and real documents), we use a randomized sampling approach instead of alternating uniformly between them. In each training step, a sample from both the forget and retain datasets is selected, tokenized, and processed by the model. To guide unlearning, each forget sample is assigned a control vector, which is scaled using a predefined steering coefficient. The unlearning loss is computed as the MSE between the model's activations and the control vector, with an adaptive coefficient that dynamically scales based on the activation norms.

Due to computational constraints, our experiments were conducted exclusively on the 1B parameter model. However, our approach demonstrates competitive performance on the 7B parameter model as well.

5 Experiments

5.1 Preprocessing

Our preprocessing pipeline involves tokenizing the text using the allenai/OLMo-1B-0724-hf tokenizer, which has a vocabulary size of 50,280. This tokenizer includes specialized tokens for personally identifiable information (PII), such as email addresses and Social Security Numbers (SSNs), ensuring a structured representation of such entities within the model.

5.2 Hyperparameter Tuning

Since the adaptive RMU approach dynamically adjusts the scaling coefficient, we primarily focus on selecting the layers for unlearning. Specifically, we experiment with all possible combinations of three consecutive layers, ranging from (0,1,2) to (13,14,15). This allows us to identify the most effective layer range for minimizing interference with retained knowledge while ensuring effective unlearning.

6 Results

We evaluated the performance of our unlearned model using the evaluation metric described in Section 3.3. Table 3 compares the performance of our approach with some baseline methods. The results of our experiments, including the task aggregate score, membership inference attack (MIA) score, and MMLU score across different layer combinations, are presented in Table 2. We find that ideal layers for unlearning with adaptive RMU are 12,13,14 for the 1B parameter model and 24,25,26 for the 7B parameter model. We conducted our experiments using four NVIDIA RTX 3090 GPUs, each equipped with 24GB of VRAM. Our approach ranked 4th among all competing teams on both the 1B parameter model leaderboard and the 7B parameter model leaderboard.

7 Conclusion

In this work, we demonstrate that applying the adaptive RMU (Rank-One Model Update) technique to later decoder layers is an effective strategy for unlearning factual information from large language models (LLMs). A key advantage of our method is its minimal hyperparameter tuning requirement, making it easily adaptable to different LLM architectures.

Decoder Layers	Task Aggregate	MIA	MMLU	Final score
0,1,2	0.547	0.062	0.244	0.284
1,2,3	0.542	0.081	0.249	0.291
2,3,4	0.355	0.401	0.250	0.336
3,4,5	0.433	0.490	0.254	0.392
4,5,6	0.508	0.355	0.229	0.364
5,6,7	**0.637**	0.357	0.262	0.419
6,7,8	0.597	0.416	0.250	0.421
7,8,9	0.616	0.332	0.245	0.398
8,9,10	0.631	0.362	**0.265**	0.419
9,10,11	0.574	0.471	0.264	0.437
10,11,12	0.282	0.279	0.243	0.268
11,12,13	0.582	0.489	0.254	0.442
12,13,14	0.565	**0.835**	0.261	**0.554**
13,14,15	0.538	0.747	0.258	0.515

Table 2: Performance of different layer combinations on task aggregate, MIA score, and MMLU score for OLMo-1B.

Method	Task Aggregate	MIA	MMLU	Final score
~~Gradient Ascent~~	~~0~~	~~0.912~~	~~0.269~~	~~0.394~~
~~Gradient Difference~~	~~0~~	~~0.382~~	~~0.348~~	~~0.243~~
~~KL Minimization~~	~~0~~	~~0.916~~	~~0.269~~	~~0.395~~
Negative Preference Optimization	0.021	0.080	0.463	0.188
Adaptive RMU	0.387	0.872	0.485	0.376

Table 3: Comparison with baseline methods for OLMo-7B. Some methods have been striked out because MMLU score is below the minimum threshold of 0.371.

Our technique achieved 4th place on the official leaderboard for both 1B and 7B parameter models, highlighting its competitiveness among various unlearning approaches. While the original RMU implementation demonstrated that unlearning from earlier layers effectively removes hazardous knowledge—such as information related to cybersecurity threats and bioweapons, which require deep contextual understanding—we extend this research by showing that factual knowledge (e.g., phone numbers, Social Security Numbers, and addresses) is more effectively unlearned from later decoder layers.

Despite these promising results, unlearning sensitive content from LLMs remains an open challenge, with several promising directions for future research. For instance, further exploration is needed to assess the trade-offs between unlearning effectiveness and generalization, particularly when removing factual knowledge versus conceptual reasoning.

Overall, our work contributes to the broader fields of model editing and mechanistic interpretability, providing valuable insights into the layerwise dynamics of unlearning and paving the way for more robust and efficient strategies in the future.

A Appendix: Analysis of layer combinations for unlearning

Figure 2(a), 2(b) show that unlearning from the middle layers achieves a balance between knowledge retention (high MMLU score) and unlearning performance (high Task Aggregate score), but it remains more susceptible to MIA (Figure 2(c)). In contrast, later layers exhibit significantly higher robustness to MIA. The substantial improvement in MIA robustness outweighs the relatively smaller decline in knowledge retention and unlearning performance, making later layers the more effective choice for unlearning (Figure 2(d)).

Abstract

The focus of SemEval-2024 Task 7 is the retrieval of relevant fact-checks for social media posts across multiple languages. We approach this task with an enhanced bi-encoder retrieval setup, which is designed to match social media posts with relevant fact-checks using synthetic data from LLMs. We explored and analyzed two main approaches for generating synthetic posts. Either based on existing fact-checks or on existing posts. Our approach achieved an S@10 score of 89.53% for the monolingual task and 74.48% for the crosslingual task, ranking 16th out of 28 and 13th out of 29, respectively. Without data augmentation, scores would have been 88.69 (17th) and 72.93 (15th).

1 Introduction

SemEval Task 7 (Peng et al., 2025) focuses on retrieving relevant fact-checks for social media posts across multiple languages. It comprises two subtasks: (1) monolingual retrieval, where posts and fact-checks share the same language, and (2) crosslingual retrieval, where they differ.

Our approach involved fine-tuning Sentence Transformers (Reimers and Gurevych, 2019) as bi-encoders on both the training data and synthetically generated samples. Given the dataset's sparsity (there are much more fact-checks than posts), we bridge this gap by generating synthetic posts using LLMs. We observed slight performance gains when generating posts for fact-checks without assignments, particularly enhancing retrieval for Turkish and Polish, despite the absence of training data for these languages. However we found that generating variations of existing posts did not enhance retrieval performance. Ultimately, we ranked 16th (of 28) in the monolingual and 13th (of 29) in the crosslingual subtask. Without data augmentation, scores would have dropped to 88.69 (17th) and 72.93 (15th). Our results suggest that the main limitation was the inability of synthetic posts to fully match the style and content of real posts.

† These authors contributed equally to this work.

2 Background

The task involves matching fact-checks to social media posts using a modified subset of the MultiClaim dataset (Pikuliak et al., 2023). It comprises two tracks: monolingual and crosslingual. In the monolingual track, each post is paired with fact-checks in the same language.

In the crosslingual track fact-checks are assigned regardless of their language. The dataset spans Arabic, English, French, German, Malay, Polish, Portuguese, Spanish, Thai, Turkish. The goal is to retrieve the top-10 most relevant fact-checks for each post. We participated in both tracks, with performance evaluated using the binary Success@10 metric, which assigns a score of 1 if at least one of the top 10 retrieved items is relevant and 0 otherwise.

Matching social media posts with applicable fact-checks is a crucial research area, since misinformation spreads rapidly on social media networks.This task aligns with information retrieval, where posts serve as queries and fact-checks as the document corpus. Pikuliak et al. (2023) tested BM25 (Robertson and Zaragoza, 2009) and Sentence Transformers, with the latter performing better. Sentence Transformers offer two retrieval strategies: Bi-encoders, which encode queries and documents separately before computing similarity, and cross-encoders, which evaluate entire sentence pairs directly. While cross-encoders provide higher accuracy, they are computationally expensive (Reimers and Gurevych, 2019), which makes them less suitable for fact-checking in a fast-paced setting like social-media platforms.

To enhance retrieval, we propose enriching the dataset with synthetic training data generated by an LLM, following Braga et al. (2024).

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1623–1638

3 Methodology: Retrieval Setup

The dataset consists of social media posts and fact-checks. Each post is divided into an ocr-text and a post-text, both available in their original language and an English translation. Either or both may contain relevant information: Our initial tests showed the best retrieval performance when concatenating the English version of both fields. For fact-checks, each entry includes a title and a claim in both the source language and English. Unlike posts, the best performance was achieved using only the English claim. Our sole preprocessing step was whitespace stripping.

3.1 Retrieval

We employ a bi-encoder setup for efficient retrieval of relevant fact-checks. Our submissions use the *all-mpnet-base-v2* Sentence Transformer model, based on *MPNet* (Song et al., 2020), while the smaller *all-MiniLM-L6-v2*, based on *MiniLM* (Wang et al., 2020), was used during development for faster testing of new approaches.

To retrieve the ten most relevant fact-checks for a given social media post, we first embed all preprocessed posts and fact-checks using the same bi-encoder. We then compute pairwise cosine similarity between embeddings, rank the results, and select the top ten.

3.2 Retrieval Training

We finetuned the bi-encoders to generate more meaningful embeddings for this task using the Sentence Transformer library (Reimers and Gurevych, 2019).

Loss Function We used *MultipleNegativesRankingLoss* (Henderson et al., 2017) as a loss function. For the larger MPNet model, we used *CachedMultipleNegativesRankingLoss* to maintain high batch sizes on the same GPU. We used the *NoDuplicatesBatchSampler* to avoid sampling false negatives.

Dataloading For development, we split the dataset into 80% training and 20% testing, except for the final runs for the submissions, where we used all available data. Initially, we created a single dataset for all tasks. Later, we found that using separate datasets – one per language and one for the crosslingual task – yielded better results (Table A1). Our training datasets are structured as [eng, deu, ..., crosslingual, synthetic], allowing us to train on all datasets simultaneously while ensuring that in-batch negatives in *MultipleNegativesRankingLoss* remain relevant within the same language or category.

For further comparisons between hyperparameter choices, see the Appendix (A.1).

4 Methodology: Data Augmentation

The dataset contains only 31,305 *fact-check-to-post pairs*, covering less than 10% of the 205,751 available fact-checks. The authors estimate their dataset could contain up to seven times more pairs than annotated (Pikuliak et al., 2023). Our goal was to enhance retrieval performance by enriching the dataset without scraping new posts or manually searching for additional *fact-check-to-post pairs*. Instead, we developed a system to generate new pairs by creating synthetic social media posts matching existing fact-checks. To ensure a relation between the synthetic post and a real fact-check, we devised two approaches detailed below.

The first approach, **generating synthetic posts from fact-checks**, employs an LLM to generate a social media post based on each fact-check. The fact-check itself serves as input, naturally maintaining the connection in content.

The second approach, **generating synthetic posts from real posts**, uses an LLM and an existing post from a *fact-check-to-post pair* to generate a new post that references the same content. This ensures that the generated post remains linked to the same fact-check.

4.1 Generating synthetic posts based on Fact-Checks

We developed three methods to create synthetic posts from fact-checks, all using the same LLM and few-shot prompting approach providing examples of real *fact-check-to-post pairs* as input.

The model we use is *mlabonne/Meta-Llama-3.1-8B-Instruct-abliterated*[1], an uncensored variant of Meta's Llama 3.1 8B Instruct[2]. Initial tests with the original version showed frequent refusals to generate posts on fake news topics. For this reason, we opt for the uncensored version.

The **first approach: SPFC-FFT** (**S**ynthetic **P**osts based on **F**act-**C**hecks using a **F**ixed **F**ew-shot **T**emplate) employs a fixed few-shot template

[1] https://huggingface.co/mlabonne/Meta-Llama-3.1-8B-Instruct-abliterated

[2] https://huggingface.co/meta-llama/Llama-3.1-8B-Instruct

(A.4) with nine randomly preselected *fact-check-to-post pairs* (three per platform: Facebook, Twitter, Instagram), using their English translations. The applied prompts are detailed in Table A4.

The **second approach: SPFC-RAFT** (**SPFC** using a **R**andomly **A**lternating **F**ew-shot **T**emplate) uses randomly alternating few-shots, sampling new *fact-check-to-post pairs* for each generated post while maintaining the same template structure. This method aims to better reflect differences in the given data, such as fact-check/post length, translation quality, and metadata availability (*title* for fact-checks, *ocr-text* for posts).

The **third approach: SPFC-ML** (**SPFC** using **M**ulti**L**ingual model output) extends the alternating template to multilingual generation, utilizing fact-checks and posts in their original language. The LLM's multilingual capabilities are leveraged, with generated posts later translated to English using the Google Translate API, ensuring consistency with dataset translations. To guide language selection, only *fact-check-to-post pairs* in the target fact-check's language are sampled, with minor prompt adjustments specifying the desired output language. The adapted prompts are listed in Table A4.

4.2 Generating Synthetic Posts Based on Real Posts

Unlike the previous approach, this method does not create new *fact-check-to-post pairs* but expands existing ones with synthetic posts. We primarily used the Llama 3.3 (70B) and Llama 3.2 (3B) models (Grattafiori et al., 2024), alongside Phi-3 (Abdin et al., 2024) and Gemma 2 (Team et al., 2024). Llama 3.3 proved most effective showing higher reliability and ability to process longer prompts. The model was also instructed to mimic social media language, including informal or exaggerated phrasing, disregarding factual accuracy where needed.

Our **first attempt** simply prompted the model to generate a social media post similar to a given post- or ocr-text. However, results were inconsistent: the model either strayed too far from the original or failed to generate a social media-style response, often defaulting to factual explanations (A.9).

In a **second attempt**, we applied a Chain of Thought (CoT) (Wei et al., 2023) approach. The model was first prompted to extract key claims from the input to ensure alignment with the original fact-check, it then generated a new post preserving the core message while ensuring sufficient variation. With **SPRP-CoT-supportive** (**S**ynthetic **P**osts based on **R**eal **P**osts using **CoT-supportive**) we explored synthesizing a new post in response to the given post. We found that this approach did not improve retrieval performance, likely due to the original dataset lacking posts adhering to these response-based structures. Ultimately, for **SPRP-CoT-different** we refined the prompt to ensure outputs followed the original message while being explicitly different (**SPRP** using **CoT-different**). To generate the CoT-prompt in a structured manner, the dspy-framework was used (Khattab et al., 2024, 2022). While this improved adherence to the correct content, it still failed to mimic the style of social media posts.

To address this stylistic issue, our **final attempt, SPRP-FS-CoT**, introduced a Few-Shot (Brown et al., 2020) template (**SPRP** using **FS-CoT**). We crafted ten high-quality post examples with GPT-4o[3] sticking to the prompt used with *SPRP-COT-different*, randomly selecting three exemplary posts for each prompt. This template retained CoT structure while aligning outputs with social media language.

Details can be found in Figure A2.

5 Results

5.1 Evaluating Different Approaches

Dataset	Monolingual	Crosslingual
Without synthetic data	89.54	74.17
SPFC-FFT	**90.09 (+0.55)**	**77.19 (+3.02)**
SPFC-RAFT	89.03 (-0.51)	75.28 (+1.11)
SPFC-ML	89.17 (-0.37)	75.78 (+1.61)
SPRP-CoT-supportive	89.05 (-0.49)	73.87 (-0.30)
SPRP-CoT-different	89.54 (±0.00)	74.17 (±0.00)
SPRP-FS-CoT	88.70 (-0.84)	74.57 (+0.40)

Table 1: Success@10 scores for the mono- and crosslingual subtasks for the augmentation approaches.

We evaluate each synthetic post-generation approach by fine-tuning the *all-MiniLM-L6-v2* model on our training split, which includes both the dataset's training split and our generated *post-fact-check pairs*, and report the results on the test split. The custom training parameters are *MultipleNegativesRankingLoss*, a batch size of 128, dataset splits as described in 3.2, and 10 epochs. All other parameters are set to their default values.

[3]https://chatgpt.com

As shown in Table 1, the fixed few-shot template approach (*SPFC-FFT*, see 4.1) performed best, improving both monolingual and crosslingual tasks compared to the baseline. Overall, fact-check-based generation (*SPFC*) consistently increased crosslingual performance.

Model Training Data	Monolingual	Crosslingual
Task Dataset Only	91.08 (+1.54)	79.70 (+5.53)
Task Dataset + SPFC-FFT	91.92 (+1.83)	80.60 (+3.41)

Table 2: Success@10 scores of *all-mpnet-base-v2*, with improvements over *all-MiniLM-L6-v2* in parentheses.

In Table 2, we evaluate the *all-mpnet-base-v2* Sentence Transformer model with the same parameters. Our synthetic data improves the larger model's performance by +0.84 for monolingual and +0.90 for crosslingual tasks, showing a larger impact on monolingual results and a smaller one on crosslingual, compared to the smaller model.

5.2 Performance on Codabench

Training Data	3 epochs Mono	3 epochs Cross	10 epochs Mono	10 epochs Cross
Only task dataset	88.69	72.93	87.90	71.25
SPFC-FFT	89.43	74.20	88.25	72.20
SPFC-FFT (incl. tur + pol)	**89.53**	**74.48**	88.80	72.68

Table 3: Success@10 scores for the mono- and crosslingual subtasks evaluated on codabench test.

We report our performance on the official test set, accessible only via Codabench, which includes Turkish and Polish—languages not part of the training set and not evaluated before submission. We fine-tuned the *all-mpnet-base-v2* model on all available *fact-check-to-post pairs*, incorporating synthetic data from the *SPFC-FFT* approach. As shown in Table 3, enriching the dataset with *SPFC-FFT* posts improved overall performance, particularly when including Turkish and Polish fact-checks. We ranked 16th (89.53) in the monolingual and 13th (74.48) in the crosslingual task. Without data augmentation, scores dropped to 88.69 (17th) and 72.93 (15th), respectively.

For more detailed results across all languages, see Table A3.

6 Analysis of Synthetic Data

The final retrieval results indicate that augmenting the dataset with synthetic *fact-check-to-post pairs* only marginally improves performance. This section explores potential reasons by analyzing differences between synthetic and real data.

We assess spelling errors as per Kumar et al. (2024) and measure vocabulary richness using the MTLD-score (Measure of Textual and Lexical Diversity) (Koizumi and In'nami, 2012), accounting for unique words while compensating for text length. Grammatical correctness is evaluated via grammatical errors per word (Kumar et al., 2024)[4].

To highlight key (semantic) differences, we embed posts using *all-MiniLM-L6-v2* (Wang et al., 2020) and reduce dimensions via UMAP (McInnes et al., 2020) for visualization. Cluster comparison is performed using intra-cluster distance, measured by the WCSS-score (Agrawal and Kushwaha, 2018), which computes the mean squared distance of each point to its cluster centroid.

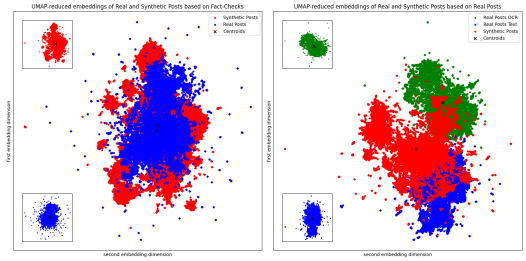

Figure 1: Left: UMAPped sentence embeddings of real and synthetic posts (*SPFC-FFT*) Right: UMAPped sentence embeddings of ocr-, post- and the synthetic texts (*SPRP-FS-CoT*). Black crosses are centroids.

6.1 Analysis of Synthetic Posts Generated Based on Fact-Checks

Since our *SPFC-FFT* approach, which uses a fixed few-shot template, yields the best retrieval results, we focus solely on synthetic posts generated with this method, comparing them to real posts.

Analyzing both clusters in Figure 1 (left), we observe considerable semantic overlap between original and synthetic posts, likely explaining this approach's superior performance, as the generated training data matches the original data closely. Metrics in Table 4 show minimal differences between real and synthetic posts in vocabulary richness, spelling, and grammar.

However, post length differs: Synthetic posts have identical mean and median values, indicating consistent LLM-generated lengths, whereas real posts vary significantly, with a maximum length of 3823 for the real vs. 153 for synthetic posts.

[4]https://github.com/jxmorris12/language_tool_python

	Real Post	Synth Post
vocabulary richness	0.85 (0.87)	0.90 (0.90)
spelling errors per post	0.19 (0.18)	0.24 (0.23)
grammar errors per post	0.06 (0.03)	0.02 (0.0)
post length	84 (46)	43 (43)
MTLD-score	81.77 (73.96)	112.72 (94.72)
WCSS-score	0.88	0.80

Table 4: Mean (median) lexical metrics for *SPFC-FFT*.

Furthermore, WCSS scores indicate greater semantic variance in real posts. This aligns with cosine similarity scores: real posts have lower mean (0.56) similarities compared to synthetic posts (0.68), suggesting synthetic posts more closely resemble their fact-checks, making retrieval easier and therefore bringing less benefits when fine-tuning the retrieval setup on them. We refer to the appendix A.7, where we list some exemplary synthetic posts that further emphasize this point.

6.2 Analysis of Synthetic Posts Generated Based on Real Posts

For the synthetic posts generated based on real posts, we analyze the data created using the *SPRP-FS-CoT* approach, as this approach had a positive impact on the crosslingual task. To better understand the overall performance, we calculate the metrics described in the beginning of section 6 for ocr-, post-, and synthetic texts separately.

Figure 1 (right) presents a scatter plot, where post- and ocr-texts form distinct, well-defined clusters. Synthetic posts also cluster separately but with less strict boundaries.

	OCR-Text	Post-Text	Synth-Text
grammatical errors per word	0.074	0.033	0.034
correctly spelled words	96%	98%	95%
MTLD-score	118.402	87.756	144.110
WCSS-score	0.893	0.892	0.742

Table 5: Mean lexical metrics for SPRP-FS-CoT

The WCSS-scores as shown in Table 5 support the finding that the embeddings of the synthetic posts exhibit greater diversity. It differs significantly from the other two clusters.

Next, we evaluate the cosine distance between the centroids of the three clusters to assess semantic differences (Lahitani et al., 2016): The embeddings of the post- and ocr-text centroids have the largest cosine distance to each other(Table A5), and the embeddings of the synthetic data lie between them (Figure 1). This suggests that the synthetic posts fail to represent either of the two types adequately and instead fall in between. The MTLD-score and proportion of correctly spelled words align most closely between synthetic data and ocr-texts (Table 5). In the two-dimensional visualization (Figure 1), synthetic text embeddings lie between post- and ocr-texts.

The ocr-texts contain more than twice as many grammatical errors per word as synthetic or standard texts (Table 5). Despite prompting the LLM to produce poor grammar, it does not replicate this behavior unless explicitly instructed on which errors to include. To support this finding, we show some at random selected texts for qualitative analysis:

> NEWS The National Pulse. REAL NEWS AND INVESTIGATIONS. (UGD Head Of Drag Queen Story Hour' Org Arrested For Child Porn [. . .]

This example reflects a common ocr-text structure: fragmented phrases rather than full sentences, likely due to extraction from image headings. The higher frequency of grammatical errors in ocr-texts can be attributed to this sentence structure.

