tennis court and not the court as government institution.

Prior works mostly focused on translation from English to European languages (Elliott et al., 2016; Specia et al., 2016) while the Indic languages remain largely unexplored, with an exception of the MMT shared task at the Workshop on Asian Translation (WAT) (Nakazawa et al., 2019, 2020, 2021, 2022, 2023).

The *English-to-Lowres Multimodal Translation Task* at WAT-2024 targets the MMT task for three Indic medium-to-low-resource languages (Hindi, Bengali, Malayalam) and a low-resource African language Hausa. To assess the importance of the image modality, the task has been decoupled into three tracks: **1).** *Text-only translation* where the source image is not used, **2).** *Image Captioning* where English source text is not used and **3).** *Multimodal translation* which uses both the image and the text. We participated in all the three tracks for Indic languages only (Hindi, Bengali, Malayalam) under a non-constrained and proprietary multilingual and multimodal Large Language Model (LLM): *Chitranuvad*[1].

In this paper, we provide a description of our multimodal LLM where we leverage a multilingual LLM backbone Krutrim (Team, 2024b), coupled with a visual image encoder. Our contributions could thus be summarized as follows:

- We introduce Chitranuvad, a Large Multimodal model, adapted for multi-lingual translation, which leverages images and language modalities to provide an image grounded translation of the English sentence in the target Indic languages.
- We showcase the effectiveness of task specific finetuning on the Visual Genome translation datasets and achieve SOTA performance.
- We evaluate Chitranuvad and prior baselines on the English-to-Lowres Multimodal Translation Task and demonstrate the ability of our model to perform grounded translation, using different training strategies and ablations.

The rest of the paper is organized as: Section 2 presents related research on multimodal machine

Object Tags: bear
Hindi: एक भालू सही काले कान।
Bengali: একটি ভালুক কানের কান ভালুক।
Malayalam: ഒരു കരടിയുടെ വലത് കറുത്ത ചെവി

Figure 1: Multimodal Machine Translation task as part of English-to-lowres track where the source sentence is translated to multiple Indic languages (Hindi, Bengali, Malayalam) grounded in the image. Meaning of words like "court" and "right" in the translations can vary significantly depending on the visual context.

translation while Section 3 explains our Chitranuvad model recipe in detail. We present the datasets used in Section 4, followed by experimental findings in Section 5 and conclusion in Section 6.

2 Related Work

Early Neural Machine Translation (NMT) and Image captioning systems (Show, 2015; Gao et al., 2018) were based on Recurrent Neural Networks (RNNs) and their variants (Cho et al., 2014; Sutskever et al., 2014; Cho, 2014; Hochreiter and Schmidhuber, 1997), often incorporating attention mechanisms (Bahdanau et al., 2014). The seminal work of transformers (Vaswani, 2017) paved the way for the development of high-quality image captioning (Chen et al., 2021) as well as translation systems (Lewis, 2019), even for low-resource languages (Dabre et al., 2021; Gala et al., 2023a). Multimodal Machine Translation (MMT) systems witnessed a similar shift in their approrach (Caglayan et al., 2016; Yao and Wan, 2020; Guo et al., 2023). Prior submissions to the MMT task at Workshop on Asian Translation (Gain et al., 2021; Gupta et al., 2021; Parida et al., 2022; Dash et al., 2023; Shahid et al., 2023) also fall in this category.

The next generation of Multimodal LLMs (Lu et al., 2024a; Laurençon et al., 2024; Tong et al., 2024; Xue et al., 2024) can handle a variety of complex tasks, including machine translation and captioning, by utilizing cutting-edge architectures as an unified general purpose agent. These models often rely on pre-trained LLMs, with an exception of few, which train the models from scratch (Team, 2024a; Lu et al., 2024b). Most of these Vision Language Models (VLMs) follow the architecture of (Liu et al., 2023a) where a CLIP (Radford et al., 2021) or a similar encoder is used to encode the image and projected into LLM's representation space using an adapter layer. Notably, Wang et al. (2023) offers a departure from conventional architectures by using distinct matrices and Feed Forward Networks for image modalities. Recent developments replace the image encoder with SigLIP (Zhai et al., 2023a) and the single-layer MLP projector with attention-based pooling (Laurençon et al., 2024).

Advanced backbone LLMs (Brown et al., 2020; Touvron et al., 2023; Achiam et al., 2023; Team et al., 2023; Jiang et al., 2024; Team et al., 2024) however have a primary focus for English and European languages. There have been relatively few LLMs for Indic languages, such as Airavata (Gala et al., 2024), Navarsa (Labs, 2023), Kannada LLaMA, Tamil LLaMA (Balachandran, 2023), Odia LLaMA (Kohli et al., 2023), to name a few. However, most of these LLMs are an extension and finetuned version of LLaMA/Gemma for Indic languages, which don't fully capture the nuances of the language. This could be attributed to the fact that Indic languages are under-represented in Common Crawl (which majorly forms the train-

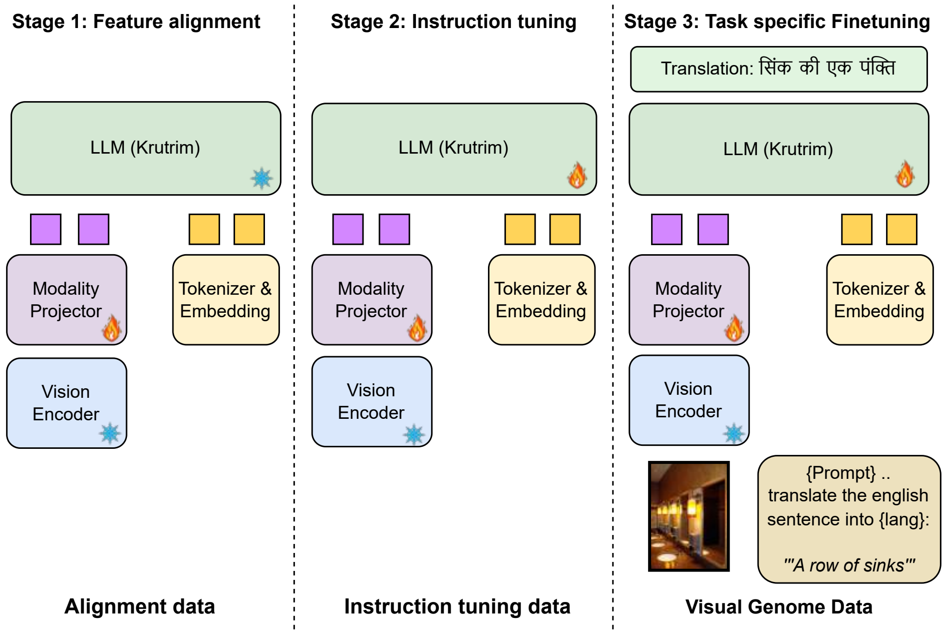

Figure 2: Chitranuvad model architecture with the three stage training pipeline described in Section 3.

ing corpus of LLMs), despite India constituting 18% of the global population. Hindi, for example, does not show-up in the top 20 languages despite being the 3rd most spoken (Buck et al., 2014; Penedo et al., 2023). Closed-source models such as Krutrim (Team, 2024b) and Sutra (Bendale et al., 2024) represent exceptions, as they are trained from scratch. Currently, PALO (Maaz et al., 2024) is a multimodal LLM that supports only Hindi and Bengali. However, to the best of our knowledge, there are no other open-source multimodal LLMs trained specifically for low-resource Indic languages. In contrast, we developed a multilingual multimodal system that supports 10 Indic languages.

3 Model and Training Recipes

Figure 2 provides an overview of our architecture and the multi-stage training pipeline. Our *Chitranuvad* model architecture borrows heavily from LLaVA-like models (Liu et al., 2023a, 2024), where we use pre-trained Krutrim LLM (Team, 2024b) instead, as the autoregressive multi-lingual LLM backbone. Our Krutrim LLM is trained across 10 languages and natively supports all the 3 Indic languages (Hindi, Bengali, Malayalam) used as part of the shared task.

For the multimodal training, we first encode images through a vision encoder. Next, the modality projection (adapter/connector) layer projects the vision embeddings into the LLM embedding space, creating a sequence of visual tokens. The multi-lingual LLM then generates the response conditioned on these visual embedding tokens. The Krutrim LLM model supports a context length of 4096 tokens, out of which 576 tokens are used for the image representation, obtained after the modality projector layer. For the projection layer, we experiment with both single layer projection (Liu et al., 2023b) as well as a two-layer MLP vision-language connector with non-linearity (Liu et al., 2023a). We also experiment with pre-trained CLIP ViT-L/14@336px (Radford et al., 2021) as well as SigLIP-SO400M (Zhai et al., 2023b) for the vision encoder. Similar to the LLaVA model, we generate multi-turn conversational data for instruction tuning our model, which we expand upon in Section 4. We train our model in multiple stages:

Stage 1: Pre-Training (PT) for Feature Alignment. In this stage, we do the pre-training with image-text pairs, where the projector layer is trained while the vision encoder and LLM is kept frozen. Here, each sample is treated as a single-turn conversational instruction tuning data.

Stage 2: Instruction Tuning. Similar to LLaVA models (Liu et al., 2023b,a), we also keep the vision encoder frozen during the second stage of training. However, here we also update the LLM weights apart from tuning the modality projection layer. This stage aims to build a general purpose Multimodal agent (chatbot) which can follow com-

Split	#Instances	English	Hindi	Bengali	Malayalam

Table 1: Total number of instances and average number of tokens for the text in English and splits of different Visual Genome datasets in other languages.

Multimodal Translation:
Human: You are given an image and coordinates of a bounding box as: x1={x1}, y1={y1}, x2={x1+x2}, y2={y1+y2}. Using the context of the objects or items available in the bounding box translate the following sentence from English into {lang} language. You are also provided labels of the objects in the image as: {labels}. English sentence is: {sentence}.
System: {translation}.
Text only translation:
Human: Translate the following sentence from English into {lang} language. English sentence is: {sentence}.
System: {translation}.
Image captioning: *Human:* You are given an image and coordinates of a bounding box as: x1={x1}, y1={y1}, x2={x1+x2}, y2={y1+y2}. You are also provided labels of the objects in the image as: {labels}. Provide a short caption of the object in {lang} language.
System: {caption}.

Table 2: Different prompt templates for creating task specific fine-tuning data, used in Stage 3 training.

plex instructions across multiple-turns of the conversation. We focus on developing a specialized multimodal translation system in the Stage 3.

Stage 3: Task-specific Fine-Tuning. We follow a similar recipe to that of Stage 2 for the (Machine Translation) task-specific fine-tuning and update weights for the projection layer and the LLM while keeping the vision encoder frozen. Here, we experiment with both LoRA style training (Hu et al., 2021; Houlsby et al., 2019) as well as full parameter fine-tuning on the shared task translation data.

4 Dataset

In this section, we describe the data resources utilized throughout our experiments.

Stage 1: In our initial experiments, we use the LLaVA-Pretrain-LCS-558K data for pre-training our model in Stage 1. However, recent works (Tong et al., 2024) showed that more adapter data is beneficial for the model, such as the 1.2M ShareGPT4V-PT (Chen et al., 2023) image-captioning dataset, which we use in Stage 1 training. We also translated this data in the 10 Indic languages that our LLM natively supports, using an in-house text Machine Translation system. We sample translations across different languages (including English) in an equal ratio and ensure that PT data limits to 1.2M data points in our final data mix.

Stage 2: For the second stage instruction tuning, eliciting visual reasoning abilities, we experiment with both LLaVA-Instruct-150K (Liu et al., 2023b) and LLaVA-1.5-665K (Liu et al., 2024) where we find continued improvements with the 665K version. Similar to pre-training data, we also translated the LLaVA-1.5-665K into multiple languages. Recently released Cauldron dataset (Laurençon et al., 2024) is a collection of 50 academic Vision-language tasks. In our final submission, we also include the translated versions and the original English language based Cauldron apart from the proprietary multi-modal dataset in the training mix. It must be noted that the English only Visual Genome might be a part of this stage's training data through various academic datasets, though not for the translation task.

Stage 3: For the Stage 3, we work with the aligned multi-lingual Visual Genome (Krishna et al., 2017) datasets, i.e. Hindi (Parida et al., 2019), Bengali (Sen et al., 2022) and Malayalam (Parida and Bojar, 2021), bundled as part of the shared task. Each row in the dataset consists of the following fields: *i).* MS COCO (Lin et al., 2014) image id *ii).* English utterance *iii).* Translated utterance in Hindi/ Bengali/ Malayalam *iv).* Bounding box of the area in the image that the utterance is based on. While there is also a track for Hausa language (Abdulmumin et al., 2022), we don't include this in our training data. Table 1 provides the statistics of the different versions of the dataset, which we transform into instruct tuning format, similar to Stage 1 and 2 data (see Table 2). To increase the efficacy of our model, we enrich the dataset with the labels of different objects in the image (object tags), similar to (Gupta et al., 2021). We use SOTA (state-of-the-art) YOLOv8 (Varghese and Sambath, 2024) for object detection compared to the prior works, which relied on Faster R-CNN models (Wu et al., 2019; Girshick, 2015). We also calculate the Intersection-over-union (IoU) for the detected and the dataset provided bounding boxes to get the most relevant object tag. However, we found a decreased performance against including the labels of all the detected objects.

5 Experimental Results and Discussion

This section details our experimental setup and presents the results of our comparative studies.

5.1 Implementation

We use HuggingFace Transformers (Wolf et al., 2019) based on PyTorch (Paszke et al., 2019) for our experiments. We consider PALO (Maaz et al., 2024) as a multi-lingual multi-modal baseline and use the code provided with the repository[2]. The shared task provides a leaderboard based on the automatics metrics of BLEU (Papineni et al., 2002) and RIBES (Isozaki et al., 2010). For reporting BLEU, we used the evaluation scripts[3] provided with (Gala et al., 2023b) and the official repository for RIBES[4]. Similar to previous works (Gupta et al., 2021), we also report the results after tokenizing the outputs using indic-tokenizer[5]. Our Stage 1 and Stage 2 tuning follow similar hyperparameters as the LLaVA model (Liu et al., 2023b) unless specified otherwise. For Stage 3 fine-tuning, we conducted multiple experiments for hyperparameter search of learning rate (1e-3, 1e-4, and 1e-5); as well as multiple epochs (1, 2, 3, and 5). We observed rapid over fitting after only one epoch while a learning rate of 1e-4 yielded the highest overall performance. All our further experiments are reported based on this configuration.

5.2 Results for different tracks

Table 3, 4 and 5 present the results for text-only, image captioning and the Multimodal translation task respectively. For the text-only task, our Chitranuvad model was trained with image data till Stage 2. In Stage 3, we only finetune with text only translations. During inference, we prompt the model with text only translations and dont provide images. Our model achieves SOTA on Hindi and Malayalam Challenge and Test sets while being competitive on the Bengali dataset (see Table 3). We were the only submission which could do image captioning in all the 3 languages (see Table 4). For the MMT task, we achieved SOTA on Hindi Challenge and Malayalam test set while being competitive on the other languages. We also provide cherry-picked system outputs of our best Multimodal LLM in Table 3. From our manual inspection, we saw that our generated translations are better than the ground truth. For example, in the last snippet, our model correctly translates the word 'downhill', which the gold translation fails to capture.

5.3 0-shot on the Shared task data

We evaluate the efficacy of our model after Stage 2 as the 0-shot setting, where we don't fine-tune specifically for the shared task translation data. In our preliminary experiments, we only use the English versions of the datasets mentioned in Section 4 for both Adapter tuning (Stage 1) and Instruction tuning (Stage 2). Exceptionally, our Krutrim LLM still retained multi-lingual capabilities, ev-

Table 6: 0-shot results for Multimodal Machine Translation track as discussed in Section 5.3. *Eng* denotes only English data is used in Stage 1 and 2. *Eng+Hindi* denotes English and Hindi data in Stage 2. As expected, we find the best scores when the training data mix consists of data from the 10 Indic languages.

ident from the scores in Table 6. When we also include Hindi data in the training mix, we find an uplift on the Hindi translation task. Including multi-lingual data in both the stages further showed improvement on all three language translation tasks in the 0-shot setting. We thus use this as the base model in the Stage 3 training. We also evaluate against the open-source baseline of PALO-7/13B (Maaz et al., 2024) in the 0-shot setting. To our surprise, our Chitranuvad model consistently outperforms the 0-shot PALO baseline, even when our model is fine-tuned with English only data in both the stages. We hypothesis that this is because the base LLM Vicuna (Zheng et al., 2024) used in PALO is not inherently multi-lingual in nature.

5.4 Other fine-tuning approaches

In this section, we elaborate on key findings with different fine-tuning approaches, with all the results reported in Table 7.

LoRA vs Full finetuning. We investigated the efficacy of full fine-tuning versus Low-Rank Adaptation (LoRA) using Visual Genome data. Our experiments (see Table 7) reveal that full fine-tuning consistently outperforms LoRA, i.e. LoRA learns less (Biderman et al., 2024).

Bi-lingual vs Multi-lingual For Stage 3 training, we experiment with training specialized models for each language (Hindi and Bengali) compared to multi-lingual setting with a mix of data from all the three Indic languages. We didn't find any improvement over multi-lingual model but instead observe catastrophic forgetting (Zhai et al., 2023c; Tong et al., 2024), where the translation abilities of the model in the other languages deteriorate completely. We hypothesize that a mix of multiple languages probably act as regularizaton and enhance the general translation capabilities.

Do we need second stage training? Similar to (Tong et al., 2024), we investigate if we even need Stage 2 instruction tuning. We find that our model, if finetuned directly on Visual Genome translation data (i.e. Stage 1 and 3 training only) performed comparable to the previous baselines. Including Stage 2 training provided an uplift in the scores with an added advantage of building a general purpose Multimodal agent.

Back translation Back translations, i.e. using the reverse translations have been a popular technique both for data augmentation as well as post-processing or re-ranking techniques in traditional Machine Translation and Natural Language Generation systems (Sennrich et al., 2015; Li et al., 2015; Agarwal et al., 2018; Edunov, 2018; Graça et al., 2019). This involves re-translating content from the target language to its source language. Thus, apart from the original task of En -> Hi/Bn/Ml, we also included in our training corpus, the task of reverse translation from Hi/Bn/Ml -> En in the Stage 3 training mix. However, in our experiments, we found that this strategy showed decreased performance in terms of automatic metrics.

Figure 3: English-to-lowres Multimodal Machine Translation track supports translation of source sentence into multiple Indic languages (Hindi, Bengali, Malayalam). We enrich the dataset to include labels of all the identified objects. We show the outputs of our best model which is trained with a mix of multi-lingual data in all the 3 stages.

Table 7: Different finetuning strategies for Multimodal Machine Translation track as described in Section 5.4 in the order of discussion. Our Stage 3 full finetuning training performs the best compared to the other training recipes.

6 Conclusion

We present Chitranuvad, a multimodal LLM that is adapted for image grounded Machine translation. Our model encodes images using a pre-trained image encoder (Alexey, 2020) and translates the English sentences autoregressively into different Indic languages (Hindi, Bengali, Malayalam) using a pre-trained LLM. Empirically, our model outperforms previous baselines for different tasks. However, we also observed that vision modality had little impact on the translation, echoing the observations from (Grönroos et al., 2018; Lala et al., 2018; Wu et al., 2021; Li et al., 2022).

Broader Impact: We believe our work paves way for building next generation assistants which can do multimodal machine translation. We believe these systems can empower different sectors like education, healthcare, banking and financial services, etc. to name a few.

Limitations and Future Work: While this work is focused to three Indic languages (Hindi, Bengali, Malayalam), we consider our approach as a first step towards building general purpose multilingual system which can handle various Indic languages. While in our current setup, we freeze the vision encoder during training, recent works have shown that unfreezing the vision encoder with Perceiver Resampler (Jaegle et al., 2021), helps learn better representations (Laurençon et al., 2024; Tong et al., 2024), which we plan to explore in the future.

Acknowledgements

We thank Bhavish Aggarwal and the rest of the Krutrim team which helped with model development at various stages. Specifically, we want to thank Anagha Bhangare, Raja Kolla and Aditya Kallappa for the discussions. Our models were trained with generous support from Krutrim cloud using Krutrim credits. We also thank the challenge organizers as well as the reviewers for their valuable feedback and suggestions.

Brotherhood at WMT 2024: Leveraging LLM-Generated Contextual Conversations for Cross-Lingual Image Captioning

Siddharth Betala
betalas5@gmail.com

Ishan Chokshi
ishan.c1671@gmail.com

Abstract

In this paper, we describe our system under the team name *Brotherhood* for the English-to-Lowres Multi-Modal Translation Task. We participate in the multi-modal translation tasks for English-Hindi, English-Hausa, English-Bengali, and English-Malayalam language pairs. We present a method leveraging multi-modal Large Language Models (LLMs), specifically GPT-4o and Claude 3.5 Sonnet, to enhance cross-lingual image captioning without traditional training or fine-tuning.

Our approach utilizes instruction-tuned prompting to generate rich, contextual conversations about cropped images, using their English captions as additional context. These synthetic conversations are then translated into the target languages. Finally, we employ a weighted prompting strategy, balancing the original English caption with the translated conversation to generate captions in the target language.

This method achieved competitive results, scoring 37.90 BLEU on the English-Hindi Challenge Set and ranking 1st and 2nd for English-Hausa on the Challenge and Evaluation Leaderboards, respectively. We conduct additional experiments on a subset of 250 images, exploring the trade-offs between BLEU scores and semantic similarity across various weighting schemes.

1 Introduction

Machine translation (MT) is a classic subfield in NLP that investigates the usage of computer software to translate text or speech from one language to another without human involvement (Yang et al., 2020). Machine translation (MT) has seen remarkable advancements in recent years, primarily due to the success of neural approaches (Bahdanau, 2014; Vaswani, 2017). However, these improvements have been predominantly observed in high-resource language pairs, leaving low-resource languages significantly behind (Sennrich and Zhang, 2019; Costa-jussà et al., 2022). The challenges in low-resource MT are multifaceted, including limited parallel corpora, lack of linguistic diversity in training data, and the absence of specialized tools and resources.

One promising direction to address these challenges is the incorporation of visual information into the translation process, known as multimodal machine translation (MMT) (Elliott et al., 2016; Specia et al., 2016; Calixto et al., 2017). The underlying hypothesis is that visual context can provide crucial disambiguating cues, especially for languages with limited textual resources. This approach aligns with the human cognitive process of language understanding, which often relies on multiple sensory inputs (Beinborn et al., 2018).

The Workshop on Machine Translation (WMT) 2024 has presented a shared task on English-to-Low-Resource Multi-Modal Translation, focusing on Hindi (Parida et al., 2019), Bengali (Sen et al., 2022), Malayalam[1], and Hausa (Abdulmumin et al., 2022). This task utilizes variants of the Visual Genome (Krishna et al., 2017) dataset, adapted for these target languages. While these datasets provide a valuable resource for research, they also present unique challenges. First, the quality of translations in low-resource languages can be inconsistent (see Table 1), potentially introducing noise into the training process. Second, the limited size of these datasets makes it difficult to train robust neural models without overfitting. Lastly, the cultural and linguistic nuances of these languages may not be fully

Source English Caption:
soap is in the dish

Target Hindi Caption:
साबुन पकवान में है

Table 1: Illustration of a translation ambiguity in the dataset. The English caption for the bounded region **“soap is in the dish”** is mistranslated into Hindi as “साबुन पकवान में है” (**“soap is in the food”**). The Hindi word “पकवान” typically means **“food dish”**, whereas the visual context clearly indicates that **“dish”** refers to a **soap holder**. This example also highlights the importance of visual context in resolving lexical ambiguities in multimodal translation tasks.

captured in direct translations (Hershcovich et al., 2022) of English captions.

Existing approaches (Calixto and Liu, 2017) to MMT often involve training complex neural architectures on large parallel corpora with paired images. However, such methods may struggle with the limited and potentially noisy data available for low-resource languages. Moreover, these approaches often fail to leverage the rich semantic understanding capabilities of recent large language models (LLMs) along with their proficiency in visual (Liu et al., 2024; Radford et al., 2021) and multilingual (Üstün et al., 2024; Workshop et al., 2022; Dubey et al., 2024; Touvron et al., 2023; Jiang et al., 2023) understanding gained through training on large corpora of data across domains.

In this paper, we propose a pipeline that addresses these challenges by leveraging multi-modal LLMs, specifically GPT-4o[2] and Claude 3.5 Sonnet[3], to enhance cross-lingual image captioning. Our approach uses instruction-tuned prompting to generate rich, contextual conversations about images using the English captions as context along with the image. These synthetic conversations, comprising detailed descriptions, simple question-answer (QA) pairs, and complex reasoning question-answer pairs, are then translated into the target languages and used to inform the final caption generation in the target language. This method allows us to:

- Mitigate the impact of limited and noisy training data by generating synthetic, high-quality contextual information.
- Leverage the advanced reasoning capabilities of LLMs to provide culturally and linguistically nuanced translations.
- Explore the balance between source fidelity and enhanced description through a weighted prompting strategy.

The main contributions of our work are:

- A pipeline for low-resource MMT that requires no traditional training or fine-tuning.
- A weighted prompting mechanism that calibrates between source caption fidelity and LLM-generated contextual information, facilitating a nuanced balance of translation accuracy, caption diversity, and exhaustive visual description coverage.
- A framework for dataset enrichment through the generation of detailed descriptions and complex reasoning QA pairs to augment existing multimodal datasets.
- Empirical analysis of LLMs' capabilities in direct translation and target language summarization, providing insights into their potential for low-resource languages.

2 Dataset

We utilized only the datasets specified by the organizers for the related tasks. However, our use of the GPT-4o and Claude 3.5 Sonnet models places our submissions in the unconstrained track. The provided datasets contain captions in English and the target language, describing

[2] gpt-4o-2024-08-06: https://platform.openai.com/docs/models/gpt-4o.

[3] Claude 3.5 Sonnet: https://www.anthropic.com/api.

rectangular regions in images of various scenes. The task involves generating captions in the target language using either the text, the image, or both. Across all languages, the training set consists of 29,000 examples. The dataset is complemented by three test sets: development (D-Test), evaluation (EV-Test), and challenge (CH-Test). Our submissions were evaluated on the EV-Test and CH-Test sets, which contain approximately 1,600 and 1,400 examples, respectively. The development set comprises around 1,000 examples.

Table 2 shows the parallel corpus statistics across the various languages. Table 3 shows that data sources of datasets for each task.

3 Methodology

The overall pipeline of our approach is shown in Figure 1.

3.1 Preprocessing

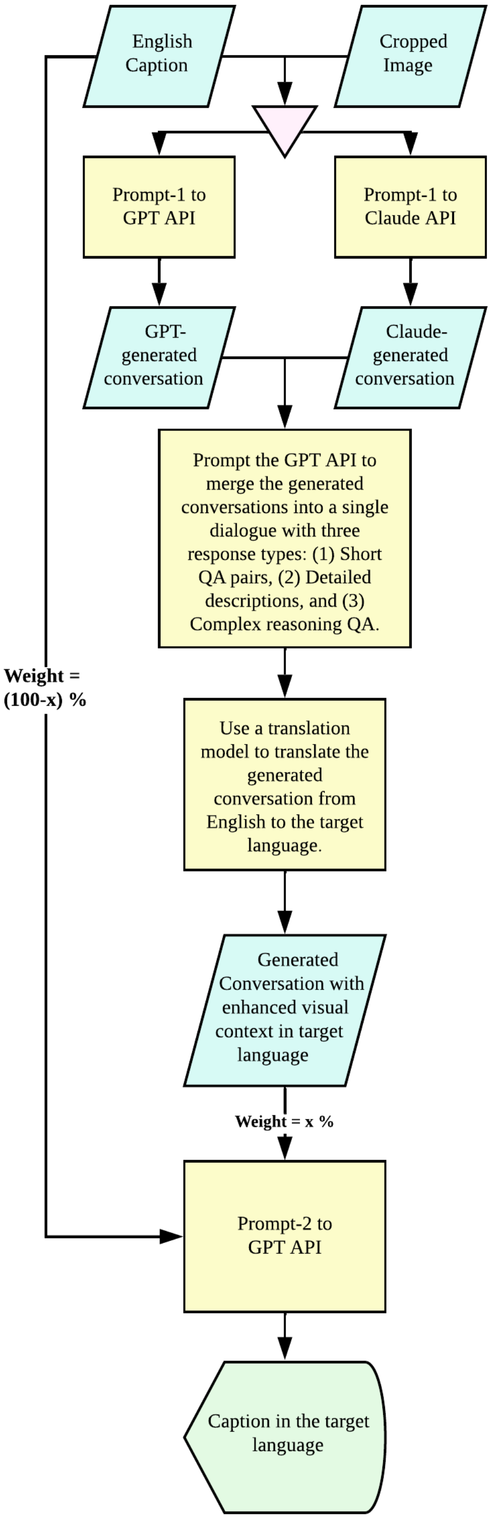
For the text data, all utterances are converted to lowercase, and punctuation is removed. The dataset includes images of complete scenes along with the coordinates of the bottom-left corner and the dimensions of the rectangular region corresponding to each caption. This information is used to crop the relevant rectangular regions from the images. Since these images are later used as part of prompts for LLMs, base64 encodings of all images in the EV and CH sets are generated.

3.2 Multi-Model Context Generation in English with a Fusion approach

In this step , we leverage the capabilities of two large language models (LLMs) - GPT-4o and Claude 3.5 Sonnet - to generate rich, contextual conversations about the input image and its associated English caption. This process involves two key stages: individual LLM processing and conversation fusion.

We separately prompt GPT-4o and Claude 3.5 using Prompt-1 from Table 4. The format of the conversation and prompt design is inspired by an example prompt from Liu et al. (2024). Both models are given the same input: the cropped image and its English caption. This parallel processing allows us to capitalize on the unique strengths of each model.

After obtaining separate conversations from GPT-4o and Claude 3.5, we employ a fusion model, implemented using the GPT-4o API,



English Caption
Cropped Image
Prompt-1 to GPT API
Prompt-1 to Claude API
GPT-generated conversation
Claude-generated conversation
Prompt the GPT API to merge the generated conversations into a single dialogue with three response types: (1) Short QA pairs, (2) Detailed descriptions, and (3) Complex reasoning QA.
Use a translation model to translate the generated conversation from English to the target language.
Generated Conversation with enhanced visual context in target language

English→Malayalam	MalayalamVisualGenome1.0[4]
English→Bengali	BengaliVisualGenome1.0 (Sen et al., 2022)
English→Hausa	HausaVisualGenome1.0 (Abdulmumin et al., 2022)

Table 3: Tasks and their corresponding dataset sources.

to integrate these conversations. This fusion process is designed to create a single, coherent dialogue that encompasses three response types: **(1) Short QA pairs, (2) Detailed descriptions, and (3) Complex reasoning QA**. The prompt has been designed to generate such types of responses to ensure that the responses can capture the context effectively. The fusion prompt is carefully crafted to ensure that the final conversation retains the most relevant and insightful elements from both initial conversations.

This fusion approach is aimed at using complementary strengths of the models for error mitigation and rich context consolidation. Recent work has shown the advantage of such fusion and ensembling approaches in mitigating hallucination across tasks such as machine translation, definition modeling, and paraphrase generation (Mehta et al., 2024). Additionally, such an approach has a flexibility advantage as it allows for future integration of additional LLMs or specialized models.

3.3 Translation of Context to Target Languages

This stage involves translating the rich contextual information generated in English to the target languages. This step is essential for preserving the nuanced understanding developed in the previous stages while adapting it to the linguistic and cultural context of each target language. For the translation of the generated conversations, we employ different approaches based on the target language:

- **Hindi, Bengali, and Malayalam:** For these Indic languages, we utilize the IndicTrans2 (Gala et al., 2023) model. This state-of-the-art translation model is specifically designed for Indian languages and has demonstrated strong performance in multilingual translation tasks.
- **Hausa**: Due to the limited availability of specialized translation models for Hausa, we leverage the GPT-4o's translation capabilities.

3.4 Weighted Prompt-Based Caption Generation

The final stage of our pipeline employs a weighted prompting strategy to generate the target language caption, balancing fidelity to the original English caption with the rich contextual information derived from our LLM-generated conversations. We utilize GPT-4o API for this crucial step, employing a carefully crafted prompt (Prompt-2, detailed in Table 5) that takes two primary inputs along with the weight value:

1. The original English caption (weight: 100-x%)
2. The translated conversation in the target language (weight: x%)

The weighting mechanism allows us to control the influence of each input on the final caption. This approach offers flexibility in balancing between direct translation fidelity and contextual enrichment. For our submissions we provide equal weightage to the given English caption and the generated conversation in the target language.

4 Results

The BLEU score (Papineni et al., 2002) serves as the primary metric for evaluating model performance on the leaderboard, complemented

You are an AI visual assistant, and you are seeing a single image. You are provided with an English caption describing the image you are looking at. Answer all questions as if you are seeing the image. Design a conversation between you and a person asking about this photo. The answers should be in a tone that a visual AI assistant would use while seeing the image and answering the questions. Ask diverse questions and give corresponding answers.

Include questions asking about the visual content of the image, including the object types, counting the objects, object actions, object locations, relative positions between objects, etc. Only include questions that have definite answers:

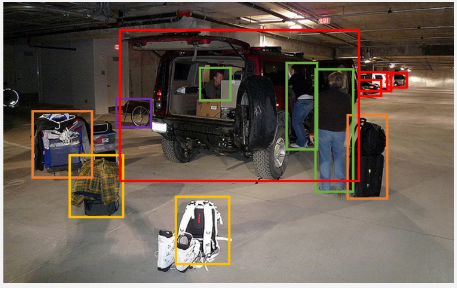
(1) one can see the content in the image that the question asks about and can answer confidently;

(2) one can determine confidently from the image that it is not in the image. Do not ask any question that cannot be answered confidently.

Also, include complex questions that are relevant to the content in the image, for example, asking about background knowledge of the objects in the image, asking to discuss events happening in the image, etc. Again, do not ask about uncertain details. Provide detailed answers when answering complex questions. For example, give detailed examples or reasoning steps to make the content more convincing and well-organized. You can include multiple paragraphs if necessary. You must include a question-answer pair asking about the number of words in the English caption.

I am giving you an example of a conversation too, so that you can follow a format in the conversation you generate.

Example Image: {example_image_link}



Associated Caption in English: A group of people standing outside of a black SUV with various luggage.

Associated Conversation in English:

Response type 1: conversation

Question: What type of vehicle is featured in the image?

Answer: The image features a black sport utility vehicle (SUV).

Question: Where is the vehicle parked?

Answer: The vehicle is parked in an underground parking area, likely in a public garage.

Question: What are the people in the image doing?

Answer: The people are trying to fit all of their luggage into the SUV, likely preparing for a trip.

Response type 2: detailed description

The image shows an underground parking area with a black SUV. Three people are packing luggage into the vehicle, with one person on the left, one in the middle, and one on the right. Scattered around the SUV are two backpacks—one near the left rear wheel, another on the right—and two suitcases, one beside the car and another near the center of the lot. A bicycle is visible on the left. Other cars are parked nearby: one directly behind, one slightly to the left, and another to the right.

Response type 3: complex reasoning

Question: What challenges do these people face?

Answer: A group of people stands outside a black SUV in a parking area, surrounded by suitcases and backpacks. They face the challenge of fitting all their luggage into the vehicle, indicating they have a lot to pack. They need to arrange the luggage efficiently to ensure everything fits and consider the comfort of passengers and the driver's visibility during the trip.

As you can see from the example, the generated text should have 3 response types: A short question-and-answer type conversation, a detailed description, and a question-answer pair for complex reasoning. Now, here is the caption and the image I want you to generate the conversation for: {english_caption}, {image_link}. Do not hallucinate!

Table 4: Prompt-1: This illustrates the prompt construction process for generating the conversation response using an AI visual assistant. The code snippet generates a prompt for GPT-4 to create a conversation based on an image and caption. The conversation includes three response types: a short Q&A, a detailed description, and complex reasoning. The generated response is capped to a maximum of 1024 tokens for this step.

Task: Generate a caption in {target_language} for an image, balancing information from the English caption and additional context.
Context:
1. English caption (Weight: {english_weight}%): {english_caption}
2. Additional context in {target_language} (Weight: {context_weight}%): {translated_conversation}
Requirements:
1. Create a caption that combines information from both sources according to their weights:
- {english_weight}% of the information should come from the English caption's structure and details.
- {context_weight}% of the information can be enriched or modified based on the additional context.
2. Maintain a level of detail appropriate to the weighted combination of sources.
3. Use natural, fluent {target_language} appropriate for image captions.
4. Ensure the final caption length is similar to the English caption, adjusting slightly if necessary for language differences.
Output:
Provide ONLY the {target_language} caption. The output must be exclusively in {target_language} without any additional text or explanations. Do not hallucinate!

Table 5: Prompt-2: This prompt guides the generation of a caption in the target language by balancing the original English caption with additional context, weighted according to specified ratios. The generated caption should reflect the natural fluency of the target language and match the original caption's length. The generated response is capped to a maximum of 300 tokens for this step.

by the RIBES metric (Isozaki et al., 2010) for a more comprehensive assessment. Table 6 presents our results across all language pairs and datasets. Notably, our approach achieves significant success in the English-Hausa task, securing the 1st position on the Challenge Leaderboard and the 2nd position on the Evaluation Leaderboard. For the English-Hindi task, we demonstrate competitive performance, obtaining strong BLEU and RIBES scores on both the evaluation and challenge sets. Our method, which requires no training, yields competitive results across all 8 submissions, underscoring its effectiveness and versatility. However, we observe relatively limited performance in the Bengali, Hausa, and Malayalam tasks. This performance discrepancy likely reflects the current limitations of state-of-the-art LLMs, whose training data may not adequately represent low-resource languages and their unique semantic characteristics.

System and Task	BLEU	RIBES	Position
English→Hindi			
MMEVMM22en-hi	29.70	0.725	5th
MMCHMM22en-hi	37.90	0.796	3rd

4.1 Weight Tuning Analysis and Performance Metrics

To thoroughly evaluate our weighted prompt-based approach, we conducted extensive experiments across different weight combinations for each target language. This section presents our findings and analyzes the impact of various weight distributions on caption quality and semantic preservation. We employed three primary metrics to assess the performance of our model under different weight configurations:

Weight	BLEU	Sem. Sim.	Norm. Sem.
0	12.24	0.7575	0.9380
10	16.47	0.7379	0.9426
20	11.67	0.6992	0.9215
30	14.29	0.6189	0.9437
40	10.06	0.5780	0.9532
50	8.83	0.5998	0.9611
60	8.43	0.5446	0.9570
70	7.10	0.5091	0.9559
80	8.50	0.5460	0.9617
90	8.81	0.5185	0.9583
100	6.43	0.5091	0.9474

Table 8: Results for Malayalam (ml) with varying context weights. The table shows Average BLEU, Semantic Similarity (ml-ml), and Normalized Semantic Similarity (en-ml).

Weight	BLEU	Sem. Sim.	Norm. Sem.
0	24.23	0.9348	0.9617
10	20.07	0.9266	0.9699
20	17.21	0.9072	0.9677
30	14.53	0.8957	0.9811
40	14.98	0.8607	0.9681
50	13.92	0.8670	0.9653
60	10.11	0.8319	0.9829
70	10.29	0.8380	0.9925
80	10.23	0.8545	0.9827
90	11.24	0.8498	0.9789
100	9.35	0.8486	0.9653

Table 9: Results for Bengali (bn) with varying context weights. The table shows Average BLEU, Semantic Similarity (bn-bn), and Normalized Semantic Similarity (en-bn).

Weight	BLEU	Sem. Sim.	Norm. Sem.
0	51.58	0.6187	0.9126
10	46.38	0.5599	0.9629
20	45.36	0.5358	0.9505
30	42.23	0.5031	0.9598
40	37.58	0.4829	0.9701
50	36.14	0.4712	0.9556
60	30.48	0.4366	0.9667
70	28.68	0.4344	0.9708
80	29.20	0.4407	0.9757
90	29.41	0.4361	0.9642
100	32.01	0.4442	0.9738

Table 10: Results for Hausa (ha) with varying context weights. The table shows Average BLEU, Semantic Similarity (ha-ha), and Normalized Semantic Similarity (en-ha).

- **BLEU Score:** Bilingual Evaluation Understudy (BLEU) (Papineni et al., 2002) measures the similarity between the generated caption and the reference caption. It provides a quantitative measure of translation quality.

- **Semantic Similarity (Sem. Sim.)**: We use cosine similarity between sentence embeddings to measure the semantic closeness of the generated caption to the reference caption in the target language. This metric is calculated using the SentenceTransformer's SentenceBERT (Reimers and Gurevych, 2019) model 'distiluse-base-multilingual-cased-v1', which provides multilingual sentence embeddings.

- **Normalized Semantic Similarity (Norm. Sem.):** This metric compares the semantic similarity of the generated caption to the English source with that of the reference translation to the English source as the ratio of the two. It helps assess how well the generated caption preserves the meaning of the original English caption relative to the reference translation.

To ensure a comprehensive evaluation of our approach across various scenarios, we conducted an in-depth analysis on a diverse subset of the corpus. This subset comprises 250 image-caption pairs, randomly selected from the training, development, evaluation, and challenge sets. Tables 7, 8, 9, and 10 present the results for Hindi, Malayalam, Bengali, and Hausa, respectively. The 'Weight' column represents the percentage weight given to the translated conversation, with the complementary weight assigned to the original English caption. The reported metrics are averaged over all 250 data points for each weight configuration.

Generally, BLEU scores decrease as more weight is given to the translated conversation. This suggests that higher weights on the original caption produce translations more closely aligned with the reference.

The semantic similarity between the generated and reference captions in the target language tends to decrease with increasing weight on the translated conversation. This indicates that while the generated captions may become more descriptive, they may deviate from the reference in terms of semantic content.

Interestingly, the normalized semantic similarity remains relatively stable across weight distributions. This suggests that our approach consistently preserves the semantic relationship between the English source and the generated caption, regardless of the weight distribution.

While the highest BLEU scores are generally achieved with lower weights on the translated conversation, there's a trade-off between BLEU score and the richness of the generated caption. A balanced approach (e.g., 50-50 weighting) often provides a good compromise between translation accuracy and contextual enrichment.

Notably, setting a 100% weight for the original English caption allows us to evaluate GPT-4's zero-shot cross-lingual transfer capabilities in direct translation tasks from English to Hindi, Bengali, Malayalam, and Hausa. Conversely, assigning a 100% weight to the additional context—which consists of the translated LLM-generated conversation in the target language—enables us to assess the model's abstractive summarization abilities in these non-English languages. This analysis provides insights into the models' multilingual competence and their capacity for language understanding and generation across diverse linguistic contexts.

5 Conclusion

Key strengths of our approach include its training-free nature, which avoids propagating errors from potentially flawed datasets, and its flexibility in balancing source fidelity with enhanced descriptiveness through a weighted prompting strategy. The method's multilingual capability and rich context generation offer promising avenues for dataset enrichment and improvement in low-resource languages. In Section 4.1, we demonstrated how our weighted prompting strategy serves as a probe for assessing LLMs' capabilities in zero-shot cross-lingual transfer for direct translation tasks, as well as their abstractive summarization abilities in low-resource target languages. However, we acknowledge limitations such as reliance on LLM APIs, potential for hallucination, and computational intensity. The challenge of evaluating enhanced descriptions with traditional metrics like BLEU also highlights the need for more comprehensive evaluation methods. Future work should focus on:

- Conducting human evaluations to better assess caption quality and appropriateness.
- Analyzing specific cases of significant improvements or detractions from original captions.
- Exploring applications in dataset error correction and enhancement.
- Investigating performance across diverse image types and caption complexities.

By addressing these areas, we aim to further refine and expand the capabilities of our approach, potentially leading to more robust and versatile multimodal translation systems. This work represents a step towards bridging the gap between high-resource and low-resource languages in multimodal machine translation, opening new possibilities for cross-lingual image understanding and dataset enrichment.

Abstract

We present the results of our constrained submission to the WMT 2024 shared task, which focuses on translating from Spanish into two low-resource languages of Spain: Aranese (spa-arn) and Aragonese (spa-arg). Our system integrates real and synthetic data generated by large language models (e.g., BLOOMZ) and rule-based Apertium translation systems. Built upon the pre-trained NLLB system, our translation model utilizes a multistage approach, progressively refining the initial model through the sequential use of different datasets, starting with large-scale synthetic or crawled data and advancing to smaller, high-quality parallel corpora. This approach resulted in BLEU scores of 30.1 for Spanish to Aranese and 61.9 for Spanish to Aragonese.

1 Introduction

This work presents the results of our constrained submission for the *Translation into Low-Resource Languages of Spain* shared task at WMT24.[1] The task involves translating from Spanish into two low-resource languages spoken in the northeast of the Iberian Peninsula: Aragonese (spa-arg) and Aranese (spa-arn).

Despite the existence of monolingual corpora for these languages, parallel data from Spanish to Aragonese is extremely scarce, amounting to only about 60, 000 parallel sentences in OPUS (Tiedemann, 2016). In the case of Aranese, fewer than a thousand parallel sentences are available (FLORES+, Guzmán et al., 2019). In addition to that, these Romance languages are notable for their graphemic instability. Although proposals for orthographic standardization (Estudio de Filología Aragonesa, 2010) and official recognition (Boletín Oficial del Estado, 2006) have been introduced, the absence of a commonly accepted writing system has hindered the development of machine translation (MT) systems into Aragonese and Aranese (Forcada, 2020).

A few previous works have explored MT for these language combinations. For instance, Apertium MT systems (Forcada et al., 2011) provided translations for the above-mentioned pairs using a rule-based approach, achieving better results than neural-based MT systems (Oliver, 2020). Similarly, Cortés et al. (2012) complemented Apertium with an additional orthographic module, and proposed a bidirectional spa-arg MT system. More recently, a multilingual MT model (No Language Left Behind, NLLB Team et al., 2022) included under-resourced Iberian languages like Asturian in its training set. However, it did not cover Aranese or Aragonese.

Given the characteristics of this low-resource scenario, we addressed the translation from Spanish into Aragonese and Aranese using a multilingual multistage approach. The multilingual aspect involved leveraging data from linguistically related languages (such as Occitan for Aranese translation), and employing multilingual pre-trained models (specifically, NLLB[2]) to facilitate generalization across different languages. The multistage approach was designed to consecutively enhance translation performance in the target languages using increasingly specific fine-tuning data sets.

Additionally, we applied data augmentation techniques to increase the volume of relevant data in our training set. This involved: *i*) resorting to LLMs within the constraint of one thousand million parameters (in particular, BLOOMZ[3]) to synthetically create more data in the target languages, and *ii*) producing aligned data through Apertium systems on

[1] The source code for the experiments discussed in this article is available at https://github.com/jonathanmutal/WMT-24-Submission.

[2] Particularly, the following model: https://huggingface.co/facebook/nllb-200-distilled-600M.

[3] Specifically: https://huggingface.co/bigscience/bloomz-560m.

the basis of real and synthetic monolingual data from both sides of the languages pairs.

The structure of this paper is as follows: Section 2 describes the methods employed to gather parallel and monolingual data for our experiments. Section 3 introduces the multistage fine-tuning approach. In Section 4, we discuss the experiments conducted on both language combinations and the results obtained. Lastly, Section 5 summarizes our findings and suggests directions for future research.

2 Data

To train our MT `spa-arn` and `spa-arg` models, we first compiled parallel data from OPUS and FLORES+ (FLORES+$_{\text{DEV}}$) bilingual corpora. We then compiled monolingual data from two sources: *i*) we sub-sampled 19 million sentences from Wikimedia and NLLB datasets available in OPUS for Spanish, and *ii*) we collected all monolingual corpora for Aragonese, Aranese and Occitan from OPUS and PILAR (Galiano-Jiménez et al., 2024) when available. Table 1 details the number of segments in the bilingual corpora, and Table 2 reports the segments counts for each monolingual corpus. The notation "k" denotes thousands, and "M" signifies millions. A ✗ indicates the absence of available data.

Corpus	spa-arn	spa-oci	spa-arg
OPUS	✗	1.11M*	60k
FLORES+$_{\text{DEV}}$	997	997**	997

Table 1: Number of parallel segments for the available bilingual dataset. *CCMATRIX was not utilized. **These sentences were not used in any experiment.

Corpus	spa	arn	oci	arg
OPUS	19M	✗	739k	213k
PILAR	✗	322k*	✗	84k

Table 2: Number of monolingual segments for each available dataset. *Monolingual paragraphs were not utilized.

2.1 Synthetic Monolingual Data

We generated synthetic monolingual data in Aranese using BLOOMZ (Muennighoff et al., 2023). To do so, we fine-tuned BLOOMZ with the monolingual data (i.e., PILAR) using a causal language modeling objective, which involves predicting the next token in a sequence. We used a learning rate of 5×10^{-5} with an early stopping mechanism based on accuracy with a patient value of 5. As for the validation data, we randomly picked $1,000$ segments extracted from the same data distribution.

To generate new sentences in the target language, we took the beginnings of sentences in FLORES+$_{\text{DEV}}$. Then, the model completed segments from varying numbers of input words (ranging from 1 to 60 words) and generated up to a maximum of 65 tokens. We produced $59,820$ (997×60) sentences in Aranese using multinomial sampling. All other generation hyperparameters were set to their default values.[4]

2.2 Synthetic Parallel Data

Using the monolingual and synthetic data described above, we produced parallel data through Apertium systems (see Table 3). The following strategies were employed to synthetically create parallel sets:

- **Forward translation** (Burlot and Yvon, 2018). We generated synthetic Aranese, Occitan and Aragonese from monolingual Spanish (see Table 2).
- **Backtranslation** (Sennrich et al., 2016). We backtranslated the segments from monolingual Occitan, Aranese, and Aragonese. We also backtranslated synthetic segments in Aranese produced by BLOOMZ (see Section 2.1).

Strategy	*Corpus*	spa-arn	spa-oci	spa-arg
FT	OPUS	20M	20M	20M
BT	OPUS	✗	1.8M	273k
	PILAR	322k	✗	✗
	BLOOMZ	59k	✗	✗
Total		20.3M	21.8M	20.2M

Table 3: Training data synthetically generated using forward translation (FT) and backtranslation (BT).

3 Approach

Our approach, termed "multistage fine-tuning" involves sequentially refining a model using multiple datasets arranged in a specific order – a method proven to improve performance in machine translation for low-resource language pairs (Dabre et al., 2019).

[4] See documentation: `https://huggingface.co/docs/transformers/en/main_classes/text_generation`.

System	*Stage*	*Data*	**BLEU**↑	**ChrF**↑	**TER**↓
Apertium	-	-	28.8	49.4	72.3
MarianNMT	1	OPUS+PILAR (38M)	25.0	47.1	76.4
Helsinki-NLP	1	OPUS+PILAR (38M)	22.3	45.6	81.9
NLLB	1	OPUS+PILAR (38M)	29.0	49.4	72.3

NLLB	2.ii	PILAR+BLOOMZ	28.9	49.2	72.5
NLLB	3.i	FLORES+$_{\text{DEV}}$	*30.0	*49.7	*71.8
NLLB	3.ii	FLORES+$_{\text{DEV}}$	***30.1**	***49.8**	***71.5**

Table 4: BLEU, ChrF and TER calculated on the test data for `spa-arn`. Scores with * are significantly better than the baseline Apertium with $p < 0.01$, calculated using paired approximate randomization with $10,000$ trials.

In this work, the models were initially trained using large-scale synthetic or crawled data aiming to match or surpass the performance of the open-source Apertium MT systems. Following this, the models underwent further fine-tuning with smaller, high-quality parallel corpora to improve their performance.

Performance comparisons for the initial models were conducted among three systems: *i*) a model built from scratch using MarianNMT (Junczys-Dowmunt et al., 2018); *ii*) a fine-tuned Helsinki-NLP model with ≈72M parameters; and *iii*) a fine-tuned large language model, NLLB, trained on 200 different languages with a larger number of parameters (600M). This enabled us to identify the best performing model for the first stage.

4 Experiments and Results

All our systems are Encoder-Decoder models based on the Transformer architecture (Vaswani et al., 2017). The models were trained until convergence, with training progress monitored using BLEU score each $5,000$ steps and an early stopping patience value of 10 using FLORES+$_{\text{DEV}}$ as validation data. The details of the training procedure and the results obtained for validation are detailed in Appendix A and B.

In the following sections, we describe the evaluation setup as well as the experiments and results obtained for each language pair.

4.1 Evaluation Setup

We evaluated our models using the FLORES+ test data ($1,012$ sentences). We calculated accuracy-based metrics BLEU (Papineni et al., 2002) and ChrF (Popović, 2015), and also computed an error-based metric, i.e., Translation Error Rate (TER, Snover et al., 2006). All metrics were calculated using the Sacrebleu implementation (Post, 2018).[5] We used paired approximate randomization with $10,000$ trials to calculate the level of significance of the results.

We compared the performance of our models with Apertium MT systems, which are strong baselines for these language pairs.

4.2 Spanish-Aranese

For this specific language pair, we had almost no parallel sentences, but we did have a larger corpus of parallel sentences from a linguistically close language, Occitan (see Tables 1 and 2). To leverage the non-negligible quantity of data in this language, we built an MT model using all available data in Occitan and Aranese. In previous experiments, we observed that fine-tuning NLLB with multilingual data (i.e., Spanish-Aranese and Spanish-Occitan) outperformed its bilingual version (i.e., Spanish-Aranese). We also observed that using special tokens to differentiate the two languages is beneficial, and thus used them whenever possible. Appendix A.1 and A.2 show the results of these experiments.

Consequently, in the first stage, the models leveraged all available multilingual data from the OPUS and PILAR (including also synthetic data produced by forward and backtranslation), comprising roughly 42M sentences in Occitan and Aranese. We excluded sentences longer than 100 tokens, resulting in a total of 38M segments. We deliberately omitted synthetic data from BLOOMZ and the validation set to mitigate the risk of overfitting and ensure generalization in the first stage.

In the second stage, the NLLB model, identified

NLLB-Post-Edition	2	FLORES+$_{\text{DEV}}$	61.0	*78.9	27.2
NLLB-Translation	2	FLORES+$_{\text{DEV}}$	***61.9**	**79.5**	***26.8**

Table 5: BLEU, ChrF and TER calculated on the test data for spa-arg. Scores with * are significantly better or worse than the baseline Apertium with $p < 0.01$, calculated using paired approximate randomization with $10,000$ trials.

as the most performing from the first stage, was fine-tuned using two different data combinations: PILAR data (2.i), and a combination of PILAR and synthetic Aranese data from BLOOMZ (2.ii). To mitigate the risk of overfitting in 2.ii, we fine-tuned the model using a fixed number of steps to reach a slightly higher validation BLEU score than the model trained in 2.i. During the third and final stage, the two models from the previous stage underwent $7,500$ additional training steps on the FLORES+$_{\text{DEV}}$ (3.i and 3.ii).

Results Results from the first stage showed that NLLB slightly outperformed the Apertium spa-arn system by 0.2 BLEU points, although this improvement was not statistically significant. MarianNMT and Helsinki-NLP performed worse than Apertium, which appears to agree to the findings in Oliver (2020). Interestingly, MarianNMT outperformed Helsinki-NLP, which might indicate that knowledge acquired during pre-training does not help to the task at hand. The underlying reasons for this discrepancy should be explored in future research.

The most performing model, NLLB (stage 3.ii), which was trained through a three-stage process, surpassed all previous models, improving the Apertium systems by 1.3 BLEU points and 0.4 ChrF points, and reduced the TER by 0.8 points.

The results indicate that the multistage approach enhance model performance. They also underscore the importance of a high-capacity model pre-trained on a diverse set of languages to improve translation from Spanish to Aranese. Additionally, the findings suggest that integrating synthetic data generated by BLOOMZ is beneficial in the third stage of fine-tuning (NLLB 3.i vs. NLLB 3.ii).[6]

4.3 Spanish-Aragonese

The model training for spa-arg was conducted in two stages. In the first stage, we used all OPUS-based synthetic data from Spanish to Aragonese to fine-tune NLLB.[7] This initial corpus amounted to roughly 20M parallel sentences, but we later filtered out the source or target sentences exceeding 100 tokens, which resulted in 15M pairs. With this set, we achieved comparable performance to the Apertium MT system in the validation data.

In the second stage, the model was fine-tuned with a lower learning rate, and utilized the FLORES+$_{\text{DEV}}$ in two different approaches:

- **Translation**, using as source the original sentences in Spanish.
- **Post-Edition (PE)**, using the Aragonese generated by the Apertium rule-based system as the source to train a post-edition model (apertium_arg-arg).

Results The experiments indicate that the performance is superior for translation tasks compared to post-edition tasks. Specifically, our optimal system, NLLB-Translation, surpassed the Apertium baseline by 0.8 BLEU points and reduced the translation error rate by 0.4 points.

Regarding the PE model, we assumed that a system trained using apertium_arg-arg could only help correct the mistakes made by such rule-based approach and thus improve its performance. Surprisingly, the resulting model (NLLB-Post-Edition) did not outperform the rule-based system, and instead degraded its results (see Table 5). One possible explanation for this is that the NLLB model from stage 1 was trained on spa-arg translation

[6] We also fine-tuned the resulting NLLB model from the first stage with FLORES+$_{\text{DEV}}$ data using $7,500$ steps. It underperformed the systems from the third stage.

[7] In previous experiments, we observed that PILAR was not helpful for the spa-arg task, so we decided to exclude it from the training set in our final models.

data rather than post-edition data. Further experiments need to be conducted in order to better understand the behavior of the PE model.

On another note, the results obtained for the fine-tuned Helsinki-NLP model revealed that the knowledge gained during pre-training does not appear to improve the results on the task. As can be observed, the model trained from scratch (MarianNMT) slightly outperforms the small-scale fine-tuned one (Helsinki-NLP), verified by the paired bootstrap statistical test.

5 Conclusions

Our experiments demonstrate the potential of combining synthetic data with multilingual pre-trained models to improve translation from Spanish into Iberian low-resource languages like Aranese and Aragonese. By leveraging data from linguistically related languages and employing a multistage approach, the `spa-arn` model achieved a BLEU score of 30.1, while the `spa-arg` model (NLLB-Translation) achieved 61.9 BLEU points. Our findings also indicate that the NLLB model, which benefited from a large number of pre-trained languages and high model capacity, delivered the best performances.

While these results are promising, we have identified several avenues for future research. One key area is to explore the impact of the ratio of real vs. synthetic data for training, as it can help evaluate how changes in data composition influence automatic metrics. Additionally, we plan to investigate the integration of external resources, such as dictionaries (Institut d'Estudis Aranesi, 2019) and orthographic standards (Academia Aragonesa de la Lengua, 2023), to determine whether these can further enhance the performance of our models.

Acknowledgments

We would like to thank the reviewers for their valuable comments and suggestions.

A Training Setup NLLB and Helsinki-NLP

We employed the Adam optimizer with a batch size of 16. We used 50 warm-up steps, and the number of beams was set to 5. The maximum sequence length was set to 100, and the remaining hyperparameters were left unchanged[8], except for the learning rates which are reported in the following sections. All experiments were conducted using the Transformers library (Wolf et al., 2020) and the University of Geneva HPC clusters, Baobab and Yggdrasil. We used a fixed seed (111) for reproducibility purposes.

A.1 Helsinki-NLP Results

Given the absence of Aragonese or Aranese as targets in any of the existing OPUS-based Helsinki-NLP MT models, we decided to fine-tune them using different target languages. More specifically, our goal was to determine which of the available Romance languages (namely, Galician, Catalan, French, Italian and Romanian) would be most relevant for the `spa-arg` and `spa-arn` tasks.

After conducting an initial round of experiments, we observed that a geographically close language, Italian (i.e., `Helsinki-NLP/opus-mt-es-it`), most aided the translation into Aragonese on the validation set. Similarly, Catalan (i.e., `Helsinki-NLP/opus-mt-es-ca`) proved to be the most helpful target language for Aranese translation. For this language combination, we also conducted experiments to evaluate the potential gain from the use of two dedicated special tokens for Aranese and Occitan. Specifically, we used `<arn>` for Aranese and `<ca>` for Occitan.

Table 6: Results of Helsinki-NLP `spa-arg` models on validation data with different learning rates.

Once we selected the most relevant model for each language pair, we used different learning rates to fine-tune them for our task at hand. Table 6 reports the BLEU and ChrF results for `spa-arg` translation. Table 7 shows the results for the two versions of our `spa-arn` models: one that uses a single special token (`<ca>`) and another one that distinguishes between the two languages with distinct special tokens (`<ca>`|`<arn>`). All experiments were conducted using the Trainer class.[9]

	LR	**BLEU**	**ChrF**
Helsinki-NLP$_{\text{<ca>}}$	1×10^{-5}	26.0	52.7
	2×10^{-5}	26.5	53.2
	3×10^{-5}	24.8	52.2
	4×10^{-5}	25.8	52.8
Helsinki-NLP$_{\text{<ca>|<arn>}}$	1×10^{-5}	**29.7**	**54.9**
	2×10^{-5}	28.6	54.3
	3×10^{-5}	28.8	54.2
	4×10^{-5}	29.0	54.9

Table 7: Results of Helsinki-NLP `spa-arn` models on validation data with different learning rates and different special token configurations.

A.2 NLLB Results

To generate Aranese, we used the Occitan special token (`oci_Latn`) in the target, which is presumably the closest language to Aranese covered by NLLB. Similarly to the Helsinki-NLP models, we used the Italian special token (`ita_Latn`) for Aragonese.

	LR	**BLEU**	**ChrF**
NLLB-Bi$_{\text{<oci>}}$	9×10^{-6}	37.7	59.9
	1×10^{-5}	37.7	59.9
	3×10^{-5}	37.6	59.8
NLLB-Multi$_{\text{<oci>}}$	9×10^{-6}	29.5	55.0
	1×10^{-5}	28.3	54.3
	3×10^{-5}	26.5	53.2
NLLB-Multi$_{\text{<oci>|<cat>}}$	9×10^{-6}	37.8	60.0
	1×10^{-5}	**38.1**	**60.1**
	3×10^{-5}	37.9	60.0

Table 8: Results of NLLB `spa-arn` bilingual (NLLB-Bi$_{\text{<oci>}}$) and multilingual models (NLLB-Multi$_{\text{<oci>}}$ and NLLB-Multi$_{\text{<oci>|<cat>}}$) on validation data with different learning rates and special token configurations.

For Aranese translation, we carried out experiments to evaluate the gain of using a dedicated special token for Aranese and Occitan. In particular, we compared the performance of a multilingual model trained with Aranese and Occitan using the same token (`oci_Latn`), NLLB-Multi$_{\text{<oci>}}$, and another model using two special tokens: one for Aranese (`oci_Latn`) and a different one for

[8] Refer to: `https://huggingface.co/docs/autotrain/en/seq2seq_params`.

[9] Refer to: `https://huggingface.co/docs/transformers/main_classes/trainer`.

Occitan (cat_Latn), NLLB-Multi$_{\text{<oci>|<cat>}}$. We also assessed the performance of a bilingual model trained only with Spanish-Aranese data for comparison purposes (NLLB-Bi$_{\text{<oci>}}$). Table 8 shows the results on the validation data for the three approaches, indicating that the use of special tokens to differentiate the language is beneficial, and so is including Occitan in the training set.

TAN-IBE participation in the Shared task: Translation into Low-Resource Languages of Spain

Antoni Oliver
TAN-IBE team - Universitat Oberta de Catalunya (UOC)
aoliverg@uoc.edu

Abstract

This paper describes the systems presented by the TAN-IBE team into the WMT24 Shared task Translation into Low-Resource Languages of Spain. The aim of this joint task was to train systems for Spanish-Asturian, Spanish-Aragonese and Spanish-Aranesian. Our team presented systems for all three language pairs and for two types of submission: for Spanish-Aragonese and Spanish-Aranese we participated with constrained submissions, and for Spanish-Asturian with an open submission.

1 Introduction

The TAN-IBE team, consisting of participants from the project *TAN-IBE: Neural Machine Translation for the Romance Languages of the Iberian Peninsula* (Oliver et al., 2023), has developed systems for all language pairs in the task and participated with two types of submissions: Spanish-Asturian (open submission), Spanish-Aragonese (constrained submission), and Spanish-Aranese (constrained submission).

The principal concern of the team was not only the scarcity of resources for these language pairs but also the inadequate quality of the available resources. In order to address these issues, we decided to:

- Clean the existing parallel corpora using a tool developed during the project that rechecks the language of the segments and calculates the cosine similarity between source and target segments.
- Create parallel corpora from Wikipedia for all three language pairs.
- Experiment with the use of backtranslation.
- Experiment with the use of synthetic corpora.
- Experiment with the use of multilingual systems.

For some of the language pairs and direction of the shared task, a freely available rule-based MT system exists: Apertium[1] (Forcada et al., 2011; Khanna et al., 2021). In previous research (Oliver, 2020), it was demonstrated that Apertium achieves highly competitive quality, and that it is challenging for a neural system to achieve superior quality results. Consequently, this system has been employed to create backtranslated and synthetic corpora. Furthermore, Apertium will be employed as a reference system to facilitate the evaluation of the trained systems prior to submission to the shared task. The specific versions of Apertium used for each language pair are: Spanish–Aragonese 0.6.0,[2] Spanish–Aranese 1.0.8,[3] Spanish–Asturian 1.1.1.[4]

2 Tools

To train the NMT systems we have used the marian-nmt[5] (Junczys-Dowmunt et al., 2018). All the systems have been trained with a Transformer-big configuration. To calculate the subwords units, we have used SentencePiece[6] (Kudo and Richardson, 2018). Additional information on other training parameters can be found in the subsections for each system.

In order to create the parallel corpora and to clean and preprocess the corpora, several components of the MTUOC project[7] (Oliver and Alvarez, 2023) have been employed. It should be noted that several of these components have been developed during the course of the TAN-IBE project. The components that have been used are as follows:

- To create parallel corpora from the Wikipedia: MTUOC-WikipediaDump[8] and MTUOC-

aligner.[9]

- To clean both the existing and the newly created parallel corpora: MTUOC-clean-parallel-corpus,[10] that performs several cleaning operations; and MTUOC-PCorpus-rescorer,[11] that rechecks the language of the segments and calculates the cosine similarity using a multilingual model, as SBERT, for example.
- To select from a large corpus the most similar segments from a large corpus: MTUOC-corpus-combination.[12]
- To preprocess the parallel corpora to train the systems: MTUOC-corpus-preprocessing.[13]

For some cleaning operations the language of the segments should be detected. As Asturian, Aranese and Aragonses are underrepresented in available language detection models, we decided to develop our own language detection model using fasttext[14] (Joulin et al., 2016). We trained a model able to detect the following languages: Aragonese, Aranese, Asturian, Catalan, English, French, Galician, Occitan, Portuguese and Spanish. For all the languages, except for Aranese, we used 400K segments from the Wikipedia. As no Wikipedia is available for Aranese, we used 297,557 segments from the PILAR corpus.[15]

The trained model performs similarly to Idiomata Cognitor[16] (Galiano-Jiménez et al., 2024), with the difference than Italian is included in this tool. In Table 1, the precisions calculated using the FLORES+ dev corpus for Idiomata Cognitor and our trained language detection model are presented.

We decided to train our own language detection model because fasttext models integrate seamlessly in our corpus cleaning scripts, and the same training strategy can be used in future experiments with language not present in Idomata Cognitor.

Language	Idiomata Cognitor	TAN-IBE fasttext model
Spanish	0.95	0.95
Catalan	1.00	0.99
Aragonese	0.96	1.00
Aranese	0.96	1.00
Occitan	0.94	0.93
Asturian	0.99	0.98
Galician	0.98	0.99
French	1.00	1.00
Portuguese	1.00	0.99

Table 1: Precision on language detection for Idiomata Cognitor and our trained fasttext model.

3 Existing resources

Table 2 provides an overview of the existing corpora that have been employed for system training, accompanied by the number of segments in the original corpora and the number of segments resulting from the cleaning process peformed with MTUOC-PCorpus-rescorer. As previously stated, this tool performs a second language detection of the segments using fasttext and calculates a cosine similarity between the source and target segments using SBERT. As the default language detection model used in fasttext have been trained with underrepresented texts for Asturian, Aragonese and Occitan (Aranese), we decided to retrain a language model for the cleaning of corpora for these languages, as explained in section 2. Please, note that there are no available parallel corpora for Aranese, and in the table we state the figures for the Spanish-Occitan parallel corpus used.

Langs	Corpus	Raw	Clean
spa-ast	NLLB	6,470,015	504,532
spa-arg	Wikimatrix	33,724	16,456
spa-oci	NLLB	925,448	108,440

Table 2: Size of the existing corpora in segments used for training the systems

4 Newly created resources

As the available corpora for the working language pairs are clearly insufficient to train NMT systems we have created a new parallel corpus from Wikipedia dumps. To this end, we have developed a series of scripts, which are freely available at the MUTOC-WikipediaDumps repository, that are capable of:

- Extract all the text from the Wikipedia dump, along with a file containing the titles of the articles. This process is performed for the smaller Wikipedias, in this case the Asturian, Aragonese and Aranese.
- Translate the list of titles of the extracted articles into Spanish using the langlinks database dump.

[9] https://github.com/mtuoc/MTUOC-aligner

[10] https://github.com/mtuoc/MTUOC-clean-parallel-corpus

[11] https://github.com/mtuoc/MTUOC-PCorpus-rescorer

[12] https://github.com/mtuoc/MTUOC-corpus-combination

[13] https://github.com/mtuoc/MTUOC-corpus-preprocessing

[14] https://fasttext.cc/

[15] https://github.com/transducens/PILAR

[16] https://github.com/transducens/idiomata_cognitor

- Extract the text of the articles of the larger Wikipedia, in our case the Spanish one, restricting the extracted articles to the titles in the translated title list.