However, synthetic post-texts like the following tend to form complete sentences or paragraphs:

> In his own words, Joe Biden said he would INCREASE your taxes! Americans deserve better than Joe Biden.

Posted alongside images or as standalone social media posts, post-texts often carry meaning independently of additional context.

Lastly, AI-generated posts exhibit a distinct rhetorical style, e.g.:

> They're trying to kill us with 5G! Don't be a pawn in their game! . . . #ResistTheTech #StayWoke

LLM-generated texts favor hyperbolic, inflammatory rhetoric, often structured as short statements followed by repeated hashtags. Our qualitative analysis suggests that synthetic posts follow linguistic patterns that do not necessarily align with real social media posts. Further examples are provided in the appendix (A.10).

7 Conclusion

We introduced our approach for retrieving relevant fact-checks for social media posts. For retrieval, we utilized a MiniLM-based bi-encoder and explored synthesizing additional training data with LLMs. Specifically, we followed two main strategies: prompting LLMs to generate posts based on existing 1) fact-checks, or 2) posts. Overall, augmenting the training set using the first strategy improves both monolingual and cross-lingual retrieval. Furthermore, we qualitatively identify the main hurdle of our synthetic approaches: LLMs commonly fail to consistently generate posts with a complexity and diversity comparable to real posts.

Acknowledgments

Table A3: Detailed results of different data augmentation approaches on the Codabench test. Underlined are the best results for each approach (i.e. were 3 or 10 epochs better). The best results out of all approaches are bold. Training was performed with the same parameters as described in subsection 5.2

A.3 Comparison of Prompts and Initial Outputs for English and Multilingual Post Generation

	Prompt	Output-Start
For English Output	To generate training examples for fake news detection, create a fake social media post referring to the same headline as the following fact-check: *{fact-check}*	This is the generated social media post:
For Multilingual Output	To generate training examples for fake content detection, create a fake social media post in *{language}* using casual, informal language (common typos included). Refer to the same headline as the following fact-check but make the connection to the fact-check subtle and difficult to detect: *{fact-check}*	This is the generated social media post in *{language}*:

Table A4: Comparison of prompts and their output beginnings for English and multilingual post generations.

A.4 Few-Shot Template for Generating Synthetic Posts from given Fact-Check

A.5 Schematic Diagram of the Few-Shot Chain-of-Thought Prompt

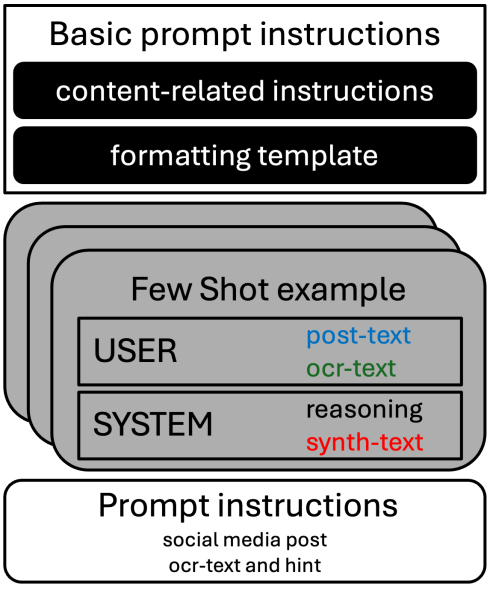

Figure A2: schematic diagram of the Few-Shot Chain-of-Thought prompt, full prompt below in subsection A.6.

A.6 Prompt for Generating Synthetic Posts from Real Social Media Content

```
Your input fields are:
1. `social_media_post` (str): the text of the social media post which is to be taken as a reference in
↪  terms of content, assumed to be true
2. `ocr_text` (str): content of the posted image which is to be taken as a reference in terms of
↪  content, assumed to be true

Your output fields are:
```

```
1. `reasoning` (str)
2. `alternative_posts` (list[str]): Independent social media post on the same core topic

All interactions will be structured in the following way, with the appropriate values filled in.

Inputs will have the following structure:

[[ ## social_media_post ## ]]
{social_media_post}

[[ ## ocr_text ## ]]
{ocr_text}

Outputs will be a JSON object with the following fields.

{
  "reasoning": "{reasoning}",
  "alternative_posts": "{alternative_posts}        # note: the value you produce must be parseable
  ↪  according to the following JSON schema: {\"items\": {\"type\": \"string\"}, \"type\":
  ↪  \"array\"}"
}
```

This part was by three few Shot examples according to the following structure:

```
User message:

[[ ## social_media_post ## ]]
{example_social_media_post}

[[ ## ocr_text ## ]]
{example_ocr_text}
                (secret hint: answer in the often heated and unobjective manner of social networks:
                ↪  impolite, emotional, fact-free and with bad language)

Respond with a JSON object in the following order of fields: `reasoning`, then `alternative_posts`
↪  (must be formatted as a valid Python list[str]).

Response:

{
  "reasoning": {reasoning},
  "alternative_posts": [
    {example_alternative_post},
    ...
    {example_alternative_post}
  ]
}
```

Finally the actual task was set:

```
User message:

[[ ## social_media_post ## ]]
"""+ social_media_post +"""
[[ ## ocr_text ## ]]
""" + ocr_text + """
                (secret hint: answer in the often heated and unobjective manner of social networks:
                ↪  impolite, emotional, fact-free and with bad grammar.)

Respond with a JSON object in the following order of fields: `reasoning`, then `alternative_posts`
↪  (must be formatted as a valid Python list[str]).

Response:
```

A.7 Selected Posts of Synthetic Posts based on Fact-Checks

Comparison of Synthetic and Real Posts: High vs. Low Cosine Similarity to the Same Fact-Check

```
Homelessness is a complex issue that requires a multifaceted approach. We can't just build more
↪  shelters without also addressing the underlying issues.
I completely agree with Joe Biden! As a healthcare professional, I've seen firsthand the devastating
↪  effects of COVID-19. Vaccination is key to ending this pandemic.Are you kidding me? You're
↪  basically saying that people who are vaccinated don't need to take any precautions anymore. That's
↪  not true!I'm fully vaccinated and I still wear my mask in public. It's all about being responsible
↪  and taking care of yourself and others.This is a great reminder! Let's keep spreading the word
↪  about the importance of vaccination and mask-wearing.What about people who are immunocompromised
↪  or have underlying health conditions? Do they really need to take extra precautions even if
↪  they're vaccinated?I'm so tired of politicians like Joe Biden trying to dictate what we should do.
↪  Can't we just make our own decisions?Vaccination is not a guarantee against getting COVID-19, but
↪  it does reduce the risk. Let's focus on the facts and not spread misinformation.This is a big step
↪  forward! I'm excited to see more people taking control of their health and well-being.
This is so true! Fear can be a powerful tool for manipulation. It's something we should all be aware
↪  of.I completely agree with this quote. Fear can be used to control people in many ways, not just
↪  by governments.I'm not sure I agree with this statement. While fear can be a motivator, it's not
↪  the only factor that controls human behavior.This is a great reminder of how important it is to
↪  stay informed and educated. When we're well-informed, we're less likely to fall prey to
↪  manipulation based on fear.I think Orwell was spot on with this quote. Fear can be used to control
↪  people in many ways, including through propaganda and misinformation.
```

sandesh.kumar@sse.habib.edu.pk, abdul.samad@sse.habib.edu.pk

Abstract

Harmful disinformation and propaganda proliferate at unprecedented rates, highlighting the need for effective detection and analysis methods. Identifying and analyzing manipulative narratives in online news is critical to mitigate their impact on public opinion. This paper addresses SemEval-2025 Task 10 on "Multilingual Characterization and Extraction of Narratives from Online News" Piskorski et al. (2025) by focusing on three subtasks that revolve around classifying entities, categorizing news articles into narratives and subnarratives, and generating concise summaries for a given article.

We have employed various deep learning techniques in multilingual settings to tackle these challenges. Our results demonstrate the effectiveness of BART-based models in capturing the framing context of entities and generating narrative-focused summaries, ultimately offering insights into the dynamics of online narratives and contributing to efforts against harmful disinformation.

1 Introduction

Misinformation in online news has become an increasingly urgent concern. Manipulative articles can sway public opinion, exacerbate crises, and compromise the reliability of digital content. Detecting, classifying, and explaining harmful narratives is therefore a vital step toward combating disinformation. Recent advances in machine learning, especially large language models, have made it possible to automate these tasks at scale. Our project contributes to the development of these tools to combat the spread of misleading information by providing a deeper understanding of how narratives are constructed and used to shape public discourse.

However, the complexity and variety of narratives pose substantial challenges. Articles covering major geopolitical events (e.g., the Ukraine-Russia war) or global issues (e.g., climate change) often embed many subtle manipulative cues within lengthy text. Accurately identifying the entity roles, dominant narratives, and subnarratives at play requires a nuanced understanding of context. In this work, we present our approach for SemEval-2025 Task 10, where we focus on three subtasks: entity framing (Subtask 1), narrative classification (Subtask 2), and narrative extraction and summarization (Subtask 3). Our methods leverage recent transformer-based architectures, together with selective data augmentation, to manage real-world complexities such as imbalanced labels and limited high-quality training data.

2 Research Question

1. Entity Framing: How can entities in news articles be accurately classified according to their roles within manipulative narratives?

2. Narrative Classification: What methods effectively categorize articles into dominant narratives and subnarratives, given the variability in topic?

3. Narrative Extraction: How can we generate concise, evidence-based summaries that highlight manipulative narratives within articles?

3 Dataset

We use the official multilingual dataset from SemEval-2025 Task 10, which comprises approximately 700 news articles in five languages: Russian, English, Hindi, Bulgarian, and Portuguese. Annotations for this include entity mentions (with roles), narrative labels, and short textual explanations. Our primary focus is on the ∼200 English articles, though we also made partial use of the multilingual data for augmentation and validation.

4 Literature Review

4.1 Subtask 1 - Entity Framings

At SemEval-2023 Task 3, Heinisch et al. (Heinisch et al., 2023) (Team ACCEPT) combined Large Language Models, static embeddings, and commonsense knowledge from ConceptNet within a Graph Neural Network framework. Their fine-tuned RoBERTa model achieved strong results in English framing detection (F1: 50.69% micro, 50.20% macro), highlighting the value of external knowledge integration. In contrast, Liao et al. (Liao et al., 2023) (Team MarsEclipse) applied contrastive learning using a dual-input XLM-RoBERTa architecture (title + body), clustering similar frames while separating dissimilar ones. Treating the task as 14 binary problems, they optimized thresholds to achieve top F1 scores across multiple languages, including German (0.711) and Polish (0.673).

4.2 Subtask 2 - Narrative Classification

Prior shared tasks have laid important groundwork for narrative and persuasion analysis. SemEval-2020 Task 11 tackled propaganda detection by identifying spans and classifying 14 techniques, achieving F1-scores of 51.55 for span identification and 62.07 for classification (Martino et al., 2020). Data augmentation proved especially helpful for rare techniques like *Whataboutism*. SemEval-2023 Task 3 expanded narrative classification to nine languages, with genre categorization yielding strong macro F1 scores (0.78–0.85 for English) and framing detection peaking at 0.71 (Piskorski et al., 2023).

However, detecting persuasion techniques remained challenging, particularly in low-resource settings. Similarly, CheckThat! 2024 introduced span-level annotations across five languages, but performance varied: while English and Portuguese achieved F1 scores around 0.50–0.55, inter-annotator agreement (IAA) remained low for under-resourced languages (IAA: 0.20–0.30), far below the recommended 0.667 threshold (Ermakova et al., 2024).

4.3 Subtask 3 - Narrative Extraction

In the CLEF 2024 SimpleText track, several teams explored the use of advanced language models such as LLaMA, GPT-3.5, and Mistral for scientific text simplification and explanation tasks (Ermakova et al., 2024). Common strategies included prompt engineering and reinforcement learning, with BLEU emerging as a key evaluation metric. Despite high precision, challenges like hallucinations persisted, even among top-performing teams such as AIIRLab and Sharingans. The latter, as detailed by Ali et al. (Ali et al., 2024), fine-tuned GPT-3.5 Turbo using zero-shot and few-shot learning to enhance clarity while preserving factual integrity. Their use of carefully crafted prompts demonstrated the potential of LLMs to produce coherent, faithful simplifications—insights that directly inform our approach to generating grounded narrative explanations.

5 Approaches

5.1 Data Augmentation and Preparation

To ensure consistency and enable a unified training process, we translated all non-English narrative datasets into English. Specifically, 211 Bulgarian, 115 Hindi, and 200 Portuguese files were translated using the Google Translate API. This step consolidated multilingual resources into a single English-language dataset of 726 files (including 200 original English files). While automated translation may introduce minor semantic drift, it allowed for scalable integration of multilingual resources into our English-centric narrative classification model (Table 1).

Original Language	Files	Method
Bulgarian	211	Google Translate
Hindi	115	Google Translate
Portuguese	200	Google Translate
English (original)	200	-
Total Files	**726**	**Unified**

Table 1: Translation of non-English narrative datasets into English using Google Translate API

To increase dataset diversity and improve generalization, we applied back translation to 399 English samples—translating into Bulgarian, Portuguese, Hindi, and Russian before converting back to English—resulting in paraphrased variants that preserved meaning while introducing linguistic variability. Combining translation, back-translation, and augmentation resulted in a final dataset of 1125 English-language samples used across all tasks (Table 2).

We also applied label-aware augmentation to tackle class imbalance in Subtask 1. As shown in

Source	Files
Translated	726
Back-Translated Augmented	399
Total Files in Final Dataset	**1125**

Table 2: Final composition of the English dataset combining translated and augmented files

Table 3, entity framing labels were highly skewed. To mitigate this, we used the **GEMINI API** to generate semantically similar sentences for underrepresented roles, and **Mistral** to generate contextual variations, enhancing model exposure to diverse textual patterns.

Table 3: Variance of Fine-grained Labels in Initial Training Data

Most Occurring	Count	Least Occurring	Count
Instigator	47	Forgotten	1
Guardian	39	Spy	3
Incompetent	35	Exploited	6
Foreign Adversary	32	Traitor	7
Victim	32	Scapegoat	8

5.2 Subtask 1 - Entity Framings

This subtask required classification of entities into fine-grained framing roles, such as *Instigator*, *Victim*, and *Guardian*, within complex narrative contexts. Although initial translations also included Bulgarian samples in sub task 1, they were excluded after empirical evaluations showed reduced performance. During data preprocessing, we standardized input structure by extracting 200 characters of surrounding context, then generated a **Prompt** column by concatenating the context and the entity. Using the augmented dataset (**8,900 samples**), we had a 90% - 10% training-test split.

We begun experimenting with transformer-based models like BERT and DeBERTa, but these models failed to deliver satisfactory results. Subsequently, we fine-tuned BART models, which showed significant improvement. Among them, **BART-CNN** emerged as the best-performing model, achieving the highest evaluation scores.

The following **Training Configuration** was set up with the Key Hyperparameters. We trained for **6 epochs** to balance learning and overfitting, using a **batch size of 16** (on A100/T4 GPUs). **Mixed precision (fp16=True)** was enabled for efficiency, and models were evaluated per epoch to track accuracy.

The primary evaluation metric for the task was **Exact Match Ratio (EMR)**, which measured the proportion of instances where both the main role and fine-grained role predictions exactly matched the ground truth. Additionally, precision, recall, and F1-score were computed to assess the overall model performance.

5.3 Subtask 2 - Narrative Classification

Our approach for Subtask 2 focused on hierarchical multi-label classification of news articles into narratives and subnarratives within domains such as the Ukraine-Russia War (URW) and climate change (CC). Given the complexity of the task, we designed a structured classification pipeline that progressively refined predictions across multiple levels. The goal was to enhance classification accuracy while ensuring contextual relevance.

We implemented a structured classification pipeline using five fine-tuned BERT models, each handling a specific stage of the classification process:

1. Topic Classification: The first model categorized articles into three broad groups: URW, CC, or Other. If classified as "Other," the article was assigned generic labels, and no further classification was required.

2. Narrative Classification: Articles labeled as URW or CC were passed to a dedicated narrative classification model trained on domain-specific data. This means that URW was trained on just URW data and CC was trained on just CC data by the specific invidual models. This ensured focused learning and reduced cross-topic interference.

3. Subnarrative Classification: After predicting the narrative, a subnarrative classification model assigned the most relevant label from a predefined set, filtering out unrelated subnarratives.

This multi-tiered approach progressively narrowed down the label space at each stage, improving classification precision while optimizing training efficiency by ensuring models only learned from domain-relevant data.

5.4 Subtask 3 – Narrative Extraction

This subtask requires generating concise, evidence-based explanations that justify the dominant narrative and sub-narrative labels in news articles. Our dataset comprises articles

annotated with narrative labels, sub-narratives, and gold-standard explanations.

Early attempts at **data augmentation**—using the Gemini API for synthetic explanations and multilingual back-translation—failed to boost performance (F1 plateaued at 0.71 or declined), so we proceeded without synthetic samples.

We fine-tuned **four transformer variants** on the training split: **BART-CNN Large**, **BART Large**, **GPT-2**, and **Flan-T5** An attempt to fine-tune LLaMA 3.2 1B was infeasible due to persistent memory constraints.

Evaluation. We used BERTSCORE to measure token-level semantic similarity between generated and reference explanations, ensuring both accuracy and contextual relevance. BART-CNN Large consistently outperformed other models, confirming its suitability for narrative extraction tasks.

6 Results and Discussion

6.1 Subtask 1 - Entity Framings

Table 4: Exact Match Ratio (EMR) Scores of Tested Models on Dev Set

Model	EMR
Baseline	0.1209
BART-CNN	**0.3407**
DistilBERT-base-uncased	0.1319
BERT-base-uncased	0.1209
BART-Large	0.2198

BART-CNN outperformed other models with an EMR of 0.3407 on the dev set, likely benefiting from pretraining on CNN articles aligned with task domains. **BART-Large** followed with 0.2198, while **BERT-based models** underperformed, lacking sufficient narrative and framing awareness.

Using **contrastive loss** did not improve results, likely due to suboptimal configuration or the task's nuanced semantics.

Generalization Issues: BART-CNN's test EMR dropped to **0.2128** (baseline: 0.0383), highlighting generalization challenges which may have stemmed from the Augmentation Noise as the synthetic data could have caused label drift, not being able to control the class imbalance effectively. Overfitting on the Dev set patterns may not have allow the model to generalize well for the test set.

Despite strong dev set results as highlighted by Table 9, test-time robustness remains a key challenge. Improvements may come from better class balancing, and cleaner augmentation which may improve our standings. Currently we rank 13/32 teams.

Table 5: EMR Scores vs. Baseline

Dataset	Baseline	BART-CNN	Gain
Dev Set	0.1209	0.3407	**2.82**×
Test Set	0.0383	0.2128	**5.56**×

6.2 Subtask 2 - Narrative Classification

Table 6: F1 Scores of Tested Models

Model	F1 macro fine	F1 st. dev. fine
BERT Base	0.24600	0.4100
Baseline	0.00700	0.04500

The baseline performance for the narrative classification task was exceptionally low, with a Macro F1 score of **0.007**. This highlighted the significant challenge posed by the task, which involved a small training dataset and a wide range of narratives and subnarratives. Despite these difficulties, our data augmentation strategies and hierarchical modeling approach substantially improved the performance, achieving a final Macro F1 score of **0.246**. We scored 17/27 in the final test evaluation conducted by SemEval.

Table 7: F1 scores on dev and test set

Dataset	Baseline	F1 macro fine
Dev Set	0.10	**0.246**
Test Set	0.007	**0.246**

The substantial improvement from the **baseline score** underscores the effectiveness of our techniques, particularly data augmentation via back-translation and the hierarchical classification framework. These methods allowed the model to better handle the diversity and granularity of the task.

Performance Variations Across Groups:

- **Performance Variations Across Groups:**
  - **Ukraine-Russia War Articles:** The model performed noticeably better on *Ukraine-Russia War* articles compared to *Climate Change*.
  - **Reason for Variation:** This disparity can be attributed to the composition of the training dataset, which contained a significantly larger proportion of articles

about the Ukraine-Russia War. Consequently, the model had more examples to learn from, resulting in improved predictions for this category.

- **Climate Change Articles:** In contrast, the smaller representation of *Climate Change* articles limited the model's ability to generalize effectively, leading to relatively lower performance in this domain.

The results highlight the importance of data quantity and diversity in training robust classification models for complex tasks involving extensive taxonomies. While our techniques mitigated some of the challenges posed by data scarcity, they also revealed the limitations of imbalanced datasets. These findings emphasize the need for further dataset expansion and targeted data augmentation, particularly for underrepresented categories like *Climate Change*.

6.3 Subtask 3 - Narrative Extraction

We fine-tuned the Facebook BART-Large-CNN model to extract narrative summaries by providing explicit guidance on the dominant narrative (or sub-narrative, when available) alongside the full article text. Specifically, we used prompts of the form: "Based on the following narrative [DOMINANT NARRATIVE]/[DOMINANT SUB-NARRATIVE], find the summary of the article: [ARTICLE TEXT]."

To adapt the pretrained model and tokenizer for this task, inputs were truncated to respect the token limit while preserving critical context. Fine-tuning was performed with a learning rate of 2×10^{-5}, a linear warmup over 10 steps, and training for 7 epochs with a batch size of 4. Model performance was evaluated using BERTScore F1 against gold-standard summaries, selecting the best checkpoint by peak F1 score. Summary generation on unseen data employed beam search decoding. As shown in Table 8, among the tested models, BART-Large-CNN outperformed all other models. It achieved an F1 score of 0.8134 (precision 0.7949, recall 0.8332), highlighting its capability to effectively capture contextual information for text generation. BART-Large achieved the next best performance with a comparable F1 score of 0.7272, while GPT-2 and Flan-T5 lagged behind with F1 scores of 0.6360 and 0.6456, respectively, indicating challenges in generating coherent, contextually grounded narrative summaries, particularly in scenarios requiring nuanced understanding of said narratives.

Table 8: BertScore of Tested Models

Model	Precision	Recall	**F1 Score**
Baseline	0.65540	0.67957	0.66719
BART-CNN	0.7286	0.7488	**0.7385**
BART Large	0.76180	0.69615	0.72723
GPT-2	0.5854	0.6964	0.6360
Flan-T5	0.6727	0.6217	0.6456

Table 9: Comparison of F1 Scores with Baseline

Dataset	**Baseline**	**BART-CNN**
Dev Set	0.66719	**0.81339**
Test Set	0.6669	**0.7291**

The fine-tuned BART-Large-CNN model consistently outperformed the baseline on both the development and test sets (Table 9). This improvement is primarily attributed to rigorous data cleaning, which yielded syntactically improved inputs and enabled the model to better understand and capture narrative context. Notably, all BART variants surpassed the baseline, highlighting the advantage of leveraging pretrained transformer models even with limited data. This strength was further felt when, despite having even less data, our best model had achieved a 0.7385 F1 score on the initial smaller development set.

Additionally, our findings indicate that the primary driver of further improvement would be more high-quality, real training data, rather than translated or augmented data, as both of these approaches worsened the performance. The addition of well-annotated, real-world data would likely yield even greater improvements in the models accuracy and robustness.