It should be noted that this process is carried out separately for Spanish-Asturian, Spanish-Aragonese and Spanish-Occitan. Once the text has been obtained, it is segmented and the resulting segments are deduplicated and a file is generated for each language pair, containing all the source segments and a file for all the target segments. For the creation of the Wikipedia corpora we have used the dumps of first of May of 2024. All the created corpora can be downloaded from Github.[17]

To align the files we use a bitext mining strategy using SBERT, implemented in the MTUOC-Aligner. The alignment process gives sets of aligned files that contain source segment, target segment and a margin score. The resulting aligned files are cleaned using MTUOC-PCorpus-rescorer, using a confidence of 0.75 for language detection and SBERT score. In table 3 illustrates the raw and cleaned number of parallel segments obtained through this process.

Langs	Raw	Clean	Backtrans.
spa-ast	2,194,031	1,193,264	4,023,140
spa-arg	153,863	32,374	386,666
spa-oci	295,476	55,112	1,151,205

Table 3: Size of the Wikipedia corpora created

Additionally, the extracted text from Wikipedia in Asturian, Aragonese and Occitan has been employed to generate back-translated Spanish-Asturian, Spanish-Aragonese and Spanish-Occitan corpora. In order to achieve this, it is necessary to have access to machine translation systems that are capable of functioning in the opposite direction. Fortunately, Apertium provides translation systems for Aragonese-Spanish and Occitan-Spanish, but not for Asturian-Spanish. To address this gap, we have trained a Transformer Neural system using the cleaned NLLB and the Wikipedia corpus created for this purpose. This system was then used for backtranslation. In subsection 5.1 more details on this system, along with evaluation figures are presented. Table 3 shows the number of segments in the backtranslated Wikipedia corpus.

As previously stated, there are no available corpora for the Spanish-Aranese language pair, and there is no Wikipedia version for Aranese either. Therefore, no parallel resources for this language pair can be employed. For this language pair, we have utilised the monolingual data available in the PILAR (*Pan-Iberian Language Archival Resource*) and backtranslated it into Spanish using Apertium. This process yielded 297,557 backtranslated parallel segments.

In order to augment the number of parallel corpora, we devised a method for the generation of synthetic data utilising the Spanish-Catalan Paracrawl corpus, which had been previously subjected to cleaning procedures. The 13 million Spanish segments were translated into Asturian, Aragonese and Aranese using Apertium. For each translated segment, a confidence score was calculated as the ratio of the unknown words (marked with an asterisk by Apertium) to the total number of words.

In the case of the multilingual system under experimentation, the parallel corpora presented in Table 4 were also employed. With regard to the Spanish-Catalan and Spanish-Galician languages, a parallel corpus was created from Wikipedia, as previously described.

Langs	Corpus	Raw	Clean
spa-cat	Paracrawl	17,238,953	13,931,594
spa-cat	Wikipedia	5,790,903	2,586,448
spa-fra	MultiParacrawl	39,026,138	-
spa-fra	WikiMatrix	905,761	-
spa-glg	Paracrawl	1,879,649	-
spa-glg	Wikipedia	1,697,307	729,840
spa-por	MultiParacrawl	26,181,054	-
spa-por	WikiMatrix	923,725	-

Table 4: Additional parallel corpora used to train the multilingual system

5 Trained systems and evaluation

In this section we will present all the trained systems for this shared task, along with evaluation figures using the FLORES+ devtest sets developed by the organisers of the shared task. To calculate the evaluation metrics (BLEU, TER and chrF will be presented), we have used Sacrebleu[18] (Post, 2018). In Appendix 8 we present the metric signatures for these metrics.

5.1 Neural Asturian-Spanish for backtranslation

In order to create back-translated corpora for Aragonese and Aranese, the Apertium system was

[17] https://github.com/mtuoc/WikipediaCorpora

[18] https://github.com/mjpost/sacrebleu

employed, given that it is available for these language pairs. However, the Asturian-Spanish pair is not available in Apertium. Consequently, a neural system was trained using Marian and the following parallel corpora: NLLB cleaned (see table 2) and the newly created Wikipedia corpus (see table 3). A transformer configuration using SentencePiece with a vocabulary size of 32K has been used.

Table 5 presents the evaluation metrics for the trained systems, along with the metrics for the Apertium system for Aragonese-Spanish and Aranese-Spanish, using the FLORES+ devtest sets.[19] For purposes of comparison, the evaluation figures for all reverse translation directions are also provided. It should be noted that Apertium systems are available for all reverse directions.

System	BLEU	chrF	TER
Marian ast-spa	24.0	53.5	57.4
Apertium arg-spa	61.4	77.9	26.7
Apertium oci-aran–spa	26.7	47.2	70.8
Apertium spa-ast	17.0	50.8	80.4
Apertium spa-arg	61.1	79.3	27.2
Apertium spa–oci-aran	28.8	49.4	72.3

Table 5: Evaluation figures for the systems used to create backtranslated corpora.

A number of conclusions can be drawn from Table 5. The Apertium systems for Aragonese-Spanish and Spanish-Aragonese achieve highly comparable results, as do the pairs Aranese-Spanish and Spanish-Aranese. Consequently, given that the Marian system for Asturian-Spanish attains superior outcomes compared to the reverse system Spanish-Asturian, it can be inferred that the quality of the training system is analogous to, and even surpasses, that of the Apertium systems utilised for backtranslation.

The Asturian-Spanish NMT system was employed to backtranslate the segments from the NLLB corpus that were identified as Asturian, but with translations in languages other than Spanish or with Spanish translations with SBERT scores below 0.75. The resulting backtranslated Spanish-Asturian corpus comprises 2,084,594 segments.

5.2 Basic neural Spanish-Asturian system

The basic neural system for Spanish-Asturian has been trained using the same configuration than the Asturian-Spanish for backtranslation, that is: NLLB cleaned (see table 2) and the newly created Wikipedia corpus (see table 3). A transformer configuration using SentencePiece with a vocabulary size of 32K has been used. In table 6 we can observe the evaluation figures for this system. It can be observed that this basic system attains inferior results in comparison to Apertium (see Table 5). The BLEU score is 15.3, whereas Apertium achieves 17.0.

5.3 Basic neural Spanish-Aragonese system

The basic neural system for Spanish-Aragonese has been trained using the same configuration than the Asturian-Spanish, using the following corpora: Wikimatrix cleaned (see table 2), the newly created Wikipedia corpus (see table 3, and the newly created backtranslated Wikipedia corpus (see table 3).

In table 6 we can observe the evaluation figures for this system. The evaluation results obtained by this system are significantly lower (18.8 BLEU) than the obtained by Apertium (see Table 5) (61.1 BLEU).

5.4 Multilingual system

As no parallel corpora are available for Aranese, and the available for Aragonese are very small, we experimented with multilingual systems to see whether the multilingual configuration may produce good results for these two languages, and may also improve the results obtained for Asturian.

We have trained a multilingual system from Spanish to the following languages: Aragonese, Aranese, Asturian, Catalan, Galician, French, Occitan and Portuguese. To train this system we have used the following corpora:

- **Spanish-Aragonese**: WikiMatrix cleaned (see table 2), newly created Wikipedia corpus (see table 3), Wikipedia backtranslated using Apertium (see table 3).
- **Spanish-Aranese**: Pilar backtranslated using Apertium.
- **Spanish-Asturian**: NLLB cleaned (see table 2), Wikipedia clean (see table 3) and the backtranslated corpus described in 5.1
- **Spanish-Catalan**: 10 M segments automatically selected form Paracrawl cleaned (see table 4)
- **Spanish-Galician**: all segments available in Paracrawl cleaned (see table 4)
- **Spanish-French**: 10 M segments automatically selected form MultiParacrawl cleaned (see table 4)

[19] Apertium v 3.9.4; linguistic data versions: spa-ast v.1.1.1-1; spa.arg v.0.6.0-1; es-oc v1.0.8-1

- **Spanish-Occitan**: NLLB cleaned (see table 2), newly created Wikipedia corpus (see table 3), Wikipedia backtranslated using Apertium (see table 3).
- **Spanish-Portuguese**: 10 M segments automatically selected form MultiParacrawl cleaned (see table 4)

To calculate the SentencePiece model for the multilingual system we have randomly selected 1M segments from each language pair, except for Aragonese and Aranese, for which we have used all the available segments. The final multilingual system uses an ensemble of the three best check points regarding BLEU DETOK.

Table 6 presents the evaluation figures for the multilingual system. With regard to Spanish-Asturian, the multilingual configuration exhibits an increase of 0.9 BLEU points in comparison to the basic system. However, this figure remains 0.8 BLEU points below the level achieved by Apertium. In the case of Spanish-Aragonese, the multilingual system exhibits a noteworthy enhancement of 13.3 BLEU points. Nevertheless, it remains considerably distant (29 BLEU points) from the performance of Apertium. In the case of Spanish-Aranese, the multilingual configuration yielded a BLEU score that was 8.7 points lower than that obtained with Apertium.

System	langs.	BLEU	chrF	TER
Basic	spa-ast	15.3	48.0	77.5
Basic	spa-arg	18.8	51.5	67.2
Multilingual	spa-ast	16.2	50.0	75.8
Multilingual	spa-arg	32.1	65.3	48.0
Multilingual	spa–oci-aran	20.1	44.5	77.8
Synth. val Flores	spa-ast	16.3	50.6	77.1
Synth. val Flores	spa-arg	57.2	78.1	29.4
Synth. val Flores	spa–oci-aran	26.9	48.8	72.7
Backt. val Flores	spa-ast	18.0	51.6	74.5
Apertium	spa-ast	17.0	50.8	80.4
Apertium	spa-arg	61.1	79.3	27.2
Apertium	spa–oci-aran	28.8	49.4	72.3

Table 6: Evaluation figures for the different systems trained and Apertium

5.5 Synthetic val Flores Spanish-Asturian

This systems uses the same configuration as the Basic Spanish-Aranese system, but adding the synthetic corpus from Paracrawl described in subsection 4. In this system we use the Flores dev corpus for validation. The final system uses an ensemble of the model corresponding the the 3 best checkpoints using the BLEU DETOK metric.

From table 6 we can observe that with this configuration we improve the basic system by 1 BLEU point, but we are still below Apertium.

5.6 Synthetic val Flores Spanish-Aragonese

This systems uses the same configuration as the Basic Spanish-Aragonese system, but adding the synthetic corpus from Paracrawl described in subsection 4. In this system we use the Flores dev corpus for validation. The final system uses an ensemble of the model corresponding the the 3 best checkpoints using the BLEU DETOK metric.

This configuration achieves an impressive improvement of 38.4 BLEU points in comparison with the basic configuration (see table 6), but Apertium keeps an advantage of 3.9 BLEU points. At this point, we can try to explain two key observations: why does Apertium achieve such strong evaluation metrics for Spanish-Aragonese? And why does the system trained with synthetic corpora created by Apertium show such a remarkable improvement? The answer may lie in how the Flores corpus was developed for this language pair. Since it was generated through machine translation from the Spanish Flores using Apertium, the system has a clear advantage when calculating automatic evaluation metrics.

This is the final submission for the Open systems for Spanish-Asturian, with id 568.

5.7 Synthetic val Flores Spanish-Aranese

This system have been trained using the backtranslated Pilar corpus and the synthetic corpus from Paracrawl described in subsection 4. For the validation set we have used the Flores dev corpus. The final system uses an ensemble of the model corresponding the the 3 best checkpoints using the BLEU DETOK metric.

This system achieves an improvement of 6.8 BLEU points in comparison with the multilingual configuration (see table 6), but it is still 1.9 BLEU points below Apertium.

This is the final submission for the Open systems for Spanish-Aranese, with id 610.

5.8 Backtranslation val Flores Spanish-Asturian

We have followed the same configuration than the Basic Spanish-Asturian, but using also the backtranslated Wikipedia corpus. For the validation set we have used the Flores dev corpus. The final system uses an ensemble of the models corresponding the the 3 best checkpoints using the BLEU DETOK metric.

This system achieves an improvement of 2.7 BLEU points in comparison with the basic system, and 1.7 BLEU points in comparison with the synthetic one (see table 6), and also outperforms Apertium by 1 BLEU point.

This is the final submission for the Open systems for Spanish-Asturian, with id 568.

6 Final submissions

Table 7 contains a comprehensive overview of the systems that have been submitted to the shared task. With regard to the Spanish-Asturian task, an open system has been submitted, whereas for Spanish-Aragonese and Spanish-Aranese, constrained systems have been submitted.

7 Energy consumption report

The training scripts generate a log with the timestamp and the GPU consumption every second throughout the entirety of the training process. This enables the calculation of the total training time and the approximate energy consumption in kWh. The total training time and the consumption of each of the two GPU units utilized, along with the total consumption, are presented in Table 8. The final submitted systems are highlighted in bold.

As we can see, all the systems are trained in short times (from 1 h. 10 m. to 3 h. 23 m.) in a relativelly modest computer wit two NVIDIA RTX A5000 GPU units with 24 GB each, a AMD Ryzen Threadripper PRO 3945WX CPU with 12-Cores and 64 GB of RAM. As the training times are short, the energy consumption is very low in all trainings, ranging from 0.481 to 1.292 kWh.

8 Conclusions and future work

In this paper we have presented the systems that the TAN-IBE team have submitted to the WMT24 Shared Task Translation into Low-Resource Languages of Spain. We have presented an open system for the Spanish-Asturian language pair, and constrained systems for Spanish-Aragonese and Spanish-Aranese.

The primary challenge in completing the task was the unavailability of high-quality parallel corpora for the specified language pairs. Fortunately, all the language pairs in question have an Apertium system, and Apertium is also available for all the reverse language pairs except Asturian-Spanish. This enabled us to conduct experiments with synthetic and backtranslated corpora. To perform backtranslation experiments for Spanish-Asturian, we trained a basic neural Asturian-Spanish system.

Additionally, monolingual and parallel corpora were generated from Wikipedia dumps for Spanish to Asturian, Aragonese and Occitan (given the unavailability of an Aranese Wikipedia).

Regarding the training strategies, we experimented with bilingual and multilingual systems. While multilingual systems demonstrated enhanced performance relative to basic systems, the use of synthetic and backtranslated corpora yielded superior outcomes.

In the period preceding the conclusion of the TAN-IBE project in July 2025, it is our intention to undertake the following actions:

- During the course of the project, a corpus of monolingual and bilingual texts in Asturian, Aragonese, Aranese and Spanish has been compiled. The next stage is to process and align these texts in order to increase the number of available parallel segments.
- We plan to train new systems using the parallel corpora and the training techniques presented in this paper. The quality of the resulting systems will then be evaluated in order to ascertain whether the inclusion of the new parallel texts has had a positive impact.
- Furthermore, we intend to learn from the other participants in the shared task and attempt to reproduce the training techniques that have yielded the most favourable outcomes, utilising the newly created parallel corpora.
- We plan to develop neural systems for Spanish to the other languages of the TAN-IBE project, namely, Portuguese, Galician, Asturian, Argonese, Catalan and Aranese. These systems will be freely released.
- We also plan to train a multilingual system able to translate to and from all the languages of the TAN-IBE project.

After the completion of the TAN-IBE project, we plan to increase the size of the Apertium monolingual and transfer dictionaries for Spanish to Asturian, Aragonese and Aranese using automatic techniques that make use of monolingual and parallel corpora. The quality of the Apertium systems is noteworthy, and the enhancement of the dictionaries has the potential to further optimise the efficiency of the Apertium systems for the generation

Abstract

We present the Spanish–Asturian Apertium translation system, which has been enhanced and refined by our team of linguists for the shared task: Low Resource Languages of Spain of this WMT24 under the closed submission. While our system did not rank among the top 10 in terms of results, we believe that Apertium's translations are of a commendable standard and demonstrate competitiveness with respect to the other systems.

1 Introduction

In this shared task: Translation into Low-Resource Languages of Spain, we present an enhancement of the machine translator *Eslema* system for Spanish–Asturian pair (Viejo et al., 2008). We present our system under the closed submission.

Asturian is not an officially recognised language in the Spanish state. The 1981 Statute of Autonomy of Asturias makes only passing reference to Asturian, citing the need to protect and disseminate it. However, it does not accord the language the same privileges as are enjoyed by other official languages of Spain, such as Galician, Catalan or Basque. Subsequently, on 23 March 1998, the Asturian Parliament enacted the Law on the Use and Promotion of Asturian. The aforementioned legislation stipulates that all citizens are entitled to utilise Asturian in verbal and written communication, and that such communication shall be deemed valid. Furthermore, it acknowledges the necessity for the dissemination of Asturian in educational and media contexts (Galán y González, 2015). Consequently, Asturian is categorised as a minority and Low-Resource Language (LRL), exhibiting a paucity of resources and a diminished presence in Natural Language Processing (NLP) relative to other co-official languages of Spain.

The objective of this shared task is to develop innovative systems and data resources for this low-resource language, the Aragonese and the Aranese. In light of the aforementioned considerations, we present an enhacement of Apertium (Forcada et al., 2011), the foundational system of the current Spanish–Asturian MT translator, *Eslema*. Based on this open-source system, a series of grammatical, syntactic and lexical improvements have been implemented in order to participate in this shared task. While the results obtained have not been sufficient to maintain a position within the top 10, they have been noteworthy.

2 Eslema

Eslema was initiated as a project of the University of Oviedo in 2004 with the objective of assembling corpora in Asturian language. The Asturian Philology Group (*Seminariu de Filoloxía Asturiana*) within the Spanish Philology Department was responsible for its research, with the aim of compiling texts of diverse typology, format and historical periods (Viejo et al., 2008).

Subsequently, at the conclusion of 2008, the Principality of Asturies (*Conseyería de Cultura del Principáu d'Asturies*) assumed the economic responsibility for the establishment of the regulatory framework for the development of a rule-based machine translator for the Spanish–Asturian language pair. This project was carried out in collaboration between the University of Oviedo and the Apertium community. The report published in early 2010 about this translator acknowledged that its functionality was satisfactory, especially in the Spanish–Asturian direction. However, it was also noted that the software still presented some residual problems that would be solved in subsequent updates (Universidad de Oviedo, 2010).

Nevertheless, it is important to recognise that, despite the best efforts of the developers to rectify all potential errors, no machine translator can be considered perfect. In particular, Rule Based Machine Translators require ongoing maintenance and revision to ensure optimal performance. Subsequently,

Proceedings of the Ninth Conference on Machine Translation, pages 878–884
November 15-16, 2024 ©2024 Association for Computational Linguistics

Eslema has been provided to the Administration and citizens free of charge until nowadays. Right now there is a new version of the machine translator in the Linguistic Policy (*Política Llingüística*) webpage.[1]

3 Apertium

Apertium is a free/open-source platform for Rule-Based Machine Translation (RBMT) (Forcada et al., 2011). It is designed to provide high-quality translation tools for several LRL pairs. Apertium was initially developed as part of a project developed by the Alacant University and different public and private Spanish institutions and companies such as **imaxin**|software[2] and El Huyar.[3] But since then, it has evolved into a collaborative endeavour involving developers, linguists and researches (Khanna et al., 2021). The platform is constructed on a rule-based translation system, which relies on predefined linguistic rules and a modular architecture. In the most recent versions of Apertium, these modules are divided into two monolingual packages and one bilingual package for each language pair. The following subsections will provide an explanation of the monolingual packages 3.1 and the bilingual package 3.2.[4] These modules constitute the various components of the Apertium engine pipeline. Modifications have been made to them with the objective of enhancing the original *Eslema* translator.

3.1 Monolingual Packages

There is a monolingual package for each language in the language-pair. For example, in this case, an Asturian package and a Spanish package. Each of these packages is formed by a dictionary 3.1.1, a post-generator 3.1.2 and a Constraint Grammar 3.1.3.

3.1.1 Monolingual Dictionary

Monolingual dictionaries[5] serve the function of regulatory modules for the system's lexicon. The dictionary is comprised of two principal sections. The initial one is the paradigm section, wherein paradigms are defined as patterns or models that delineate the potential declensions of each term, contingent on its category or morphology. The subsequent section is where the lexicon is incorporated. Each novel word is introduced in the format of an entry, which encompasses the term in its fundamental form and the paradigm ascribed to it.

3.1.2 Post-generator

The post-generator[6] is a module that is employed to rectify minor spelling issues in each language. To illustrate, in languages where contractions or the use of apostrophes is prevalent, these orthographic phenomena are regulated by the post-generator. It is typically a module that remains consistent for each language and does not necessitate significant updates.

3.1.3 Constraint Grammar

As posited by Bick and Didriksen (2015), the Constraint Grammar (CG) may be conceived of as a declarative whole of contextual possibilities and impossibilities for a language or genre. However, in programming terms, it is implemented procedurally as a set of consecutively iterated rules that add, remove or select tagged-encoded information.

In Apertium, each language package is equipped with a CG tool, which serves to clarify the source text. One illustrative example of a CG rule is as follows[7]:

The rule "SELECT VERB IF (1 (det))" indicates that the verb category must be selected whenever the following word is a determiner.

This tool is of vital importance in an RBMT engine, as disambiguation errors can lead to significant translation errors. Therefore, the more developed the CG is, the more accurate the translation will be. For this particular pair, the Spanish CG[8] has been used, which was previously created by the Apertium community and, due to errors detected, has had to be modified on some occasions.

3.2 Bilingual Package

There is one bilingual package for each language pair. Each bilingual package is formed by a bilin-

gual dictionary 3.2.1, the transfer rules 3.2.2 and the lexical selection rules 3.2.3.

3.2.1 Dictionary

In bilingual dictionaries,[9] the terms of both languages are aligned with one another. As a general rule, in this type of engine, each term in the source language can only have one correspondence in the target language. In other words, a term in the source language will be translated by the same term in all contexts, with the exception of specific cases which will be addressed in the subsequent modules.[10]

3.2.2 Transfer Rules

Transfer rules[11] are employed to oversee the most intricate structural divergences between two languages, whether pertaining to syntax, morphology, or grammar. To illustrate, transfer rules facilitate the rearrangement of a sentence in the target language, the alteration or insertion of tags by category, and other modifications that enhance the coherence of the target language. In essence, this module is responsible for managing the majority of complex changes that are contingent upon grammatical or lexical context.

3.2.3 Lexical Selection Rules

In instances where a term in the source language has two or more potential translations in the target language, the lexical transfer rules module[12] is responsible for selecting one or the other option, depending on the surrounding context. This context may be either grammatical or lexical in nature.

4 Dependencies

The dependencies of our translation system are presented in the following list. It is imperative that all modules are in place for the correct functioning of the pair: Apertium-3.8.3, lttoolbox-3.7.1, apertium-lex-tools-0.4.2 and cg3-3.9.

5 Methodology

In order to participate in this shared task, the team at **imaxin**|software has utilized the open-source translator published in 2010 by *Eslema*[13] and made available on the Apertium project website,[14] to enhance it in the morphological 5.1 and lexical 5.2 linguistic areas. The implementation of these alterations and enhancements was overseen at all times by a team of linguists with expertise in Asturian, over a period of 18 months, during which not only the Spanish–Asturian direction was considered, but also the Asturian–Spanish.

5.1 Morphological Enhacement

With regard to morphological errors, three principal categories may be identified. Firstly, this pair presented a multitude of disambiguation issues. To illustrate, the preposition *para* (for) in Spanish was frequently analyzed as the third person singular of the verb *parar* (to stop). This resulted in errors such as: *Ir para casa* (go home) in Spanish was translated to Asturian as *ir* ***para*** *casa* innstead of *Ir* ***pa*** *casa*. These types of errors were corrected in a generic way by making use of the Constraint Grammar that had already been created by the Apertium community. However, it was also necessary to create new rules for specific cases.

Furthermore, the paradigms created for different grammatical categories contained various errors, either because the term had been assigned the wrong paradigm or because the assigned paradigm contained errors in its definition. To illustrate, Asturian verbs ending in *-ñir* or *-xir* (e.g. *teñir* (to dye) and *dirixir* (to address)) exhibited erroneous conjugation of the third person singular present indicative and subjunctive forms. This resulted in the generation of incorrect forms, such as *tiñió* (dyed) or *dirixió* (addressed), rather than the intended *tiñó* and *dirixó*. This was due to an erroneous assignment of the paradigm. It was thus necessary to create a specific paradigm for this type of verbs. Furthermore, a considerable number of Asturian verbs with enclitic pronouns were not correctly translated, resulting in the translation of their infinitive form instead of the expected conjugation. To address this issue, it was imperative to rectify the verb paradigms, which, due to inconsistencies with the paradigms of the Spanish dictionary, led to this

[9] See:https://wiki.apertium.org/wiki/Bilingual_dictionary

[10] The latest versions of Apertium include the Lexical Selection Rules module 3.2.3, which enables to assign a specific meaning and translation to the target language depending on the context. This module will be explained in subsection.

[11] See:https://wiki.apertium.org/wiki/A_long_introduction_to_transfer_rules

[12] See:https://wiki.apertium.org/wiki/Constraint-based_lexical_selection_module

[13] https://eslema.it.uniovi.es/comun/traductor.php

[14] https://github.com/apertium/apertium-spa-ast

type of error.

Finally, the transfer rules for this pair were found to contain numerous errors, which resulted in a significant decline in the quality of the translation. These errors manifested in various ways, including inconsistencies in gender or number between related nouns and adjectives, the absence of verb conjugation or declension, incorrect disambiguation, and other issues that affected the whole translation.

The aforementioned examples illustrate the work that has been carried out on the monolingual and bilingual packages. As a result, 172 transfer selection rules were corrected for both translation directions and 11 paradigms for each monolingual dictionary.

5.2 Lexical Enhacement

The dictionaries have been expanded to include new terms drawn from a number of fields, including administration, toponymy from both Asturias and Spain, and anthroponymy. In total, 3100 new terms have been incorporated into the dictionaries, with the inclusion of each new term informed by the preferences of the Dictionary of the Asturian Academy (*Diccionariu de la Academia de la Llingua Asturiana*) (DALLA[15]). Indeed, one of the most significant alterations implemented at the generic level within the Apertium dictionaries has been the selection of the cultured form in lieu of the vocalised form of the term. To illustrate, the choice of *-pt-* instead of *-ut-* in terms such as *conceptu/conceutu*, the choice of *-ps-* instead of *-us-* in terms like *cápsula/cáusula*, the choice of *-cd-* instead of *-ud-* in terms such as *anécdota/anéuduta* and the preference for the intervocalic *-x-* rather than the *-s-* found in terms such as *exame/esame* are examples of the aforementioned changes. Similarly, the *-zar* ending is preferred for verbs such as *forzar/forciar*, in contrast to the *-ciar* ending. Otherwise, as mentioned above, the DALLA shape was always preferred in all cases where there were two possibilities.

6 Results

Table 1 presents the BLEU (Papineni et al., 2002) and chrF++ (Popović, 2015) scores received from the OCELoT system. The table includes the ten best systems presented to this shared task and our own system, identified by the ID 580.

ID	BLEU	chrF++
576	**23.2**	**55.2**
606	19.8	52.2
574	19.7	52.2
528	18.4	52.1
609	19.8	52.1
551	18.2	51.6
557	17.9	51.6
629	18.0	51.6
568	18.0	51.6
564	18.0	51.6
580	17.6	51.2

Table 1: The best 10 scores obtained in the OCELoT system in the WMT24 Shared Task: Low Resource Languages in Spain (Spanish–Asturian) and the enhaced Apertium system, ID 580.

7 Analysis

In order to elucidate the outcomes yielded by our system and the top ten in this shared task, it is essential to examine the functioning of the BLEU and chrF++ metrics, on the one hand, and the FLORES test, on the other.

From one perspective, BLEU and chrF++ are lexical-based metrics that rely on a reference corpus to assess the quality of a translation. In essence, BLEU assesses the quality of the system by comparing the MT output with the reference test token by token at sentence or corpus level (Papineni et al., 2002). In contrast, the chrF++ metric functions in a comparable manner, albeit by comparing character by character rather than token by token (Popović, 2015). Both metrics have been the subject of criticism on the grounds of their reliance on a reference corpus, which presents a significant challenge for low-resource languages, such as Asturian. In the absence of the requisite test datasets, the evaluation with these metrics is often impractical. Furthermore, these metrics fail to account for the inherent variability and versatility of languages. In many cases, multiple translations may be equally valid for a given source sentence. However, these metrics treat any deviation from the reference corpus as an error, leading to artificially low metrics when the deviation is linguistically correct (Lee et al., 2023).

In light of the aforementioned considerations, it is pertinent to highlight that the FLORES+ corpus, which serves as the basis for the evaluation of the systems in this shared task, comprises 3001

[15] See:https://www.diccionariu.alladixital.org/

English sentences extracted from Wikimedia and translated manually by linguists into 200 minority languages, including Asturian. Subsequently, these translations are subjected to automatic revision and post-editing as required (Costa-jussà et al., 2022). It should be noted that the parallel corpora generated by this project are not direct translations. However, the translated text maintains the meaning of the original sentence while deviating from the structure of the source language. This may be due to the fact that the corpus was generated from English. Furthermore, as stipulated in the terms of reference for this shared task, the Asturian corpus has been duly revised by the Asturian Academy for use as a reference corpus in this shared task.

For illustrative purposes, three examples can be found in Table 2. In this table it can be found the original sentence in Spanish from the FLORES+ devtest in the first column, the original sentence in Asturian from the FLORES+ devtest in the second column and the version of the same sentence in English in the third column. This version in English is also taken from FLORES+ devtest. It is evident from these sentences that the translation from Spanish to Asturian is not a literal one, but rather a free rendering. In some cases, the meaning may even change. For instance, in the first sentence, the English meaning is retained in the Spanish sentence, but is lost in the Asturian translation. The direct translation of the sentence from Asturian to English would be: "They all ran back **when the accident happened**". "From where the accident had happened" and "when the accident happened" is not meaning the same. Furthermore, information can also be lost, as evidenced by the second sentence. Once more, the Asturian translation does not convey the same information as the original English sentence and the Spanish translation. In this instance, information is lost. Rather than referencing the navigable canals, the translation merely states that they are located inland, and instead of indicating that they are an optimal destination for "holidays", the translation simply uses the word *viaxes* (travels) which is not an equivalent expression. Furthermore, as evidenced in the third sentence, this phenomenon also occurs in the context of English–Spanish sentence translation. In such instances, the order of the sentence may undergo a change from English to Spanish, even when there is no necessity to align with the grammatical conventions of the target language. Even minor alterations such as this one have a deleterious impact on evaluation using lexical-based metrics.

These discrepancies within the parallel test corpora give rise to suboptimal results in metrics such as BLEU or chrF++, particularly in instances where the translated text may not be technically incorrect. This is not only the case for our system, but for all of them. The highest metric for BLEU is 23.2, while for chrF++ it is 55.2. These results are considerably low.

In regard to the results obtained by our system, it can be stated that Apertium, as a RBMT, produces translations that are literal in nature. In other words, unless it is a syntactic or grammatical feature intrinsic to the target language, the structure of the source language will always be replicated. In the case of Spanish and Asturian, which are two closely related languages, the MT output produced by Apertium will invariably adhere to the structure of Spanish, rather than exhibiting a more Asturian-specific structure. For illustrative purposes, consider the sentences presented in Table 3. This table presents the same sentences as in Table 2, with the second column displaying the translations generated by our system instead of the FLORES+ devtest Asturian sentences. The examples illustrate that the translation produced by Apertium preserves the structure of the source sentence in Spanish, but the translations are all accurate. It should be noted, however, that the system itself is not without limitations. It should first be noted that a word in Spanish has only one possible translation into Asturian, irrespective of context. While this can be managed in some specific cases, it may result in the translation failing in other sentences. It is possible that the inflexibility of this system, which does not always permit adaptation to context, may have had an adverse effect on our results, extending beyond the aforementioned metrics and the test employed. Nevertheless, we consider the output of our system to be a satisfactory translation that could be competitive with other systems despite the results. However, it would be necessary to carry out more tests in order to go deeper and identify the aspects in which the quality of our translation system could be improved, since the RBMT systems, as already mentioned, require constant revision and improvement.

Finally, and this is a strong point of our proposal, this type of system does not have a high computational consumption like Statistical Machine

Original Sentences in Spanish	**Original Sentences in Asturian**	**Original Sentences in English**
Todos volvieron corriendo desde el lugar del accidente.	*Volvieron p'atrás corriendo cuando ocurrió l'accidente.*	They all ran back from where the accident had happened.
Los canales navegables internos pueden ser una buena temática para las vacaciones.	*Les canales d'interior son un bon tema de viaxe.*	Inland waterways can be a good theme to base a holiday around.
En Inglaterra, las vías de tren ya se habían instalado hacia el siglo XVI.	*Les primeres víes foron construyíes n'Inglaterra nel sieglu XVI.*	Wagonways were built in England as early as the 16th Century.

Table 2: Illustrative sentences of the FLORES test dataset taken from the FLORES+ devtest in Spanish, Asturian and English languages.

Original Sentences in Spanish	**Apertium MT output**	**Original Sentences in English**
Todos volvieron corriendo desde el lugar del accidente.	*Toos volvieron corriendo dende'l llugar del accidente.*	They all ran back from where the accident had happened.
Los canales navegables internos pueden ser una buena temática para las vacaciones.	*Les canales navegables internos puen ser una bona temática pa les vacaciones.*	Inland waterways can be a good theme to base a holiday around.
En Inglaterra, las vías de tren ya se habían instalado hacia el siglo XVI.	*N'Inglaterra, les víes de tren yá s'instalaren escontra'l sieglu XVI.*	Wagonways were built in England as early as the 16th Century.

Table 3: Apertium MT output from the Spanish–Asturian translation of three sentences taken from FLORES+ devtest in their Spanish and English version.

Translation (SMT) and Neural Machine Translation (NMT) in its training, as signalled by Shterionov and Vanmassenhove (2023). Comparing the quality produced by this system with its consumption, both for training/development and for use, Apertium is still a competitive system for low-resource languages such as Asturian. Furthermore, it is also more cost-effective to produce than other types of systems. Therefore, it is essential to consider the trade-off between quality, consumption and price in order to assess the performance of the different systems.

8 Conclusions

In conclusion, although our enhanced Apertium system has not yet achieved a position among the top ten systems in this shared task, the results obtained in terms of machine translation quality have been exemplary. As previously stated in the Section 7, the test employed and the metrics utilized do not permit an accurate assessment of the quality of a MT system. Additionally, it is noteworthy that a RBMT exhibits a markedly lower consumption rate in comparison to NMTs. Consequently, we regard our system as being competitive with those submitted to this shared task, although it still necessitates further enhancements and revisions.

Abstract

This paper describes the submissions of the Transducens group of the Universitat d'Alacant to the WMT 2024 Shared Task on Translation into Low-Resource Languages of Spain; in particular, the task focuses on the translation from Spanish into Aragonese, Aranese and Asturian. Our submissions use parallel and monolingual data to fine-tune the NLLB-1.3B model and to investigate the effectiveness of synthetic corpora and transfer-learning between related languages such as Catalan, Galician and Valencian. We also present a many-to-many multilingual neural machine translation model focused on the Romance languages of Spain.

1 Introduction

Spain is home to several languages, each with different levels of representation in neural machine translation (NMT) technologies and availability of training data. For example, Spanish (spa) has abundant data resources and is included in many multilingual translation models and large language models (LLM). Other languages, such as Catalan (cat) and Galician (glg), are relatively well-supported and have enough data to train NMT models from scratch. However, languages such as Asturian (ast), Aragonese (arg) and Aranese (arn) face significant challenges due to the limited availability of data needed to train these systems.

Despite these challenges, the linguistic similarity between some of these languages simplifies their integration into multilingual translation models, allowing them to benefit from transfer-learning from more widely represented languages; an example of this is the inclusion of Asturian in NLLB-200 (NLLB Team et al., 2022). In addition, shallow-transfer rule-based machine translation (MT) systems such as Apertium (Forcada et al., 2011), exist for some of these languages, including Spanish–Asturian[1], Spanish–Aragonese[2] and Occitan–Spanish[3]; the development of rule-based systems does not require large amounts of training data, but linguistic knowledge to construct dictionaries and translation rules.

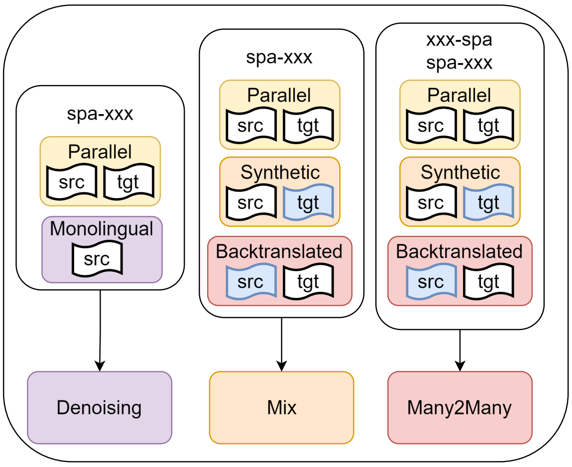

Figure 1: Submitted models for the shared task. Blue in *src* or *tgt* indicates text generated by MT. The Denoising and Mix models were trained for a single translation direction, whereas the Many2Many model was trained with multiple language pairs and in both translation directions for each pair. xxx represents any of the target languages: Aragonese, Aranese and Asturian.

Our approach to developing NMT systems for the WMT 2024 Shared Task on Translation into Low-Resource Languages of Spain (Sánchez-Martínez et al., 2024) for Aragonese, Aranese and Asturian is based on pre-trained models that include similar languages, such as NLLB-200, to incorporate languages that were not originally seen during training. Given the scarcity of corpora for Asturian, Aragonese and Aranese, we used Apertium to generate synthetic corpora. This involved translating monolingual corpora into Spanish and vice versa to generate additional resources for fine-

tuning NLLB-200.

By combining pre-trained multilingual models, synthetic data generation and rule-based translation systems, we aim to improve the quality and accessibility of NMT for these low-resource languages.

All of our submissions, shown in Figure 1, are classified as *open* because they are based on the NLLB-200 model with 1.3B parameters, exceeding the 1B parameters limit for *constrained* submissions. However, we only used the corpora allowed for constrained submissions, as described in Section 3.

2 State-of-the-Art Methods Used

Our submission makes use of well-established techniques such as denoising pre-training (Lewis et al., 2020), transfer-learning (Zoph et al., 2016), back-translation (Sennrich et al., 2016) and sequence-level knowledge distillation (Kim and Rush, 2016). The languages involved in this shared task are related, making knowledge transfer by a multilingual model an effective solution. This transfer can be achieved by bilingual fine-tuning of a pre-trained model (Zoph et al., 2016), using the knowledge it already possesses, or by multilingual training from scratch (Bommasani et al., 2021), using multiple languages simultaneously during the training process. In our approach, we fine-tune the NLLB-200 model and investigate the effects of training with only one specific translation direction with different types of data, as well as adding more languages during training.

A common technique is to pretrain a system on monolingual corpora with the denoising task[4] to learn language generation, and then train the system on parallel bilingual corpora for translation (Lewis et al., 2020). It is well known that combining both tasks simultaneously improves the translation results (Kamboj et al., 2022). Since NLLB-200 was trained in this way (NLLB Team et al., 2022), it is reasonable to use the same technique for fine-tuning to leverage the available monolingual corpus.

Corpus	Sentences	Src words	Tgt words
spa-arg	33,723	3,706,154	3,589,002
spa-arn	85,491	14,720,677	14,266,772
spa-ast	45,506	6,844,424	6,663,424
spa	500,000	62,004,331	—
arg	24,675	2,718,855	—
arn	229,886	29,110,670	—
ast	38,868	5,504,371	—
spa-cat	559,805	91,543,160	88,057,754
spa-glg	184,861	30,716,538	28,753,332
spa-val	287,403	52,836,299	53,137,411

Table 1: Number of sentences and words in each of the corpora used.

Another method of exploiting monolingual corpora is to create synthetic parallel corpora. For this purpose, we used the rule-based MT systems built using the Apertium platform (Forcada et al., 2011). Specifically, we used Catalan–Spanish, Aragonese–Spanish, Aranese–Spanish, Spanish–Aragonese, Spanish–Aranese and Spanish–Asturian systems. Translating from source (spa) to target and using this synthetic corpus as a target for training is a type of sequence-level knowledge distillation (Lai et al., 2021; Yu et al., 2021). In contrast, translating from the target language and using this synthetic corpus as the source for training is called back-translation (Sennrich et al., 2016). The latter has the advantage that potential translation errors in the synthetic corpus do not affect the generation of the target language, as the synthetic corpus is used as input during training rather than as the desired output.

3 Data

We used only the corpora allowed for the constrained submissions: Opus[5] and PILAR (Galiano-Jiménez et al., 2024)[6]. For the development set, we used the FLORES+[7] (NLLB Team et al., 2022) dev versions (997 sentences) for Spanish (spa), Aranese (arn), Aragonese (arg) and Asturian (ast) (Pérez-Ortiz et al., 2024). The specific details of the corpora used are described below and shown in Table 1.

3.1 Parallel Corpora

Aragonese and Asturian: We used parallel corpora with Spanish available in OPUS,[8] consisting of 33,723 Spanish–Aragonese sentences and 45,506 Spanish–Asturian sentences.

[4] The denoising task is a self-supervised learning strategy that helps models learn effective representations from monolingual data by training them to restore original sentences from corrupted inputs.

[5] `https://opus.nlpl.eu/`

[6] `https://github.com/transducens/PILAR`

[7] `https://github.com/openlanguagedata/flores`

[8] `https://opus.nlpl.eu/`

Aranese: We used the parallel Catalan-Aranese corpus available in PILAR (85,491 sentences) and translated the Catalan part into Spanish using Apertium. This corpus was not included in the synthetic data description in section 3.3, as it was not automatically translated from or into Aranese.

3.2 Monolingual Corpora

We used the monolingual corpora available in PILAR, which contains 24,675 sentences in Aragonese, 229,886 in Aranese and 38,868 in Asturian.

3.3 Synthetic Corpora Generation

We used Apertium to generate different synthetic corpora. By translating the above monolingual corpora into Spanish, we created two corpora (there is no Asturian–Spanish system for Apertium) that were used for back-translation. Since these corpus sizes are relatively small for training NMT models, we also translated 500,000 Spanish sentences extracted from Paracrawl[9] into Aranese[10], Aragonese[11] and Asturian[12]. This resulted in synthetic corpora with the target language as the synthetic part.

3.4 Additional data

For our multilingual system, we used all the above corpora and added Wikimedia Spanish–Catalan (559,805 sentences) and Spanish–Galician (184,861 sentences) corpora from OPUS, as well as the Spanish–Valencian (val) corpus available in PILAR, making 287,403 sentences.

4 Methodology

We trained several models for each language pair to analyse the effects of different types of corpora and transfer-learning between different tasks and languages. Below we describe the methodology we used and the different systems we trained.

4.1 Model Architecture and Baseline

All our models are based on a fine-tuning of the NLLB-200 (NLLB Team et al., 2022) model with 1.3 billion parameters. We chose this model because it is a transformer (Vaswani et al., 2017) pretrained with 200 languages and specialised in translation tasks. These 200 languages include Spanish and Asturian, which correspond to one of the translation directions in this shared task, as well as other related languages, such as Catalan, Galician and Occitan.

As a baseline, we used Apertium to compare the effectiveness of a rule-based system with a neural-based system.

4.2 Training Approaches

In this section, we describe the different approaches we used to train the translation models for each language pair.

Bilingual parallel: For each translation direction, we trained a specific model using only the parallel corpus available for that language pair. These models correspond to the `Parallel` row in tables 2 and 3.

Bilingual Parallel + Monolingual: We trained a model for each translation direction by combining the translation task using the parallel corpus with a denoising task using monolingual data of the target language. This approach helps to improve translation quality by exploiting additional monolingual resources. These models correspond to the `Denoising` row in tables 2 and 3.

Bilingual Synthetic Generated with Apertium: For each translation direction, we trained a model using only synthetic parallel corpora generated by translating the Spanish monolingual corpora into the target language using Apertium. These models correspond to the `Synthetic` row in tables 2 and 3.

Bilingual Parallel with Synthetic and Back-translation: For each translation direction, we trained a model using a combination of parallel corpora, synthetic corpora generated with Apertium, and back-translation. For back-translation, we used Apertium to translate the monolingual target language data into Spanish. These models correspond to the `Mix` row in tables 2 and 3.

Multilingual Parallel with Synthetic and Back-translation: This model extends the previous approach by training a single model on all three translation directions. This multilingual training allows

[9] https://opus.nlpl.eu/ParaCrawl/es&ca/v9/ParaCrawl

[12] https://github.com/apertium/apertium-spa-ast/releases/tag/v1.1.1

the model to benefit from common linguistic features across languages. This model corresponds to the `Multilingual` row in tables 2 and 3.

Multilingual Many-to-Many: This model extends the multilingual approach by incorporating parallel corpora from related languages and including both translation directions for each language pair. This model can translate between Spanish, Aragonese, Aranese, Asturian, Catalan, Galician and Valencian. This model corresponds to the `Many2Many` row in tables 2 and 3.

Model	spa-arg	spa-arn	spa-ast
Apertium	66.0	38.0	17.1
Parallel	41.4	34.4	17.9
Denoising*	41.6	35.7	17.8
Synthetic	65.3	37.6	17.0
Mix*	65.1	37.8	17.0
Multilingual	64.8	37.5	17.0
Many2Many*	65.2	37.9	17.0

Table 2: BLEU scores on the FLORES+ dev. Models marked with an asterisk are those we submitted for the Shared Task.

4.3 Evaluation Metrics

To measure the quality of the translation models, we used BLEU (Papineni et al., 2002)[13] and chrF2 (Popović, 2015)[14] scores on the translation of the development set. For the NLLB-200 based models, we translated using beam search (Graves, 2012) with a beam size of 5.

5 Experiments and Results

In this section, we present the experimental setup, including hyperparameters and training configurations. We compare the performance of each system against the baseline provided by Apertium and discuss the results for each translation direction.

5.1 Experimental Setup

All our translation models were trained using the Transformers (Wolf et al., 2020) library on an Nvidia A100 GPU with 40 GB of memory. We extended the library to support simultaneous training with multiple tasks, including different datasets with different languages and combining translation and denoising tasks[15]. To balance the training data from datasets of different sizes, we used temperature upsampling with $1/T = 0.3$, following the approach used in NLLB-200 training (NLLB Team et al., 2022).

Due to GPU memory constraints, we used a batch size of 16 and accumulated gradients as many times as the number of different datasets used in the training to ensure that all tasks were seen before updating the model weights. The learning rate was set to 5e-5, and we used the AdamW optimizer (Loshchilov and Hutter, 2017) with β_1=0.9, β_2=0.999 and ε=10^{-8}. Models were trained for a maximum of 100 epochs with early stopping, and evaluations were performed every 1000 training steps. The stopping criterion was based on the BLEU score on the development set, with a patience of 6 evaluations.

We used the NllbTokenizer[16] class for corpus segmentation. This tokenizer uses the SentencePiece (Kudo and Richardson, 2018) model used by NLLB-200 and applies language tokens to both the source and target texts.

NLLB-200 uses language tokens in both the source and target sentences. When training with a new language, it is possible to use the language token of a similar language, but this eliminates the possibility of translating to or from the language of the original token. In our case, we added new language tokens for Aragonese, Aranese and Valencian. To avoid learning the embeddings for these tokens from scratch, we initialised them with the embeddings of the most similar languages included in NLLB-200. Specifically, we initialized the embeddings for Aragonese and Valencian with the Catalan embedding, and the embedding for Aranese with the Occitan embedding[15].

5.2 Results

Tables 2 and 3 show the results of the translation models in terms of BLEU and chrF scores, respectively. The first row corresponds to the Apertium baseline and the remaining rows show the results of each trained model.

For the shared task, we submitted specific Denoising and Mix models for each translation direction, and the Many2Many model for all three

Table 3: chrF2 scores on the FLORES+ dev. Models marked with an asterisk are those we submitted for the Shared Task on Translation into Low-Resource Languages of Spain.

Model	spa-arg	spa-arn	spa-ast
Denoising	37.8	27.0	17.4
Mix	60.2	28.5	16.9
Many2Many	59.8	28.5	16.8

Table 4: BLEU scores on the WMT 2024 Shared Task on Translation into Low-Resource Languages of Spain test.

directions [17]. This allows us to compare a model trained only on the available corpus for each language, another that incorporates a synthetic corpus, and one that includes multiple translation directions and additional languages. The results on the test set of the task, which correspond to the FLORES+ devtest versions of these languages, are shown in Tables 4 and 5.

When analysing the results, it is important to consider how the development sets were created (Pérez-Ortiz et al., 2024). The Asturian sentences were first professionally translated from English by Meta (NLLB Team et al., 2022) and then revised by academics. In contrast, the Aragonese and Aranese sentences were first machine translated from Spanish using Apertium, then manually edited by language specialists and finally reviewed by academics. This means that the development sets for Aragonese and Aranese may be biased towards the results produced by Apertium.

We conducted paired significance tests to determine whether the submitted models outputs were significantly different despite the similarity of some results. Specifically, we calculated paired approximate randomisation (Riezler and Maxwell, 2005) as implemented by SacreBLEU on the devtest using BLEU and chrF2. The results indicated that the differences between the Mix and Many2Many models for Asturian and Aranese were not statistically significant, whereas the differences between all the other pairs of models were statistically significant.

Model	spa-arg	spa-arn	spa-ast
Denoising	67.5	48.3	50.7
Mix	78.9	49.3	50.9
Many2Many	78.8	49.3	50.9

Table 5: chrF2 scores on the WMT 2024 Shared Task on Translation into Low-Resource Languages of Spain test.

Effect of adding a monolingual corpus: The results show a minimal difference when adding a monolingual corpus compared to training only with parallel corpora (rows 2 and 3 of Tables 2 and 3). However, this could be due to the amount of training data available. The improvement in the quality of the translations for the Aranese direction is particularly remarkable, since it is the largest monolingual corpus.

Effect of using the synthetic corpus produced by Apertium: The increase in performace for the synthetic models compared to the Denoising models for Aragonese and Aranese can be explained both by the difference in data volume and by the bias of the development sets. Conversely, there is a decrease in the results for Asturian, suggesting a bias in the other sets.

The combination of parallel and synthetic corpora in both target and source (Mix models) shows minimal variation in the results. Again, this may be due to the difference in the proportion of the corpus generated by the spa-xxx translation and that generated by the xxx-spa translation.

Effect of multilingual training: Combining multiple translation directions in the same training session complicates the learning task for the model, but also increases the amount of data available. Adding more languages slightly improves the results compared to training with only the languages of the common task.

6 Conclusions

Overall, the results highlight the critical role of training data volume in the development of effective NMT models. The challenge with large neural models lies in the insufficient amount of training

[17] The Many2Many model is available at https://huggingface.co/Transducens/IbRo-nllb

data available for low-resource languages, which limits the full potential of these architectures.

However, rule-based systems remain a viable option for these languages, although they require linguistic expertise to build. The use of these systems to generate synthetic corpora is proving beneficial in integrating low-resource languages into neural translation models and exploiting the advantages they offer.

Abstract

This paper details the submission of Samsung R&D Institute Philippines (SRPH) Language Intelligence Team (LIT) to the WMT 2024 Low-resource Languages of Spain shared task. We trained translation models for Spanish to Aragonese, Spanish to Aranese/Occitan, and Spanish to Asturian using a standard sequence-to-sequence Transformer architecture, augmenting it with a noisy-channel reranking strategy to select better outputs during decoding. For Spanish to Asturian translation, our method reaches comparable BLEU scores to a strong commercial baseline translation system using only constrained data, backtranslations, noisy channel reranking, and a shared vocabulary spanning all four languages.

1 Introduction

This paper details our constrained system for translating from Spanish to Aragonese (spa→arg), Aranese/Occitan (spa→arn), and Asturian (spa→ast) for the WMT24 Shared Task: Translation into Low-Resource Languages of Spain. We trained standard sequence-to-sequence Transformer architecture (Vaswani et al., 2017) from scratch combined with heavy data preprocessing (Cruz, 2023), data augmentation via backtranslation (Sennrich et al., 2016a), and noisy channel reranking (Yee et al., 2019) to achieve performance that is comparable to Apertium (Khanna et al., 2021) v3.9.6 for spa→ast. We present ablation results of the effect of data augmentation via backtranslation and noisy channel reranking with respect to BLEU scores. Furthermore, we analyzed the generated translations and we found that the model learned to regurgitate, i.e. repeat with minor modifications, the source Spanish sentences for the spa→ast case. We also identify rarely occurring characters that the model failed to learn. Lastly, we also investigated the effect of the length of back-translated data on improving model performance.

2 Methodology

2.1 Environment

For preprocessing, training, and generation, we used fairseq 0.12.2 and PyTorch 1.12.1. The training was done on either 2x NVIDIA Quadro GPUs or 8x NVIDIA P100 GPUs. We used Apertium[1] v3.9.6 for generating baseline results and generating backtranslated (BT) data whenever available for the language pair.

2.2 Data Preprocessing

We trained on the OPUS dataset (Tiedemann, 2016) for all language pairs. The data preprocessing pipeline utilizes the ratio-based filters and embedding-based filters of Samsung R&D Institute Philippines' WMT23 entry (Cruz, 2023). The dataset statistics before and after preprocessing can be found in Table 1.

For the parallel data, the data preprocessing pipeline are as follows: remove exact duplicate parallel data → ratio-based filters → embeddings-based filters. The ratio-based filters remove sentences based on sentence length, token length, character to token ratio, pair token ratio, and pair length ratio. Exact details on these criteria are explained in (Cruz, 2023). Similar to last year's paper, we tokenized and detokenized sentences using SacreMoses[2] before and after running our filters, respectively. The embeddings-based filter filters data based on the cosine similarity of a sentence pair using LaBSE (Feng et al., 2022). Using the methodology of (Cruz, 2023), pairs with a cosine similarity $0.7 \leq s \leq 0.96$ are kept.

For monolingual data, we combined the monolingual data of the target language and the target

side of parallel data from OPUS and then removed exact duplicates. We used this monolingual data to train language models for each target language.

After preprocessing of parallel and monolingual data, we apply train and validation split of 95% and 5%, respectively.

Lastly, for the training corpus of the tokenizer, we combined the filtered parallel data of all three language pairs. We used this combined data to learn a shared BPE (Sennrich et al., 2016b) vocabulary that spans Spanish, Aragonese, Aranese, and Asturian consisting of 31,960 tokens using SentencePiece (Kudo and Richardson, 2018). This shared vocabulary was used by all models for generating submissions to WMT24. We used this approach as the four languages belong to the same language family.

2.3 Augmenting Data with Backtranslation

We augmented the filtered training data using backtranslation (Sennrich et al., 2016a). For each language pairs for both source→target (except spa→ast) and target→source directions, Apertium 3.9.6 was used to generate BT data. Due to the lack of direct translation support for some language pairs in Apertium, the translation for arg→spa went through the following translation path: Aragonese → Catalan → Interlingua → Spanish[3]. For arn→spa, it goes through Aranese → Catalan → Spanish[4].

Translation from Asturian to Spanish is not supported by Apertium. Alternatively, we used the ast→spa model that was originally intended for noisy channel reranking (NCR), a technique which will be explained in Section 2.5, to generate BT data. For decoding, we used combined top-k and nucleus sampling:

$$\sum_{i=0}^{\delta_k} P(\hat{y}_i^{(T)}|x;\hat{y}^{(T-1)}) \cdot \delta_{temp} \leq \delta_p \qquad (1)$$

where δ_k is the top values considered for top-k sampling, δ_{temp} is temperature, δ_p is the maximum total probability for nucleus sampling. For these hyperparameters, we used the same values as (Cruz, 2023) which are as follows: δ_k = 50, δ_{temp} = 0.7, and δ_p = 0.93.

Once the BT data for each language pairs and translation direction are generated we took a subset in different ways. For BT data for training Direct Translation Models (spa→arg/ast/arn), we used all the generated BT data for spa→arg since it's less than 300K. For BT data of spa→ast and spa→arn, we keep the longest 300K sentences.

For BT data for training Channel Translation Models (arg/ast/arn→spa), we used all the BT data for arg→spa since it's less than 100K. For ast→spa, we randomly sampled 100K sentences. Due to time constraints, we did not generate BT data for arn→spa.

2.4 Model Training

For each language pair, we trained three types of models: a **Direct Translation Model**, a **Channel Model**, and a **Language Model** which will be detailed in the following subsections. These three models will be combined via Noisy Channel Reranking (Yee et al., 2019) which will be explained in Section 2.5.

2.4.1 Direct Translation Models

For each direct translation models (spa→arg/arn/ast), we trained encoder-decoder

[3] Apertium language codes: arg-cat→cat-ina→ina-spa

[4] Apertium language codes: oc_aran-ca→cat-spa

Transformer architecture (Vaswani et al., 2017) from scratch with and without BT data. We used the large variant of transformers which has 213M parameters[5]. We describe two training configurations: **tf-large60k** which was trained for 60,000 steps of which 3,000 are warmup steps, and **tf-large100k** which was trained for 100,000 steps of which 10,000 are warmup steps. Training settings with "-plusbt" suffix indicates that the model was trained on a mixture of provided training data and BT data. Otherwise, it indicates the model is trained only on the provided training data. For example, **tf-large100k-plusbt** means the model was trained on the mixture of provided training data and BT data for 100,000 steps of which 10,000 are warm up steps.

For both settings and all language directions, unless stated otherwise, we used the same hyperparameters in Table 2. For generating WMT24 submissions, we used models trained on **tf-large100k-plusbt** setting as our Direct Translation Model.

2.4.2 Channel Translation Models

For the channel translation models (arg/arn/ast→spa), we used the same architecture and hyperparameters as the direct translation models, except it was trained on **tf-large60k-plusbt** setting, batch size/max tokens of 10,000, and learning rate of 7e-4 (arg→spa and arn→spa) and 5e-5 (ast→spa). These were used as channel models for noisy channel reranking which is explained further in Section 2.5 and for performing hyperparameter sweeps of noisy channel reranking parameters detailed in Section 2.6.

2.4.3 Language Models

We trained monolingual language models for Aragonese, Aranese, and Asturian from scratch using the decoder-only part of the original Transformer architecture as described in (Vaswani et al., 2017). We used the base variant which has 65M parameters[6]. For all languages, we used Adam optimizer (Kingma and Ba, 2017) with β_1=0.90, β_2=0.98. We trained for a maximum of 250,000 steps of which 4,000 are warmup steps. The warmup initial learning rate is 1e-7 and the max learning rate is 5e-4 and then decayed following an Inverse Square root learning rate schedule. The batch size / max tokens is 40,000, and the dropout is 0.1. These models were used in noisy channel reranking which is explained further in Section 2.5 and for performing hyperparameter sweeps of noisy channel reranking parameters detailed in Section 2.6.

Training Hyperparameters	
Vocab Size	31,960

Adam ϵ	ϵ=1e-6
Learning Rate	5e-5
LR Schedule	Inverse Sqrt
Batch Size	8,000 tokens

Table 2: Fixed hyperparameters for direct translation models.

2.5 Noisy-Channel Reranking

Similar to (Cruz, 2023), we experimented with using Noisy Channel Reranking (Yee et al., 2019) to improve translations. This works by using a direct translation model (source→target), channel model (target→source) and a monolingual language model (target only) to rescore every candidate translation token during beam search decoding. The score of the candidate translation token $\hat{y}_i^{(T)}$ at time step T is recomputed using a linear combination of all three models:

$$\begin{aligned} P(\hat{y}_i^{(T)}|x;\hat{y}^{(T-1)})' &= \frac{1}{t}\log(P(y|\hat{x}^{(T-1)}) \\ &+\frac{1}{s}[\delta_{ch}\log(P(x|\hat{y}^{(T-1)}) \\ &+\delta_{lm}\log(P(\hat{y}^{(T-1)}))] \end{aligned} \tag{2}$$

where t is the length of target sentence y and s is the length of source sentence x which serves as debiasing terms. The δ_{ch} and δ_{lm} are weights of the channel model and language model, respectively, which controls the influence of the models to the final score. For this paper, both δ_{ch} and δ_{lm} were set to 0.5

2.6 Hyperparameter Sweeping

Similar to (Cruz, 2023), we utilized a Bayesian hyperparameter search to find an optimal value for

length penalty. The length penalty sweep was performed for 137 iterations sampling from a uniform distribution with minimum 0.0 and maximum 2.0. Hyperparameter sweeping was performed using the **tf-large60k-plusbt** direct translation models with noisy channel reranking enabled on the Spanish to Aragonese language pair. Translations for the hyperparameter sweep were generated from the copy of FLORES+ (Team et al., 2022) found in the PILAR (Galiano-Jiménez et al., 2024) repository[7]. The results of this sweep were used on all language pairs. We performed the sweep on spa→arg only and on a **tf-large60k-plusbt** model due to hardware and time constraints. Our sweeps showed that setting length penalty to 1.726 is optimal.

3 Results and Discussion

In this section, we discuss the results of our experiments and discuss our findings. Experiments were performed using the copy of FLORES+ (Team et al., 2022) found in the PILAR (Galiano-Jiménez et al., 2024) repository were computed using SacreBLEU[8] (Post, 2018).

For all translations, we used the following decoding hyperparameters: top_k=50, top_p= 0.93, temperature=0.7, beam=5. Additional hyperparameters are specified per experiment.

3.1 Comparison Against Baselines

We compare our system against Apertium 3.9.6. Results are listed in Table 3. We observe that Apertium yields the highest BLEU score for spa→arg and spa→arn. For spa→ast, the systems trained with BT data both outperform the Apertium baseline.

Our method performs worst on the spa→arn language pair while it performs best for spa→arg. However for both of these pairs our system is outperformed by Apertium. From this we can conclude that our current pipeline cannot overcome the low resource nature of these language pairs in order to close the gap with Apertium. For spa→ast, we were able to outperform Apertium with a difference of 1.8 BLEU.

3.2 Ablations

We perform an ablation study by varying model size, use of BT data, and use of noisy channel reranking. Due to hardware and time constraints, we only perform our ablations in the spa→arg direction. Results are summarized in Table 4.

We observe that the addition of BT data and

[7] https://github.com/transducens/PILAR

[8] SacreBLEU signature: nrefs:1|case:mixed|eff:no|tok:flores101|smooth:exp|version:2.4.2

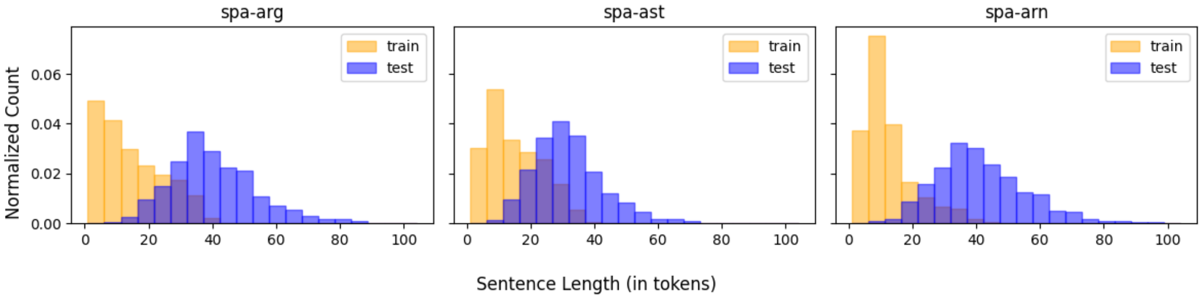

Figure 1: Sequence length distribution of the target side of the train (filtered) and test set per language pair. spa-arn has the least overlap between train and test and has the most short examples in training data which hints why the BLEU score is relatively lower compared to other language pairs.

noisy channel reranking resulted in an increased BLEU score. Using both strategies yields the highest BLEU score for both base and large model sizes. It is notable that the base model with both BT data and noisy channel reranking yields the highest BLEU score in our ablation study. We speculate that this be due to the large model having too many parameters for the given task or a lack of data. Another reason is that spa-arn is relatively easier compared to other language pairs because the source and target are more similar with each other as shown in Table 6. More experiments are needed to confirm these.

3.3 Adding Longer Examples Improves BLEU Better than Shorter Examples

For the spa→arn baseline model (No BT), we observed a BLEU score of 8.7 on FLORES+ dev set. One possible explanation for the low score is the mismatch between the length distribution of training and test data. We observed that the training data is comprised mostly of short examples while the FLORES+ dev set is relatively longer (see Figure 1). We hypothesize that adding longer examples to the training set will improve BLEU score, especially on longer examples.

To provide evidence for the hypothesis, we generated BT data of size 100,000 for different length groups namely, short-BT (1-10 words), mid-BT (11-20 words), long-BT (20+ words). We mixed the BT data with the training data then trained a model for each setup. We trained each model for 50,000 of which 5,000 are warmup steps. We used the same training hyperparameters as in Table 2. For fair comparison, we trained a baseline model (no-BT) using the same training hyperparameters. For generating the translations, we did not use noisy channel reranking and we fix the length penalty to 1.0. The results are summarized in Table 5.

The result shows that long-BT gives an absolute BLEU score improvement of +6.1 over baseline, followed by mid-BT (+3.4), and then short-BT (+2.3). This tells us that while augmenting with BT data generally improves the performance, strategically adding more long examples can give the most improvements in a resource-constrained setting. To strengthen this claim further, we performed a fine-grained test by grouping FLORES+ dev set by length groups (mid/long). For this experiment, we did not include the short length group because it only contains 3 examples after grouping. The results shows that long-BT gives the most improvements on mid and long test groups, followed by mid-BT and short-BT (see Table 5). This suggests that training on longer sequences also improves performance on shorter sequences.

While this experiment shows empirical results that adding longer examples improves the overall BLEU score better than adding shorter examples, it does not say something about the quality and diversity of the text. It is possible that these findings might not hold if the long examples are of low quality. Another possible explanation on why long-BT outperforms its shorter counterparts is because, with the same number of examples of 100,000, long-BT contains more tokens than short-BT and mid-BT. To further solidify the claim that adding longer examples improves the overall BLEU score better than adding shorter examples, more experiments are needed where total token count per length group are equal or close to each other.

Language Pair	JS (generated) ↑	ED (generated) ↓	JS (ground truth) ↑	ED (ground truth) ↓
spa→arg	0.34	0.59	**0.34**	**0.57**
spa→arn	0.23	0.69	0.13	0.83
spa→ast	**0.44**	**0.44**	0.23	0.76

Table 6: Average Jaccard similarity (JS) and average normalized edit distance (ED) between source and generated translations and ground truth translations. Results confirm our observatoin that our system is regurgitating Spanish source sentences in the spa→ast direction. Results also suggest that the Spanish and Aragonese sentences in the FLORES+ dev set are more similar to each other compared to others.

3.4 Regurgitation of Spanish Sentences in Generated Translations

We observed that our model was producing some translations that were only slightly altered versions of the source Spanish sentence. To empirically evaluate the extent of this problem for our system, we compare the BPE tokenized source Spanish sentences of the FLORES+ dataset from PILAR to the corresponding generated translations made by our system and the corresponding ground truth. We compared this system via two metrics: Jaccard similarity (JS) and normalized edit distance (ED). To compute the two metrics between two BPE encoded sentences S_1 and S_2, we get the set of tokens of each sentence T_1 and T_2 and compute Jaccard similarity as

$$JS = \frac{|T_1 \cap T_2|}{|T_1 \cup T_2|}$$

and normalized edit distance as

$$ED = \frac{D(S_1, S_2)}{\max(|S_1|, |S_2|)}$$

where $D(S_1, S_2)$ denotes token-level Levenshtein distance between BPE encoded sentences S_1 and S_2. We divide by the maximum length between S_1 and S_2 to ensure that we get a value between 0 and 1. Results of this analysis are summarized in Table 6.

We observe that spa→ast shows the highest average Jaccard similarity and the lowest normalized edit distance among language pairs for generated translations; however, the corresponding metrics for the spa→ast ground truth translations tell a different story. Ground truth translations for spa→ast show a lower Jaccard similarity and a higher normalized edit distance, indicating that we may be regurgitating Spanish sentences.