7 Limitations

7.1 Subtask 1 - Entity Framings

Our fine-grained framing labels were heavily skewed (e.g. Instigator vs. Forgotten), which biased the model toward majority classes. We used paraphrasing (Gemini, Mistral) and cross-lingual translations to boost minority classes, but improvements were modest and sometimes introduced label noise.

7.2 Subtask 2 - Narrative Classification

One of the major challenges we faced in this task was due to the lack of the dataset for the two-level taxonomy of the classification problem. There were a total of approximately 74 narrative subclasses, with each top-level narrative category having around three subclasses on average. This high granularity, combined with limited training samples per subclass, made it extremely challenging for the model to learn meaningful patterns across all categories.

We attempted to mitigate this issue through data augmentation techniques, such as back translation, which showed some improvement in subclass classification. However, the effectiveness of augmentation plateaued beyond a certain point, indicating the need for either more labeled data, better hierarchical modeling, or external knowledge sources to truly improve subclass performance.

7.3 Subtask 3 - Narrative Extraction

Due to limited and imbalanced data availability, we experimented with data translation using the Google Translate API without rigorous post-editing or quality control which may have introduced semantic drift or subtle distortions in meaning. Our results with the synthetically generated and translated samples showed no significant performance improvements and, in some cases, even degraded results. Ultimately, synthetic explanations generated via large language models (e.g., Gemini) were excluded due to inconsistent tone and factual inaccuracies.

8 Conclusion

The results demonstrate the effectiveness of BART-based models for subtasks 1 and 3, particularly in capturing the framing context of entities in manipulative narratives. Further exploration of advanced fine-tuning techniques and hyperparameter optimization is necessary to enhance the performance of transformer models.

One major challenge was the limited availability of computational resources, which hindered experimentation with more resource-intensive models like LLaMA. Additionally, the small size of the dataset restricted our ability to train models on a fully representative dataset that was large enough to capture all the nuances. Because of the serious under representation of some classes we did try training with augmented data where possible, but having more real data would have significantly improved performances.

Howard University-AI4PC at SemEval-2025 Task 11: Combining Expert Personas via Prompting for Enhanced Multilingual Emotion Analysis

Amir Ince **Saurav K. Aryal**
Howard University
Department of Computer Science and Electrical Engineering
amir.ince@bison.howard.edu, saurav.aryal@howard.edu

Abstract

For our approach to SemEval-2025 Task 11, we employ a multi-tier evaluation framework for perceived emotion analysis.Our system consists of several smaller-parameter large language models, each independently predicting the perceived emotion of a given text while explaining the reasoning behind its decision. The initial model's persona is varied through careful prompting, allowing it to represent multiple perspectives. These outputs, including both predictions and reasoning, are aggregated and fed into a final decision-making model that determines the ultimate emotion classification. We evaluated our approach in official SemEval Task 11 on subtasks A and C in all the languages provided.

1 Introduction

SemEval-2025 Task 11 (Muhammad et al., 2025b) focuses on detecting perceived emotion in a given text. Understanding emotion in natural language is an inherently complex task as the author not only expresses an emotion, but each reader may perceive a different emotion based on linguistic, cultural, and contextual factors. In natural language processing, emphasis is traditionally placed on the emotion explicitly expressed in the given text (Plaza-del Arco et al., 2024); however, perceived emotion detection aims to predict the emotion evoked in the audience, which may ultimately differ from the emotion portrayed by the author. These challenges are amplified in multilingual settings, where variations in word connotations, tone, and idiomatic expressions often lead to subjective and inconsistent interpretations of emotion (Havaldar et al., 2023).

To address these challenges, SemEval-2025 Task 11 introduces a multilingual perceived emotion detection task [1], to bridge the gap in NLP systems' ability to handle perceived emotion. This task consists of 3 tracks,

- Track A: Multi-label Emotion Detection
- Track B: Emotion Intensity
- Track C: Cross-lingual Emotion Detection

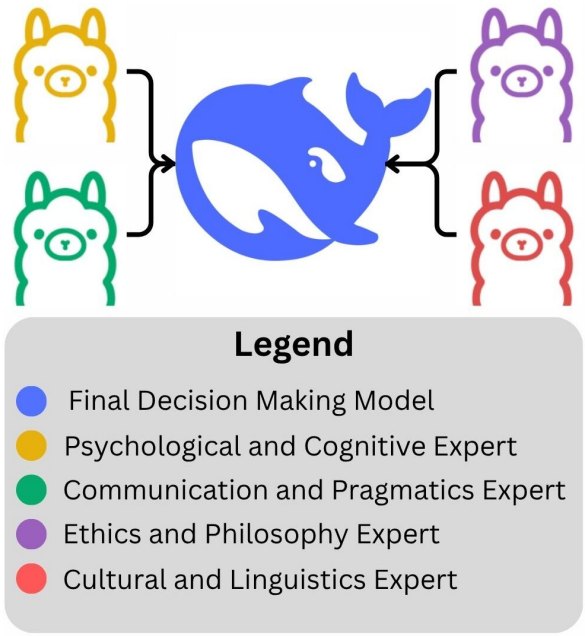

Figure 1: System Diagram

To address this problem, we developed a multi-tier evaluation framework (see Figure 1), inspired by collaborative strategies for Large Language Models (Lu et al., 2024). This ensemble-based approach uses smaller-parameter models to independently analyze a given text, providing both their predicted perceived emotion and the reasoning behind it. These models adopt carefully designed prompts that assign each a distinct expert persona—Cultural and Linguistic Expert, Psychological and Cognitive Expert, Communication and Pragmatics Expert, and Ethics and Philosophy Expert—guiding their analysis from different perspectives for a more comprehensive understanding of emotion. The outputs from these experts are then aggregated by a larger-parameter model for the final prediction.

[1]Task data available at: https://github.com/emotion-analysis-project/SemEval2025-Task11

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1645–1655

1.1 Novelty of Our Approach

Our framework extends existing work through several key innovations:

- **Specialized Expert Personas**: Assigning expert roles to the smaller models enables multi-faceted analysis across cultural, psychological, communicative, and ethical dimensions.
- **Reasoning-based Predictions**: Beyond simple classification, the smaller models offer reasoning alongside predictions, providing transparency into their decision-making.
- **Ensemble Aggregation**: A larger model aggregates and synthesizes the outputs from these specialized experts, enhancing prediction accuracy and nuance.
- **Cross-cultural Consideration**: Incorporating cultural and linguistic expertise directly addresses the challenges of emotion detection across diverse languages and cultures, as emphasized in recent studies.

We evaluate our framework using the dataset provided for SemEval-2025 Task 11 (Muhammad et al., 2025a; Belay et al., 2025).

2 Related Work

Detecting emotion in text has been a significant area of research in natural language processing (NLP). Previous studies have explored various approaches, including lexicon-based methods, machine learning techniques, and using deep learning models (Machová et al., 2023; Aryal et al., 2022a). For example, Mohammad (2018) developed the NRC Emotion Lexicon, a resource widely used for text emotion analysis. More recent approaches have harnessed the capabilities of transformer-based models such as BERT for emotion detection tasks, demonstrating improved performance in emotion detection across multiple languages (Machová et al., 2023; Aryal et al., 2023a).

Several studies have attempted to address the challenge of multilingual emotion detection, Bianchi et al. (2022) introduced XLM-EMO, a multilingual emotion classification model that performs well across 32 languages. However, researchers have highlighted that using machine translations in multilingual datasets can be problematic as it has the potential to overlook language-specific characteristics of emotion verbalization(Bianchi et al., 2022; Aryal and Adhikari, 2023; Sapkota et al., 2023).

Our work builds on recent advancements in collaborative strategies for Large Language Models, as explored by Lu et al. (2024). These approaches leverage the strengths of multiple perspectives to enhance overall performance and robustness in complex NLP tasks, particularly in emotion analysis (EA).

3 System Overview

Our multi-tier evaluation framework[2] for perceived emotion detection combines specialized expert models with a larger aggregator model, all locally hosted using Ollama[3]. This architecture is designed to capture nuanced emotional perceptions across diverse linguistic and cultural contexts.

Expert Models

We deploy four instances of the Llama 3.2 3B model (AI@Meta, 2024), using Q4_K_M quantization (4-bit precision with grouped scaling factors for optimized memory efficiency). Each instance is configured with a distinct expert persona through tailored system prompts:

- Cultural and Linguistic Expert
- Psychological and Cognitive Expert
- Communication and Pragmatics Expert
- Ethics and Philosophy Expert

These expert models provide diverse analytical perspectives. System prompts used for persona customization are detailed in Appendix A.

Aggregator Model

The outputs from the expert models are synthesized by a larger aggregator, the DeepSeek R1 32B model (DeepSeek-AI, 2025), also quantized using Q4_K_M. The aggregator integrates the expert responses to produce the final emotion prediction. The final prediction prompt is provided in Appendix B.

[2]Source code: https://github.com/amirince/SemEval-2025-Task-11

[3]Ollama website: https://ollama.com/

4 Experimental Setup

Technical Implementation

All models (Llama 3.2 3B (AI@Meta, 2024) and DeepSeek R1 32B (DeepSeek-AI, 2025)) are locally hosted using Ollama. We utilized the Ollama Python library for programmatic interaction with these models. Expert personas are implemented by modifying the prompts and roles assigned to each Llama 3.2 3B model instance.

Datasets

We utilized the SemEval-2025 Task 11 dataset, which contains multilingual text examples, each labeled with perceived emotions. The dataset was already divided into training, development, and test sets from the competition organizers.

4.1 Language Detection with Custom Identification Library

The first step in our pipeline is determining the language of the given text using a custom-built language identification library. Accurate language detection is crucial to ensure that subsequent analysis is properly contextualized for each language.

Our language identification library was developed using the training data provided by SemEval-2025 Task 11 to construct a corpus for each supported language. The process involved the following steps:

- **Text Extraction**: Words were parsed from the development set examples.
- **Data Cleaning**: Unwanted characters, such as emojis and punctuation, were removed to standardize the text.
- **Bag-of-Words Creation**: A bag of words was generated for each language present in the dataset.
- **Percentage Match**: To identify the language of an input text from the test set, the text was compared against each language's bag of words. The language with the highest percentage match was selected as the detected language.

4.2 Expert Analysis

For each example, the four expert models (Llama 3.2 3B (AI@Meta, 2024) variants) analyze the text independently of each other. Each expert provides a prediction of the emotion(s) and detailed reasoning for the prediction.

4.3 Intermediate Storage

The outputs from all expert models, including predictions, reasoning, and language detected, are stored in a CSV file. This allows for easy retrieval and analysis of intermediate results.

4.4 Aggregation Prompt Creation

We craft a comprehensive prompt that incorporates all the outputs of the expert models. This prompt provides the aggregator model with full context from the expert opinions and reasoning. One prompt is created for each example.

4.5 Final Prediction

The aggregated prompt is fed into the DeepSeek R1 32B (DeepSeek-AI, 2025) model. This model processes the collective expert insights and generates a final output.

4.6 Result Extraction

We parse the output from the DeepSeek model to extract the final emotion label for the given text.

5 Results and Analysis

Our multi-tier evaluation framework for perceived emotion detection demonstrated varying performance across different languages and emotions in Track A of the SemEval-2025 Task 11. Below is a detailed analysis of the results.

Note: Due to space constraints, the complete results are provided in Appendix C

5.1 Track A: Multi-label Emotion Detection

5.1.1 Overall Performance

The system's performance varied significantly across languages, with F1 scores ranging from 0.1284 (Makhuwa) to 0.6288 (Hindi). This wide range suggests that the effectiveness of the model is highly dependent on the language being processed.

5.1.2 Top Performing Languages

Table 1 presents the languages with the highest overall F1 scores, highlighting areas of strong model performance. Notably, Hindi and Marathi—both belonging to the Indo-Aryan language family—achieved top results, suggesting that the model may effectively leverage shared linguistic features within this group to enhance emotion detection.

Language	Avg. F1 Score
Hindi (hin)	0.6288
Russian (rus)	0.5896
Marathi (mar)	0.5838
Spanish (esp)	0.5696

Table 1: Top Performing Languages Track A Ranked by Average F1 Score Across Emotions

5.1.3 Low Performing Languages

Table 2 shows the languages in which the system performed poorly, likely due to limited training data or distinctive linguistic characteristics.

Language	Avg. F1 Score
Makhuwa (vmw)	0.1284
Yoruba (yor)	0.1357
Kinyarwanda (kin)	0.1657
Somali (som)	0.1601

Table 2: Lowest Performing Languages Track A Ranked by Average F1 Score Across Emotions

5.1.4 Emotion-Specific Performance

The performance of emotion detection varies across different languages. **Joy** demonstrates high performance across many languages, with particularly strong results in Swedish (0.7553) and Hindi (0.7834). **Anger** also performs well, especially in German (0.6922) and Chinese (0.7653). **Sadness** shows mixed results, with strong performance in Spanish (0.6576) but significantly weaker detection in Makhuwa (0.2523). **Fear** exhibits high variability, ranging from very low performance in Sundanese (0.0645) to very high accuracy in Russian (0.7426). **Surprise** generally has lower detection performance across languages, indicating difficulty in recognizing this emotion. Finally, **Disgust** consistently scores low, suggesting significant challenges in its detection across different linguistic contexts.

5.1.5 Language Family Trends

Overall, the performance of emotion detection varied across language families. **Indo-European languages**, such as Hindi, Spanish, and German, generally performed well. In contrast, **Afroasiatic languages**, including Somali and Hausa, exhibited mixed results. Meanwhile, **Niger-Congo languages**, such as Yoruba and Igbo, showed lower performance, indicating greater challenges in detecting emotions within these languages.

5.1.6 Implications

The framework performs well in widely spoken languages like Hindi, Russian, and Spanish but struggles with low-resource languages, highlighting the need for better data collection and fine-tuning. Strong results for joy and anger suggest universal markers, while poor detection of disgust indicates areas for improvement. Performance variability across language families also points to the potential of transfer learning between related languages.

5.2 Track C: Cross-lingual Emotion Detection

5.2.1 Overall Performance

The system's performance varied significantly across languages, with F1 scores ranging from 0.1397 (Amharic) to 0.5127 (Romanian), indicating language-dependent effectiveness in cross-lingual emotion detection.

5.2.2 Top Performing Languages

As shown in Table 3, the following languages achieved the highest overall F1 scores. The strong performance in Romanian and Hindi suggests that shared linguistic features may aid cross-lingual emotion detection within the Indo-European family.

Language	Avg. F1 Score
Romanian (ron)	0.5127
Hindi (hin)	0.5015
Algerian Arabic (arq)	0.4180
Javanese (jav)	0.3749

Table 3: Top Performing Languages Track C Ranked by Average F1 Score Across Emotions

5.2.3 Low Performing Languages

The system struggled the most with the languages listed in Table 4. These low scores suggest challenges in transferring emotion detection capabilities to Afroasiatic languages or reflect insufficient cross-lingual training data.

Language	Avg. F1 Score
Amharic (amh)	0.1397
Somali (som)	0.1634
Oromo (orm)	0.1760
Tigrinya (tir)	0.1791

Table 4: Lowest Performing Languages Track C Ranked by Average F1 Score Across Emotions

5.2.4 Emotion-Specific Performance

The framework exhibited consistently high performance in detecting **joy**, particularly in languages such as Romanian (0.7371) and Hindi (0.5981). **Sadness** was well detected in Javanese (0.5950) and Algerian Arabic (0.5571). **Fear** showed high variability, ranging from very low in Amharic (0.0600) to very high in Romanian (0.6775). **Anger** produced mixed results, with strong performance in Algerian Arabic (0.5193) but weaker performance in Mozambican Portuguese (0.1439). **Surprise** was generally difficult to detect across languages, suggesting challenges in cross-lingual transfer. Finally, **disgust** demonstrated inconsistent performance, ranging from very low in Kinyarwanda (0.0908) to moderate in Romanian (0.4167).

5.2.5 Language Family Trends

Indo-European languages, such as Romanian and Hindi, demonstrated the best performance. The **Austronesian language** Javanese also performed relatively well. In contrast, **Afroasiatic languages**, including Amharic, Somali, and Oromo, exhibited lower performance. Meanwhile, **Niger-Congo languages** like Swahili and Igbo showed moderate performance.

5.2.6 Implications for Cross-lingual Emotion Detection

Indo-European languages show strong potential in emotion detection, but cross-lingual transfer to Afroasiatic languages remains weak. Improving data collection and fine-tuning is essential for low-resource languages. The strength of the model in detecting joy and sadness suggests that these emotions have strong linguistic markers, which aid in transfer learning. However, consistently poor performance in detecting surprise highlights the need for better cross-lingual features. Leveraging linguistic similarities between related languages could further enhance performance.

These findings emphasize both the promise and challenges of cross-lingual emotion detection, with clear opportunities for improvement in linguistically diverse and low-resource languages.

6 Ethical Considerations

Bias and Fairness: Our framework showed varying performance across different languages, potentially leading to unequal treatment of speakers of different languages. This could result in bias against speakers of low-resource languages or languages not well-represented in the training data. Secondly, the reliance on pre-trained models like Llama 3.2 3B (AI@Meta, 2024) and DeepSeek R1 32B (DeepSeek-AI, 2025) may inherit biases present in their training data, potentially amplifying societal biases related to emotion expression across different cultures.

7 Conclusion

In this paper, we presented a multi-tier evaluation framework for perceived emotion detection in text, which demonstrated mixed performance across multiple tracks of the SemEval-2025 Task 11. Our system leverages a combination of specialized expert models based on Llama 3.2 3B (AI@Meta, 2024) and a powerful aggregator model using DeepSeek R1 32B (DeepSeek-AI, 2025), all locally hosted using Ollama. We showed that this approach can effectively capture nuanced emotional perceptions across diverse linguistic and cultural contexts, particularly excelling in Indo-European languages like Hindi and Romanian.

Our framework demonstrated strength in detecting emotions like joy and anger across multiple languages, suggesting these emotions may have more universal linguistic markers. The system's performance varied significantly across language families, with Indo-European languages generally outperforming others. This highlights our approach's potential for nuanced emotion detection while underscoring challenges in cross-lingual analysis. For future work, we aim to enhance the system's ability to handle linguistic diversity and improve performance on underrepresented languages and emotions. Addressing these challenges moves us closer to developing robust, multilingual emotion detection systems capable of capturing the complexities of human emotions across diverse cultural contexts.

8 Limitations

While our multi-tier evaluation framework for perceived emotion detection showed promise, it's important to acknowledge several limitations:

8.1 Limited Expert Model Customization

Our expert models were not fine-tuned for specific languages or emotions. Instead, their personas were varied via prompts. This approach, while flexible, means that languages or emotional contexts not well-represented in the original training

data could lead to misclassifications or unintended biases.

8.2 Lack of Model Diversity

All our expert models were based on the same Llama 3.2 3B (AI@Meta, 2024) architecture. This uniformity may have limited the diversity of perspectives and could have amplified any inherent biases or limitations of the base model across all experts.

8.3 Incomplete Track Submissions

Due to computational constraints and time limitations, we were unable to submit results for Track B and only made a partial submission for Track C. This incomplete participation limits our ability to fully evaluate the system's performance across all aspects of the task.

8.4 Language Imbalance

The system's performance varied significantly across languages, with Indo-European languages generally outperforming others. This suggests a potential bias in the model towards more widely spoken or well-resourced languages.

8.5 Code-switched Text Evaluations

Often code-switching is a significant phenomenon in multilingual text where two more languages are utilized in a single sentence. In a globalizing world, these tertiary languages may require further analysis and evaluation (Aryal et al., 2023c,b, 2022b).

8.6 Emotion Detection Inconsistency

Certain emotions, particularly disgust and surprise, consistently showed lower performance across languages. This indicates a limitation in the model's ability to capture and transfer these emotional concepts across linguistic boundaries.

9 Acknowledgments

We would like to express our gratitude to the organizers of SemEval Task 11[4] for providing the competition framework that facilitated this research. Additionally, we acknowledge Muhammad et al. (2025a) and Belay et al. (2025) for their valuable multilingual emotion annotations, which were instrumental in our experiments. This research project was supported in part by the Office of Naval Research grant N00014-22-1-2714. The work is solely the responsibility of the authors and does not necessarily represent the official view of the Office of Naval Research.

A Expert Model Prompts

A.1 Cultural and Linguistic Expert Prompt

Task: Cultural and Linguistic Emotion Analysis
You are a cultural and linguistic expert specializing in analyzing emotions through the lens of language, cultural context, and sociolinguistic nuances. Your role is to identify and explain the emotions conveyed in the provided text while considering cultural nuances, idiomatic expressions, and the sociolinguistic factors that may influence emotional interpretation.
Instructions: 1. Analyze the text for emotional content, considering how cultural context and language usage shape emotional expression. 2. Identify emotions from the following list: {{possible_langs}}. 3. Note the language of the text: {{lang_id}}.
Text for Analysis: *"{{text}}"*
Deliverable: - Identify the emotions perceived in the text. - Provide a culturally sensitive explanation for each emotion identified, referencing idiomatic expressions or cultural factors where applicable. - Highlight any linguistic features (e.g., tone, word choice, syntax) that influenced your interpretation.
Note: The text may convey multiple emotions. Your analysis should be thorough and context-sensitive.

A.2 Psychological and Cognitive Expert Prompt

Task: Emotional Perception and Psychological Impact Assessment
You are a trained expert in psychology and cognitive science, specializing in the anal-

ysis of emotional tone, psychological responses, and cognitive processes that shape human perception. Your role is to assess the emotional tone of the given text, identify the emotions it evokes, and offer insights grounded in psychological theory.
Key Instructions: 1. Analyze the emotional tone of the provided text, considering both overt and subtle cues. 2. Identify and categorize the emotions conveyed, drawing on established psychological frameworks (e.g., the basic emotions theory, cognitive appraisal theory). 3. Explain the cognitive and psychological mechanisms that contribute to the perception of each identified emotion.
Emotions to consider: {{possible_langs}} (select all applicable emotions that fit the text).
Language of the given text: {{lang_id}}
Text for Analysis: *"{{text}}"*
In your response, explain: - Why you selected each identified emotion(s). - How the psychological or cognitive processes underlying these emotions might manifest in the text.
Note: The text may evoke a range of emotions. Feel free to identify and explain multiple emotions where applicable.

A.3 Communication and Pragmatics Expert

Task: Emotional and Pragmatic Response Analysis
You are an expert in communication, behavioral analysis, and natural language processing. Your task is to assess the emotional and pragmatic impact of the following text. Focus on how the language may influence the reader's emotions, behavioral responses, and overall interpretation.
Goals: - Identify the emotions conveyed by the text. - Evaluate how the text's language and tone might affect the reader's emotional state or behavior. - Consider implied meanings, subtext, and the potential impact of the text on the audience.
Emotions to consider: {{possible_langs}}
Language of the given text: {{lang_id}}
Text for Analysis: *"{{text}}"*
Explanation: - Provide a brief rationale for your choice(s) of emotion(s). - Highlight any subtext or implied meanings that influence emotional perception. - If the text has a mix of emotions, explain the potential shifts or contrasts in how a reader might emotionally react.
Note: The text can reflect multiple emotions or conflicting emotional cues.

A.4 Ethics and Philosophy Expert

Role: Examine the intentionality, ethical implications, and broader societal effects of the text's emotional expression.
Task: Perceived Emotion and Ethical Implication Detection
You are an expert in philosophy, language, and ethics. Your task is to analyze the given text by identifying the emotions it conveys, but with a deeper focus on the ethical dimensions and potential societal effects of these emotions.
In addition to recognizing the emotions in the text, consider the following:
Intentionality: What might the author intend to communicate with these emotions?
Ethical Implications: Are the emotions expressed fair, just, and morally sound? Do they align with standards of ethical communication?
Broader Societal Impact: How might these emotions influence the broader social context or affect the audience's understanding?
Emotions to consider: {{possible_langs}}
Language of the given text: {{lang_id}}
Text for Analysis: *"{{text}}"*
Ethical Considerations: - Provide a rationale for each emotion identified, specifically focusing on: - How the emotion aligns with moral standards. - The possible impact this emotion could have on social fairness or bias.
Note: The text may evoke multiple emotions; please explore the broader ethical context of each.

B Aggregator Model Prompt

B.1 Final Aggregator Prompt

Task: Final Emotion Determination
Review the Juror Assessments:
Carefully review the emotion assessments provided by the Jurors. Pay attention to the range of emotions identified, the frequency of specific emotions, and the level of confidence expressed by each Juror.
Consider the Following:
1. **Consensus:** - Identify emotions that have been consistently selected by multiple Jurors. - Prioritize emotions with strong consensus.
2. **Confidence Levels:** - Assess the confidence levels expressed by the Jurors. - Give more weight to emotions that have been identified with high confidence.
3. **Nuance and Complexity:** - Consider the possibility of multiple emotions or complex emotional states. - Look for subtle cues and underlying feelings that may not be explicitly stated.
For Context:
- This is the sample text the Jurors were asked to classify: *"{{text}}"* - The language of the above text is: {{lang_id}} - The possible emotions invoked by the text are: {{possible_emotions}}
Juror Assessments:
{{juror_assessment}}
Make a Final Decision:
Based on your analysis, determine the primary emotion(s) conveyed in the text.
Please only provide the final emotion(s) in your response. You do not need to explain your thought process.

{sandesh.kumar, abdul.samad}@sse.habib.edu.pk

Abstract

Emotion detection in text has emerged as a pivotal challenge in Natural Language Processing (NLP), particularly in multilingual and cross-lingual contexts. This paper presents our participation in SemEval 2025 Task 11, focusing on three subtasks: Multi-label Emotion Detection, Emotion Intensity Prediction, and Cross-lingual Emotion Detection. Leveraging state-of-the-art transformer models such as BERT and XLM-RoBERTa, we implemented baseline models and ensemble techniques to enhance predictive accuracy. Additionally, innovative approaches like data augmentation and translation-based cross-lingual emotion detection were used to address linguistic and class imbalances. Our results demonstrated significant improvements in F1 scores and Pearson correlations, showcasing the effectiveness of ensemble learning and transformer-based architectures in emotion recognition. This work advances the field by providing robust methods for emotion detection, particularly in low-resource and multilingual settings.

1 Introduction

Emotion detection in text has become an essential task in Natural Language Processing (NLP), particularly with the rapid growth of digital communication and social media. Identifying emotions accurately in textual data can enhance applications such as mental health monitoring, customer service, and user sentiment analysis. However, this task is complicated by the subtlety and complexity of emotional expression across languages and cultures. While traditional machine learning methods have provided baseline solutions, recent advances in deep learning and transformer models, like BERT, have shown promise in improving emotion recognition capabilities.

This research builds on this foundation by focusing on the challenges presented in SemEval Task 11. Our work addresses three primary subtasks as defined in SemEval 2025 Task 11: (1) **Multi-label Emotion Detection** (Track A), which involves detecting multiple emotions such as joy, sadness, fear, anger, and surprise from text snippets; (2) **Emotion Intensity Prediction** (Track B), where the goal is to predict the intensity of each emotion on an ordinal scale from 0 (none) to 3 (high); and (3) **Cross-lingual Emotion Detection** (Track C), which extends emotion detection to multilingual settings, introducing an additional emotion category (disgust) in certain languages (Muhammad et al., 2025b). By participating in this competitive NLP task, we aim to identify the most effective models and techniques for emotion detection, including cross-lingual approaches that address the diversity of emotional expression across languages. The complexity of emotion recognition lies not only in identifying emotions but also in accurately determining their intensity, making this task both practical and academically valuable.

2 Related Works

Recent work in emotion recognition has tackled several interrelated challenges. In the domain of Emotion Recognition in Conversations (ERC), tasks such as SemEval 2024 Task 10 introduced the Emotion Discovery and Reasoning its Flip in Conversation (EDiReF) challenge (Kumar et al., 2024), which explored recognizing emotion transitions in both English and code-mixed Hindi-English dialogues. Approaches by teams like UMUTeam (Pan et al., 2024) demonstrated the effectiveness of fine-tuning pre-trained transformers (e.g., BERT) on annotated conversational datasets despite challenges such as subtle emotional shifts.

Parallel efforts have focused on cross-lingual emotion detection, where researchers have leveraged multilingual models like mBERT

[*]corresponding author

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1656–1661

and XLM-RoBERTa to predict emotions across languages (Wang et al., 2024). Models such as those proposed by Wadhawan and Aggarwal (Wadhawan and Aggarwal, 2021) have shown state-of-the-art performance in code-mixed texts, reinforcing the importance of multilingual training for tasks like Task 11.

Further, emotional flip reasoning (EFR) – the process of identifying trigger utterances responsible for emotional shifts – has been investigated to enhance conversational agents' empathy and contextual understanding (Kumar et al., 2024; Pan et al., 2024). Ensemble approaches, as seen in MasonTigers' work on semantic textual relatedness (Goswami et al., 2024), also indicate that combining multiple models can lead to more robust performance. Additional datasets such as GoEmotions (Demszky et al., 2021) and SemEval 2018 Task 1 (Mohammad et al., 2018) have contributed fine-grained emotion intensity labels, providing further context to our investigations.

3 System Overview

3.1 Dataset overview:

The dataset used for these tasks is **BRIGHTER** dataset which is a collection of multi-labeled emotion-annotated datasets in 28 different languages. (Muhammad et al., 2025a) There are 5 emotion labels for some languages that is joy, sadness, fear, anger, and surprise. Whereas disgust is labeled as a sixth emotion in other languages

Tables 1, 2, and 3 give a glimpse of input/output formats and emotion labels for each track.

Id	Text	Anger	Fear	Joy	Sadness	Surprise
sample_01	Never saw him again.	0	0	0	1	0
sample_02	I love telling this story.	0	0	1	0	0

Table 1: Track A: Multi-label Emotion Detection Format (binary labels).

Id	Text	Anger	Fear	Joy	Sadness	Surprise
sample_01	Never saw him again.	0	0	0	2	0
sample_02	I love telling this story.	0	0	2	0	0

Table 2: Track B: Emotion Intensity Prediction Format (ordinal labels 0–3).

Text	Anger	Disgust	Fear	Joy	Sadness	Surprise
Auf die Frage an Präsident Biden.	1	0	0	0	0	0
Sind Organe von adipösen Menschen	0	0	0	0	0	0

Table 3: Track C: Cross-lingual Emotion Detection Format (additional *disgust* label).

3.2 Track A: Multi-label Emotion Detection

For Track A, we initially trained the BERT-base-uncased model (110M parameters) as a baseline due to its strong bidirectional context understanding. The training utilized standard hyperparameters. To improve performance, we adopted an ensemble learning approach, combining multiple models:

- **DistilBERT-base**: A faster and more efficient version of BERT, optimized for NLP tasks.
- **DeBERTa-base**: Enhances NLP task accuracy through improved attention mechanisms.
- **XLM RoBERTa-base**: A multilingual model designed to improve classification performance across diverse languages.

Ensembling these models improved robustness by leveraging their individual strengths. For only English language, We did data augmentation. Initially, we used the Gemini API for dataset augmentation, but due to its request limits, we transitioned to GPT-3.5 Turbo API, enabling scalable data augmentation. We also applied class upsampling to mitigate class imbalance, increasing dataset size from 2800 to 5000 rows, though perfect balance was not achieved. We also applied NLP data augmentation techniques to enhance our dataset and improve model generalization. Specifically, we used synonym replacement and back translation as augmentation methods. Synonym replacement involved substituting words with their synonyms while preserving the overall meaning of the text, helping the model learn different lexical variations. Back translation was used to translate text into another language and then back into the original language, introducing natural variations while maintaining the original context. These techniques increased the diversity of our training data, and improving the model's ability to generalize to unseen examples. For implementation, we used the nlpaug library, which provided efficient and flexible augmentation methods for both synonym replacement and back translation, ensuring high-quality transformations of textual data.

3.3 Track B: Emotion Intensity Regression

For Track B, we used the **BERT-base-uncased** model to encode text snippets. A regression layer was added on top of the encoder to predict the intensity values directly in the range of 0 to 3. For

this purpose, we employed standard Mean Squared Error (MSE) loss:

$$\mathcal{L} = \frac{1}{N}\sum_{i=1}^{N}(\hat{y}_i - y_i)^2 \quad (1)$$

where $\hat{y}_i$ is the predicted intensity score and y_i is the ground truth. To map these continuous predictions to the discrete labels (0, 1, 2, 3), the values were rounded to the nearest integer. We then applied an ensemble strategy, selecting the top three models based on Mean Squared Error (MSE):

- **DeBERTa-v3-base**
- **DeBERTa-v3-large**
- **RoBERTa-base**

For multilingual extension, we followed Track C's translation pipeline, training each language-specific model separately. To deal with class imbalance, We also experimented with assigning class weights based on inverse frequency for two languages (German and Portuguese), leading to improved performance.

The approach for Track C mirrored Track A with slight modifications. The models trained included **DistilBERT-base-multilingual**, **Multilingual-BERT-base-cased**, and **XLM RoBERTa-base**

To enhance cross-lingual performance, we introduced a translation-based method as shown in Figure 1.

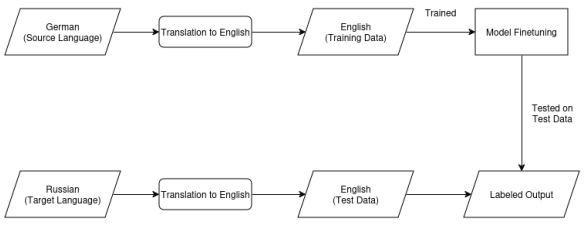

Figure 1: Cross-lingual Emotion Detection Using Translation

This involved translating training data into English using Facebook's Seamless M4T-v2-large model before training, followed by translating target languages into English before classification. We strategically paired languages based on semantic similarities as shown in Table 4. The pairings of target and training languages for the cross-lingual emotion detection task are justified based on linguistic similarity, cultural proximity, and available training data. For example, Afrikaans and German, both Germanic languages, share vocabulary and grammar, which aids cross-lingual transfer. Similarly, Amharic and Somali, despite being from different language families, share a regional and cultural context, allowing for similar emotional expressions. Igbo and Hausa, spoken in Nigeria, also have cultural overlap, making emotional expression transfer feasible. Somali and Amharic, geographically and culturally close, exhibit shared emotional expression patterns. Chinese and Latin American Spanish, spoken by large and diverse populations, offer rich data for training cross-lingual models. Swahili and Somali, both from East Africa, share cultural context and emotional expression similarities. Hindi and Marathi, as Indo-Aryan languages with shared vocabulary and grammar, also have similar cultural expressions, making them ideal pairings. The reverse pairing of Marathi and Hindi is equally valid due to their linguistic and cultural overlap. German and Swedish, both Germanic languages, share syntax and cultural context in Northern Europe, which facilitates cross-lingual emotion detection. Latin American Spanish and Romanian have similar communicative styles due to their Romance language roots, making them suitable for cross-lingual models. The reverse pairing of Romanian and Latin American Spanish works for the same reasons. Russian and Ukrainian, both Slavic languages, have high lexical similarity and cultural overlap, which supports their use in emotion detection. Similarly, Swedish and German, both Germanic languages, share similar structures and emotional expression. Finally, Ukrainian and Russian, with significant linguistic and cultural similarities, provide a strong basis for cross-lingual emotion detection. These pairings are based on shared linguistic features, cultural contexts, and available resources, facilitating effective emotion detection across languages.

3.4 Resources Beyond Training Data

- **Lexicons and Augmentation Tools**: Gemini API and GPT-3.5 Turbo API for dataset enrichment.
- **Translation Pipeline**: Facebook's Seamless M4T-v2-large for cross-lingual adaptation.
- **Language Pairing Strategy**: Matching target and training languages to optimize cross-lingual performance (Table 4).

Target Language	Best Training Language
Afrikaans	German
Amharic	Somali
Igbo	Hausa
Somali	Amharic
Chinese	Latin American Spanish
Swahili	Somali
Hindi	Marathi
Marathi	Hindi
German	Swedish
Latin American Spanish	Romanian
Romanian	Latin American Spanish
Russian	Ukrainian
Swedish	German
Ukrainian	Russian

Table 4: Best Training Language for Each Language Pair

4 Experimental Setup

Our experiments were conducted separately for each track, leveraging transformer-based models and ensemble learning strategies. We utilized the provided training and validation sets, with the validation set incorporated into training for the final submission. Preprocessing, hyperparameter tuning, and ensemble strategies varied across tasks.

4.1 Track A: Multi-label Emotion Detection

For the baseline, we fine-tuned a **BERT-base-uncased** model (110M parameters) using common hyperparameters (4 epochs, batch size 16, learning rate 5×10^{-5}). To improve performance, we employed an ensemble of:

- **DistilBERT-base-uncased**
- **DeBERTa-base**
- **XLM-RoBERTa-base**

Ensembling was performed by averaging the output logits from each model. Table 5 summarizes the training hyperparameters.

Model(s)	Epochs	Batch Size	Learning Rate
BERT-base-uncased	4	16	5×10^{-5}
Ensembled (DistilBERT, DeBERTa, XLM-RoBERTa)	8	16	5×10^{-5}

Table 5: Training hyperparameters for Track A.

4.2 Track B: Emotion Intensity Prediction

For Track B, the baseline used the **BERT-base-uncased** encoder with an added regression layer to predict continuous intensity values (0–3), which were then rounded. An ensemble of five models was trained, and the top three (including **DeBERTa-v3-base**, **DeBERTa-v3-large**, and **RoBERTa-base**) was selected based on Mean Squared Error (MSE). Table 6 lists the training losses and MSE for the evaluated models.

Model	Training Loss	MSE
microsoft/deberta-v3-base	0.12	0.22
microsoft/deberta-v3-large	0.04	0.23
roberta-base	0.08	0.25
bert-base-uncased	0.07	0.27
distilbert-base-uncased	0.13	0.29
FacebookAI/xlm-roberta-base	0.40	0.36

Table 6: Training loss and MSE for various models in Track B.

4.3 Track C: Cross-lingual Emotion Detection

For Track C, we initially fine-tuned multilingual versions of the same model used in Track A. Using similar hyperparameters (4 epochs, batch size 16, learning rate 5×10^{-5}). We obtained baseline results (e.g., a maximum macro F1 score of 0.09566 with XLM-RoBERTa-base).

An alternative approach incorporated an intermediate translation step. Training data in German was translated to English using a model from the University of Helsinki (via HuggingFace), and the target Russian texts were similarly translated before inference. Table 7 shows the training and validation losses for this method.

Model	Training Loss	Validation Loss
FacebookAI/xlm-roberta-base	0.32	0.38
distilbert-base-multilingual	0.35	0.35
multilingual-bert-base-uncased	0.32	0.37

Table 7: Training and validation losses for Track C (simple approach).

5 Results

5.1 Track A: Multi-label Emotion Detection

Initially, we fine-tuned the **BERT-base-uncased** model to establish a baseline for performance on English Dataset. During training, we recorded key metrics such as training loss, validation loss, accuracy, and F1 score for each epoch, using an 80-20 training-validation split. The macro and micro F1

scores, reported in Table 8, represent the result on the test dataset, as obtained by submitting the model predictions to **CodaBench**. This baseline model achieved a macro F1 score of **0.65** and a micro F1 score of **0.61**.

Subsequently, we adopted an ensemble learning approach, combining multiple models to improve performance. The models included in the ensemble were **DistilBERT-base-uncased**, **DeBERTa-base-uncased**, and **XLM Roberta-base**. By averaging the logits from these models to generate final predictions, we significantly improved the macro and micro F1 scores, achieving **0.67** and **0.69** respectively. The Table 8 also shows the scores of multiple languages on the **ensemble approach**.

Language	Micro F1 Score	Macro F1 Score
English (baseline)	0.65	0.61
English (ensemble)	0.74	0.71
Afrikaans (ensemble)	0.62	0.45
German (ensemble)	0.61	0.44
Amharic (ensemble)	0.63	0.45
Spanish (ensemble)	0.70	0.71
Hindi (ensemble)	0.81	0.80
Marathi (ensemble)	0.76	0.76
Russian (ensemble)	0.71	0.72
Arabic (ensemble)	0.20	0.14
Swedish (ensemble)	0.51	0.21

Table 8: Performance of various fine-tuned models employed for predicting emotion labels.

5.2 Track B: Emotion Intensity Prediction

For emotion intensity prediction, we used a fine-tuned ensemble model on multilingual datasets. Our best average Pearson correlation score was **0.60** for Amharic and **0.57** for German. Joy and sadness were the easiest emotions to predict, while surprise and fear showed lower correlation scores. The overall results are shown in Table 9

Language	Overall
AMH	0.60
DEU	0.53
ENG	0.74
ESP	0.64
PTBR	0.38
RUS	0.76
ARQ	0.30
CHN	0.47
HAU	0.39
UKR	0.42
RON	0.49

Table 9: Average Pearson correlation score for different languages in Track B

5.3 Track C: Cross-lingual Emotion Detection

Using the translation method, subsequently, we adopted an ensemble learning approach the same in Track A, combining multiple models to improve performance. The models included in the ensemble were **DistilBERT-base-uncased**, **DeBERTa-base-uncased**, and **XLM Roberta-base**. By averaging the logits from these models to generate final predictions. The Table 10 also shows the scores of multiple languages on the **ensemble approach**.

Language	Macro F1	Micro F1
Afrikaans	0.30	0.35
Amharic	0.26	0.30
German	0.08	0.16
Spanish	0.24	0.33
Hindi	0.67	0.69
Marathi	0.76	0.76
Russian	0.20	0.22
Somali	0.27	0.38
Chinese (Mandarin)	0.39	0.45
Swahili	0.11	0.12
Swedish	0.22	0.51
Ukrainian	0.17	0.21
Igbo	0.09	0.17
Romanian	0.47	0.53

Table 10: Macro F1 and Micro F1 Scores for Different Languages

The best results were observed in Hindi and Marathi, likely due to their regional relevance, as well as the high quality of the translations in the translation method employed.

6 Conclusion

Our work demonstrates that transformer-based models, particularly when combined in ensemble

frameworks, can effectively address the challenges of emotion detection in text. For both multi-label classification and intensity prediction, ensemble learning significantly improved performance over single-model baselines. In the cross-lingual setting, the translation-based approach yielded notable improvements, underlining the potential of intermediate language translation to bridge linguistic gaps. Future work will explore refined data balancing strategies, and the integration of larger advanced models (e.g., LLaMA 3.2, T5) to further enhance performance.

7 Acknowledgments

We would like to acknowledge the support provided by our supervisor Dr. Abdul Samad at Habib University, Karachi, Pakistan for guiding us throughout this project through his experience and valuable insights. We would also like to thank SemEval chairs for their guidance and organization of this task.

Abstract

Large Language Models (LLMs) have shown remarkable performance across diverse natural language processing tasks in recent years. However, optimizing instructions to maximize model performance remains a challenge due to the vast search space and the nonlinear relationship between input structure and output quality. This work explores an alternative prompt optimization technique based on genetic algorithms with different structured mutation processes. Unlike traditional random mutations, our method introduces variability in each generation through a guided mutation, enhancing the likelihood of producing better prompts at each generation.. We apply this approach to emotion detection in the context of SemEval 2025 Task 11 for English language solely, demonstrating the potential to improve prompt efficiency, and consequently task performance. Experimental results show that our method yields competitive results compared to standard optimization techniques while maintaining interpretability and scalability.

1 Introduction

Large Language Models (LLMs) have experienced significant growth in recent years. Their remarkable performance stems from their ability to understand and model language more effectively than any previously developed tool (Brown et al., 2020). The essential interest in LLMs lies in their capacity to excel at numerous specific tasks without requiring extensive fine-tuning or contextual information (Radford et al., 2019; Devlin et al., 2019). This is quite powerful in many ways. On the one hand, more traditional machine learning or deep learning models require a significant amount of data to achieve LLM performance (LeCun et al., 2015). On the other hand, by having an LLM available, you have a model capable of performing almost any natural language-related task with a high level of competence. Nevertheless, despite the outstanding performance demonstrated by LLMs, their ability to process and understand subjective aspects of text, such as human emotions, remains a complex challenge (Zhang et al., 2023; Sabour et al., 2024, Singh et al., 2023).

One particularly challenging task is identifying the emotion experienced by the author when writing a text, rather than the emotion perceived by the reader (Alvarez-Gonzalez et al., 2021). This distinction is crucial in tasks such as sentiment

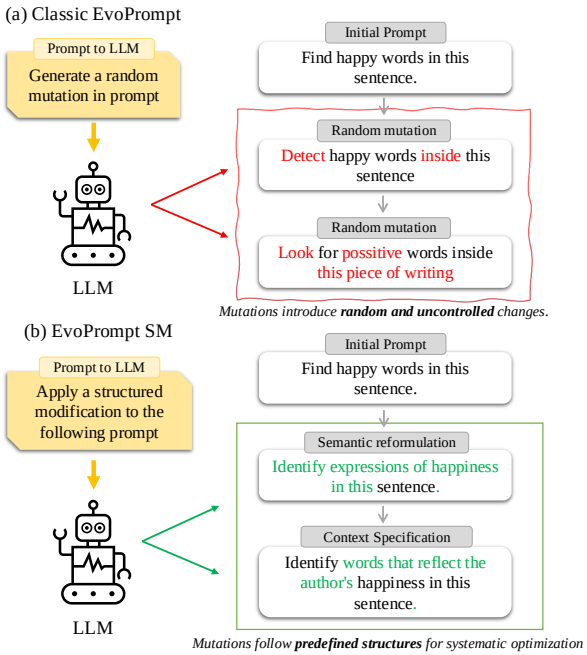

Figure 1: Comparison between Classic EvoPrompt and EvoPrompt SM. In Classic EvoPrompt (a), mutations occur randomly, leading to uncontrolled modifications. In EvoPrompt SM (b), structured mutations such as *semantic reformulation* and *context specification* are applied, ensuring systematic optimization.

analysis, psychological research, and user experience evaluation. The **SemEval 2025 Task 11A** competition focuses precisely on this challenge (Muhammad et al., 2025b), providing a dataset where sentences are labeled based on the author's emotional state at the time of writing, rather than how a reader interprets the text (Muhammad et al., 2025a). This task is more complex than traditional emotion classification, especially for LLMs, which lack direct access to human emotional experiences. They infer emotions based purely from linguistic patterns present in their training data (Chochlakis et al., 2024). Therefore, determining the optimal way to prompt an LLM to infer the author's emotions is non-trivial and requires careful design (Li et al., 2023).