Below is a sample of a Spanish sentence together with a generated Asturian translation which exhibits regurgitation and the corresponding ground truth translation. Notice how the generated translation is closer in similarity to the Spanish sentence than the correct Asturian translation. In the below example, "S -" is the source spanish sentence, "H -" is the generated Asturian translation, "T -" is the ground truth Asturian translation, "J -" is the jaccard similarity compared to the source Spanish sentence, and "E -" is the normalized edit distance compared to the source Spanish sentence. All sentences are BPE encoded.

```
S - _Apenas _pas adas _las _11: 00 _h , _los
    _integrantes _de _la _manifestación _bloque
    aron _la _circulación _del _car ril _de
    _White h all _que _va _hacia _el _norte .

H - _Ap enes _pasa es _les _11: 00 _h , _los
    _integrantes _de _la _manifestación _blo qui
     aron _la _circulación _del _car ril _de
    _White h all _que _va _escontra ' l _norte .
J - 0.553
E - 0.303

T - _X usto _depués _de _les _11: 00, _los
    _manifestantes _blo qui aron _el _trá ficu
    _nel _sentíu _norte _en _White h all .
J - 0.244
E - 0.833
```

For spa→arg, Jaccard similarity and normalized edit distance are similar for both generated translations and ground truth translations. We note that this language pair has the highest Jaccard similarity and lowest normalized edit distance between its source Spanish sentences and ground truth Aragonese translations. This indicates that there is a degree of similarity between the Spanish and Aragonese sentences in the dataset which may explain why the spa→arg model exhibited the highest BLEU score in our baseline comparison. We provide a sample below where the source Spanish sentence is similar to the ground truth Aragonese translation.

```

We plot the histogram of Jaccard similarity and normalized edit distance for all language pairs in Figures 2, 3, and 4.

3.5 Character Set Analysis

We observe that our generated translations do not contain all characters present in the ground truth as shown in Table 7. For all languages, the missing characters are present in the training data with the exception of Õ for Asturian and Aragonese. All missing characters constitute less than 1% of the training data which may explain why they were not learned by our models.

4 Conclusions

We detailed our constrained system for translating from Spanish to Aragonese (spa→arg), Aranese/Occitan (spa→arn), and Asturian (spa→ast). These systems were trained from scratch on constrained data, augmented by backtranslated (BT) data. Translations were further improved by utilizing Noisy Channel Reranking. This approach outperformed Apertium on the spa→ast translation direction. Our ablation study for spa→arg showed that utilizing backtranslation and noisy channel reranking improves BLEU score. However, more experiment is needed for other language pairs. Our ablation experiment also suggests that smaller models are capable enough for spa→arg, at least for this train and test set.

We investigated the cause of low BLEU score for spa→arn despite having more data (after filtering) than spa→arg and spa→ast. We linked it to the train-test mismatch of spa-ast data in terms of sequence length. We also found that adding longer backtranslated data improves overall BLEU score even in shorter sequences.

Lastly, we observed that our model for spa→ast was regurgitating Spanish sentences in Asturian translations and that characters with low frequencies in the training data are not being learned by our models.

Limitations

We are unable to evaluate whether the translations we generate are syntactically or semantically sound due to the fact that none of us speak Spanish, Aragonese, Asturian, or Aranese/Occitan.

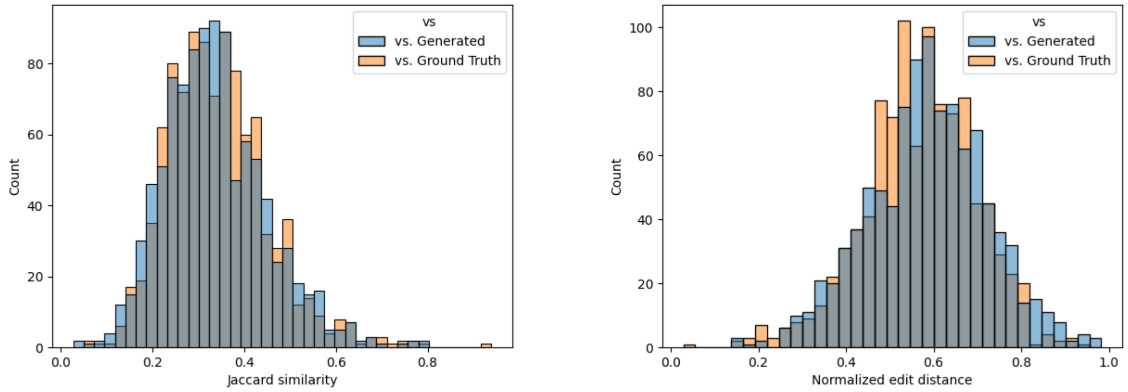
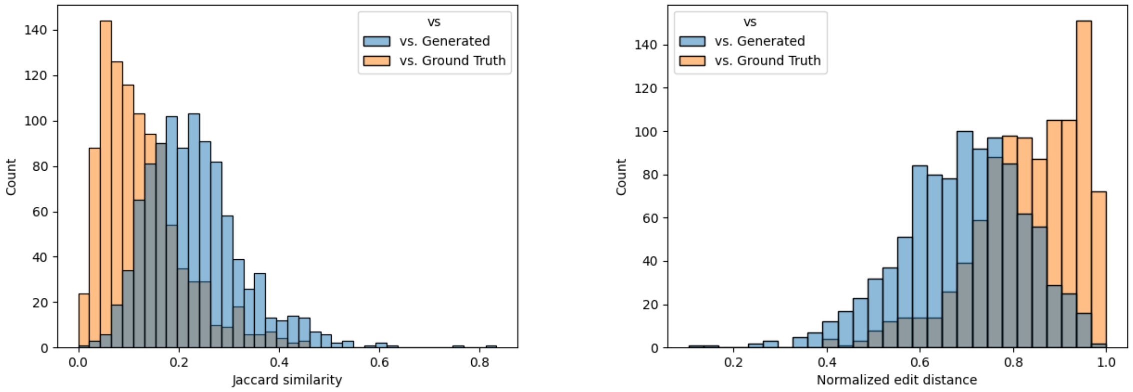
Language	Missing Characters	Frequency in Training Data	# Characters in Training Data
Aragonese	» «] & õ [Õ	1,583	4,713,907
Aranese/Occitan	& « » Ç Ò Õ *U+0301* ’	96,233	36,014,337
Asturian	" Õ Ú *U+1E24* ḥ – — ’	56,798	42,897,857

Table 7: Characters present in ground truth translations but missing in generated translations together with their frequency in training data compared to the total number of characters in training data. Unicode symbol code in italics listed when a character is unsupported by LaTeX. All missing characters constitute less that 1% of the training data.



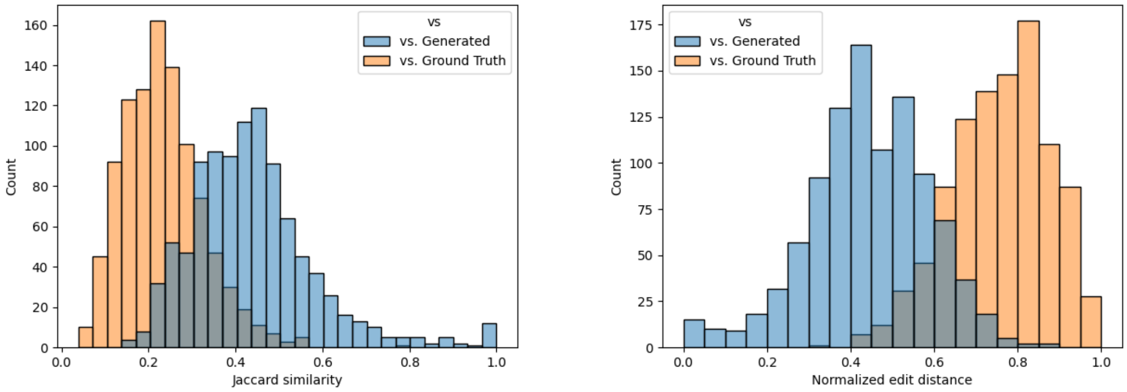
(a) (b)

Figure 2: Distribution of Jaccard similarity and normalized edit distance for spa→arg of source sentences vs generated translations and ground truth translations. We can see that the distributions for both Jaccard similarity and normalized edit distance almost entirely overlap. Taken together with the means from Table 6, these show that any regurgitation our model exhibits can also be seen in the ground truth test data.



(a) (b)

Figure 3: Distribution of Jaccard similarity and normalized edit distance for spa→arn of source sentences vs generated translations and ground truth translations. We can see in (a) that while Jaccard similarity of generated translations vs. source Spanish sentences is higher compared to that of ground truth translations vs. source Spanish sentences, they both tend to be less than 0.4. In (b), we see that while normalized of generated translations vs. source Spanish sentences is lower compared to that of ground truth translations vs. source Spanish sentences, they both tend to be greater than 0.6. This indicate low amounts of regurgitation in the case of our spa→arn system.



(a)

(b)

Figure 4: Distribution of Jaccard similarity and normalized edit distance for spa→ast of source sentences vs generated translations and ground truth translations. We see in (a) that the Jaccard similarity of generated Asturian translations compared to source Spanish sentences is higher than that of ground truth translations compared to source sentences. In (b), we see that the normalized edit distance of generated translations compared to source sentences is lower than that of ground truth vs. source sentences. This indicates that our model is regurgitating more Spanish words rather than translating to Asturian.

Abstract

This paper describes our submission to the *WMT24 shared task for Low-Resource Languages of Spain* in the Constrained task category. Due to the lack of deep learning-based data filtration methods for these languages, we propose a purely statistical-based, two-stage pipeline for data filtration. In the primary stage, we begin by removing spaces and punctuation from the source sentences (Spanish) and deduplicating them. We then filter out sentence pairs with inconsistent language predictions by the language identification model, followed by the removal of pairs with anomalous sentence length and word count ratios, using the development set statistics as the threshold. In the secondary stage, for corpora of significant size, we employ a Jensen-Shannon divergence-based method to curate training data of the desired size. Our filtered data allowed us to complete a two-step training process in under 3 hours, with GPU power consumption kept below 1 kWh, making our system both economical and eco-friendly. The source code, training data, and best models are available on the project's GitHub page[1].

1 Introduction

We[2] participated in the **Constrained submission** category of the WMT24 shared task for Low-Resource Languages of Spain (Sánchez-Martínez et al., 2024), focusing on the **Spanish-Asturian** language pair. For the **Constrained submission** category, we are limited to using only the resources provided on the official shared task site[3], and all models utilized must not exceed 1 billion parameters.

Previous shared tasks on data filtering have used deep learning-based scoring methods like LASER (Heffernan et al., 2022) and LaBSE (Feng et al., 2022), as well as sentence alignment methods such as SentAlign (Steingrimsson, 2023) and Vecalign (Thompson and Koehn, 2019). However, these methods often fail with low-resource languages (LRL) due to a lack language of support.

Following prior work (Cruz and Sutawika, 2022; Vegi et al., 2022; Zhang, 2023), we focus on statistical data filtration and sampling techniques to curate our datasets, ensuring our method is not limited to specific languages. Given our compute resource constraints, we design our pipeline to utilize small dataset sizes, enabling a larger volume of experiments. As noted in Ranathunga et al. (2024), randomly sampling a large corpus and training on that sample yields sub-optimal results. Therefore, we use the Jensen-Shannon Divergence (JSD) (Lu et al., 2020) to filter subsets from large corpora (see Section 3.1.1). We favor JSD over Kullback-Leibler (KL) divergence and higher-order domain discriminators due to its symmetric property and relatively simple implementation.

In addition to data filtration, we experiment with a two-step training schema. First, we train the entire model on a larger filtered dataset. Then, in the second step, we freeze the encoder layers and fine-tune the model on the filtered dataset for fine-tuning. This approach proved effective for the task. We select models with under 1 billion parameters for all experiments to adhere to the rules of the *Constrained task*.

Our key contributions are:

- We propose a two-stage data filtration system that can be applied to any language. This system includes statistical data filtration methods for bilingual and monolingual data, along with a Jensen-Shannon divergence-based filtration method.

November 15-16, 2024 ©2024 Association for Computational Linguistics

- We achieve competitive results in a compute resource-constrained environment (Table 4).
- Based on our experiments, we show that fine-tuning a multilingual translation model for a high-resource source language and a low-resource target language is most effective when high-quality monolingual target data is leveraged, and the encoder is frozen to preserve the source language knowledge while training the model.
- We maintain an effective training time well under 3 hours and keep the total GPU power consumption of our best model (training + fine-tuning) under 1 kWh, resulting in a minimal carbon footprint and enhancing the eco-friendliness of our training schema.

2 Related Work

Bilingual parallel data curated from web-mined corpora are prone to various types of noise. Kreutzer et al. (2022) investigated the issue of noise in web-mined corpora by analyzing a sample of 100 sentence pairs, providing evidence of the problem. In a similar vein, Khayrallah and Koehn (2018) examined how different types of noise in parallel training data impact the quality of neural machine translation systems. Building on this body of work, Ranathunga et al. (2024) further established that data quality is more critical than data quantity, particularly for low-resource languages. These studies collectively highlight the importance of addressing *bad* data in web-mined corpora.

Handling noisy parallel data in machine translation had been extensively studied, with various methods proposed in the literature. Below, we present these methods, grouping them into two main categories: (1) deep learning-based approaches and (2) statistical-based approaches. Additionally, we include methods that do not fit broadly into these categories under the section *Other Approaches*.

Deep Learning-Based Approaches. Recent advances in deep learning have introduced several methods to handle unclean data. Zhang (2023) proposed a denoising approach by pretraining on corrupted data and regenerating the original content. They utilized text corruption techniques as proposed by Lewis et al. (2020), including token masking, sentence permutation, document rotation, token deletion, and text infilling. They pretrained models on synthetic and monolingual data and fine-tuned them on clean parallel corpora, achieving translation perplexity scores by training two models and analyzing prediction difficulties. Ensembling methods were also employed to enhance performance. Chaudhary et al. (2019) utilized LASER and an ensemble of scoring methods to check the similarity between embeddings and cross-entropy scores for both directions, penalizing significant differences. Abdulmumin et al. (2022) developed a binary classifier to predict translation accuracy, collecting positive data from a gold standard dataset and negative data from the worst LASER alignment scores. Unfortunately, majority of the methods and models mentioned above do not support Asturian, Aragonese, or Aranese.

Statistical Approaches. Steingrímsson et al. (2023) applied rules such as filtering sentences with three tokens or less, ensuring 60% or more token overlap between languages, and requiring at least 70% alphabetical characters in both sentences. Vegi et al. (2022) introduced constraints such as filtering sentences where the source or target exceeds 800 characters, where the length ratio is greater than 2.5 or less than 0.4, or where words exceed 10 characters. Cruz and Sutawika (2022) extended these rules to include sentences with too many contiguous punctuations (three or more), a large percentage of numbers or punctuations, and additional filtering criteria. Minh-Cong et al. (2023) proposed building a dictionary using MGiza++ and clean parallel corpora, translating source sentences, calculating edit distances, and iteratively training NMT models, assuming the availability of clean parallel corpora.

Other Approaches. Other approaches for handling unclean data include additional filtering rules proposed by Vegi et al. (2022), such as removing sentences that are empty or identical between source and target. Cruz and Sutawika (2022) suggested removing sentences with missing punctuations in one language, sentences containing HTML or URLs, ensuring numbers appear in both source and target, and deduplicating data after preprocessing. Steingrímsson et al. (2023) recommended using a language filter to ensure both languages are in the top two predictions and removing near-duplicate pairs.

3 Methodology

Training Datasets: For training, we use bilingual datasets from OPUS[4] CCMatrix and WikiMedia (Spanish-Asturian), subjected to the filtration outlined in section 3.1.1. We also use monolingual datasets, specifically the PILAR (Galiano-Jiménez et al., 2024b) Asturian monolingual dataset and the Spanish side of the English-Spanish Wikimedia dataset from OPUS, with filtration procedures detailed in section 3.1.2.

Development Set: We evaluate the trained models using the FLORES+[5] Spanish-Asturian development set, referred to as the development set throughout the paper.

Hardware Specifications: All experiments were conducted on a single machine with an Intel i9-9900K CPU, 64GB of RAM, and an Nvidia Quadro RTX 6000 (24GB VRAM).

Software Specifications: All models and training code were developed using the HuggingFace (HF) Transformers (Wolf et al., 2020) library. For evaluation, we use chrF and BLEU scores from the `evaluate`[6] library of HF. We utilized the work done by Nayak et al. (2023) to obtain the Jensen-Shannon divergence scores.

Models: We use NLLB-200-600M (NLLB Team et al., 2022) (we will address it as NLLB-600M throughout the paper), M2M100-418M (Fan et al., 2020) (we will address it as M2M100 throughout the paper), and SMaLL-100 (Mohammadshahi et al., 2022) to conduct experiments. All training and fine-tuning was performed on SMaLL-100 (see section 3.2)

Training Details: We use the HF Transformers Trainer API with the AdamW optimizer, a learning rate of 1×10^{-5}, and a batch size of 16. Gradient accumulation steps of 16 were used to increase the effective batch size to 256. Training is conducted in two steps: first, training the entire model using the filtered Spanish-Asturian CCMatrix dataset (Table 3); then, fine-tuning the best model from the training phase by freezing the encoder layers (Table 4).

Dataset used in fine-tuning step: For fine-tuning, we combined multiple datasets as follows (see Table 4 for results): Dataset A is the filtered Spanish-Asturian Wikimedia; Dataset B includes A + the filtered PILAR crawled monolingual data; Dataset C includes B + the filtered PILAR literary monolingual data; Dataset D includes C + the Spanish monolingual data from English-Spanish Wikimedia. All monolingual data were translated using NLLB-600M.

3.1 Data Filtration and Curation

3.1.1 Bilingual Data Filtration

Our Bilingual Data Filtration pipeline consists of two stages: Primary and Secondary.

Primary Filtration: We start by removing punctuation and whitespace from the Spanish text, then deduplicate it. Using Idiomata Cognitor (Galiano-Jiménez et al., 2024a), we classify the language of each sentence, removing those with inconsistent predictions. We analyze sentence length ratios and word counts, using the development set as a benchmark to remove anomalies.

Dataset	Before (M)	After (M)	% drop
Wikimedia - es_ast	0.04	0.03	38.99
CCMatrix - es_ast	5.39	2.01	62.72
Wikipedia - es_en	2.80	1.26	55.19
Wikimedia - es_en	1.81	1.31	27.47

Table 1: The table presents the sample count (in millions) before and after primary filtration, along with the percentage of samples dropped during this phase.

Secondary Filtration: For datasets over 300K sentences, we limit the size to 50K-300K sentences. We use the Jensen-Shannon divergence to refine the data. We sample sets of 2000 sentence pairs (with replacement) to form 1000 sets, remove Spanish stop words and punctuation with the *NLTK library*[7], and calculate word frequency distributions for each sample and the development set. We sort the samples by their divergence scores (Nayak et al., 2023) against the development set, and iteratively merge and deduplicate low-divergence samples until we have the target dataset size (as specified in Table 3). The implementation of the secondary filtration method is detailed in Algorithm 1.

$current\_size \leftarrow 0$
while $current\_size < S$ do
    $B_{candidate} \leftarrow scores[i].batch$
    $B_{final} \leftarrow B_{final} \cup \{B_{candidate}\}$
    De-duplicate(B$_{final}$)
    $current\_size \leftarrow Length(B_{final})$
end
return $B_{final}$
```

3.1.2 Monolingual Data Filtration

We extract monolingual data from PILAR crawled and literacy datasets for Asturian, and Wikimedia OPUS datasets for Spanish using the English-Spanish direction. Using *sentence-splitter*[8], we segment the PILAR text into sentences using the Spanish setting, achieving good performance despite the library's lack of support for Asturian. We removed URL links and retained sentences with a word count between four and sixty (the maximum in the development set). Sentences were then classified using the language identifier model Idiomata Cognitor (Galiano-Jiménez et al., 2024a), and those not identified as Spanish or Asturian were removed.

3.2 Model Selection

Translation Model Selection: Based on zero-shot performance scores, NLLB-600M was selected as the best model for translating the filtered monolingual dataset, outperforming both M2M-100 and SMaLL-100 in chrF and BLEU scores (Table 2).

Training Model Selection: Given the limited GPU resources in our training environment, we selected SMaLL-100 as the model for training and experimentation due to its smaller size and superior performance compared to M2M-100 (Table 2).

4 Results and Discussion

In this section, we present the results of our experiments using the proposed methods. The results from our primary data filtration step (Section 3.1.1) demonstrate the row counts of each dataset before and after filtration. Notably, our filtration method had the most significant impact on the CCMatrix (es-ast) and Wikipedia (es-en) datasets, with data reduction percentages exceeding 50%. Further investigation could be conducted to understand the factors contributing to this substantial data drop in these sources and to determine whether this observation is consistent across other language pairs in these datasets.

Table 2 displays the zero-shot performance of three state-of-the-art open-source models: NLLB-600M, M2M100, and SMaLL-100. NLLB-600M was selected as the model for generating translations for monolingual sentences due to its significantly better performance compared to the other two models. Given its smaller size and superior performance compared to M2M100, SMaLL-100 was chosen as the model for training and experimentation. By choosing the SMaLL-100 model, we gained the added advantage of using larger batch sizes due to the model's small size. This proved crucial in our low-compute resource environment.

Table 3 presents the results from the first step of the two-step training regime described in Section 3, applied to the CCMatrix filtered dataset. The data was incrementally filtered based on increasing Jensen-Shannon divergence scores in steps of 50k. We observe that model performance improves up to a subset size of 100K, after which it gradually declines. This observation aligns with the findings of Ranathunga et al. (2024), emphasizing that data

Model	chrF	BLEU	# of Trainable Params (M)
NLLB-600M	**49.77**	**17.16**	615.07
M2M100	46.27	14.71	483.91
SMaLL-100	48.47	14.85	**332.74**

Table 2: Scores for the zero-shot performance of the models evaluated on FLORES+ Spanish-Asturian dev set and number of trainable parameters for each model.

quality is more important than the sheer size of the dataset. Selecting smaller, higher-quality datasets not only enhances performance but also offers the additional benefits of reduced training time and lower computational requirements, which in turn minimizes the carbon footprint. As shown in Table 3, the best-performing subset required only 1.48 hours of training and consumed just 0.44 kWh of GPU power.

Size (k)	chrF	BLEU	Time (hrs)	Power (kWh)
50	49.63	17.25	0.72	0.21
100	**50.04**	**17.52**	1.48	0.44
150	49.84	17.26	2.25	0.66
200	49.95	17.34	2.92	0.86
250	49.81	17.36	3.68	1.09
300	49.70	17.02	4.42	1.30

Table 3: Scores, training durations, and GPU power consumption for training CC-Matrix Spanish-Asturian filtered datasets at intervals of 50K jumps. This is the first step in the training phase.

The results of our second step of model training (fine-tuning), where the encoder layers were frozen, are presented in Table 4. Among the various combinations, Dataset C demonstrated the best performance. This dataset includes Spanish-Asturian Wikimedia data as well as Spanish-Asturian PILAR crawled and literary datasets. Notably, the Spanish side of this dataset was generated using the translation model (NLLB-600M) for the PILAR Asturian monolingual crawled and literary datasets.

Interestingly, the performance drops when using Dataset D, which consists of Dataset C combined with Spanish data (Spanish-English Wikimedia) translated into Asturian using the translation model. This observation underscores the importance of high-quality target-side sentences, as the monolingual PILAR dataset comprises carefully curated, high-quality Asturian data. We hypothesize that since Spanish is a high-resource language, the model's encoder has likely been exposed to extensive Spanish data. By freezing the encoder and allowing the model to learn during this fine-tuning step, the model was better able to focus on the target language. Based on these observations, we conclude that when fine-tuning a pre-trained multilingual translation model for a high-resource source language and a low-resource target language, it is essential to leverage high-quality monolingual data for the target language and freeze the encoder to retain the learned knowledge of the source language while making the other layers trainable.

	Size (k)	chrF	BLEU	Time (hrs)	Power (kWh)
A	24.8	51.14	17.80	0.28	0.08
B	38.5	51.38	18.02	0.60	0.18
C	60.2	**51.47**	**18.17**	0.95	0.28
D	84.9	50.92	17.97	1.35	0.40

Table 4: Dataset name, Size, Scores, Time duration and the GPU Power consumption of fine-tuning the best model from Table 3. A = filtered Spanish-Asturian Wikimedia; B = A + filtered and translated PILAR crawled data; C = B + filtered and translated PILAR literary data; D = C + Spanish-Asturian data from English-Spanish Wikimedia.

The training time and GPU power consumption for the best datasets from our two-step training procedure (as shown in Table 3 and Table 4) remains well within 3 hours and consumes less than 1 kWh of GPU power. This makes our proposed method highly suitable for low-compute environments.

5 Conclusion

We presented a purely statistical-based pipeline for data filtering, demonstrating that simple statistical methods should not be overlooked, particularly for low-resource languages where deep learning-based methods may fail to provide adequate support. Our proposed pipeline achieved competitive performance in a low-compute environment for the constrained task, proving to be both economical, with training times well under 3 hours as well as eco-friendly, with GPU power consumption kept under 1 kWh. This work reinforces the findings of previous studies that emphasize the importance of data quality over quantity. We hope that our methodology will encourage and empower researchers in low-compute environments to contribute to an egalitarian representation of languages.

Acknowledgements

We would like to thank the National Languages Processing (NLP) Center, at the University of Moratuwa for providing the GPUs to execute the experiments related to the research.

We would like to thank Emojot Private Limited for allowing us to utilize their compute resources for this paper.

Abstract

The Helsinki-NLP team participated in the 2024 Shared Task on Translation into Low-Resource languages of Spain with four multilingual systems covering all language pairs in the open submission track. The task consists in developing Machine Translation (MT) models to translate from Spanish into Aragonese, Aranese and Asturian. Our models leverage known approaches for multilingual MT; namely, data filtering, fine-tuning, data tagging, and distillation. We use distillation to merge the knowledge from neural and rule-based systems and explore the trade-offs between translation quality and computational efficiency. We demonstrate that our distilled models can achieve competitive results while significantly reducing computational costs. Our best models ranked 4th, 5th, and 2nd in the open submission track for Spanish–Aragonese, Spanish–Aranese, and Spanish–Asturian, respectively. We release our code and data publicly at `https://github.com/Helsinki-NLP/lowres-spain-st`.

1 Introduction

In this work, we describe the participation of our team to the Shared Task on Translation into Low-Resource Languages of Spain 2024 (Sánchez-Martínez et al., 2024), the first edition of its kind. The task involves developing Machine Translation (MT) systems for translating from Spanish (*spa*) into three closely related Romance target languages: Aranese (*arn*), Aragonese (*arg*) and Asturian (*ast*). Aranese is a variety of Occitan spoken in the northwestern part of Catalonia; Aragonese is spoken in Aragon, in northwest Spain; and Asturian is spoken in Asturias, in northeast Spain.

Although these minority languages have some form of official status in their respective regions, they are all considered endangered. According to the linguistic taxonomy proposed by Joshi et al. (2020), these languages fall into the category of the "Scraping Bys". This means that, while there is some available unlabeled data, substantial and coordinated efforts are necessary to raise awareness and gather labeled datasets to improve the prospects of these languages in the future. This task is designed precisely to address these challenges by fostering the development of resources and tools for these under-resourced languages.

In terms of current technological support, some linguistic resources are available for these languages, including online dictionaries and established orthographic standards. Apertium (Forcada et al., 2011) is an open-source Rule-Based MT (RBMT) toolkit initially developed for related languages, that offers substantial coverage for the three target languages. Nevertheless, resources remain notably sparse for data-driven approaches like Neural Machine Translation (NMT). By contributing to this task, we aim to change this picture.

We focus our participation efforts on data collection – by gathering additional data from Wikipedia and online dictionaries –, data augmentation – by producing back-translations (Sennrich et al., 2016) of monolingual data –, and data preparation – by carrying out corpus-targeted cleaning. We also experiment with different data tagging strategies. We submit four multilingual models, which arise from fine-tuning and applying Knowledge Distillation (KD), by leveraging both neural and RBMT outputs, similarly to Aulamo et al. (2021). We evaluate our models both for translation quality and efficiency, resulting in a diverse set of submissions that balance accuracy and speed. Our contributions, including our code and data, are publicly available for further research in our Github repository.

The rest of the paper is organised as follows. Section 2 describes the benchmarking of existing models. Section 3 provides a detailed description of our data collection and preparation efforts. Section 4 describes the submitted models in detail. Section 5 outlines the results and, finally, section 6 concludes our work.

2 Benchmarking of Existing Models

The first step we took when approaching this task was to benchmark existing models for the target languages. This process enabled us to assess the current landscape of available models, identify those suitable for fine-tuning, and determine which models could be utilized for back-translation.

We evaluate three types of models: OPUS-MT models[1], the smaller NLLB variants (Costa-jussà et al., 2022), and the rule-based Apertium systems. OPUS-MT models are trained with the Tatoeba Translation Challenge dataset[2] (Tiedemann, 2020) and data from the massively parallel Bible corpus (Mayer and Cysouw, 2014) as part of the JHUBC corpus (McCarthy et al., 2020). These are all *transformer-big* (Vaswani et al., 2017) systems. The NLLB models are trained on a diverse collection of multilingual text and come in different sizes. Apertium and OPUS-MT cover all three target languages, whereas NLLB does not support Aragonese.

We evaluate the systems with the provided development set by the organizers and BLEU (Papineni et al., 2002), as implemented in sacreBLEU (Post, 2018). The development set consists on a manually-crafted revision of the 997 sentences from Flores+ (Goyal et al., 2022). Results are shown in Table 1.

We can see how OPUS-MT models, although much smaller in size, outperform all NLLB variants when the target language is the Romance minority language. All NLLB variants perform similarly, independently of their size. We attribute the lower score on the Spanish–Aranese language pair to the models being trained on Occitan data rather than Aranese. Additionally, the remarkable performance of the Apertium models in translating from Spanish stands out, as they surpass the neural systems, except in the case of Asturian.[3] This demonstrates the effectiveness of rule-based systems in handling closely related languages.

With Spanish as the target language, the NLLB models follow the scaling laws and their score increases along their size, as would be expected. The OPUS-MT models exhibit comparable performance. As expected, the compact OPUS-MT models are much faster when considering the decoding speed of the different models. OPUS-MT models have been trained using Marian (Junczys-Dowmunt et al., 2018), while the NLLB family was trained using Fairseq (Ott et al., 2019).

Taking this into account, we decide to select two OPUS-MT models from Table 1 for our work: the model marked with * for fine-tuning; and model ** for producing back-translations. Given that the NMT models significantly outperform the Apertium systems for translation into Spanish, the rule-based back-translation strategy employed by Aulamo et al. (2021) did not suit our context.

3 Data

The data used to train our NMT systems consists of parallel and monolingual datasets provided by the organizers, as well as additional Wikipedia and dictionary data. We utilize the monolingual datasets by back-translating them to create synthetic parallel

[1] https://github.com/Helsinki-NLP/OPUS-MT-train

[2] Version v2023-09-26.

[3] Asturian sentences were professionally translated from English, while Aragonese and Aranese sentences were machine translated from Spanish using Apertium and later post-edited. Hence, the higher score for Apertium and the language pairs involving Aragonese and Aranese.

Table 2: Number of sentence pairs in training datasets. The "raw" line shows the sizes before any filtering, the "langid" line shows the number of sentence pairs in the correct language according to Idiomata Cognitor, and the "filtered" line shows the final sizes of the clean datasets. The Aranese and Occitan data are separated into two sets after language identification. The final cleaned data size for each language is shown in bold.

training data. We remove noise from the training data using the Idiomata Cognitor (Galiano-Jiménez et al., 2024a) language identification tool, OpusCleaner (Bogoychev et al., 2023) and its visual user interface, and the configurable filtering toolbox OpusFilter (Aulamo et al., 2020).

3.1 Data Collection

Table 2 shows the sizes of the datasets used for training. As original parallel data, we use only the Tatoeba Challenge data[4] (Tiedemann, 2020), which contains all data in OPUS (Tiedemann, 2012), deduplicated and shuffled. We also use the crawled and literary PILAR corpora (Galiano-Jiménez et al., 2024b) as monolingual data for all three language pairs. Additionally, we use the Aranese side of the Catalan-Aranese PILAR corpus also as monolingual data.

We also leverage monolingual data that is not provided by the organizers, which puts our models in the open track: Wikipedia and online dictionaries for Aranese[5] and Asturian[6]. From Wikipedia, we obtain the latest dump per language. Moreover, for Occitan, we also make use of OcWikiDisc (Miletic and Scherrer, 2022), a corpus extracted from the talk pages associated with the Occitan Wikipedia. We assume that Occitan datasets include Aranese data, since it is a variety of Gascon, one of the main dialects of Occitan. For the online dictionaries, we develop our own scraping scripts to gather definitions. The scripts can be found in our Github repository. For the monolingual data, we produce back-translations into Spanish with the openly available OPUS-MT model (marked with ** in Table 1) to produce synthetic parallel data.

3.2 Data Cleaning

The first step of our data cleaning pipeline is language identification. We use the Idiomata Cognitor tool (Galiano-Jiménez et al., 2024a) to identify the correct target languages in all data sets. Idiomata Cognitor also allows us to distinguish Aranese from other Occitan varieties. Hence, from this point onwards, we treat Aranese and (non-Aranese) Occitan data separately in order to experiment with different model training strategies as described in Section 4.

Next, we create customized filtering configurations for each corpus (and for each subcorpus in Tatoeba) to apply optimal data cleaning based on the style and domain of the texts. To this end, we use OpusCleaner (Bogoychev et al., 2023), which is a parallel data cleaning tool that allows the user to add and adjust filters and see their effects on a sample of the corpus in real time in a graphical interface. The filters most commonly applied

[4] We use the same version as the original OPUS-MT model.

Model	Submission	oci tag	arn tag	spa–arg	spa–arn	spa–ast
OPUS-MT	-	-	-	42.6	9.6	16.9
A.1	1	`»oci«`	`»oci«`	**54.8**	12.3	18.5
A.2	1	–	`»oci«`	51.5	**28.2**	18.5
B.1	–	`»oci«`	`»xxx«`	51.6	26.1	18.5
B.2	–	`»xxx«`	`»oci«`	51.5	**26.8**	18.5
B.3	–	`»oci«»oci«`	`»oci«»xxx«`	**55.2**	26.0	18.5
B.4	–	`»oci«»xxx«`	`»oci«»oci«`	52.8	25.7	18.5

Table 3: BLEU scores on the development set of fine-tuning the OPUS-MT model with different tagging strategies. We provide the scores of the OPUS-MT model for reference. We report the best checkpoint score per language pair. Model A.2 does not use Occitan data.

to our training sets are: (1) `src_trg_ratio`: The ratio between the number of source and target tokens. (2) `num_mismatch`: The ratio between the number of overlapping and differing numerals. (3) `alpha_ratio`: The ratio between the number of words and non-words, and the ratio between the number of language and non-language characters.

Additionally, some corpora contain unwanted structures, such as HTML tags or transcription content between double square brackets in Wikipedia data, which we remove from the sentences. Finally, we apply OpusFilter to concatenate the different corpora, normalize whitespace characters, remove all sentences shorter than 3 or longer than 150 words and remove all duplicate sentence pairs. Table 2 shows the data sizes for each language pair after applying language identification and corpus cleaning. The final size of our corpus is 4,35M sentences, with 66.14% spa–ast, 7.63% spa–arg, 7.75% spa–arn, and 18.45% spa–oci. All of our data cleaning configuration files can be found in our Github repository.

4 Models

In this section, we detail our modeling choices for the four submissions, all of which employ one-to-many multilingual models. Our models leverage fine-tuning and data tagging, and the integration of RBMT with neural models via Sequence-Level KD (Seq-KD) (Kim and Rush, 2016). All models are based on the Transformer architecture (Vaswani et al., 2017) and use the OPUS-MT model, as described earlier, as the initial checkpoint in some form. For tokenization, we use the OPUS-MT model's SentencePiece vocabularies (Kudo and Richardson, 2018), two distinct 32k piece vocabularies: one shared among all source languages (in our case, only Spanish) and another shared among all targets. All models are trained on 4 Nvidia V100 GPUs, except models C.2 and D.2, which are trained on 8 AMD MI250x GPUs. Further configuration details are provided in Appendix A.

4.1 Models A: Fine-tuning

As an initial step, we use the openly available OPUS-MT model described in Section 2 and fine-tune it using different data sampling schemes. We train one model with all available training data (model A.1) and another excluding the Occitan data (A.2). The decision to exclude Occitan data was made because both languages share the same language tag, which could potentially confuse the model, since there is much more training data on Occitan than on Aranese. The development set scores are presented in Table 3.

Compared to the original OPUS-MT model, we observe a significant increase in BLEU scores for the spa–arg language pair (+12.2) and for spa–arn (+18.6). However, for Asturian, the increase is more modest (+1.6). Removing the Occitan data results in an increased score of almost +16 BLEU points for the spa–arn language pair. Interestingly, despite having the largest amount of new data for Asturian, the model quickly reaches a performance plateau during training, as shown in Figure 2 in Appendix B. This trend persists throughout our experiments, leading us to conclude that the spa–ast language pair is the most challenging task.

For our **Submission #1**, we ensemble the best n checkpoints per language pair across both A.1 and A.2 models.[7]

[7] We perform ensembling using the top 10 best checkpoints for each language pair and submit the ensemble with the highest score on the development set.

Model	Teacher(s)	Size	Submission	spa–arg	spa–arn	spa–ast
C.1	A	base	2	53.6	**28.1**	18.5
C.2	A	tiny	–	51.3	25.5	18.2
C.3	B.3	base	–	55.4	26.6	18.5
D.1	A + RBMT	base	2	**54.2**	27.3	18.5
D.2	A + RBMT	tiny	3	**52.8**	**27.1**	18.2
D.3	B.3 + RBMT	base	4	56.9	**30.2**	18.5
D.3_fixed	B.3 + RBMT	base	–	**57.0**	26.9	18.5
D.4	RBMT	base	–	62.4	36.8	16.9

Table 4: Comparison of BLEU scores for our distillation experiments between NMT-only models and NMT+RBMT systems across different language pairs on the development set. We report the best checkpoint score per language pair, except for models D, where we use the same single checkpoint.

4.2 Models B: Data tagging

In multilingual systems, it is a common practice to prepend a language tag to the source sentence to indicate the target language. For consistency, we applied uniform tagging across all models. Nevertheless, for Aranese, we experimented with different tagging schemes, given that it is a variety of Gascon, a dialect of Occitan.

Exploring the OPUS-MT vocabulary, we identified an unused tag, »`xxx`«, which prompted us to experiment with various combinations of the »`oci`« and »`xxx`« tags, including the use of double tags. We fine-tune the original OPUS-MT model with all available training data and different tagging schemes. Results of are provided in Table 3.

While the performance of Asturian remained unaffected, using different tags for Aranese and Occitan led to a much higher BLEU on the spa–ara language pair compared to model A.1; due to the effectiveness of the data tagging schemes. Notably, Aragonese appeared to be the most impacted by data tagging, although we are unsure why. On average, the best performing model leverages double tags (B.3). We do not submit any of these, but use B.3 as a teacher in our distillation experiments.

4.3 Sequence-Level Distillation

Seq-KD (Kim and Rush, 2016) is a technique where a student model is trained using translations generated by one or more teacher model(s), with the goal of transferring knowledge from a large, powerful teacher model to a smaller, more efficient student model. We experiment with Seq-KD to train fast students.

Models C: NMT-distilled

First, we distill student models using the previously fine-tuned *transformer-big* NMT systems as teachers. We leverage Sequence-Level Interpolation (Kim and Rush, 2016), generating 8-best candidate translations for all the training data using the best checkpoint for each language pair. From these, we select the translation with the highest ChrF (Popović, 2015) with the reference to create a distilled dataset, which is then used to train the student model. We use ChrF instead of BLEU as a more fine-grained metric at character level.

To explore the tradeoff between translation quality and speed, we use models A[8] as the teachers and train two students of different sizes. Model C.1 is a *transformer-base* model (67.5M parameters), while model C.2 follows the *tiny* architecture described in Bogoychev et al. (2020), its size is 20.4M parameters (3.3 times smaller). We train model C.2 using the OpusDistillery[9], a pipeline for multilingual Seq-KD of open NMT models. In addition, to investigate the effect of multi-teacher distillation, we distill another *transformer-base* model (C.3) using a single NMT teacher, in this case, model B.3. The development set scores for these student systems are shown in Table 4.

When comparing models C.1 and C.2, it becomes evident that the capacity gap between the teacher and student models significantly impacts student performance. In KD, student models are typically smaller than their teacher counterparts, which can hinder their ability to effectively learn and fit noisy data. This is reflected in the lower scores of the smaller C.2 model across all language pairs compared to C.1. On the other hand, models C.1 and C.3 share the same size, but their training

[8] For Occitan, we use the original OPUS-MT model, as our fine-tuned model has a lower score on Occitan, due to the catastrophic forgetting phenomenon (Goodfellow et al., 2013).

[9] https://github.com/Helsinki-NLP/OpusDistillery

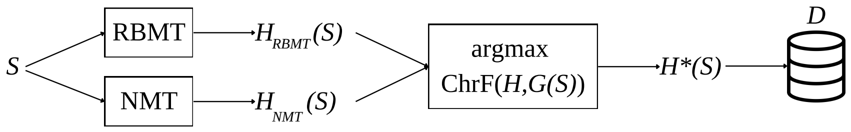

Figure 1: Overview of our Seq-KD distillation process to merge NMT and RBMT data. Given a source sentence *(S)*, we produce a hypothesis translation *(H)* with both our RBMT and NMT models. Then, we choose the translation *(H*)* that has the maximum ChrF with the ground truth *(G)* to create the distilled dataset *(D)*.

strategies differ. Model C.1 is distilled from multiple teachers, while C.3 is distilled from a single teacher. Notably, distilling from a single model in C.3 appears to offer greater stability.

Models D: Hybrid-distilled

Since rule-based translation models are remarkably good for the given language pairs, as shown in Table 1, we further experiment with Seq-KD to train student models that benefit from both RBMT and NMT outputs.

In this case, we use two types of teachers: (1) the best checkpoint per language pair of the NMT model(s) (as in the previous section) and (2) the Apertium RBMT models. We forward translate the training data with both teachers. For each source sentence, we select the translation that has the highest ChrF score with the ground truth to create the distilled dataset. Finally, we train a new student model on the distilled dataset. An overview of this process is depicted in Figure 1.

For each of the former models C, we train a comparable hybrid-distilled student using a combination of the NMT and RBMT data. The development set scores for these models (D.1–D.3) are shown in Table 4. The proportions of RBMT data selected for the final distilled dataset are provided in Appendix C.

The inclusion of RBMT data in the distillation process leads to better performance across all language pairs overall. For model D.1, the addition of rule-based distilled data results in a slight decrease for spa–arn, in comparison to C.1. For spa–ast, the performance is identical across all models. It is remarkable to note that model D.3 surpasses the performance of its own teacher with +1.7 BLEU for spa–arg and +4.2 BLEU for spa–arn.

After the submission deadline, we discovered that the NMT distilled dataset for model D.3 had been generated using incorrect language tags for Aranese and Occitan (»oci« instead of »oci«»oci« and »oci«»xxx«, respectively). We provide the corrected results for the D.3 model (model D.3_fixed in Table 4). Interestingly, the initial D.3 model performed better for Aranese due to the higher proportion of RBMT data for that language (as shown in Appendix C, 15% vs. 2.3%), which favored the RBMT-heavy development set. Motivated by this finding, we trained a student using RBMT-only distilled data after the submission deadline (model D.4 in Table 4), which outperforms all other models except for Asturian. This opens up a new avenue of research, leveraging linguistically informed methods for distillation.

Table 4 demonstrates the effectiveness of using distillation to train a single model that performs well across all three language pairs. Among the language pairs, Aragonese shows the most significant improvement when RBMT data is incorporated, highlighting the particular benefit of combining rule-based and neural translation methods for this language. This aligns with our expectations since as can be seen from Table 1, the spa–arg Apertium model achieves the highest BLEU score.

Out of our distillation experiments, we make three submissions. For **submission #2**, we ensemble the best n checkpoints per language pair across models C.1 and D.2. For **submission #3**, we submit model D.2. In this case, we do not use ensembling because we want to test it for speed. Finally, for **submission #4**, we ensemble the best n checkpoints per language pair from model D.3.

5 Results

We make four submissions in the open submission track. The test set corresponds to the 1,012 lines of Flores+ evaluation set. We summarize our submissions' test results in Table 5, as provided by the organizers of the Shared Task. For comparison, we also include the scores of the top-performing competitor, overall and in the open submission track. The official evaluation metrics of the task are BLEU and ChrF. Additionally, we report the average decoding speed and the model sizes.

Our best models ranked 4th, 5th, and 2nd in the open submission track for spa–arg, spa–ara, and

#	Method	BLEU / ChrF			Params (M)	Speed (s)
		arg	arn	ast		
1	Fine-tuning Data Sampling Ensembling	51.5 / 75.6	22.1 / 45.1	18.2 / 51.6	222.9	852.22
2	Distillation RBMT+NMT Ensembling	50.6 / 75.4	22.4 / 45.7	18.0 / 51.6	65.7	361.33
3	Distillation RBMT+NMT	49.1 / 75.4	21.6 / 45.0	17.9 / 51.4	20.4	4.06
4	Distillation Data Tagging RBMT+NMT Ensembling	52.7 / 75.9	24.3 / 46.6	18.0 / 51.5	67.5	891.76
Best (overall)	–	63.0 / 80.3	30.4 / 50.1	23.2 / 55.2	–	–
Best (open)	–	62.7 / 80.0	28.8 / 49.4	23.2 / 55.2	–	–

Table 5: Summary of our submissions. BLEU refers to the score obtained by the best ensemble on the development set; Speed refers to the averaged decoding speed for submission across language pairs on one single AMD MI250x GPU. In addition, we provide the best competitor scores for each target language.

spa–ast, respectively. On average, our best submission for each language pair falls short of the top competitor by 4 BLEU points and 3.8 ChrF points. This narrow margin reflects the competitive nature of this year's task, which saw over 178 submissions.

Our best model is submission #4, followed closely by submissions #1, #2 and, finally #3, in that order. It is noteworthy that our distilled models perform really well compared to their teachers. Submission #2, a distilled model from Submission #1, demonstrates an increase of +0.3 BLEU for spa–arn over its teacher, highlighting the potential of distillation to not only preserve but even enhance translation quality. Moreover, our smallest model, Submission #3, although showing a slight average decrease of –1.1 BLEU compared to its teacher, offers a significant advantage in terms of speed—it is 210 times faster.

6 Conclusions

In this work, we have presented our participation in the Shared Task of Translation into Low-Resource Languages of Spain 2024. We have described our data collection and preparation efforts, as well as our four submissions based on multilingual models. We explore fine-tuning of an existing open model with different data tagging schemes and use Seq-KD to train small efficient student models. Furthermore, to our knowledge, we are the first to leverage RBMT to improve distillation for similarly related languages and prove its effectiveness.

This study opens up new research directions for advancing in low-resource MT by demonstrating the potential of data tagging strategies and hybrid distillation methods, ensuring these languages are both preserved and accessible in the digital age.

7 Ethical Considerations

In addition to evaluating the performance of our models in terms of translation quality, it is equally important to consider the computational resources required for their training and deployment. By analyzing the GPU consumption of our experiments, including the time spent and energy consumed for each task, we aim to provide a comprehensive assessment of the efficiency and sustainability of our approaches. This will allow the community to take informed decisions about model selection and optimization in real-world applications, where computational efficiency is often as critical as accuracy. We report the energy consumption of the totality of our experiments in Table 6, which amounts to 508 kWh.

Task	Model	Time (h)	Energy (kWh)
Back-translation		18.9	19.5
Fine-tune	A.1	35.3	37.0
	A.2	22.4	23.0
	B.1	50.5	52.2
	B.2	27.4	28.9
	B.3	28.9	29.6
	B.4	28.0	28.8
Forward translation		7.9	6.6
Train via Seq-KD	C.1	64.6	66.9
	C.2	11.5	18.1
	C.3	57.1	54.2
	D.1	53.4	55.3
	D.2	11.2	17.8
	D.3	66.6	68.6
	D.3_fixed	55.9	57.1
	D.4	56.0	57.8
Ensembling		30.2	3.52
Submission		1.7	0.19
	Total	627.3	**625.1**

Table 6: Energy consumption of our work. We report the time (hours) and energy consumption across the different tasks of our experiments, run on 4 Nvidia V100 GPUs. The training of models D has been run on 8 AMD MI250x GPUs. Ensembling and translations for submission have been run on 1 Nvidia V100 GPUs.

A Hyperparameters

All models are based on the transformer architecture. They all share the following: the Adam optimizer is used with β_1=0.9 and β_2=0.998. The models are trained until convergence with early-stopping on development data after BLEU has stalled 10 times. Next, we specify each model's unique configuration details.

Models A and B are *transformer-big* models. They use a 6-layered transformer with 16 heads, 1024 dimensions in the embeddings and 4,096 dimensions in the feed-forward layers.

Models C.1, C.3, D.1 and D.3 use a 6-layered transformer with 8 heads, 512 dimensions in the embeddings and 2,048 dimensions in the feed-forward layers.

Models C.2 and D.2 are trained using tiny architecture proposed in Bogoychev et al. (2020). The student model has a transformer encoder with 6 layers and a light-weight RNN based decoder with Simpler Simple Recurrent Unit (SSRU) (Kim et al., 2019) with 2 layers; 8 heads, 256 dimensions in the embeddings and 1,536 dimenstions in the feed-forward layers.

B Learning Curves

Figure 2 shows the BLEU score progression over training updates per language pair for model A.2. It shows how the performance for spa–ast quickly reaches a plateau.

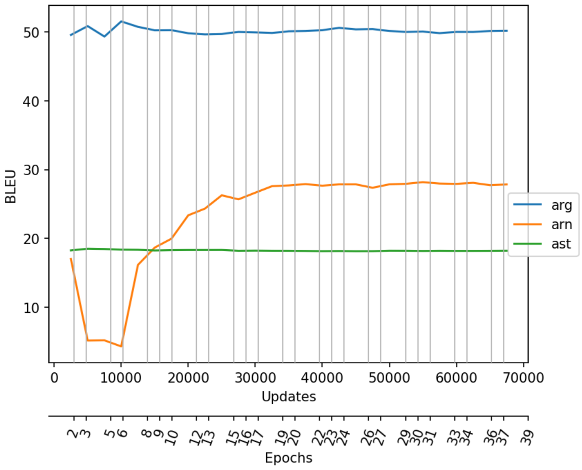

Figure 2: BLEU score progression over training updates and epochs for model A.2.

C Rule-based MT Data

For the distilled models D, we use a combination of NMT and RBMT teachers to build a distilled dataset. The RBMT teachers are the Apertium models. For each source sentence, we generate a hypothesis translation using both teachers and then compute the ChrF score against the ground truth. We retain the hypothesis with the highest ChrF score for each sentence. Table 7 shows the proportion of sentences originating from RBMT across our experiments.

Teacher(s)	A.1, A.3	B.3	B.3
Model(s)	C.1, C.2	D.3	D.3_fixed
Submission	#2 #3	#4	-
Pair	%	%	%
spa–arg	4.39	7.37	7.37
spa–arn	1.32	15.32	2.33
spa–ast	3.85	3.75	3.75
spa–oci	8.95	1.69	1.64

Table 7: Distribution of distilled data coming from RBMT in sentence count and percentage (%).

Robustness of Fine-Tuned Models for Machine Translation with Varying Noise Levels: Insights for Asturian, Aragonese and Aranese

Abstract

We present the LCT-LAP proposal for the shared task on *Translation into Low-Resource Languages of Spain* at WMT24 within the constrained submission category. Our work harnesses encoder-decoder models pretrained on higher-resource Iberian languages to facilitate MT model training for Asturian, Aranese and Aragonese. Furthermore, we explore the robustness of these models when fine-tuned on datasets with varying levels of alignment noise. We fine-tuned a Spanish-Galician model using Asturian data filtered by BLEU score thresholds of 5, 15, 30 and 60, identifying BLEU 15 as the most effective. This threshold was then applied to the Aranese and Aragonese datasets. Our findings indicate that filtering the corpora reduces computational costs and improves performance compared to using nearly raw data or data filtered with language identification. However, it still falls short of the performance achieved by the rule-based system Apertium in Aranese and Aragonese.

1 Introduction

Spain is home to a rich linguistic landscape, yet this diversity is accompanied by disparities in terms of speaker numbers and language resources. Languages with co-official status, such as Basque, Catalan and Galician, were previously considered to have limited resources but are now included in numerous popular LLMs. Consequently, research in this field has shifted towards cases where data scarcity is even more pronounced, such as Asturian, Aragonese and Aranese. These languages are the focus of a shared task at the Conference on Machine Translation 2024. The objectives of this task include investigating transferability among Romance languages and determining the most effective methods for utilizing pretrained models in translations between Spanish and low-resource Romance languages.

The methodology employed involved the following steps:

1. Implementing automated methods for curating data. The constrained submission framework enables researchers to utilize corpora that may be notably noisy. Our work aims to propose solutions to this challenge.

2. Creating synthetic data for the monolingual PILAR Galiano-Jiménez et al. (2024b) corpora.

3. Harnessing models trained on other, resource-richer (Iberian) Romance languages with the presumption that this facilitates cross-lingual transfer. The model fine-tuned for Asturian was originally trained on Galician, while the models fine-tuned for Aranese and Aragonese were originally trained on Catalan.

The official metrics for the shared task are BLEU and chrF. The metrics employed in this study are BLEU and chrF++, as they are relatively straightforward to calculate and there is currently no robust neural-based metric for our target languages.

2 Background

2.1 Spanish Linguistic Landscape

Although the official language in Spain is Spanish, it coexists with other co-official and minority languages. The predominance of Spanish over the other languages and dialects is associated with historical reasons: since the Middle Ages, Spain had undergone a process of Castilianisation, which became very important in the 14th century, when the dominance of the Kingdom of Castile in the centre of the Iberian Peninsula led to the expansion of the use of Castilian. This continued until the 20th century, with the consequent marginalisation of the other vernacular languages (Martínez, 1982). The

Proceedings of the Ninth Conference on Machine Translation, pages 918–924
November 15-16, 2024 ©2024 Association for Computational Linguistics

co-official languages, Basque, Catalan and Galician, were considered to have limited resources in the past. This picture has changed, as efforts from both research and industry have contributed significantly to integrating them into the field of Language Technology. However, there are also non-official Ibero-Romance languages that are considered as having limited resources:

- Asturian: spoken in Asturias, the northeastern part of Leon, Zamora and the north of Portugal (ARIAS, 2002).
- Aragonese: spoken in the north of the province of Huesca and in the extreme northwest of Zaragoza (Marco Villanueva, 2012).
- Aranese: a variant of Occitan, spoken in the province of Aran (Rey and Canalís, 2006).

In this context, initiatives such as PILAR (Pan-Iberian Language Archival Resource) work to enrich and expand the resource availability of these languages (see Section 3).

2.2 Other related works

The interest in low-resource languages has recently increased, leading to a considerable amount of research on the subject (Ranathunga et al., 2023). Several studies on machine translation for low-resource languages can be found, such as the article by Karakanta et al. (2018), which works with non-parallel corpora, or Kumar et al. (2021), which focuses on recasting systems from high-resource languages to low-resource languages.

As far as Iberian languages are concerned, there are other investigations, such as the one published by Oliver et al. (2023), which explores techniques for training NMT systems applied to high- and low-resource Iberian languages or the work by Ko et al. (2021), which adapts high-resource NMT models to translate low-resource languages related to Spanish.

With respect to WMT, since its first edition in 2016, there have been three shared tasks related to the field: In 2020, a task was proposed on unsupervised and very low-resource languages, focusing on Upper Sorbian (Fraser, 2020). The following year, a workshop on multilingual low-resource translation for Indo-European languages was presented, focusing on North Germanic languages such as Icelandic and Romance languages such as Occitan (Libovickỳ and Fraser, 2021). Finally, in 2022, a task related to unsupervised MT and very low-resource supervised MT was suggested, with Upper and Lower Sorbian languages (Weller-Di Marco and Fraser, 2022).

3 Data

This research falls into the constrained submission category, as all data used was obtained from the mentioned sources in the shared task: the Open Parallel Corpora, also known as OPUS (Tiedemann, 2009), and the Pan-Iberian Language Archival Resource, shortened as PILAR (Galiano-Jiménez et al., 2024b).

The Spanish development set is part of the FLORES+ Evaluation Benchmark (NLLB Team et al., 2022). The Asturian, Aragonese, and Aranese counterparts of FLORES+ are published alongside PILAR.

Finally, both the BLEU reference translations for the OPUS data and the synthetic Spanish counterparts for the PILAR data were generated with Apertium (Forcada and Tyers, 2016).

3.1 OPUS corpora

OPUS is a public multilingual collection of parallel corpora that gathers open-source documents available on the Internet (Tiedemann and Thottingal, 2020) and supports 744 languages. The constraint submission is limited to all data in OPUS, thereby enabling researchers to create synthetic translations from other languages into Asturian (ast), Aragonese (arg), Aranese (arn), or Spanish (es). However, the data utilized in this work exclusively employs the corpora for the combinations es <> ast/arg/arn.

Given that the collected corpora were not consistently well-aligned, we implemented a filtering pipeline, as detailed in Section 3.2, to produce a smaller but cleaner dataset. The effectiveness of this approach is reflected in the "BLEU 15" column of Table 1.

3.2 OPUS Data filtering

Around 8 million aligned sentences were collected from OPUS for the three target languages, although this number was significantly reduced when applying a filtering pipeline. Three main steps were followed to filter out invalid sentences:

- **Basic filtering:** removing unnecessary white spaces, empty lines, and characters not supported by the file encoding for all target languages.

- **Idiomata Cognitor:** filtering out all sentence pairs whose target language was not labeled as Asturian, Aragonese or Aranese and whose source language was not labeled as Spanish by Idiomata Cognitor (Galiano-Jiménez et al., 2024a), a high-precision classifier trained using Bayesian methods and capable of identifying 10 Romance languages.

- **BLEU threshold filtering**[1]: we first translated the Spanish counterparts of the Asturian/Aragonese/Aranese datasets into the respective target languages using Apertium. Next, we calculated BLEU scores for the original Asturian/Aragonese/Aranese sentences as references and their translations as hypotheses. Then, we filtered the datasets to various BLEU thresholds, assuming that alignments are more likely to be correct if the sentence pairs have high BLEU scores[2]. For Asturian, this was done using four different BLEU thresholds: 60, 30, 15 and 5 BLEU. For Aragonese and Aranese, we only used one threshold.

3.3 PILAR Corpora

PILAR is a recently created corpus of texts from different languages spoken in the Iberian Peninsula, including Asturian, Aragonese, Aranese, Balearic and Valencian.

For our purposes, the monolingual data from Asturian, Aragonese and Aranese, and the Aranese counterpart from the Catalan-Aranese parallel corpora was backtranslated into Spanish (see Table 2) using Apertium: backtranslation can be understood as providing monolingual training data with a synthetic sentence source obtained by automatically translating the target sentence into the source language (Sennrich et al., 2015).

4 Methodology

The methodology of this work involved fine-tuning two pretrained models (see section 4.1) on backtranslated PILAR and filtered OPUS data (see section 3 and section 3.2). The total number of sentences for each language is presented in Table 3.

The experimental setup utilized a Tesla V100-PCIE-32GB GPU running with NVIDIA driver version 535.104.12 and CUDA version 12.2, alongside the HuggingFace Transformers library for model loading and fine-tuning.

All models underwent training for at least 1 epoch (Table 3 shows when each model converged). The best model selection was based on the BLEU score derived from the development set. Additionally, zero-shot translation without fine-tuning was conducted as a baseline for comparing results.

4.1 Models

Two models from `Helsinki-NLP` (Tiedemann and Thottingal, 2020) were used for our experiment:

- `opus-mt-es-gl`: a transformer-align model from Spanish into Galician that achieved a BLEU 67.6 and a chr-F score of 80 in the Tatoeba test. Given the close linguistic relationship between Asturian and Galician-Portuguese, we aimed to explore transfer learning when fine-tuning on Asturian data.

[1] We used Bleualign as a reference (Sennrich and Volk, 2010). However, we did not calculate the BLEU score between the hypothesis and reference sentences for both languages, nor did we compute the subsequent harmonic mean, given the fact that Apertium web tool does not support translations from Asturian into Spanish. Instead, we limited our calculations to the BLEU score of the original Asturian/Aragonese/Aranese sentences as references and the translation of its Spanish counterpart obtained with Apertium as hypotheses.

[2] BLEU evaluates translations by comparing n-grams between the model output and a reference, favouring those that are closest in terms of word and order. This may favour sentences in both the source and target languages that are easier to translate for Apertium.

Table 3: BLEU and chrF++ scores on the FLORES+ devset comparing baselines (`apertium` and models with `noft` in their names) and fine-tuned models (`-ft-`) across varying levels of alignment noise. Baselines always occupy the first two rows for each language. Subsequent models are listed in ascending order of BLEU scores. Best performing architectures are highlighted in bold.

- `opus-mt-es-ca`: a transformer-align from Spanish into Catalan with a BLEU score of 68.9 and a chr-F score of 0.832 in the Tatoeba test. We aimed to explore transfer learning when fine-tuning Catalan for Aranese and Aragonese.

5 Results

As Table 3 shows, the results of our experiments were compared with two baselines: Apertium, a rule-base system that supports translations in the same languages as those investigated in this work, and the respectively selected model for our experiments with zero-shot translations (i.e. without fine-tuning).

Overall, the results for Aragonese and Aranese show the same trend: the highest performance was achieved by fine-tuning on data filtered with a BLEU threshold of 15, combined with the back-translated PILAR corpora. While the backtranslated data yielded improvements of 18.85 BLEU for Aranese, this improvement was only 0.14 BLEU for Aragonese. Interestingly, fine-tuning on data that had only undergone basic cleaning outperformed our approach of filtering out sentences in other languages. The zero-shot translation approach yielded the lowest results by a significant margin. Despite these efforts, our results still fall short of the baseline Apertium by approximately 9 points in Aranese and nearly 25 points in Aragonese.

Our best result for Asturian is the only one comparable to the baseline Apertium. Our fine-tuned model, which uses a BLEU score threshold of 15 and the PILAR corpora, outperforms the baseline by 0.8 BLEU points. However, it falls short of the baseline by 0.11 chrF++ points.

See the following sections for a more detailed description of each language's results.

5.1 Asturian

Our results show that setting a threshold of 15 BLEU for OPUS-aligned corpora yields the best performance in Asturian. It slightly outperforms thresholds of 5 and 30 BLEU and achieves an improvement of almost 0.25 over the cleanest filtered set of corpora with a threshold of 60 BLEU.

Note that an Asturian tokenizer was trained and implemented; however, its performance did not exceed a BLEU score of 17.6 and it was consequently omitted from Table 3. Consequently, no tokenizer was trained for Aranese and Aragonese.

Integrating backtranslated Asturian PILAR results in almost a 1-point BLEU score improvement compared to the slightly preprocessed raw OPUS data (basic clean in Table 3), and a slight improvement of 0.05 compared to the filtered OPUS data with 15 BLEU threshold without PILAR data.

Regarding the baselines, our best method (data filtered with a 15 BLEU threshold and backtranslated PILAR) achieves similar performance as Apertium, with a 0.8 BLEU score improvement and a 0.11 lower chrF++ score. The zero-shot translation results are by far the worst, with scores approximately 12 points below the best results.

5.2 Aragonese

As detailed in section 7, only the best filtering threshold for OPUS data in Asturian was also applied to Aragonese.

Our best result is again the result of fine-tuning the bleu_15 + PILAR corpora on a model initially fine-tuned for Spanish-Catalan translation. It outperforms the model finetuned on almost raw data by 8.36 BLEU points. Comparing these results to a model only trained on the bleu_15 data, reveals that using the backtranslated data only yielded an improvement of 0.14 BLEU. However, these results lag behind the Apertium baseline, which obtains scores with approximately 25 points difference in BLEU and around 12 points in chrF++.

The zero-shot baseline model (`es-ca-noft-arg`) achieved a similarly low score as the zero-shot models in the other languages and performed significantly worse than the other approaches. It lags behind the best result from Apertium by approximately 58 BLEU points and around 36 chrF++ points.

5.3 Aranese

As detailed in section 7, only the best filtering threshold for OPUS data in Asturian was applied to Aranese.

Showing the same trend as the results for the other two languages, the approach using bleu_15 + PILAR corpora is the most effective. It achieves an improvement of about 20 BLEU points and approximately 14 chrF++ points over the other data sets, which only underwent basic cleaning or language filtering with Idiomata Cognitor. In contrast to our results for Aragonese, the Aranese backtranslated data helped to increase performance tremendously (+18.8 BLEU). As expected, the zero-shot baseline performs the worst, with even greater score disparities.

Despite this significant improvement compared to our other techniques, the BLEU filtering approach fails to outperform the Apertium baseline. Apertium performs significantly better, with approximately 9 points difference in BLEU and over 5 points in chrF++.

6 Conclusions

This work was conducted within the constrained category of the shared task *Translation into Low-Resource Languages of Spain* at WMT24. It introduces a pipeline for filtering low-quality alignments in parallel corpora and subsequently fine-tuning translation models to assess the noise robustness of Neural Machine Translation. The paper details the data collection and curation processes for the three target languages selected for this task (Asturian, Aragonese and Aranese), with a particular focus on fine-tuning models for Spanish to Asturian under varying levels of noise and generalizing the results to the other two language pairs.

The initial phase involved curating the OPUS corpora for the Asturian-Spanish pair. This pipeline included **1)** cleaning unsupported characters and blank spaces, **2)** filtering out sentence pairs that were not in Spanish or one of the target languages using Idiomata Cognitor, and **3)** generating translations with Apertium to determine alignment quality of the sentence pairs and establishing four different BLEU thresholds for filtering. After observing that a BLEU threshold of 15 yielded the best performance, we incorporated backtranslated PILAR data into the filtered OPUS corpora. Part of step **3** was omitted for Aranese and Aragonese due to computational constraints.

Despite these filtering approaches resulting in the loss of some significant portions of the available corpora, we observed that the fine-tuned models effectively leveraged prior knowledge from the chosen related languages (Galician and Catalan).

- Our best performing fine-tuned model for Asturian outperformed the baseline Spanish-Galician model by 12.15 BLEU points.
- Our best performing fine-tuned model for Aragonese outperformed the baseline Spanish-Catalan model by 33.15 BLEU points.
- Our best performing fine-tuned model for Aranese outperformed the baseline Spanish-Catalan model by 23.29 BLEU points.

The results for our best fine-tuned Asturian model were relatively strong, achieving competitive scores compared to Apertium. Although the same approach was applied to Aranese and Aragonese, it did not surpass the Apertium baseline by a significant margin.

Overall, we demonstrated that 1) filtering out low-quality translations from a noisy parallel dataset improves fine-tuning results and yields faster training times, and 2) results for Asturian can reach baseline levels with a smaller, cleaner and more computationally efficient corpus, suggesting that the selected models can handle noise only to a certain degree. However, we cannot assert that this approach is effective for Aranese and Aragonese, as the results for these languages fall short of the rule-based baseline.

7 Limitations

The scope of this work is mainly limited by computational resources. The HiTZ Basque Center for Language Technology kindly allowed the authors access their resources, but understandably, priority was given to projects more closely related to their main research focus at the time. This led us to 1) implement our own BLEU score filter and dispense with newer, more accurate sentence alignment algorithms, 2) generalize the best BLEU score threshold in Asturian to the other two languages, Aranese and Aragonese.

One potential improvement to our approach would be the application of curriculum learning, where initial fine-tuning is performed on large synthetic data, followed by further fine-tuning on high-quality parallel data.

8 Further Work

Future work could address the limitations discussed in Section 7 by 1) exploring the outcomes of fine-tuning a language model on corpora cleaned using not just one, but various sentence alignment algorithms such us Bertalign (Liu and Zhu, 2022) or Vecalign (Thompson and Koehn, 2019), and 2) investigating whether Aranese and Aragonese tolerate different noise thresholds compared to Asturian. Additionally, future research might:

- estimate the amount of KWh required to fine-tune different amounts of corpora,
- examine whether data augmentation through backtranslation of additional OPUS corpora could enhance performance, as this is permitted in the constrained category,
- explore whether a tokenizer trained on a larger corpus and specialized in Asturian, Aranese, and Aragonese could improve results.

Ethics Statement

The authors of this study adhered to the principles outlined in the ACL Ethics Policy and the ACM Code of Ethics. Our goal is for this research to benefit society by exploring language transferability among three low-resource languages, thus advancing machine translation techniques for underrepresented languages. All data used in this study was sourced from institutional and legal channels, explicitly approved and aligned with the original guidelines of the constrained submission for the shared task on *Translation into Low-Resource Languages of Spain* at WMT24. Throughout the research process, we prioritized transparency and fairness. We conducted honest and reliable evaluations and clearly communicated the limitations of our methods.

Acknowledgements

We would like to express our gratitude to Gorka Labaka and Nora Aranberri for their feedback and support. Furthermore, we would like to thank the HiTZ Basque Center for Language Technology for providing us with access to their computational resources, which will facilitate further research. This work was co-funded by the Erasmus Mundus Masters Programme in Language and Communication Technologies, EU grant no. 2019-1508.

Abstract

In this paper, we present the two strategies employed for the WMT24 Shared Task on Translation into Low-Resource Languages of Spain. We participated in the language pairs of Spanish-to-Aragonese, Spanish-to-Aranese, and Spanish-to-Asturian, developing neural-based translation systems and moving away from rule-based approaches for these language directions. To create these models, two distinct strategies were employed. The first strategy involved a thorough cleaning process and curation of the limited provided data, followed by fine-tuning the multilingual NLLB-200-600M model (Constrained Submission). The other strategy involved training a transformer from scratch using a vast amount of synthetic data (Open Submission). Both approaches relied on generated synthetic data and resulted in high ChrF and BLEU scores. However, given the characteristics of the task, the strategy used in the Constrained Submission resulted in higher scores that surpassed the baselines across the three translation directions, whereas the strategy employed in the Open Submission yielded slightly lower scores than the highest baseline.

1 Introduction

This article presents the work done by the ILENIA team, which includes researchers from the Barcelona Supercomputing Center and Proxecto Nós (CiTIUS - Universidade de Santiago de Compostela), for the WMT24 Shared Task on Translation into Low-Resource Languages of Spain[1]. Our participation covered three translation directions: Spanish-to-Aragonese, Spanish-to-Aranese, and Spanish-to-Asturian, all of which are Romance languages.

Aragonese is spoken in several valleys of the Pyrenees in the autonomous community of Aragon. It is one of Europe's smallest language communities, with around 8,500 native speakers and 25,000 total speakers. According to UNESCO, Aragonese is an increasingly endangered language (Moseley, 2010).

Aranese is spoken in Vall d'Aran, in the northwest of Catalonia. It is the native language of this unique region, with approximately 5,090 native speakers. Aranese is a variant of Gascon, one of the main dialects of the Occitan language.

Asturian is the variant of Astur-Leonese spoken in the autonomous community of Asturias, in northern Spain. Currently, around 250,000 people have the ability to understand, speak, read, and write Asturian, representing the 25% of this autonomous community.

For this Shared Task, we participated in two types of submissions. In the **Constrained Submission**, we were allowed to use the specified resources, such as corpora, dictionaries, Apertium-based systems, and documents defining the contemporary orthographic conventions for each language. Regarding the models, we could use publicly available models, provided they did not exceed 1 billion parameters. To meet these requirements, we collected and generated synthetic data from the available resources, built and applied a comprehensive cleaning pipeline to preprocess the data, and fine-tuned three separate NLLB-200-600M (Costa-jussà et al., 2022) on the corresponding Spanish-to-Aragonese, Spanish-to-Aranese, and Spanish-to-Asturian translation directions. BSC researchers conducted the experiments for this submission.