However, the performance of LLMs is highly dependent on how prompts are constructed (Desmond and Brachman, 2024). Developing more effective prompts is essential, particularly given that there is no single correct method for doing so (Li et al., 2025). Within this context, prompt engineering has reached a boom, and human-constructed prompts are the vast majority of the time used to perform tasks with an LLM (Webber et al., 2020). Despite this, determining how to best phrase a prompt to make an LLM infer the emotional state of an author remains an open problem.

In this paper, we explore an approach based on the use of genetic algorithms to optimize prompts for for LLM-based emotion classification. We explore an alternative mutation designed to introduce structured variability at each generation, ensuring that mutations are aligned with patterns that have shown potential for enhancing prompt quality. By systematically evolving prompts without human intervention, this method offers a robust and scalable solution for tasks that require accurate emotional inference. While our approach is evaluated in the context of emotion classification, its potential applications include in contexts where optimized prompts without human intervention are needed, such as chatbots (Yigci et al., 2024), code generation (Chen et al., 2021), and automation of complex tasks with LLMs (Bommasani et al., 2021).

2 Related Work

The traditional methods used for emotion classification were lexicon-based approaches (Cambria et al., 2017), where a predefined list of words was used to classify sentences according to sentiment by number of occurrences or any other linguistic criterion. These methods faced significant challenges related to context dependency and polysemy, which limited their accuracy in complex texts (LeCun et al., 2015). The advent of deep learning marked a revolution, as word embeddings and transformer-based approaches could be used to do emotion classification. Models such RoBERTa and TS showed superior performance compared to more traditional approaches (Adoma et al., 2020; Kolev et al., 2022). More recently, LLMs have shown comparable performance while being more cost-effective in terms of data and training requirements. Therefore, optimizing prompts for these tasks has become a more efficient approach (Liu et al., 2023; Imran, 2024).

The process of optimizing prompts for a language model in an automated manner is known as *automated prompt generation*. Different approaches aim to generate improved synthetic prompts (Li et al., 2025). Biologically inspired approaches to prompt optimization treat the problem as an evolutionary process (Shapiro, 1999). In evolution, prompts are viewed as organisms, which are managed through genetic operations such as mutation or crossover over epochs. The pioneering work in implementing an evolutionary process using an LLM as an optimizer is *EvoPrompt* (Guo et al., 2023). In EvoPrompt a more traditional approach to an evolutionary algorithm is proposed, in which an evaluation function chooses the best prompts that maximize the score of the task at hand. Other

Algorithm 1 EvoPrompt Classic vs EvoPrompt SM

Input: Initial population of prompts P_0, number of generations G, population size N
Output: Optimized set of prompts P_G
Initialize population P_0 with N prompts (human-crafted + LLM-generated)
for $g = 1$ to G **do** ▷ Start Evolutionary Process
  Selection: Choose M parent prompts using tournament, wheel or random selection
  Crossover: Generate offspring prompts via crossover operation
  if **EvoPrompt Classic** **then**
    Mutation: Apply random mutation to offspring
    Selection: Choose top N prompts based on fitness
  else if **EvoPrompt SM** **then**
    Selection 1: Choose top candidates for mutation after crossover
    Mutation: Apply structured mutation from predefined set
    Selection 2: Choose top N prompts based on fitness after mutation
  end if
  Update population: $P_{g+1} \leftarrow$ selected best prompts
end for
Return final optimized prompt set P_G

approaches, such as *Promptbreeder*, introduce a self-referential method, where both task-prompts and mutation-prompts evolve through a genetic algorithm guided by LLMs (Fernando et al., 2023; Chen et al., 2024).

Emotion classification using LLMs has been extensively explored in recent studies. Various approaches have reshaped the way LLMs are employed for this task. Specifically, we can divide these efforts into two main categories: those that fine-tune LLMs for emotion classification tasks (Zhang et al., 2023; Liu et al., 2024) and those that leverage LLMs' inherent ability to detect emotions, assessing their performance across different contexts solely through prompt optimization (Venkatakrishnan et al., 2023; Peng et al., 2024). In both contexts, an automated approach to find optimal prompts for emotion classification is a highly desirable need. Therefore, this study explores an alternative framework that mitigates the stochastic nature of genetic algorithms by changing the way mutations are performed.

3 Methodology

To tackle the problem, we propose a solution based on LLMs using a zero-shot/few-shot approach. As previously discussed, selecting the optimal prompt is challenging and directly impacts LLM performance. We employed a genetic algorithm to optimize prompts through an evolutionary process customized to the requirements of the task.

The overall structure follows a classical genetic algorithm approach, where prompts undergo iterative selection, crossover, and mutation to improve a fitness function. The distinction between random mutations (classical EvoPrompt) and systematic mutations (our approach) is visually depicted in Figure 1, highlighting the key differences between both strategies. The step-by-step process is outlined in Algorithm 1.

The process begins with an initial population of $2n$ prompts, comprising both human-crafted prompts, manually designed based on linguistic heuristics and task-specific considerations, and those generated by GPT-4o. All initial prompts are evaluated individually. The elements then enter the evolutionary cycle, following an approach similar to **EvoPrompt**, which utilizes a classical genetic algorithm. Prompt selection is performed using three different methods: tournament selection, roulette wheel selection, and random selection.

Once a pair of parent prompts is selected, a crossover operation is applied resulting in a child prompt. After all crossover operations, the top n prompts are evaluated and selected for the next generation. This process is iterated for a predetermined number of epochs using the top n prompts. The prompts from the final epoch are expected to be superior to those from the initial population. The typical range in which we use our approach is $10 \leq n \leq 30$. For this work we use $n = 10$. The optimization process was run for 10 epochs due to computational limitations.

The prompts are evaluated using the same LLM as the fitness function. The main idea is to iteratively refine the prompts generated during evolution, as these prompts are directly used to perform the emotion detection task. Each prompt is evaluated over the validation set of the dataset by calculating the F1 score for its predictions. The selection process is detailed in Algorithm 1. The process is run for each sentiment independently. Predictions are made through a discrete prompting setup: the LLM is asked to make a binary decision using prespecified target words. Initially, the words used are `positive` and `negative`, where the model predicts the presence or absence of a target emotion in a sentence. To further understand the sensitivity of the evaluation, we include an ablation study where the target words are replaced with `present` and `absent`, and analyze the resulting impact on prompt performance.

3.1 Mutation Strategy: Random vs Systematic Evolution

In classical genetic algorithms, mutations are typically random perturbations that introduce uncontrolled variations that could enhance performance. However, this mutation approach often fails to produce the desired effect. The stochastic nature of random mutations reduces the likelihood of generating beneficial variations tailored to the specific task at hand.

To overcome this limitation, our approach replaces random mutations with **systematic mutations**, designed to introduce structured linguistic variation in each generation. Rather than relying on stochastic modifications, our model selects transformations from a predefined set, ensuring that each mutation follows linguistic optimization principles. Each type of mutation is validated to have a positive impact on performance, avoiding disruptive changes that could degrade the prompt's effective-

Emotion	Best Prompt	Macro F1-Score
Anger	Analyze if the sentence expresses anger [...] identify indicators of hostility [...] examining language, structure, or context.	0.4309
Fear	As a Linguistic Analyst, classify phrases that create unease or fear [...] identify specific words contributing to a nervous or tense tone.	0.7734
Joy	Identify happy words in this sentence.	0.7221
Sadness	Assess if the sentence conveys gloom or sorrow [...] identifying words that contribute to a somber tone.	0.6667
Surprise	Does the sentence contain a surprising event or plot twist [...] creating shock or astonishment?	0.5251

Table 1: Best performing prompt per emotion with corresponding Macro F1-score.

ness. By aligning mutations with known patterns that enhance LLM interpretability and task adaptation, this deterministic approach improves convergence speed, reduces variance in performance across generations, and ensures a more consistent refinement of prompts. Unlike random mutations, which may generate unproductive or even detrimental variations, structured modifications incrementally optimize the prompt space, leading to a more stable and efficient evolutionary process.

The structured mutations:

- **Context Specification**: Clarifies and refines the prompt's focus.
- **Lexical Reformulation**: Rewords prompts while preserving meaning.
- **Profiling**: Adapts prompts based on predefined linguistic traits.
- **Simplification**: Reduces complexity for clearer interpretation.

By controlling each mutation, we enhance replicability while preserving diversity in the evolutionary search space. The comparative impact of systematic versus random mutations is discussed in more detail in Figure 1.

3.2 Experimental Setup

The model used for evaluation tasks, crossover generation, and systematic mutations is **Llama 3.1 8B**. The implementation was carried out using `PyTorch` with the `transformers` library from Hugging Face (Wolf et al., 2020), leveraging the `bitsandbytes` library for optimized inference in low-precision configurations (Dettmers et al., 2022).

The model is executed in an **8-bit quantized configuration**, which significantly reduces memory consumption and computational requirements while maintaining comparable performance to full-precision models (Frantar et al., 2022). The execution hardware consists of two **NVIDIA Titan RTX graphics cards** with 24 GB of DDR6 memory, hosted by the Supercomputing Laboratory of the Bajío, located at the Center for Research in Mathematics (CIMAT), Guanajuato, Mexico (Centro de Investigación en Matemáticas A.C, n.d.).

4 Results and Discussion

The model was executed using the random mutation configuration, following an approach similar to *EvoPrompt*. This was done to compare the results obtained with the proposed systematic mutation model. Likewise, the systematic mutation model was executed, and its results are presented in Table 3. Table 2 shows the results using the validation dataset for English solely. The performance of the initial Llama model with a generic initial prompt is compared, along with the classical EvoPrompt approach and EvoPrompt with systematic mutations.

One of the best-performing prompt was from the *joy* category (Table 1), specifically: *Identify happy words in this sentence*. The notable aspect of this prompt is that it resulted from a systematic mutation. All prompts in that population generally had low scores (Macro F1-Score ~ 0.55), and even after evolution, the validation score only improved slightly (Table 2). The reason this prompt achieved such a high score is that it aligns closely with the dataset's focus on the author's perceived emotion. The prompt guides the language model to identify linguistic patterns that reflect the author's emotional state, as *identifying happy words* is more related to the expressed emotion than to the perceived emotion.

This reasoning explains the overall structure of the best-performing prompts for *fear* and *joy*, as

Emotion	Anger	Fear	Joy	Sadness	Surprise
Llama Initial	[0.5941, 0.6170]	[0.6522, 0.6955]	[0.5401, 0.5452]	[0.6477, 0.6697]	[0.6064, 0.6720]
Llama EvoPrompt	[0.6397, 0.6470]	[0.7395, 0.7522]	[0.5401, 0.5452]	[0.6842, 0.6892]	[0.7108, 0.7225]
Llama EvoPrompt SM	[0.6528, 0.6602]	[0.7546, 0.7676]	[0.5533, 0.8131]	[0.6982, 0.7033]	[0.7253, 0.7372]

Table 2: Validation F1-score range $[min, max]$ per emotion category. The values represent the Macro F1-score per emotion, calculated on the validation set. The range corresponds to the results of the final epoch for Llama EvoPrompt and Llama EvoPrompt SM (Systematic Mutation). In the case of the initial model evaluation (Llama Initial), it refers to the range of values obtained from the initially evaluated prompts.

Emotion	EvoPrompt Modified	EvoPrompt Original
Anger	0.4309	0.4223
Fear	0.7734	0.7579
Joy	0.7221	0.7077
Sadness	0.6667	0.6534
Surprise	0.5251	0.5146
Macro F1	0.6236	0.6111
Micro F1	0.6571	0.6440

Table 3: Comparison between EvoPrompt Original and Modified. All values correspond to the F1-score metric. These results were part of the official SemEval submission.

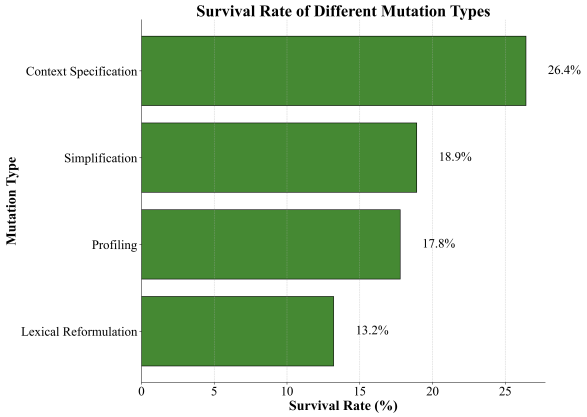

Figure 2: Survival rates of prompts based on the applied mutation type. The rates represent the percentage of prompts that survived the selection process after each specific mutation was applied, aggregated across all emotion categories.

well as the lower performance observed for *anger*, *sadness*, and *surprise*. The prompts obtained for these emotions share a common approach of searching for the emotion within the sentence, making them more suitable for detecting the emotion perceived by the reader.

These findings underscore the potential of systematic mutations, which, relying solely on prompt engineering assumptions, produced targeted modifications. This approach generated prompts that effectively identified task-relevant patterns, surpassing the EvoPrompt method, where random mutations failed to yield superior results. This suggests that replacing stochastic mutations with structured linguistic modifications enhances both effectiveness and consistency in prompt generation, leading to improved overall performance.

Another possible explanation for the model's success in prediction could come from a class imbalance. From the dataset paper (Muhammad et al., 2025a), we know that the most represented emotion is *fear*, while the least represented is *anger*, which aligns with the results obtained in Table 3. However, *joy* is the second least represented emotion and still achieved the second-best score, which challenges this explanation. Additionally, reinforcing this point, the results in Table 4 show that under the alternative evaluation, the *surprise* class performed worse, even though it has similar representation to the *sadness* class, which achieved a higher score.

4.1 Mutation Success Analysis

To better understand the internal dynamics of our evolutionary process, we analyzed the survival rates of different mutation types across generations. Figure 2 shows the percentage of surviving prompts after applying each mutation type. The most successful mutation was `context specification`, followed by `simplification`, while `lexical reformulation` exhibited the lowest survival rates. These results suggest that mutations focusing on refining the task specification were more effective, whereas mutations that altered the way the model is addressed tended to be less successful.

4.2 Evaluation Ablation Study

As mentioned in the methodology, the evaluation method was carried out using the same language model. The results presented in Table 3, corresponding to the official competition submission, the tokens `positive` and `negative` were used as target tokens. However, it is possible that these tokens introduce issues when detecting certain emotions, since restricting the prediction to positive or negative biases emotions like *anger* or *surprise*, which are not easily distinguishable with only these two labels. For this reason, a second study was conducted using different tokens `present` and `absent`, which are more aligned with the dataset's design and the task of predicting the emotion itself. The idea was that they would better capture whether the emotion was present or not. The results obtained are shown in Table 4. Comparing the two evaluations, the second approach clearly achieves superior performance, demonstrating a significant impact of this adjustment on the model.

Emotion	**EvoPrompt Modified**	**EvoPrompt Original**
Anger	0.6909	0.6557
Fear	0.7568	0.6176
Joy	0.7593	0.7600
Sadness	0.7550	0.7381
Surprise	0.6625	0.5967
Macro F1	0.7249	0.6736
Micro F1	0.7451	0.6781

Table 4: EvoPrompt Modified evaluated using an alternative evaluation approach. All values correspond to the F1-score metric. These results were not included in the official SemEval submission.

5 Conclusion

This study introduced a novel approach for optimizing prompts via systematic mutations guided by genetic algorithm principles. By replacing stochastic mutations with structured linguistic modifications, the proposed method enhanced prompt effectiveness and consistency, leading to superior performance across all emotion categories. Notably, the improvements in joy and fear suggest that aligning mutations with underlying linguistic patterns can significantly impact classification accuracy. These findings highlight the potential of systematic mutation strategies in prompt engineering, paving the way for more efficient and automated optimization techniques in LLM-driven emotion classification. Future work could explore refining mutation strategies further and extending this approach to other NLP tasks.

Limitations

This study has some limitations that should be taken into account for future improvements. First, the optimization process was limited to ten iterations due to time and computational constraints. This probably restricted the potential of the model, especially in emotions such as anger, sadness, and surprise, where it is more difficult to capture subtle linguistic patterns. With more iterations and more precise and above all perhaps somewhat more deterministic mutation rules, performance could be improved, especially by generating messages capable of detecting emotional nuances more effectively.

Second, the systematic mutations were designed based on general prompt engineering assumptions, which may not fully capture the complexity of all linguistic expressions. Furthermore, the evaluation was performed only on the SemEval Task 11A dataset, which limits the generalizability of the results. It is important to test the method on datasets with different annotation schemes and language models to assess its robustness. Future work could also explore integrating other prompt tuning techniques for a more complete comparison.

Acknowledgments

Abstract

This paper presents our system developed for SemEval-2025 Task 6: PromiseEval: Multinational, Multilingual, Multi-Industry Promise Verification. The task aims at identifying "promises" made and "evidence" provided in company ESG statements for various languages. Our team participated in Subtasks 1 and 2 for the languages English, French, and Japanese. In this work, we propose using BERT and finetuning it to better address the task. We achieve competitive results, especially for English and Japanese.

1 Introduction

Corporate Environmental, Social, and Governance (ESG) statements often contain forward-looking promises – commitments to sustainability, social responsibility, or ethical governance – that significantly influence public trust and corporate reputation. In recent years, there has been increasing emphasis placed on companies' ESG commitments (Curtis et al., 2021; Li et al., 2021). Ensuring the integrity of ESG promises is not only vital for transparency, but also for upholding stakeholder trust and holding organizations accountable for their commitments.

However, the complexity and lack of standardization in these statements pose a challenge to innovate new natural language processing (NLP) approaches to assess their strength and verifiability.

In this context, promise verification has emerged as an important task: systematically checking if a stated promise is made and supported by evidence in company reports in the form of SemEval Task 6 Chen et al. (2025). The task we address here, is titled PromiseEval: Multinational, Multilingual, Multi-Industry Promise Verification and is divided into the following sub-tasks:

(A) ESG promise identification

(B) Evidence identification in support of promise

Analyzing multilingual corporate commitments means NLP models must handle diverse linguistic expressions of promises – from English and French to Japanese, Chinese, and beyond – often with limited annotated data in each language. Recent efforts have begun to address this: for instance, Seki et al. (2024) introduced ML-Promise, the first multilingual dataset for corporate promise verification, covering five languages (English, French, Chinese, Japanese, Korean) to facilitate cross-lingual ESG promise analysis.

Given that the data implies a classification task, one significant approach is to fine-tune pre-existing language models for each language. This is the methodology taken in this paper.

Advances in Natural Language Processing offer a promising path toward automating promise verification. In particular, transformer-based language models such as BERT have proven highly effective at modeling context and meaning in text, especially against traditional machine learning text classification methods such as TF-IDF (Garrido Ramas et al., 2021). BERT's flexible architecture enables finetuning for custom classification tasks by adding only a simple output layer, yet achieves robust performance.

Verifying ESG promises is inherently a multifaceted and multilingual challenge. As will be discussed earlier, results performed better for single-language BERT models, where learning in multilingual models did not transfer to other languages.

Promise evaluation in natural language processing is an important area of research which focuses on evaluating if promises are made in certain statements and if they are supported by evidence. This paper systematically explores methodologies for training language models to identify and evaluate these things. Recent developments have led to several promising approaches for evaluating multilingual text, which will be explored in Background.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1670–1676

2 Background

The training data sets were provided by the PromiseEval2025 organizers, covering five languages, including English, French, Japanese, Chinese, and Korean (Seki et al., 2024; Chen et al., 2025). Each data set, covering one of the five languages, was created by extracting texts from ESG reports released by various corporate organizations headquartered in countries where the language is the native tongue. For example, the Japanese data set used Japanese ESG reports published by companies primarily operating or originating from Japan, while the French data set used those from France. Following extraction, the texts were segmented into paragraphs or sentences. They were later annotated with labels related to the four subtasks set by the organizers.

Our team focused on subtasks 1 ("Identifying Promises") and 2 ("Linking Evidence to the Promise") for data sets pertaining to the languages English, French, and Japanese. For the goal of each subtask, "Identifying Promises" required creating models that could determine whether each segmented text contained promise statement(s), while "Linking Evidence to the Promise" focused further on being able to identify whether each text (assuming they contained promise statements) have any evidence statements to support their claim. Additionally, for Asian languages (including Japanese), the subtasks further required models to be able to extract the exact sentences. However, given the complexity and challenge of accurately extracting exact promise and evidence texts, we had limited our model to verify whether a dataset contains promise and evidence text. As for the labels, we used "promise_status" and "evidence_status" to create models for subtasks 1 and 2, respectively. Note that in the Asian language data sets (including Japanese), annotators further included "promise_string" and "evidence_string," which referenced the specific sentences within the data where promise and evidence statements were made.

Concerning ESG specifically, there has been growing interest in methods to assess the credibility of ESG promises. Early NLP research in this domain involves analyzing ESG reports for insights, such as Shi Bowen (2023) analyzing similarities in sustainability reports through the application of latent dirichlet allocation, and support vector machine models to analyze ESG scores against a list of company mergers and acquisitions, and Petridis et al. (2022) utilizing a retrieval-augmented generation approach to idenfity Sustainable Development Goals in environmental impact assessments.

Aside from the aforementioned methods, some of the algorithms that can be found in the literature for identification and classification tasks are Naive Bayes (Bayes, 1968), stochastic gradient descent (Zhang, 2004), k-nearest neighbors (Liao and Vemuri, 2002), decisions trees (Charbuty and Abdulazeez, 2021), Convolutional Neural Networks (Zhang and Wallace, 2015) and Support Vector Machines (Tong and Koller, 2001; Joachims et al., 1999). In 2018, however, a revolutionary language model was released by Google, titled Bidirectional encoder representations from transformers (BERT) (Devlin et al., 2019). Utilizing an encoder-only transformer architecture, it dramatically improved over previous state-of-the-art models, and remains to perform exceptionally well.

An example in utilizing BERT in classifying text to quantify ESG ratings, Schimanski et al. (2024) trained RoBERTa and DistilRoBERTa, while Pasch and Ehnes (2022) utilized transformer-based models to train an ESG sentiment model based on ESG ratings and text documents.

Relatedly, an annotated environmental claim detection dataset was presented by Stammbach et al. (2023), focusing on identifying statements about environmental actions or impacts in corporate communications. This work, along with efforts by Seki et al. (2024) further highlight the importance of identifying ESG claims. Our work builds on these efforts, thus contributing to the field of promise and claim detection and verification.

3 System Overview

Given our team's focus on creating robust models for Promise-verification tasks by fine-tuning existing state-of-the-art LLM models, our strategy for detecting promise and evidence statements in both subtasks revolved around leveraging the base BERT model and its derivatives for French, Japanese and multilingual.

The decision to adopt BERT models for our task is primarily associated with its flexible architecture. It enables researchers to train task-specific models with only another output layer added to the base model, producing highly satisfactory results (Devlin et al., 2019). The successful application of BERT has also been noted in text classification tasks for ESG-related research. Addi-

tionally, BERT's transfer learning feature further allows models to be created from relatively small datasets with limited computational resources. This was another reason to adopt BERT models, as the datasets for each language contained only 400 rows of data, which is even smaller than the traditional number of what is considered a 'small dataset.'

Our team's approach to creating accurate models that can verify Promise and its associated evidence was to use monolingual models explicitly dedicated to each language, alongside a multilingual one encompassing all three languages. For English, we adopted the base BERT model for fine-tuning, while French and Japanese used language-specific BERT models.

For the French model, we chose to fine-tune CamemBERT, a BERT model dedicated to French texts. CamemBERT's architecture is based on RoBERTa, an improved iteration of the original BERT model, and its training was done using French datasets extracted from the OSCAR corpus (Martin et al., 2020). In terms of performance, it has produced superior results in downstream tasks, such as part-of-speech tagging and natural language inference, against mBERT. In addition, research by Kelodjoue et al. (2022), further found that CamemBERT and in text-classification tasks on verbatim transcripts alongside online posts compared to FlauBERT (another BERT model fine-tuned on French dataset).

Regarding the Japanese models, we used tohoku BERT[1], a well-known BERT model that was fine-tuned for Japanese data and is one of the widely adopted models in Japanese NLP research. In particular, research by Shibayama and Shinnou (2021), found that fine-tuning Tohoku BERT led to creating a Japanese-based sentence-BERT that demonstrated higher performance than other models they created.

Finally, we also utilized mBERT[2] to create multilingual model for both promise and evidence verification tasks. Previous researches that compare performances of monolingual and multilingual models in various classification tasks often provide differing results on which strategies are overall better than the other. Nonetheless, in many of the same studies, researchers have also highlighted how multilingual models offer competitive results with similar performance metrics to monolingual models (Velankar et al., 2022; Zhao and Aletras, 2024; Lothritz et al.). Most critically, however, multilingual models have been found to produce superior results in complex classification and retrieval tasks (Conneau et al., 2020; Ranaldi et al., 2025). For example, in the paper by Hu et al. (2020), they found models like XLM-R perform well in natural langauge inference tasks. Another research by Dementieva et al. (2022) which is directly related to evidence verification, showcased models trained on cross-lingual fake news evidence datasets can yield advantageous results in evidence classifications.

[1]https://github.com/cl-tohoku/bert-japanese

[2]https://github.com/google-research/bert/blob/master/multilingual.md

4 Experimental Setup

4.1 Pre-processing

The pre-processing process for both subtasks was generally the same regardless of the dataset's language. We first began by label encoding the values of "promise_status" and "evidence_status" using the preprocessing module of the Scikit-learn library. For the Japanese dataset, several values within the "evidence_status" also contained NA values aside from the standard boolean values of "Yes" and "No." As the organizers did not give specific explanations or instructions about handling NA values, we treated them as being the same as "No" values (evidence statement is not present inside the data) and converted them accordingly before the encoding process. For the multilingual model training, after label encoding all 3 language datasets, we concatenated them into a single single dataset.

Since our initially strategy was to create monolingual models specialized for each language, we used the AutoTokenizer class from the HuggingFace library for the tokenization process. AutoTokenizer is a practical tool that automatically chooses the correct tokenizer based on the BERT model we set, including CamemBERT and TohokuBERT. Thus, making it easier to fine-tune the three languages without alternating parts of our code. After the tokenization, the data and labels were split into training and testing data with a ratio of 8:2.

4.2 Model Training and Hyper-parameters

The four models we fine-tuned included bert-base-uncased, camembert-base, and cl-tohoku/bert-base-japanese for English, French, and Japanese data, respectively alongside mBERT for multilingual training. As we noticed during the pre-processing phase, all three datasets had a problem with the balance of labels, with the "promise_status" being the most

serious with an average ratio of "Yes" to "No" being 3:1. While "evidence_status" was relatively more balanced, "Yes" was more prevalent for all datasets. Therefore, to mitigate the potential issue of model bias against the minority label, we added class weights as part of our code.

For hyper-parameters, we set the sequence length for all models to 256 instead of the traditional 128 to account for any variations in the length of each dataset. Others, specifically, batch size, epochs, and learning rate, were determined via multiple trials using metrics of training and validation loss to determine the optimum number. The final results for hyper-parameters for each model used for the competition are shown below.

Model	Bs	Ep	LR
English Subtask 1	8	5	1e-05
French Subtask 1	8	5	2e-05
Japanese Subtask 1	16	4	2e-05
Multilingual Subtask 1	16	4	2e-05
English Subtask 2	16	6	5e-06
French Subtask 2	16	6	2e-05
Japanese Subtask 2	16	5	1e-05
Multilingual Subtask 2	16	4	1e-05

Table 1: Batch Size (Bs), Epoch (Ep) and Learning Rate (LR) for each models submitted for the competition

5 Results

5.1 Monolingual Model Performances

5.1.1 Subtask 1 Results

Language	Accuracy	F1-Score (4.s.f)
English	80.25%	0.8672
French	76.75%	0.8558
Japanese	94%	0.9687

Table 2: Accuracy and F1-Score for Subtask 1 models

In terms of general accuracy for the subtask 1 models which were submitted for evaluation, English was 80.25%, French 76.75%, and Japanese scored 94%. As promise_status had a serious issue of label imbalance, we further calculated each model's F1 score as well, and the results, which were rounded to 4 significant figures, are as follows (in the same language order): 0.8672, 0.8558, and 0.9687. We find that our model performs generally well from the accuracy results, producing competitive results with new, unseen data. Additionally, the F1 score for all models can be interpreted that the class weights helped mitigate potential bias against the minority class of "No" values for our models.

The Japanese model is particularly noteworthy in both accuracy and F1 score. Not only did the fine-tuned Tohoku model outperform the other languages in terms of accuracy, but it also had the highest F1 score. The latter result was especially impressive for our team, given the imbalance in the "promise_status" of the Japanese dataset, with "No" values representing only around 11% of the data while others averaged at least 20%.

5.1.2 Subtask 2 Results

For the models submitted for subtask 2, accuracy-wise, it was 71.75%, 76.75%, 73.5% for English, French, and Japanese, respectively. Regarding the F1 score, again in the same order of language, it was 0.7483, 0.8239, and 0.80. For Japanese, as the evidence_status in the final test dataset used for evaluating our Japanese models included NA values, we used the same pre-processing steps during the training phase. We converted them to "No" before calculating the accuracy and F1 score.

Language	Accuracy	F1-Score (4.s.f)
English	71.75%	0.7483
French	76.75%	0.8239
Japanese	73.5%	0.80

Table 3: Accuracy and F1-Score for Subtask 2 models

Compared to subtask 1 models, we see that subtask 2 models have an accuracy issue in correctly verifying whether or not a dataset contains evidence statements, with the French being an exception, where its evidence verification model performed slightly better than its promise model. The same can be partially said about the F1 scores, as the performance of all models dips compared to the results seen in subtask 1. In particular, we found that the English subtask 2 model performed the worst among all models submitted for this task. However, considering that the scores ranged from 0.74 to around 0.82, our models perform relatively well in detecting both majority and minority classes.

5.2 Multilingual Model Performance

5.2.1 Subtask 1 Results

Comparing the multilingual model's performance across the three languages with the monolingual model, we see that it yields similar results in accu-

Language	Accuracy	F1-Score (4.s.f)
English	78.25%	0.8581
French	77%	0.8585
Japanese	92.25%	0.9593

Table 4: Accuracy and F1-Score for Subtask 1 with Multilingual Model

racy and F1 Score. In terms of figures, the model slightly underperformed in English and Japanese, by around 2% in accuracy; it performed better with French data compared to the CamemBERT model. Overall, the multilingual model for subtask 1 produced results comparable to those of monolingual models.

5.2.2 Subtask 2 Results

For subtask 2, the multilingual model noticeably demonstrated an overall higher performance in classifying evidence status in the data when directly compared with monolingual models. Unlike the results we've seen in the subtask 1, it demonstrated better performances in both areas of accuracy and F1-scores for English and Japanese against the monolingual model created from the baseline BERT and TohokuBERT. However, when compared to CamemBERT, the multilingual model's performance was significantly worse, by around 9 points, and was the worst-performing metric across all models and tasks.

Language	Accuracy	F1-Score (4.s.f)
English	73.75%	0.7870
French	67.25%	0.7745
Japanese	75%	0.8148

Table 5: Accuracy and F1-Score for Subtask 2 with Multilingual Model

5.3 Monolingual Models or Multilingual Model

Comparing the results of monolingual models against multilingual model across both subtasks, we see that by performance metrics alone we found that each strategy offered different advantages in classification task with ESG datasets. For subtask 1, we found that the monolingual approach outperformed in promise verification. For subtask 2, multilingual model was able to handle the detection of evidences better, with the exception of French data. This result is relatively supportive of past research that have shown multilingual model's pretraining leading to favorable metrics in complex classification/retrieval tasks such is the case with evidence verifications (Conneau et al., 2020; Ranaldi et al., 2025). Regardless, as we observed both strategy's overall performance to be comparable, we found that using either approach can lead to competitive results.

5.4 Competition Ranking

Our official ranking in the competition is as follows: 10th out of 11 for English, 3rd out of 4 for French, and 2nd out of 3 for Japanese. Based on ranking alone, our model's performance was not the best in the competition for the three languages. However, we note that the PromiseEval submission on Kaggle (in all languages) for the evaluation phase on Kaggle was not segregated by task. Instead, participants were required to submit a copy of the evaluation dataset where we had replaced the values for the labels related to the tasks we did (for our case, promise_status and evidence_status), while keeping other labels unedited. This means that our submission was evaluated for all subtasks (1 through 4) available on PromiseEval rather than just the subtasks we actually worked on, making it difficult to assess our models' performance for subtask 1 and 2 compared to other participants.

6 Conclusion

In this paper, we introduce our results for the Semeval task. Our scores on evaluation data show that models fine-tuned on general corpora can obtain competitive results, especially for English. BERT performed well on promise identification, and less well on evidence identification.

However, a more thorough comparison between multilingual and language-specific BERT is expected to yield more definitive answers as to which methodology is superior overall. While we addressed label imbalance by adjusting class weights during training, our model may still be more biased towards 'yes' data. As such, techniques such as Synthetic Minority Over-sampling Technique (SMOTE), undersampling the majority class, or implementing alternative loss functions such as Focal Loss may further improve model robustness, especially in tasks with severe imbalance in the training dataset.

The introduction and successful implementation of the Promise Verification tasks are expected to have impacts on various fronts, including enhanced

accountability and transparency, empowerment of stakeholders, policy and regulation shaping, and increased social and environmental impact. For example, by providing a systematic and scalable approach to verify promises, this task could significantly improve the transparency of organizations and public figures, compelling them to adhere more closely to their commitments. This, in turn, could foster greater trust and credibility among stakeholders and the general public. Additionally, equipped with data and insights from the Promise Verification task, stakeholders, including consumers, investors, and the general public, could make more informed decisions based on the verifiable actions and commitments of organizations and leaders. Ultimately, by holding entities accountable for their promises, especially those related to ESG commitments, this task could contribute to more tangible progress in addressing environmental issues, promoting social justice, and ensuring ethical governance, leading to a more sustainable and equitable world.

Abstract

Emotion intensity prediction in text enhances conversational AI by enabling a deeper understanding of nuanced human emotions, a crucial yet underexplored aspect of natural language processing (NLP). This study employs Transformer-based models to classify emotion intensity levels (0–3) for five emotions: anger, fear, joy, sadness, and surprise. The dataset, sourced from the SemEval shared task, was preprocessed to address class imbalance, and model training was performed using fine-tuned *bert-base-uncased*. Evaluation metrics showed that *sadness* achieved the highest accuracy (0.8017) and F1-macro (0.5916), while *fear* had the lowest accuracy (0.5690) despite a competitive F1-macro (0.5207). The results demonstrate the potential of Transformer-based models in emotion intensity prediction while highlighting the need for further improvements in class balancing and contextual representation.

1 Introduction

Emotion analysis in natural language processing (NLP) has emerged as a pivotal area of study, driven by the need to enhance human machine interaction across domains such as affective computing, digital healthcare, and conversational AI. While sentiment analysis provides a coarse-grained understanding of text polarity positive, negative, or neutral emotion analysis demands a finer lens, capable of discerning nuanced states like joy, anger, or sadness, and even their intensity. Transformer-based models, with their ability to capture contextual dependencies, have revolutionized NLP tasks, yet predicting emotion intensity in text remains a complex challenge. This complexity arises from the subtle interplay of linguistic cues, contextual dynamics, and the inherent unpredictability of human emotions, particularly when constrained to a single language like English, where cultural and expressive variations further enrich the task.

Recent advancements in Transformer-based architectures have begun to address these challenges by integrating innovative approaches to emotion recognition Zhao et al., 2024 Pereira et al., 2024, Liu et al., 2024. These studies underscore a growing trend: enhancing Transformer models with specialized techniques from sensory integration to handling unbalanced datasets offers a promising pathway to deepen the understanding of emotional nuances in text, particularly within a monolingual framework.

This research aims to build on these foundations by exploring how Transformer-based models can be optimized to predict emotion intensity in English textual data. While prior work has advanced emotion classification, the specific focus on intensity quantifying the strength of emotions like mild annoyance versus intense anger remains underexplored, especially in single language settings. By examining the strengths and limitations of existing models and proposing refinements, this study seeks to contribute to the evolving landscape of emotional AI. The investigation not only aligns with the interdisciplinary bridge between NLP and cognitive science but also addresses practical applications, such as improving real-time conversational systems, where accurately gauging emotion intensity could transform user experiences.

2 Literature Review

Text detection and classification has evolved significantly in recent years, attracting considerable attention from researchers in the field of Natural Language Processing (NLP). Various classifiers and models have been explored, with several new, more accurate models developed by researchers, playing pivotal roles in a series of recent experiments (see Abiola et al., 2025a, Kolesnikova and Gelbukh, 2020, Ojo et al., 2024, Adebanji et al., 2022, Abiola et al., 2025b). A range of traditional

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1677–1682

machine learning (ML) methods (Ojo et al., 2021, Ojo et al., 2020, Sidorov et al., 2013) as well as deep learning (DL) models (Aroyehun and Gelbukh, 2018, Ashraf et al., 2020, Han et al., 2021, Hoang et al., 2022, Poria et al., 2015, Muhammad et al., 2025a) have been applied in recent years for text prediction across various domains.

In their study, Zhao et al., 2024 introduce SensoryT5, an innovative model that integrates sensory knowledge into the T5 (Text-to-Text Transfer Transformer) framework to enhance emotion classification in natural language processing (NLP). Unlike traditional approaches that often overlook the interplay between sensory perception and emotion, SensoryT5 embeds sensory knowledge within the model's attention mechanism, elevating its sensitivity to the nuanced emotional states conveyed in text. The authors demonstrate that this approach significantly outperforms state-of-the-art baselines, achieving a maximal improvement of 3.0 in both accuracy and F1 score across four emotion classification datasets. This advancement highlights the potential of leveraging neuro-cognitive resources, such as the intimate relationship between emotion and sensory experiences well documented in overlapping neural regions like the amygdala Zhao et al., 2024 —to deepen the comprehension of emotional intensity and nuance in transformer-based models, suggesting a promising interdisciplinary bridge between NLP and cognitive science.

Pereira et al., 2024 provide a comprehensive survey on Deep Emotion Recognition in Conversations (ERC), underscoring its critical role in advancing human–machine interaction through the lens of textual conversations. The authors highlight how recent progress in ERC has unveiled both opportunities and challenges, such as capturing conversational context, modeling speaker and emotion dynamics, and interpreting informal language or sarcasm—elements vital for predicting emotion intensity in text. Their review details prominent approaches leveraging pre-trained Transformer Language Models to extract utterance representations, often combined with Gated and Graph Neural Networks to model inter-utterance interactions, achieving robust performance across benchmark datasets with diverse emotion taxonomies. Notably, the survey emphasizes the efficacy of employing Transformer-based architectures.

Liu et al., 2024 propose a novel fuzzy multimodal Transformer (FMMT) model designed to advance personalized emotion analysis by addressing the limitations of existing state-of-the-art Transformer-based approaches in capturing the complexity and unpredictability of human emotions. Unlike conventional models that struggle with intricate contextual semantics and input interdependencies, FMMT integrates audio, visual, and textual data through three specialized branches, enhancing its comprehension of emotional contexts within a single language framework. By incorporating fuzzy mathematical theory and a unique temporal embedding technique, the model effectively traces the evolution of emotional states and manages inherent uncertainties, offering a significant leap in emotion intensity prediction. Experimental results demonstrate that FMMT outperforms baseline methods, with detailed performance comparisons and ablation studies validating its robustness.

Cross-linguistic speech emotion recognition (SER) has gained significant attention due to its wide range of applications. Previous studies have primarily focused on adapting features, domains, and labels across languages while often overlooking underlying linguistic commonalities. Recent work, such as Phonetically-Anchored Domain Adaptation for Cross-Lingual Speech Emotion Recognition Sultana et al., 2025, explores vowel-phonetic constraints as anchors to enhance cross-lingual SER. Inspired by this, transformer-based models offer a promising alternative by leveraging self-attention mechanisms to capture deep contextual relationships in speech. This study builds on prior research by integrating transformer architectures for multi-class emotion detection, enhancing language adaptation with minimal supervision

3 Methodology

Our study employs a systematic methodology to predict emotion intensity in English text using Transformer-based models, focusing on a dataset comprising training, development, and test splits sourced from the dataset released by the task organizers Muhammad et al., 2025b. The dataset contains textual samples annotated with intensity levels '0 to 3' for five emotions—anger, fear, joy, sadness, and surprise, the preview of the representation of the dataset per emotion and classes is displayed in table 1. Initial data exploration revealed imbalanced distributions prompting a preprocessing step to mitigate this bias. The processed datasets were then tokenized using the BERT tokenizer (bert-base-uncased), with a maximum se-

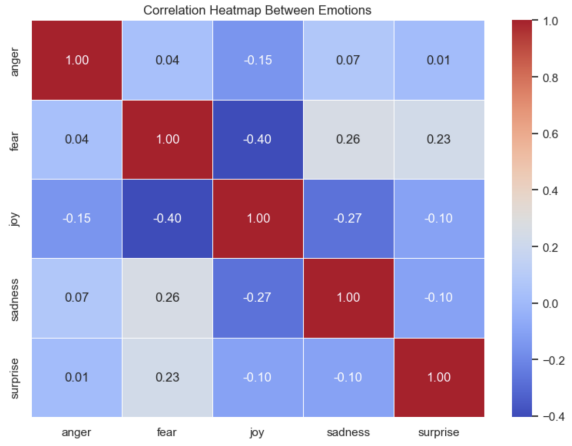

Figure 1: Heat map showing correlation between the emotions

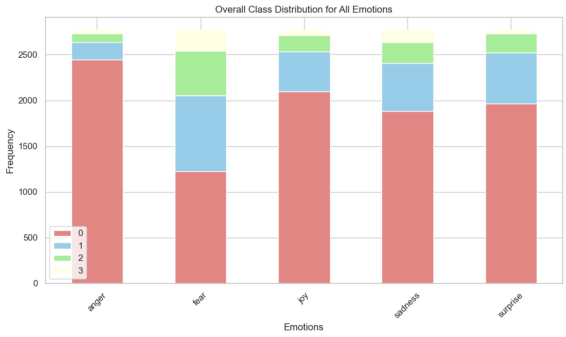

Figure 2: Class Distributions for All Emotions

quence length of 512 tokens, preparing them for model input. Figure 1 and 2 shows heatmap that shows the correlation between the Emotions and the class distribution chart.

Emotion	Class 0	Class 1	Class 2	Class 3
Anger	2435	207	88	38
Fear	1157	857	546	208
Joy	2094	449	161	64
Sadness	1890	505	248	125
Surprise	1929	588	215	36

Table 1: Emotion Class Distribution

The core of our methodology leverages the BERT architecture 'bert-base-uncased' fine-tuned separately for emotion to predict intensity levels as a multi-class classification task 0–3. We use a custom WeightedLossTrainer that incorporates class weights to address data imbalance. Training was conducted on a CUDA-enabled GPU RTX 3080 with the Hugging Face Trainer API, configured with 20 epochs, a batch size of 16, and early stopping based on the micro F1 score on the development dataset. The loss function, a weighted cross-entropy loss, penalizes misclassifications of minority classes more heavily, while evaluation metrics include accuracy, macro F1, and per-label F1 scores.

The evaluation and optimization process involved iterative refinement to ensure robust performance. The development set served as a validation split to tune hyperparameters and assess model generalization, with sample predictions like "Older sister... Scumbag Stacy" predicted as anger=2, fear=1 guiding qualitative checks. Test predictions were finalized using the best-performing multi-class models, maintaining consistency with the single-language 'English' focus. All code was implemented in Python using libraries like pandas, transformers, and scikit-learn, with results saved for subsequent analysis.

4 Result and Discussion

The implementation of the BERT-based multi-class classification models yielded promising results in predicting emotion intensity across the five target emotions—anger, fear, joy, sadness, and surprise in English text. Evaluation on the test set revealed varying performance, with anger achieving the highest accuracy 0.8403 and macro F1 score 0.3715, while fear showed the lowest accuracy 0.5876 despite a competitive F1 macro 0.5387, The full result displayed in Table 2. Per-label F1 scores highlighted challenges with minority classes, reflecting the dataset's imbalance despite weighted loss adjustments. Sample predictions on the development set, such as "Older sister... Scumbag Stacy" 'anger=2, fear=1', aligned with intuitive expectations, suggest the model's ability to capture contextual nuances enhanced by bigram preprocessing. Test set predictions followed similar trends, with examples like "I slammed my fist..." predicted as anger=2 and surprise=2, indicating robustness in real-world scenarios.

Emotion	Accuracy	F1-macro
Anger	0.8403	0.3715
Fear	0.5876	0.5387
Joy	0.7636	0.5139
Sadness	0.7228	0.5053
Surprise	0.7091	0.5093

Table 2: Performance metrics for each emotion

These results underscore both the strengths and

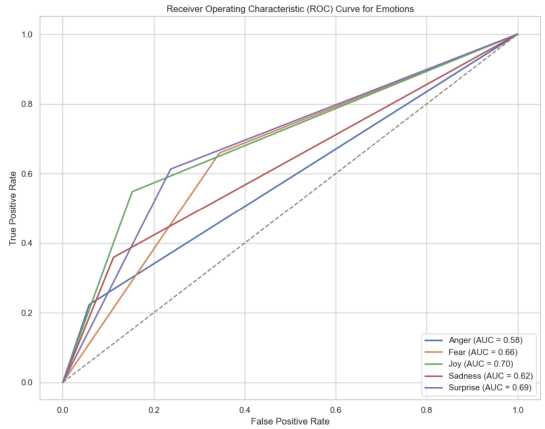

Figure 3: ROC curve on the Emotion Intensity Prediction

limitations of the Transformer-based approach in this context. The superior performance on sadness and surprise F1 macro=0.6614 for surprise) aligns with findings from Zhao et al., 2024, who enhanced emotion classification through sensory integration. However, the lower performance on fear and joy, particularly for higher intensity levels, may stem from their underrepresentation in the training data, a challenge also noted by Pereira et al., 2024 in handling unbalanced ERC datasets. The multi-label experiment with bert-base-cased and optimized thresholds offered an alternative perspective, but its binary focus diverged from the study's intensity prediction goal, reinforcing the multi-class framework's relevance. Future iterations could explore Liu et al., 2024 fuzzy logic or hybrid architectures to better handle uncertainty and class imbalance, which can potentially elevate overall F1 scores.