For the **Open Submission**, we were allowed to use any publicly available resources, including corpora and models of any size, as long as the resulting

Proceedings of the Ninth Conference on Machine Translation, pages 925–933
November 15-16, 2024 ©2024 Association for Computational Linguistics

outputs were made available. For this submission, we chose to generate large amounts of synthetic corpora from data released by ILENIA and the Proxecto Nós using Apertium, a rule-based translator (Khanna et al., 2021). We then trained three models based on the transformer architecture (Vaswani et al., 2017) from scratch using OpenNMT-py 3.2[2] (Klein et al., 2018). The researchers from Proxecto Nós were responsible for this second submission.

2 Data

2.1 Data Collection and Synthetic Creation

2.1.1 Constrained Submission

OPUS The organizers created the Aragonese and Aranese FLORES+ dev and devtest sets using Apertium, translating the corresponding Spanish texts from the FLORES-200 multilingual dataset (NLLB Team, 2022) into these languages. We consider this to be a limitation of the Shared Task since the reference test sets are biased towards Apertium-generated data. Nevertheless, in order to achieve the highest possible score on our submission for the Shared Task, we decided to use Apertium to generate synthetic Aragonese and Aranese translations from Spanish monolingual data, instead of directly using the parallel data provided by OPUS (Nygaard and Tiedemann, 2003). Specifically, we used the Spanish side of the es-arg and es-oc parallel corpora from OPUS to generate synthetic data. For Aragonese, we used the GNOME, Ubuntu, Wikimatrix, and Wikimedia corpora, and for Aranese, we used these same corpora in addition to Kde4 and NLLB.

For Asturian, we did not generate any synthetic data from OPUS since the Asturian FLORES+ dev and devtest sets were simply enhanced versions of the original FLORES-200. Instead, we downloaded the following es-ast parallel data: GNOME, Kde4, NLLB, Tatoeba, Ubuntu, and Wikimedia.

PILAR[3] We generated synthetic Spanish translations from the monolingual data provided by the organizers in the three respective Romance languages (Galiano-Jiménez et al., 2024b). For Aragonese and Aranese, we used Apertium, while for Asturian, we employed NLLB-200-600M, which fell within the submission's limits. Given the similarity between Aranese and Aragonese to Catalan, we explored whether cascading through Catalan could enhance translation quality. In machine translation, cascading refers to the sequential use of multiple translation systems to improve overall translation accuracy. As demonstrated in Table 1, this method yielded higher scores when translating from Aranese. Consequently, we generated synthetic Spanish translations from Aranese by cascading through Catalan, while for Aragonese and Asturian, we produced the translations directly into Spanish.

	Aragonese → Spanish		Aranese → Spanish	
	ChrF	BLEU	ChrF	BLEU
`Direct`	**80.93**	**66.09**	68.79	45.02
`Cascade`	79.41	63.00	**69.67**	**47.29**

Table 1: Scores obtained with and without cascading through Catalan for FLORES+ dev test.

Provided PDFs We extracted monolingual data in Aragonese and Aranese from the provided `ortografia-aragones.pdf` and `DICCIONARI-DER-ARANÉS.pdf` respectively. After the text extraction, we semi-automatically post-processed the data to obtain a structured and clean corpus. Then we generated the corresponding Spanish translations using Apertium following the same method described in the previous paragraph.

FLORES+ It consists of an extension of FLORES-200 (NLLB Team, 2022), a multilingual English-centric machine translation dataset involving 200 languages, that includes Aragonese, Aranese, and an improved version of Asturian. The FLORES+ dev set for each language served as the validation set during the training phase to optimize our MT engines, while the devtest set was used to evaluate participants' models in the competition. After the final submissions, the devtest set was released, allowing us to obtain scores for the baseline models in this additional set.

2.1.2 Open Submission

For this submission, we used Apertium to generate synthetic data. We created synthetic datasets using a parallel corpus of 30M Galician-Spanish sentence pairs. We only kept the Spanish side of the corpus as the source language data, and then used Apertium to translate it into Aragonese and Asturian, resulting in two 30M sentence parallel corpora (Spanish-Aragonese and Spanish-Asturian).

[2] `https://github.com/OpenNMT/OpenNMT-py`

[3] `https://github.com/transducens/PILAR`

In the case of Aranese, we used a high-quality 30M sentence Spanish-Catalan parallel dataset. We translated the Catalan side into Aranese using Apertium, creating a Spanish-Aranese corpus.

2.2 Data Preprocessing and Cleaning

2.2.1 Constrained Submission

For this submission, we dedicated substantial effort to cleaning, curating, and normalizing the provided data. We designed a comprehensive cleaning pipeline that processed all the parallel data described in the previous section, resulting in well-structured parallel corpora for the Spanish-Aragonese, Spanish-Aranese, and Spanish-Asturian language pairs.

Following the automatic cleaning, we curated the resulting data to ensure it aligned to the orthographic standards outlined in the task statement and matched the characteristics of the corresponding FLORES+ sets for each language.

Blank Spaces, Hard- and Soft-Duplicates Removal The initial step involved removing any unnecessary blank spaces and exact duplicates within the corpus. Then, NLPDedup[4] was used to remove near duplicates.

Idiomata Cognitor[5] This language identifier (Galiano-Jiménez et al., 2024a), specifically designed for certain Romance languages, was employed to accurately determine the languages of each data pair and exclude pairs with sentences belonging to other languages. This method ensures that the translator model is trained on appropriate data.

Perl Corpus Cleaner We employed Moses (Koehn et al., 2007) preprocessing script `clean-corpus-n.perl` to further clean the parallel corpus. It eliminates sentences containing more than 150 tokens and discards sentence pairs with a length ratio exceeding 3.

Linguistic Data Normalization Since the released corpora included text in various orthographies, and both the FLORES+ dev and devtest sets adhered to the current standards endorsed by their respective language academies, we ensured that our training data conformed to these established norms through a normalization process. This process was carried out semi-automatically: incorrect patterns in the data were detected and replaced with the correct ones according to the relevant linguistic rules. This normalization was primarily applied to the Aragonese and Aranese monolingual data. For example, in Aragonese, we encountered different types of definite articles used interchangeably, such as "o"/"lo", "a"/"la", "os"/"los", and "as"/"las", as well as various ways to write the word "university", including "unibersidad", "unibersidá", and "universidat". In the case of definite articles, all forms needed to be standardized to "lo"/"la"/"los"/"las", except when following a word ending in 'n', where the forms are "o"/"a"/"os"/"as". For the term "university", the officially accepted word is "universidat".

Data Curation Using the FLORES+ dev set as our reference, we further examined the parallel data to identify misleading translations in the training data. This curation process involved both semi-automatic and manual methods, primarily focusing on the word level. For example, Apertium often leaves unknown words unchanged in the target sentence or produces incorrect translations due to insufficient contextual understanding of the source sentence. These are common behaviors of rule-based translators. We aimed to detect these issues and correct these translation errors.

According to Table 2, a large number of sentence pairs are discarded, mainly due to the high volume of duplicates in the three corpora, with Aranese and, particularly, Asturian exhibiting the highest number of duplicates.

	Aragonese	Aranese	Asturian
`Original`	74,014	1,336,229	6,603,733
`Filtered`	47,521	407,397	704,933

Table 2: Parallel corpus statistics per target language. `Original` refers to all the collected data pairs before going through the pipeline. `Filtered` refers to the number of pairs resulting from the data cleaning pipeline.

LaBSE scoring To evaluate the quality of translations in the parallel datasets, we used a sentence embedding model. Specifically, we employed LaBSE (Feng et al., 2022) to generate embeddings for both source and target sentences and calculated the co-

sine similarity score between them. Following the approach outlined in (Garcia Gilabert et al., 2024), we obtained scores across various thresholds of cosine similarity to determine the most suitable training dataset for fine-tuning (Table 3). However, the low standard deviation among the results indicates no considerable differences in performance between the sets. We selected a threshold of 0.6 for Aragonese, a threshold of 0.3 for Aranese, and a threshold of 0.1 for Asturian, prioritizing a higher BLEU over a ChrF.

2.2.2 Open Submission

No extra preprocessing or cleaning was performed on the synthetic corpora generated with Apertium for this submission. The source data had previously been processed before publication with their own pipeline [6]. This prepossessing includes fixing encoding issues, deduplication, perplexity filtering and language recognition.

3 Methodology

3.1 Baselines

In Table 4, ChrF and BLEU scores on the FLORES+ dev set for the state-of-the-art models including the directions of interest are shown. Except for the NLLB models, which employ deep learning, all the other evaluated engines are rule-based.

3.2 Constrained Submission: Fine-tuning

3.2.1 Model

NLLB-200-600M is the smallest model from the NLLB family of multilingual machine translation models. It is a dense transformer model distilled from the pre-trained NLLB-200, a 54.5B sparsely gated mixture-of-experts model, designed to support translations between 202 languages, including many low-resource languages. Therefore, it incorporates substantial cross-lingua knowledge, making it suitable for further fine-tuning to other languages. It has a vocabulary size of 256k tokens, plus additional tokens for the language tags corresponding to all the languages supported by the model. With respect to our languages of interest, it just handles Asturian. Occitan is also in the list of languages, but not the Aranese variant.

3.2.2 Fine-tuning

For this approach, we fully fine-tuned three separate NLLB-200-600M models for Spanish-to-Aranese, Spanish-to-Aragonese, and Spanish-to-Asturian, leveraging the cross-lingua knowledge NLLB possesses.

Adding New Language Tags Among the languages of interest, NLLB only supports Asturian natively. To extend NLLB's translation capabilities to translate to Aragonese and to Aranese, we incorporated new tokens referring to their respective language tags (`arn_Latn` and `arg_Latn`), since these languages are not present in NLLB[7]. Language tags enable NLLB to identify the source and target languages for translation. Adding new language tags implies extending the embedding matrix with additional embeddings. These new embeddings were initialized using the embeddings of other language tags already supported by NLLB, which were linguistically close to our target language. Specifically, we used the `spa_Latn` embedding for Aragonese and the `oci_Latn` embedding for Aranese. Finally, we retrained the embedding matrix during the fine-tuning to enable correct Spanish-to-Aragonese and Spanish-to-Aranese translation. For Asturian, since NLLB already supports translation to this language, our objective was simply to improve the model's performance

[6] https://github.com/proxectonos/corpora

[7] Aranese is a variant of Occitan, but due to observed differences in the test sets, we treated Aranese as a distinct language with its own language tag.

Table 4: Evaluations computed on the FLORES+ dev set.

through fine-tuning.

Treatment of "«" and "»" tokens Given that "«" and "»" symbols are not in the NLLB vocabulary and they were present in the reference test sets, we decided to preprocess the training data by replacing "«" and "»" with "<<" and ">>" (as these tokens are in the vocabulary) and then revert this replacement after the model's inference.

3.2.3 Inference experiments

The generated translation is restricted to a length of 512 tokens. Testing on FLORES+ dev, we conducted a grid search on the top-performing model obtained from the LaBSE scoring step. We experimented with various beam sizes (B) and repetition penalty terms (β). We tried all combinations between $B = [3, 5, 10]$ and $\beta = [1, 3, 4]$. Nevertheless, no significant differences in performance were observed for these languages, so we ended up using the same hyperparameters employed during training: $B = 5$ and $\beta = 1$. For detailed results, see Appendix.

3.2.4 Configurations

In the fine-tuning, we used the AdamW optimizer (Loshchilov and Hutter, 2019) with $\beta_1 = 0.9$, $\beta_2 = 0.98$, $\epsilon = 10^{-6}$, and $\lambda = 0.001$. The learning rate was set to 3×10^{-4}. We applied an inverse square root scheduler with 15,000 warmup steps.

For Aragonese, the batch size was set to 16, the gradient accumulation steps to 8, and the model was trained for 15 epochs. For Aranese and Asturian, the batch size was set to 8, the gradient accumulation steps to 4, and the models were trained for 10 epochs. All models were fine-tuned using the Transformers[8] library on H100 GPUs. Every 1,000 training steps, the ChrF score was computed on the FLORES+ dev set, and the model checkpoints were saved when the score improved.

3.3 Open Submission: Training

3.3.1 Model

We trained three transformer models from scratch using OpenNMT-py 3.2, each with its own BPE vocabulary. The vocabulary size for each model was set to 20,000 units, based on previous internal research investigating the impact of vocabulary size on BLEU scores (Outeirinho et al., 2024).

3.3.2 Configurations

All three models were trained on a single A100 GPU using the AdamW optimizer with $\beta_1 = 0.9$, $\beta_2 = 0.9998$, $\epsilon = 10^{-8}$, and learning rate 5×10^{-4}. The batch size was set to 2048 sentences, with a maximum length of 150 tokens per sentence. All models were trained for a maximum of 10 epochs.

3.4 Evaluation

To evaluate the performance of our models during the development phase, we used the FLORES+ dev set, which contains 997 general domain sentences. The results obtained on this test set for the two developed strategies can be seen in Table 4.

Table 5: Evaluations computed on the FLORES+ devtest set.

3.4.1 Constrained Submission

Following this strategy, we surpassed the baselines across the three languages, achieving better performance than the state-of-the-art. We observed an increase of +2.63 in ChrF and +5.8 in BLEU for Aragonese (compared to Apertium), +3.41 in ChrF and +6.54 in BLEU for Aranese (compared to Apertium), and +1.49 in ChrF and +1.37 in BLEU for Asturian (compared to Eslema and NLLB-200-3.3B, respectively). These results suggest that both the thorough curation of data and the cross-lingual knowledge possessed by NLLB contributed to these improvements.

3.4.2 Open Submission

Leveraging transformer models has led to results that are only slightly behind the best rule-based approaches. However, the significance of these results lies in the fact that they enable the community to access and develop neural models that perform competently in a relatively short time compared to developing a new rule-based system from the ground up. These neural models, particularly transformers, offer new possibilities, such as the ability to learn from limited data and improved scalability, which can help prevent languages with fewer speakers from being marginalized in the online world.

4 Results

The FLORES+ devtest set, containing 1,012 sentences, was used to evaluate and rank the participants' models. Once the competition ended, the organizers made the FLORES+ devtest set public. To further expand the evaluation of our new models, we also obtained scores for the baselines using this test set. Consult Table 5 for all the scores. We see the same trend as with the FLORES+ dev set. Using the fine-tuned version of NLLB-200-600M on the cleaned data, we surpass all the baseline models for the three languages, whereas training the models with OpenNMT-py 3.2 lags behind. Specifically, we enhance the scores by +0.57 in ChrF and +1.21 in BLEU for Aragonese (compared to Apertium), +0.63 in ChrF and +1.27 in BLEU for Aranese (compared to Apertium), and +1.23 in ChrF and +1.26 in BLEU for Asturian (compared to Eslema). At the time of writing this paper, the final ranking scores were not available, so no mention of our final positions in the competition is included in this paper.

5 Discussion

Compared to traditional rule-based translation systems, neural models offer greater flexibility, scalability, and adaptability, making them the state-of-the-art in Machine Translation. Hence, our work in developing neural systems for Aragonese, Aranese and Asturian represents an advance in the preservation and promotion of the use of these languages. It also allows the research community to use our models for further advancements in language technology, linguistic research, and the development of more sophisticated and accurate translation systems.

6 Conclusions

This paper summarizes the work done by the ILENIA team for the Shared Task on Translation into Low-Resource Languages of Spain. By participating in this public competition, we have contributed to the creation and improvement of NMT models for Aragonese, Aranese, and Asturian - three minority languages of Spain. Prior to this task, no NMT models were available for Spanish-to-Aragonese and Spanish-to-Aranese translation.

We presented a Constrained and an Open Submission, each employing different approaches. For the Constrained Submission, adhering to data and model restrictions, we fine-tuned the NLLB-200-600M model, with considerable effort devoted to data cleaning and curation. For the Open Submission, we generated a large amount of synthetic data using Apertium, a rule-based MT system, and used it to train a transformer-based model from scratch.

Results on both FLORES+ dev and devtest sets across the three language directions show that the first strategy achieves better performance and improves translation quality compared to the baselines, whereas the second strategy lags slightly behind the best baseline models.

{adponce,hgete,tetchegoyhen}@vicomtech.org

Abstract

We describe Vicomtech's participation in the WMT 2024 Shared Task on translation into low-resource languages of Spain. We addressed all three languages of the task, namely Aragonese, Aranese and Asturian, in both constrained and open settings. Our work mainly centred on exploiting different types of corpora via data filtering, selection and combination methods, along with synthetic data generated with translation models based on rules, neural sequence-to-sequence or large language models. We improved or matched the best baselines in all three language pairs and present complementary results on additional test sets.

1 Introduction

Despite significant progress in Machine Translation (MT) in recent years, notably with the advent of Neural Machine Translation (NMT) approaches (Bahdanau et al., 2015; Vaswani et al., 2017), translation from and into low-resource languages remains a challenge.

Spain features a large variety of languages beyond Spanish, with varying degrees of MT support. Important quality gains have thus been achieved for the Basque language within the NMT framework (Etchegoyhen et al., 2018), with large public deployments of quality MT systems[1]. For Catalan, a romance language with closer proximity to Spanish, earlier NMT improved over rule-based (RMT) and statistical (SMT) models, although with performance losses on out-of-domain test sets (Costa-jussà, 2017); more recent work on translation between similar languages, that included Catalan-Spanish, showed a predominance of NMT approaches to the task (Akhbardeh et al., 2021).

In addition to the aforementioned languages, there are languages such as Aragonese, Aranese and Asturian which could be viewed as extremely low-resourced in terms of MT technological support. For most, the main technology is still RBMT, based on the Apertium framework (Forcada and Tyers, 2016). The WMT 2024 shared task on translation into low-resourced languages of Spain addresses translation from Spanish into all three of these languages. In this work, we describe Vicomtech's participation in the shared task, where we submitted entries to both the constrained and open tracks.

In the remainder of this paper, we describe our approaches to improve MT performance for the three selected language pairs. We explored data selection, generation, and combination, comparing the use of different types of data to train end-to-end NMT models as well as fine-tuning pretrained multilingual MT models. In addition to typical parallel data curation, where we filtered the available parallel and comparable data according to sentence similarity, length differences and language identification, we also explored the generation of synthetic data along different lines. We notably compared the use of RBMT systems and large language models (LLM) to generate synthetic parallel datasets from the available monolingual data. The latter approach in particular showcased the potential of LLMs to create back-translations from the selected three low-resource Romance languages into the high-resource Spanish language.

2 Methodology

2.1 Parallel Data Curation

Despite the limited amount of data available for the languages addressed in this task, several crawled corpora were made available. However, after manually examining sampled of the data, they appeared to feature large amounts of noise, including poor alignments, language identification errors, or sentence pairs with empty information in one of the

[*] Equal contribution.

Proceedings of the Ninth Conference on Machine Translation, pages 934–942
November 15-16, 2024 ©2024 Association for Computational Linguistics

languages. We therefore performed various types of filtering, described below.

Language Identification. We performed language identification with the Idiomata Cognitor tool[2], a Bayesian language identifier specialised on Romance Languages (Galiano-Jiménez et al., 2024a). We filtered all sentence pairs where the identified language on either side mismatched the expected language in the parallel dataset.

Length Ratio. We filtered all sentence pairs where the ratio of lengths, in terms of characters, was above a predefined threshold. Unless otherwise specified, we used a default ratio of 3.0. Our goal with this type of filtering was to remove obvious erroneous alignments rather than determine an optimal threshold in terms of length differences.

Sentence Similarity. We filtered all sentence pairs whose similarity score was below a predefined threshold. Similarity was computed as the cosine similarity of the sentence embeddings for each sentence pair. After preliminary experiments with different models, we opted for the all-MiniLM-L6-v2 model of the Transformers library[3], as it provided sufficient quality for the considered pairs, while also supporting sufficiently fast processing to run multiple filtering experiments. For each language pair, we assigned similarity scores to the parallel corpora after language and length filtering, manually examined samples of the data and determined a similarity threshold accordingly.

2.2 Synthetic Data Creation

For low-resource languages, parallel data are typically scarce and monolingual corpora are a rich source of complementary data. We aimed to explore different approaches to exploit this type of data, generating synthetic data by translating via RBMT systems, NMT models and LLMs (see Frontull and Moser (2024) for a similar approach). Depending on model availability and/or quality, we generated data to be used as either back-translations (BT) (Sennrich et al., 2016) from the low-resource languages into Spanish, or as forward-translations (FT) (Li and Specia, 2019) in the opposite translation direction. In either case, the synthetic data generated from monolingual data were used as parallel data to translate into the low-resource languages. Additionally, we used pivot machine-translation from Catalan to Spanish to complement the Spanish-Aranese parallel datasets, as described below.

RBMT data (BT + FT). As back-translations, we translated the available monolingual corpora in Aragonese and Aranese into Spanish with the corresponding Apertium systems.[4] As forward-translations, we generated synthetic data from Spanish into all three low-resource languages, since Apertium covered all three language pairs in that direction. Our goal in both the BT and FT cases was to evaluate the impact of data translated via transformation rules that tend to closely follow the structure of the original Spanish data.

NMT data (BT). We generated back-translations into Spanish for all three language pairs with baseline NMT models, either trained from scratch or pretrained and fine-tuned, on the curated parallel data, as described in Section 2.3. Considering the low volumes of clean parallel data and the relatively low quality of the baselines, we discarded the use of forward-translations in this scenario. Back-translations are more robust in this type of scenario, as the target language monolingual data are expected to be correct for the decoder to model and the noise in corresponding synthetic source data can be handled relatively well by NMT models in general. Our aim with NMT-based NMT data was to generate synthetic data of relatively fluid translations that would differ from, and could complement, RBMT translations.

LLM data (BT). We also leveraged a general-purpose language model in zero-shot fashion to generate back-translations, querying the model to translate from the low-resource language into Spanish. Our preliminary assessment on the three language pairs was that translation into the low-resource languages could not constitute a reasonable alternative, as most translations from Spanish into either low-resource language were of low quality, irrespective of the size of the selected model. However, in the reverse direction, in all three pairs translation quality was markedly better, indicating that the meaning of the text in the low-resource language could be properly captured by the model, while generating correct output in the high-resource Spanish language.

[3] https://huggingface.co/sentence-transformers/all-MiniLM-L6-v2

[4] https://www.apertium.org/ Note that there was no readily available system for Asturian to Spanish.

Pivot MT data. Among the available corpora for the task were data in Catalan-Aranese (see Section 3.1), which could be exploited as well via pivot MT. To this end, we translated the available corpora from Catalan to Spanish with a high-quality in-house NMT model trained on OPUS parallel data (see Appendix C for further details).

2.3 Models & Training

Models. We trained two main types of models: Transformer-base encoder-decoder models trained from scratch on the available parallel, with or without complementary synthetic data, and a pretrained multilingual model fine-tuned with the same data, namely an NLLB-200-600M model (Costa-jussà et al., 2022). By opting for two parallel approaches, we aimed to evaluate the positive or negative impact of accessing pretrained multilingual knowledge on the task. With either type of model, we trained baseline variants on the curated parallel data, which were used used to generate back-translations, as described in Section 2.2. Both types of models were also used on the combined datasets to train final models, as our main aim was to contrast and compare the use of pre-trained multilingual knowledge vs. focused training on a specific low-resource language pair.

Tagging. To train the model variants, we performed several experiments around data tagging, which has been shown to be an efficient approach to training data discrimination, for back-translations (Caswell et al., 2019) or comparable data (Gete and Etchegoyhen, 2022), for instance. We used specific tags, prepended to each training instance, to indicate the type of data at hand, namely <BT> or <FT>. We aimed to investigate in particular whether data tags would be beneficial or detrimental in the case of low amounts of parallel data, combined with larger sets of synthetic data.

3 Experimental Setup

3.1 Corpora

For the constrained track, we selected the parallel corpora for Asturian, Aranese, and Aragonese from the PILAR collection (Galiano-Jiménez et al., 2024b), the monolingual WikiMedia data for Spanish and Asturian, the parallel data for Spanish-Asturian and Spanish-Occitan (with Occitan related to Aranese) from CCMatrix (Schwenk et al., 2021b) and WikiMatrix (Schwenk et al., 2021a) for Spanish-Aragonese, all of which were downloaded from the OPUS repository (Tiedemann, 2012). We performed language identification to keep only the Aranese sentences from Occitan, and also translated the Catalan portion of the Catalan-Aranese dataset via pivot translation into Spanish. For the open track, we included Asturian and Aragonese monolingual data extracted from WikiDump[5], for additional back-translations.

Corpus	Lang.	# Sent.	# Filt.	Constr.

	arg	508.5K	255.1K	✗

Table 1: Corpora statistics. We indicate the number of initial (# Sent.) and filtered (# Filt.) sentences and corpus use in the constrained track (Constr.). x/y indicates filtering with similarity thresholds of 0.5 (x) and 0.7 (y).

Excepting the PILAR datasets, which were used as is, we filtered the contents from the parallel corpora using the methods described in Section 2.1. The similarity threshold was set at 0.7 after manually reviewing portions of the data. For Aragonese and Aranese, since significant portions of the datasets were discarded at this threshold, we also created an additional dataset with a 0.5 threshold. For the constrained task, we selected these larger, though noisier, datasets. For the open task, we opted for the smaller, higher-quality datasets, due to the greater availability of data.

As evaluation data, we selected the dev sets available in PILAR, as well as a filtered subset of 3,000 highquality sentence pairs from CCMatrix for Asturian, with a similarity threshold set at 0.9. The latter was created as all models consistently yielded significantly lower scores on the Asturian PILAR dev set, compared to the other language pairs, and Marian models trained with this development set struggled to converge effectively. We report results on the official development set throughout the paper, but discuss additional results on our own development set in Section 5.

Corpora statistics are summarised in Table 1.

3.2 Models

In this section, we describe the translation models we used for the task, including the baselines and the models trained on the selected data described in the previous section. Since we generated synthetic data for both forward (from Spanish) and backward (into Spanish) translation, we present each type of model in turn. Training details, including additional model characteristics and training hyper-parameters are described in Appendix A. All models were evaluated in terms of BLEU and chrF, computed with the sacreBLEU toolkit [6]. Statistical significance was computed via bootstrap resampling (Koehn, 2004) for all results. Best results, for $p < 0.05$, are indicated in bold in all tables.

3.2.1 Translation from Spanish

For translation from Spanish, we first assessed the quality of three baseline models not trained on any of the selected data: the rule-based Apertium for each language pair, as a reference MT system for these languages; the multilingual NLLB-200-distilled-600M model, pretrained on a broad range of languages including Asturian and Occitan, as a neural baseline under the constrained track limitation of pretrained models with fewer than one billion parameters; and the Llama3-8B instruction model (AI@Meta, 2024), as an experimental testbed for zero-shot LLM-based translation.

Lang.	Model	Dev	
		BLEU	chrF
ES→AST	Apertium	**17.1**	**50.7**
	NLLB	14.3	44.2
	Llama3	15.2	48.9
ES→ARG	Apertium	**66.0**	**82.**2
	NLLB	7.9	42.1
	Llama3	30.4	64.5
ES→ARN	Apertium	**38.0**	**60.0**
	NLLB	8.5	39.2
	Llama3	4.5	32.6

Table 2: Baseline model results on the development sets for translation from Spanish

Table 2 presents the results for each baseline model in this translation direction, in terms of BLEU (Papineni et al., 2002) and chrF (Popović, 2015). Apertium achieved the highest scores in all three language pairs, demonstrating the value of an RBMT approach for the selected languages. NLLB and Llama3 were notably both outperformed by large margins on ES-ARN; the former performed equally poorly on ES-ARG but the latter achieved a more reasonable performance of 30.4 BLEU points in this case, still far from the scores obtained by the Apertium baseline. The only language pair where all three models achieved relatively similar low scores was ES-AST, which might be due to the specifics of this development set (see Section 5 for further discussion).

Considering these results, we used Apertium to generate forward synthetic data for all ES→XX translation pairs. To prepare the final models, all related to translation from Spanish in the task, we used two types of approaches: fine-tuning the NLLB model on the selected data and training from scratch a Transformer-base model with 6 encoder layers and 6 decoder layers, trained with the Marian NMT toolkit (Junczys-Dowmunt et al., 2018).

3.2.2 Translation into Spanish

Model	Aranese	Aragonese	Asturian
Apertium	**34.8**	66.2	-
NLLB	31.0	55.6	64.1
Llama3	33.1	64.3	71.5
Marian	**34.0**	**69.6**	**86.5**

Table 3: BLEU scores for translation into Spanish on the PILAR development sets for Aranese and Aragonese, and on a custom development set for Asturian.

Translation into Spanish was performed to generate synthetic back-translations. For this task, we used the three baseline approaches described in the previous section (except for AST-ES with Apertium, as it is not currently supported) and trained an additional XX→ES Marian model on the selected parallel and forward-translation data.

Table 3 presents the BLEU scores for these models on the task-provided development sets for Aranese and Aragonese, and on our custom development set for Asturian. For Aranese, there was no statistically significant difference between the Marian and Apertium models, both outperforming NLLB and Llama3; in Aragonese, Marian outperformed all other models, with NLLB performing notably worse; in Asturian, it again significantly outperformed both NLLB and Llama3. Considering these results, we selected the Marian model to generate all back-translations. Additionally, since forward-translations were all generated using Apertium, the incorporation of a neural model could add more variety to the synthetic data.

Table 5: BLEU and chrF scores for our primary submissions in the open track

A notable result are the relatively high scores of Llama3 zero-shot translation into Spanish, confirming our initial assessments of the potential leveraging this type of LLM to translate from low-resource into high-resource languages. Further variants such as few-shot translation might be worth exploring in this type of scenarios.

4 Main Results

The best results for our shared task submissions are summarised in Table 4 and Table 5 for the constrained and open tracks, respectively. We report BLEU and chrF scores on the PILAR development sets and on the task test sets, as reported on the OCELoT website.

4.1 Constrained Track

In the constrained setup, our focus was on optimising translation models within the set limits of OPUS data and pretrained models under one billion parameters. For Asturian, the best results were achieved via a fine-tuning of NLLB using both parallel data from CCMatrix and back-translations generated from the PILAR, CCMatrix and WikiMedia corpora using our custom Marian model.

In the case of Aragonese and Aranese, training Marian models from scratch proved to be the most successful strategy. Given that NLLB was not specifically trained on these languages, this result was not unexpected. For these languages, we also incorporated forward-translations generated using Apertium and back-translations created with our Marian models. For Aranese, the use of parallel

Table 6: BLEU scores comparison between models trained with and without tags in the forward-translated data.

data from CCMatrix resulted in lower performance, likely due to the lower quality of these data, which were originally Spanish-Occitan alignments. The inclusion of the pivot translations from Catalan was also beneficial for the Spanish-Aranese pair.

Overall, when comparing our results to the baselines in Table 2, our custom models consistently outperformed the vanilla NLLB across all languages, particularly for Aragonese and Aranese, which were unseen by this model. The models trained for Asturian and Aranese also achieved higher scores than the Apertium baseline. For Aragonese however, our best submission could only match the Apertium baseline scores. This limitation is likely due to the influence of the forward-translations from the rule-based Apertium system, a factor which was not mitigated with data tagging.

4.2 Open Track

Our contributions to the open track were twofold: augmenting the training data by incorporating Asturian and Aragonese Wikipedia content, and generating back-translations using Llama3 in a zero-shot setting.

As shown in Table 5, these additions improved the BLEU score for Asturian by 0.5 points compared to the constrained track. However, the results for Aragonese did not benefit from the extra data, showing a slight decrease of 0.1 BLEU. For Aranese, the use of back-translations from Llama3 appeared to be detrimental, resulting in a performance drop of 0.8 BLEU points.

Overall, the open track models yielded mixed results, as the augmented data generated via back-translation and zero-shot LLM translation resulted in either minor gains or losses. This might be due to the specifics of the development and test sets, in the sense that the augmented data might come from domains of little benefit to improve the translation on these datasets. The results of Section 3.2 are still important in our view, notably the quality of NMT and LLM translations for either direct use or data augmentation.

5 Discussion

As previously indicated, given the low performance of all models in Asturian in preliminary experiments, we used a filtered subset of 3,000 sentences from CCMatrix as development set. However, to ensure consistency across languages, we relied on the best-performing model on the original PILAR dev set as the criterion for model selection for submission, leading to the exclusion of models that performed better on our custom dev set.

Model	Source	Official Dev	Custom Dev
Apertium	-	17.1	79.8
Open Submission	-	**18.6**	78.4
Marian	CCMatrix	17.2	**87.4**

Table 7: BLEU scores in Spanish-Asturian on the official WMT development set and on our custom development set from CCMatrix.

For reference, Table 7 presents the results of the top-performing model on our dev set: a Marian model trained exclusively on CCMatrix data without any synthetic data. While this model shows lower performance than the one chosen for the official submission and is comparable to the baseline obtained with Apertium, it performed notably better on our own development set. Considering the large differences in scores between the PILAR and custom dev sets, it would be interesting to examine in detail the differences between the two datasets in future work.

Among our best submissions to both tracks, only one dataset was tagged, namely the forward-translations based on Wikimedia in ES-ARG. We performed several additional experiments on the use of tags to discriminate between types of data, with the most salient results shown in Table 6. Tags on forward-translations were beneficial for Asturian and Aranese, but for Aragonese their use resulted in a substantial decrease of almost 20 BLEU points on the dev set. This variation might be due to the differing amounts of data available: Asturian and Aranese featured 500K and 364K sentence pairs without tags, respectively, while Aragonese only counted with 119K such pairs. Whereas tags have been shown to be a successful means to discriminate between parallel and other types of data, their use might thus be detrimental when tagged data largely dominate the other types of data.

6 Conclusions

We described our submission to the WMT 2024 shared task on translation into low-resource languages of Spain. We followed a multi-pronged approach based on data filtering and augmentation, with multiple types of models trained on different combinations of data with or without tagging. Although we improved over the baselines in general, the gains were minor overall on the development sets provided for the task. Nonetheless, our experiments showed the benefits of training dedicated NMT models, which proved optimal in most cases over fine-tuning pre-trained translation models. We also demonstrated the potential of zero-shot LLM-based translation for translation of the selected low-resource languages into Spanish, an interesting path for future research as standalone translation or as a source of data augmentation.

Acknowledgments

We wish to thank the anonymous WMT reviewers for their helpful comments. This work was partially supported by the Department of Economic Development and Competitiveness of the Basque Government (Spri Group) via funding for project ADAPT-IA (KK-2023/00035).

A Training Hyperparameters

The Marian models were transformer-base models. Optimization was performed with Adam (Diederik P. Kingma, 2015), with $\alpha = 0.0003$, $\beta_1 = 0.9$, $\beta_2 = 0.98$, and $\epsilon = 10^{-9}$. We used a working memory of 20GB and automatically chose the largest mini-batch that fit the specified memory. The learning rate was set to increase linearly for the first 16,000 training steps and decrease afterward proportionally to the inverse square root of the corresponding step. The validation data was evaluated every 5000 steps.

For fine-tuning the NLLB model, optimization was performed using Adafactor (Shazeer and Stern, 2018), with a learning rate of 0.0001, a clipping threshold of 1.0, and weight decay set to 0.001. The training used a batch size of 32 and a maximum sequence length of 128 tokens.

Each model was trained on a Nvidia L40 with 48GB of VRAM. Early stopping was applied with a patience of 10 epochs to prevent overfitting.

B Generation Parameters

For inference with Marian, we set a beam size of 6 and a normalization factor of 0.6.

For the NLLB model, implemented on the transformer library, the maximum input length was configured to 200 tokens, with a beam size of 4.

For Llama3, we set a maximum of 256 new tokens, enabled sampling with a temperature of 0.1, and set top-p to 0.9. We used the following prompt to direct the model to generate translations in the specified target language without additional commentary: "*Traduce a [Español|Aragonés|Aranés|Asturiano] la siguiente frase. No añadas ningún otro comentario.*" .

C Catalan-Spanish MT Model

We considered two main options to translate Catalan into Spanish, as a means to create additional Aranese-Spanish data via pivot translation: the pretrained multilingual NLLB model or an in-house Marian model trained on parallel corpora from OPUS (namely: dogc, gnome, opensubs, tatoeba, ubuntu, globalvoices, wikimatrix, ted and paracrawl). The latter achieved significantly better results, as shown in Table 8 on a test set of 2,000 sentence pairs randomly sampled from OPUS data.

Translation Model	**BLEU Score**
NLLB Model	55.4
Marian Model	**70.7**

Abstract

This paper describes Shanghai Jiao Tong University low-resource languages of Spain translation systems for WMT24 shared task. We participate in the translation task on Spanish → Aragonese, Spanish → Aranese and Spanish → Asturian. Initially, we conduct preliminary experiments to assess the basic translation capabilities of various models and evaluate the impact of fine-tuning with different data types. We then choose to fine-tune the Qwen2-0.5B model using a forward synthesized pseudo-corpus from the Apertium translation system to replicate its fundamental performance. Building on this distillation model, we explore three optimization strategies across the three language directions: (1) Assembling the provided FLORES+ dev sets into a 5-shot format translation training dataset and performing few-shot fine-tuning to enhance model performance. (2) Utilizing the FLORES+ dev sets as training data and applying the Contrastive Preference Optimization (CPO) strategy for further refinement. (3) Retrieving the 20 most similar translation examples from the FLORES+ dev sets using the BM25 algorithm and performing 20-shot translations with the Claude 3.5-sonnet model. After evaluating these strategies, we select the best-performing approach for each language pair as our submission result.

1 Introduction

This paper introduces our submissions to the WMT24 Low-Resource Languages of Spain Task. We participate in the competitions for three translation directions: Spanish → Aragonese, Spanish → Aranese, and Spanish → Asturian. For the Spanish → Aragonese and Spanish → Aranese directions, we ultimately submit constrained results, while for Spanish → Asturian, we provide unconstrained (open system) results.

Neural machine translation (NMT) systems have achieved substantial advancements in recent years (Vaswani et al., 2017). However, training neural translation models typically necessitates large-scale parallel corpora (Ranathunga et al., 2021). In many low-resource scenarios, the availability of sufficient parallel data for training is limited, making low-resource translation a critical and valuable research area (Arivazhagan et al., 2019; Wang et al., 2021; Ranathunga et al., 2021). This competition task focuses on translating between Spanish and three other languages: Aragonese, Aranese, and Asturian. Of these, Aragonese and Aranese face particular challenges due to their relatively scarce parallel corpora. While the OPUS[1] website provides a considerable amount of parallel data, the quality of this data remains relatively low.

We initially conduct a preliminary evaluation of translation capabilities using models such as Apertium[2], GPT4 (Achiam et al., 2023), Llama-3 (AI@Meta, 2024), and Qwen2 (Yang et al., 2024) across the three language pairs. Our findings indicate that the Apertium translation system serves as a strong baseline, particularly in terms of BLEU (Papineni et al., 2002; Post, 2018) scores. Subsequently, we explore fine-tuning the Qwen2-0.5B model with various types of synthetic data and data from diverse domains. This exploration reveals that this task presents unique challenges compared to previous low-resource translation tasks. Specifically, forward-translated (Zhang and Zong, 2016) data and data from the OPUS NLLB corpus result in improved performance on dev test sets. We ultimately select the NLLB Spanish corpus from OPUS and perform forward translation using Apertium to generate the corresponding parallel pseudo-corpus. Fine-tuning Qwen2-0.5B with this synthetic data enables us to closely replicate the performance of the Apertium translation system.

[*] Tianxiang and Pei contributed equally. Work was done when Tianxiang was interning at Tongyi Lab.

Although simple forward distillation can effectively replicate the performance of the Apertium system, it does not exceed it, and the distilled model does not yield further performance improvements. To enhance the model's effectiveness, high-quality data is crucial. We randomly select a portion of the provided dev test set for additional fine-tuning, with the remaining portion designated as the new dev set. Building on this distilled model, we explore three optimization strategies across three language pairs: (1) We aggregate the provided FLORES+ dev sets into a 5-shot format translation training dataset and perform few-shot fine-tuning (Alves et al., 2023) to further refine the model. (2) We use the FLORES+ dev sets as training data and apply the Contrastive Preference Optimization (CPO) (Xu et al., 2024) strategy to improve model performance. (3) We retrieve the 20 most similar translation examples from the FLORES+ dev sets using the BM25 algorithm and employ the Claude 3.5-sonnet model[3] for 20-shot translations (Agrawal et al., 2022).

2 Preliminary Experiment

In this section, we first investigate the basic translation capabilities of various models and identify the Apertium translation system as a particularly strong baseline. We then examine the fine-tuning of the Qwen2-0.5B model using different types of data, which reveals that this task presents unique challenges compared to previous low-resource scenarios. Ultimately, we select the NLLB[4] Spanish corpus from OPUS, forward-translate it using Apertium to create a parallel pseudo-corpus, and fine-tune Qwen2-0.5B with this synthetic data.

Data The results presented in this section are derived from experiments conducted on the official FLORES+ dev test sets[5], which come from Pan-Iberian Language Archival Resource (PILAR). The three language pairs under consideration are Spanish → Aragonese (spa-arg), Spanish → Aranese (spa-arn), and Spanish → Asturian (spa-ast), each comprising 997 sentences.

2.1 Translation capabilities of different models

We begin by evaluating the BLEU (Papineni et al., 2002; Post, 2018) performance of five models (Apertium, GPT-4, Llama3-8B, Llama3-70B, and Qwen2-0.5B) on the three language pairs in this task using the FLORES+ dev sets. For the 1-shot scenario, the format used is as follows: "Translate the following sentence from <src lang> into <tgt lang>.\n <src lang>: <src example1>.\n <tgt lang>: <tgt example1>.\n \n Translate the following sentence from <src lang> into <tgt lang>.\n <src lang>: <src sentence>.\n <tgt lang>:". In the 5-shot scenario, this format is extended by providing five examples instead of one. The few-shot examples are randomly sampled from the corresponding language FLORES+ dev sets without repetition.

As shown in Table 1, our results indicate that the Apertium translation system serves as a very strong baseline, significantly outperforming other large models in BLEU scores for the Spanish → Aragonese (spa-arg) and Spanish → Aranese (spa-arn) language pairs. Notably, even the widely used GPT-4 scores considerably lower in BLEU compared to the Apertium system. This superior performance of Apertium may be attributed to the fact that the dev test sets for these two language pairs were derived from Apertium's translations with post-editing. Additionally, we observed that increasing the number of example shots in translation leads to a substantial improvement in performance. This suggests that, for these low-resource languages, providing translation examples enhances the ability of large models to learn and perform the translation task more effectively.

	spa-arg	spa-arn	spa-ast
Apertium	66.0	38.0	17.1
GPT4 1shot	35.9	16.1	18.6
GPT4 5shot	37.4	17.7	19.1
Llama3-8B 1shot	36.3	7.8	16.6
Llama3-8B 5shot	41.0	10.6	18.3
Llama3-70B 1shot	46.4	15.6	19.4
Llama3-70B 5shot	52.4	19.9	22.4
Qwen2-0.5B 1shot	22.7	4.1	8.6
Qwen2-0.5B 5shot	22.7	4.2	8.9

Table 1: BLEU evaluation of different models on dev test sets for three language pairs. Apertium translation system demonstrates a strong baseline.

2.2 Effects of different types of data

To explore the types of data that can be used for fine-tuning the base model, we conduct preliminary experiments focusing exclusively on Aragonese.

[3] https://claude.ai

[4] https://opus.nlpl.eu/NLLB/corpus/version/NLLB

[5] https://github.com/transducens/PILAR

As shown in Table 2, we evaluate the impact of different data types on fine-tuning performance. Our findings indicate that forward translation (FT) (Zhang and Zong, 2016) outperforms back translation (Sennrich et al., 2016). This result may be attributed to the fact that the dev test set is derived from Apertium with post-editing, which means that the Aragonese side of the dev test set reflects Apertium's translation style rather than the natural language style of Aragonese. In contrast, back translation targets the authentic Aragonese language style, which does not align with the style of the dev test set, potentially leading to BLEU scores that do not accurately represent the actual translation quality. However, due to the extremely low-resource nature of this language, we have to rely on the official dev test set and BLEU scores for optimization.

Additionally, the table highlights another critical factor affecting performance: the source of the fine-tuning data. Using Spanish monolingual data from the OPUS NLLB corpus[6] provides a noticeable performance advantage over using WMT news[7], Pilar[8] or random samples from OPUS[9]. This suggests that the domain of the dev test set is more closely aligned with the OPUS NLLB corpus, facilitating better adaptation to the dev set for this task. Furthermore, we observe that mixing data from different domains or simultaneously using both BT and FT does not enhance performance, despite increasing the volume of data. In fact, this approach slightly degrades the original performance.

2.3 Final Distillation Experiment

Based on the experimental results discussed above, we first perform basic filtering on the NLLB Spanish corpus from OPUS and then randomly sample 1 million sentences. We use the Apertium translation system to translate these 1 million Spanish sentences into the three target languages, creating a parallel pseudo-corpus. We then fine-tune the open-source Qwen2-0.5B model separately for each language using this pseudo-corpus. During training, we fine-tune the model for 1.5 epochs with a batch size of 64, a learning rate of 1e-05, and a weight decay of 0.1. For decoding, we employ beam search with a beam size of 4. As shown in Table 3, this approach effectively replicates the baseline performance of the Apertium translation system.

Data size	Data source	Data type	BLEU
16k	OPUS	bilingual	37.7
16k	OPUS	FT	61.7
16k	News	FT	53.0
16k	OPUS NLLB	FT	63.8
16k	OPUS	BT	41.1
16k	Pilar	BT	34.3
32k	OPUS	FT+BT	59.6
32k	OPUS+News	FT	59.8

Table 2: BLEU evaluation on fine-tuning Qwen2-0.5B using different types of data. Data size refers to the training data size. FT refers to forward translation of Spanish to comprise synthesized parallel data; BT refers to backward translation of Aragonese to comprise synthesized parallel data; News referes to the WMT news.

	spa-arg	spa-arn	spa-ast
Apertium	66.0	38.0	17.1
distillation model	66.0	38.0	17.0

Table 3: BLEU evaluation of the distillation model on dev test sets for three language pairs. We have replicated the baseline capability of Apertium translation system.

3 Method

In Section 3, we initially replicate the performance of the strong baseline system Apertium using the Qwen2-0.5B model but are unable to surpass it. We also observe that fine-tuning the model with filtered bilingual data resulted in decreased BLEU scores, likely due to the low quality of available bilingual data. The synthetic pseudo-corpus generated through forward translation reach its performance limits, as further improvements could not be achieved with the distilled model. To address this, we randomly select 700 sentences from the provided dev test set for additional fine-tuning, reserving the remaining 297 sentences as the new dev set. We next explore three optimization strategies to further enhance translation performance for these three language pairs.

3.1 Dev 5shot SFT

In Table 1, we observe that providing few-shot examples to large language models improves trans-

[6] https://opus.nlpl.eu/NLLB/corpus/version/NLLB

[7] https://www.statmt.org/wmt11/translation-task.html

[8] https://github.com/transducens/PILAR

[9] https://opus.nlpl.eu

lation performance. However, supervised fine-tuning can reduce some of these few-shot capabilities (Alves et al., 2023). To maintain consistency in the inference format, we structure the fine-tuning data into a 5-shot format during training. For inference, we also use the 5-shot format, with few-shot examples randomly selected from the dev test set. The fine-tuning data consists of 700 sentences from the previously mentioned dev test set.

3.2 Dev CPO

Given that the official dev test set is derived from post-edited results, our goal is to assist the model in learning the subtle distinctions between pre-edited and post-edited translations, thereby enhancing its translation capabilities. DPO (Rafailov et al., 2023) is a training strategy focused on optimizing preferences, while CPO (Xu et al., 2024) builds upon DPO by providing further refinements. The following is the formulation of CPO loss:

$$\begin{aligned}\mathcal{L}(\pi_\theta) = & -\mathbb{E}_{(x,y_w,y_l)\sim\mathcal{D}}\Big[\log\sigma\Big(\beta\log\pi_\theta(y_w|x) \\ & -\beta\log\pi_\theta(y_l|x)\Big)\Big],\end{aligned} \tag{1}$$

$$\min_\theta \underbrace{\mathcal{L}(\pi_\theta)}_{\mathcal{L}_{\text{prefer}}} \underbrace{-\mathbb{E}_{(x,y_w)\sim\mathcal{D}}[\log\pi_\theta(y_w|x)]}_{\mathcal{L}_{\text{NLL}}}, \tag{2}$$

where x is source sentence, y_w is preferred translation, y_l is less preferred translation, $\mathcal{D}$ is a dataset of comparisons.

In our approach, we use translations produced by Apertium as negative examples and the corresponding results from the dev test set as positive examples. This CPO training allows the model to learn the nuanced differences between positive and negative instances.

3.3 Dev fewshot BM25 with LLM

Previous research suggests that providing similar parallel translation pairs as guidance can improve translation quality with large language models (Agrawal et al., 2022). To leverage this, we use the BM25 algorithm to retrieve several of the most similar translation examples from the dev test set based on the source sentences. These examples are concatenated into the previously described few-shot translation format and positioned before the sentence to be translated. We then employ state-of-the-art LLMs, such as GPT-4 and Claude-3.5, for the translation process.

3.4 Post-processing

We observe that translations produced by large language models may encounter issues such as omissions, over-translation, and non-following with instructions (Jiao et al., 2023; Xu et al., 2023). To address these issues, we apply the following rule-based post-processing:

1. For translations generated by the Dev 20-shot BM25 method with LLMs, if the output fails to adhere to instructions, for instance, if it includes phrases such as "I apologize" or "sorry", we perform a retranslation. If the correct translation is not achieved after three attempts, we revert to the translation produced by the Apertium software.

2. Replace any translations where language detection is incorrect with those generated by Apertium software.

3. Replace any translations where the ratio of the length of the source text to the translated text is less than 0.75 or greater than 1.3 with translations generated by Apertium software.

4 Experiment

Data In this Section, we randomly selected 700 sentences from the provided dev test set for additional fine-tuning, leaving the remaining 297 sentences as the new dev set.

Experiment Details For SFT, we fine-tune the distillation model for 5 epochs with a batch size of 8, a learning rate of 1e-05, and a weight decay of 0.1. For decoding, we use beam search with a beam number of 4. For few-shot BM25, we use the BM25 algorithm to select a number of the most similar examples (excluding the sentence itself) from the 997 sentences in the dev set for few-shot translation.

Results As illustrated in Table 4, the BLEU scores for the three language pairs across various methods demonstrate noticeable performance improvements over the Distillation model. Specifically, the best performance for Spanish → Aragonese (spa-arg) is achieved with the Distillation model + dev 5-shot SFT, for Spanish → Aranese (spa-arn) with the Distillation model + dev CPO, and for Spanish → Asturian (spa-ast) with Claude 3.5-sonnet + 20-shot BM25.

Furthermore, the dev 5-shot SFT method yields a more consistent performance improvement compared to direct dev SFT. Among the models evaluated, Claude 3.5-sonnet generally outperforms GPT-4-turbo across these three low-resource language pairs, and BM25 retrieval of similar examples significantly boosts translation performance.

	spa-arg	spa-arn	spa-ast
Distillation model	67.4	39.5	17.0
+ dev SFT	69.3	40.5	17.3
+ dev 5shot SFT	**69.9**	40.8	17.4
+ dev CPO	69.7	**41.4**	17.3
GPT4-turbo			
+ 5shot	40.5	32.3	20.1
+ 5shot BM25	44.3	33.2	20.5
+ 20shot BM25	47.5	33.6	21.4
Claude3.5-sonnet			
+ 5shot	47.8	35.2	22.9
+ 5shot BM25	53.6	37.4	24.2
+ 20shot BM25	59.9	38.1	**25.2**

Table 4: BLEU evaluation of different methods on partitioned dev test sets for three language pairs. Our methods all achieve certain performance improvements. For the Aragonese language pair, the best strategy is dev 5-shot SFT. For the Aranese language pair, the optimal strategy is dev CPO. For Asturian language pair, the best approach is using Claude 3.5-sonnet for 20-shot BM25 translation.

5 Conclusion

This paper presents the Shanghai Jiao Tong University translation systems for low-resource Spanish languages in the WMT24 shared task. We first create synthetic data through forward distillation using the Apertium translation system, then fine-tune the Qwen2-0.5B model to establish a basic baseline capability. Subsequently, we apply three optimization strategies using the dev test sets: 5-shot format fine-tuning, Contrastive Preference Optimization, and 20-shot translation with BM25 retrieval. Our experiments demonstrate that all three methods lead to performance improvements.

Abstract

This article introduces the submission status of the Translation into Low-Resource Languages of Spain task at (WMT 2024) by Huawei Translation Service Center (HW-TSC). We participated in three translation tasks: spanish to aragonese (es→arg), spanish to aranese (es→arn), and spanish to asturian (es→ast). For these three translation tasks, we use training strategies such as multilingual transfer, regularized dropout, forward translation and back translation, labse denoising, transduction ensemble learning and other strategies to neural machine translation (NMT) model based on training deep transformer-big architecture. By using these enhancement strategies, our submission achieved a competitive result in the final evaluation.

1 Introduction

Neural machine translation (MT) (Lyu et al., 2019; Bahdanau et al., 2014; Gehring et al., 2017) allows translation systems to be trained end-to-end without having to deal with issues like word alignment, translation rules, and complex decoding algorithms that characterize statistical machine translation systems (SMT) (Koehn et al., 2007). Recently, MT technology has evolved towards large language models (LLMs) (Guo et al., 2024). Although neural machine translation has developed rapidly in recent years, it relies heavily on big data - large-scale, high-quality bilingual corpora. Due to the cost and scarcity of real corpora, synthetic data plays an important role in improving translation quality. Existing methods for synthesizing data in NMT focus on leveraging monolingual data during training. Among them, forward translation (Abdulmumin et al., 2021), back translation (Abdulmumin et al., 2021) and data diversity (Nguyen et al., 2020) have been widely used to generate synthetic bilingual corpora. Such synthetic data can be used to improve the performance of NMT models(Wu et al., 2023b). (Wei et al., 2023) also considers the style of the training data and exploits it to improve performance. Although synthetic data is efficient, synthetic data inevitably contains noise and erroneous translations. Denoising can prevent the training of NMT models from being interfered by noisy synthetic data by introducing high-quality real data as guidance. Another direction to improve the performance of NMT models is to use more efficient training strategies. For example, by mixing similar language data together to train a multi-language pre-training model (Li et al., 2022), due to the shared vocabulary, encoding layer and decoding layer parameters and language similarity, languages with less data can benefit from languages with more data. Regularized dropout (Wu et al., 2021) allows the NMT model to more effectively utilize limited data during the training process. Transduction ensemble learning (Wang et al., 2020) can aggregate the translation capabilities of multiple models into one model.

For the Translation into Low-Resource Languages of Spain task of WMT 2024, we participated in the es→arg, es→arn and es→ast language pair. We use training strategies such as multi-language pre-training models (Li et al., 2022), regularized dropout (Wu et al., 2021), forward translation (Abdulmumin et al., 2021), back translation (Abdulmumin et al., 2021), Labse denoise (Feng et al., 2020) and transduction ensemble learning (Wang et al., 2020) to train neural machine translation (NMT) models based on deep Transformer architecture.

Next, this article will expand on the details of our translation system in different translation tasks. The structure of the remaining sections is as follows: Section 2 introduces the data scale and data preprocessing process; Section 3 describes the overview of the NMT system; Section 4 gives the parameter settings, data processing results and experimental results; Section 6 gives System conclu-

sions were drawn.

2 Dataset

2.1 Data Size

In accordance with the requirements of the WMT 2024 outline, on the Translation into Low-Resource Languages of Spain machine translation task, we used the officially provided data to train the NMT system from scratch. Table 1 shows the training data size for each language pair of the bilingual machine translation task. These language pairs include Spanish to Aragonese (es→arg), Spanish to Arabic (es→arn) and Spanish to Asturian (es→ast).

	es→arg	es→arn	es→ast
Bilingual	0.06M	2.04M	13.36M
Source Monolingual	0.4M	8M	8M
Target Monolingual	0.26M	6M	3M

Table 1: Data size for each bilingual machine translation task

2.2 Data Pre-processing

The data pre-processing process is as follows:

- Remove duplicate sentences or sentence pairs.
- Remove invisible characters and xml escape characters.
- Convert full-width symbols to half-width symbols.
- Use fast_align (Dyer et al., 2013) to filter poorly aligned sentence pairs.
- Filter out sentences with more than 80 tokens in bilingual data.
- Remove sentences with duplicate tokens.
- When performing subword segmentation, joint sentencepiece (Kudo and Richardson, 2018) is used for es→arg, es→arn and es→ast translation tasks.

3 NMT System

3.1 System Overview

Transformer is the state-of-the-art model structure in recent MT evaluations. There are two parts of research to improve this kind: the first part uses wide networks (eg: Transformer-Big (Vaswani, 2017)), and the other part uses deeper language representations (eg: Deep Transformer (Wang et al., 2019)). For all MT tasks, we combine these two improvements, adopting the Deep Transformer-Big (Wu et al., 2023a) model structure to train the NMT system. Deep Transformer-Big uses pre-layer normalization, features 25-layer encoder, 6-layer decoder, 16-heads self-attention, 1024-dimensional word embedding and 4096-dimensional ffn embedding.

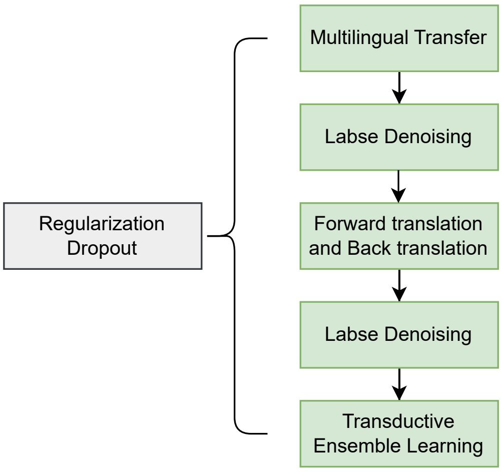

Figure 1: The overall training flow chart of our NMT system on the different translation tasks.

Fig. 1 shows the overall training flow chart of our NMT system on the Translation into Low-Resource Languages of Spain task, we use multilingual transfer (Li et al., 2022), regularization dropout (Wu et al., 2021), forward translation (Abdulmumin et al., 2021), back translation (Abdulmumin et al., 2021), Labse denoise (Feng et al., 2020) and transduction ensemble learning (Wang et al., 2020) and other training strategies are used to train neural machine translation (NMT) models based on deep Transformer-big architecture.

3.2 Multilingual Transfer

Recent researches have shown that multilingual models outperform their bilingual counterparts, particularly when the number of languages in the system is limited and those languages are related (Li et al., 2022). This is mainly due to the capability of the model to learn interlingual knowledge (shared semantic representation between languages). Transfer learning using pre-trained multilingual model has shown very promising results for low resource tasks. In this task, we first select a multilingual system as the base system, then fine-tune the system with low resource language pairs.

Specifically, we add the "<arg>" tag to the Spanish side of the es→arg bilingual data, the "<arn>" tag to the Spanish side of the es→arn bilingual data, and the "<ast>" tag to the Spanish side of the es→ast bilingual data, and sample them. Mix shuf to train a one-to-many pre-training model; sample the es→arg, es→arn and es→ast original bilingual data and then mix shuf to train a many-to-one pre-training model. Then, the one-to-many pre-training model and the many-to-one pre-training model are trained by using the original bilingual data, and three translation models from Spanish to Aragonese, Arabic, and Asturian and three translation models from Aragonese, Arabic, and Asturian to Spanish are obtained.

3.3 Regularization Dropout

Dropout (Srivastava et al., 2014) is a widely used technique for regularizing deep neural network training, which is crucial to prevent over-fitting and improve the generalization ability of deep models. Dropout performs implicit ensemble by simply dropping a certain proportion of hidden units from the neural network during training, which may cause an unnegligible inconsistency between training and inference. Regularized Dropout (R-Drop) (Wu et al., 2021) is a simple yet more effective alternative to regularize the training inconsistency induced by dropout. Concretely, in each mini-batch training, each data sample goes through the forward pass twice, and each pass is processed by a different sub model by randomly dropping out some hidden units. R-Drop forces the two distributions for the same data sample outputted by the two sub models to be consistent with each other, through minimizing the bidirectional Kullback-Leibler (KL) divergence (Van Erven and Harremos, 2014) between the two distributions. In this way, the inconsistency between the training and inference stage can be alleviated.

3.4 Forward translation and Back translation

Forward translation, also known as self-training (Abdulmumin et al., 2021), is one of the most commonly used data augmentation methods. FT has proven effective for improving NMT performance by augmenting model training with synthetic parallel data. Generally, FT is performed in three steps: (1) randomly sample a subset from the large-scale source monolingual data; (2) use a “teacher” NMT model to translate the subset data into the target language to construct the synthetic parallel data; (3) combine the synthetic and authentic parallel data to train a “student” NMT model.

Apertium is a free/open-source rule-based architecture for MT that consists of a pipeline of modules performing part-of-speech disambiguation and tagging, lexical transfer, lexical selection, chunk-level or recursive structural transfer, and morphological generation. To make our model better, we use Apertium as a "teacher" model to produce pseudo-corpus.

Back translation (BT) (Abdulmumin et al., 2021) refers to translating the target monolingual data into the source language, and then using the synthetic data to increase the training data size. This method has been proven effective to improve the NMT model performance.

We use the machine translation model obtained by Multilingual Transfer to produce back translation synthetic parallel data, and mix it with forward translation synthetic parallel data and authentic parallel data for training, which can achieve better results than FT or BT.

3.5 Labse Denoising

Due to the low quality of our bilingual data, we use LaBSE (Feng et al., 2020) to calculate the semantic similarity of each bilingual sentence pair and exclude bilingual sentence pairs with similarity scores below 0.7 from our training corpus. Use these clean data to better train the model.

3.6 Transductive Ensemble Learning

Ensemble learning (Garmash and Monz, 2016), which aggregates multiple diverse models for inference, is a common practice to improve the accuracy of machine learning tasks. However, it has been observed that the conventional ensemble methods only bring marginal improvement for NMT when individual models are strong or there are a large number of individual models. Transductive Ensemble Learning (TEL) (Wang et al., 2020) study how to effectively aggregate multiple NMT models under the transductive setting where the source sentences of the test set are known. TEL uses dev sets finetune a strong model, which boosts strong individual models with significant improvement and benefits a lot from more individual models.

	BLEU			ChrF++

+ FT & BT	41.7	9.5	16.9	64.8	34.9	45.5
+ Labse denoising	48	10.1	17.5	72.4	38.8	47.5
FLORES+ devtest sets	es→arg	es→arn	es→ast	es→arg	es→arn	es→ast
+ TEL	**63**	**26.3**	**19.8**	**80.3**	**47.9**	**52.2**

Table 2: BLEU and ChrF++ scores of es→arg, es→arn and es→ast NMT systems

4 Experiment

4.1 Setup

We use the open-source fairseq (Ott et al., 2019) to train NMT models, and then use SacreBLEU (Post, 2018) and Chrf++ to measure system performance. The main parameters are as follows: each model is trained using 8 V100 GPUs, batch size is 4096, parameter update frequency is 1, and learning rate is 5e-4. The number of warmup steps is 4000, and model is saved every 1000 steps. The architecture we used is described in section 3.1. We adopt dropout, and the rate varies across different training phases. R-Drop (Srivastava et al., 2014) is used in model training, and we set λ to 5.

4.2 Data processing

	es→arg	es→arn	es→ast
Bilingual	0.06M	2.04M	13.36M
Data Pre-processing	0.04M	1.51M	3.91M
Labse Filter	0.03M	1.16M	1.92M
Upsampling	0.56M	1.74M	1.92M

Table 3: Data size for each bilingual machine translation task after data pre-processing

Due to the poor quality of bilingual data in low-resource languages, after the rule cleaning mentioned in section 2.2 and the labse model cleaning mentioned in section 3.2, the amount of data is smaller, and the data amount of es→arg, es→arn and es→ast is quite different. When training one-to-many and many-to-one pre-training models, if the amount of bilingual data for a certain language direction is too small, the translation quality will be extremely poor. Therefore, Following (Conneau and Lample, 2019; Liu et al., 2020) we re-balance the training set by upsampling data from each language l with a ratio:

$$\lambda_l = \frac{1}{p_l}\frac{p_l^{1/T}}{\sum_{l=1}^{n} p_l^{1/T}} \quad with \quad p_l = \frac{n_l}{\sum_{l=1}^{n} n_l}$$

where, T is the temperature parameter and we set T to 2. n_l is the number of utterances for language l in the training set. The data amount changes as shown in the following table 3.

4.3 Results

Tables 2 shows the evaluation results of es→arg, es→arn and es→ast NMT systems on the brand new FLORES+ dev sets and devtest sets, the results of dev test sets are obtained through OCELoT submission. We use Multilingual Transfer and R-Drop to build a strong baseline, then use FT and BT for data enhancement, and use Labse denoising for more efficient training, and finally use Transductive Ensemble Learning to ensemble multiple models ability.

As can be seen from the table above, after FT & BT and Labse denoising, the translation quality from Spanish to three directions has been improved to varying degrees. This shows that for low-resource scenarios, these two strategies can expand the amount of data and improve the quality of the data. Enhance the translation quality of machine translation models. Among them, the improvement of both strategies in the es→arg direction is higher than that of the other two directions, and the bilingual data of es→arg is also the least. This shows that FT & BT's strategy of expanding the amount of data and labse denoising's strategy of improving data quality are both in situations where the amount of bilingual data is small, The effect is more obvious.

In addition, after Transductive Ensemble Learning, the BLEU value of FLORES+ devtest sets has been greatly improved compared to the FLORES+ dev sets test set. Although it is not the same test set, the BLEU value has improved across latitudes, which shows that The fields of dev sets and devtest sets are very consistent, and Transductive Ensemble Learning, a strategy that utilizes dev sets, can maximize the translation effect of the model on the test set in the same field.

5 Conclusion

This paper presents HW-TSC's submission to the Translation into Low-Resource Languages of Spain task of WMT 2024. For both translation tasks, we use a series of training strategies to train NMT models based on the deep Transformer-big architecture. By using these enhancement strategies, our submission achieves a competitive result in the final evaluation. For example, #607 in the spanish to aragonese constrained submissions, #608 in the spanish to aranese constrained submissions, and #606 in the spanish to asturian constrained submissions.

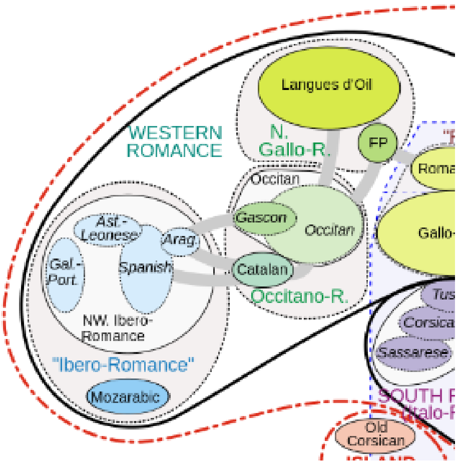

Figure 1: Language family tree diagram (partial) focusing on the Iberian peninsula

1 Introduction

In this short overview paper[1], we describe our system submission for the language pairs Spanish→Aragonese (spa-arg), Spanish→Aranese (spa-arn), and Spanish→Asturian (spa-ast)[2]. We train a unified model for all language pairs in the **constrained** scenario. In addition, we add two language control tokens for Aragonese and Aranese Occitan, as there is already one present for Asturian.

1.1 Linguistic background

The Iberian peninsula - which includes the territory of Spain, Portugal and Gibraltar - is a hotspot for linguistic diversity, especially among languages in the Romance family. Spanish, Portuguese and English have official status across these three respective territories.

Basque (a non-Indo-European language) has co-official status in the Spanish Autonomous Communities of the Basque Country and the northern portion of Navarre. In Galicia, Galician is co-official and in the Balaeric Islands, the Valencian Community and Catalonia Catalan/Valencian also enjoys this status.

This status ensures visibility of these languages in the socio-political space as well as a sizeable presence online. Catalan, Basque and Galician are included in many high-performing machine translation (MT) systems (and large language models (LLMs) capable of the task) (Armengol-Estapé et al., 2021) and benchmarks (Federmann et al., 2022).

This is not necessarily the case for the languages which are the focus of this challenge. They are a diverse set of languages, all from different subbranches of the Romance language family. Figure 1 shows their relation to other languages in the Romance family, and to each other, using the wave model (Heggarty et al., 2010) of linguistic evolution. Note the dialect continuum which appears to form between Portuguese → Asturian → Spanish → Aragonese → Catalan and Gascon Occitan.

Figure 2 provides a visual overview of the languages that are translated into from Spanish as part of this challenge. **Aranese**, a dialect of Gascon Occitan, also has co-official status in Catalonia but provision is only made in the Aran Valley for its use.