5 Conclusion

This study successfully demonstrated the application of BERT model, in predicting emotion intensity in English text, achieving notable accuracy and F1 scores across a range of emotions while highlighting areas for refinement. We carried out experiment on some other ML classifiers like SVM, LR but reported BERT in the competition as it performed better on the development dataset, the methodology addressed data imbalance and contextual complexity, aligning with trends in advanced emotion analysis Zhao et al., 2024; Pereira et al., 2024. The results, with sadness and surprise outperforming fear and joy, validate the potential of fine-tuned BERT models for nuanced NLP tasks, offering practical implications for enhancing conversational AI systems where understanding emotional depth is critical. The generated predictions on the test set further affirm the approach's applicability, providing a foundation for real-time emotion intensity detection in single-language settings.

Nevertheless, the research also reveals limitations that pave the way for future exploration. The persistent challenge of minority class prediction, despite class weighting, suggests that additional techniques—such as data augmentation, ensemble methods, or Liu et al., 2024 fuzzy multi-modal strategies—could enhance performance, particularly for underrepresented intensity levels. This work contributes to the evolving intersection of NLP and cognitive science, echoing the interdisciplinary call from prior studies, and sets a baseline for extending intensity prediction to multilingual contexts or integrating multimodal inputs. Ultimately, refining these models could bridge the gap between machine understanding and human emotional expression, advancing both theoretical and applied dimensions of emotional AI.

6 Limitations

Despite the promising outcomes of this study, several limitations constrain its scope and generalizability. The primary challenge lies in the dataset's imbalance, leading to poor F1 scores for minority classes. While weighted loss functions mitigated this to some extent, the models struggled to generalize across all intensity levels. Additionally, our research focus on a single language (English) limits cross-linguistic applicability, potentially overlooking cultural nuances in emotion expression that a multilingual approach, as hinted by Pereira et al., 2024, could address. The reliance on BERT's bert-base-uncased model, while effective, may also cap performance compared to larger or domain-specific Transformer variants.

Acknowledgments

We would like to thank the organizers of the SEMEVAL workshop for providing the datasets and evaluation platform used in this study. We also appreciate the support and guidance from our mentors and colleagues throughout the development of this work. Their feedback and encouragement were invaluable in shaping this research.

NLP_CIMAT at SemEval-2025 Task 3: Just Ask GPT or Look Inside. A prompt and Neural Networks Approach to Hallucination Detection

Jaime Stack-Sánchez, Miguel A Alvarez-Carmona and Adrián Pastor López-Monroy
Mathematics Research Center (CIMAT)
jaime.stack@cimat.mx
miguel.alvarez@cimat.mx
pastor.lopez@cimat.mx

Abstract

This paper presents NLP_CIMAT's participation in SemEval-2025 Task 3 (Vázquez et al., 2025), which focuses on hallucination detection in large language models (LLMs) at character level across multiple languages. Hallucinations—outputs that are coherent and well-formed but contain inaccurate or fabricated information—pose significant challenges in real-world NLP applications. We explore two primary approaches: (1) a prompt-based method that leverages LLMs' own reasoning capabilities and knowledge, with and without external knowledge through a (RAG)-like framework, and (2) a neural network approach that utilizes the hidden states of a LLM to predict hallucinated tokens. We analyze various factors in the neural approach, such as multilingual training, informing about the language, and hidden state selection. Our findings highlight that incorporating external information, like wikipedia articles, improves hallucination detection, particularly for smaller LLMs. Moreover, our best prompt-based technique secured second place in the Spanish category, demonstrating the effectiveness of in-context learning for this task.

1 Introduction

Since the introduction of the transformer architecture in 2017 (Vaswani et al., 2017), large language models have rapidly advanced, finding applications in both scientific research and everyday life. However, these models face two major challenges (Mickus et al., 2024): They often generate false or misleading information that appears syntactically correct and current evaluation metrics prioritize fluency and grammatical accuracy over factual correctness.

This combination leads to what is known as hallucination, that is, where models produce outputs that are coherent and well-formed but contain inaccurate or fabricated information—an issue that remains difficult to detect automatically. Hallucinations pose a significant barrier to the practical development of LLMs and their mass adoption as reliable tools in everyday life.

Although in this work we treat hallucination detection as a task, hallucinations can appear in various domains and some works address hallucination detection in fields like machine translation (Dale et al., 2022; Guerreiro et al., 2023), summarization (Huang et al., 2021; Van der Poel et al., 2022), definition modeling (Mickus et al., 2024) and dialogue generation (Lei et al., 2023), we are still far from establishing a unified dataset and system for hallucination detection.

Despite some progress in hallucination detection, current works and datasets do not attack the problem with a granularity that allows one to know exactly where the hallucination is in the text. SemEval-2025 task 3 introduces a test bed that allows us to tackle the problem with character level granularity and information to compare the correlation between the proposed systems and human annotations. The task is closely related to fact checking and consist of identifying the parts of the model output that are hallucinated at character level given the model input. The dataset includes 14 languages where every instance indicates the language, the ranges of hallucinated characters and the probability assigned to these hallucinations.

This paper presents the participation of NLP_CIMAT in the shared task which consist on the development and study of two main approaches. The first one is a prompt-based method that leverages the intrinsic knowledge and capabilities of the LLM, where the model is directly asked to highlight the hallucinated parts of its output. We explore two key variants of this method: Without external knowledge – The model relies solely on its internal knowledge; and with external knowledge (RAG-like framework) – We investigate whether incorporating retrieved external information im-

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1683–1689

proves hallucination detection performance.

The second approach is a neural network that leverages the encoded information in the internal hidden state representations of a LLM to predict whether a token is hallucinated. This method explores several key aspects to optimize performance:

1. Individual vs. Multilingual Training – We investigate whether training on a single language or across multiple languages leads to better generalization.

2. Incorporating a Language Vector – We assess whether adding a one-hot encoded vector indicating the language improves model performance.

3. Number of Parameters – We analyze whether a larger classifier architecture (more layers and neurons) leads to better hallucination detection.

4. Hidden State Layer – We determine which hidden state layer contains the most relevant information for hallucination prediction.

5. Concatenating Multiple Hidden States – We evaluate whether using hidden states from multiple layers enhances model performance compared to using a single layer.

2 Related Works

Prompt-based techniques represent the state of the art in hallucination detection, with most top-performing approaches in the SemEval 2024 Shared Task 6 (Mickus et al., 2024) relying on prompt-based methodologies to achieve strong results.

SELFCHECKGPT (Manakul et al., 2023): utilizes a sample based strategy to generate multiple stochastic samples. This work proposes that a model with a good understanding and knowledge of the task or concept is less likely to generate inconsistent information and hallucinations. This work demonstrates the effectiveness of prompt based approaches to detect hallucinations, we took inspiration in their prompt based approach modifying their structure to not rely on samples.

Fact-checking performance of LLMs improves notably when they are given contextual information, as shown by Quelle and Bovet (2024); Krishnamurthy and Balaji (2024). LLMs can effectively leverage external knowledge to generate responses and support claims with factual accuracy. We took inspiration from their work and provided our prompt approach with external information retrieved from wikipedia.

In recent years there have been numerous studies about using hidden states of a LLM to detect hallucinations. Azaria and Mitchell (2023) train a MLP on the hidden states of a LLM to detect hallucinations at sentence level and investigate which hidden states contain relevant information to correctly classify hallucinations. Similarly, Duan et al. (2024) analyze the changes in the internal states of a LLM when it generates factual versus non-factual claims, using these differences to determine whether a hallucination has occurred. Our work draws inspiration from both studies: we adopt the MLP architecture from the first and leverage insights from the second to develop a token-level hallucination classifier.

3 Methodology

In this section we will introduce our proposed systems for hallucination detection, dividing them in two groups: Prompt based approach and Hidden States Neural Network approach.

3.1 Prompt based approach

The core idea behind these methods is to leverage the inherent knowledge and reasoning capabilities of LLMs to detect hallucinations effectively.

We present two prompt based approaches for hallucination detection:

- Few-shot without external knowledge – This method relies solely on the intrinsic capabilities and knowledge of the model to classify hallucinated characters in a response.

- Few-shot with external knowledge – In this approach, Wikipedia articles are retrieved as external knowledge, allowing the model to combine its internal knowledge with up-to-date factual information to improve classification accuracy.

In all of our submissions for the prompt based approach we used a few shot scheme to reduce the probability of the LLM generating an answer that we couldn't analyze automatically. The models we used were gpt-4o and gpt-3.5-turbo.

We decided to use these models because there have been multiple studies showing their great capabilities on solving a diverse amount of tasks (Chen et al., 2024) and they are trained in recent data,

"You are an expert fact checker, your job is to answer with the parts of the hypothesis that contain inaccuracies or false information given the context provided and the query. Answer with the exact same text as the hypothesis but using < > to highlight the incorrect parts of the hypothesis.
For example:
Context: [wikipedia page]
Query: [Model Input]
Hypothesis: [Model output]
Answer: [Model output with hallucination highlighted]

Context: [wikipedia page]
Query: [Model Input]
Hypothesis: [Model output]
Answer: [Model output with hallucination highlighted]"

Figure 1: Prompt scheme: Highlighted in green we have the Role, in red we have the Examples (3) and last in purple the Context (optional)

which makes them fit for the task. We also aim to compare the performance of these models to assess the impact of model size and the quality of training data on hallucination detection.

3.1.1 Few-shot without external information

The idea is to give the model an instance composed on the original input and output with a few examples and ask it to directly, without any additional information, tell us where the hallucinations are.

For the prompt construction we first gave a role for the model, which has been shown to improve the models capabilities compared to when no role is given. Then we followed with the format in which the answer was to be given, we opted to indicate the model to answer with the same exact text as the model output but highlighting the hallucinated parts of the output. Then we gave three examples to the model, tackling the three different possible cases: the output has one hallucination, the output contains no hallucinations and the output contains multiple hallucinations. The prompt scheme can be seen in Figure 1.

3.1.2 Few-shot using external information

RAG consists in providing the model with external information that can help to answer the task that the model is given. We hypothesize that giving the model extracts from wikipedia can improve the model performance to identify the incorrect information from the model output. To extract the wikipedia page we used the Model input followed by the word "Wikipedia" and then we proceeded to retrieve the first wikipedia link we found in google search, later retrieving the unformatted wikipedia text and gave it, completely, to the model as context.

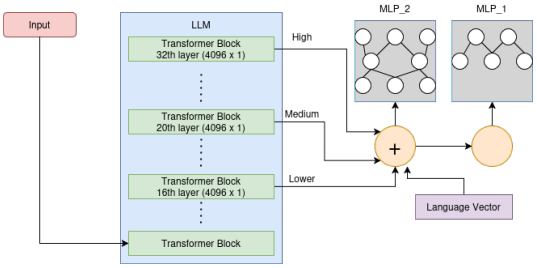

Figure 2: Framework for the Neural Network approach. We extract hidden state vectors from three different transformer blocks, concatenate them, and add a Language Vector (LV). The combined representation is then fed into our MLP classifiers for hallucination detection.

3.2 Hidden States Neural Network approach

The proposed model takes the encoded information on the extracted hidden states of the LLM that contains relevant information to correctly classify an hallucination. To extract the hidden states, we structured the sequence that we pass to our LLM like: "[Model input] [Model output]".

We focused on developing an MLP model trained on hidden states from LLaMA 3.1 8B Instruct. We extract and concatenate up to three hidden states, (H, M, L)[1], incorporating a Language Vector (LV)—a one-hot encoded vector of length 10, representing the 10 languages in the validation dataset. This vector was concatenated at the beginning of the hidden states. The resulting representation was then passed to the MLP model, which predicted whether the corresponding token was hallucinated. Our framework is illustrated in figure 2.[2]

We experimented with different training configurations, including:

- Training the model on all languages (Multilingual) vs. individual languages (M or I)
- Using one hidden state vs. concatenating three hidden states
- Adding or omitting the Language Vector (LV)

[1] 32, 20 and 16

[2] For all the models we trained with a batch size of 16, a learning rate of 1e-4 and cross entropy loss as the loss function.

4 Results

We first present the best results submitted for each language, followed by a study analyzing the impact of the different strategies we implemented.

4.1 Best prompt results

For the prompt-based approach, we focused only on Spanish and English due to time and budget constraints. The objective of this experiment is to evaluate the effectiveness of prompt-based approaches for hallucination detection in LLMs. Specifically, we analyze the impact of external knowledge integration and compare the performance of models of different sizes. Table 1 presents our best prompt results, with one of our Spanish submission achieving second place.

Language	IoU	Cor	RAG	Model
***ES**	**0.520**	**0.523**	**TRUE**	**gpt-4o**
ES	0.518	0.520	FALSE	gpt-4o
ES	0.353	0.351	TRUE	gpt-3.5-turbo
ES	0.267	0.253	FALSE	gpt-3.5-turbo
EN	0.457	0.370	TRUE	gpt-4o
EN	0.434	0.415	FALSE	gpt-4o
EN	0.328	0.341	TRUE	gpt-3.5-turbo
EN	0.299	0.291	FALSE	gpt-3.5-turbo

Table 1: Best prompt results. Incorporating external knowledge (RAG) consistently improved performance, especially for GPT-3.5-Turbo, with an 8.6% IoU gain. GPT-4o achieved overall better results. *Second place winner in the spanish category

From Table 1, we observe that RAG has a greater impact on GPT-3.5-Turbo than on GPT-4o. In GPT-3.5-Turbo, the IoU gain is more significant, reaching 8.6% higher, whereas in GPT-4o, the maximum difference is only 2.3%.

Additionally, as expected, GPT-4o significantly outperforms GPT-3.5-Turbo in hallucination detection. Interestingly, GPT-3.5-Turbo with RAG still couldn't surpass the results of GPT-4o without RAG, suggesting that GPT-4o's superior architecture and training enable better information retrieval and utilization, even without external augmentation.

4.2 Best Hidden States Neural Network results

The objective of this experiment is to evaluate effectiveness of using hidden states from a LLM to detect hallucinations at token level. Table 2 presents our best submitted results for the Hidden States Neural Network Approach, selected from a set of experiments with varying parameters. In the Concat Layers column, the letters H, M, and L represent the hidden states extracted from layers 32, 20, and 16, respectively.

From the table we can see that multilingual appeared much more in the best results, giving us an idea that training with data in all languages can improve the performance of the models. Concatenating layers doesn't appear to have a significant impact in the results, and we can observe that using more layers in our MLP appears to yield better performance. But we will explore this ideas in the following sections.

Language	IoU	Cor	IoU Bas. mark all	Cor Bas. mark all	M or I	Layers	# Layers	LV	Epoch
Arabic	0.204	0.077	0.316	0.007	I	[H,L,M]	2	False	5
Catalan	0.141	0.069	0.242	0.06	M	L	2	False	5
Chinese	0.220	0.145	0.477	0	M	L	3	False	5
Basque	0.175	0.052	0.367	0	M	L	3	False	5
Farsi	0.0316	0.394	0.203	0.01	M	L	2	False	15
Finnish	0.374	0.031	0.486	0	M	[H,L,M]	3	True	15
French	0.353	0.071	0.454	0	M	[H,L,M]	3	True	15
Italian	0.189	0.045	0.283	0	I	[H,L,M]	3	False	15
Swedish	0.238	0.054	0.537	0.014	I	[H,L,M]	2	True	15
English	0.174	0.129	0.349	0	M	[H,L,M]	3	TRUE	15
Spanish	0.111	0.092	0.185	0.013	M	L	3	TRUE	15

Table 2: Best results Hidden States Neural Network approach

4.3 Study of internal structure of the MLP models

The objective of this experiment is to analyze the impact of the complexity of the MLP along with which hidden state configuration provides the most useful information for the neural network to make accurate classifications. Tables 3,4 and 5 present the results of varying internal parameters of our classifier. We focused on two sets of languages: Languages with abundant training data in our model and languages with limited training data in our model.

For the well represented languages we chose English and Spanish, for the languages with limited training data we chose Finnish and Swedish. This distinction allows us to analyze in a more meaningful way the impact of varying the internal structure of our classifier.

We observe clear differences in the achieved metrics. While our preliminary results on the validation dataset suggested that layer L was the most effective, the test dataset results indicate that layer H performed best, achieving the highest overall metrics. A possible explanation for this is that layer H, being the last layer, encodes information closely related to the logits of the generated token. These logits reflect the probability distribution assigned by the model to the generated token. If the model is uncertain about its response, this probability distribution is likely to shift compared to a more confidently generated token. The classifier can leverage these probability variations to improve the identification of hallucinated tokens.

Surprisingly, concatenating multiple layers does not improve results compared to using only layer H. This outcome was unexpected. One possible explanation is that the MLP model is relatively small and may not have the capacity to effectively utilize the additional information provided by concatenating three hidden states. For this same reason it is not surprising that the model with 3 hidden layers outperformed the model with 2 hidden layers.

Table 4: Results of the MLP with: One hidden state, multilingual with LV, 3 hidden layers in MLP and trained for 15 epoch

4.4 Study of the relevance of information in the MLP models

In this experiment we analyze the impact of multilingual training and the addition of the language vector. In Table 6, we observe that while the best results were achieved using multilingual training with a language vector, the comparison between training on an individual language versus multilingual training without a language vector is less conclusive. The results do not show a clear advantage for either approach, suggesting that the impact of multilingual training without explicit language

Language	IoU	Cor	# Layers
English	0.158	0.135	2

All languages	0.190	0.108	3

Table 5: Results of the MLP with: Concatenated hidden states [H, L, M], multilingual with LV and trained for 15 epoch

information varies depending on the specific conditions.

We observe that for languages with abundant training data in our proxy model, multilingual training slightly improves performance. However, for languages with limited training data, training on multiple languages reduces performance.

We hypothesize that this occurs because, in well-represented languages in our model, the encoded information in the hidden states is more distinct and easily differentiable. In contrast, for languages with less training data, the encoded information is more subtle, making it harder for the model to generalize effectively across multiple languages.

5 Conclusion

This work summarizes the approach of the NLP_CIMAT team in the SemEval 2025 Shared Task 3. We present two primary methodologies for hallucination detection: A prompt-based approach that leverages the capabilities and knowledge of LLMs to accurately identify hallucinated characters in a generated output; and a neural network approach trained on hidden states to classify whether a token is hallucinated.

Our findings indicate that incorporating external information in the prompt-based approach significantly improves performance for GPT-3.5-Turbo, while for GPT-4o the difference is negligible. We hypothesize that this discrepancy is closely related to model size and the quantity and quality of training data used. For the neural network approach, we identified the optimal configuration as follows: Using a three layer MLP architecture trained using the last hidden state layer and multiple languages while informing the classifier about the language. While the prompt-based method achieved better results, the model sizes used in the two approaches are not directly comparable.

A key direction for future work is to evaluate both methods using the same language model to determine which approach yields superior performance under equal conditions.

Abstract

Question Answering over large tables is challenging due to the difficulty of reasoning required in linking information from different parts of a table, such as heading and metadata to the values in the table. We investigate using Large Language Models (LLM) for tabular reasoning, where, given a pair of a table and a question from the *DataBench* benchmark, the models generate answers. We experiment with three techniques that enable symbolic reasoning through code execution: (1) a direct code prompting (DCP) approach, DCP_{Py}, which uses Python; (2) Multi-Step Code (MSC) prompting MSC_{SQL+FS} using SQL and ReAct prompting; and, (3) MSR_{Py+FS}, which combines multi-step reasoning (MSR), few-shot (FS) learning and Python tools. We also conduct an analysis exploring the impact of answer types, data size, and multi-column dependencies on LLMs' answer generation performance, including an assessment of the models' limitations and the underlying challenges of tabular reasoning in LLMs.

1 Introduction

Table Question Answering (Table QA)—answering questions on a table—has multiple applications in different domains, such as in finance (Nararatwong et al., 2025; Nararatwong et al., 2024; Papicchio et al., 2023; Chen et al., 2022; Zhao et al., 2022; Zhu et al., 2021; Chen et al., 2021) and scientific literature (Zhao et al., 2024a: Ghosh et al., 2024; Korkmaz and Del Rio Chanona, 2024; Katsis et al., 2022; Moosavi et al., 2021). In some scientific domains, such as medicine, tables contain information that is not present in the text of a research paper (Bardhan et al., 2024; Johnson et al., 2023; Bardhan et al., 2022; Park et al., 2021). Answering questions based on information hidden in tables faces challenges such as dealing with table structure, size, linking headings to the content and in the case of numerical values, may require mathematical operations over multiple cells (Deng et al., 2024; Wu et al., 2024; Nahid and Rafiei, 2024; Wu et al., 2023; Pal et al., 2023; Cheng et al., 2022).

Table QA in natural language processing or information retrieval often includes identifying a table in a text that can answer a question and then reasoning and generating an answer (Pramanick et al., 2024; Ji et al., 2024; Dong et al., 2024; Zhao et al., 2024a; Wan et al., 2024; Herzig et al., 2021). However, we focus on a subproblem where a table is provided along with the question. We report on our participation in SemEval shared task[1] where given a question and table, the task is to determine the answer and the type of answer within the required columns. The question must only be answered with tabular data from the provided dataset, *DataBench* benchmark.

We investigate using LLMs to generate answers over tables with symbolic reasoning through code execution to select the appropriate columns and rows for a given question. Namely, a direct code prompting approach, DCP_{Py}; multi-step code prompting with few-shot learning, MSC_{SQL+FS}; and, ReAct (Yao et al., 2023) prompting, MSR_{Py+FS}, which uses multi-step reasoning with few-shot learning. Furthermore, we analyse the connection between the LLMs' answering capacity and the answer types, data sizes and cases when multiple columns are required to answer a question.

2 Related Work

Transformer-based models Some existing table QA models are transformer-based and pre-trained on tables and texts from Wikipedia. For example, TaPas (Herzig et al., 2020) with BERT encoder for parsing tabular structures, TableFormer with modified TaPas by learnable attention bias for en-

[1] https://semeval.github.io/SemEval2025

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1690–1701

coding tables (Yang et al., 2022), TaBERT with BERT encoder for a joint understanding of textual and tabular data (Yin et al., 2020), TaPEx with pre-trained BART encoder-decoder on executable SQL queries (Liu et al., 2022), and OmniTab with pre-trained TaPEx on natural language questions (Jiang et al., 2022). However, the performance of these models decreases with out-of-domain distributions and adversarial data, e.g., variations in table header and content (Zhao et al., 2023c).

Open-source generalist LLMs Several studies investigated these models for Table QA (Pal et al., 2024; Zhang et al., 2024a; Zhao et al., 2023a; Zhao et al., 2023b). These models have yet to demonstrate generalisation abilities on out-of-domain datasets and tasks. Zhang et al. (2024c) fine-tuned Llama-2-7b on the instruction data for several table-based tasks without incorporating task-specific designs. Their experiments revealed that instruction tuning improved performance with transformer-based models in in-domain settings but not for out-of-domain settings.

Osés Grijalba et al. (2025) experimented with direct and code prompting to answer the questions. For direct prompting, they used LLAMA2 models, and for direct code prompts, they used Code-LLAMA models with 7B and 13B parameters and found the Code-LLAMA to be the overall best model on *DataBench* benchmark.