Aragonese and **Asturian** are spoken by larger numbers of people, but mostly as either second language learners or legacy speakers such as the elderly. It is for this reason that these languages all fall under the category of “Endangered” languages according to Ethnologue (Eberhard et al., 2024). All three languages are, however, considered “Vital" in terms of Digital Language Support (Simons et al., 2022). This is the second highest category behind “Thriving", meaning that there are extant corpora and resources available. However, this does not necessarily mean that there is decent quality technology such as MT available for these lan-

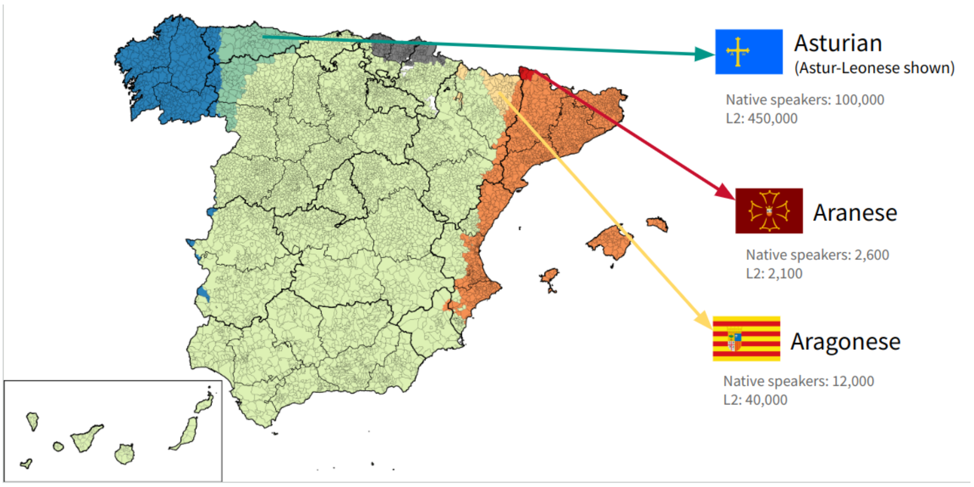

Figure 2: The languages involved in the WMT shared task and some demographic information

guages.

1.2 Extant technology for these languages

There is a recent increased push towards including languages with a small digital presence in language technology (Bapna et al., 2022), and effort has been made already to cover the languages of this challenge, including efforts to generate clean corpora from multilingual content from the internet (González and Álvarez, 2023; Ruder et al., 2023).

The first rule-based system to involve translation into and between the present languages is the open source Apertium (Forcada et al., 2011). Other systems and improvements have been built on top of this service such as Softcatalà (Ivars-Ribes and Sánchez-Cartagena, 2011) which focuses on translation into and out of Catalan, and a neural MT translator (NMT) between Spanish→Aragonese (Cortés et al., 2012).

In addition, the Spanish government-funded TAN-IBE project (Oliver et al., 2023) - of which this challenge is a part - seeks to apply modern techniques across NMT and LLM-based approaches to improve this low-resource MT task.

2 System description

We take the distilled NLLB-200 model (Costa-jussà et al., 2022) with 600M parameters and extend special tokens with 2 tokens that denote target languages (arn_Latn, arg_Latn) because Asturian was already presented in NLLB-200 model. After we initialized the weights of the new tokens using weights from existing tokens in the vocabulary. We used oci_Latn (Occitan) for arn_Latn (Aranese) and spa_Latn (Spanish) for arg_Latn (Aragonese) because this languages are from the corresponding language family.

2.1 Training and data filtering

To create our corpus, we sampled OPUS[3] and PILAR[4] FLORES+ (revised pairs), which contain Catalan->Aranese (from PILAR), Spanish->Aranese, Spanish->Occitan, Spanish->Asturian and Spanish->Aragonese directions. We used Apertium (Khanna et al., 2021) to translate Catalan to Spanish, but we kept both source languages in our training set. Additionally, for the Occitan target language, we used idiomata cognitor (Galiano-Jiménez et al., 2024) to keep only corresponding target languages. We applied the adapted MOSES Punctuation Normalizer provided by Meta Research group under the stopes library[5] for all language pairs because NLLB was trained on preprocessed texts. Further data filtering followed the NLLB paper (Costa-jussà et al., 2022). We used fastText[6] to delete all pairs with English examples. After that, we computed length ratios and kept all sentences where the length was from five to 1050 characters, with a max length ratio lower than 0.9 and a unique ratio higher than 0.125. Finally, we de-duplicated all translation language pairs, keeping a maximum of two source duplicates and three target duplicates. Additionally we kept all pairs where distance score was in [0.6;1.0]. The result distribution of the source and target languages in

[6] https://fasttext.cc/

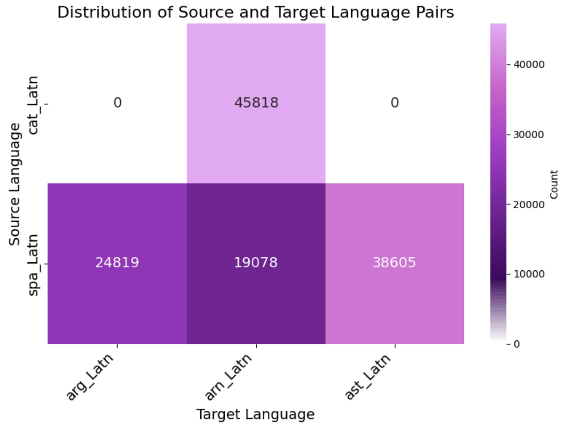

Figure 3: Distribution of language pairs from processed dataset.

our result corpora is captured at the Figure 3.

For the rest of the language pairs, we excluded all samples where the target language did not match the language predicted by idiomata cognitor.

2.2 Data augmentation

We adapt the model by training on a special regime of data augmentation with both monolingual and bilingual training data for the language pairs in this challenge.

The OPUS data were filtered in order to discard the spurious sentence pairs. We do that by performing translation of the Spanish sentence to the appropriate target language using Apertium and comparing the translation to the sentence present in the corpus. We assume that certain differences are possible due to imperfect performance of Apertium and natural variability of language, but the two variants should preserve some resemblance. To quantify that, we compute the Levenshtein (Levenshtein, 1966) edit distance ($d(s_1, s_2)$) between the two strings (s_1, s_2) and transform it into a similarity score defined as:

$$sim(s_1, s_2) = 1.0 - \frac{d(s_1, s_2)}{max(|s_1|, |s_2|)}$$

Based on manual analysis of the scores, we assume the similarity score of minimum 0.6 to be sufficient for the sentence pair to be used. Otherwise, it is discarded.

2.3 Fine tuning

The NLLB-200 model with 600M parameters, distilled from a 54B parameter Mixture-of-Experts model, demonstrated superior performance compared to the baseline version. Building on this foundation, we implemented a series of adaptation steps described above to further enhance the model's capabilities on a new target languages. In this sections, we detail our training methodology and the specific hyperparameters employed to optimize the model's performance across diverse linguistic tasks. The fine-tuning process was done with one T4 GPU using Hugging Face Transformers (Wolf et al., 2020) library with the following hyperparameters presented at the Table 1. Our result model is available at the Hugging Face repository[7].

Hyperparameter	**Value**
Learning Rate	1e-4
Weight Decay	1e-3
Train Batch Size	4
Eval Batch Size	4
Training Epochs	2
Optimizer	Adafactor
Clip Threshold	1.0
Warmup Steps	10% of total steps

Table 1: Hyperparameters for NLLB-200 Fine-tuning.

3 Results

Our results for the translation task from the Spanish language test set[8] to the target languages, as evaluated through OCELoT[9] submission system are reasonably positive, with respective BLEU and chrF+ scores of 49.2 and 73.6 for spa-arg, 17.9 and 15.5 for spa-arn, and 23.9 and 46.1 for spa-ast.

In terms of comparing the current approach with previous approaches such as Apertium and its successors, many of these studies only report word error rate whereas we used BLEU and chrF+. In those studies where BLEU is reported, it is known that BLEU favours SMT and NMT systems over rule-based ones. Moreover, this challenge introduces the present test set - so there is no previous work on the same data for direct comparison.

We find that this method of training is relatively efficient, with energy usage of 2.93kWh and emissions of approximately 1.81kg of CO$_2$[10].

CloudSheep System for WMT24 Discourse-Level Literary Translation

Lisa Liu, Ryan Liu, Angela Tsai, Jingbo Shang
University of California, San Diego
{lil043, ryl001, cjt002, jshang}@ucsd.edu

Abstract

This paper describes the CloudSheep translation system for WMT24 Discourse-Level Literary Translation shared task. We participated in the Chinese-English direction on the unconstrained track. Our approach to the task used a pipeline of different tools in order to maximize the translation accuracy and flow of the text by combining the strengths of each tool. In particular, our focus was to translate names consistently and idioms correctly. To achieve consistent names throughout a text, a custom name dictionary was generated for each text, containing person and place names, along with their translations. A common honorific dictionary was applied for consistency with titles, especially in historical or cultivation novels. The names were found and translated with GPT 3.5-turbo. To achieve accurate and concise translations of idioms, which are often translated literally and verbosely, we integrated the CC-CEDICT library to provide official definitions. Then, we used GPT-4 to pick the best dictionary definition that fit the context and rephrase it to fit grammatically within a sentence. For the translation of non-name and non-idiom terms, we used Google Translate. We compared our approach's performance with Google Translate as a baseline using BLEU, chrF, and COMET, as well as A/B testing.

1 Introduction

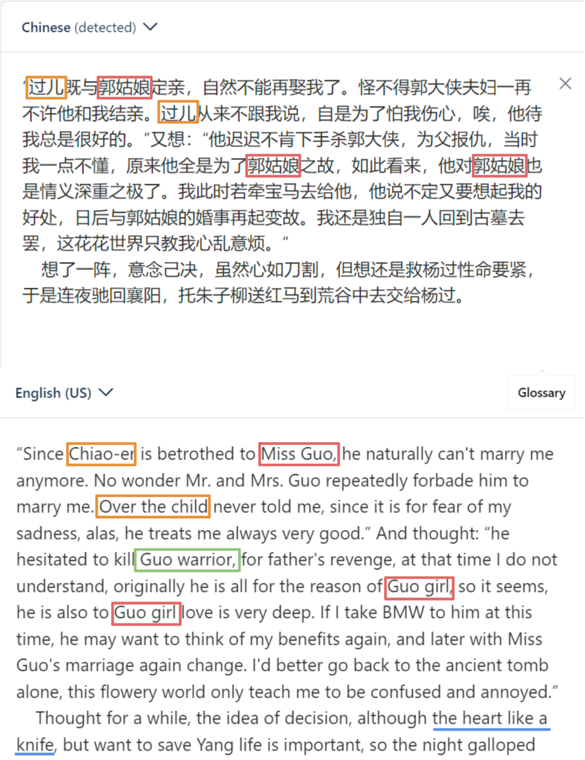
Machine translation techniques customized for webnovels have been researched more during the past few years (Wang et al., 2023). With the widespread availability of commercial and open-source large language models, it has become easier to fine tune existing models for a specific kind of data. Many of the top translation solutions to last year's task approach the problem of webnovel translation from the fine tuning perspective, experimenting with combining and tuning different machine learning models to find the best method for translation (Lopez et al., 2023; An et al., 2023).

When scored by human annotators, each of last year's machine translation systems, without exception, had more errors in the categories of Accuracy and Fluency compared to the other categories of Style, Terminology, Localization, and Other (Wang et al., 2023). This may indicate that inconsistency and inaccuracy are still issues that need more attention.

With a background in reading and translating webnovels as human translators, specifically in the Chinese to English direction, we wanted to approach the machine translation problem from the human readability perspective. As a reader, one of the biggest qualities of a translation is consistency. When a character is referred to as A in one sentence and referred to as B in the next, it is very hard to follow the translation, even if the writing style and vocabulary choices are immaculate. On the other hand, even if the character is wrongly referred to as B the whole time, the consistency allows the reader to follow the translation and the events. At the time of our background research, the most up-to-date version of DeepL, a popular machine translation tool in the webnovel translation community, still had name translation inconsistencies even within the same sentence, as shown in Figure 1.

Another important aspect of a good translation from a reader's perspective is correctly translating Chinese phrases with an English equivalent that matches it in tone. As a translator, that means that we often aim to convey the figurative meaning, rather than the literal meaning. This is especially common for idioms, or "chengyu" in Chinese. These phrases often originated from ancient texts, and their meaning often comes from the myth, story, or historical event they were derived from, rather than the actual characters. Due to this, a literal translation fails to convey the meaning, and often is too formal for the modern settings where they are used as a casual part of speech. For example, the phrase "脑子进水" literally translates to

Proceedings of the Ninth Conference on Machine Translation, pages 960–966
November 15-16, 2024 ©2024 Association for Computational Linguistics



“过儿既与郭姑娘定亲，自然不能再娶我了。怪不得郭大侠夫妇一再不许他和我结亲。过儿从来不跟我说，自是为了怕我伤心，唉，他待我总是很好的。”又想：“他迟迟不肯下手杀郭大侠，为父报仇，当时我一点不懂，原来他全是为了郭姑娘之故，如此看来，他对郭姑娘也是情义深重之极了。我此时若牵宝马去给他，他说不定又要想起我的好处，日后与郭姑娘的婚事再起变故。我还是独自一人回到古墓去罢，这花花世界只教我心乱意烦。”

想了一阵，意念己决，虽然心如刀割，但想还是救杨过性命要紧，于是连夜驰回襄阳，托朱子柳送红马到荒谷中去交给杨过。

“Since Chiao-er is betrothed to Miss Guo, he naturally can't marry me anymore. No wonder Mr. and Mrs. Guo repeatedly forbade him to marry me. Over the child never told me, since it is for fear of my sadness, alas, he treats me always very good.” And thought: “he hesitated to kill Guo warrior, for father's revenge, at that time I do not understand, originally he is all for the reason of Guo girl, so it seems, he is also to Guo girl love is very deep. If I take BMW to him at this time, he may want to think of my benefits again, and later with Miss Guo's marriage again change. I'd better go back to the ancient tomb alone, this flowery world only teach me to be confused and annoyed.”

Thought for a while, the idea of decision, although the heart like a knife, but want to save Yang life is important, so the night galloped

Figure 1: Name inconsistencies within DeepL translation for a single passage.

"water entered the brain," but the meaning is "lost one's mind" or "gone crazy." Making the appropriate choice between them depends on the sentence's tone and context.

With these two aspects in mind, our translation system aims to target inconsistencies in name translation and inaccuracies in idiom translation. We accomplished the former through generating a dictionary of the names found in the Chinese raws along with their English translations. We accomplished the latter through finding the figurative meaning of idioms from an open-source dictionary and using GPT-4 to rephrase the best definition to fit the sentence.

2 Data and Tools

We primarily used the GuoFeng Webnovel Corpus provided by the organizers (WMT23, 2023) (Wang et al., 2024). The data we used for self-evaluation came from the test data in last year's dataset, because of the relatively short lengths of the texts provided per novel and the reference English translation provided as well. We also looked for short excerpts of novels through publicly available translations (found through NovelUpdates) and their original Chinese texts (found through JJWXC) to test our system's ability to translate idioms and names.

We also used public blog posts to compile a dictionary of honorific translations, in order to maintain consistent translations across novels and texts. We used open-source dictionaries like CC-CEDICT to obtain the most accurate translation for idioms. Finally, we used prompt engineering and GPT models to tie together the different translation tools we used to create a comprehensive translation.

3 Translation Pipeline

3.1 Text Segmentation (Name Translation)

We wanted to find a way to reliably build a name dictionary that would get a majority of the names without incurring too much cost. The first place submission in last year's task's unconstrained task, DUTNLP (Zhao et al., 2023), used Jieba, a segmentation tool for Chinese. Text segmentation is the process of dividing text into meaningful words or phrases. Different segmentation granularities can significantly impact translation performance, especially for languages like Chinese (Zhao et al., 2013). In Chinese, spaces are not used to separate words, which can be made up of multiple characters, making good text segmentation very important for determining which words are present in a sentence.

We tested Jieba in our own system, aiming to use its ability to identify proper nouns to form a basic dictionary of names in the text. Specifically, we filtered for phrases tagged "nr" (person name) and "ns" (place name) (Jieba, 2020). Unfortunately, Jieba had a high false positive rate, and often split up phrases or names, which made it unsuitable to form our name dictionary. For example, if the name contained a common noun that could be part of many phrases, replacing that part of the name with the English meaning would be very unhelpful and create a weird-sounding name. However, although Jieba was not suitable for identifying proper nouns, it was still useful for determining a phrase's part of speech.

A name dictionary's main purpose is to translate names consistently, and is more useful when it contains names that appear often. If a character or place appears only once within the story, readers do not need a consistent translation across mentions to recognize it. Additionally, it is likely to be insignificant to the story, so even if the translation is not the best, it is unlikely to affect enjoyment much.

Names commonly occurring in the text are likely to be re-occurring characters, such as the main protagonist or important supporting characters.

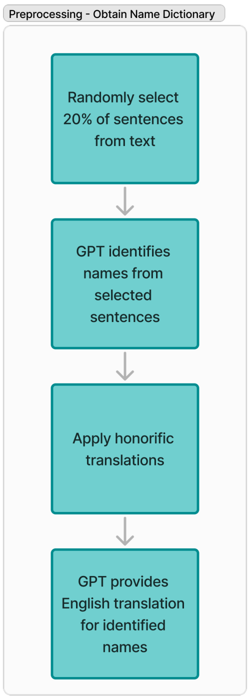
We decided to try to feed a percentage of lines to GPT-3.5 for name identification. GPT-3.5 was good at identifying names, rarely returning false positives. However, we didn't need to get every single name from a text, just the re-occurring ones. This meant that GPT was sifting through a large number of duplicates, and incurring extra cost through the API.

We manually identified the names within the sample dataset from last year's task, and for each text, we calculated the total number of unique names, the total percentage of characters within the text that belonged to a name, and the average number of lines that would contain a name. We found that the character percentages ranged from 5% to 10%, and the line percentages ranged from 11% to 22%.

By only giving GPT a certain percentage of lines that were randomly selected from the text, we introduced an element of chance into our pipeline that meant GPT may not be able to see all the names from the text it is given. We selected 20% as a number on the higher end of the range we found, so it was likelier that GPT would be given a majority of the names.

In order to pick lines more likely to contain names, we used Jieba to identify the number of nouns within a line. We theorized that it was unlikely for lines to contain no names, so if Jieba didn't identify any nouns at all within a sentence, it likely missed a name, which may be a combination of characters that are verbs or adjectives on their own. We first ran Jieba's segmentation on the text, and then selected only from a pool of longer sentences without any nouns identified.

We also theorized that for characters such as these, their introductions are more likely to be concentrated within the beginning or middle of the text, rather than the end. As we only need to get one occurrence of each name, we decided to weigh sentences earlier as more likely to be selected. We picked 15% of the lines from the first $\frac{3}{4}$ of the text, and 5% of the lines from the last $\frac{1}{4}$ of the text.[1]



Preprocessing - Obtain Name Dictionary
Randomly select 20% of sentences from text
GPT identifies names from selected sentences
Apply honorific translations
GPT provides English translation for identified names

Figure 2: Flow chart describing name translation process.

3.2 Honorifics (Name Translation)

We compiled a list of honorifics, ranging from common honorifics such as "哥哥" (brother) to martial art novel honorifics such as "师爷" (grandmaster) (Mountain, 2017) to historical novel honorifics such as "公公" (eunuch) (Wyhcwe, 2022). We acknowledge that the translations of such terms can sometimes vary across different translations, but we wanted to make a standard translation across all of our translations.

The names identified by Jieba and GPT-3.5 in the previous subsection include these honorifics, so by first applying the honorific translation and only asking GPT to translate the remaining characters left behind as the name, it can standardize the name translations and also ensure the honorifics aren't translated as pinyin directly. For example, our code would go through these steps to translate a name: 韩少爷→ Young Master 韩→ Young Master Han. We used the prompt: "Translate this name to English: [name]. Only list the English name."

3.3 CC-CEDICT (Idiom Translation)

We used the Chinese-English dictionary, CC-CEDICT. It is an free online dictionary that is regularly updated through crowdsourcing, and every contribution is verified regularly and added to

[1] "Lines" in the text file are sometimes multiple sentences in the Chinese raws; so if Jieba identifies 0 nouns in a "line", that can equate to 0 nouns in a paragraph.

the database (CC-CEDICT, 2020). Due to continual updates by the owners, CC-CEDICT is a good choice for getting the most updated figurative meanings of idioms, slang, and other culturally specific terms. For example, the phrase "脑子进水" from the introduction section has the CC-CEDICT entry "to have lost one's mind crazy soft in the head."

We searched through all entries labelled as "idioms" within the CC-CEDICT dictionary. If any such idioms were found within a line of the original Chinese text, the Chinese idiom would be replaced directly with its corresponding CC-CEDICT English entry. Other Chinese text in the line not identified as idioms would not be translated at this step. The raw dictionary replacements did not account for grammatical context surrounding the idioms, and some entries contained more than one English translation phrase per Chinese idiom. Furthermore, in their raw formatting these entries were surrounded by brackets and contained a text flag "(idiom)". We kept the raw replacement formatting as-is, which we then processed further after translating the rest of the text.

3.4 Overall Translation

We were left with text that was primarily still in the original Chinese, but with names and idioms programmatically replaced with English translations. We experimented with two different translation engines, DeepL and Google Translate, to translate the remainder of the text. These engines are the two most mentioned translation engines amongst online webnovel forums before ChatGPT. The engines translated the remaining Chinese text without any modification to the already-present English idiom replacements, thus requiring a step to smooth out the sentences containing idioms.

GPT selects best meanings for the idiom according to the context
GPT rephrases the meaning for flow
No
No, iterate to next sentence
End of text?
Yes
Done!!

Figure 4: Flow chart describing final rephrasing process.

3.5 GPT Rephrasing (Idiom Translation)

We decided to use GPT-4 and LangChain (LangChain, 2024) to replace every line that contained a raw idiom definition, as identified by their surrounding brackets and accompanying "(idiom)" flag, with a grammatically correct rephrasing. Langchain is an open-source framework that makes it easier to develop using GPT's API. We found that GPT-4 was better than GPT-3.5 at rephrasing only the sentences with idiom definitions within a given line. Because any output from this section would be inserted directly into the text as the final step, we decided to switch to GPT-4 for this step for better quality. To minimize the API cost in the rephrasing phase, we recorded the line numbers for the lines modified in the CC-CEDICT step, and only gave those lines to Langchain. Only about 2%-11% of lines across the samples we encountered contained idioms, so GPT-4 was only used on a small percentage of the text.

We used the prompt: "Please pick the idiom definition that best fits the context for the following sentences and rephrase only the part of the sentence with the idiom grammatically. Only output the new translation. Don't change the sentences without idioms. Favor the more concise meaning and find an English equivalent if possible." We added many instructions to our prompt as a result of experimentation; not asking for the "more concise meaning" or "English equivalent" often resulted in translations that were complicated amalgamations of every definition provided by the dictionary entry; not asking for "don't change the sentences without idioms" often resulted in sentences without idioms being changed and other content given being cut out.

Once the GPT-4 rephrasing was complete, the text translation was considered to be finished.

3.6 Evaluation

We used three metrics for automatically evaluating machine-translated text: BLEU, chrF, and COMET. BLEU evaluates word-level n-grams, calculating the precision between the machine translation and the reference, weighted by a brevity penalty (Papineni et al., 2002). ChrF evaluates character-level n-grams, scoring the overlap of short sequences of characters between the machine translation and the reference (Popović, 2015). COMET is a fine-tuned neural framework that takes in sentence embeddings from the source text, translation, and reference (Rei et al., 2020). We used these because last year's conference proceedings summary paper used them for the automatic evaluation (Wang et al., 2023).

A shortcoming of automatic metrics such as BLEU is that they lack the ability to evaluate based upon semantics, instead favoring direct word-to-word matches between a translation and reference (Callison-Burch et al., 2006). This means a translation that achieves high grammatical quality but uses different words than a provided reference could potentially score poorly. As such, we also surveyed human readers to compare the quality of our system's translations. Participants were given 4 separate translations of a text sample ranging from 200-300 English words, each generated using a different method: one generated by our translation system using Google Translate ("pipeline Google Translate"), one generated by our translation system using DeepL ("pipeline DeepL"), one generated using only Google Translate ("pure Google Translate"), and one using only DeepL ("pure DeepL"). These translations were given in a random order, and participants were not informed of which translation came from which source. After reading the translations, participants were asked to rank them from best to worst based on how readable they found the translations. This process was repeated over several different samples, and the rankings were recorded for each sample.

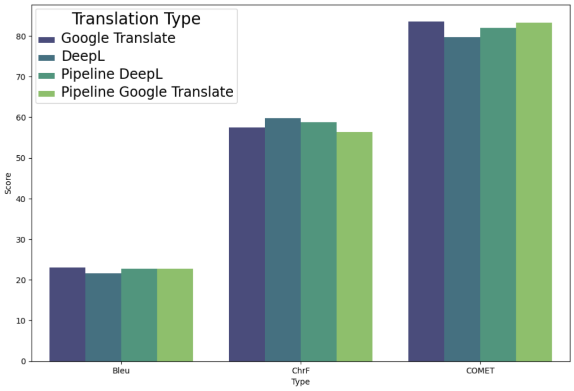

Figure 5: random sample 1, video games (20%)

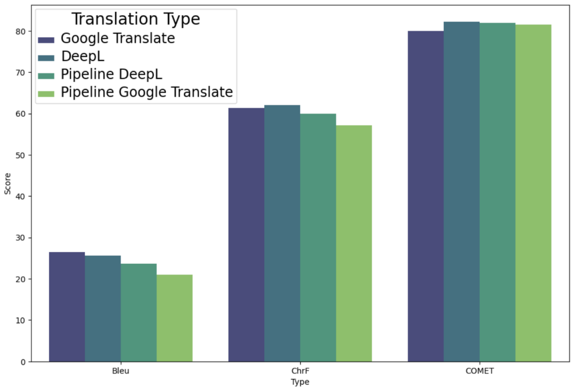

Figure 6: random sample 2, science fiction (23%)

4 Results

We used the automated metrics to evaluate the results of the four techniques: pure Google Translate, pipeline Google Translate, pure DeepL, pipeline DeepL. To decide between Google Translate and DeepL for our final submission, we decided to compare the pure Google Translate and pure DeepL results. In this paper, we show the results for three random samples selected across the dataset, shown in Figures 5, 6, and 7. The genre of the sample is labelled, along with their distribution percentage in the training set (Wang et al., 2023). Google Translate and DeepL performed about the same for the first two samples, but Google Translate was signifi-

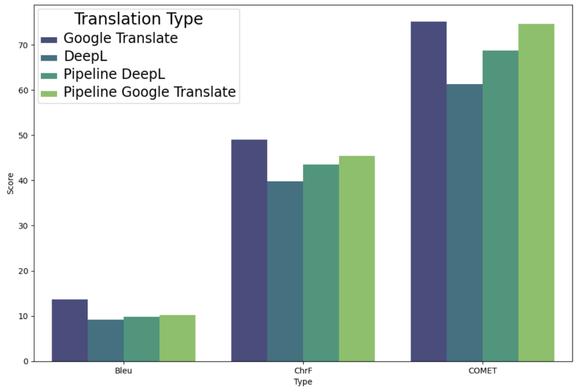

Figure 7: random sample 3, martial arts (2%)

cantly better than DeepL in the third sample, which was a classical martial arts novel. Although martial arts novels only make up a small percentage of the dataset, because idioms originate from classical Chinese literature, we decided to employ the translation pipeline with Google Translate ("pipeline Google Translate") for our final conference submission.

In our A/B testing, across all the samples, we found that participants ranked the pipeline Google Translate output the highest most, and the pure DeepL the lowest, as shown in Table 1. However, the distribution was mostly even, and about half the time, participants reported that the difference between translations was slight, which could be due to the limitations mentioned in the following limitations section.

Technique	1st	2nd	3rd	4th
pure Google (2)	2	2	1	2
pipeline Google (1)	3	1	3	0
pure DeepL (4)	1	3	0	3
pipeline DeepL (3)	2	0	4	1

Table 1: Times each technique was ranked 1st, 2nd, 3rd, or 4th across 7 samples. Ties were allowed.

5 Conclusion

We created a machine translation system that creates consistent translations for names and accurate translations for idioms, both of which enhance human readability despite making up a small ratio of the overall text. Even though our pipeline did not see any major improvements in the automated evaluation metrics, the positive reception among human survey participants points to the potential value that our process provides.

6 Limitations

When providing lines of text for ChatGPT to identify names, we randomly selected a certain percentage of lines to use in order to reduce API usage costs. Though the selected lines were weighted based on factors such as whether or not Jieba found any proper nouns in a line, there is nonetheless a slight element of randomness that is introduced during our process. One limitation that could be further explored is how consistently our pipeline performs over multiple runs on the same input.

Another limitation in our results lay in our use of human evaluators. Participants were asked to rank translations that used our system against translations that did not. Though they were not informed which translations did or did not use our system, they also were not given any specific metrics to quantify their decisions. Participants also sometimes reported that the passages provided were too long to quickly judge the difference, and that reading four passages in a row that described the same content made it hard to evaluate the difference without an earnest effort to study the differences within the text. In the future, our team could work on developing a more robust approach to the human side of evaluations that addresses these limitations.

Acknowledgements

This research project was fully funded by the Halıcıoğlu Data Science Institute at UC San Diego, through their HDSI Undergraduate Scholarship Program. We would like to thank them for their support throughout the year. We would also like to thank our mentor, Professor Jingbo Shang, for guiding us through the project, consistently checking in with us on our progress, and supporting us in publishing our first paper.

Abstract

This paper describes Shanghai Jiao Tong University (SJTU LoveFiction) Discourse-Level Literary Translation systems for the WMT24 shared task. We participate in the literary translation task on Chinese → English, Chinese → German and Chinese → Russian with unconstrained tack. Our system is based on Qwen2-72B(Yang et al., 2024), Claude3.5(Anthropic, 2023) and GPT-4o(OpenAI, 2024) with novel techniques that improve literary translation performance on the target language pairs. (1) Chunk-based SFT and inference: we put several sentences together to form a chunk and try different chunksize during SFT and inference. (2) Merge multi-model translations by agents: we design a Translation Editor Agent based on GPT-4o to generate a better new translation by referencing the source text and merge 3 candidate translations generated by Qwen2-72B, Claude-3.5 and GPT-4o. (3) Terminology Intervention: to ensure terminology consistency, a Term Proofreader Agent, based on GPT-4o, is utilized to extract term pairs from source texts and translations. For each Chinese term, we decide its optimal translation and request the Term Proofreader to modify the translation generated by Translation Editor Agent. In model evaluation:(1) We employ d-BLEU for single model evaluation. (2) We design a Client Agent based on Claude-3.5 to assess the win-tie rate between two translations for cross-model evaluation.

1 Introduction

Despite great advancements in machine translation (MT) these years(Artetxe et al., 2017; Wang et al., 2022), achieving high-quality translations for literary texts remains a formidable task, primarily due to the complexities involved in maintaining coherence, consistency, and cultural context across larger text spans (Voita et al., 2019; Lopes et al., 2020).

This paper describes SJTU LoveFiction's submission to WMT24 Discourse-Level Literary Translation. We participate in all 3 language pairs (Chinese → English, Chinese → German and Chinese → Russian) with unconstrained tack.

Our system builds upon Qwen2-72B, Claude-3.5 and GPT-4o models with various practical techniques. We adopt a chunk-based strategy, grouping several sentences into a chunk during supervised fine-tuning (SFT) and inference phase.

Multi-agent structure demonstrates strong performance in discourse-level machine transaltion(Wu et al., 2024). To enhance translation quality, we develop a Translation Editor Agent based on GPT-4o. This agent references the source text and merges muliti-model translations to produce a refined output. While different models may generate varied translations for the same Chinese term, we also implement a Term Proofreader Agent powered by GPT-4o. This agent extracts term pairs from source text and corresponding translations. For each Chinese term, the optimal translation is determined manually, then the term proofreader applies these optimal terms to the merged translations.

In terms of evaluation, we use d-BLEU to assess the performance of a single model under different experimental settings. For cross-model evaluation, we design a Client Agent based on Claude-3.5. This agent references the Chinese source text to evaluate and rank the translations produced by different models by accuracy, fluency, and the preservation of stylistic elements.

This paper is structured as follows: Section 2 describes our data pre-processing strategies, followed by the details of our method in Section 3. Section 4 presents the experimental results and analysis, then we draw conclusions in Section 5.

2 Data Processing

We perform Supervised Fine-Tuning (SFT) on the GuoFeng Webnovel Corpus (Wang et al., 2023) . Handling the noise within the dataset is crucial as it can significantly impact LLM's translation performance. We adopt a series of rigorous data filtering strategies.

2.1 Chinese-English Data Filtering

1. **Remove lines without Chinese-English pairs**: Delete any line that contains only a single Chinese or English sentence.

2. **Eliminate garbled text, emojis, foreign language characters, and emoticons**: These elements can degrade model performance. We use Unicode range identification and regular expressions for precise removal.

3. **Delete lines containing only punctuation marks**: Such lines typically lack linguistic value and retaining them would introduce noise, thereby impairing model training.

4. **Standardize punctuation**: Convert all Chinese punctuation to English punctuation to enhance model consistency and coherence in translation results.

2.2 Chinese-German and Chinese-Russian Data Filtering

Chinese-German/Russian data has the following features.

1. **Chapter-Level Alignment Only**: The alignment is maintained only at chapter level. Within chapters, paragraph or sentence level alignment is not achieved.

2. **Chapter Containment Differences**: In the Chinese files, each file contains a single chapter. In contrast, the German and Russian files may contain multiple chapters per file.

The following filtering strategies are employed:

1. **Remove Unaligned Chapter Pairs**: Delete Chinese-German/Russian file pairs that are not aligned at the chapter level.

2. **Eliminate garbled text, emojis, foreign language characters, and emoticons.**

3. **Remove Chapters Exceeding 8k Tokens**: LLMs struggle with long passages, thus chapters exceeding 8k tokens are excluded.

3 Method

In this section, we describe our method and provide a comprehensive explanation of the key components.

3.1 System Overview

We depict the overview of our system in Figure 1, which can be divided into four steps:

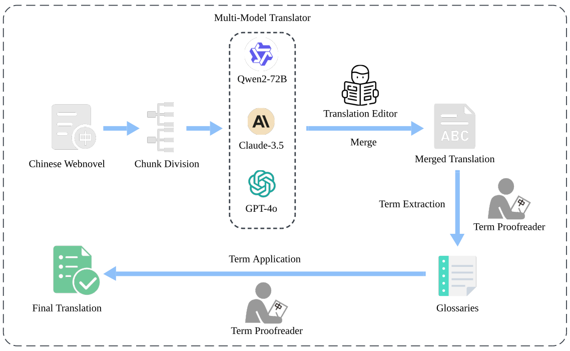

Figure 1: System Overview

1. **Chunk Division**: To maintain contextual information, we combine several sentences into a single chunk.

2. **Supervised Fine-Tuning & 1-shot Inference for Multi-Model Translator**: We SFT the Qwen2-72B model on Guofeng Webnovel Corpus. Afterwards, we use the fine-tuned Qwen2-72B, Claude-3.5, and GPT-4o to perform 1-shot inference on the test set, generating translation results.

3. **Translation Merging**: We employ a Translation Editor Agent based on GPT-4o to merge the translation outputs of the three models.

4. **Terminology Intervention**: We utilize a Term Proofreader Agent based on GPT-4o to extract term glossaries from source texts and translations. We select the optimal term pairs manually and ask the term proofreader to apply them to the merged translation as the final output.

3.2 Chunk Division

The lack of contextual information in sentence-level data poses a significant challenge for achieving high-quality translation results. Combining multiple sentences within each chapter into chunks can alleviate this problem(Zhao et al., 2023). During the SFT phase, we experiment with various chunksizes of 5, 10, and 20 sentences to determine the optimal size for training. In the inference phase, we further extend our experiments to chunksizes of 1, 5, 10, 20, 40, and 80 sentences. This strategy aims to provide the model with more contextual information, thereby improving the translation quality.

3.3 Supervised Fine-Tuning (SFT) & 1-shot Inference

In order to find the best setting for Qwen2-72B, we SFT Qwen2-7B on the Guofeng Webnovel Corpus and conduct inference on the in-domain dev set. Given consistent distribution between the two datasets, this approach will reveal the best setting for LLM to learn the knowledge embedded in Guofeng Webnovel Corpus. d-BLEU scores under different settings are shown in Figure 2.

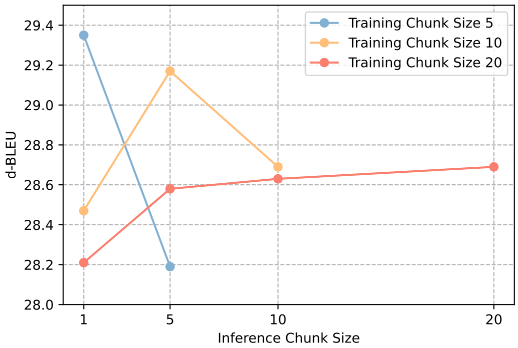

Figure 2: d-BLEU for Qwen2-7B on In-domain Dev Set

Although training with 5-sentence chunks and inferring with 1-sentence chunks yields the highest d-BLEU score of 29.35, we prefer 10-sentence chunks for training and 5-sentence chunks for inference. This configuration, with a d-BLEU score of 29.17, maintains nearly equivalent performance while preserving contextual information during inference.

As we aim to capture more context, the model must handle longer inputs. However, LLM's ability to handle long inputs is inherently limited. It's essential to acknowledge that we need to strike a balance, i.e. **maintaining sufficient contextual information without exceeding the model's capacity for processing long inputs.**

In our inference experiments with Claude-3.5 and GPT-4o, we employed 1-shot inference, a form of few-shot learning. Few-shot learning aims to enable models to generalize from a limited number of examples(Brown et al., 2020).We determine the best inference chunksize according to the following results.

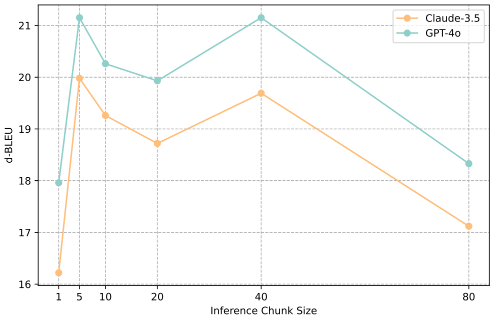

Figure 3: d-BLEU for Claude-3.5 & GPT-4o on OOD Dev Set

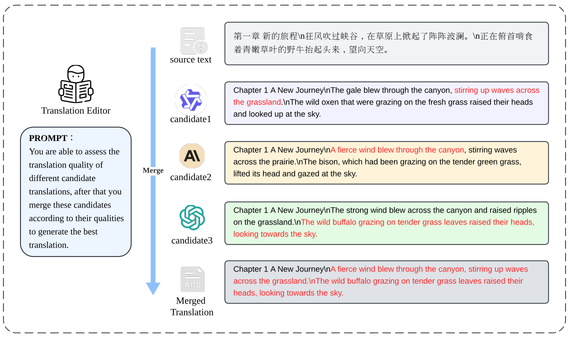
Both models perform best with 5-sentence chunk size, achieving d-BLEU scores of 19.98 and 21.15, respectively. We choose 5-sentence chunksize as the inference setting for Claude-3.5 and GPT-4o.

3.4 Translation Merging

After obtaining multi-model translations, we randomly select a chapter for manual verification and observe that different models exhibit distinct strengths in their translations for the same chunk. **To leverage the advantages of all three translations, we employ a Translation Editor agent based on GPT-4o, which is prompted to merge the three candidate translations into an improved version.** Workflow of the Translation Editor is as follows.



PROMPT：
You are able to assess the translation quality of different candidate translations, after that you merge these candidates according to their qualities to generate the best translation.

Figure 4: Workflow of The Translation Editor

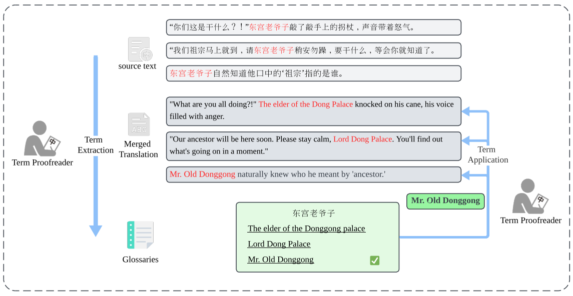
1. **Quality Assessment.** Assess the quality of different translation referencing the source text. After this step, the agent knows the relatively better part in each translation.

2. **Translation Merging.** Put these parts together to form the merged translation.

This process allows the Translation Editor agent to integrate the best elements (highlighted in red in Figure 4) of the three candidate translations, generating a superior translation.

3.5 Terminology Intervention

While the Translation Editor agent generates improved results by blending three candidate translations, **different models may produce different translations for the same Chinese term, leading to consistency issues.** To address this, we develop a **Term Proofreader Agent**. Workflow of the agent is as follows.



“你们这是干什么？！”东宫老爷子敲了敲手上的拐杖，声音带着怒气。

“我们祖宗马上就到，请东宫老爷子稍安勿躁，要干什么，等会你就知道了。

东宫老爷子自然知道他口中的‘祖宗’指的是谁。

"What are you all doing?!" The elder of the Dong Palace knocked on his cane, his voice filled with anger.

"Our ancestor will be here soon. Please stay calm, Lord Dong Palace. You'll find out what's going on in a moment."

Mr. Old Donggong naturally knew who he meant by 'ancestor.'

Mr. Old Donggong

Figure 5: Workflow of The Term Proofreader

1. **Term Extraction.** The terminology proofreader agent begins by extracting term pairs from the Translation Editor's output, referencing its Chinese source. Glossaries are obtained after this step.

2. **Manual Determination.** For each Chinese term in the glossaries, we manually determine the optimal translation. This step involves reviewing the context and ensuring that the chosen translation accurately reflects the meaning and nuance of the original term.

3. **Term Application.** Once the optimal translations are determined, the terminology proofreader agent applies these optimal translations to Translation Editor's output.

3.6 Evaluation

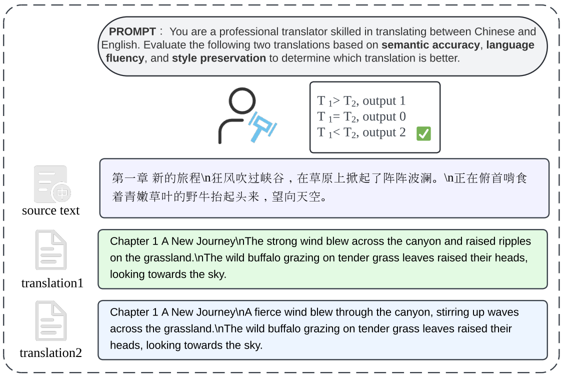
3.6.1 Single Model Evaluation

We calculate d-BLEU scores between our translations and reference texts to evaluate single model performance and determine the optimal experimental settings (i.e. training & inference chunksize). d-BLEU measures N-gram matching, reflecting the similarity between two distributions.The distribution of the in-domain dev set and the train set are consistent. Thus d-BLEU can assess the model's learning of train set during SFT stage, enabling us to select the optimal SFT setting by d-BLEU. On the other hand, distribution of the ood dev set is inconsistent with the train set. d-BLEU can assess the model's fitting to the ood dev set distribution. Thus we can select the optimal inference setting by d-BLEU.

3.6.2 Cross-model Evaluation

For cross-model evaluation, we find that human-preferred translation can have low d-BLEU score. This discrepancy arises because d-BLEU relies solely on N-gram matching and is unable to capture deeper semantic information. For human-preferred translation, there can be significant lexical differences from the reference translations, even though the semantic content is accurately conveyed. d-BLEU is ineffective in evaluating such cases.

Previous works reveal that LLM-Evaluators can achieve high consistency with human expert on system-level evaluation(Kocmi and Federmann, 2023; Moosa et al., 2024). We build a Client Agent based on Claude-3.5, which considers accuracy, fluency, and the preservation of stylistic elements.



PROMPT： You are a professional translator skilled in translating between Chinese and English. Evaluate the following two translations based on **semantic accuracy**, **language fluency**, and **style preservation** to determine which translation is better.

$T_1 > T_2$, output 1
$T_1 = T_2$, output 0
$T_1 < T_2$, output 2 ✓

Figure 6: Workflow of The Client

3.6.3 Human Evaluation

We employ 3 language experts to do fine-grained evaluation. They are requested to perform Linguistic Quality Rating (LQR) by the following standard in Table 1.

4 Results

We present the effect of our method in this section.

Score	Quality Description
1	Incomprehensible or incorrect.
2	Severe errors, hard to understand.
3	Some errors, but understandable.
4	Mostly correct, minor errors.
5	Completely correct and fluent.

Table 1: LQR Scoring Standards

4.1 Supervised Fine-Tuning (SFT) & Inference

We train Qwen2-72B on GuoFeng Webnovel Corpus with 10-sentence chunksize. The following table shows the d-BLEU scores for various inference chunksizes on both in-domain and out-of-domain dev sets.

Inference Chunksize	In-domain	OOD
1	27.32	22.51
5	27.05	24.64
10	26.05	**24.74**
20	27.74	24.65
40	**28.11**	24.25
80	20.49	24.04

Table 2: d-BLEU of Qwen2-72B on In-domain & OOD Dev Set

Qwen2-72B achieves best performance under 40-sentence inference chunksize on in-domain dev set while the best performance on OOD dev set is achieved with the 10-sentence chunksize. This indicates that although Qwen2-72B has a stronger capability for handling long texts, out-of-domain data distribution still poses difficulties for translation.

Results for Claude-3.5 and GPT-4o on OOD dev set is in Figure 3.

4.2 Translation Merging

We randomly selected 200 chunks from the final test set to evaluate the performance of individual models and our translation merging strategy.

GPT-4o ranks 1st place in single model performance while our translation merging strategy surpasses every single model, indicating that better translation is generated by the Translation Editor Agent.

Model	LQR3	LQR4	LQR5
Translation Merging	**65%**	**44%**	**24%**
GPT-4o	60%	30%	9%
Claude-3.5	54%	33%	12%
Qwen2-72b	42%	24%	3%

Table 3: LQR Scores for Different Models

We also employed the Client Agent to compare GPT-4o's results and the merged translations. Table 4 presents the win-tie rate relative to GPT-4o.

Metric	Rate
Win	41%
Tie	21%
Lose	38%
Net Win Rate	**3%**

Table 4: Win-tie Rate Compared to GPT-4o

The LLM evaluator also acknowledges that our translation merging strategy brings a slight improvement.

4.3 Terminology Intervention

We employ the Term Proofreader Agent to extract term pairs from the entire test set. The following table presents the results before and after the terminology intervention.

	Before	After
Chinese Terms	806	806
English Translations	3012	902
Average Correspondence	3.73	1.12

Table 5: Term Correspondence Before and After Intervention

Before the intervention, 806 unique Chinese terms correspond to 3012 English translations, with an average of 3.73 English translations per Chinese term, indicating high variability and inconsistency.

After the intervention, the number of English translations is reduced to 902. This significant reduction demonstrates that the Term Proofreader Agent effectively standardized the terminology, ensuring consistent translations for each Chinese term.

5 Conclusion

Through chunk splitting, multi-model translation merging, and terminology intervention, our system demonstrates strong performance in the WMT24 Discourse-Level Literary Translation task. The translation merging strategy surpasses all individual models in LQR scores. Terminology intervention significantly improves terminology consistency, reducing the average correspondence from 3.73 translations to 1.12. Future work will focus on further optimizing these techniques and exploring new strategies to enhance translation quality, especially in handling long texts and preserving literary styles.

Abstract

This report outlines our approach for the WMT24 Discourse-Level Literary Translation Task, focusing on the Chinese-English language pair in the Constrained Track. Translating literary texts poses significant challenges due to the nuanced meanings, idiomatic expressions, and intricate narrative structures inherent in such works. To address these challenges, we leveraged the Chinese-Llama2 model, specifically enhanced for this task through a combination of Continual Pre-training (CPT) and Supervised Fine-Tuning (SFT). Our methodology includes a novel Incremental Decoding framework, which ensures that each sentence is translated with consideration of its broader context, maintaining coherence and consistency throughout the text. This approach allows the model to capture long-range dependencies and stylistic elements, producing translations that faithfully preserve the original literary quality. Our experiments demonstrate significant improvements in both sentence-level and document-level BLEU scores, underscoring the effectiveness of our proposed framework in addressing the complexities of document-level literary translation.

1 Introduction

Machine Translation (MT) (Brown et al., 2020; Chowdhery et al., 2023; Touvron et al., 2023) has become an essential tool in breaking language barriers, enabling the automatic translation of text from one language to another. While significant advancements (Vaswani et al., 2017; Sennrich et al., 2016; Wei et al., 2023; Gu et al., 2018; Ghazvininejad et al., 2019; Wang et al., 2021; Guo et al., 2021; Yu et al., 2021) have been made in MT for various text genres, translating literary texts remains a formidable challenge. Literary texts are rich in complex linguistic phenomena, such as nuanced meanings, idiomatic expressions, and intricate narrative structures. Unlike technical or news-related texts, literary works demand a deeper understanding of context, tone, and style, making them particularly challenging for MT systems. This difficulty is compounded by the scarcity of high-quality parallel datasets in the literary domain, limiting the ability of MT models to learn from extensive, diverse examples.

Document-level translation (Sun et al., 2020; Du et al., 2024; Wu et al., 2024) introduces another layer of complexity to MT, especially when dealing with longer texts such as novels. Unlike sentence-level translation, where context is limited to a single sentence, document-level translation requires the model to consider the broader discourse context to maintain coherence and consistency throughout the entire text. This is particularly crucial in literary translation, where the narrative thread, character development, and thematic elements must be preserved across sentences and paragraphs. Long-range dependencies, where information introduced early in a text influences later parts, pose a significant challenge for MT systems, which often struggle to retain and apply such context effectively over extended texts.

In this system report, we describe our participation in the WMT24 Discourse-Level Literary Translation Task, focusing on the Chinese-English language pair under the Constrained Track. Our approach leverages the Chinese-Llama2 model, specifically designed for this task, through a combination of Continual Pre-training (CPT) and Supervised Fine-Tuning (SFT). This methodology allows us to refine the model's understanding of literary texts while adapting it to the specific nuances of Chinese-English translation. Additionally, we employ an Incremental Decoding framework, which enables the model to translate documents sentence by sentence, ensuring that each translation is informed by the broader context. This approach is designed to tackle the challenges of document-level literary translation, aiming to produce translations

that are not only accurate but also faithful to the original text's literary quality.

2 Background: TP3

Machine Translation (MT) is the automated process of converting text from one language to another using computational methods. Traditionally, MT relies on encoder-decoder models, where the encoder processes the source language and the decoder generates the translation, often requiring large bilingual datasets and data augmentation to improve performance. Recently, Large Language Models (LLMs) like GPT have become prominent in MT, enabling translation through zero-shot or few-shot learning by conditioning on a source sentence (Jiao et al., 2023; Zeng et al., 2023; Chen et al., 2023; Xu et al., 2023; Yang et al., 2023; Zhang et al., 2023). These models can also be fine-tuned with high-quality bilingual data and tailored instructions to enhance translation accuracy and robustness, offering new possibilities for MT with limited resources.

TP3 Guo et al. (2024) propose a novel training paradigm, consisting of Three-Stages Translation Pipeline (TP3), to boost the translation capabilities of LLMs. The training paradigm includes:

Stage 1: Continual Pre-training using Extensive Monolingual Data. This stage aims to expand the multilingual generation capabilities of LLMs. While it is inherently related to machine translation tasks, it is not essential.

Stage 2: Continual Pre-training with Interlinear Text Format Documents. They construct interlinear text format from sentence-aligned bilingual parallel data and utilize them for continual pre-training of LLMs. Experimental results demonstrate the critical importance of this stage, resulting in a significant improvement in translation quality, particularly for English-Other translations.

Stage 3: Leveraging Source-Language Consistent Instruction for Supervised Fine-Tuning. In this stage, they discover that setting instructions consistent with the source language benefits the supervised fine-tuning process.

3 Methods

3.1 TP3 for Discourse-Level Literary

We introduce the TP3 training paradigm into the literary translation task, with the entire training process illustrated in Figure 1.

Stage 1: Continual Pre-training using Chinese and English Monolingual Literary Data In this stage, we adapt a general-purpose large language model (LLM) into a specialized Literary LLM by using monolingual literary data in both Chinese and English. While existing LLMs like Llama perform well in English-centric tasks, their capabilities in other languages, especially in literary contexts, are often limited. To improve this, we employ continual pre-training with extensive monolingual literary texts, enhancing the model's understanding of nuanced language, stylistic elements, and narrative structures. This step is critical for enabling the model to generate more coherent and contextually appropriate translations.

For this task, continual pre-training is essential, transforming a general LLM into one tailored for

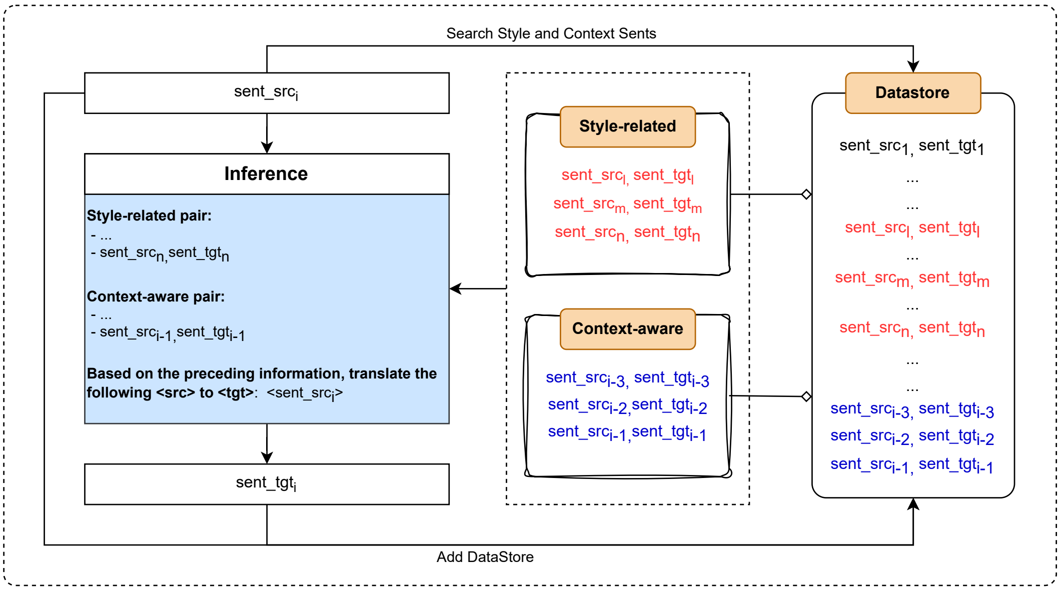

Figure 2: The overall of our incremental decoding framework.

literary translation. We treat each novel as a distinct training unit, combining sentences within each chapter into paragraphs to capture long-range dependencies and context. This approach is vital for maintaining consistency and preserving the literary quality of translations. By focusing on both Chinese and English literary data, the model gains a balanced understanding of the stylistic and structural intricacies in both languages.

Stage 2: Continual Pre-training with Aligned Chinese-English Interlinear Text Format Literary Documents In Stage 2, we enhance the model's cross-lingual translation capabilities by using aligned Chinese-English interlinear text format literary documents, building on the foundation established in Stage 1. The interlinear text format, where each source sentence is directly aligned with its translation at the word or phrase level, is essential for enabling the model to understand and map the syntactic and semantic structures between Chinese and English, which is crucial for producing high-quality translations. We implement a continual pre-training approach using LoRA (Low-Rank Adaptation of Large Language Models) (Hu et al., 2021) to efficiently adapt the model with these interlinear text documents.

Initially, the model was trained on general sentence-aligned parallel data to establish a strong cross-lingual alignment foundation. Subsequently, we performed incremental pre-training with literary-specific interlinear data. By focusing on literary documents, we ensure the model becomes finely attuned not only to general cross-lingual translation but also to the unique stylistic and structural nuances of literary texts. This approach enables the model to capture the intricate relationships between Chinese and English in a literary context, significantly improving translation quality and fidelity.

Stage 3: Supervised Fine-Tuning with Context-aware and Style-related Instructions In the final stage of our approach, we conduct supervised fine-tuning using context-aware and style-related instructions, specifically tailored to address the challenges of semantic coherence and stylistic consistency in literary translation. Unlike the traditional approach of using Source-Language Consistent Instruction, which emphasizes alignment with the source language, our method focuses on ensuring that the translated output maintains a consistent narrative flow and adheres to the stylistic nuances of the original text. This adjustment is crucial for literary translation, where preserving the author's voice and the overall tone of the work is just as important as achieving accurate translation.

The fine-tuning process leverages the LoRA to refine specific parameters of the model efficiently. By applying LoRA, we can update the model with low-rank adaptations, which helps in preventing overfitting while ensuring that the model adapts effectively to the task-specific requirements. This targeted fine-tuning allows the model to better capture the long-range dependencies and stylistic elements that are essential for producing translations that are not only accurate but also faithful to the literary qualities of the source text.

3.2 Incremental Decoding framework

In traditional machine translation, sentences are often translated independently of one another, leading to issues with semantic coherence and stylistic consistency when viewed from a broader, document-level perspective. To address these challenges, we propose an Incremental Decoding framework that considers the translation of each sentence as part of a continuous process, taking into account the translations of previous sentences. This method ensures that the translated text maintains a cohesive flow and consistent style throughout the entire document.

The Incremental Decoding framework incorporates two key components: Context-aware information and Style-related information. Context-aware information involves using the translations of the previous n sentences as historical context when translating the current sentence. This helps maintain continuity in the narrative and ensures that the translation aligns with the broader context established in earlier sentences.

Style-related information further refines this process by incorporating translations of sentences that are similar to the current sentence in terms of content and style. These sentences are selected based on sentence and keyword similarity, ensuring that the translation reflects the stylistic nuances present in the original text. By integrating both context-aware and style-related information, the Incremental Decoding framework produces translations that are not only accurate but also harmonious in tone and structure, closely mirroring the original literary work.

4 Experiments

4.1 Datasets and Evaluation Metrics

We utilized data from the general MT shared task and the GuoFeng Webnovel Corpus. The GuoFeng Webnovel Corpus was employed in Stages 1, 2, and 3, while the general MT data was used exclusively in Stage 2. Detailed statistics of the data are presented in Table 2.

For the evaluation metrics, we utilized SacreBLEU (Papineni et al., 2002) to assess system performance. Given that the test set was segmented into sentence-level units, we conducted evaluations using both s-BLEU (sentence-level BLEU) and d-BLEU (document-level BLEU) scores to provide a comprehensive analysis of the translation quality.

4.2 Experiment Settings

In our experiments, we used Chinese-LLaMA2 (Cui et al., 2023) as the foundation model. Chinese-LLaMA2 is an enhanced and optimized version of Llama-2, specifically designed for Chinese language understanding and instruction comprehension. This model includes a larger Chinese vocabulary and benefits from incremental pretraining on a large-scale Chinese dataset, which significantly improves its semantic understanding capabilities.

For both the Continual Pre-training and Supervised Fine-Tuning stages, we adhered to the hyperparameters utilized in the Chinese-LLaMA2 project. During Stage 2, the model was trained for 1 epoch, while in Stage 3, the training was extended to 3 epochs to ensure more refined adjustments.

All experiments were conducted using 8 Nvidia GPUs, each with 64GB of memory, and employed DeepSpeed (Rasley et al., 2020) ZeRO 2 for model parallelization, which allowed for efficient handling of the large-scale model and dataset.

4.3 Compared Baselines

- **General Sent-Trans**: In this baseline, we directly create sentence-level translation instruction data and use it to perform Supervised Fine-Tuning on the Chinese-LLaMA2 model. This approach focuses on training the model with general sentence-level translation tasks without any specialized pre-training.

- **Literary Sent-Trans**: This baseline builds on the previous stages, as outlined in Stage 1 and Stage 2. We first subject the Chinese-LLaMA2 model to Continual Pre-training using monolingual and bilingual literary data. Following this pre-training, the model undergoes Supervised Fine-Tuning using the same sentence-level translation instruction data as in the General Sent-Trans baseline. This approach is designed to adapt the model to the literary domain before fine-tuning it with general sentence-level instructions.

	Valid 1		Valid 2		Test 1		Test 2	
	s-BLEU	d-BLEU	s-BLEU	d-BLEU	s-BLEU	d-BLEU	s-BLEU	d-BLEU
General Sent-Trans	16.81	24.1	10.74	17.39	17.97	25.87	13.32	20.37
Literary Sent-Trans	23.35	30.51	14.64	21.81	20.91	28.51	18.02	25.38
Literary Doc-Trans	23.78	31.85	14.94	22.12	20.97	29.43	18.28	25.62

Table 1: **The overall results.**

Data Source	Data Size
General MT	25M
GuoFeng Webnovel Corpus	1.9M

Table 2: Data Statistics.

- **Literary Sent-Trans**: **This represents our final proposed approach**. After the Continual Pre-training conducted in Stage 1 and Stage 2, we further train the model using the Supervised Fine-Tuning method from Stage 3, which incorporates Context-aware and Style-related Instructions. This method aims to enhance the model's ability to maintain semantic coherence and stylistic consistency across sentences in literary document translation.

4.4 Results

The comparison between Literary Sent-Trans and General Sent-Trans reveals significant improvements in both s-BLEU and d-BLEU scores across various test sets, indicating that Stage 1 and Stage 2 effectively incorporated literary knowledge into the model. Furthermore, when comparing Literary Doc-Trans with Literary Sent-Trans, we observe additional gains in both s-BLEU and d-BLEU metrics, demonstrating the effectiveness of Stage 3's Context-aware and Style-related Instructions. These results collectively highlight the incremental benefits of each stage in enhancing the model's performance in literary translation. The detailed results are presented in Table 1.

5 Conclusion

In this work, we addressed the complex task of literary translation within the WMT24 Discourse-Level Literary Translation Task, focusing on the Chinese-English language pair. By leveraging the Chinese-Llama2 model, enhanced through Continual Pre-training and Supervised Fine-Tuning, we successfully adapted the model to capture the unique nuances of literary texts. Our Incremental Decoding framework further ensured that each sentence was translated with awareness of its broader context, resulting in more coherent and stylistically consistent translations. The improvements observed in both sentence-level and document-level BLEU scores validate the effectiveness of our approach. These results highlight the potential of combining advanced language models with specialized training strategies to tackle the intricacies of literary translation, paving the way for further research in this challenging domain.

Abstract

This paper describes our submission system, NovelTrans, from NLP^{2}CT and DeepTranx for the WMT24 Discourse-Level Literary Translation Task in Chinese-English, Chinese-German, and Chinese-Russian language pairs under unconstrained conditions. For our primary system, three translations are done by GPT4o using three different settings of additional information and a terminology table generated by online models. The final result is composed of sentences that have the highest xCOMET score compared with the corresponding sentences in other results. Our system achieved an xCOMET score of 79.14 which is higher than performing a direct chapter-level translation on our dataset.

1 Introduction

In the rapidly evolving field of natural language processing (NLP), discourse-level literary machine translation remains a challenging task. It involves not only complex semantic phenomena but also long-term dependency, rare or new terminologies, and cultural background (Pang et al., 2024; Liu et al., 2023). These factors pose a high requirement for the translation model. Training or fine-tuning such a model is extremely costly. To address this, pretrained large language models (LLMs) and training-free methods like in-context learning (Brown et al., 2020) are widely used. Up to now, significant advancements have been made in sentence-level machine translation using training-free methods. These methods, such as TEaR (Feng et al., 2024), DUAL-REFLECT (Chen et al., 2024), Multi-Aspect Prompting and Selection (He et al., 2024), and Multi-Agent Debate (Liang et al., 2024), have proven effective. However, few studies have been conducted on the document level.

This paper presents our submission to the WMT24 Discourse-Level Literary Translation shared task. We utilize online commercial general-purpose LLMs, DeepSeek (DeepSeek-AI et al., 2024) and GPT4o (OpenAI et al., 2024), to perform the translation with the help of techniques including *Document-level Multi-Aspect Prompting and Selection* (*d-MAPS*), *LLM-generated terminology table* and *dynamic retrieval of in-context learning examples using Reranked BM25* (R-BM25; Agrawal et al. 2023). We also explore the potential of *post-correction of punctuation errors* in LLMs' translation results. Using the above method, NovelTrans achieves an xCOMET score of 79.14, 0.68 points higher than the GPT4o baseline. Moreover, the consistency of rare or unseen terminologies has significantly improved and the number of mistranslated or awkwardly translated phrases is greatly reduced. The remaining part of this paper is structured as follows. Section 2 contains an overview of our pipelines and detailed descriptions of each procedure in the pipelines. Experiments and results analysis of our method are given in Section 3. Finally, the conclusion is presented in Section 4.

2 System Overview

2.1 Pipeline

For our pipeline, we implemented three variants which were named Primary, Contrastive-1, and Contrastive-2. The Primary system has a pipeline shown in Figure 1. For each input document, we first generate a terminology table and then replace all terminologies in the document with their corresponding translations, ensuring the consistency of terminology translation throughout the document. Then the document is split into chapters using regular expressions. Each chapter is divided into 20-line segments. Each segment is translated using GPT4o, with MAPS and R-BM25 enhancing the translation quality. The translated text will then proceed to the post-correction stage, where the GPT4o model will detect and resolve punctuation errors. For the

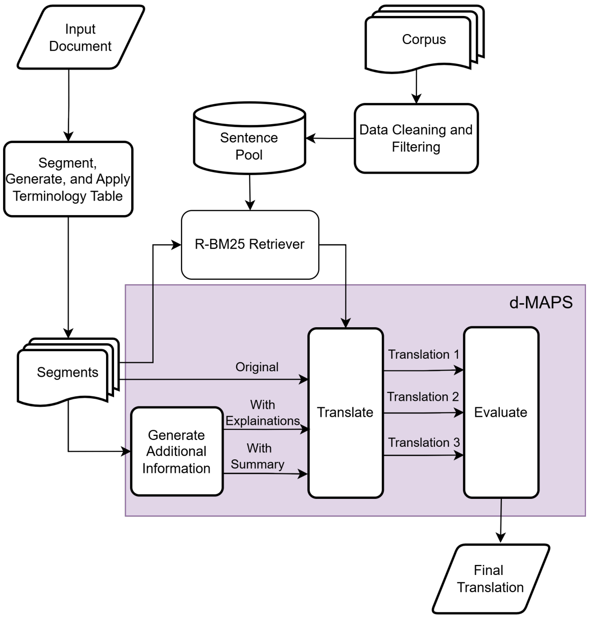

Figure 1: The translation flowchart of our NovelTrans system where post-correction is not included.

Contrastive-2 system, the MAPS uses a different way to determine the quality of translation and will be discussed in Section 2.2. The Contrastive-1 system is the same as the primary system except for the removal of the post-correction stage. As the API service for GPT4o we used contains a content filter, if a segment's translation is filtered by the content filter, the process will be handled using the DeepSeek API.

2.2 Document-level Multi-Aspect Prompting and Selection

Multi-Aspect Prompting and Selection (MAPS) is a powerful prompting strategy that can help a model understand the complicated relationships in discourse-level corpus better. Inspired by the MAPS, we chose to transfer MAPS to the document-level (d-MAPS). Considering both resource limitations and characteristics of web novels, we implemented d-MAPS as follows. We first acquire explanations for colloquialisms and the segment summary through the cooperation of DeepSeek and GPT4o. Then, three different translations are produced by GPT4o: one with explanations, one with the summary, and one without any extra information. Afterward, the COMET-22-kiwi reference-free translation quality evaluation model (Rei et al., 2022) is applied to obtain the quality score of each sentence in these three results. To select the final translation result, we employ two different strategies. In the Primary and Contrastive-1 system, the final result is composed of sentences that have the highest xCOMET score compared to the corresponding sentences in other translations. In Contrastive-2, the final translation is determined by choosing the result with the highest average xCOMET score.

2.3 LLM-generated Terminology Table

In the traditional novel translation pipeline, it is crucial to set up a terminology table before the translation to unify the translations of those rare terms throughout the corpus. To generate the terminology table, we use the DeepSeek API which has better knowledge of Chinese cultural backgrounds to retrieve proper nouns and then translate these words into the target language considering their context. With the terminology table acquired, we then replace all the terms in the source corpus with their corresponding translations to ensure consistency. The consistency mentioned above refers to the uniformity of special terminology translation.

2.4 Re-ranked BM25

Re-ranked BM25 (R-BM25; Agrawal et al. 2023) is an in-context example retriever that can ensure both sample quality and retrieving speed. After 100 sentences are retrieved by a normal BM25 retriever, a score will be computed for each sentence using the following formula, in which S and Q denote the source and retrieved sentence's n-grams separately.

$$R_n = \frac{\sum_{\text{ngram} \in S \cap Q} \text{Count}_{\text{matched}}(\text{ ngram })}{\sum_{\text{ngram} \in S} \text{Count}_S(\text{ ngram })} \tag{1}$$

$$\text{Score } = \exp\left(\frac{1}{n}\sum_{n}\log\left(R_n\right)\right) \tag{2}$$

Then these sentences are re-ranked using these scores to solve the problems that BM25 favors rare words (Robertson and Zaragoza, 2009). To form the sentence pool for the R-BM25 to search, we utilize the GuoFeng Webnovel Corpus[1] (Wang et al., 2023) which has three subsets named TRAIN, VALID1, and VALID2. By combining all three subsets, we formed a large dataset and then filtered out sentences with low xCOMET scores. During the experiment, VALID2 is not included because our valid set is sampled from VALID2. To generate the in-context learning examples for a particular segment, we retrieve three samples for each sentence

w/o ICL & Terminology Table	78.71	20.60	18.63
w/o ICL, Terminology Table & d-MAPS	78.68	**20.80**	**18.97**

Table 2: Ablation study of our proposed pipeline. ICL examples are selected by R-BM25 score. Terminology table represents the terminology table obtained by the cooperation of GPT4o and DeepSeek. The GPT4o baseline is generated by directly translating the text at the chapter level.

in that segment using R-BM25 and then randomly sample eight sentences to form the final in-context learning example. It is tested that choosing eight examples will result in the best performance boost.

2.5 Post-Correction of Translation

After reviewing the translation results, we observed that punctuation errors, such as comma splices, appeared at a high frequency due to the inappropriate use of punctuation in the source corpus. To solve this, we employed a post-processing method that uses GPT4o to correct punctuation errors at the sentence level. Given the sentence above and below the target sentence, we asked the model to check and resolve punctuation errors. This method resulted in a better version of the target sentence.

3 Experiments

3.1 Experiments Setup

The datasets we used are GuoFeng Webnovel Corpus V1 and V2. V1 contains a Chinese-English parallel corpus while V2 contains Chinese-German and Chinese-Russian nonparallel corpus. For the Chinese-English direction, we performed experiments on 10 chapters in VALID2 of the dataset. These chapters are taken from different books to avoid bias. For Chinese-German and Chinese-Russian direction, we chose 4 chapters from different books and aligned them separately using GPT4o API before experimenting. The GPT4o API we used is provided by OpenAI. The DeepSeek API is provided by DeepSeek Open Platform[2]. Since the BLEU score faces the problem of inaccuracy in evaluating Zero Pronoun Translation tasks (Zhan et al., 2023; Xu et al., 2023), we focused more on the COMET score. To be better aligned with the human evaluation, we chose to use **XCOMET-XL** (Guerreiro et al., 2023) to compute the xCOMET score. BLEU and d-BLEU scores are all computed by **SacreBleu** (Post, 2018). To compute d-BLEU, we join all sentences in the document together and treat them as a single sentence since it is the method used to compute the d-BLEU score in the previous year's WMT literary translation task (Wang et al., 2023).

3.2 Results

Table 1 shows the comparison between our system and other online models in Chinese-English, Chinese-German, and Chinese-Russian translation direction. The result shows that our system achieves a higher xCOMET score in exchange for the d-BLUE performance.

3.3 Ablation Study

We conduct ablation study on Chinese-English direction. The result, provided in Table 2, shows that

Source	GPT4o Baseline	NovelTrans
走，全部跟我走，去破坏对方的 (rival) 世界级传送阵.	Go, all of you come with me to destroy the *other side's* (Wrong) world-class teleportation array.	Let's go, everyone follows me to destroy the *enemy's* (Correct) world-class teleportation array.
这四个字，是郑州城人类最后的绝唱 (the last song of mankind in the city of Zhengzhou).	These four words were the *last human song of Zhengzhou* (Bad Phrase Translation).	These four words were the *last elegy of humanity in Zhengzhou city* (Correct).

Table 3: Case study where examples are taken from different pipeline methods.

Source	Without Correction	With Correction
“别紧张，自己人。”	"Don't be nervous, I'm one of you."	"Don't be nervous; I'm one of you."
他们打开背后的涡旋引擎跳了下去	They activated the vortex engine on their backs, jumping down	They activated the vortex engine on their backs before jumping down.

Table 4: Comparison of translation results with or without post-translation correction.

Position	Source	Without Term Table	With Term Table
Near the start of a chapter	若非此刻在天渡船上,可能已经大打出手.	If they weren't on the *Tian Du ship*, he might have already started a fight.	If they weren't on the *Heavenly Ferry*, he might have already started a fight.
Near the end of the same chapter	不多时,天渡船抵达对岸.	Before long, the *Heaven Crossing Boat* (Inconsistent) reached the other side.	Before long, the *Heavenly Ferry* (Consistent) reached the opposite bank.

Table 5: Comparison of translation results with or without LLM-generated terminology table.

removal of component in our system will result in a performance drop on xCOMET.

3.4 Analysis

Table 3 shows two examples taken from our experiment. In the first example, the direct translation of GPT4o uses an ambiguous phrase, “other side”, which can mean both an enemy and a geographically opposite side. However, with the context, we can easily determine that the “other side” here conveys only the meaning of “rival”. In the second example, the Chinese word “绝唱” which means the best art piece an artist has ever made is misused as “last song before their death” in the source sentence. Our system understood what the author wanted to convey and chose a suitable word, “elegy”, rather than doing a literal translation. These examples show that, compared with the baseline, our method has a stronger understanding of the context and Chinese cultural background. Table 4 demonstrates the effect of post-correction. The GPT4o model can detect and correct punctuation errors, especially comma splices that occur at high frequency, in various ways. Table 5 shows an example of inconsistency in the translation of special terms and our method can greatly reduce this type of problem.

4 Conclusion

We successfully deployed a discourse-level translation pipeline using online language models and adapted several sentence-level techniques for discourse-level translation. Our system achieved a higher xCOMET score than direct translation using GPT-4o. However, our research has some limitations. Adapting MAPS to discourse-level translation may disrupt long-term dependencies, indicating a need for further investigation in this area. Additionally, our method utilizes significantly more tokens than direct translation, necessitating further discussion on how to reduce token usage.

Abstract

The rapid growth of deep learning has spurred significant advancements across industries, particularly in machine translation through large language models (LLMs). However, translating literary still presents challenges, including cross-cultural nuances, complex language structures, metaphorical expressions, and cultural differences. To address these issues, this study utilizes the Llama and Phi models using both LoRA and full-parameter techniques, alongside a prompt-based translation system. Full-parameter tuning of the Llama-3-Chinese-8B-Instruct model was unsuccessful due to memory constraints. In terms of the WMT task, the fully fine-tuned Phi 3 model was selected for submission due to its more natural and fluent translations. Nonetheless, results showed that LoRA and the prompt-based system significantly improved the Llama3 model's performance, surpassing other models in BLEU and ROUGE evaluations.

1 Introduction

In recent years, the development of deep learning has spread across various industries (Ji et al., 2024), and the impact of large language models (LLMs) on these industries has been particularly significant (Lyu et al., 2023). Despite the fact that many challenges in machine translation (MT) have been overcome (Wang et al., 2023), literary translation still encounters cross-cultural issues, including such as processing complex languages, understanding metaphorical expressions, and addressing cultural differences (Lyu et al., 2020). Meanwhile, choosing the right model has become a key topic in terms of neural network-based (NN-based) MT (Xia, 2020), as models based on the source language typically have advantages in handling tasks regarding that language. Two main models are involved in this research: Llama3-Chinese-8B-Instruct[1] and Phi-3-mini-128k-instruct-Chinese[2]. The former fine-tuned the Llama3 model (Dubey et al., 2024) with 5 million instruction data points from the community, which significantly enhances its performance in Chinese-language tasks with a better ability of understanding Chinese contexts. The latter is with less than half the size (3.8B parameters) of the Llama3 8B version, which can surpass the performance of Llama3 with less computational resources.

LoRA (Sundaram et al., 2019) is a lightweight fine-tuning technique mainly used for efficiently training large models. Compared to traditional full-parameter fine-tuning, LoRA decomposes the trained parameter matrices into low-rank forms, resulting in a reducing number of parameters and less computational cost of training. It is especially appropriate for fine-tuning LLMs with constrained resources while maintaining high performance. In this research, we utilize Llama-Factory[3] (Zheng et al., 2024), an optimized framework designed specifically for fine-tuning LLMs like Llama. It supports various advanced training techniques, including mixed precision training and gradient accumulation, to improve training efficiency and reduce computational resource requirements. By integrating lightweight methods like LoRA, it can achieve efficient and stable model fine-tuning in resource-constrained environments, helping to quick adjustment and deployment of LLMs.

In general, our contributions can be summarized as follows:

- We conduct a comprehensive experiment of two major large language models, Llama-3-Chinese-8B-Instruct and Phi-3-mini-128k-instruct-Chinese, for the task of WMT2024

[1] https://huggingface.co/hfl/Llama-3-chinese-8b-instruct

[2] https://huggingface.co/shareAI/Phi-3-mini-128k-instruct-Chinese

[3] https://github.com/hiyouga/Llama-Factory

Proceedings of the Ninth Conference on Machine Translation, pages 987–992

Literary Translation. Our results demonstrate that both models perform excellently in handling Chinese tasks, especially when facing cross-cultural challenges in literary translation.

- We applied the LoRA technique to efficiently fine-tune the Llama model, significantly reducing computational costs while maintaining high translation quality. We additionally optimized the fine-tuning process by leveraging the Llama-Factory framework. Our experimental results demonstrate that the combination of LoRA and Llama-Factory can effectively support the adaptation and deployment of large-scale models in resource-constrained environments.

- We investigate the strengths and weaknesses of each model, particularly in terms of fluency and diversity (captured by ROUGE) as well as accuracy (captured by BLEU).

2 Related Work

Large Language Models (LLMs) for Machine Translation The application of Large Language Models (LLMs) in machine translation (MT) has seen significant advancements, particularly in general domain translation (Wang et al., 2023). Pretrained models such as Llama and Phi3 have been increasingly employed for tasks requiring semantic understanding across languages. Studies have highlighted how instruction-tuned LLMs can improve translation quality by adapting to the syntactic structures and cultural nuances of target languages. This is particularly relevant for our work as we evaluate the Llama-3 Chinese model (Cui et al., 2023), which is fine-tuned for literary translation.

Challenges in Literary Translation While MT systems have progressed in many domains (Du et al., 2024), the translation of literary texts remains particularly challenging due to the need to capture nuanced expressions, idioms, and stylistic elements. Literary translation (Jones, 2019) is often considered the "last frontier" for MT. Prior work has explored how traditional sentence-based MT systems struggle with long, complex passages found in literary texts (Aliguliyev, 2009). This is in line with the focus of our experiments, which attempt to handle these unique challenges using Llama-3 Chinese models and fine-tuning techniques.

Fine-Tuning Techniques for MT In order to address the computational limitations and language understanding challenges associated with large models, various fine-tuning approaches have been proposed (Nicholas and Bhatia, 2023). Recent studies on Low-Rank Adaptation (LoRA) have demonstrated that memory-efficient fine-tuning methods allow for high-quality performance on GPUs with limited memory. LoRA's success in reducing memory consumption while maintaining model accuracy has been a key technique in our experiments, particularly with the Llama-3 Chinese model.

Evaluation of Translation Quality The evaluation of literary translations poses its own challenges, as traditional metrics like BLEU may not fully capture the nuances of a good translation. (Pang et al., 2024) Newer approaches, such as Monolingual Human Preference (MHP) and Bilingual LLM Preference (BLP), have been proposed to better assess translation quality in a literary context. (Wu et al., 2024) Our experiments draw on these evaluation techniques, comparing model outputs through both automated metrics and human preference assessments to gauge the effectiveness of different fine-tuning strategies.

3 Experiment

3.1 Evaluation Metrics

To achieve accurate evaluation of MT result (Chang et al., 2024), two prevailing evaluation metrics are utilized: BLEU (Papineni et al., 2002) and ROUGE (Lin, 2004). BLEU is an automated evaluation metric based on n-gram matching, primarily used to measure the similarity between machine translation outputs and reference translations. By calculating the overlap of n-grams of different lengths between the model's output and the reference translation, BLEU can reflect the accuracy of the translation to a certain extent. ROUGE is a widely used automatic text evaluation metric mainly used to compare the similarity between generated text and reference text. ROUGE-L, in particular, is based on the Longest Common Subsequence (LCS) (Bergroth et al., 2000) and measures the similarity between generated text and reference text in terms of length matching and word order. Compared to BLEU, ROUGE captures both text diversity and fluency.

3.2 Prompt Engineering

The prompt design focuses on the task of translating Guofeng (traditional Chinese-style) novels, aiming to ensure that the translated text faithfully conveys the literary and cultural nuances of the original, while maintaining translation efficiency and accuracy. By establishing clear guidelines, the prompt emphasizes fidelity to the original text, concise output, and quality control to ensure that the translation remains fluent while preserving the original style and tone. The prompt is designed following the CoT (Chain of Thoughts) framework (Wei et al., 2022), with the specific approach outlined below:

First, the prompt introduces automatic language detection and translation features, enabling efficient Chinese-to-English translation of Guofeng novels to enhance processing speed and coherence. Secondly, fidelity to the original is critical, requiring the preservation of the original tone, style, and expression. Special attention is given to details such as pronouns, with a focus on word-for-word translation to avoid distorting the literary essence due to cultural or linguistic differences. The prompt further emphasizes objectivity in translation, avoiding any omissions or commentary, ensuring the completeness and authenticity of the translated text.

Additionally, the translated text must be concise, with no added annotations, ensuring that the classical charm and cultural context of the novel are naturally conveyed, enhancing the reader's experience. To ensure quality, the prompt requires thorough review and correction of the translated output, avoiding mistranslations or omissions, and ensuring that the text aligns with the target language's fluency and conventions. The prompt is task-oriented, providing only the final, revised translation, avoiding irrelevant information or excessive explanation, which improves processing efficiency and suits large-scale Guofeng novel translation projects.

3.3 Experiment 1: Training with Llama-3-Chinese-8B-Instruct

An initial attempt was made to fully train the Llama-3-Chinese-8B-Instruct model on the dataset. However, the process failed due to insufficient memory. The model's large size and the memory requirements exceeded the capabilities of the available hardware, necessitating use a smaller model or shift to a more memory-efficient fine-tuning method.

3.4 Experiment 2: Fine-Tuning Llama3 8B Model with LoRA

Given the memory constraints, the Llama3 8B model was fine-tuned using the LoRA technique on a dataset of 10,000 samples. The fine-tuning was performed with several key hyperparameters to optimize model performance and manage computational resources effectively. The learning rate was set to 1e-5 (Jin et al., 2023), using a cosine learning rate scheduler to gradually reduce the learning rate and improve training efficiency (Kim et al., 2021). A per-device train batch size of 2 was chosen to balance between memory usage and model update frequency, with gradient accumulation over 16 steps to simulate a larger batch size without requiring additional GPU memory. The training process was conducted over 10 epochs to ensure sufficient learning from the data, utilizing a maximum of 10,000 samples. Additionally, the model was trained with mixed precision (fp16) (Le Gallo et al., 2018) to reduce memory usage and accelerate computation. The evaluation strategy was set to evaluate the model performance at regular steps to monitor its progress closely. The results of this fine-tuning experiment are summarized in Table 1.

Table 1: Results of Fine-Tuning Llama3 8B Model with LoRA

Metric	Value	Description
BLEU-4	55.28	A metric which evaluates the quality of a candidate by computing the n-gram ($n = 4$) precision with references.
ROUGE-1	60.18	A variation of ROUGE where 1 means unigrams.
ROUGE-2	37.40	A variation of ROUGE where 2 means bigrams.
ROUGE-L	55.91	A variation of ROUGE where L means longest common subsequences (LCS).
Runtime	3m8s	Total runtime
Sample/s	1.594	Samples processed per second
Step/s	1.594	Training steps per second

Analysis: The results from this experiment were quite promising, with high BLEU and ROUGE scores. The LoRA technique allowed the model to be fine-tuned without running into memory issues, demonstrating that it is an effective method for working with large models on limited hardware. The high ROUGE scores suggest that the model was able to generate translations that were both accurate and fluent.

3.5 Experiment 3: Full Fine-Tuning with Phi Chinese Model

The Phi Chinese model was fully fine-tuned on a smaller dataset of 2,000 samples.

Table 2: Results of Full Fine-Tuning with Phi Chinese Model

Metric	Value
BLEU-4	50.93
ROUGE-1	51.90
ROUGE-2	27.19
ROUGE-L	46.41
Runtime	16m34s
Sample/s	0.503
Step/s	0.503

Analysis: The performance of the Phi Chinese model, while adequate, was noticeably lower than that of the Llama3 8B model fine-tuned with LoRA. The lower BLEU and ROUGE scores could be attributed to the smaller model size and the limited dataset, which may not have provided enough data for the model to generalize well.

3.6 Experiment 4: Full Fine-Tuning with Phi3 Chinese 3.5B Model

The Phi3 Chinese 3.5B model was fully fine-tuned on a dataset of 1,500,000 samples. The fine-tuning process was carefully configured with a set of key hyperparameters to optimize the model's performance while efficiently managing computational resources. We set the learning rate to 1e-5, which is low enough to ensure stable training and prevent the model from overshooting optimal weights but sufficient to allow for meaningful updates to the model parameters. A batch size of 128 was chosen to strike a balance between training speed and memory constraints. To further accommodate large batch sizes, a gradient accumulation step of 16 was used, effectively increasing the batch size without exceeding GPU memory limits. The model was trained using mixed-precision floating-point, allowing for faster computation and reduced memory usage, which is crucial when dealing with large-scale models. We set the number of epochs to 3.0 to provide sufficient training cycles while minimizing the risk of overfitting. A temperature parameter of 0.4 was employed during the generation phase to control the randomness and diversity of the model's output, balancing between creativity and coherence. The results of this fine-tuning experiment are summarized in Table 3.

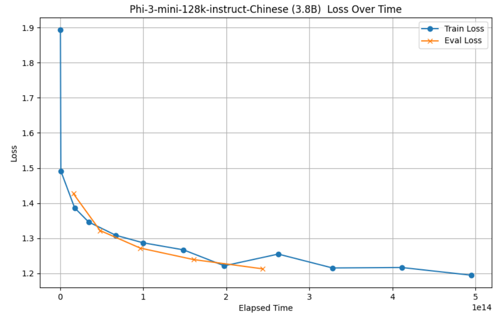

Figure 1: Loss Over Time for the Phi-3-mini-128k-instruct-Chinese (3.8B) model.

Table 3: Results of Full Fine-Tuning with Phi3 Chinese 3.5B Model

Metric	Value
BLEU-4	49.14
ROUGE-1	49.80
ROUGE-2	25.09
ROUGE-L	45.24
Runtime	2m36s
Sample/s	1.278
Step/s	1.278

Training and Evaluation Loss: To evaluate the fine-tuning process of the Phi-3-mini-128k-instruct-Chinese model, we tracked the training and evaluation loss over time, as illustrated in Figure 1. The model, which consists of 3.8 billion parameters, was fine-tuned on a diverse dataset using LoRA and full-parameter tuning techniques. Both the training and evaluation losses were monitored to assess model convergence and stability during the fine-tuning process.

Loss Over Time: As shown in Figure 1, the initial training loss starts relatively high, around 1.9, and decreases sharply during the early stages of training. By the end of the first epoch, the loss drops to approximately 1.3, indicating that the model quickly learns to generalize to the underlying patterns in the training data. The evaluation loss follows a similar trend, closely mirroring the training loss, which suggests that the model generalizes well without overfitting during the training process. By the second epoch, the loss stabilizes around 1.2 for both training and evaluation, demonstrating the model's ability to maintain consistent performance throughout the training process. The convergence of the loss indicates that the model is reaching its optimal capacity under the current fine-tuning setup.

Observations and Insights: The relatively close alignment of training and evaluation losses suggests that the fine-tuning process successfully mitigated the risk of overfitting, which is often a concern when dealing with large models and smaller, task-specific datasets. Moreover, the overall reduction in loss suggests that the Phi-3-mini-128k-instruct-Chinese model was able to effectively capture the nuances of the Chinese language and the intricate nature of literary translation tasks, as intended in this study.

4 Conclusion and Future Work

In this paper, we conduct experiments to provide valuable insights into the performance of different models and fine-tuning techniques for the WMT2024 Literary Translation Task. The Llama3 8B model, when fine-tuned using the LoRA technique, demonstrated the best performance, highlighting the importance of memory-efficient training methods in dealing with large models on limited hardware. The results from the Phi and Phi3 models suggest that model size alone may not guarantee the better performance, and the choices of fine-tuning method and dataset size are critical factors in achieving high-quality translations. In the future, we plan to investigate the performance of even larger models (e.g., Llama3 70B) to explore the trade-offs between model size, computational resources, and translation quality. In addition, since the metrics we used may correlate negatively with human judgements (Ji et al., 2022), developing task-specific evaluation metrics would be valuable for the accurate assessment of model performance.

Abstract

This paper describes Unbabel+IT's submission to the Chat Shared Task held at the Workshop of Machine Translation 2024. The task focuses on translating customer support chats between agents and customers communicating in different languages. We present two strategies for adapting state-of-the-art language models to better utilize contextual information when translating such conversations. Our training strategy involves finetuning the model on chat datasets with context-augmented instructions, resulting in a specialized model, TOWERCHAT. For inference, we propose a novel quality-aware decoding approach that leverages a context-aware metric, CONTEXTCOMET, to select the optimal translation from a pool of candidates. We evaluate our proposed approach on the official shared task datasets for ten language pairs, showing that our submission consistently outperforms baselines on all and competing systems on 8 out of 10 language pairs across multiple automated metrics. Remarkably, TOWERCHAT outperforms our contrastive submission based on the much larger TOWER-V2-70B model while being 10× smaller. According to human evaluation, our system outperforms all other systems and baselines across all language pairs. These results underscore the importance of context-aware training and inference in handling complex bilingual dialogues.

1 Introduction

The focus of this year's chat translation (Chat MT) shared task is the translation of conversations in customer service applications. This task differs from classical MT in that the interactions are bilingual and the texts are often more dynamic, contextualized, and informal than the structured content typically found in news or Wikipedia articles. In such scenarios, leveraging conversation context could potentially help avoid cases of lexical inconsistency and incoherence (Läubli et al., 2018; Toral et al., 2018). However, previous editions of the Chat MT shared task have shown that standard MT models are still incapable of doing so (Farajian et al., 2020; Farinha et al., 2022).

Squad Building Challenge

Thank you for the clarification.

Figure 1: A WMT24 sample conversation (some turns omitted) with reference English translations. Without context, TOWERCHAT mistranslates "montagem de elencos" to "casting". With context, it correctly translates the source, understanding the customer is talking about a squad building challenge ("dme").

Large Language Models (LLMs) present a promising avenue to address this issue. Not only are they becoming the state-of-the-art solution for multilingual machine translation (Zhang et al., 2023; Wei et al., 2023; Alves et al., 2023; Reinauer et al., 2023; Zhu et al., 2024), but they are also known to handle context adeptly (Karpinska and

[*] Equal contribution.

Proceedings of the Ninth Conference on Machine Translation, pages 993–1003

Iyyer, 2023; Wang et al., 2023; He et al., 2024). Despite their potential, the application of LLMs in understanding and translating bilingual chat conversations remains underexplored. We aim to bridge this gap by investigating how translation LLMs can be adapted for the Chat MT task and how they can effectively leverage conversational context to produce better translations.

Using TOWER LLM (Alves et al., 2024), a strong LLM specialized for MT and related tasks, we show that an LLM not fine-tuned for the chat domain struggles to leverage context for disambiguation, often resulting in translations that are worse than those produced without context. We thus propose two solutions to improve context usage for translation LLMs. First, we build a translation model tailored for Chat MT – TOWERCHAT – finetuned on a carefully constructed context-augmented dataset. Second, to further improve the usage of contextual information during inference, we take a novel approach of performing quality-aware decoding (Fernandes et al., 2022, QAD) with a context-aware MT evaluation metric, CONTEXTCOMET (Agrawal et al., 2024). QAD approaches select one best hypothesis from a pool of candidates using an MT metric, and have been shown to improve translation quality (Freitag et al., 2022; Fernandes et al., 2022; Farinhas et al., 2023).

This serves as our primary submission to the WMT24 Chat MT shared task, along with two contrastive ones – TOWERCHAT without QAD, and TOWER-V2-70B. The TOWER-V2-70B model is the strongest version of TOWER, which was developed for the General MT shared task.[1] The translations obtained from our approach consistently achieve the best scores across all language pairs tested, as measured by both automatic MT metrics (neural and lexical) and lexical cohesion metrics (MUDA accuracy) and human evaluation, beating strong baselines that disregard the context of conversations. Furthermore, TOWERCHAT without QAD maintains general translation capabilities and achieves better or comparable quality to TOWER-V2-70B, outlining the importance of in-domain adaptation of translation LLMs on Chat MT data.

2 Chat Translation Shared Task: Dataset and Challenges

This year's chat MT dataset includes bilingual online customer service chats between an English-speaking agent and clients who speak Portuguese, French, Italian, Dutch, or Korean. These conversations are often unplanned, informal, and nonstandard, contrasting with the well-formed text of most other translation domains. An example conversation is shown in Figure 1.

We present the general statistics from this year's shared task datasets in Table 1, including (i) the number of instances in the dataset for each language pair; (ii) the average character length of the source segments; (iii) the average number of segments in a conversation and (iv) the percentage of segments tagged with MUDA (Fernandes et al., 2023), an automatic tagger for identifying tokens belonging to certain discourse classes (lexical cohesion, verb forms, pronouns, formality) of potentially ambiguous translations. While the development and test sets exhibit a similar distribution in terms of segment length and count, they differ significantly from the training dataset. Furthermore, up to 30% en↔fr instances are tagged as requiring disambiguation according to MUDA, highlighting the complexity and the need for contextual information to generate high-quality translations.[2]

Next, we describe the process of building TOWERCHAT, which was conditioned by the aforementioned inherent complexities of Chat MT.

3 Adapting TOWER for Chat Translation

LLMs have shown the potential to use contextual information to perform many NLP tasks (Karpinska and Iyyer, 2023). In this work, we investigate whether providing contextual information can improve translation quality for bilingual chats using strong translation LLMs like TOWERINSTRUCT. Contrary to our expectations, our preliminary results indicate that incorporating context into the prompt instruction diminishes overall translation quality. We believe this is due to TOWERINSTRUCT's training data lacking chat-specific MT examples, which results in the model's unfamiliarity with the context format and the inability to adequately use context (Section 5). To mitigate this and improve the usage of contextual information, we propose two strategies – one for training and one for inference.

[1] Private model, but since we developed it, we have access.

[2] Note that MUDA only tags formality for Korean and does not detect instances of semantic ambiguity. The dataset likely features many more complex context phenomena.

Language Pair	# Instances			Avg. Source Length			Avg. # Segments per Conversation			% MuDA tagged

{target_lang}: **{target_seg}**

Figure 2: Instructions with context for Chat MT. Parts in purple are only included when a context is available.

3.1 Finetuning on Context-augmented Chats

For a conversation C of length L with segments $\{(x_t, y_t, c_t)\}_{i=1}^{L}$, where x_t is a text generated by the agent or the customer, y_t is its reference translation in the target language, and c_t is the preceding bilingual context, we train the model to minimize the cross-entropy loss using the input prompt shown in Figure 2:

$$\mathcal{L} = -\log P(y_t|x_t, c_t). \tag{1}$$

The context c_t includes all previous turns of the conversation, capturing important discourse-level information such as pronoun references, formality, and other pragmatic elements that influence the translation. For the first turn, no context is available, so the prompt reduces to the standard format used for zero-shot MT, as described in Alves et al. (2024). We train TOWERCHAT by finetuning TOWERBASE 7B on the concatenation of TOWERBLOCKS and the entire training dataset of the shared task, using context-aware prompts. This endows the model with the capacity to better understand and leverage conversational context, enabling it to generate high-quality translations.

3.2 QAD with Context-aware Metrics

Decoding strategies informed by translation quality metrics such as Minimum Bayes Risk Decoding (MBR) and Tuned Reranking (TRR) have been shown to consistently improve output quality over greedy decoding (Fernandes et al., 2022; Freitag et al., 2022; Nowakowski et al., 2022; Farinhas et al., 2023). In QAD, the goal is to find a translation among a set of candidates that maximizes the expected utility function, often measured using an MT metric like reference-based COMET. Recently, Agrawal et al. (2024) showed that context-aware MT metrics correlate better with human judgments compared to their non-contextual counterparts, especially when evaluating out-of-English chat translations. The context-aware versions of COMET (Vernikos et al., 2022; Agrawal et al., 2024) compute quality scores for a source-reference-hypothesis tuple, $(x, y, \hat{y})$, using the representations extracted from a context-augmented input, $([c; x], [c; y], [c; \hat{y}])$.

As such, we use CONTEXTCOMET for MBR decoding in our submission. For a given source text x, the previous bilingual context, c, and a set of candidate translations sampled from the model $\mathcal{Y}$, the utility of each candidate $\hat{y} \in \mathcal{Y}$, is given by

$$u = \frac{1}{|\mathcal{Y}|} \sum_{y \in \mathcal{Y}} \textsc{ContextComet}([c; x], [c; y], [c; \hat{y}]). \tag{2}$$

The best translation is selected using:

$$y_{\text{mbr}} := \text{arg max}_{\hat{y} \in \mathcal{Y}} [u(\hat{y}, \mathcal{Y})]. \tag{3}$$

This enables the model to select a translation amongst alternative hypotheses, potentially leading to more accurate and contextually appropriate outputs. QAD with TOWERCHAT serves as our primary submission to the Chat Shared Task.

4 Experimental Configurations

Baselines. We report the shared task's official baseline: NLLB-3.3B with beam search decoding (beam width: 4). Additionally, we report greedy decoding results with TOWERINSTRUCT-7B, and TOWER-V2-70B, the strongest TOWER model. The former serves as a direct baseline for our method, while the latter is a state-of-the-art baseline for MT.

TOWERCHAT. We report greedy and QAD results with the TOWERCHAT-7B model. For

Table 2: Main Results on Official Test Set: QAD with TOWERCHAT outperforms all baselines across the board. Models with statistically significant performance improvements are grouped in quality clusters

QAD, we perform MBR with COMET or CONTEXTCOMET on 100 candidates obtained via epsilon sampling with $\epsilon = 0.02$ (Hewitt et al., 2022).

Instruction settings. To assess whether systems can properly leverage conversational context, we prompt the LLM-based MT with two instruction formats (see Figure 2): 1) **w/o context**, where the model is prompted without any conversational context (without the purple highlighted text). 2) **w/ context**, where the entire previous bilingual conversation is provided as the context in the prompt.[3]

Evaluation. We report the final results on the shared task's test set on all ten language pairs. As exemplified in Figure 1, ambiguous contextual phenomena often arise in Chat MT that require nuanced evaluation. As such, we leverage three types of assessments: 1) automatic metrics for measuring overall translation quality – two neural and one lexical – COMET-22 (Rei et al., 2022), CHRF (Popović, 2015) and METRICX-XL (Juraska et al., 2023); 2) a reference-free neural metric that uses context for quality assessment, CONTEXT-QE (Agrawal et al., 2024); 3) F1-score on MUDA tags for measuring whether models correctly resolve lexical ambiguities (Fernandes et al., 2023). Considering METRICX, CHRF, and MUDA is crucial in our case, as COMET may favor the QAD strategies we use.

On Tables 2 and 3 we report performance clusters based on statistically significant performance gaps at a 95% confidence threshold.[4] We create per-language groups for systems with similar performance, following Freitag et al. (2023), and obtain system-level rankings using a normalized Borda count (Colombo et al., 2022), which is defined as an average of the obtained clusters. Note that a first cluster will not exist if no model significantly outperforms all others on a majority of languages.

5 Main Results

Table 2 presents the average results for EN→XX and XX→EN translation directions. TOWERCHAT with QAD outperforms all baselines across all settings on automatic metrics and human evaluation.

TOWERCHAT leverages context more adeptly than TOWERINSTRUCT. Our primary goal in this task was to create a model that can effectively leverage context to generate high-quality translations with LLMs. As shown in Table 2, TOWERCHAT consistently outperforms TOWERINSTRUCT across all settings, language pairs and evaluation metrics. Furthermore, TOWERCHAT shows an average improvement of 4 CHRF points for en-xx when using context (*w/ context*), compared to a context-agnostic prompt (*w/o context*).[5] This trend also holds when evaluating translation quality using the primary metric, COMET, for 8 out of 10 language

[3] Note that **{target_seg}** is unavailable during inference and the model is asked to perform prompt completion.

[4] For segment-level metrics, such as COMET, we perform significance testing at the segment level. For CHRF, we substitute segment-level scores with corpus-level scores calculated over 100 random samples, each with a size equal to 50% of the total number of segments.

[5] The improvement is statistically significant with a 92.1% accuracy (Kocmi et al., 2024).

Table 5: COMET scores for TOWERINSTRUCT and TOWERCHAT on the WMT23 test set.

pairs as shown in Table 3. We attribute this to the inclusion of context-augmented Chat MT instruction dataset in TOWERCHAT's training, highlighting the effectiveness of in-domain fine-tuning.

QAD results in consistent gains over greedy decoding, surpassing 70B models. The highest-quality translations according to all metrics considered are obtained after performing QAD with COMET or CONTEXTCOMET on top of TOWERCHAT-7B, even outperforming the much larger TOWER-V2-70B, which uses few-shot examples. Moreover, QAD closes the gap in quality as measured by METRICX and CONTEXT-QE between TOWERCHAT-7B (greedy) and TOWER-V2-70B models, demonstrating that advanced inference techniques can effectively make smaller models competitive against much larger ones.

Context-aware QAD improves MUDA F1 over Context-agnostic QAD. While all neural and lexical metrics indicate that QAD with CONTEXTCOMET and COMET perform comparably, these metrics may not fully capture nuanced differences in translation quality. To address this, we evaluate MUDA F1 accuracy scores for a subset of models in Table 4. The results show that QAD with CONTEXTCOMET consistently outperforms QAD with COMET across all dimensions, except pronouns. Our qualitative analysis suggests that the pronoun accuracy might have been lower due to potential paraphrasing. Coupled with the previous results, these findings strongly motivate further exploration of QAD with context-aware metrics.

Finetuning on Chat data does not degrade general translation capabilities. To ensure that adding chat MT dataset in the mix does not impact the generic translation capabilities of LLMs, we report COMET on the standard WMT23 benchmark (Kocmi et al., 2023) averaged across EN→XX and XX→EN directions for TOWERINSTRUCT and TOWERCHAT in Table 5. TOWERCHAT suffers only minor degradation (-0.3) relative to TOWERINSTRUCT, validating the viability and effectiveness of our finetuning approach.

Table 6: Human Evaluation results on the official test set. T and C represent aggregated turn-level and conversation-level direct-assessment scores respectively.

6 Human Evaluation

TOWERCHAT is the winner of the WMT24 Chat MT Shared Task across all language pairs according to human evaluation. Table 6 shows that our model significantly surpasses the baseline on both turn-level (T) and conversation-level (C) evaluations in all language directions. Notably, it reaches an average direct assessment score of $>$ 90 at both turn-level and conversation-level for EN-FR, EN-NL, and EN-KO translation pairs. The victory on conversation-level evaluation outlines the superior capacity of TOWERCHAT to incorporate bilingual conversational context when translating.

That said, there is a visible drop between turn-level and conversation-level scores, leaving room for improvement on how well TOWERCHAT leverages context for translation. In future work, we wish to explore thoroughly under what circumstances context is useful to produce a better translation, and to what extent TOWERCHAT can leverage it appropriately.

7 Conclusion

In this work, we present two strategies for improving context usage for bilingual chat translation using LLMs. Our training strategy involves finetuning LLMs on context-augmented instructions resulting in higher-quality translations during inference when using bilingual context. Second, we propose a novel quality-aware decoding strategy with a context-aware metric (CONTEXTCOMET) that significantly improves translation quality across the board, surpassing a state-of-the-art 70B translation model and all other baselines. Our findings show successful usage of contextual information as measured by MUDA in resolving ambiguities for the highly contextual domain of chat translation. Crucially, our system finished first in human evaluation across all the shared task's language pairs.

Abstract

This paper describes SheffieldGATE's submission to WMT 2024 Chat Shared Translation Task. We participate in three language pairs: English-German, English-Dutch, and English-Portuguese (Brazil). In this work, we introduce a context-aware sliding window decoding method to track dependencies between chat messages. We fine-tune a large pre-trained language model based on the training data provided by the shared task Our experiments (i) compare the model performance between multilingual and bilingual fine-tuning and (ii) assess the impact of different window sizes. Our experimental results demonstrate that utilising contextual information yields superior performance in document-level translation compared to translating documents as isolated text segments, and that models fine-tuned with multilingual data perform better than those fine-tuned with bilingual data.

1 Introduction

Translating chat text is an important and challenging application of machine translation technology (Farajian et al., 2020; Farinha et al., 2022). The purpose of this task is to build a translation model that addresses the challenges of multilingual customer support for multinational companies. In informal conversations, people often use abbreviations and incomplete sentences and may include spelling errors, leading to significant noise in the dialogue text (Varnhagen et al., 2010). These factors complicate the translation of such texts, a challenge that traditional machine translation methods struggle to address (Almansor et al., 2020).

Recently, large language models (LLMs) have gradually taken over the mainstream in the field of natural language processing (Ouyang et al., 2022). LLMs have demonstrated impressive capabilities in a wide range of domains such as computational social science (Mu et al., 2024), question answering (Tan et al., 2023), and machine translation(Wang et al., 2023). Their ability to be well robust to noise in the input data provides new ideas to address the challenges of chat translation.

At the sentence level, Neural Machine Translation (NMT), represented by pre-trained large language models, is approaching the quality of professional human translations or even exceeding that of crowd-sourced non-professional translations in a few resource-rich languages (Hassan et al., 2018). For document-level translation, NMT systems still have certain errors that are difficult to detect in sentence-level translation (Läubli et al., 2018). Such as language ambiguity, which frequently results in numerous translation errors. Depending on the context, a single word or phrase can have multiple meanings (Abeysiriwardana and Sumanathilaka, 2024). Without the use of contextual information, problems including co-reference (Guillou and Hardmeier, 2016), lexical cohesion (Carpuat, 2009), or lexical disambiguation (Rios Gonzales et al., 2017) will be difficult to address (Jin et al., 2023).

In this work, we focus on modelling strategies based on contextual information. Our submission is based on an existing pre-trained model and fine-tuned using multilingual chat data, behaviour without incorporating additional contextual information during the fine-tuning process. We implemented context-aware sliding windows for the inference stage to perform translation tasks. We also conducted the following experiments (i) to compare the performance difference between using multilingual data and bilingual data in the fine-tuning process and (ii) the impact of window size, or the extent of contextual information, on the quality of translation.

With this study, we aim to shed light on the great potential of large language models for machine translation tasks and their ability to utilise contextual information for document-level translation and learn from migrating across linguistic data.

Table 1: Number of source segments in the released dataset.

2 Data

The dataset for this task comprises authentic bilingual customer support conversations across five language pairs: English-German, English-French, English-Korean, English-Dutch, and English-Portuguese (Brazil). Table 1 displays the number of training, validation and test samples for each language pair in the dataset.

2.1 Dataset Characteristics

The chat content flows freely without strict format constraints, authentically reflecting the characteristics of real conversations. This natural language use includes incomplete sentences, interjections, and context-dependent responses, which, while representative of genuine dialogue, increases the complexity of processing and translation.

3 System Description

3.1 Context-Aware Sliding Window

To effectively utilise contextual information, we use a context-aware sliding window mechanism. This approach allows model to consider context sentences when translating each individual message, thereby enhancing the overall coherence and accuracy of the translation. In addition, we improve translation efficiency by reusing the Key-Value (KV) cache. KV caching is a crucial technique in transformer models, involves storing and reusing previously computed Key and Value matrices in the self-attention mechanism. This method significantly enhances inference speed by eliminating redundant calculations, particularly beneficial for long sequences or auto-regressive generation tasks such as machine translation. It enables the model to efficiently leverage information from the source language when generating the target sequence, substantially reducing computational overhead, especially for longer texts.

Structure of the Sliding Window Our context-aware sliding window comprises four key components:

- Task Description: Provides the model with clear instructions about the translation task.
- Source language tag: Identifies the beginning of the original text.
- Original Text: Contains the message to be translated along with its context.
- Target Language Label: Indicates the end of the original text and directs the model to give the translation.

Figure 1 illustrates the structure of the Context-Aware Sliding Window. This system comprises a task description and a window containing a sequence of source sentences, which together function as input to the model. The model generates new translations based on the contextual information available within the window. After each translation is produced, it is inserted into the list of translated sentences, and the window shifts to incorporate new source sentences. If the number of sentences in the source text window exceeds a predefined limit, the earliest sentence in the window is removed to maintain the set window size. This sliding mechanism ensures that the model consistently has track dependencies throughout the translation process.

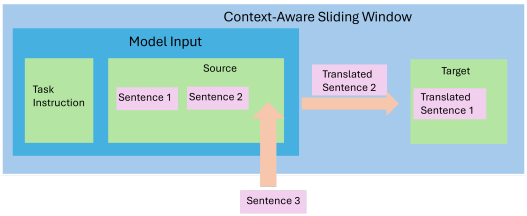

Figure 1: Context-Aware Sliding Window

Prompt We used the following prompt for translation:
You are a translation specialist serving multinational companies. Your task is to translate the given text from [source language] to [target language]. Provide the translation result in [target language] directly without including any additional content.

Workflow The operation of our context-aware sliding window can be described as follows:

- Initialisation: The sliding window starts empty and gradually fills with sentences from the chat log up to the predefined window size.

- Generation: The language model generates the translation for the most recent sentence, considering both the original sentences in the window and their existing translations.

- Window Shift: After generating a translation, the window shifts by one position. It incorporates the next sentence from the chat log and removes the earliest one and its corresponding translation if the window is full. If the translation direction of the next sentence changes , the windows storing the original text and the translated text are swapped. This approach allows for seamless handling of bidirectional translations within the same conversation, maintaining context in both languages.

- Iteration: Steps 2 and 3 are repeated until all sentences in the chat log have been processed.

The workflow of the context-aware sliding window is illustrated in pseudocode in Algorithm 1.

Algorithm 1 Context-Aware Sliding Window Translation Algorithm with Bidirectional Support

```
Initialise:
    source-window ← [ ]
    target-window ← [ ]
    window-size ← predefined window size
    translation-result ← [ ]
    current-direction ← initial translation direction
for each sentence in input text do
    if sentence-direction $\neq$ current-direction then
        source-window, target-window ← target-window, source-window
        current-direction ← sentence-direction
    end if
    if len(source-window) $<$ window-size then
        source-window.append(sentence)
        translation ← Generate(source-window, target-window)
        target-window.append(translation)
        translation-result.append(translation)
    else
        source-window.pop(0)
        target-window.pop(0)
        source-window.append(sentence)
        translation ← Generate(source-window, target-window)
        target-window.append(translation)
        translation-result.append(translation)
    end if
end for
Output translation-result
```

Advantages This approach offers several benefits:

- Improved Coherence: By considering the surrounding context, the model can maintain better consistency in tone, style, and terminology across the translation.

- Enhanced Accuracy: Contextual information helps resolve ambiguities and choose more appropriate translations for words or phrases with multiple meanings.

4 Experiments

In this section, we describe the experiments conducted to select the fine-tuning strategy and determine the optimal window size for our system. The hyperparameters used in this experiment are listed in Table 2. All experiments were executed on a single Nvidia A100 GPU equipped with 40GB of memory.

Three evaluation metrics are used in this experiment, aligned with the automatic evaluation metrics of the shared task, they are:

- BLEU (Bilingual Evaluation Understudy) (Papineni et al., 2002): Measures translation quality based on n-gram overlap between the candidate and reference translations. BLEU primarily assesses fluency and adequacy at the phrase level. It is widely used but may not always capture deeper semantic nuances.

- chrF (Character n-gram F-score) (Popović, 2015): Evaluates translation quality at the character level. It is particularly effective for capturing morphological accuracy and subtle differences in word forms. chrF is sensitive to grammatical correctness and precise word choice.

- COMET (Cross-lingual Optimised Metric for Evaluation of Translation) (Rei et al., 2020): A more recent metric that focuses on seman-

Hyperparameter	Value
LoRA rank (r)	8
LoRA alpha	16
LoRA dropout	0.05
Learning rate	2.5e-5
Weight decay	0.001
Batch size	8
Training epochs	10
Warmup ratio	0.3
Max gradient norm	0.3
LR scheduler	Linear

Table 2: Fine-tuning Hyperparameters

tic similarity between the source, translation, and reference. COMET uses contextual embedding to evaluate meaning preservation and overall translation quality, aiming to correlate better with human judgements.

4.1 Multilingual and bilingual Fine-tuning

Given the computational resources and time constraints, we choose the LLaMA3-8B instruct model (LLaMA) (Dubey et al., 2024) as our base model. We fine-tune LLaMA using Low-Rank Adaptation (LoRA) (Hu et al., 2022) with training and validation data provided by the shared task. We employed two distinct fine-tuning strategies, i.e., (i) multilingual fine-tuning and (ii) bilingual fine-tuning.

For the multilingual fine-tuning, we feed five language pairs simultaneously: English <-> German, English <-> French, English <-> Brazilian Portuguese, English <-> Korean, and English <-> Dutch. This strategy allows the model to learn from multiple languages concurrently and potentially leverage cross-lingual information.

In contrast, our bilingual strategy involved fine-tuning separate models for each language pair, using solely the training and validation data specific to that pair. This approach enables more focused adaptation to each language pair.

The motivation for employing these two strategies was to explore the cross-linguistic learning and transfer capabilities of large language models (Lample and Conneau, 2019). By comparing these approaches, we aim to investigate whether the model can extract universally applicable translation patterns and linguistic features from multiple language pairs, thereby potentially improving its performance on new language pairs.

The experiment results are shown in Table 3. The multilingual fine-tuned models outperform bilingual fine-tuned models. This may be because multilingual dataset provide more samples than each bilingual datasets, offering a broader and more diverse set of data, which helps prevent the model from overfitting. Also, the model can learn translation patterns through transfer learning from other languages. Hence, in our final submission, the model was fine-tuned using the multilingual dataset.

4.2 Impact of Window Size

We also investigated the effect of different window sizes on the translation quality. In this work, the window size determines the amount of context available to the model during the translation process.

To that end, we conducted experiments with window sizes ranging from 1 to 3 sentences. For each window size, we translated five language pairs from the validation set provided by shared task and evaluated the results using automated metrics. Table 4 presents the detailed results for chrF, BLEU, and COMET scores across different window sizes and language pairs.

The window size used in our submission is 3. Our findings indicate that the translation quality generally improves as the window size increases, but the extent and nature of improvement varies across translation directions and metrics. We observe that the COMET metric tends to favour larger window sizes more consistently than chrF or BLEU.

COMET scores show improvement or maintain high performance with larger windows in 5 out of 6 translation directions (de-en, en-de, pt-br-en, nl-en, en-nl).

For en-pt-br, small windows have the best performance across all metrics. This unique behavior might be attributed to several factors. Firstly, the structural similarities between English and Brazilian Portuguese allow for effective translation with minimal context.(Angeli and Mota, 2023) The relatively simple morphology of English compared to Portuguese's more complex system might also contribute to this phenomenon. Additionally, the direct lexical correspondence between many English and Portuguese words could lead to high accuracy in word-to-word translations, which is particularly well-captured by chrF and BLEU metrics.

In contrast, chrF and BLEU metrics often peak

Table 4: Translation Quality Metrics for Different Window Sizes. The highest scores for each metric are marked in bold.

at window size 2 or even size 1 for some translation directions. For example, en-pt-br achieves its highest chrF and BLEU scores with window size 1. The en-nl pair is a notable exception, showing consistent improvement across all metrics as the window size increases.

This pattern suggests that the COMET metric may be more sensitive to the broader context provided by larger window sizes, while chrF and BLEU might prioritise local fluency or accuracy that can sometimes be captured effectively with smaller windows.

5 Conclusion

In this paper, we compared the performance of fine-tuning using multilingual data and bilingual data. Additionally, we conducted an ablation study by evaluating the translation quality with different window sizes. Our research indicates that fine-tuning models on multilingual data results in superior translation capabilities compared to fine-tuning on a single language. This approach could improve translation quality for low-resource languages. Furthermore, we also found that increasing the contextual information provided to the model can enhance its semantic performance in translation. Our future work will focus on:

- **Named Entity Handling** We plan to integrate a named entity recognition system and leverage external knowledge resources, such as Wikipedia, to ensure accurate translations of named entities.
- **Model Fine-tuning Comparison** We also aim to conduct a comparative analysis between fine-tuning the foundation model and the instruction-tuned model, exploring the trade-offs between general and task-specific performance.

Abstract

Translating conversational text, particularly in customer support contexts, presents unique challenges due to its informal and unstructured nature. We propose a context-aware LLM translation system that leverages conversation summarization and dialogue history to enhance translation quality for the English-Korean language pair. Our approach incorporates the two most recent dialogues as raw data and a summary of earlier conversations to manage context length effectively. We demonstrate that this method significantly improves translation accuracy, maintaining coherence and consistency across conversations. This system offers a practical solution for customer support translation tasks, addressing the complexities of conversational text.

1 Introduction

The WMT 2024 Chat Shared Task addresses the unique challenges of translating conversational text, with a particular focus on customer support chats. Unlike formal or structured texts, conversations are typically spontaneous and casual, presenting several key challenges. First, the system must comprehend the dialogue's flow while accurately translating content from one language to another. Second, it is crucial to maintain logical continuity throughout entire conversations, preserving the context and intent of each exchange. Third, the task requires effectively handling the inherent noise and colloquial nature of chat data.

To tackle these challenges, we developed a context-aware LLM translation system that leverages both dialogue history and conversation summarization. Our approach is designed to maintain coherence and accuracy in translation by referencing two key elements: (1)'History' field: The two most recent dialogues of the target conversation, provided as raw data. (2)'History Summary' field: A concise summary (maximum 200 characters) of earlier conversations, excluding the two most recent dialogues.

We utilize both history and history summary in our approach for the following reasons. Dialogues often require multi-turn information for accurate understanding, as context within a single turn can be insufficient or misleading. Furthermore, while referencing all previous conversations would be ideal, it is often prohibited by the context length limitations of LLMs. Our method addresses these challenges by using recent parts of the conversation verbatim and summarizing earlier parts of the dialogue, effectively reducing context length while maintaining overall contextual information.

Our approach is informed by previous research demonstrating the effectiveness of context-aware models. Current study has shown that stimulating LLMs to memorize small dialogue contexts first and then recursively produce new memory using previous memory helps the chatbot generate highly consistent response (Wang et al., 2023). The History-Aware Hierarchical Transformer (Zhang et al., 2022) also used historical information to improve the understanding of the current conversation context. The TiM (Think-in-Memory) framework (Liu et al., 2023), a LLM agent also recalls relevant thoughts from memory before generating response, and then integrates both historical and new thoughts to update the memory. By incorporating these insights, our system aims to produce translations that are not only accurate in language conversion but also maintain the coherent tone and appropriate word selection crucial in conversational contexts.

The Gemma-2-27B-it model (Team, 2024) is used as the foundation for our translation system, specifically focusing on the English-Korean language pair. Our experiments demonstrated that incorporating recent dialogues and previous dialogue summaries significantly improved translation performance compared to methods that did not utilize

Proceedings of the Ninth Conference on Machine Translation, pages 1011–1015
November 15-16, 2024 ©2024 Association for Computational Linguistics

this contextual information. We further refined our system by implementing more detailed instructions, which yielded additional improvements in translation accuracy. Furthermore, we used the GPT-4o mini (OpenAI, 2024) model for efficient conversation summarization. These combined methods resulted in substantial enhancements to overall translation quality, clearly demonstrating the effectiveness of our approach in boosting translation accuracy.

2 Methodology

2.1 Data Preparation

Among the five language pairs provided by the WMT 2024 Chat Shared Task, we selected the en-ko dataset for our experiments. The dataset provided by WMT consists of 16,122 training instances, 1,935 validation instances, and 1,982 test instances.

Example 1

```
“source_language”: “ko”,
“target_language”: “en”,
“source”: “비밀번호 재설정 메일이 도착하지 않습니다.”,
“reference”: “I don’t receive a password reset email.”,
“doc_id”: “64619c16ab8523e90010b544”,
“client_id”: “0015800001EMz0vAAD”,
“sender”: “customer”,
“history”: “As I understand you are unable to login to your account as it asks you to reset the password and you are not getting reset password email.”,
“제가 알기로는 비밀번호를 재설정하라는 메시지가 표시된 후 비밀번호 이메일을 재설정하지 않기 때문에 계정에 로그인할 수 없으십니다.”
“Am I correct?”,
“맞습니까?”

“Instruction”: “You are tasked with translating the following sentences from Korean to English. These sentences are part of conversations between a customer and a customer service agent.\nWhen translating, keep the following instructions in mind:\n- Provide only the translation of the ‘source’ text.\n- Keep the translated text in a single line.\n- The context involves a game user contacting a game company’s customer service center online. Since the inquiries are typed, there may be many typos. Please translate with this in mind.\n- Consider the summary of the previous conversation, referred to as ‘Dialogue Context’, if it is given.\n- Refer to the context from the previous conversation if it is provided.\n- Ensure your translations maintain the intended meaning and tone of the original dialogue.\nDialogue Context: The customer, NAME-N, contacted PRS-ORG for help signing in and reported not receiving a password reset email.”,
“History_summary”: “Dialogue Context: The customer, NAME-N, contacted PRS-ORG for help signing in and reported not receiving a password reset email.”,
“System”: “You are a professional translator fluent in both Korean and English.”
```

During the data preparation process, we utilized several fields from the provided dataset and introduced two new ones to enhance context awareness. The original fields are source_language, target_language, source, reference, and doc_id. The newly inserted fields are history and history_summary. Example 1 shows the final preprocessed dataset used for model training. The source_language and target_language fields specify the language pair to be translated, source contains the text to be translated, reference provides the correct translation, and doc_id is used to uniquely identify each conversation session. The history and history_summary refer to the conversation context as described in the following sections.

2.1.1 History

The history field includes the raw data from the two previous dialogues of the targeted dialogue that needs to be translated. This information enables the model to capture the conversation's flow and maintain coherence in the generated translation.

2.1.2 History Summary

The history_summary field contains a concise summary of earlier conversations, excluding the two most recent dialogues. It helps to understand the overall context and background of the current conversation. For summary generation, we used the GPT-4o mini model with a prompt that limits the summary to a maximum of 200 characters. This approach allows the model to focus on the essential part of the previous content without being overwhelmed by excessive details.

2.1.3 System Prompt and Translation Instructions

To ensure consistency in model training and translation tasks, we developed a prompt strategy. We defined a base prompt that positioned the model as a professional translator fluent in both Korean and

English. We provided detailed guidelines for instruction, making the model focus on maintaining the context and tone of customer service dialogues, accounting for possible typos, and incorporating provided conversation summaries. To effectively guide the model, we supplied detailed prompts and instructions separately. The content of the system prompt and translation instructions can be found in the 'system' and 'instruction' fields in Example 1. This approach enhances translation quality by providing clear, context-specific guidance to the model.

2.2 Context-Aware LLM Translation System Using Conversation Summarization and Dialogue History

After data preparation, we used the provided Chat Template for Gemma's Instruct-Tuning to structure our data and fine-tuned the Gemma-2-27B-it model for translating customer support dialogues in Korean and English. We used DeepSpeed library to quantize the model and applied LoRA (Low-Rank Adaptation) for model compression. The key parameters of our training setup were as follows: per device train batch size of 4, gradient accumulation steps of 8, learning rate of 1.0e-4, 5 training epochs, cosine learning rate scheduler, warmup ratio of 0.1 and bfloat16 precision enabled. The GPU we used was NVIDIA H100 and the training process took about one hour to complete.

While optimizing our model's performance, we also addressed the unique challenges of dialogue translation. Context plays a pivotal role, significantly influencing the accuracy of interpreting and translating each turn. However, this importance presents a dual challenge. On one hand, preserving the conversation's history is crucial for coherent translations. On the other hand, as dialogues extend, managing this context becomes increasingly complex. Including all previous turns becomes impractical and can degrade the quality of subsequent translations.

To address these challenges, we implemented the following strategy:

- **Recent Dialogues (history)**: We utilized the history field to include the two most recent dialogue in their raw form. This preserves the immediate context necessary for accurate and coherent translations.

- **Dialogue Context (history_summary)**: For earlier parts, we provided a condensed summary of essential points, generated prior to inference. This helps the model grasp the broader context without being overwhelmed by excessive information (Bae et al., 2022).

This approach balances detailed immediate context with summarized background, allowing the model to capture both current dynamics and overall dialogue context.

Our prompt structure consists of three key components: a system role-play definition, a task instruction, and the sentence to be translated. This setup was critical for guiding the model's performance in customer support dialogue contexts. By structuring the context using natural language and leveraging the model's instruction-tuned capabilities, we aimed to enhance its ability to generate translations that are not only accurate but also contextually appropriate. This method allowed us to capture the natural flow and nuances of conversations more effectively.

3 Experimental Results and Application

The performance of our translation model was evaluated through both human assessment and various automated metrics. Table 1 shows translation performance scores by human evaluation. The 'sentence' columns indicate the evaluation scores for translation quality at the individual sentence level, while the 'Document' column reflects how well the translation maintains consistency and context across a full conversation. Our DeepText-Lab team received notably high evaluations, with scores of 91.35 for translating sentences from English to Korean and 95.71 for translating sentences from Korean to English. Our team also received a score of 90.04 at the document level. These results demonstrate our system's strong performance at both sentence and document levels.

Besides human evaluation, the performance on the test dataset was also evaluated using several automated metrics, including COMET, chrF, BLEU, and Contextual-Comet-QE. The results are summarized in Table 2. We achieved strong results across all metrics. The COMET score of 93.5 indicates high translation quality, while the chrF score of 66.0, BLEU score of 47.6, and Contextual-Comet-QE score of 0.161 demonstrate solid performance.

Beyond assessing overall performance, we explored how the inclusion of conversation history, history summaries, and detailed prompts influenced our model's translation quality. Table 3 illustrates

Team	Sentence (en→ko)	Sentence (ko→en)	Document
unbabel+it	93.39	96.31	93.21
DeepText_Lab	91.35	95.71	90.04

baseline	79.13	90.47	85.63

Table 1: Human Evaluation of Sentence and Document-Level Translation (Test Dataset Results)

Team	COMET	chrF	BLEU	C-COMET-QE
unbabel+it	95.0	70.2	51.5	0.214
DeepText_Lab	93.5	66.0	47.6	0.161
DCUGenNLP	92.3	59.8	39.4	0.158
baseline	87.6	48.9	26.0	0.041

Table 2: Automatic Evaluation Using Multiple Metrics (Test Dataset Results)

Configuration	Direction	COMET	chrF	BLEU	C-COMET-QE
w/ recent dialogues and dialogue context	en→ko	0.916	51.52	32.97	0.138
	ko→en	0.893	61.57	40.73	-
w/o recent dialogues and dialogue context	en→ko	0.910	48.96	29.82	0.126
	ko→en	0.889	59.65	38.86	-
w/o prompt modification	en→ko	0.911	49.96	31.30	0.135
	ko→en	0.894	61.15	40.64	-

Table 3: Impact of Contextual Elements on Translation Performance (Validation Dataset Results)

the significant impact of these elements on various performance metrics, especially chrF and BLEU scores. The absence of these contextual elements led to a significant decrease in translation quality, emphasizing the importance of context preservation and precise guidance in producing high-quality translations.

In addition to the above evaluations, we also assessed our model's performance in terms of formality and lexical cohesion using the MuDA (Fernandes et al., 2023) framework. The results of these assessments are presented in Table 4 and Table 5. For formality, the model achieved a precision score of 73.0, and a recall of 35.1, resulting in an overall F1-Score of 47.4. For lexical cohesion, the model demonstrated strong performance with a precision of 70.5, and a recall of 73.8, leading to an F1-Score of 72.1.

Team	Precision	Recall	F1
unbabel+it	69.4	44.2	54.0
DeepText_Lab	73.0	35.1	47.4
DCUGenNLP	25.5	18.2	21.2

DCUGenNLP	73.5	68.3	70.8
baseline	66.1	65.1	65.6

Table 5: Lexical Cohesion Results

4 Conclusion

We participated in the WMT English-Korean Chat Translation Task using the Gemma-2-27B-it model enhanced with dialogue history for context-aware translations. We effectively reduced the context length by summarizing earlier conversations and enhanced the model's translation performance by including the history of the two most recent dialogues and the summary of the previous dialogues, excluding the most recent two.

As a result, the translation performance has significantly improved, though there is still room for enhancement. Despite our team's high score, certain issues were identified in the generated translations. For instance, the Gemma 2 model occasionally produces translations in unexpected languages like Turkish, French, and Polish. This stems from the model's multilingual pretraining and presents an area for further exploration in future work.

Abstract

For this shared task, we have used several machine translation engines to produce translations (en ⇔ fr) by fine-tuning a dialog-oriented NMT engine and having NMT baseline translations post-edited through prompt engineering. Our objectives are to assess the effectiveness of a fine-tuning strategy with a robust NMT model, to advance towards a comprehensive pipeline that covers the entire translation process (from fine-tuning and machine translation to automatic post-editing (APE)), and to evaluate the strengths and weaknesses of NMT systems.

1 Introduction

We had three research objectives in carrying out our experiments. The first objective was to assess the feasibility of fine-tuning an in-domain neural machine translation (NMT) baseline model using minimal unlabelled data. The second objective involved utilising large language models (LLMs) and prompt engineering techniques to post-edit translations within the same domain. The third objective was to examine the linguistic features of various models' erroneous translations, particularly in bilingual customer service conversations. For example, in their description of the data of the first edition of the Chat Task, (Farajian et al., 2020) noted the excessive use of pronouns in the dataset.

The remaining sections of the paper are organised as follows: section 2 mentions previous research, section 3 outlines our methods and describes our NMT systems, section 4 delves into our results[1], section 5 provides a discussion of these results, and section 6 outlines future work.

2 Previous Research

2.1 Fine-tuning Strategies for NMT and Domain Adaptation

Fine-tuning a pre-trained LLM baseline model with low-resource NMT has been the subject of previous MT empirical studies (Galiano-Jiménez et al., 2023) and the back-translation approach is often used to improve the accuracy of models (Hoang et al., 2018). Open source toolkits are available for building pipelines, such as `fairseq`[2]. However, some models require a higher level of expertise in pipeline construction and rely on cutting-edge hardware for optimal performance[3]. In terms of domain adaptation, filtering back-translations is considered one of the most frugal and efficient techniques (Kumari et al., 2021). In addition, more and more domain adaptations rely on prompt engineering.

Based on what was reported in the findings of the Chat Task 2022 (Farinha et al., 2022), MT systems handle source-related issues more or less similarly. Analysing the distribution of error types presented in the task indicates that "mistranslation" is the most frequent error across all systems. Furthermore, prompt-based machine translation has shown a significant impact in medical domains. For example, Ramachandran et al. (2023) demonstrated that using GPT-4 for extracting Social Determinants of Health (SDOH) from electronic health records achieved a 0.652 F1 score, which is comparable to the 7th best system among traditional supervised approaches.

[1] https://github.com/lichaozhu/team_MULTITAN-GML_WMT24_Chat_Shared_Task

[2] https://github.com/facebookresearch/fairseq

[3] For example, NLLB-200-3.3.B requires Hydra (Yadan, 2019) and very high GPU resources. We were unable to load and train the model using a dual A100 40GB setup due to persistent memory overflow problems.

Proceedings of the Ninth Conference on Machine Translation, pages 1016–1022
November 15-16, 2024 ©2024 Association for Computational Linguistics

2.2 Automatic Post-editing of MT and Prompt Engineering

Automatic post-editing (APE) systems are designed to enhance the quality of machine translation (MT) by *leveraging* data (Raunak et al., 2023; Gao et al., 2023). These systems work by taking both the source text and the initial MT output as inputs, then applying learned post-editing patterns to refine the translation, and the final output is an improved translation (Chollampatt et al., 2020; Sharma et al., 2021; Bhattacharyya et al., 2023). To further improve performance, APE systems often employ domain adaptation and fine-tuning on in-domain data (Moslem et al., 2023). Based on previous studies, prompting for machine translation still suffers from issues such as copying, mistranslation of entities, and hallucinations (Zhang et al., 2023). Furthermore, previous comprehensive evaluations of GPT models for machine translation across various language pairs indicate that GPT models perform competitively for high-resource languages, but face limitations with low-resource languages (Hendy et al., 2023; Jiao et al., 2023; Peng et al., 2023).

3 Methods and Tools

3.1 Fine-tuning via NMT Engine

For our primary submission, we have used a neural machine translation (NMT) engine, its in-domain baseline model, and in-domain training data to fine-tune the model. To create our fine-tuning dataset, we used the Chat Task 2022's valid and test sets (en ⇔ fr) as well as the Chat Task 2024's `train` and `valid` sets and compiled 13,622 aligned segments (122,905 words in English and 127,335 words in French). We used this dataset to fine-tune the *Dialog* in-domain model on the training server Model Studio Lite of Systran®[4] since we did not manage to fine-tune Facebook's NLLB-200-3.3B model, which was our first choice.

3.2 Translation and Post-editing with LLMs

For our two contrastive submissions, we have used NLLB-200-3.3B (NLLB Team et al.) baseline model and deep-translator[5] which was used by ChatGPT (GPT-4-turbo) to generate translations. All translations are then post-edited using prompt engineering via ChatGPT-4o.

4 Results

4.1 Qualitative Assessment

We have then compared three models in Systran Model Studio Lite to verify whether the in-domain Dialog model is adapted or not to the custom service conversation domain, by using the test set and reference translations published by the organisers of the Chat Task 2024. Table 1 compares the performance of three different models for language translation tasks: a fine-tuned model, an in-domain baseline model, and a generic baseline model. The performance is measured for two translation directions: English to French (en → fr) and French to English (fr → en).

	Fine-tuned model	In-domain baseline model	Generic baseline model
en → fr	**57.19**	48.05	50.47
fr → en	**55.02**	48.28	48.19

Table 1: Comparison of generic baseline, in-domain baseline and fine-tuned models of Systran®

The fine-tuned model shows a significant improvement over both baseline models in both translation directions. This highlights the effectiveness of fine-tuning in enhancing model performance for specific tasks. The in-domain baseline model performs slightly worse than the generic baseline model for en → fr but slightly better for fr → en. This suggests that the in-domain data may not always provide a consistent advantage over generic data without further fine-tuning. The results indicate the importance of model fine-tuning in achieving superior translation quality and accuracy, especially in specialised domains. They seem to support our approach and the effectiveness of our fine-tuning dataset.

To compare translations, we used quantitative methods such as *vocabulary growth*, *characteristic elements computation*, and *correspondence analysis* (Lebart et al., 1997; Fleury and Zimina, 2014; Zimina-Poirot et al., 2020) implemented in *iTrameur*[6] and *Voyant Tools*[7]. In Figure 1, generated with *iTrameur*, the vocabulary growth curves of three predictions, fine-tuned Systran (*systran_ft*), NLLB-200-3.3B (*nllb*), and Deep translator (*deep-translator*) can be compared

[6] https://itrameur.clillac-arp.univ-paris-diderot.fr

[7] https://voyant-tools.org

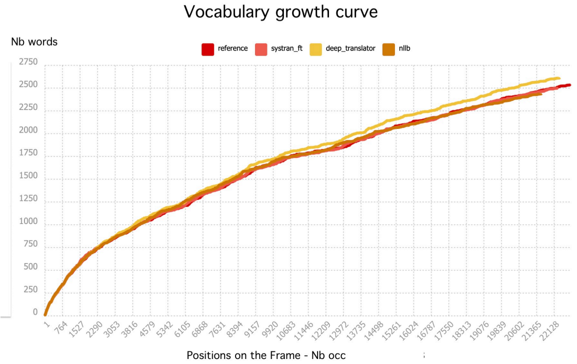

Figure 1: Vocabulary growth curve of reference translation and predictions of fine-tuned Systran, NLLB-200-3.3B and Deep translator.

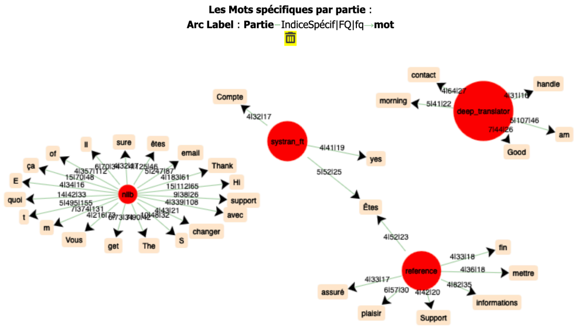

Figure 2: *Characteristic elements* computation for comparison of specific lexical features of reference translation and predictions of fine-tuned Systran (`systran_ft`), NLLB-200-3.3B (`nllb`) and Deep translator (`deep_translator`).

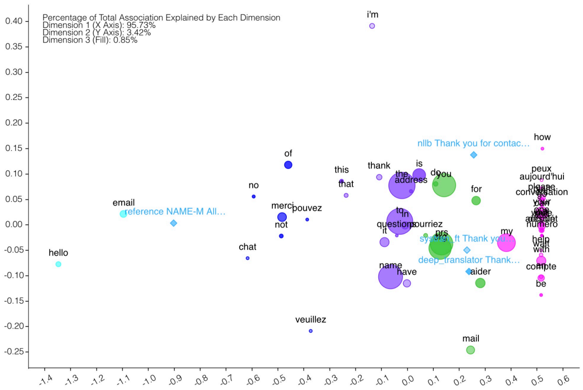

Figure 3: Correspondence analysis of the *reference* translation and tree predictions: fine-tuned Systran (*systran_ft*), NLLB-200-3.3B (*nllb*), and Deep translator *deep-translator.*

with the (*reference*) translation. While the reference translation is the longest (Nb occurrences: 22,834), it is followed by fine-tuned Systran (Nb occurrences: 22,291), which is the closest to the reference in terms of vocabulary growth.

In Figure 2 generated with *iTrameur*, we used *characteristic elements* computation to compare three predictions with the reference translation. The results show that many translation errors (including the occurrences of *E, S, t, Thank*, etc.) are over-represented in NLLB-200-3.3B prediction, while the reference translation and fine-tuned Systran prediction share common lexical features, such as identical translations *Are you still there?* ⇒ *Êtes-vous toujours là ?* attested by the over-representation of *Êtes*.

In Figure 3, we used correspondence analysis in *Voyant Tools* to compare our three predictions with the reference translation. The results suggest that the reference translation was carried out with human intervention, as it is clearly opposed to three predictions (Zimina-Poirot et al. (2020) provides a discussion on this phenomenon). Although fined-tuned Systran is closer to `reference`, it is also very close to Deep translator, with NLLB-200-3.3B having a distinct profile.

Table 2 presents examples of segments that were incorrectly translated in our primary submission. It includes a comparison between the original source text, the reference translation, and our system's primary output, along with corresponding sentence-level BLEU and TER scores.

4.2 Comparisons of Primary and Contrastive Translations

In Table 3, we compared sentenceBLEU and TER scores of our *Primary* predicted by fine-tuned Systran model and two *Contrastives* predicted respectively by NLLB-200-3.3 baseline and Deep Translator. Except NLLB-200-3.3's predictions which have noticeably lower score, Deep Translator and fine-tuned Systran model have higher similar scores, which confirms our analysis of Figure 3. Deep Translator gets a slightly higher mean sentenceBLEU score, but its TER score is also higher. We noticed however that Deep Translator provided more literal or inaccurate translations of pragmatic expressions. It has translated *Bonjour* (greetings in French used in the daytime) by *Good morning*, and wrongly translated *You're welcome* by *Vous êtes les bienvenus*, which means "You are most welcome" in French.

Following the release of human evaluations, we have focused on mistranslations which scored 0 points, e.g. *I hope you have an excellent day* (source) is translated to *Merci pour l'information*

	Source	Reference	Primary	sentenceBLEU	TER
1	Is there anything else I can assist you with today?	Avez-vous besoin d'aide pour autre chose aujourd'hui ?	Y a-t-il autre chose que je puisse faire pour vous aider aujourd'hui ?	0.25	1.125
2	I am so sorry to hear that.	Je regrette sincèrement d'apprendre cela.	Je suis vraiment désolé de l'apprendre.	0.00	1.0
3	You are welcome!	Avec plaisir !	Je vous en prie.	0.00	1.33
4	You are welcome!	Ce fut un plaisir de vous parler.	C'était agréable de parler avec vous.	0.00	1.0
5	ok merci	Ok, thanks	Ok, thank you	0.00	1.0

Table 2: Mistranslated segments in our primary submission

("Thank you for the information"). The presence of these translation segments probably reflects misalignments in the fine-tuning data, as Systran Model Studio Lite does not necessarily filter out mismatching segments during the training process. These segments of the translation memory can be deemed correct as part of the normalisation process.

5 Discussion

5.1 Automatic Post-editing vs. Prompt Engineering

Pipelines for translation and post-editing using LLM engines were proposed with LLM engines (Vidal et al., 2022). The primary submission and the two contrasting submissions were subsequently post-edited by ChatGPT-4o using instructions such as:

> "Post-edit the translations in file XX according to the source texts in file YY where English sentences are translated into French, and French sentences translated into English. Send me back in one single file",

where two raw text files are given: XX is line-separated source file and YY translation file. We noticed that when we asked ChatGPT-4o to post-edit by performing domain adaptation considering our dataset as a reference or knowledge base, it did not work.

The default instructions are ineffective when used with Anthropic Claude. To detect the language accurately, it is necessary to use language columns. In this context, using tags enhances the precision of the translation (without them, the translation will default to a single language). Adhering to the token limit is crucial, as failure to do so may lead to overlooking the total number of tokens in the input. Although the tag has been modified to "tear", it still functions as the translated message.

Another hallucination occurred when the instructions themselves were translated. Figure 4 illustrates the interface and the applied prompt. The French text contained several misspellings, homophonic confusions, such as *est* versus *ait*, participle versus infinitive confusions, and various conjugation errors. We also attempted to prompt LLMs to translate from the initial CSV file, but this strategy has limitations. The LLMs may suggest Python code to extract sentences in both languages, translate only one language, or perform the task for a limited number of sentences.

Using Anthropic Claude for translation also highlights the variability in LLM translations. For example, for the sentence *Pardonnez-moi je n'ai pas du bien formuler ma question.* Three translations were obtained: 1) "I'm sorry I must not have formulated my question well." 2) "I apologize I must not have phrased my question well." 3) "I apologize, I may not have phrased my question well."

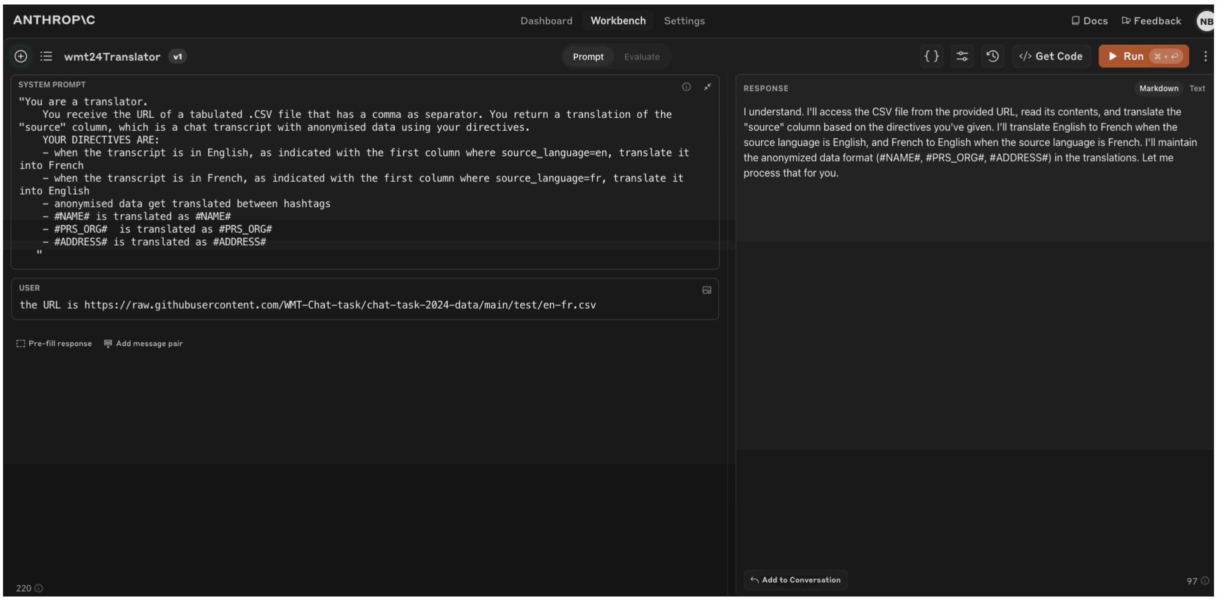
6 Further Research

6.1 Retrieval-Augmented Generation (RAG)

The database serves as a vital resource for addressing the challenges posed by rare or complex structures that may not be well-represented in translation models (Gao et al., 2024). Retrieval-augmented generation (RAG) is a technique for enhancing the accuracy and reliability of generative AI models with facts fetched from external sources. Future improvements could involve aug-

Primary (Systran® fine-tuned)		Contrastive 1 (NLLB-200-3.3)		Contrastive 2 (Deep translator)	
sentenceBLEU	TER	sentenceBLEU	TER	sentenceBLEU	TER
0.70	0.25	0.57	0.50	0.71	0.28

Table 3: Primary and Contrastives metrics comparison (arithmetic mean)



```
"You are a translator.
    You receive the URL of a tabulated .CSV file that has a comma as separator. You return a translation of the
"source" column, which is a chat transcript with anonymised data using your directives.
    YOUR DIRECTIVES ARE:
    - when the transcript is in English, as indicated with the first column where source_language=en, translate it
into French
    - when the transcript is in French, as indicated with the first column where source_language=fr, translate it
into English
    - anonymised data get translated between hashtags
    - #NAME# is translated as #NAME#
    - #PRS_ORG#  is translated as #PRS_ORG#
    - #ADDRESS# is translated as #ADDRESS#
   "
```

```
the URL is https://raw.githubusercontent.com/WMT-Chat-task/chat-task-2024-data/main/test/en-fr.csv
```

I understand. I'll access the CSV file from the provided URL, read its contents, and translate the "source" column based on the directives you've given. I'll translate English to French when the source language is English, and French to English when the source language is French. I'll maintain the anonymized data format (#NAME#, #PRS_ORG#, #ADDRESS#) in the translations. Let me process that for you.

Figure 4: Anthropic Claude's interface with a prompt based on the URL of the WMT shared task test set

menting the training set with more examples, either through synthetic data or diverse real-world instances, to enhance the model's performance to translate challenging constructions, such as dislocations.

6.2 Explainability: Probing MT Systems for Trustworthy Outputs

Controlling LLM outputs and their repeatability is crucial for trustworthy AI. We tried to probe LLMs with (a) the detection of explicit representations and (b) their potential use in the LLM outputs. Similarly, in NMT, information might be available but not used by the system, as seen in the case of gender information discrepancies (Wisniewski et al. (2022a,b).

7 Conclusion

In this paper, we outline our methods for participating in the Chat Task 2024, focusing on enhancing translation quality in dialog-oriented machine translation systems through fine-tuning and prompt engineering. Our translation data files are available on GitHub[8]. Key findings indicate that fine-tuning an in-domain NMT model is feasible with minimal unlabelled data, resulting in significant improvements in translation quality. The research also emphasises the importance of analysing linguistic features in translations to identify strengths and weaknesses of different machine translation models. The study also highlights the necessity of ensuring explainability in LLM outputs to foster trust in AI systems.

Abstract

This paper presents the SETU-ADAPT submissions to the WMT24 Chat Translation Task. Large language models (LLM) currently provides the state-of-the-art solutions in many natural language processing (NLP) problems including machine translation (MT). For the WMT24 Chat Translation Task we leveraged LLMs for their MT capabilities. In order to adapt the LLMs for a specific domain of interest, we explored different fine-tuning and prompting strategies. We also employed efficient data retrieval methods to curate the data used for fine-tuning. We carried out experiments for two language pairs: German-to-English and French-to-English. Our MT models were evaluated using three metrics: BLEU, chrF and COMET. In this paper we describes our experiments including training setups, results and findings.

1 Introduction

There have been drastic transformation in many areas of natural language processing (NLP) in recent times mainly due to the emergence of powerful LLMs. The LLM-based solutions are becoming more powerful and accurate than ever before. Notably, we have seen the unprecedented successes in many MT tasks in recent years, thanks to multilingual LLMs. In sum, the LLMs are the current state-of-the-art in MT research and development.

In our submission for the French-to-English and German-to-English Chat Translation Tasks, we built our MT systems using multilingual LLMs such as NLLB-200-600M (Team et al., 2022),[1] Llama-3-8B (Dubey et al., 2024), [2] and mBART-50 (Tang et al., 2021).[3] We fine-tuned these models using both domain-specific and synthetic back-translated data.

Due to the lack of high-quality domain parallel data, we used a data generation approach. For this, we utilised a freely available monolingual data. We retrieved domain-specific monolingual sentences of target language and translated them back to source language for creating new synthetic data (Sennrich et al., 2016). This synthetic data was then combined with the original data for fine-tuning the LLMs. This approach ensured that our MT models are better adapted to the domain, thereby improving the quality of translations. We retrieved domain-specific monolingual German sentences from OPUS ELRC-4992 Customer Support MT [4] for creating our synthetic data. We also explored the idea of in-context learning by fine-tuning LLMs with a few-shot approach. These techniques helped our MT systems better adapt in translating agent input from the source language to the target language and customer response from the target language to the source.

The rest of the paper is organised as follows. Section 2 describes our related work. Our datasets are explained in Section 3 and Section 4 tells about the models and their fine-tuning. Section 5 discusses the experimental setup describing the parameters tuned in our systems. In Section 6, we discuss our results. Finally, Section 7 presents the conclusion of our work.

2 Related Works

In this section we discuss the papers that are related to our work. Alves et al. (2022) conducted experiments on fine-tuning mBART-50 using domain-specific data retrieved through semantic search. For this, they used LaBSE (Language-Agnostic BERT Sentence Embedding) (Feng et al., 2020). They demonstrated how this approach leads them to large gains across all language pairs under evaluation. They also performed experiments using this data to further adapt the model using KNN-MT (Khandelwal et al., 2021). Note that this approach involves a nearest neighbor retrieval strategy, through which a set of relevant examples are provided at decoding time. They demonstrate how combining these approach leads to improved translation quality, over regular fine-tuning.

Liang et al. (2022a) used pre-trained LLMs and fine-tuned them to the domain of interest. For this, they first trained their models on general domain data and then fine-tuned them with chat translation training data. They used strategies such as including the multi-encoder framework, speaker tag prompt-based fine-tuning and boosted Self-COMET-based (Rei et al., 2020a) ensemble models to incorporate the potential context. They found their strategies helpful in improving the quality of translations produced by their MT models.

Yang et al. (2022) participated in the English-to-German task of the WMT22 Chat Translation Task. For this, they utilised the models previously submitted to the WMT21[5] news task (Wei et al., 2021) as their MT baseline systems. These baseline models are built upon a deep Transformer architecture (Vaswani et al., 2017). They used widely adopted optimisation strategies to improve model performance, including domain transfer, data selection, back-translation, self-training, noisy self-training, fine-tuning, and model averaging. Their results showed the effectiveness of their approached in improving the quality of translations.

Zhou et al. (2022) presented a multi-task multi-stage transitional (MMT) training framework, where they trained their model using the bilingual chat translation dataset and additional monolingual dialogues. To incorporate dialogue coherence and speaker characteristics in their model, they designed two auxiliary tasks: utterance discrimination and speaker discrimination. Their training had three stages: sentence-level pre-training on the large-scale parallel corpus, intermediate training with auxiliary tasks using additional monolingual dialogues and context-aware fine-tuning with a gradual transition. They found that the second stage served as a medium to reduce the training discrepancy between the pre-training and fine-tuning stages. They also trained their model using a gradual transition strategy, i.e. gradually transitioning from monolingual to bilingual dialogues, to make their stage transition smoother. Their results demonstrated the effectiveness of their framework, giving them better translations.

Liang et al. (2022b) contributed to the two large-scale in-domain paired bilingual dialogue corpora (28M for English-to-Chinese and English-to-German) through their framework. Their framework consisted of scheduled multi-task learning with three training stages, in which a gradient-based scheduling strategy was designed to take advantage of the auxiliary tasks for their model for higher translation quality. They conducted extensive experiments on four chat translation tasks, and their model achieved new state-of-the-art performance and outperformed the existing chat MT models by a significant margin.

3 Data Statistics

For our experiments we used the data provided by the WMT-24 Chat Translation Task[6] organisers. The dataset consists of authentic bilingual customer support conversations. This includes parallel data of interactions between an agent and a customer within the customer support domain. We detail the data description in Table 1. Note that we removed duplicates from the training data.

4 The LLMs

This section details the configurations of the LLMs that were used for our experiments.

4.1 mBART

mBART (Liu et al., 2020) is a pre-trained encoder-decoder Transformer model that was first trained on an auto-denoising task with monolingual data of twenty five languages. For adapting the mBART to the MT task, Tang et al. (2021) performed multilingual fine-tuning using data from fifty supported languages. For our experiments we used facebook/mbart-large-50-many-to-many-mmt

checkpoint. We used the following hyperparameters setup for our experiments: `batch size: 4, number of training epochs: 5, predict_with_generate: True, evaluation strategy: epoch, logging steps: 2,000, and checkpoint save steps: 500.` The remaining parameters were set to default values.

4.2 NLLB

NLLB is a cutting-edge multilingual translation model developed to support many languages, mainly low-resource languages. Initially, the model was trained using diverse, multilingual data that includes various underrepresented languages. This comprehensive pretraining allows NLLB to effectively handle translation tasks across many languages that typically lack sufficient data. For our experiments we used `facebook/nllb-200-distilled-600M` checkpoint for building our MT systems. Our training configuration is as follows: `batch size: 4, 8; max sequence length: 128 tokens; training steps: 10,000, 20,000, 40,000; learning rate: 0.0001; optimiser: Adafactor; weight decay and gradient clipping applied; and model saved every 1000 steps.`

4.3 Llama

Llama is an auto-regressive language model that pretrained and fine-tuned in different sizes of data. We used `unsloth/llama-3-8b-bnb-4bit` checkpoint for building our MT systems. Our training parameters we set are as follows: `max seq length: 2048 tokens, batch size: 2 per device, gradient accumulation steps: 4, learning rate: 2e-4, mixed precision training enabled: (fp16 or bf16), learning rate scheduler: linear with 5-step warmup, maximum training steps: 500, optimiser: adamw-8bit, logging steps: 1, seed: 3407.`

5 Methodology

In this section, we discuss our methodologies.

5.1 mBART50

We used mBART for building three different MT systems for German-to-English. More specifically, mBART was fine-tuned on three distinct datasets: WMT-20,[7] WMT-22,[8] and WMT-24[9]. For French-to-English we used two datasets from WMT: WMT-22 and WMT-24. we detailed the datasets and hyperparameters setups in Section 3 and 4, respectively.

We performed data preprocessing the original data such as normalisation by removing special characters, removing duplicates and performing lowercase conversions. The source and target sentences were then tokenized using a predefined tokenizer.

In order to handle data during training and evaluation, a collator named as `DataCollatorForSeq2Seq`[10] is instantiated with the tokenizer and pretrained model checkpoint from Transformers library. This collator is designed to dynamically pad inputs to the maximum length within a batch, ensuring efficient processing. The `Seq2SeqTrainer` is then instantiated with the pretrained model checkpoint, training arguments, tokenized datasets, evaluation function, data collator, and tokenizer. This setup ensures a structured and efficient fine-tuning process, evaluating the model's performance at each epoch.

Fine-tuning is performed using the `Seq2SeqTrainer` class from the Transformers library. The training arguments are specified through `Seq2SeqTrainingArguments`, where parameters such as the output directory, batch sizes for training and evaluation and the number of training epochs were defined in Section 4.

[10] https://huggingface.co/docs/transformers/en/main_classes/data_collator

5.2 NLLB

We built four MT systems for English-to-German and two MT systems for English-to-French considering NLLB as the baselines. We evaluated our MT systems on the development and blind test sets. The MT training setups are detailed below. Our first MT systems involves fine-tuning the baseline NLLB model on the original data. For our second MT system we used normalised data (i.e. removing special characters and duplicates, and lowercasing) for fine tuning to observe any impact of data cleaning on performance.

We build two additional MT systems for for English–German. We back-translated monolingual data in order to create a synthetic bilingual data. For this, we mined monolingual data from OPUS [11]. The domain of the monolingual data is customer support. We combined the generated synthetic data with the original data for fine-tuning. The first and second MT systems were fine-tuned on the combined data, and this gave us the third and fourth MT systems, respectively.

For training we handled out-of-memory errors by dynamically creating training batches, i.e. the Adafactor (Shazeer and Stern, 2018) optimizer is employed instead of AdamW (Loshchilov and Hutter, 2017) to save GPU memory. Weight decay and gradient clipping (Loshchilov and Hutter, 2017) were applied to stabilize the training. Training batches were created by randomly choosing the translation direction (source to target or reverse) and sampling sentence pairs. To enhance robustness against memory issues, a function was implemented to release memory, with parameters set to different batch-sizes, maximum sentence length, and different training-steps. For the German-to-English and French-to-English tasks the best performing models were found to be the ones with 40,000 and 10,000 training steps, respectively. The model is saved every 1,000 steps, allowing for interruptions to adjust parameters or evaluate translations. Training typically runs for a short period of time, which is sufficient for a language similar to those already known by NLLB.

Post-training evaluation involves testing translation quality using parameters like $num-beams =$ 4, which affects accuracy, speed, and memory consumption, and parameters a and b, which control the maximum length of a generated text. The number of beams (or beam size) controls how many alternative sequences are kept during the search. This means that the model keeps the top 4 translations at each step during decoding.

5.3 Llama

We also used LLaMA for English-to-German and English-to-French. We built two MT systems for each of the translation tasks. This time, we focused on a specific learning technique, i.e. few-shot in-context learning. For this, we constructed a sentence retrieval system based on dense vector embeddings. Initially, sentence embeddings were generated using SentenceTransformer. More specifically, we used `all-MiniLM-L6-v2` [12] for our task. This model was applied to the source sentences of the dataset, transforming them into high-dimensional vector representations. These embeddings were then indexed using FAISS (Facebook AI Similarity Search) (Douze et al., 2024)[13], creating a searchable database of vectors. In other words, in order to create in-context learning examples, we encode the source test sentence using the pre-trained SentenceTransformer model. The resulting embedding is then used to query the FAISS index, which retrieves the most semantically similar sentences from the training dataset (note that we set $k = 3$). For constructing prompts, we retrieve the source sentences, their corresponding target sentences, and the associated language labels from the training dataset using the indices returned by FAISS. These sentences are then iteratively combined to construct three-shot prompts. Figure 1 shows the structure of a prompt. As can be seen from Figure 1, the prompt consists of initial instruction followed by three components: an instruction, an input, and a response. The instruction guides the task of translating from English-to-German/French or German/French-to-English. The language in an instruction is set dynamically based on labels provided with the sentence in our dataset. The input provides context, and the response is the desired output.

For the fine-tuning process tokenizer was instantiated using the `FastLanguageModel` class with parameters tailored to support efficient training on large sequences. The model is loaded from the `unsloth/llama-3-8b-bnb-4bit` pre-trained

[11] https://opus.nlpl.eu/ELRC-4992-Customer_Support_MT/de&en/v1/ELRC-4992-Customer_Support_MT

[12] https://huggingface.co/sentence-transformers/all-MiniLM-L6-v2

[13] https://github.com/facebookresearch/faiss

checkpoint. Subsequently, the model was further configured with $get-peft-model$, which applies Parameter-Efficient Fine-Tuning (PEFT) (Xu et al., 2023) techniques.

The fine tuning process was managed by `SFTTrainer`, which was integrated into `TrainingArguments` from the Transformers library. The training configurations were discussed in Section 4. Throughout the training, logging was performed at every step and the training process was seeded with a fixed value to ensure reproducibility. This training approach leveraged the state-of-the-art techniques to enable fine-tuning LLMs on extensive datasets while minimizing the computational overhead. The same parameters were tuned for both language-pairs.

The construction of a prompt for inference is identical to those constructed for training. The prompt instructs the model to translate a chat abstract from one language (source) to another (target). The instruction is specifically tailored to the languages involved in the translation, which are specified in the input-row. The source text is included in the prompt, while the output field is left blank, allowing the model to generate the translation. The prompt is tokenized using the pre-trained tokenizer, and the inputs are formatted as tensors compatible with PyTorch, with the computation offloaded to a GPU. The tokenized inputs are then passed to the model's $generate$ method, which performs the translation. The generated output is then decoded from the tokenized format back into a human-readable string using the batch-decode method.

```
Below is an instruction that
   describes a task, paired with
   an input that provides further
    context. Write a response
   that appropriately completes
   the request.
Instruction:
Translate this chat from German
   to English:
Input:
German 1: <German sentence 1>
English 1: <English sentence 1>
German 2: <German sentence 2>
English 2: <English sentence 2>

6 Results

This section describes the results obtained. Table 2 shows the performance of our MT systems on the validation sets. Tables 3 and 4 show the results obtained on the blind test set provided by the task organisers.

As mentioned in Section 5, we normalised the original data by removing special characters and duplicate sentences and lowercasing to see the impact of data cleaning on performance. We see from Table 2 that the MT models fine-tuned on normalised data are better than those fine-tuned on original data for the German-to-English translation task. This clearly shows us the effectiveness of data normalisation. Our primary submission for German-to-English was based on fine-tuned Llama with few-shot prompting. For this setup, we obtained 42.08 BLEU, 66.84 chrF and 85.25 COMET points on the validation set (cf. row 12 of Table 2). We also submitted two contrastive systems, i.e. NLLB and mBART50 fine-tuned on augmented data. The performance fine-tuned NLLB and mBART50 are shown in rows 9 and 3 of Table 2, respectively. Our constrastive submission 1 was based on NLLB. For this setup, we obtained 48.21 BLEU, 70.31 chrF and 84.60 COMET points on the validation set (cf. row 9 of Table 2). Our constrastive submission 2 was based on mBART50. For this setup, we obtained 47.73 BLEU, 69.17 chrF and 84.09 COMET points on the validation set (cf. row 3 of Table 2).

As for primary submission of the French-to-English task, we considered NLLB as our baseline and its performance is reported in row 19 of Table 2). We see from the table that this setup provided us 54.79 BLEU, 73.88 chrF, and 85.5 COMET points on the validation set. As in the German-to-English-task, we also submitted two contrastive systems for the French-to-English task. We fine-tuned Llama-3-8B and mBART50 following the few-shots prompt generation strategies described in Section 5. Our constrastive submission 1 was based on fine-tuned Llama-3-8B. For this setup, we obtained 38.23 BLEU, 66.54 chrF and 89.08 COMET points on the validation set (cf. row

24 of Table 2). Our constrastive submission 2 was based on mBART50. For this setup, we obtained 53.15 BLEU, 72.67 chrF and 84.55 COMET points on the validation set (cf. row 17 of Table 2).

Our primary submission of the German-to-English task was based on Llama. As can be seen from Table 4, we obtained 55.0 BLEU, 72.1 chrF, 90.8 COMET and 0.167827 CONTEXT-COMET-QE (Rei et al., 2020b) points on the WMT 2024 blind test sets. Our primary submission of French-to-English was based on NLLB. For this setup we obtained 31.3 BLEU, 60.9 chrF, 82.4 COMET and -0.23095 CONTEXT-COMET-QE points. Our best-performing system of the German-to-English task is Llama with few-shot learning. We secured the top place for German-to-English in this competition. Table 3 shows our precision for pronouns in the French-to-English system. Our submission for the French-to-English translation task is in fact the best-performing system in terms of pronoun translatiosn.

Model	COMET	ChrF	BLEU	COMET-QE

NLLB WMT24	82.4	60.9	31.3	-0.23

Table 4: Official results. Performance of our MT systems on the blind set (primary submissions).

7 Conclusion

This paper described our submissions to the WMT 2024 Chat Translation Task for German-to-English and French-to-English language pairs. We applied several training and fine-tuning strategies such as standard fine-tuning and fine-tuning with few-shot prompting. We investigated our approaches using three different LLMs: NLLB, Llama and mBART. This allowed us to make a comparative analysis between different architectures and strategies. One of the key findings of our investigation is that the performance of the MT systems on translating conversational messages can be improved with knowledge transfer. We also found that our MT systems exhibit robustness on this *difficult-to-translate* domain.

For future investigations, given the shortage of conversational data, we plan to focus on exploring the use of advanced data augmentation techniques. We also intend to further investigate to what extent synthetic data can be beneficial in chat translation scenarios.

Abstract

This paper describes the submissions of Huawei Translation Services Center(HW-TSC) to WMT24 chat translation shared task on English↔Germany (en-de) bidirection. The experiments involved fine-tuning models using chat data and exploring various strategies, including Minimum Bayesian Risk (MBR) decoding and self-training. The results show significant performance improvements in certain directions, with the MBR self-training method achieving the best results. The Large Language Model also discusses the challenges and potential avenues for further research in the field of chat translation.

1 Introduction

Neural machine translation (NMT) (Sutskever et al., 2014; Bahdanau et al., 2015; Gehring et al., 2017; Wu et al., 2023) has made substantial progress in recent years, largely due to the adoption of the transformer (Vaswani et al., 2017) architecture. NMT has demonstrated promising translation results across various scenarios. However, research in the field of chat translation remains limited, primarily due to the scarcity of chat data. In prior chat-related tasks, we utilized data from related domains, such as spoken dialogue and subtitles, to augment our translation models, but the outcomes were only mediocre.

Like the preceding two chat shared tasks, the WMT24 chat shard task concentrates on translating conversations between consumers and servers in different languages. We participated in the en-de bidirectional translation task. The en-de bidirectional models we submitted to the WMT22 chat task (Yang et al., 2022) function as our baseline models, leveraging the deep transformer (Dou et al., 2018) architecture. Building on this foundation, we employed the Minimum Bayesian Risk (MBR) strategy to select the optimal translation outcomes, and iterative self-training yielded the best results on the development set.

Beyond traditional NMT models, the emergence of large language model(LLM) has introduced a new paradigm to translation tasks(Wang et al.; Moslem et al., 2023; Guo et al., 2024). Due to its extensive context length and powerful language modeling capabilities, large language models significantly outperform NMT in the translation of lengthy texts and the fluency of translation results. We input the translation output from the NMT model into the LLM as a prompt, allowing the LLM to combine the reference translatio from traditional NMT model to produce an improved translation. However, the comet metric of the LLM's output did not surpass the optimal results of the NMT model.

Recognizing that chat translation is a context-aware task, we conducted a series of context-aware experiments(Wu et al., 2024) using LLMs with WMT and IWSLT document data . We fine-tuned the LLM by constructing streamed translations and contextualized translation data, and translated the development set in the same format. Unfortunately, the results were unsatisfactory.

The structure of this paper is as follows: Section 2 describes our data volume and format for fine-tuning the LLM. The model structure and key methods utilized are presented in Section 3. Section 4 outlines our experiment setting. Results and analysis are presented in Section 5, and we conclude our work in Section 6.

2 Data

2.1 Data Size

All experiments conducted for this task are based on the model developed by our team, as participated in the WMT22 chat shared task. For details on the training data and strategies used for this model, please refer to the system report Yang et al. (2022); Wei et al. (2021). Table 1 and Table 2 list all

Table 2: Document-level data used for LLM related experiments

the data used in this experiment. Based on the prior tasks experience, the contribution of out-domain data to the improvement of translation quality is limited. Therefore, we only further optimize our translation model using the data shown in Table 1, which consists of historical chat tasks. The data in Table 2 is used for fine-tuning the LLM, enabling it to translate context-aware texts and validate the impact of paragraph information on dialogue translation quality.

2.2 Data pre-processing

Since the domain-specific data listed in Table 1 is limited, no special treatment was applied to this portion of the data; it was simply tokenized and input into the NMT model. For the document data in Table 2, we constructed the two formats shown in Table 3 by considering the characteristics of chat tasks, and used them to fine-tune the LLM, separately validating the impact of only preceding information and both preceding and context information on chat translation quality.

In the format of streamlined translation, during each translation session, only preceding information is visible. The LLM generates results based on this preceding information and the previews translation output, resulting in a translation that leans more towards the style of the reference.

In the context-aware translation format, during each translation session, preceding and following N sentences are provided along with the output of the NMT model, guiding the LLM to combine context information to produce a more natural translation.

3 System Overview

3.1 Model

The baseline models for WMT24 chat task use the Transformer-Big architecture. Deep transformer is an improvement of Transformer, which increases the number of encoder layers and uses pre-layer-normalization to further improve model performance. Therefore, in this task, we adopt the following model architecture:

- Deep 25-6 large Model: This model features 25-layer encoder, 6-layer decoder, 1024 dimensions of word vector, 4096 domensions of FFN, 16-head self-attention, and pre-layer-normalization.

For experiments related to large language model, we choose llama2-8b as the base.

3.2 MBR Decoding

Minimum Bayesian Risk (MBR) decoding was initially introduced during the era of statistical machine translation(Kumar and Byrne, 2004; Jinnai et al., 2024). This strategy calculates the output with the minimum expected error among multiple candidates, rather than simply selecting the result with the highest probability during the decoding process. In our experimental approach, we utilize the outputs of 10 distinct models as candidates. These candidates are then used to score each other's comet, and the candidate with the highest average comet is chosen as the final output. Algorithm 1 show the detail.

3.3 Regularized Dropout

Regularized Dropout (R-Drop) [1](Liang et al., 2021) presents a simple yet more effective approach to regulate the training inconsistency caused by dropout (Srivastava et al., 2014). Specifically, during each mini-batch training, each data sample is processed twice through the forward pass, with each pass utilizing a distinct sub-model and randomly dropping out some hidden units. R-Drop minimizes the bidirectional Kullback-Leibler (KL) divergence (van Erven and Harremos, 2014) between the two distributions outputted by the two sub-models for the same data sample, thereby regulating the outputs of two sub-models randomly sampled from dropout for each data sample in training. This method effectively alleviates the inconsistency between the training and inference stages.

3.4 Self-Training

Self-Training(ST) (Imamura and Sumita, 2018), also known as forward translation (FT) (Wu et al., 2019), typically involves utilizing a forward NMT

Table 3: LLM Supervised fine-tuning(SFT) data format

model to translate source-side monolingual data into target-side text, thereby generating synthetic bilingual data. The generated data is then employed to train the forward translation model. Typically, beam search (Freitag and Al-Onaizan, 2017) is applied for forward translation. In our experimental approach, we set the beam size to 4. Furthermore, we utilized the MBR selection results as self-training data, which led to the best results on the validation set.

Algorithm 1 MBR decoding algorithm

```
Input:
    The set of translation candidates file, $MT_n$;
    The source text file, $SRC$;
    Comet metric model, $M_{comet}$;
Output: final translation output
initialize output list $out[]$
for each $line \in [MT_1, ..., MT_n, SRC]$ do
    initialize $tmp\_max\_comet = 0$
    initialize $candidate\_mt ='' $
    for each $candidate \in [mt_1, mt_2, ..., mt_n]$ do
        let each $mt_x$ as ref, $candidate$ as mt and calculate the comet score with source text using $M_{comet}$
        $mean\_comet = \frac{\sum_{x=1}^{n} comet_x}{n}$
        if $mean\_comet > tmp\_max\_comet$ then
            $tmp\_max\_comet = mean\_comet$
            $candidate\_mt = candidate$
        end if
    end for
    out.append($candidate\_mt$)
end for
return out
```

3.5 Back Translation

Back-translation (Edunov et al., 2018; Wei et al., 2023) is acknowledged as a highly effective data augmentation strategy to boost NMT model performance. Unlike forward translation, back-translation converts target-side monolinguals into source-side text, thereby producing synthetic parallel corpora. Numerous back-translation techniques have been explored, with sampling (Graça et al., 2019), noise (Edunov et al., 2018), and tagged back-translation (Caswell et al.) demonstrating superior results. In our experimental setup, we opted for sampling back-translation.

3.6 Model Averaging

Model averaging (Dormann et al., 2018) is a widely utilized technique to enhance translation quality. Typically, models (in our experiment, 5 models) that exhibit the highest performance on the development set are chosen for parameter averaging, which leads to substantial improvements.

3.7 LLM Few-shot Prompting

Although large language models exhibit impressive zero-shot capabilities, they still struggle with more complex tasks in the zero-shot setting. To address this, few-shot prompting can be employed as a technique for in-context learning, where demonstrations are provided in the prompt to guide the model towards enhanced performance. In our approach, we provide 5 reference translations to assist the large language model in producing superior results.

3.8 LLM SFT with LoRA

LLM SFT (Supervised Fine-Tuning) is a technique for fine-tuning large language models using specific datasets, which effectively enhances the performance of large language models on tasks such as text generation, machine translation, or sentiment analysis. LoRA (Low-Rank Adaptation)(Hu et al., 2022) is a technique that reduces the computational burden during large language model training by decreasing the number of model parameters through matrix decomposition. This technique maintains performance while lowering computational and memory requirements. By applying LoRA, large language models can perform better under limited computational resources, reducing training costs and resource consumption.

4 Experiment Setting

During the NMT model training phase, we use Pytorch-based Fairseq[2] (Ott et al., 2019) open-source framework as our benchmark system. Each model is trained using 8 GPUs with a batch size of 2048. The update frequency is 4 and the learning rate is 5e-4. The label smoothing rate is set to 0.1, the warm-up steps to 4000, and the dropout to 0.3. Adam optimizer (Kingma and Ba, 2015) with $\beta1$=0.9 and $\beta2$=0.98 is also used. Beyond that, we have configured the hyper parameter reg-alpha of the R-Drop technique to a value of 5. In the evaluation phase, We employ the official automatic evaluation scripts and primarily base our model and result selection on the comet metric(Rei et al., 2022)[3].

In the experiments related to large models, we utilize the open-source model llama2_8b_instruct from Meta and the training scripts from HF to train our models, setting the max_seq_length to 1024. For inference on large models, we employ the vllm tool.

5 Result and Analysis

Table 4 displays the results of the official test set, ranked according to the comet-22 score, where our system achieved the top position in comet-22, chrF, and BLEU metrics.

The primary results we submit are obtained by translating the source text of the test set with multiple NMT models, selecting the optimal output using MBR strategy, then training on the best models from the validation set using self-training method. The models are averaged over 5 epochs before being used to translate the test set to yield the final results.

5.1 Sentence-level NMT

In the previous chat tasks, we have tried various strategies to optimize the model, and the results from the validation set indicate that the baseline model from 2022 was already sufficiently powerful. On this basis, we combined this year's training set, the 2022 validation and test sets, and conducted BT and ST reinforcement strategies, only in the direction of translation from English to German has there been a noticeable improvement. The results shown in Table 5.

To further improve the results, we attempted the MBR decoding strategy, generating 10 alternative outputs for the validation set using different NMT models in previous steps. These outputs were scored using comet, and the output with the lowest Bayesian risk was selected as the final result. The results in Table 5 indicate that improvement was only seen in the en→de direction. Further, we utilized the MBR results to perform another ST on each direction, ultimately achieving the best results in both directions in the validation set. The reason for the improvement we observed is that the MBR algorithm can integrate the capabilities of multiple models. When performing self training, it essentially utilizes the optimal results of multiple models for a round of knowledge distillation.

5.2 Document-level MT with LLM

According to the test results shown in Table 6, on the chat task valid set, the results of LLM (Large Language Model) are significantly worse than sentence-level under both comet or doc-comet metrics. The few-shot capabilities of LLM is in-

Table 5: Sentence-level NMT results.

deed far better than zero-shot, but it still falls short of sentence-level results. After using the document-level data for LLM SFT, the results became even worse. We analyzed that the reason is the large domain shift, as the IWSLT and WMT datasets we used are far from the domain of the chat task.

To validate the capability of LLM in translating document-level content, we tested the results on the iwslt2017 en-de document-level test set. The results in the right half of Table 6 demonstrate that LLM's few-shot capability surpassed that of the chat task's sentence-level model on this test set. Further, by fine-tuning the large model with document-level data, we obtained better results.

Comparing the results of stream translation and context-aware translation, we originally expected context-aware format data to yield better results because the model could refer to contextual information during translation. However, we analyzed that stream translation sees the previous step's translation result each time, which is more consistent with the translation style of large model. On the contrary, context-aware requires input of the reference MT result from sentence-level model in one go, which is less consistent with the style of large model, causing the model to fail to effectively utilize these information.

6 Conclusion

This paper presents the submissions of HW-TSC to the WMT 2024 Chat Translation Shared Task. For both direction in en↔de translation task, we perform experiments with a series of training strategies. The results show that MBR self-training achieves the best results. In the future, we will continue to explore the applicability of MBR strategy mentioned in this paper.

Beyond that, due to time constraints, further fine-tuning of large language models using chat task data was not conducted to assess its performance. Additionally, there is room for continued exploration of the translation capabilities of large language models.

Abstract

In this paper, we present our approach to the WMT24 - Chat Task, addressing the challenge of translating chat conversations. Chat conversations are characterised by their informal, ungrammatical nature and strong reliance on context posing significant challenges for machine translation systems. To address these challenges, we augment large language models with explicit memory mechanisms designed to enhance coherence and consistency across dialogues. Specifically, we employ graph representations to capture and utilise dialogue context, leveraging concept connectivity as a compressed memory. Our approach ranked second place for Dutch and French, and third place for Portuguese and German, based on COMET-22 scores and human evaluation.

1 Introduction

Machine translation (MT) has been a prominent area of research, leading to the development of various approaches over the years (Maruf et al., 2021). While significant progress has been made, the majority of research has concentrated on refining methodologies rather than exploring the different types of text that require translation. A notable gap exists in the automatic translation of chat conversations—a gap that the WMT24 - Chat task specifically aims to address.

Chat conversations present unique challenges due to their informal, spontaneous nature, and frequent grammatical inconsistencies (Gonçalves et al., 2022). These characteristics starkly contrast with the more structured and formal text types, such as news articles, technical manuals, and political or medical documents, which have been the traditional focus of MT systems. In the context of chat translation, it is crucial to incorporate dialogue context effectively and to model the speakers and their language direction.

Figure 1: Approach 1: Triple-TowerInstruct

Recent advances in machine translation have increasingly leveraged large language models (LLMs). However, as noted by Maharana et al. (2024), LLMs often struggle with tasks requiring long-term memory, reasoning over historical context, and establishing long-range temporal or causal connections. These limitations are particularly problematic to dialogue tasks, where maintaining coherence and consistency across a conversation is vital.

To address these challenges, our system proposes enhancing LLMs with explicit memory mechanisms designed to support the generation of more consistent and coherent translations in dialogue settings[1]. We hypothesise that utilising graph representations will further improve the translation of chat conversations by capturing the connectivity between concepts, thus serving as a compressed memory of the dialogue context.

2 Related Work

In this section, we provide a brief overview of related work in the areas of conversational NLP, machine translation of conversational text, and text generation methods that incorporate knowledge graphs as an additional source of information.

November 15-16, 2024 ©2024 Association for Computational Linguistics

Conversational NLP Dialogue systems have a long-standing history in NLP. The advent of LLMs has led to significant improvements in the quality of these systems. However, a persistent challenge has been the limited context window of LMs, which restricts their ability to manage long chat histories effectively (Xu et al., 2021). To address this, retrieval-augmented models have been developed, which retrieve relevant passages from prior interactions to maintain coherence in dialogue over extended conversations (Xu et al., 2021). Recently, advancements in model architecture have resulted in substantially larger context windows, enabling state-of-the-art dialogue systems, such as ChatGPT, to operate effectively with this extensive LMs (Achiam et al., 2023).

Machine Translation Machine translation has seen remarkable advancements with the rise of large language models (Wang et al., 2023; Robinson et al., 2023). However, translating dialogues remains a particularly challenging task due to the informal and often context-dependent nature of conversational text (Gonçalves et al., 2022). The findings of recently shared tasks highlight ongoing difficulties and emerging solutions in this area (Farinha et al., 2022).

Our work is particularly related to the use of knowledge graphs in translation tasks (Moussallem et al., 2018; Zhao et al., 2021). In most existing approaches, multilingual knowledge graphs are leveraged to disambiguate and translate key entities within the text. This approach differs significantly from our method, as we employ a monolingual graph to store key information from the dialogue in a compressed format, facilitating more accurate and context-aware translations.

Graph-based Dialogue Systems Knowledge graphs have proven to be a valuable resource for grounding dialogue systems. The most common approach involves integrating large, external knowledge graphs to provide additional context and information that can enhance the dialogue's quality and relevance (Liu et al., 2019; Tuan et al., 2019; Zhang et al., 2020). While these approaches share a similar objective with our work, they fundamentally differ in that the knowledge graphs used are independent of the dialogue content itself.

In contrast, other approaches leverage graphs to represent the dialogue history, offering a structured way to maintain and utilise past interactions (Xu et al., 2020; Chen et al., 2023). This method enhances transparency, reduces the likelihood of hallucinations, and improves the system's ability to manage long-term conversations (Baez Santamaria et al., 2023). Our work aligns with this approach by utilising a graph to capture and organise key dialogue information, enabling more effective and contextually grounded dialogue systems.

3 Shared Task description

A dataset of original bilingual customer support conversations is provided. The language pairs available are English ⇌ German (`en-de`), English ⇌ Dutch (`en-nl`), English ⇌ French (`en-fr`), English ⇌ Brazilian Portuguese (`en-pt_br`), and English ⇌ Korean (`en-ko`). Due to our team's language expertise, we decided to focus on the first four pairs.

4 System Overview

All our systems work with graphs extracted from dialogues. We employ a multi-step process to extract entities and relationships from the dialogue data and utilise these in various model settings. Our primary submission, **Triple-TowerInstruct**, integrates dialogue history into the translation process at inference, leveraging contextual cues to enhance performance across four language pairs. In addition to this, we explored an ablation study (TowerInstruct without dialogue history) and a novel model, **GraphFlanT5**, which combines graph and text embeddings within a unified framework.

4.1 Pre-processing

For generating the graphs, we perform entity and relation extraction by prompting GPT-4o. The prompt used for this process (see Prompt 1) is designed to extract relevant triples from the dialogue data, capturing the essence of interactions in a structured format. The system is instructed to analyse the dialogue and break it down into triples, each consisting of a subject, predicate, and object. These triples serve as the fundamental building blocks of the graph, representing the interactions between speakers.

In addition to extracting these triples, the prompt also instructs the system to annotate each triple with several attributes that provide deeper insights into the nature of the interactions. These annotations include:

- **Sentiment**: This attribute captures the emotional tone of the interaction, with values ranging from -1 for negative sentiment, 0 for neutral, and 1 for positive sentiment. This allows us to understand the emotional context in which the interaction takes place.

- **Polarity**: Polarity indicates whether the interaction involves a negation, affirmation, or is neutral or questioning. It is coded as -1 for negation, 0 for neutral or questioning, and 1 for affirmation. This helps in identifying the stance or intent behind the speaker's words and keeps the predicates uniform across negation, statements and questions (e.g. "don't travel" and "travel" receive the same predicate *travel* with different polarity scores)

- **Certainty**: This attribute is on a scale from 0 (uncertain) to 1 (certain), reflecting the speaker's confidence or the definitiveness of the statement. This helps in distinguishing between statements of fact and those that are speculative or uncertain and can subsequently be used by the model to communicate certainty about its knowledge more effectively.

- **Dialogue Act**: Dialogue acts categorise the type of speech act being performed, with predefined categories such as greeting, farewell, negative reaction, positive reaction, concern, query, and others.

4.2 Approach 1: Triple-TowerInstruct

In our first approach, we use the TowerInstruct-7B-v0.2[2] model, a variant of the Tower (Alves et al., 2024) family specifically designed for translation-related tasks.

TowerInstruct-7B-v0.2 is based on the LLaMA-2 architecture, which has been extended through additional pretraining and fine-tuning to enhance its multilingual capabilities, outperforming other open models of similar scale. The model's foundation, TowerBase, was developed by continuing the pretraining on a diverse multilingual dataset across 10 languages (including Dutch, German, French, and Portuguese) incorporating both monolingual and parallel data to improve translation quality. Subsequently, TowerInstruct was fine-tuned using the TowerBlocks dataset, which includes a broad range of translation-related tasks and, relevant for the task of chat translation, multi-turn dialogue data from UltraChat (Ding et al., 2023). This fine-tuning process tailored the model specifically for translation workflows, making it adept at handling complex, multilingual interactions.

Prompt 1: Triple extraction with GPT-4o

```
system_prompt =
You will analyze a dialogue and break it down
into triples consisting of a subject, predicate,
and object. Each triple should capture the
essence of interactions between speakers.
Additionally, annotate each triple with:
- Sentiment (-1 for negative, 0 for neutral,
1 for positive)
- Polarity (-1 for negation, 0 for neutral/
questioning, 1 for affirmation)
- Certainty (a scale between 0 for uncertain
and 1 for certain)
- Dialogue act (
  0 : "greeting",
  1 : "farewell",
  2 : "negative_reaction",
  3 : "positive_reaction",
  4 : "concern",
  5 : "query",
  6 : "other")

Ensure that predicates are semantically
meaningful. Separate multi-word items with
an underscore.

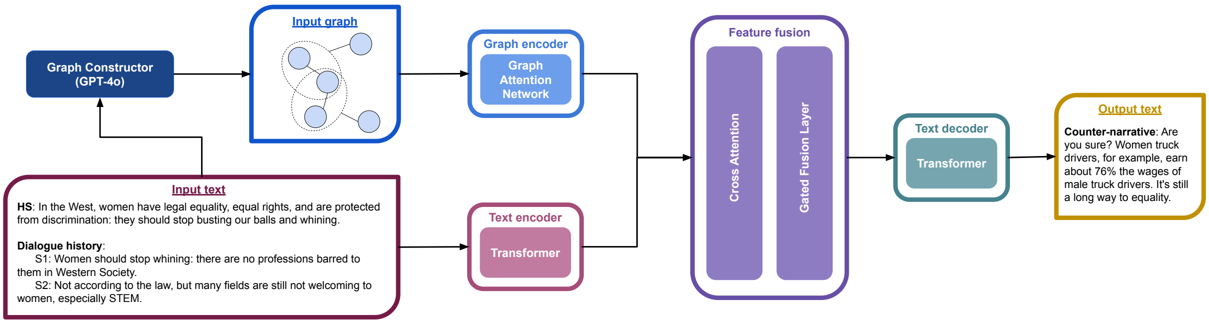
Triple-TowerInstruct During inference, we merge the triple-based dialogue history, generated in the pre-processing stage (see Section 4.1), with

[2] https://huggingface.co/Unbabel/TowerInstruct-7B-v0.2.



HS: In the West, women have legal equality, equal rights, and are protected from discrimination: they should stop busting our balls and whining.

Dialogue history:
S1: Women should stop whining: there are no professions barred to them in Western Society.
S2: Not according to the law, but many fields are still not welcoming to women, especially STEM.

Counter-narrative: Are you sure? Women truck drivers, for example, earn about 76% the wages of male truck drivers. It's still a long way to equality.

Figure 2: Approach 2: GraphFlanT5

the current source sentence. This combined input, which encapsulates both the conversational context and the immediate translation task, is then fed into the model to ensure that the output accurately reflects the dialogue's ongoing flow and context.

As an ablation, we also evaluated the model's performance without providing dialogue history graphs.

4.3 Approach 2: GraphFlanT5

We have developed a unified framework named GraphFlanT5 (see Figure 2), which integrates both graph and text input into a single architecture, similar to (Yao et al., 2023). This model is designed to generate target sequences in text based on the dialogue history and the source sequence represented in text and graph forms.

As further preprocessing for this approach, we use spaCy's NeuralCoref[3] to resolve co-references, limiting the number of nodes to a maximum of 100. These are then represented as an adjacency matrix and fed into the main model.

To encode the graph, we employ a Graph Attention Network (GAT) (Veličković et al., 2018) with a single attention layer, followed by a dense layer and normalization. On the text side, we use a Transformer encoder for encoding. We specifically used FlanT5-base[4] for its multilingual capabilities. After obtaining the encoded features from both the graph and text, we apply cross-attention to align the text representation with the graph representation. A gated fusion mechanism (Wu et al., 2021) is then used to combine the outputs of the cross-attention. Finally, the fused features are passed into the Transformer decoder to generate the final textual answer.

We fine-tuned our model for 25 epochs with a learning rate of 5e-5 and a weight decay of 0.05. Training was conducted using mixed precision on two A10 GPUs.

5 Results & Discussion

5.1 Automated Metrics

Our primary submission, Triple-TowerInstruct, and its ablation variant without dialogue history graphs (NH) are compared against our second approach GraphFlanT5, the baseline (NLLB-200's (Team et al., 2022) 3.3B variant[5]), and the top-performing Unbabel system, using COMET-22 (Rei et al., 2022), Contextual-COMET-QE (Vernikos et al., 2022), BLEU (Papineni et al., 2002), and ChrF (Popović, 2015) scores [6].

Tables 1 and 2 show the results from our experiments across four language pairs: `en-de`, `en-nl`, `en-nl`, and `en-pt_br`. While we only submitted Approach 1 (Triple-TowerInstruct), we include the evaluation of the other approaches which were conducted after the shared task submission deadline. From the submitted approach, our team ranked second place for `en-nl` and `en-fr`, and third place for `en-pt_br` and `en-de` on the COMET-22 (Rei et al., 2020a) score.

Triple-TowerInstruct performed well across all language pairs, consistently outperforming the baseline based on COMET and in the majority of instances for the other metrics. For instance, in the `en-de` task, Triple-TowerInstruct achieved a COMET score of 91.3, outperforming the baseline's 89.8. The BLEU and ChrF scores further support this, with Triple-TowerInstruct scoring 53.0 in BLEU and 71.9 in ChrF for `en-de`, both above the baseline scores of 51.1 and 70.8, respectively. The

[6] Sacrebleu is used for the implementation of BLEU and ChrF (Post, 2018).

Model	**en-de**				**en-nl**			
	COMET	**ChrF**	**BLEU**	**Context-COMET-QE**	**COMET**	**ChrF**	**BLEU**	**Context-COMET-QE**
Triple-TowerInstruct	91.3	71.9	53.0	0.2039	90.9	70.6	48.0	0.0816
TowerInstruct NH	91.2	72.2	53.9	0.2128	91.3	66.2	44.7	0.1982
GraphFlanT5	85.3	65.1	44.5	0.0120	88.4	68.5	48.7	0.0697
Baseline	89.8	70.8	51.1	0.1730	88.1	62.6	38.7	0.0873
Unbabel+it	92.9	78.2	62.0	0.2526	93.6	79.8	63.9	0.1167

Table 1: Translation Results for German (en-de) and Dutch (en-nl). NH models refer to ablations without dialogue history. Results for the baseline and best performing system in the task (Unbabel+it) are included for comparison.

Model	**en-fr**				**en-pt**			
	COMET	**ChrF**	**BLEU**	**Context-COMET-QE**	**COMET**	**ChrF**	**BLEU**	**Context-COMET-QE**
Triple-TowerInstruct	91.6	75.7	58.8	0.0775	91.3	66.8	45.3	0.1909
TowerInstruct NH	91.7	75.2	57.9	0.0756	90.6	71.0	50.9	0.0686
GraphFlanT5	85.8	67.4	47.0	-0.1007	90.4	75.0	56.7	-0.0095
Baseline	90.1	76.2	58.7	0.0101	86.2	62.2	35.3	-0.0613
Unbabel+it	92.8	79.8	65.7	0.1034	93.9	79.7	65.0	0.2367

Table 2: Translation Results for French (en-fr) and Portuguese (en-pt). NH models refer to ablations without dialogue history. Results for the baseline and the best performing system in the task (Unbabel+it) are included for comparison.

NH variant, which omits dialogue history, saw a minor drop in performance for `en-de` and `en-pt_br`, with a drop in COMET score of 0.1 and 0.7 respectively, and slightly lower BLEU and ChrF scores. Interestingly, the opposite is true for the `en-nl` and `en-nl` language pairs. The Context-COMET-QE scores (Rei et al., 2020b), which are intended for reference-free machine translation evaluation and trained to reflect human judgements of the quality of translations, also demonstrated variability. For `en-de`, Triple-TowerInstruct scored 0.2039 in Context-COMET-QE (Rei et al., 2020b), while the NH variant scored 0.2128, showing a slight improvement when dialogue history was removed. While for `en-pt_br` including the history increased the score by 0.0383[7]. We also observed that COMET-based metrics and n-gram matching metrics (ChrF and BLEU) disagreed in ranking our TowerInstruct variants. When COMET favoured one variant, the n-gram metrics ranked it lower, and vice-versa. Underscoring the importance of using a combination of metrics, as relying on a single metric could give an incomplete picture of model performance.

GraphFlanT5 which integrates graph and text input within a unified framework, showed moderate results and did not outperform our TowerInstruct variants or the baseline in most cases. In the `en-de` task, GraphFlanT5 recorded a COMET score of 85.3, lower than both TowerInstruct and the baseline. Its BLEU and ChrF scores were also lower, at 44.5 and 65.1, respectively. However, in some tasks like `en-nl`, GraphFlanT5 performed competitively with a BLEU score of 48.7, suggesting that the integration of graph representations may offer benefits in certain contexts, but requires further optimisation to be competitive to more traditional approaches.

[7] See Kocmi et al. (2024) for an explanation of the different dynamic ranges of the mentioned metrics.

Model	en-de				en-nl			
	Formality	Lexical Cohesion	Pronouns	Verb Form	Formality	Lexical Cohesion	Pronouns	Verb Form
Triple-TowerInstruct	86.3	74.1	78.5	–	35.5	66.4	–	40.0
Baseline	79.4	76.0	79.1	–	53.0	57.4	–	35.7
Unbabel+it	88.6	82.9	70.5	–	93.9	87.7	–	54.5

Table 3: F1 Scores for German (en-de) and Dutch (en-nl) across different evaluation dimensions of MUDA. Where entries are left blank, the metric does not evaluate the language for that dimension.

Model	en-fr				en-pt			
	Formality	Lexical Cohesion	Pronouns	Verb Form	Formality	Lexical Cohesion	Pronouns	Verb Form
Triple-TowerInstruct	89.6	78.6	88.6	68.1	78.7	88.5	55.0	–
Baseline	86.9	82.1	82.0	70.2	45.7	81.0	55.8	–
Unbabel+it	91.3	90.2	92.9	74.2	88.0	95.5	74.4	–

Table 4: F1 Scores for French (en-fr) and Portuguese (en-pt) across different evaluation dimensions of MUDA.

5.1.1 MUDA

Tables 3 and 4 present the F1 scores for different evaluation dimensions—Formality, Lexical Cohesion, Pronouns, and Verb Form—of the Multilingual Discourse-Aware (MuDA) benchmark (Fernandes et al., 2023). We compared our primary model, Triple-TowerInstruct, against the baseline and the top-performing system, Unbabel+it. MuDA is designed to systematically evaluate machine translation models on their handling of discourse phenomena that require context. Unlike traditional metrics that focus broadly on translation accuracy, it specifically targets the model's ability to correctly translate discourse elements, such as pronouns and verb forms, that depend heavily on the surrounding context.

The performance of our model varied across different dimensions and language pairs, outperforming the baseline in 7 out of 13 cases. Overall, it demonstrated relatively strong performance on the **Formality** dimension, achieving competitive F1 scores in language pairs such as `en-de`, `en-nl`, and `en-pt_br`, with a notable increase of 33 points over the baseline for the latter. The exception was the `en-nl` pair, where the model's formality score was notably lower compared to both the baseline and top-performing systems, indicating a need for targeted improvements in handling formality specific to Dutch translations. However, performance on **Lexical Cohesion**, **Pronouns**, and **Verb Form** was less consistent across language pairs, with the model outperforming the baseline in only half of the cases.

5.2 Human Evaluation

Human evaluation confirms that our approach outperforms the baseline, and ranked second place for `en-nl` and `en-fr`, and third place for `en-pt_br` and `en-de` across all submitted approaches.

	en-de	en-nl	en-fr	en-pt
Triple-TowerInstruct	78.6	84.37	73.32	69.85
Baseline	74.5	53.07	67.81	56.37
Unbabel+it	84.22	92.22	79.62	78.0

Table 5: Human Evaluation Scores on document level for German (en-de), Dutch (en-nl), French (en-fr), and Portuguese (en-pt) across models.

The human evaluation was facilitated by the task organisers. It was conducted by professional linguists and translators using a combination of Direct Assessment and scalar quality metric (DA+SQM) implemented via the Appraise framework (Federmann, 2018).

6 Conclusion & Future Work

Our results underscore the importance of incorporating dialogue history in improving translation quality, highlighting its role in maintaining coherence and context throughout chat-based translations. The integration of graph-based representations also shows promise, particularly in capturing and leveraging the structural relationships within dialogue contexts. However, our findings indicate that further optimisation is required to fully realise the benefits of this approach, especially in terms of consistently outperforming more traditional text-based models.

In future work, one of our key objectives is to combine the strengths of TowerInstruct's translation capabilities with the advanced context modelling offered by our graph-based approach. By integrating these two methodologies, we aim to create a more robust system that can better handle the complexities of chat dialogue translation.

Furthermore, we plan to investigate the incorporation of additional contextual information, such as certainty or sentiment scores derived during preprocessing. These scores could potentially enhance the model's ability to weigh different parts of the dialogue based on their reliability and emotional tone, thereby improving overall translation accuracy. By factoring in sentiment, the model can better preserve the nuances of emotional expression within the conversation, leading to more contextually appropriate translations, which is particularly important in the task's customer service domain where frustration is common. By pursuing these directions, we aim to refine our models further, making them more adaptable and effective in real-world chat translation and dialogue tasks.

Abstract

This paper presents a multi-pipeline Japanese-to-English machine translation (MT) system designed to address the challenge of translating repeated elements from Japanese into fluent and lexically diverse English. The system was developed as part of the Non-Repetitive Translation Task at WMT24, which focuses on minimizing redundancy while maintaining high translation quality. Our approach utilizes MeCab, the de facto Natural Language Processing (NLP) tool for Japanese, to identify repeated elements, and Claude Sonnet 3.5, a Large Language Model (LLM), for translation and proofreading. The system effectively accomplishes the shared task by identifying and translating in a diversified manner 89.79% of the 470 repeated instances in the test dataset and achieving an average translation quality score of 4.60 out of 5, significantly surpassing the baseline score of 3.88. The analysis also revealed challenges, particularly in identifying standalone noun-suffix elements and occasional cases of consistent translations or mistranslations.

1 Introduction

In the Japanese language, repetition at the word and phrasal levels is frequently employed (Fujimura-Wilson, 2007). One reason for this is that Japanese is a topic-prominent language, where the topic of the sentence is often explicitly stated and reiterated to ensure clarity and prominence (Tsujimura, 2013). Additionally, Japanese is highly context-dependent and typically omits subject pronouns, relying on the repetition of key nouns and verbs to maintain coherence (Maynard, 1997). Specifically for personal names, repetition is commonly used instead of pronouns to convey politeness and respect (Mogi, 2000).

In contrast, English typically favors variety and succinctness to maintain reader engagement (Hinkel, 2002; Halliday, 1994). Research in translation studies emphasizes the importance of lexical variety to ensure fluency and readability in translated texts (Baker, 1992; Newmark, 1988). Therefore, effectively translating repeated elements from Japanese to English may require the use of more diverse expressions while ensuring consistency and clarity.

The Non-Repetitive Translation Task at WMT24 addresses the challenge of translating repeated elements from Japanese into English (Kinugawa et al., 2024). This task aims to develop machine translation (MT) systems capable of identifying repeated expressions in Japanese text and translating them into lexically diverse and fluent English sentences. Participants are provided with training and test datasets comprising Japanese-English parallel corpora, in both raw and annotated formats with repeated targets tagged. Systems are evaluated on their ability to minimize redundancy while maintaining high translation quality.

Our contribution includes the development of a multi-pipeline MT system that effectively avoids redundancy in translating repeated words and phrases from the source Japanese text. Specifically, we utilized MeCab (Kudo, 2005) for tokenization and lemmatization of Japanese sentences to identify repeated elements and adopted the Large Language Model (LLM) Claude Sonnet 3.5 (Anthropic, 2024) for translation and proofreading. When compared with the baseline system provided by the task organizers, our system achieved an average translation score of 4.60, significantly higher than that of the baseline system at 3.88; and a BLEU metric of 24.4

compared with human benchmark translation.

2 Related work

The identification of repeated elements in Japanese poses unique challenges due to the language's agglutinative nature (Tsujimura, 2013). Unlike Indo-European languages where word boundaries are clearly delineated (Baker, 1992), Japanese requires sophisticated tokenization methods to accurately segment text into meaningful units. As far as we are aware, no previous NLP studies have specifically focused on identifying repeated tokens in Japanese, although some have explored the identification of repetition at the semantic level, not necessarily of the same words (Kawamoto, 2022). However, the repeated elements in this shared task need to be identical, the most straightforward method is to adopt an Natural Language Processing (NLP) tool designed specifically for the Japanese language. Previous studies have recommended MeCab as the de facto text segmentation library capable of part-of-speech (POS) tagging, tokenization and lemmatization for Japanese (Kudo, 2005). Even with MeCab, challenges in identifying repeated elements persist. For example, for "国文学" (Japanese literature) and "漢文学" (Chinese literature), humans may easily detect the repeated element "文学" (literature). However, for MeCab, "国文学" is regarded as one token, while "漢文学" is regarded as two tokens, "漢" and "文学". As such, no repetition can be detected as the tokens do not match.

Recent advancements in LLMs have prompted us to explore them for identifying repeated elements in Japanese text. Prior to building our system, we experimented with GPT-3.5[1] (fine-tuned on the WMT24 training dataset), GPT-4[2] (used direct prompting), and Claude Sonnet 3.5[3] (also used direct prompting) to assess their ability to detect repeated tokens. However, none of these LLMs consistently identified repetitions. This indicates that rule-based approaches using MeCab remain necessary.

Machine translation (MT) between Japanese and English has long been challenging due to the significant linguistic differences between the two languages (Wang et al., 2022). While Neural Machine Translation (NMT) systems, particularly those based on Transformer models (Vaswani et al., 2023), have demonstrated success in handling structured text, they face limitations when dealing with informal language, idiomatic expressions, and culturally specific references. Meanwhile, LLMs such as GPT-3.5 and GPT-4 have shown considerable promise in improving translation quality in Japanese-English (JA-EN) tasks (Vincent et al., 2024). These models benefit from extensive training on diverse datasets, which allows them to generate more contextually appropriate translations, particularly in cases where traditional supervised NMT systems may struggle (Siu, 2023).

Previous studies have compared NMT systems and LLMs in translating high-resource and low-resource languages and found that LLMs such as GPT series perform better in high but not low-resource languages (Robinson et al., 2023). Since Japanese is not considered a low-resource language, we expect LLMs to perform better in this shared task. As thus, we piloted with Google Translate[4], GPT4o and Claude Sonnet 3.5 with the training dataset and found the Claude Sonnet 3.5 performed the best in translating the Japanese texts.

In addition to translation, we aimed to incorporate a proofreading pipeline to enhance overall translation quality. This idea was inspired by the translation-review-revise methodology, which emphasizes iterative improvement of translated content through multiple stages of refinement (Ng, 2024). In line with this methodology, we aimed to incorporate a proofreading process with LLMs as well. In the following, we'll describe in detail the system design and implementation results of our system for the shared task.

3 System description

Our system comprises of four pipelines: 1) the preprocessing pipeline for identifying and subsequently assigning IDs and reference numbers

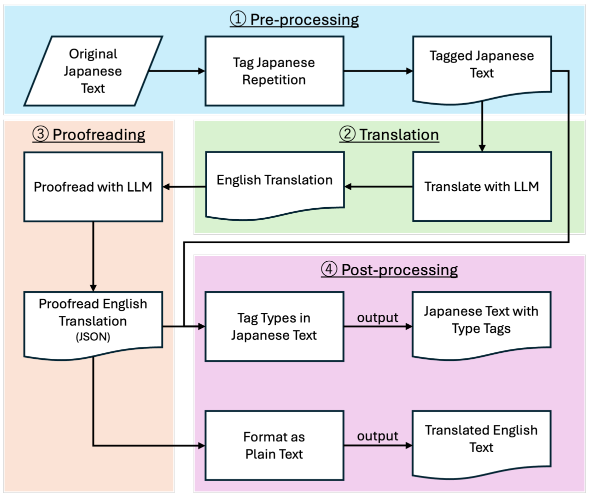

Figure 1: Workflow of the system

(ref numbers) to repeated elements, i.e., targets, in Japanese sentences; 2) the translation pipeline for translating the Japanese sentences into English while trying to reduce redundancy; 3) the proofreading pipeline for revising the translated sentences; and 4) the post-processing pipeline for appending the types of strategies, i.e., substitution or reduction, to the IDs and ref numbers of the repeated targets in the Japanese sentences. The input of the system is the raw Japanese sentences while the output includes the Japanese sentences with repeated targets assigned IDs, ref numbers and types, and raw translated English texts. Figure 1 shows the workflow of the four pipelines. The source code of the developed system can be found at our GitHub repository[5].

3.1 Preprocessing pipeline

For identifying and subsequently assigning IDs and ref numbers to repeated targets in Japanese sentences, we adopted MeCab. The POS tags in MeCab are structured into a maximum of three hierarchical layers. For example, a three-layered POS tag can be “名詞-普通名詞-副詞可能” (noun-common-adverbial), with the top layer indicating the token is a noun, the second layer further explaining it is a common noun, and the third layer showing that the noun can also be used as an adverb.

Step 1: POS tagging We performed POS tagging on all the Japanese sentences in the training dataset, creating a pool of tokens with their POS tags.

Step 2: POS screening From the pool, we first did a simple token match to find repeated tokens. Then, we compared the repeated tokens with the tagged repeated targets in the training dataset to decide what POS tags should be included and what should not in identifying repeated tokens. The result was a ‘whitelist’ of POS tags at different layers. In the first layer, we focused only on content words, including nouns, verbs, adjectives, adverbs and prefixes, while excluding function words such as auxiliaries, conjunctions and particles. For the POS tags from the second layer on, we maximized the coverage of POS tags found in the training dataset while reducing noises. Table 1 shows the POS tags in the ‘whitelist’. Blanks in the third layer indicate that all the third-layer tags have been selected.

Step 3: Identifying targets When identifying the repeated targets, the easiest way is to do exact match. However, for some POS tags, special treatment was necessary. These include Verb, Noun-Suffix, and Prefix-Noun connection.

For Verb, we adopted their lemmatized forms using MeCab. This is due to the fact that Japanese verbs are rich in inflections. For example, the verb “食べる” (*taberu*, meaning “to eat”) can appear in various forms depending on the tense, politeness level, and grammatical context, such as “食べた” (*tabeta*, past tense “ate”), “食べます”(*tabemasu*, polite form “eat”), or “食べられる” (*taberareru*, potential form “can eat”).

For Noun-Suffix and Prefix-Noun, as they are suffixes or prefixes, they should be bound to another token. We thus added a rule where when tokens with the two POS tags are repeated, their neighboring tokens, i.e., the token before the suffix and the token after the prefix, should also be bound together with them. If the bound elements still match, then they are valid targets. Otherwise, they will be dismissed. For example, with the Noun-Suffix “者” (person), if it is preceded twice by the verb “容疑”(suspect), the compound noun

[5] https://github.com/judywq/non-repetitive-translation

Layer 1	Layer 2	Layer 3
Adverb (副詞)	General (一般)	
Verb (動詞)	Independent (自立)	
Noun (名詞)	Suffix (接尾)	Adjectival noun stem (形容動詞語幹) Personal name (人名) Area (地域) Special (特殊)
	Dependent (非自立)	Adverbial (副詞可能)
	Suru verb (サ変接続)	
	Nai adjective stem (ナイ形容詞語幹)	
	General (一般)	
	Proper noun (固有名詞)	
	Adverbial (副詞可能)	
	Adjectival noun stem (形容動詞語幹)	
Adjective (形容詞)	Independent (自立)	
Prefix (接頭詞)	Noun connection (名詞接続)	

Table 1: POS tags in the ‘whitelist’

“容疑者”(a suspected person) will be the valid target. However, if it is preceded by “容疑” once and by “被爆”(be bombed) the second time, they will be dismissed as “容疑者” does not match “被爆者”(an atomic bomb victim).

Step 4: Assigning IDs and ref numbers We assigned IDs and ref numbers to targets based on their order of occurrence in the Japanese sentence. The output of step 4 are Japanese sentences with repeated targets tagged.

3.2 Translation pipeline

The translation pipeline is responsible for translating the Japanese sentences into English while trying to adopt diversified expressions for the repeated targets tagged in the Japanese sentences; singling out the translation for each occurrence of the targets; and deciding which type and subtype of strategy was used. It should be noted that to facilitate understanding of output from the pipeline, we introduced two new types: “first occurrence” and “consistency” and another subtype: “literal translation”, to the original types (substitution and reduction) and subtypes from the official website of the task (WMT24, 2024). First occurrence is assigned to translation of a target where the translation appeared for the first time and thus there is no need to reduce redundancy. Consistency refers to situations where the target is translated into the same English expressions across multiple occurrences. The subtype “literal translation” is added to complement “non-literal translation” original included in the examples from the official website.

For this pipeline, we adopted Claude Sonnet 3.5 with few-shot in-context learning prompting techniques. In our prompt, we included the explanation of the shared task and the examples of reduction and substitution from the task’s official website. Then we asked the translation pipeline to translate the sentences while trying its best to adopt diversified expressions for the repeated targets tagged in the Japanese sentences, single out the translations for the targets and decide which type and subtype of strategy was used.

For example, for the input sentence:

> RCEP では、7 月 1 日に東京で閣僚 <target id=0 ref=0> 会合 </target> が開かれ、妥結に向け 11 月下旬にシンガポールで首脳 <target id=0 ref=1> 会合 </target> が開催できるよう、交渉に注力する方針を確認。

the output from the translation pipeline is as follows:

```
{
"en_translation": "For RCEP, a ministerial
meeting was held in Tokyo on July 1,
confirming the policy to focus on negotiations
with the aim of holding a summit in Singapore
in late November to reach an agreement.",
  "targets":
  [
    {
      "id": "0",
      "ref": "0",
      "ja_element": "会合",
      "en_element": "meeting",
      "type": "f",
      "subtype": "lt"
    },
    {
      "id": "0",
      "ref": "1",
      "ja_element": "会合",
      "en_element": "summit",
      "type": "s",
      "subtype": "syn"
    }
  ]
}
```

3.3 Proofreading pipeline

For the proofreading pipeline, we also adopted Claude Sonnet 3.5. Few-shot in-context learning prompt was also designed for this pipeline as for the translation pipeline. The proofreading pipeline receives the Japanese sentence and the translated text, the translations for each occurrence of repeated targets and the types and subtypes of strategies used. It is asked to check if the translation is faithful to the Japanese sentence and if redundancy can be further reduced. If changes are not necessary, it returns

```
{"changed": "No"}
```

Otherwise, it returns

```
{"changed": "Yes"}
```

followed by a revised output in the same format as the translation pipeline. A sample output from the pipeline is shown below:

```
{
  "changed": "Yes",
  "en_translation_updated": "Toshiba stated
  that there is no change to its previous
  projection, as the reversal is already
  incorporated into the full-year earnings
  outlook for the fiscal year ending
  March 2019.",
  "targets_updated":
  [
    {
      "id": "0",
      "ref": "0",
      "ja_element": "予想",
      "en_element": "outlook",
      "type": "f",
      "subtype": "lt"
    },
    {
      "id": "0",
      "ref": "1",
      "ja_element": "予想",
      "en_element": "projection",
      "type": "s",
      "subtype": "syn"
    }
  ]
}
```

3.4 Post-processing pipeline

With the proofread sentence translation and translations of each occurrence of repeated targets together with the types and subtypes of strategies, the post-processing pipeline first appends the types of the translations to the ID and ref number of each occurrence of repeated targets in the Japanese text. Then it replaces the two types we added with the two official types, reduction or substitution. Specifically, in the case of first occurrence, the type of same ID but the following/previous ref number target will be adopted. For example, if for a target A where it appears twice in a sentence, it has two occurrences: ID=0, Ref=0, Type= first occurrence; and ID=0, Ref=1, Type= substitution. The type in ref=0 is replaced by the type in ref=1, substitution. For consistency, which means our system deems it unnecessary to reduce redundancy, we remove the IDs and ref numbers of the targets in the Japanese text. This is based on the official dataset where only the targets that require redundancy reduction are tagged with IDs and ref numbers.

After the post-processing pipeline, the system outputs the Japanese sentences with IDs, ref numbers and types tagged for repeated targets and the raw English translation without any tags.

We also considered situations where our system may fail to identify any repeated targets in the pre-processing pipeline. In such cases, the raw Japanese sentences will be translated into English by Claude Sonnet 3.5 and the system will directly output the raw Japanese sentence and its English translation.

JPO Adequacy	<NON-REP>	<REP>	<INCORRECT>	Total
[5,5]	127	20	0	147
[4,5)	280	17	3	300
[3,4)	15	1	7	23
[2,3)	0	0	0	0
[1,2)	0	0	0	0
Total	422	38	10	470

Table 2: JPO adequacy and translation style

4 System implementation and results

Our system was applied to translate 470 sentences from the test dataset provided by the Non-Repetitive Translation Task at WMT24. The output from our system was rigorously evaluated by three human raters assigned by the task organizers. Each rater independently reviewed the translation of the repeated targets and assigned each target a translation quality score ranging from 1 to 5 based on criterion for translated patent documents from the Japanese Patent Office (JPO), with 5 representing the highest quality (JPO adequacy). The raters also labelled each translation target with one of the following translation styles: "c" (consistent/repetitive translation), "s" (substitution), "r" (reduction), or "m" (mistake in translation). The final evaluation score for each sentence was determined by averaging the scores given by the three raters and the label was determined by a majority vote.

In the 470 sentences, there are a total of 489 repeated targets tagged by the organizers in the dataset, meaning that some sentences contain more than 1 repeated target. When there are multiple targets in one sentence, the evaluation of all targets is aggregated to one by the organizers, resulting in 470 evaluation instances for the 470 sentences in total. Results suggest that our system produced 38 instances of repetitive translations, 422 instances of correct non-repetitive translations, and 10 incorrect translations. This shows a correct non-repetitive translation rate of 89.79% for our system.

Table 2 shows the detailed evaluation results including the instance counts of translation styles (non-repetitive, repetitive and incorrect translation) and translation quality (JPO adequacy).

The average JPO adequacy of our system is 4.60, significantly higher than that of the baseline system at 3.88 (t=14.09, p<0.00). To view the balance between translation quality and style, the JPO adequacy score for each instance are converted to 0 if its style is not '<NON-REP>', i.e., correct non-repetitive translation. The average of this filtered JPO scores is 4.13. This is significantly higher than the baseline system at 2.13 (t=16.60, p<0.00).

For reference purposes, our system's performance was also evaluated using the BLEU metric (Papineni et al., 2002). The BLEU score for our system was 24.4, indicating moderate similarity to the human benchmark translations provided by the organizers. The verbose BLEU score breakdown shows a precision of 58.3% for 1-grams, 30.0% for 2-grams, 18.0% for 3-grams, and 11.3% for 4-grams. No Brevity Penalty (BP) was applied, as the length of the system's output (15,700 words) closely matched that of the benchmark (15,579 words), with a length ratio of 1.008.

5 Discussions

Our system demonstrated high performance in the shared task, effectively combining multiple NLP and LLMs pipelines to achieve impressive results. However, some issues were observed that highlight the challenges of this task and the limitations of our approach.

One challenge our system faced was in certain tagging targets deemed repetitive by human raters, particularly those related to standalone noun-suffix elements. For example:

> **Japanese:** 専門家の 1 人は、鑑定した 110 個の遺骨の中で日本人の DNA<target_1> 型 </target_1> は 5 個、フィリピン人の <target_1> 型 </target_1> が 54 個だったと報告。
>
> **System Translation:** One of the experts reported that among the 110 bone samples examined, 5 had DNA patterns matching Japanese individuals, while 54 had patterns matching Filipino individuals.

In this instance, our system failed to identify the target "型" (type), a noun-suffix, as a repeated element and subsequently the translation style was consistent. According to Step 3 in the pre-processing pipeline, noun-suffixes are only identified as repeated targets if their preceding tokens also match. This rule was implemented to reduce noise; however, it led to the negligence of independent suffixes tagged by humans in the benchmark dataset. A similar issue occurred with the word "量" (quantity) in the following sentence:

> **Japanese:** 国際貨物 <target_1> 量 </target_1> は 10%減の 16 万 8510 トン。|| ジェット燃料給油 <target_1> 量 </target_1> は 2%減の 37 万 3805 キロリットルだった。
>
> **System Translation:** International cargo volume decreased by 10% to 168,510 tons. Jet fuel supply volume fell by 2% to 373,805 kiloliters.

In this example, "量" was not identified as a repeated target, resulting in the translation being repeated instead of diversified.

Moreover, there were instances where our system correctly identified repeated targets but still opted for consistent translations. This occurred in cases where the system judged consistent translation to be preferable or where it misinterpreted derivatives or inflected forms of a word as non-repetitive. For example:

> **Japanese:** 同氏は <target_1> 五輪 </target_1> には 04 年アテネ <target_1> 五輪 </target_1> から 4 大会連続で出場した。
>
> **System Translation:** He competed in four consecutive Olympic Games, starting with the 2004 Athens Olympics.

In this case, our system treated "Olympic Games" and "Olympics" as substitutions. However, human raters considered these terms to be consistent translations, as the word "Olympic" and its inflected form "Olympics" are essentially the same. Though we stated specifically in our prompts to Claude that derivatives and inflected forms are consistent translations, it failed to perform the translation/proofreading task adequately in some cases.

In the 10 instances where the system produced incorrect translations, these errors occur because the translations are too flexible and non-literal, compromising the "faithfulness" of translation. An example of such an error is:

> **Japanese:** 一方、66 歳以降も働きたいと答えた人が挙げた理由は、「<target_1> 経済的 </target_1> にゆとりある生活を送りたい」が 28.9%、「働き続けないと生活費が足りないと思う」24.9%などで、<target_1> 経済的 </target_1> な理由が半数を超えた。
>
> **System Translation:** On the other hand, among those who expressed a desire to continue working beyond the age of 66, over half cited financial reasons. The most common reasons were 'wanting to maintain a comfortable lifestyle' (28.9%) and 'believing that living expenses would be insufficient without continued employment' (24.9%).

In this example, "the most common reasons" should be interpreted as "the most common comments given by those who cited financial reasons". However, the translation assumes that readers can infer from the text, but the same word "reasons" makes the sentence confusing.

6 Conclusions

In conclusion, the proposed multi-pipeline Japanese-to-English machine translation system successfully addresses the challenge of translating repeated elements from Japanese into fluent and varied English. By integrating MeCab for accurate tokenization and Claude Sonnet 3.5 for translation and proofreading, the system achieved a high rate of correct non-repetitive translations, with a translation quality score that significantly exceeded the baseline. However, certain challenges remain, particularly in identifying and translating standalone noun-suffix elements and in cases where consistent translation is deemed preferable. Additionally, the study highlighted the limitations of current human evaluation processes, where inter-rater reliability was low, affecting the consistency of the evaluation results. Future work could explore more advanced language models and refined evaluation methodologies to further enhance the system's performance and address these challenges.

Limitations

In our translation pipeline, we compared the performance of Claude with Google Translate and GPT-4 before selecting Claude as the translation model. However, it is important to acknowledge that more effective LLMs may emerge in the future, which could offer improved performance. Besides, one of the inherent issues of relying on commercial LLMs like Claude is the issue of token limits, which can pose challenges in large-scale projects where the tasks requires days to complete.

Furthermore, the inter-rater reliability among the human raters was relatively low. We noticed that one of the raters was conspicuously more severe in their evaluations compared to the other two raters. The inter-rater reliability analysis also revealed only a slight agreement among the raters for JPO Adequacy, with an average Weighted Kappa (Cohen, 1968) of 0.161. The Fleiss' Kappa (Fleiss, 1971) for Style was -0.204, suggesting that the agreement among the raters was not only poor but worse than what would be expected by chance. This means that the evaluation results may have differed if the inter-rater reliability was higher. To illustrate, the raters did not reach consensus on some mistranslations. The following shows an example:

> **Japanese:** JAXA によると、<target_1> クレーター </target_1> は直径 10 メートル規模と推測され、小惑星への人工 <target_1> クレーター </target_1> 生成に成功したのは世界で初めてだという。
>
> **System Translation:** According to JAXA, the crater is estimated to be about 10 meters in diameter, marking the world's first successful artificial impact on an asteroid.

In this example, the word "impact" can be considered a term referring to "a collision between astronomical objects causing measurable effects" (Rumpf et al., 2017) in planetary science, which usually results in the formation of an impact crater. In this sense, it may be a substitution to "crater". Indeed, one rater regarded it as an appropriate substitution and scored it a 5, while the other two raters considered it an incorrect translation. Such disagreement highlights the importance of a more rigorous and standardized human evaluation process in future tasks.

Acknowledgement

We would like to thank the task organizer and their raters who evaluated the performance of our system. Our gratitude also extends to Jiji Press LTD for providing the datasets used in this study.

Abstract

Many contemporary NLP systems rely on neural decoders for text generation, which demonstrate an impressive ability to generate text approaching human fluency levels. However, in the case of neural machine translation networks, they often grapple with the production of repetitive content, also known as repetitive diction or word repetition, an aspect they weren't explicitly trained to address. While not inherently negative, this repetition can make writing seem monotonous or awkward if not used intentionally for emphasis or stylistic purposes. This paper presents our submission to the WMT 2024 Non-Repetitive Translation Task, for which we adopt a repetition penalty method applied at learning inspired by the principles of label smoothing. No additional work is needed at inference time. We modify the ground-truth distribution to steer the model towards discouraging repetitions. Experiments show the ability of the proposed methods in reducing repetitions within neural machine translation engines, without compromising efficiency or translation quality.

1 Introduction

The Non-Repetitive Translation Task of the ninth Conference on Machine Translation (WMT24) focuses on lexical choice in machine translation, especially choice regarding repeated words in a source sentence. Generally, the repetition of the same words can create a monotonous or awkward impression in English, and it should be appropriately avoided. Typical workarounds in monolingual writing are to

1) remove redundant terms if possible (reduction) or

2) use alternative words such as synonyms as substitutes (substitution).

These techniques are also observed in human translations. The goal of this task is to study how these techniques can be incorporated into machine translation systems to enrich lexical choice capabilities. From a practical standpoint, such capability would be important, for example, in news production, where high quality text that goes beyond robotic word-by-word translation is required.

In addition, repetitions do not always have a negative impact on readability. Without aiming to be exhaustive : i) repetitions play a role when summarizing information or reinforcing a concept ; ii) common expressions are formed using word repetitions, and altering them to eliminate repetition would alter their intended meaning ; iii) in highly specialized domains, expressions convey precise meanings that disallow being reformulated. The following examples illustrate these observations :

i) once closed, the door stays closed

ii) over and over ; to be or not to be ; step by step

iii) the congenital muscular dystrophy in newborns presenting with muscular hypotonia

As previously introduced, finding suitable alternatives without altering the meaning of a sentence can be a challenging task.

Participants are required to control a machine translation system using reduction or substitution so that it does not output the same words for certain repeated words in a source sentence. The translation direction is Japanese to English.

2 Related Work

The fluency levels achieved by LLMs are widely acknowledged to be high, primarily owing to the extensive availability of monolingual datasets, which surpasses that of standard neural machine translation (NMT) models trained solely on parallel texts. To the best of our knowledge, no dedicated research has been conducted on addressing the repetition issue tackled in this work within NMT systems.

Proceedings of the Ninth Conference on Machine Translation, pages 1056–1062
November 15-16, 2024 ©2024 Association for Computational Linguistics

Closely related, Welleck et al. (2019) describe a method to train neural language models that in addition to maximizing likelihood to model the overall sequence probability distribution, also includes an unlikelihood term in the loss function to correct known biases such as repeated tokens. Li et al. (2020) use the same approach to control copy effect and repetitions observed in dialogue tasks. Su et al. (2022) present a contrastive solution to encourage diversity while maintaining coherence in the generated text.

Various studies have addressed diversity in neural MT systems, which is a closely related topic. Sampling predictions from the output distribution can be an effective decoding strategy for back-translation, as described by Edunov et al. (2018), or sampling from less likely tokens Holtzman et al. (2020). Results show that such techniques enlarge diversity and richness of the generated translations when compared to data generated by beam or greedy search, but introduce semantic inconsistency in translations. In Lin et al. (2022) is proposed a multi-candidate optimization framework for augmenting diversity. The authors propose to guide an NMT model to learn more diverse translations from its candidate translations based on reinforcement learning. During training, the model generates multiple candidate translations, of which rewards are quantified according to their diversity and quality.

A different approach attempts to condition the decoding procedure with diverse signals. Typically, Shu et al. (2019) use syntactic codes to condition the translation process. Lachaux et al. (2020) replace the syntactic codes with latent domain variables derived from target sentences. Similarly, Schioppa et al. (2021) use prefix-based control tokens and vector-based interventions for controlling output translations from a NMT system. In the context of paraphrase generation Vahtola et al. (2023) propose a translation-based guided paraphrase generation model that learns useful features for promoting surface form variation in generated paraphrases.

3 Adjusting the ground-truth distribution

Throughout the training process, at every time-step t, neural machine translation networks generate predictions over the target-side vocabulary based on the input x and previous predictions $y_{<t}$:

$$p_t^i = p(y_t^i | x, y_{<t}),\ i \in [1, ..., V]$$

where V indicates the size of the target vocabulary.

The loss function evaluates the neural network's capacity to model the training data by comparing its predictions to a reference target vector $r = [r_1, r_2, ..., r_T]$, where T denotes the sequence length. This loss is utilized to update the network's parameters, aiming to minimize the observed error in the model. The loss at time-step t is usually computed as the cross-entropy between the model predictions $p_t = [p_t^1, ..., p_t^V]$ and the ground-truth distribution $q_t = [q_t^1, ..., q_t^V]$:

$$_t = -\sum_{i=1}^{V} q_t^i \, log(p_t^i) \qquad (1)$$

Note that the vector q_t is a one-hot encoding representation of r_t, with all entries set to 0 except for the token indicated by r_t, which is set to 1. Addressing the over-fitting risk illustrated by the previous q_t distribution, label smoothing Szegedy et al. (2015); Müller et al. (2019) (LS) is widely employed to achieve a smoother distribution:

$$q_t^{\epsilon LS} = (1 - \epsilon) q_t + \frac{\epsilon}{V} \qquad (2)$$

with ϵ being a commonly small hyper-parameter.[1]

t	1	2	3	4	5	6
r	I	like	cookies	and	cookies	.

.	0	0	0	0	0	0
I	0	0	0	0	0	0
and	0	0	0	0	0	0
like	0	0	0	0	0	0
cookies	0	0	0	0	1	0

Figure 1: Matrix for the ground-truth r =’*I like cookies and cookies.*’. Rows t and r represent respectively the time-step and the corresponding ground-truth token. A reduced model vocabulary (matrix rows) is used to facilitate reading.

LS can be interpreted as penalizing the probability of the ground-truth class by a factor of $1 - \epsilon$, while evenly distributing the removed probability mass among all classes, ϵ/V. Building upon a strategy akin to label smoothing, we make additional adjustments to the ground-truth distribution and reduce the likelihood of repeated tokens, with the

[1] $\epsilon = 0$ yields the initial distribution q_t, whereas $\epsilon = 1$ implies a uniform distribution.

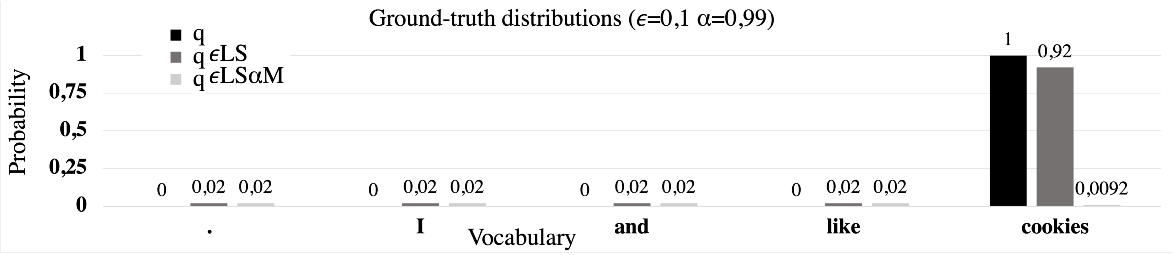

Figure 2: Ground-truth distributions for the 5^{th} time-step of our example: the original one-hot encoding q; adjusted with label smoothing $q^{\epsilon LS}$; and further adjusted with repetitions $q^{\epsilon L\alpha}$.

goal of enabling the model to learn to predict repetitions with lower probability. We introduce a matrix, denoted as $_{V\times T}$, which indicates whether the ground-truth token r_t is also present in the preceding time-steps.[2] Figure 1 illustrates an example of matrix with ground-truth *I like cookies and cookies.* as translation of the Japanese sentence クッキーとビスケットが好き with a model vocabulary of 5 tokens (matrix rows). Both Japanese terms クッキー *[cookies]* and ビスケット *[biscuits]* are correctly translated into English as *cookies*, yet this choice clearly reduces the fluency and clarity of the translation. As it can be seen, only $_{[i=5,t=5]}$ is set to 1 since only r_5 =’*cookies*’ occurs in a preceding time-step ($t = 3$).

We consequently update the ground-truth distribution following:

$$q_t^{\epsilon LS\alpha} = (1-\epsilon)(1-\alpha_t)\; q_t + \frac{\epsilon}{V} \qquad (3)$$

where α is a hyper-parameter, and α is used as a penalty, much like ϵ in the case of LS. Note that only the label smoothing probabilities discounted are distributed among all classes. As a result, time-steps with repeated tokens (such as $t = 5$ in our example) do not constitute proper probability distributions, as their sum does not add to 1. Figure 2 illustrates ground-truth distributions for our example at time-step $t = 5$: the original one-hot encoding q; the original distribution adjusted using label smoothing $q^{\epsilon LS}$, and further adjusted using repetitions $q^{\epsilon LS\alpha}$.[3] A significant challenge with the aforementioned techniques that modify q distribution with repetitions is their limited impact on the training process, primarily caused by the scarcity of repeated tokens in datasets. In the following section, we present alternative approaches to address this challenge.

4 Gathering Examples with Repetitions

As previously depicted, our intention is to instruct the model to minimize certain repetitions while preserving others deemed necessary for an accurate translation. To achieve this, we must compile a relatively large dataset of examples that demonstrate this behavior to the model. We initially focus on repetitions of content words such as *nouns*, *adjectives*, *verbs*, and *adverbs*. Function words, which serve a distinct grammatical role in a sentence, are excluded from this analysis. Current MT networks reliably generate these words based on their understanding of grammatical correctness.

We back-translate the Japanese side of the JiJi corpus (further detailed in Section 5.1) into English and annotate word (or sequence) repetitions of content words based on automatic morpho-syntactic annotations performed by Spacy[4]. We employ word-alignments between Japanese and English words performed by the Giza++ Och and Ney (2003) toolkit[5] in order to consider only repetitions of English content words aligned to Japanese content words (Verbs, Nouns, Adjectives and Adverbs). The resulting set of examples with repetitions from src/tgt training pairs will be regarded as instances that the model needs to learn to discourage. Consequently, we utilize them for training after annotating the repeated target words in their respective matrices.

It’s worth noting that the presented approach does not require any alterations to the network architecture and maintains the same training and inference efficiency.

[2] Note that repetitions are computed over words while matrix refers to tokens $r \in V$ for each time-step $t \in T$.

[3] As previously discussed, distribution $q^{\epsilon LS\alpha}$ does not form a proper distribution since probabilities do not add to 1 ($0,02+0,02+0,02+0,02+0,0092 = 0,0892$). We leave for future experiments the normalization of the output scores in order to allow for a valid probability distribution.

Table 1: example of Japanese-English translation: raw translation is shown at the top, and the tagged translation to annotate repetitions is shown at the bottom.

5 Experimental Framework

5.1 Datasets

We evaluate the proposed methods in a Japanese-to-English translation task. Thus, we utilize Japanese-English parallel corpora freely obtained from the WMT24 for Non-Repetitive Translation Task website[6]. The corpus is compiled by Jiji Press Ltd in collaboration with the National Institute of Information and Communication Technology (NICT) with various categories, including politics, economy, nation, business, markets, sports, etc., for use in machine translation, in particular for previous the Workshop on Asian Translation (WAT)[7].

Table 2 presents various statistics of the corpora used in this work, including the total number of sentences, vocabularies, words, and average sentence length. Statistics are computed after performing a light tokenization aiming to split-off punctuation. For testing, we use the supplied Japanese-English datasets made available by the task organizers.

Lang	#Sents	#Vocab	Words	Length
Training-set				
Jap	200k	$49K$	6.9M	4.46
Eng		118K	4.5M	24.64
Repetition-set				
Jap	470	$3,297$	$23,472$	4.22
Eng		$4,341$	$13,814$	11.91

Table 2: Corpora statistics. M and K stand for millions and thousands respectively.

Due to the poor alignment quality of the Japanese-English parallel sentences present in the provided dataset (sentence pairs are coupled using an automatic cross-lingual sentence similarity score) we decided to back-translate the English side using an in-house English-Japanese model. Then, using the resulting Japanese[8]-English dataset we fine-tune our baseline Japanese-English model.

In addition, we use a test set of repetitions also provided by the challenge, consisting of reference English machine translations and their corresponding Japanese machine translations that include at least one word repeated on the target (English) side for a more nuanced analysis of repetition. Among the files corresponding to the test datasets are those containing tagged files in which repeated words and their translations in each sentence pair are marked with tags <*target*> and <*/target*>. Marked words indicate that they are evaluated repetitions. Three labels, 'id', 'ref' and 'type' are embedded within the tags. Table 1 illustrates an example, where:

id indicates IDs of repated words. In the above example, two tagged repeated words are included, i.e., 機能 (id=0) and 製品 (id=1). The number of instances including multiple id's, such as the above example, are limited.

ref indicates IDs of pairs of source/target words, such as 製品/*models* (id=1, ref=0) and 製品/*products* (id=1, ref=1).

type indicates whether they are substituted (*s*) or reduced (*r*).

The *Repetition-set* is mainly used to evaluate the performance of our models in handling repetition problems, as well as to assess overall translation accuracy.

5.2 NMT Models

Our NMT model is built using an in-house implementation of the state-of-the-art Transformer architecture Vaswani et al. (2017). Details of the network hyper-parameters emplooy for training are given in Table 3.

size of word embedding	512
size of hidden layers	512
size of inner feed forward layer	$2,048$
number of heads	8
number of layers	6
batch size	$4,000$ (tokens)
batch accumulation	25 (batches)

Table 3: Network hyperparameters.

For optimization work we use the lazy Adam algorithm Kingma and Ba (2014). We set warmup steps to $4,000$ and update learning rate for every 8 iterations. All models are trained using a single NVIDIA V100 GPU.

We limit the source and target sentence lengths to 150 tokens based on BPE Sennrich et al. (2016) preprocessing. A total of $28K$ BPE merge operations are separately computed for each language. We finally use a joint Japanese and English vocabulary of $58K$ tokens. In inference we use a beam size of 5.

Our *baseline* English-to-Japanese model is trained during more than 3 million iterations using all the parallel data available in the Opus website[9].

6 Results

To evaluate the method presented in this paper we consider the previous *baseline* model that we update with 15K additional iterations for two different configurations of the ground-truth distribution:

$q^{\epsilon LS}$ follows the same configuration than our *baseline* model with label smoothing set to $\epsilon = 0.1$.

$q^{\epsilon LS\alpha}$ further penalizes the ground-truth distribution with repetition penalties as detailed in Section 3 with $\epsilon = 0.1$ and for different values of α.

Note that for both configurations, we use the same training corpus detailed in Table 2 (*Training-set*).

We also assess the effectiveness of two large language models (LLM) with translation capabilities to overcome the repetition issue:

$GPT3.5$ consists of the *GPT3.5-turbo* version of the OpenAI LLM. Built upon the Generative Pre-trained Transformer architecture Radford and Sutskever (2018) which employs only a transformer decoder. Following an auto-regressive approach, the model ensures that the generated text maintains coherence and relevance to the context provided by the input text. Translations are conducted using the OpenAI API, while emphasizing the importance of minimizing word repetitions through the provided prompt: *Translate the following text from English to Japanese, ensuring that the translated output maintains coherence and fluency while minimizing the repetition of words or phrases. Pay attention to using synonyms, varied sentence structures, and appropriate linguistic devices to enhance the overall quality of the translation. Feel free to creatively adapt the language to achieve a natural and engaging tone in the target language. I want you to only reply the translation, do not write explanations.*

$NLLB$ is a family of machine translation models based on the Transformer encoder-decoder architecture, enabling translation between any of the 202 language varieties NLLB Team et al. (2022). We use the *nllb-200-distilled-600M*[10] version and perform translations with the efficient CTranslate2[11] inference toolkit.

To evaluate the presented methods, we report `BLEU` results computed by `sacrebleu`[12] Post (2018) respectively over test sets. We also report the number of word repetitions that hinder fluency, *Degrading*, after a human evaluation performed on translation hypotheses. Table 4 summarize results obtained by different system configurations.

Models fine-tuned from the *baseline* network exhibit nearly identical quality scores across the *test* set. This suggests that training with the method presented to adjust the ground-truth distribution does not compromise translation quality. On the contrary, unlike Configuration $q^{\epsilon LS}$, Configurations $q^{\epsilon LS\alpha}$ demonstrate a significant decrease in the number of repetitions that degrade fluency over the *Repetition-set*, while retaining most of the acceptable repetitions in the translated output.

[9] `https://opus.nlpl.eu/`

[10] `https://huggingface.co/facebook/nllb-200-distilled-600M`

[11] `https://github.com/OpenNMT/CTranslate2`

[12] `https://github.com/mjpost/sacrebleu`

Results from both LLMs demonstrate a reduced number of repetitions, suggesting an elevated level of diversity and fluency of such models. However, the translation quality scores of LLMs do not align with those achieved by the models presented in this study in either of the test sets, especially translations obtained by GPT-3.5. These findings are consistent with those presented by Bawden and Yvon (2023) where the authors note the challenge of controlling translations performed by BLOOM[13], a multilingual LLM.

Configuration	BLEU	*Degrading*
$q^{\epsilon LS}$	28.41	77
$q^{\epsilon LS\alpha}, 1-\alpha = 10^{-6}$	28.91	60
$GPT3.5$	19.29	64
$NLLB$	16.12	74

Table 4: Translation accuracy results and number of repetitions present in translations performed by models under different configurations. ϵ is always set to 0.1.

7 Conclusions and Further Work

We presented SYSTRAN submission to the WMT24 Non-Repetitive Translation Task. Our NMT systems introduce a method to reduce the occurrence of repetitions in translation hypotheses, which significantly affects the readability of the generated texts. The method is solely implemented during fine-tuning at the conclusion of the training phase, without any modifications to the inference process. Experiments indicate the ability of our proposed methods in reducing the repetition problem.

We aim to further study the impact of the ratio between the number of reference sentences and synthetic translations that include repetitions during the training process. Additionally, we plan to analyze the influence of the distance (measured in number of words) between repetitions and explore the possibility of replacing the binary penalty in matrix with a softer approach.

Mitigating Metric Bias in Minimum Bayes Risk Decoding

Geza Kovacs and **Dan Deutsch** and **Markus Freitag**
Google
{geza, dandeutsch, freitag}@google.com

Abstract

While Minimum Bayes Risk (MBR) decoding using metrics such as COMET or MetricX has outperformed traditional decoding methods such as greedy or beam search, it introduces a challenge we refer to as *metric bias*. As MBR decoding aims to produce translations that score highly according to a specific utility metric, this very process makes it impossible to use the same metric for both decoding and evaluation, as improvements might simply be due to *reward hacking* rather than reflecting real quality improvements. In this work we find that compared to human ratings, neural metrics not only overestimate the quality of MBR decoding when the same metric is used as the utility metric, but they also overestimate the quality of MBR/QE decoding with other neural utility metrics as well. We also show that the metric bias issue can be mitigated by using an ensemble of utility metrics during MBR decoding: human evaluations show that MBR decoding using an ensemble of utility metrics outperforms a single utility metric.

1 Introduction

Minimum bayes risk (MBR) decoding is a decoding approach where n candidate translations are sampled from the MT system, and they are used as pseudoreferences for a reference-based *utility metric*. MBR decoding computes the utility metric for all $O(n^2)$ pairs of candidates and pseudoreferences, selecting the candidate that achieves the best average score across all pseudoreferences. Quality Estimation (QE) decoding[1] selects the candidate that scores best according to a QE utility metric. Previous work on MBR decoding has shown that it results in improvements on the utility metric (Amrhein and Sennrich, 2022; Cheng and Vlachos, 2023; Eikema and Aziz, 2022), however other metrics do not improve as much as the utility metric (Guttmann et al., 2024; Vamvas and Sennrich, 2024). This issue of MBR/QE decoding exhibiting bias towards the utility metric complicates our ability to use automatic metrics to compare the quality of MBR/QE-based MT systems, as we cannot tell whether improvements in automatic metrics from MBR/QE decoding correspond to actual improvements in quality, or if it simply reward hacking. Prior work has assumed that this issue can be avoided by using a different metric for evaluating MBR decoding outputs (Tomani et al., 2023), though this assumption has never been tested.

In this work we compare the results of human vs metric-based evaluation of MBR/QE decoding with a wide variety of metrics to show that the quality of MBR/QE decoding is overestimated by not only the utility metric, but also other similar metrics. While MBR/QE decoding with a single utility metric results in significant gains in automatic metrics, it does not perform better than greedy decoding in our human evaluations. This may be due to MBR decoding preferring fluent yet inaccurate candidates. Using an ensemble of metrics as the utility helps us mitigate the metric bias issue, with human evaluations showing that MBR decoding with an ensemble utility metric results in significantly better translations than greedy decoding or MBR/QE decoding with a single utility metric.

In this paper we contribute:

1. A large-scale analysis of metric bias in MBR and QE decoding with metrics commonly used in MT, showing that this metric bias issue holds across many different metrics and language pairs, and is not resolved by simply using a different metric for evaluation.
2. Mitigation strategies for MBR bias using QE filtering followed by MBR decoding, as well as MBR decoding using an ensemble of metrics as the utility function.
3. A human evaluation showing that MBR decoding with ensembles outperforms MBR decoding with a single metric.

[1] Also known as QE reranking or QE filtering.

2 Related Work

Cheng and Vlachos (2023); Eikema and Aziz (2022); Guttmann et al. (2024) find that MBR decoding improves automated metrics on various high, medium, and low resource language pairs. Freitag et al. (2023a, 2022); Tomani et al. (2023) find that human raters prefer the outputs of MBR/QE decoding over greedy decoding.

MBR variants achieve speedups via heuristics (Trabelsi et al., 2024; Jinnai and Ariu, 2024), filtering pseudoreferences via a QE metric (Deguchi et al., 2024, 2023) or filtering via another reference-based metric (Vamvas and Sennrich, 2024; Eikema and Aziz, 2022). Quality-aware translation, which incorporates quality estimation into the training process, has been found to improve translation quality over standard MBR (Tomani et al., 2023).

Other techniques for aligning translation models with human preferences include direct preference optimization (Rafailov et al., 2024; Yang et al., 2024), reinforcement learning from human feedback (Christiano et al., 2017), and reinforcement learning from AI feedback (Bai et al., 2022).

Guttmann et al. (2024); Vamvas and Sennrich (2024) show evidence of metric bias in MBR decoding, as they find that neural evaluation metrics favor models using MBR on the metric used as the utility function. However, these papers only cover only 2 metrics, and neither have human evaluations.

Sellam et al. (2020b); Freitag et al. (2023b); Glushkova et al. (2023) find that ensembling metrics can improve their ability to detect critical errors and improve agreement with human preferences, though they do not investigate the effects of ensembling utility metrics on MBR decoding.

Reward hacking (Skalse et al., 2022) is an issue in reinforcement learning where the reward function improves but the system's behavior is not aligned with human preferences. The metric bias problem in MBR decoding can be viewed as an instance of reward hacking, as the utility function improves while not necessarily improving quality.

3 Study 1: Metric Bias in MBR Decoding

3.1 Methodology

To investigate metric bias in MBR/QE decoding, we perform MBR/QE decoding via various utility metrics and compare how they perform on various evaluation metrics. We investigate MBR decoding using these reference-based utility metrics:

1. MetricX-23 (Juraska et al., 2023)
2. XCOMET-XXL (Guerreiro et al., 2023)
3. XCOMET-XL (Guerreiro et al., 2023)
4. COMET22 (Rei et al., 2022a)
5. AfriCOMET (Wang et al., 2024)
6. IndicCOMET (Sai B et al., 2023)
7. BLEURT (Sellam et al., 2020a)
8. YiSi-1 (Lo, 2019)
9. sentBLEU (Papineni et al., 2002)
10. chrF (Popović, 2015)
11. chrF++ (Popović, 2017)
12. TER (Snover et al., 2006)

We also investigate QE decoding (Fernandes et al., 2022) using the following QE metrics:

1. MetricX-QE (Juraska et al., 2023)
2. CometKiwi23-XXL (Rei et al., 2023)
3. CometKiwi23-XL (Rei et al., 2023)
4. CometKiwi22 (Rei et al., 2022b)
5. AfriCOMET-QE (Wang et al., 2024)

We used a dev set for selecting ensembles, and a test set for reporting final results and human evaluation. The dev datasets and language pairs are:

1. FLORES-200 dev set (Costa-jussà et al., 2022): English-Swahili (en-sw), Igbo (en-ig), Hindi (en-hi), Tamil (en-ta), Somali (en-so), Hausa (en-ha), Malayalam (en-ml), Gujarati (en-gu), Hungarian (en-hu), Vietnamese (en-vi)
2. WMT2022 (Kocmi et al., 2022): English-Chinese (en-zh), Chinese-English (zh-en), English-German (en-de), German-English (de-en)

The test set datasets and language pairs are:

1. FLORES-200 test set: en-sw, en-ig, en-hi, en-ta, en-so, en-ha, en-ml, en-gu, en-hu, en-vi
2. WMT2023 (Kocmi et al., 2023): en-zh, zh-en[2], en-de, de-en

We produced translations using Gemini 1.0 Pro (Gemini Team Google, 2023) with prompts including 5-shot examples. We used epsilon sampling as recommended by Freitag et al. (2023a) with a sample size of 128. See Appendix A for prompts used for generating translations and instructions for computing scores from metrics.

[2] Due to errors in the WMT2023 zh-en reference translations, we use the references from Liu et al. (2024) for zh-en.

Table 1: Reference-based and QE evaluation scores for greedy and MBR/QE decoding (1^{st} block), and ensembles (2^{nd} block), averaged across all languages (test datasets). Higher scores are better, except MetricX, MetricX-QE, and TER, where lower is better. Green is better than greedy, red is worse. Ensembles are defined in Table 2. Significant differences from greedy (pairwise t-test) indicated by * for $p<0.05$, † for $p<0.01$, ‡ for $p<0.001$. The green diagonal in the 1^{st} block shows metrics prefer outputs from MBR/QE decoding using the same utility metric.

Table 2: Metrics included in each ensemble. Rows are ensembles, columns are metrics. Black cells indicate that the metric is included in a single-step ensemble. Green cells indicate the metric is used for the 1^{st} step (QE filtering) in a 2-step ensemble. Red cells indicate the metric is used for the 2^{nd} step (MBR decoding) in a 2-step ensemble.

3.2 Results

Results are shown in Table 1 for average scores across all language pairs on the test datasets. We observe that for all reference-based metrics, the best-performing system is MBR decoding using the same utility metric. This result also holds for all QE metrics, but that is by definition, because QE decoding picks the sample with the best QE score. These results also hold on individual languages and the dev set (Appendix G and E).

We can also see that MBR decoding outputs for utility metrics which are similar to the evaluation metric tend to score better than when the MBR utility metric is dissimilar to the evaluation metric. For example, MBR/QE decoding with neural metrics (MetricX and COMET families) performs better than greedy when evaluated with other neural metrics, but worse than greedy if evaluated via lexical metrics. Likewise, MBR decoding with lexical metrics (sentBLEU, chrF, chrF++, and TER) and semantic metrics (YiSi) perform highly when evaluated by lexical and semantic metrics, but poorly when evaluated via neural metrics. The pattern also holds for similar metrics within the same family – XCOMET-XXL prefers MBR/QE decoding using CometKiwi23-XXL and XCOMET-XL, and MetricX prefers outputs from MetricX-QE.

These results suggest the existence of metric bias in MBR decoding – that is, they suggest that MBR decoding will result in a disproportionately large improvement in the utility metric and metrics similar to the utility metric, relative to the actual improvement in quality. In order to address this issue, in the next section we will investigate ensembling metrics during MBR decoding as a means of avoiding overfitting to a particular utility metric.

4 Study 2: MBR Decoding using Ensembles of Metrics

4.1 Methodology

As a mitigation strategy for utility metric bias in MBR decoding, we investigate how using an ensemble of metrics performs for MBR decoding. We explore the following ensembling techniques (see Appendix C for pseudocode for these techniques):

1. rankAvg: For each metric, assigns a rank to each of the 128 samples (where 0 is best and 127 is worst). Select the sample where the average rank across metrics is minimized.
2. rankMed: Select the sample where the median rank across metrics is minimized.
3. rankMax: Select the sample where the maximum rank across metrics is minimized.
4. rank75q: Select the sample where the 0.75th quartile rank across metrics is minimized.

For each of these ensembling techniques, we compute ensembles with the following groups of metrics (see Table 2 and Appendix B for the complete list of metrics included in each ensemble):

1. all: All metrics
2. qe: All QE metrics
3. top: Top-performing metrics in WMT2023 metrics shared task (Freitag et al., 2023b)
4. topQe: Top-performing QE metrics
5. mxmxqe: MetricX + MetricX-QE ensemble
6. noLex: Non-lexical metrics
7. noNC: Metrics that permit commercial use
8. noNCnoLex: Non-lexical metrics that permit commercial use
9. noNCQe: QE metrics that permit commercial use

In addition to the ensembles above, we also investigate QE filtering followed by MBR decoding (QE filtering selects the top N candidates according to a QE metric, where N can be either 4, 8, 16, 32, 64). This two-step approach is faster than standard MBR decoding, as QE filtering is linear-time whereas MBR decoding is quadratic time. We include the following two-step ensembles:

1. allQE(N)allMBR: QE filter with all QE metrics, then MBR decode with all reference-based metrics
2. allQE(N)nolexMBR: QE filter with all QE metrics, then MBR decode with non-lexical reference-based metrics
3. topQE(N)topMBR: QE filter with top QE metrics, then MBR decode with top reference-based metrics
4. noncQE(N)noncMBR: QE filter with QE metrics that permit commercial use, then MBR decode with reference-based metrics that permit commercial use
5. noncQE(N)noncnolexMBR: QE filter with QE metrics that permit commerical use, then MBR decode with non-lexical reference-based metrics that permit commercial use
6. mxQE(N)xcMBR: QE filter with MetricX-QE, then MBR decode with XCOMET-XXL
7. ckQE(N)xcMBR: QE filter with CometKiwi23-XXL, then MBR decode

with XCOMET-XXL

8. mxQE(N)mxMBR: QE filter with MetricX-QE, then MBR decode with MetricX
9. ckQE(N)mxMBR: QE filter with CometKiwi23-XXL, then MBR decode with MetricX

The metrics included in each ensemble is shown in Table 2 and Appendix B.

4.2 Results

Results for a subset of ensembles averaged across all language pairs on the test sets are at Table 1 with additional ensembles shown in Appendix F. Results on the dev sets are shown in Appendix E. Breakdowns per language pair can be found in Appendix G. As expected, ensembles tend to perform better if judged by metrics that are better represented in the ensemble; for example, if judging by MetricX, the best ensembles are mxQE(32)mxMBR and rankAvg:mxmxqe, both of which are ensembles consisting of MetricX and MetricX-QE.

That said, observe that compared to MBR/QE decoding with a single utility metric, ensembles often improve on automated evaluations even according to metrics not included in the ensemble. For example, if we use the XCOMET or CometKiwi families of metrics to evaluate rankAvg:noNCnoLex and noncQE(32)noncnolexMBR (which do not include any metrics from the XCOMET or CometKiwi families), they outperform MBR/QE decoding with any single metric outside the XCOMET or CometKiwi families. Similarly, if lexical metrics are used to evaluate the rankAvg:noLex and allQE(32)nolexMBR ensembles, which do not include any lexical metrics, they still outperform MBR/QE decoding with any single neural metric. This suggests that ensembles help reduce metric bias towards a single metric, which results in improved automated evaluation scores according to other metrics not included in the ensemble.

5 Study 3: Human Evaluation

5.1 Methodology

For the human evaluation, we chose the following baselines and ensembles to evaluate:

1. Greedy decoding
2. Reference translation
3. MetricX (MBR decoding)
4. MetricX-QE (QE decoding)
5. AfriCOMET for African languages (MBR decoding)
6. AfriCOMET-QE for African languages (QE decoding)
7. IndicCOMET for Indic langauges (MBR decoding)
8. rankAvg:noNC (single-step ensemble)
9. rankAvg:noNCnoLex (single-step ensemble)
10. mxQE(32)mxMBR (multi-step ensemble)
11. noncQE(32)noncnolexMBR (multi-step ensemble)

We evaluated the following conditions only on en-de and zh-en due to budget constraints:

1. XCOMET-XXL (MBR decoding)
2. CometKiwi23-XXL (QE decoding)
3. COMET22 (MBR decoding)
4. rankAvg:all (single-step ensemble)

We chose MetricX, MetricX-QE, AfriCOMET, AfriCOMET-QE, and IndicCOMET because they had shown good performance in previously-published evaluations (Tomani et al., 2023; Wang et al., 2024; Sai B et al., 2023; Freitag et al., 2023b), had good performance in automated evaluations on the dev set (Appendix E), and lacked restrictions on commercial use. In our en-de and zh-en evaluations we also included metrics and ensembles with restrictions on commercial use (XCOMET, CometKiwi, rankAvg:all) for comparison. The 6 language pairs and datasets we evaluate are en-ha en-sw en-ml en-hi (from FLORES200 test) and en-de zh-en (from WMT2023). We chose these languages to have a wide distribution in resource level. For each language pair, we sampled 400 source segments to evaluate. WMT2023 was evaluated with document context, whereas FLORES200 segments were evaluated in isolation. We asked each rater to provide MQM annotations for all translation candidates for each source segment (we evaluted 15 systems on en-de and zh-en and 11 systems on others), and compute scores as described in Freitag et al. (2021). Scores range from 0 to 25, lower is better. To control for variance between raters, the same rater was used to score all candidate translations resulting from each source segment.

5.2 Results

Results are shown in Table 3. We observe that overall the best-performing system is rankAvg:noNC, which significantly outperforms greedy ($p<0.001$ on pairwise t-test). rankAvg:noNC also performs

	Greedy	Reference	MetricX	MetricX-QE	XCOMET-XXL	CometKiwi23-XXL	COMET22	AfriCOMET	AfriCOMET-QE	IndicCOMET	rankAvg:all	rankAvg:noNC	rankAvg:noNCnoLex	mxQE32mxMBR	noncQE32noncnolexMBR

Table 3: Human evaluation results broken down by language and MQM error type. Columns indicate the system used for MBR/QE decoding; ensembles are defined in Table 2. Rows starting with “all” shows results across all languages. 1st block is total error scores, 2nd is fluency error scores, 3rd is accuracy error scores, 4th is other error scores. For each system, average human evaluation scores across the evaluated segments are shown. Lower scores are better. Colors are relative to greedy, green is better than greedy, red is worse. Black cells were not evaluated. Significant differences from greedy (pairwise t-test) indicated by * for p<0.05, † for p<0.01, ‡ for p<0.001.

the best on each language pair except en-hi. Interestingly, rankAvg:noNC and greedy decoding beat the reference translation in all language pairs, suggesting either that the reference translations in WMT2023 and FLORES200 are of poor quality, or that Gemini’s translation quality has achieved human parity for these language pairs.

A surprising result from our human evaluation was that although MBR decoding with an ensembles of metrics was judged as having superior quality to greedy decoding, MBR/QE decoding with a single metric (MetricX, MetricX-QE, XCOMET-XXL, CometKiwi23-XXL, COMET22, AfriCOMET, AfriCOMET-QE, IndicCOMET) did not generally improve over greedy decoding (Table 3). In fact, translations from MetricX MBR decoding for zh-en, MetricX-QE decoding for en-ml, AfriCOMET-QE decoding for en-sw, and IndicCOMET MBR decoding for en-ml were rated by humans as significantly worse than greedy decoding (Table 3), even though automatic evaluation with other neural metrics such as MetricX and XCOMET-XXL estimated those translations as being significantly better than greedy (Appendix G). This suggests that evaluation with neutral metrics overestimates the quality of MBR/QE decoding, even if different metrics are used for decoding and evaluation. Our findings contrast with previous

Table 4: An example where MetricX and XCOMET-XXL MBR decoding result in an inaccurate translation. The source text is 卖家说还没，下午才能发。 ("Seller says not yet, can ship in the afternoon.") The preceding sentence is 结果，第二天打电话问，发货了吗？ ("So the next day I called to ask, has it shipped?"). MetricX and XCOMET-XXL MBR decoding, as well as the reference-based MetricX and XCOMET-XXL evaluations, all prefer a translation which inaccurately states the item is out of stock. The other metrics assign a lower score to the inaccurate translation. Lower scores are better for MQM, MetricX, and MetricX-QE, for other metrics higher is better. Green is better than greedy, red is worse. Spans marked as errors by the rater are bolded.

studies which find that MBR decoding with a single metric outperforms greedy decoding in human evaluations (Freitag et al., 2022, 2023a; Tomani et al., 2023).

We hypothesize a few potential causes of the failure of single-metric MBR/QE decoding to outperform greedy decoding: firstly, machine translation quality has improved considerably in recent years. This is reflected by how in our study the greedy decoding outputs achieved better human evaluation results compared to the references generated by professional human translators, especially when looking at fluency scores (Table 3), in contrast with previous work where reference translations were rated as better (Freitag et al., 2022, 2023a). Therefore, it is possible that improvements in greedy translation quality have reduced the quality gains from MBR/QE decoding, and have resulted in the adverse effects of metric bias from MBR/QE decoding with a single utility metric outweighing the benefits to translation quality. For example, in Table 3 we can see that single-metric MBR/QE decoding generally improves fluency on high-resource languages, and reduces errors in style, terminology, and locale convention (labeled "other"). However, accuracy suffers with single-metric MBR/QE decoding for most language pairs (Table 3). We show an example in Table 4, where MetricX and XCOMET-XXL MBR decoding favor a fluent yet inaccurate translation. Perhaps part of the reason for this decrease in accuracy is that MBR decoding with metrics such as MetricX considers only similarity to the pseudoreferences and does not consider the source sentence, so fluent hallucinations that occur in a large number of pseudoreferences will be favored by MBR decoding. Therefore, we hypothesize that past gains from single-metric MBR/QE decoding might have been driven by improvements in fluency and style, but modern LLMs have become good at producing fluent outputs (as indicated by the low fluency error scores for the greedy condition in Table 3), so we are no longer seeing overall quality improvements from single-metric MQM/QE decoding.

We also considered the effects of domain on the quality of single-metric MBR/QE decoding. Since the WMT2023 datasets which were used include novel domains such as speech transcripts and mastodon posts which are not well-represented in the data that metrics such as MetricX and

Table 5: Human evaluation results broken down by domain and MQM error type for en-de and zh-en. Columns indicate the system used for MBR/QE decoding; ensembles are defined in Table 2. 1st block is total error scores, 2nd is fluency error scores, 3rd is accuracy error scores, 4th is other error scores. For each system, average human evaluation scores across the evaluated segments are shown. Lower scores are better. Colors are relative to greedy, green is better than greedy, red is worse. Significant differences from greedy (pairwise t-test) indicated by * for p<0.05, † for p<0.01, ‡ for p<0.001.

XCOMET-XXL were trained on, we hypothesized that this may adversely impacting MBR quality. However, contrary to our expectations, as we can observe in Table 5 there is no clear effect of the domain on the quality of MBR decoding results. Thus, we do not believe effects of domain to be the primary factor behind our findings.

We also considered whether MBR decoding with other metrics we did not evaluate with human raters, such as BLEURT, would have performed better than the metrics we evaluated. To do so, we looked at the correlation between the MQM scores from our human evaluation, compared to the scores assigned by metrics. We include scores from QE metrics (to simulate QE decoding), scores from reference-based metrics based on the 128 pseudoreferences (to simulate MBR decoding), as well as scores form reference-based metrics using the actual references (to simulate a reference-based metric oracle). Table 6 shows Kendall-Tau correlation and Table 7 shows Pearson correlation. Note that this an imperfect simulation of what would happen if we actually performed human evaluation with the MBR/QE decoding outputs for these metrics, as we are considering correlations with human judgements only the subset of candidates which were evaluated (which is a biased sample, as they are the results of MBR/QE decoding), not all 128 samples.

We observe that among the individual metrics that we did not evaluate, simulated XCOMET-XL MBR decoding seems to correlate the best with human judgements, and the other metrics are generally worse than MetricX/XCOMET-XXL MBR decoding. We also include some ensembles, finding that they are generally better correlated with human judgements than individual metrics in our simulation. Therefore, we do not expect that changing to another metric for MBR/QE decoding would have resulted in significantly better translation quality.

6 Discussion

While previous work has sometimes assumed that MBR decoding outputs can be evaluated by automated metrics so long as a non-utility metric is used (Tomani et al., 2023), we find MBR/QE decoding outputs are often preferred by automated metrics despite the fact that human raters believe they are worse quality. For example, while MetricX-QE decoding outputs are considered by human raters to be of worse quality than greedy decoding (Table 3), they still achieve higher scores when evaluated by XCOMET-XXL, XCOMET-XL, MetricX, CometKiwi22, CometKiwi23-XL, and CometKiwi23-XXL (Table 1 and Appendix G). Thus, the metric bias issue that results from MBR/QE decoding complicates evaluation with automated metrics.

That said, while we have shown that MBR/QE decoding generated translations with higher automated evaluation scores are not always judged as having better quality by humans, this does not mean that automated metrics are no longer useful. In our study, automatic reference-based metrics, QE metrics, and ensembles of metrics are still somewhat correlated with MQM scores, as shown in Table 6. Therefore, while it is advisable to perform a human evaluation when feasible if evaluating systems that make use of MBR/QE decoding, existing metrics still correlate with human preferences. Additionally, using an ensemble of metrics for MBR decoding results in improved translation quality compared to greedy decoding and MBR/QE decoding with a single metric (Table 3).

Table 6: Kendall-Tau correlation between MQM evaluation scores and automated evaluation scores. For reference-based metrics, rows with ":mbr" indicate pseudoreference-based evaluation. Bottom rows are ensembles that take the average between the listed metrics. Higher scores indicate better agreement with human raters. See Table 7 for Pearson correlation.

Why is it that using an ensemble of metrics for MBR decoding improves translation quality compared to just using a single metric (Table 3)? We hypothesize that each metric has its own biases that lead it to prefer bad translations, but different metrics have different biases, so using an ensemble reduces metric bias. We see an example of this in Table 4 where MetricX and XCOMET-XXL assign high scores to an inaccurate translation, but this translation is rated poorly by CometKiwi23-XXL and COMET22, so the ensemble ends up picking a good translation that is preferred by all metrics.

Techniques other than MBR/QE decoding for making use of human preferences to improve translation quality, such as DPO (direct preference optimization) (Rafailov et al., 2024; Yang et al., 2024)) and RLHF (reinforcement learning from human feedback) (Christiano et al., 2017), might be more resilient to this metric bias issue, as they do not directly make use of the evaluation metric. However, given that the data used for DPO/RLHF is similar to the data used to train evaluation metrics, and given that the reward hacking issue is prevalent throughout reinforcement learning (Skalse et al., 2022), issues similar to metric bias may still occur with these techniques.

An open question that remains is how to develop new evaluation techniques that are resilient to metric bias in MBR/QE decoding. One potential way is to develop metrics specialized for evaluating MBR/QE decoding outputs from a particular system, by generating MBR/QE decoding outputs from a translation model, obtaining human annotations for those, and training a metric with them. This process is unfortunately costly and time-intensive, and the learned metric might not be able to generalize beyond translations generated by the particular utility metric and translation model it was trained on. Perhaps a better approach would be to view the metric bias problem as an adversarial learning problem, and apply techniques such as generative adversarial training (Yang et al., 2018) to help train metrics resilient to MBR bias.

7 Conclusion

In this paper we have explored the problem of metric bias, where MBR or QE decoding with a single utility metric shows improvements on automated evaluation with the utility metric and related metrics, but does not actually improve quality when judged by a human rater. We find that the metric bias issue is most severe when using a single utility metric, and using an ensemble of metrics to perform MBR decoding can help improve quality as judged by a human rater. While we have shown that metric bias can result in overly-optimistic automatic evaluations of systems that make use of MBR/QE decoding, the question of how to resolve this issue and automatically evaluate systems that make use of MBR/QE decoding is still an open problem which we leave to future work.

Dataset

Dataset is at `https://mbrbias.github.io/`

Limitations

In this work we compare to only full MBR decoding and QE filtering as baselines, but there are many alternative approaches, such as MBR approximation heuristics (Trabelsi et al., 2024; Jinnai and Ariu, 2024; Deguchi et al., 2024, 2023; Vamvas and Sennrich, 2024; Eikema and Aziz, 2022), direct preference optimization training (Yang et al., 2024), quality-aware training (Tomani et al., 2023), or training on MBR decoding outputs (Finkelstein and Freitag, 2023), that are more practical to use if translation latency is important. In this work we only look at translations coming from Gemini 1.0 Pro with 5-shot sample prompts and epsilon sampling, and it is possible that results may differ if using a different translation system, different prompts, or a different sampling technique. In this work we only look at using 128 samples due to the computationally expensive $O(n^2)$ cost of running full MBR decoding, but it is possible that using additional samples can achieve further quality improvements. In this work we only looked at segment-level translation, and it is possible that results may differ if performing document-level translation. However, MetricX and the COMET families of models have input token limits – 1024 tokens for MetricX, 512 tokens for COMET – which make it difficult to use them for document-level MBR decoding. Our human evaluation used only a single rater for each translation, which introduces the question of how reliable and consistent the ratings are – using multiple raters and looking at inter-rater agreement is preferable, but was beyond our budget constraints.

Ethics Statement

MBR decoding is resource-intensive, and using ensembles of multiple metrics increases computational complexity compared to a single utility metric. To mitigate this issue, we presented two-step ensembles that use QE filtering followed by MBR decoding, which reduce the computational cost below the cost of standard MBR decoding with a single metric.

A Methodology Details

A.1 Prompts Used for Generating Samples

For each language pair, we obtained 5-shot examples for our prompts from the dev split of FLORES-200 by randomly sampling among those reference pairs that had perfect MetricX QE scores (scores of 0). We used MetricX QE filtering to ensure we used high-quality examples as our 5-shot examples. The sampled examples and prompt text for each language pair is included in our dataset release.

A.2 Instructions for Computing Metrics

sentBLEU, chrF, chrF++, and TER scores were computed with sacreBLEU 2.4.2 (Post, 2018) on python 3.11.8 with the following parameters:

chrF: -m chrf

chrF++: -m chrf –chrf-word-order 2

sentBLEU: -m bleu –sentence-level

TER: -m ter

For other metrics, we used the publicly released models on HuggingFace, running with the unbabel-comet package version 2.2.1 available on pip, on Python 3.10.14. We ran on an NVIDIA A100 GPU for all metrics except XCOMET-XXL and CometKiwi23-XXL, which required an NVIDIA A100 80GB GPU.

B Metrics Included in Each Ensemble

This section presents the same information that is present in Table 2, but in textual format. The following are the groups of metrics included in the single-step ensembles that we include in our study. For each of these metric groups the rankAvg, rankMed, rankMax, and rank75q ensembling techniques are used to generate an ensemble.

1. all: All metrics, both reference-based and QE (MetricX, MetricX-QE, XCOMET-XXL, XCOMET-XL, CometKiwi23-XXL, CometKiwi23-XL, CometKiwi22, COMET22, BLEURT, YiSi, chrF, chrF++, sentBLEU, TER, AfriCOMET and

AfriCOMET-QE for African languages, IndicCOMET for Indic languages)

2. qe: All QE metrics (MetricX-QE, CometKiwi23-XXL, CometKiwi23-XL, CometKiwi22, and AfriCOMET-QE for African languages)
3. top: MetricX, MetricX-QE, XCOMET-XXL, XCOMET-XL, CometKiwi23-XXL, CometKiwi23-XL
4. topQe: MetricX-QE, CometKiwi23-XXL, CometKiwi23-XL
5. mxmxqe: MetricX, MetricX-QE
6. noLex: All non-lexical metrics (MetricX, MetricX-QE, XCOMET-XXL, XCOMET-XL, CometKiwi23-XXL, CometKiwi23-XL, CometKiwi22, COMET22, BLEURT, YiSi, AfriCOMET and AfriCOMET-QE for African languages, IndicCOMET for Indic languages)
7. noNC: All metrics that permit commercial use (MetricX, MetricX-QE, CometKiwi22, COMET22, BLEURT, YiSi, chrF, chrF++, sentBLEU, TER, AfriCOMET and AfriCOMET-QE for African languages, IndicCOMET for Indic languages)
8. noNCnoLex: All non-lexical metrics that permit commercial use (MetricX, MetricX-QE, COMET22, BLEURT, YiSi, AfriCOMET and AfriCOMET-QE for African languages, IndicCOMET for Indic languages)
9. noNCQe: All QE metrics that permit commercial use (MetricX-QE, and AfriCOMET-QE for African languages)

In addition, we also investigate QE filtering followed by MBR decoding (here we define QE filtering as selecting the top N candidates according to a QE metric, where N can be either 4, 8, 16, 32, 64). We include the following ensembles of this form:

1. allQE(N)allMBR: Use QE filtering with an ensemble of all QE metrics (MetricX-QE, CometKiwi23-XXL, CometKiwi23-XL, CometKiwi22, AfriCOMET-QE for African languages), then perform MBR decoding on the N resulting candidates with all reference-based metrics (MetricX, XCOMET-XXL, XCOMET-XL, COMET22, BLEURT, YiSi, chrF, chrF++, sentBLEU, TER, AfriCOMET for African languages, IndicCOMET for Indic languages).
2. allQE(N)nolexMBR: Use QE filtering with an ensemble of all QE metrics (MetricX-QE, CometKiwi23-XXL, CometKiwi23-XL, CometKiwi22, AfriCOMET-QE for African languages), then perform MBR decoding on the N resulting candidates with all non-lexical reference-based metrics (MetricX, XCOMET-XXL, XCOMET-XL, COMET22, BLEURT, YiSi, AfriCOMET for African languages, IndicCOMET for Indic languages).
3. topQE(N)topMBR: Use QE filtering with an ensemble of top-performing QE metrics (MetricX QE, CometKiwi23-XXL, CometKiwi23-XL), then perform MBR decoding on the N resulting candidates with an ensemble of top-performing reference-based metrics (MetricX, XCOMET-XXL, XCOMET-XL).
4. noncQE(N)noncMBR: Use QE filtering with an ensemble of QE metrics that permit commercial use (MetricX-QE, AfriCOMET-QE for African languages), then perform MBR decoding with an ensemble of reference-based metrics that permit commercial use (MetricX, COMET22, BLEURT, YiSi, chrF, chrF++, sentBLEU, TER, AfriCOMET for African languages, IndicCOMET for Indic languages).
5. noncQE(N)noncnolexMBR: Use QE filtering with an ensemble of QE metrics that permit commercial use (MetricX-QE, AfriCOMET-QE for African languages), then perform MBR decoding with an ensemble of non-lexical reference-based metrics that permit commercial use (MetricX, COMET22, BLEURT, YiSi, AfriCOMET for African languages, IndicCOMET for Indic languages).
6. mxQE(N)xcMBR: Use QE filtering with MetricX-QE, then perform MBR decoding with XCOMET-XXL
7. ckQE(N)xcMBR: Use QE filtering with CometKiwi23-XXL, then perform MBR decoding with XCOMET-XXL
8. mxQE(N)mxMBR: Use QE filtering with MetricX-QE, then perform MBR decoding with MetricX
9. ckQE(N)mxMBR: Use QE filtering with CometKiwi23-XXL, then perform MBR decoding with MetricX

C Pseudocode for Ensembles

rankAvg ensembling strategy:

```
def rankAvg(
  sample_list: List[str], metric_list: List[str]
):
  sample_ranks =
      get_ranks_for_samples_by_ensemble(sample_list,
      metric_list)
  score_list = [np.mean(x) for x in
      sample_ranks]
  return select_samples_by_score(sample_list,
      score_list)
```

rankMed ensembling strategy:

```
def rankMed(
  sample_list: List[str], metric_list: List[str]
):
  sample_ranks =
      get_ranks_for_samples_by_ensemble(sample_list,
      metric_list)
  score_list = [np.median(x) for x in
      sample_ranks]
  return select_samples_by_score(sample_list,
      score_list)
```

rankMax ensembling strategy:

```
def rankMax(
  sample_list: List[str], metric_list: List[str]
):
  sample_ranks =
      get_ranks_for_samples_by_ensemble(sample_list,
      metric_list)
  score_list = [np.max(x) for x in sample_ranks]
  return select_samples_by_score(sample_list,
      score_list)
```

rank75q ensembling strategy:

```
def rank75q(
  sample_list: List[str], metric_list: List[str]
):
  sample_ranks =
      get_ranks_for_samples_by_ensemble(sample_list,
      metric_list)
  score_list = [np.quantile(x, q=[0.75])[0] for
      x in sample_ranks]
  return select_samples_by_score(sample_list,
      score_list)
```

Here are helper functions that were used:

```
def get_ranks_for_samples_by_ensemble(
  sample_list: List[str], metric_list: List[str]
):
  output = [[None for y in metric_list] for x
      in sample_list]
  for metric_idx, metric in
      enumerate(metric_list):
    sample_to_rank =
        rank_samples_by_metric(sample_list,
        metric)
    for sample_idx, sample in
        enumerate(sample_list):
      output[sample_idx][metric_idx] =
          sample_to_rank[sample]
  return output

def select_samples_by_score(
  sample_list: List[str],
  score_list: List[float]
):
  sample_with_score = zip(sample_list,
      score_list)
  top_candidate, top_score =
      min(sample_with_score, key=lambda x: x[1])
  return top_candidate
```

Table 7: Pearson correlation between MQM evaluation scores and automated evaluation scores. For reference-based metrics, rows with ":mbr" indicate pseudoreference-based evaluation. Bottom rows are ensembles that take the average between the listed metrics. Higher scores indicate better agreement with human raters. See Table 6 for Kendall-Tau correlation.

Table 8: Reference-based and QE evaluation scores for greedy, MBR, and QE decoding using a single-step ensemble utility metric, averaged across all languages (test datasets). Higher scores are better, except MetricX, MetricX-QE, and TER, where lower is better. Green is better than greedy, red is worse. Ensembles are defined in Table 2. Significant differences from greedy (pairwise t-test) indicated by * for p<0.05, † for p<0.01, ‡ for p<0.001.

Table 10: Reference-based and QE evaluation scores for greedy, MBR, and QE decoding using a two-step ensemble (QE filtering followed by MBR) utility metric, averaged across all languages (test datasets). Higher scores are better, except MetricX, MetricX-QE, and TER, where lower is better. Green is better than greedy, red is worse. Ensembles are defined in Table 2. Significant differences from greedy (pairwise t-test) indicated by * for p<0.05, † for p<0.01, ‡ for p<0.001.

Table 11: Reference-based and QE evaluation scores for greedy and MBR/QE decoding (1st block), and ensembles (2nd block), on en-sw (FLORES200 test dataset). Higher scores are better, except MetricX, MetricX-QE, and TER, where lower is better. Green is better than greedy, red is worse. Ensembles are defined in Table 2. Significant differences from greedy (pairwise t-test) indicated by * for p<0.05, † for p<0.01, ‡ for p<0.001. The green diagonal in the 1st block shows metrics prefer outputs from MBR/QE decoding using the same utility metric.

Table 12: Reference-based and QE evaluation scores for greedy and MBR/QE decoding (1st block), and ensembles (2nd block), on en-ha (FLORES200 test dataset). Higher scores are better, except MetricX, MetricX-QE, and TER, where lower is better. Green is better than greedy, red is worse. Ensembles are defined in Table 2. Significant differences from greedy (pairwise t-test) indicated by * for p<0.05, † for p<0.01, ‡ for p<0.001. The green diagonal in the 1st block shows metrics prefer outputs from MBR/QE decoding using the same utility metric.

Table 14: Reference-based and QE evaluation scores for greedy and MBR/QE decoding (1st block), and ensembles (2nd block), on en-so (FLORES200 test dataset). Higher scores are better, except MetricX, MetricX-QE, and TER, where lower is better. Green is better than greedy, red is worse. Ensembles are defined in Table 2. Significant differences from greedy (pairwise t-test) indicated by * for p<0.05, † for p<0.01, ‡ for p<0.001. The green diagonal in the 1st block shows metrics prefer outputs from MBR/QE decoding using the same utility metric.

G.5 Results for English-Hindi (en-hi) on FLORES200 test dataset

Table 15: Reference-based and QE evaluation scores for greedy and MBR/QE decoding (1st block), and ensembles (2nd block), on en-hi (FLORES200 test dataset). Higher scores are better, except MetricX, MetricX-QE, and TER, where lower is better. Green is better than greedy, red is worse. Ensembles are defined in Table 2. Significant differences from greedy (pairwise t-test) indicated by * for p<0.05, † for p<0.01, ‡ for p<0.001. The green diagonal in the 1st block shows metrics prefer outputs from MBR/QE decoding using the same utility metric.

G.6 Results for English-Tamil (en-ta) on FLORES200 test dataset