Table structure One promising direction to improve table QA is to develop capabilities for understanding table structure, such as the table schema and row and column semantics. When fine-tuned, models can better locate answers over tables to predict the probability of containing the answer to a question in the rows and columns of tables (Glass et al., 2021). Retrieving the relevant columns and rows from tables with millions of tokens can boost the performance of LLMs while reducing computational complexity (Chen et al., 2024).

Zhao et al. (2024b) shows that modular and synergistic approaches can also improve the quality of generated responses. LLM hallucinations on tabular data can be mitigated with modular approaches for generating faithful and interpretable answers, e.g., conditioning answers on a QA-based plan of sub-questions with extracted relevant table data. The final answer can be selected from candidate answers generated by both pre-trained table QA and text-to-SQL models (Zhang et al., 2023; Chemmengath et al., 2021), which predict SQL queries to represent the questions before executing them on tables to find the answers (Zhang et al., 2024b). The semantic parsing and question decomposition methods help generate SQL queries based on the table schema and questions (Eyal et al., 2023; Lin et al., 2020).

Table QA Datasets and Evaluation Most benchmark datasets for table reasoning tasks are mainly based on factual questions with short-form answers (Kweon et al., 2023; Li et al., 2023; Chen et al., 2021, 2020; Parikh et al., 2020; Yu et al., 2018; Novikova et al., 2017; Pasupat and Liang, 2015). A common metric for evaluating models across all related tasks is the exact match accuracy and ROUGE-L (Lin, 2004). General benchmark datasets representing human interactions, reasoning about structured knowledge retrieval, and longer free-form responses are currently unavailable for table QA (Nan et al., 2022).

3 DataBench

The dataset in this shared task is from the *DataBench* Osés Grijalba et al. (2025)[2], a comprehensive collection of tabular data designed for evaluating question answering over tables in English. *DataBench* consists of 65 datasets covering five domains of business, health, social, sports, and travel, with varying numbers of rows and columns and varied data types.

Table 1 provides an overview of the number of datasets collected, as detailed by Osés Grijalba et al. (2025), along with information on the rows and columns they contain. The corpus includes 65 real-world datasets with 3,269,975 rows and 1,615 columns, designed to evaluate language models on the task of QA over tabular data. It includes a total of 1,300 questions, each paired with a gold-standard answer, along with additional metadata such as answer type (i.e., true/false, categorical values from the dataset, numerical values, or lists), the corresponding data columns and their types.

Expected answer types are:

- Boolean. The answer can be True/False, Y/N, or Yes/No.
- Category. The answer contains a value from one cell or part of a cell.

[2] https://huggingface.co/datasets/cardiffnlp/databench

Domain	Datasets	Rows	Columns
Business	26	1,156,538	534
Health	7	98,032	123
Social	16	1,189,476	508
Sports	6	398,778	177
Travel	10	427,151	273
Total	65	3,269,975	1615

Table 1: *DataBench* domain taxonomy from Osés Grijalba et al. (2025).

- Number. The answer is a numerical value from one or multiple data table cells, which can also represent statistics (e.g., average, maximum and minimum).
- List[category]. Multiple values from one or more table cells are listed as the answer.
- List[number]. A list of numbers as the answer.

4 Task Description and Setup

For each tuple of a question and the relevant table, we must answer the question in two different settings:

1. Task A (*DataBench*): questions are answered with a given dataset; and,
2. Task B (*DataBenchLite*): questions are answered with a sampled version of the given dataset containing a maximum of 20 rows.

During the development phase, the training and development set of the data tables is made available for training or fine-tuning. The testing phase has only the test set of the *DataBench*.

5 Methods

Following Osés Grijalba et al. (2025), we explore three symbolic reasoning approaches through code execution to tabular reasoning for QA using LLMs—DCP$_{Py}$, a direct prompting approach to generate executable Python code and MSR$_{Py+FS}$, an agentic multi-step few-shot learning approach using Python tools, and MSC$_{SQL+FS}$, direct prompting approach for generating SQL statements. In this section, we detail our methodologies along with their implementation details.

5.1 DCP$_{Py}$

DCP$_{Py}$ uses direct code prompting (Figure 1 in appendix) to generate executable Python query code. This code is executed to obtain the relevant information from the corresponding table for post-processing. Specifically, (1) we directly prompted GPT-4o (2024-10-21) to generate executable Python code given the table columns, table column types, and the question, (2) the code is then executed returning the raw results from the table, and (3) this result is converted to the required format, e.g., changed 'yes' or 'no' answers to boolean types, changed the categories to a list of categories, etc., based on the expected answer types.

5.2 MSR$_{Py+FS}$

MSR$_{Py+FS}$ uses a ReAct (Yao et al., 2023) prompt (See Appendix, Figure 2) containing *DataBenchLite* as a sample table, and few-shot exemplars from the training set of *DataBench* for multi-step reasoning. Specifically, we (1) prompted Claude Sonnet 3.5 v2 (2024-10-22) with the question, sample table and few-shot exemplars to generate Python code to execute and the reasoning behind the code; (2) we then executed the code inside an isolated environment that contained the entire table; and then, (3) passed the result back to the model for observation. After observation, the model decides whether to generate the final answer or continue from step 1.

5.3 MSC$_{SQL+FS}$

MSC$_{SQL+FS}$ uses a multi-step prompt with few-shot learning by: (1) generating an SQL query statement—adding the list of table columns in the prompt; (2) Executing the generated query—looping until the LLM retrieves at least one record; and, (3) then, prompting the LLM to generate answer—prompt contains the question, SQL query, retrieved rows and few-shot exemplars from *DataBenchLite*. On the dev set, we experiment using Gemma2-9B and GPT4o-mini models, and on the test set, in our final submission, we submit the predictions obtained using the Gemma2-9B model.

6 Results and Discussions

The obtained accuracy scores and final rankings are presented in Table 2. Overall, the method with the highest performance is MSR$_{Py+FS}$ with an accuracy score of 88.12 % on *DataBench* and 87.70 % on *DataBenchLite*. DCP$_{Py}$ is the second and

	Task A		Task B	
	DataBench	Rank	*DataBenchLite*	Rank
DCP_{Py}	80.46	19	76.05	24
MSR_{Py+FS}	88.12	5	88.70	3
MSC_{SQL+FS}	64.94	36	69.16	30

Table 2: Final competition exact match accuracy scores and ranking.

MSC_{SQL+FS} is the lowest-performing ones. All methods, except the MSC_{SQL+FS} achieved better performance in some cases with the *DataBench* data compared to its smaller *DataBenchLite* subset.

Compared to the leaderboard, our highest-performing model, MSR_{Py+FS} achieves competitive results compared to the top scorer (Team TeleAI) of 95.1% on *DataBench* and 92.91% on *DataBenchLite*. The best-performing proprietary model (Team AILS-NTUA) has an accuracy of 89.85% and 88.89% on *DataBench* and *DataBenchLite*, respectively.

6.1 Error Analysis: Validation Set

The errors in our best-performing method, MSR_{Py+FS}, are analyzed on 320 question-answer pairs from the validation set. Differences between ground truth and predicted values are evaluated using the exact match accuracy metric with boolean outputs of the basic evaluation function for the *DataBench* corpus.[3]

Tabular question answering challenges. The main reasoning challenges in tabular QA (Table 3) are understanding and reasoning over the table data, which in our case is to understand the columns and their data types and enumerate over multiple columns to produce an answer that may have a list of strings or numbers.

Ground truth data quality. The ground truth answers are manually verified by inspecting the questions and executing the required queries on the validation data. At least 10% of the ground truth answers and questions are poorly defined, making an automatic evaluation of the models less objective and more challenging.

Poorly defined questions. The questions do not specify how to deal with the possibility of multiple or repeated values in the answers. Instructions for dealing with data quality, such as duplicated and empty values in datasets, are also missing in the questions.

[3]eval code: https://tinyurl.com/3wcxfvbm

 # Challenge — table schema understanding
Example — Recognizing the table schema and the data types of the table **Question —**"Did any respondent indicate that they will not vote?" requires models to identify a single 'Vote Intention' column and understand its list[category] type and 'I will not vote' textual values to correctly respond with a Boolean value
 # Challenge — question & answer type understanding
Example — Defining unambiguous instructions **Question —** "What are the three least commonly ordered quantities?" offers multiple interpretations to include or exclude the rows with returned purchases based on the meaning of invoices with negative quantities
 # Challenge — multi-column integration
Example — Enumerating over number lists in columns **Question —** "Which 5 patents (by ID) have the most targets associated?" requires models to identify two columns ('id' and 'target'), understand a list[number] column type, and count the items in number list for each ID to correctly respond with a list[number] value
 # Challenge — numeric answer generation
Example — Defining numeric precision and list order **Question —** "What are the highest 5 levels of Extraversion?" lacks definitions of answers with specified numerical precision and sorting of numbers in a list

Table 3: Examples of model reasoning and benchmarking challenges in tabular QA.

Unsuitable generic evaluation metric. Our findings indicate that questions about tables in benchmark datasets must be defined following the underlying table data and the desired evaluation methods. For example, the exact match metric leaves almost no room for interpretation of questions and requires an explicit definition of answers. The quality and structure of data need to be considered and disclosed to ensure models can arrive at the same ground truth answers.

6.2 Tabular Reasoning: Test Set

The tabular reasoning capabilities of our methods were analyzed with the 522 pairs of questions and answers in the test set of the *DataBench* data. Our focus was on understanding the effects of table sizes and answer types on the model performance under a few-shot in-context learning setting.

Different answer types. The type of answers (for example, *boolean, list[number] and list[category]*) influences the performance of the models, as shown in Table 4. The most accurate LLM predictions were for *boolean* answers, with 90.07% on *DataBench* and 93.02% on *DataBenchLite*. In contrast, the least accurate answers are generated for

	DCP_{Py}		MSR_{Py+FS}		MSC_{SQL+FS}	
	DB	DBL	DB	DBL	DB	DBL
Boolean	86.05	87.60	**90.07**	**93.02**	66.67	71.32
Category	85.14	82.43	**87.84**	**89.19**	74.42	81.08
Number	79.49	75.00	**85.26**	**87.82**	59.62	67.95
List[cat.]	69.94	68.06	**77.78**	**83.33**	51.39	50.00
List[num.]	58.24	56.04	**76.92**	**81.32**	64.84	68.13

Table 4: Accuracy per answer type in *DataBench* (DB) and *DataBenchLite* (DBL) test data.

	$\text{DB}_{Largest}$	$\text{DB}_{Smallest}$
Overall	88.24	90.24
Boolean	87.50	100.00
Category	100.00	100.00
Number	85.71	92.86
List[category]	100.00	85.71
List[number]	66.67	71.43

Table 5: Accuracy of MSR_{Py+FS} further split into the answer types for the largest and smallest table of *DataBench* test data.

number-lists with 76.92% and 81.32% accuracy, respectively, on *DataBench* and *DataBenchLite*.

LLMs struggle when generating list-type responses when tested for exact match accuracy, as the models might not extract all the items in the specific order. With *number-lists* being harder to produce than *category-lists*, this outcome resonates with our error analysis findings. Unlike the list of categories, each item in a list of numbers might require further aggregation (operations such as sum and average) after retrieval. However, for MSC_{SQL+FS}, the accuracy of the *number-lists* (68.13% on *DataBenchLite*) is higher than *category-list* (50% on *DataBenchLite*), as the intermediate SQL query generated by the LLMs already applies the aggregation operator.

Effect of data size. In this analysis, we only consider the question-answer pairs over the largest and the smallest table from *DataBench*. In the test set, the largest table is *068_WorldBank_Awards* with 4,789,220 cells in 20 columns and 239,461 rows (88.24% accuracy), and the smallest table is the 080_Books table with 520 cells in 13 columns and 40 rows (90.24% accuracy). Using the MSR_{Py+FS} method, we observe, as illustrated in Table 5, the size of the tables does not significantly influence the LLM predictions and the overall performance is slightly better on the smallest table (90.24%) than the largest (88.24%), showing the method's robustness to increases in the data size. As before, the answers with a number and list of numbers are challenging answer types for the model, more pronounced for the largest table.

We observed that when the number of columns increased, QA performed better, despite it adding to the complexity of column-wide reasoning. The accuracy when using the table with the least number of columns (Table: 074_Lift with 5 columns and 3,000 rows) and the table with the most columns (Table: 066_IBM_HR with 35 columns and 1,470 rows) is 74.29% and 94.87%, respectively.

Multi-column questions. On a manually sampled 202 pairs of questions and answers (38.70% of the *DataBench* test set), where the models need more than one column to produce an answer, we found the accuracy of our best method MSR_{Py+FS} is 80.20% with an 8% drop compared to the overall accuracy of 88.12% (Table 2). In contrast, for the rest of the records requiring single columns to answer, the accuracy is 87.19 %, which closely aligns with the overall accuracy, implying the model's difficulty in understanding and reasoning for multi-column answers. Examples of sampled multi-column QA are in the app. Table 6.

7 Conclusions

Table question answering is challenging because of how information can be organised in tables, with relevant information being located in columns from diverse data types, requiring integration of information across columns. We proposed three different methods for Table QA, with our best model, MSR_{Py+FS}, which uses Reasoning and Acting (ReAct) prompting, led to our team ranking in the top-5 among over 100 submissions in the shared task. Through our analysis, we found that numbers and list answer types, and questions requiring answers over multiple columns of the table are the most challenging factors for table QA.

Future research may focus on advanced prompting strategies, e.g., chain-of-thought or building answer-type specific pipelines.

Limitations

In our work, we only consider few-shot prompting without fine-tuning the models on the downstream QA tasks to address some reasoning problems using the available training data in the development phase. We did not do any data cleaning or pre-processing of the tables considering real-world conditions where the data tables might contain erroneous or missing data, which could improve the

overall performance. Model bias was also found as LLMs refused to answer some questions, including questions about pregnant people on table data without a specified 'female' gender, which requires further investigation. Ensembling our results from the three approaches could also improve our outcome. Furthermore, there is always the scope of using more advanced few-shot selection methods or stronger models such as `Llama-405b`, `Deepseek R1`, `OpenAI O3`, or `O1` models.

Appendix

A Prompting Approaches

The prompts used for DCP$_{Py}$, MSR$_{Py+FS}$, and MSC$_{SQL+FS}$ are shown in Figures 1, 2, and 3, respectively.

B Additional Analysis

Table 6 shows question and answer pairs from *DataBench* that we sample for the evaluation of answering questions that require information from multiple columns and illustrate the differences between the ground truth and the predictions of the MSR$_{Py+FS}$ method.

Question	Required Columns	Table	Ground Truth	Prediction
Which rating given to the stated purpose of students is associated with the highest accumulated grade point average?	University Rating (uint8) CGPA (float64)	072_Admissions	4.5	5
What is the single label associated with the most products? Answer with a single category.	labels_en (object) product_name (object)	070_OpenFoodFacts	'No gluten'	'Green Dot'
What cause corresponds to the lowest mortality rate?	Cause (category) Rate (float64)	075_Mortality	'Suicide'	'Nephritis'
What is the name of the windiest day on average?	wind (float64) day (uint8) calendar_names_2 (object)	078_Fires	'Monday'	'March'
What is the product type of the transactions with yielded the most money in revenue? Answer with a category.	product_type (category) Revenue (category)	079_Coffee	'Premium Beans'	'Barista Espresso'
Is any entry in the third tier a (direct or otherwise) descendant of 150?	Tier 3 (category) Parent (category)	069_Taxonomy	TRUE	FALSE
Is Barbados considered overall more expensive than the country ranked in the 10th place?	Country (category) Rank (uint8) Local Purchasing Power Index (float64)	071_COL	TRUE	FALSE
What are the top 5 total lifts by Weight Class?	Amount Lifted (kg) (uint16) Weight Class (category)	074_Lift	[88849, 88071, 87862, 83245, 81271]	['93 kg', 'Open', '59 kg', '83 kg', '52 kg']
List the weights of women with a height of exactly 1m and 45cm.	Weight (uint8) Height (uint8)	077_Gestational	[49.0, 50.0, 55.0, 66.0, 61.0]	[49, 50, 55, 66, 61, 71, 95, 55, 67, 69, 89, 55, 90, 58, 61, 78, 80]
List the ratings of the top four books with the most reviews?	Ratings (float64) Reviews (float64)	080_Books	[73.0, 85.0, 50.0, 30.0]	[30, 39, 27, 25]
List the 5 players with the least games played.	PLAYER (category) GP (uint8)	076_NBA	['Harrison Barnes', 'DeMar DeRozan', 'Jeff Green', 'P.J. Tucker', 'Andre Drummond']	['Quentin Richardson', 'Andrew Goudelock', 'Darko Milicic', 'Matt Carroll', 'Vladimir Radmanovic']

Table 6: Examples of multi-column questions based on manual inspection of table schema in the test data. The examples show the prediction errors from MSR_{Py+FS} and the corresponding ground truth.

DCP$_{Py}$ Prompt

Convert the given question to executable Python code based on the table columns and table column types. The dataframe is already given and the Python code should print out the answer only.

Table columns are: {list of table columns}
For each column types are: {list of table type}
Question: {question}
Python code:

Figure 1: DCP$_{Py}$ prompt.

MSR$_{Py+FS}$ Prompt

You are a helpful AI assistant that can execute Python code to analyse tables.
The user will ask a question that is related to a markdown table of which you are given a sample of.
The user's question can pertain to one or more rows within the table, so ensure you take this into account. You will be given a set of example questions and answers.
Only provide the answer in the form of a boolean, list[category or number], category or number and do not write anything else. Do not write anything aside from the direct answer.
You must use the Python tool to get your answer, and you must use Python's builtin print in order to see your results.
Assume that the full table is located in a parquet file at /sandbox/all.parquet

###Example Questions and Answers
{{Few-shot examples}}

###SAMPLE TABLE
{{markdown_sample_table}}

Figure 2: MSR$_{Py+FS}$ prompt.

MSC$_{SQL+FS}$ Prompt

QUESTION: {input}

You have to generate an answer to the above question from a table. The SQL query below is executed on the table: {query}

Output of the SQL query: {result}

Based on the above SQL query output, generate an appropriate answer to the given question. Check if the answer is below rules:

Rule #1: If a question that starts with 'are there..', 'is there..', the answer would be whether the records exist, in such cases, return True or false.
Rule #2: If the question is asking about a count of items or maximum, minimum or average of the items, apply that aggregation (count, min, max, average) on the items and return a numeric value, not a list of items. For example, "How many distinct HHS regions are present ?" is asking about the total number of regions and the answer is 10.
Rule #3: Avoid repetition in the answer.
Rule #4: Always put multiple values in the answer within a [] bracket. If the list items are strings, add single quotations around the strings.

EXAMPLES:
{sampleqa}

Your response should only contain the question's answer.

RESPONSE:

Howard University-AI4PC at SemEval-2025 Task 8: DeepTabCoder - Code-based Retrieval and In-context Learning for Question-Answering over Tabular Data

Saharsha Tiwari and **Saurav K. Aryal**
EECS, Howard University
Washington, DC 20059, USA
https://howard.edu/
saharsha.tiwari@bison.howard.edu and saurav.aryal@howard.edu

Abstract

Question answering over tabular data requires models to understand diverse table structures and accurately reason over structured information. To address these challenges, we introduce DeepTabCoder, our approach to SemEval 2025 - Task 8: DataBench. We combine a code-based retrieval system with in-context learning to generate and execute Python code for answering questions, leveraging DeepSeek-V3 for code generation. DeepTabCoder outperforms the competition baseline, achieving accuracies of 81.42% on the DataBench dataset and 80.46% on the DataBench Lite dataset. These results demonstrate the potential of in-context learning with code execution methods for improving table reasoning tasks.

1 Introduction

Recent advances in large language models (LLMs) have significantly improved open-domain question answering; however, question answering over structured tabular data remains a challenging problem. Unlike text-based QA, tabular QA requires the model to understand schema structures, handle a variety of data types, and perform logical and numerical operations over cell values. Additionally, models must operate without external knowledge sources, relying solely on the information contained within the tables themselves.

SemEval 2025 Task 8: DataBench (Grijalba et al., 2024) focuses on question-answering over tabular data, introducing a large-scale benchmark designed to evaluate how well models extract and reason over structured information. The dataset includes 65 diverse tables from multiple domains, each varying in size, structure, and data types, making it a comprehensive test for tabular reasoning. Accompanying these datasets are 1,300 manually curated questions, covering different answer types: Boolean (True/False), categorical values, numerical values, and lists. The competition itself features a subset of 15 datasets and 522 questions, providing a focused yet challenging evaluation setting. Unlike open-domain QA, models must (1) derive answers solely from the provided tables, (2) handle heterogeneous table schemas, and (3) execute complex queries without relying on external knowledge. The task is further divided into two categories: DataBench, which uses the full datasets, and DataBench Lite, which provides a smaller 20-row sample for each dataset, testing a model's ability to generalize with limited data.

DeepTabCoder follows a three-step approach leveraging in-context learning to tailor prompts for each dataset. First, we generate dataset-specific prompts that include metadata and relevant schema details to guide the model. Second, we inject the question into the dataset-specific prompt and infer the response from the model. Third, we extract the Python code generated by the model and execute it against the dataset to retrieve the answer. By maintaining modular and reusable functions, our method ensures flexibility across different tabular structures. We extend and modify the approach from *Tool-Augmented Reasoning Framework for Tables (TART)* (Lu et al., 2024), which integrates LLMs with specialized tools to enhance table understanding and numerical reasoning. TART consists of three key components: a table formatter for accurate data representation, a tool maker for constructing computational tools, and an explanation generator for interpretability. We adapt TART's methodology to better align with the specific requirements of the DataBench competition, focusing on structured table reasoning.

Our system combines fixed schema templates with code execution to handle diverse table structures. The system shows particular strength in Boolean reasoning and numerical queries, though challenges remain in complex aggregation tasks requiring multi-hop reasoning. Detailed implementation and results analysis are presented in subsequent sections.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1702–1708
July 31 - August 1, 2025

2 Related Works

In this section, we review prior research across four key areas that form the basis of DeepTabCoder. For each area, we explain how our work extends existing methods, with special emphasis on our modification to the TART framework.

2.1 Tabular Question Answering

Early work in tabular question answering, such as TAPAS (Herzig et al., 2020) and TaBERT (Yin et al., 2020), converts tables into textual representations to apply semantic parsing and reasoning. These approaches focus on leveraging pre-trained language models to interpret table data. In contrast, DeepTabCoder embeds dataset-specific metadata and schema details directly into the prompt. This design ensures that each table's inherent structure is maintained without exposing full table details, allowing our model to reason more effectively over heterogeneous data formats, as required by the DataBench challenge (Grijalba et al., 2024).

2.2 Code-based Retrieval and Execution Models

Recent work has demonstrated two complementary approaches to code-based table reasoning:

- **Pre-training with synthetic executions**: TAPEX (Liu et al., 2022) introduced table-aware pre-training by exposing the model to 26 million synthetic (SQL query, execution result) pairs. This approach enhances structural reasoning through the learning of SQL execution patterns, though it necessitates expensive, task-specific pre-training instead of relying on general code understanding.
- **Prompt-time decomposition**: DIN-SQL (Pourreza and Rafiei, 2023) showed that decomposing text-to-SQL tasks into subproblems—such as schema linking and classification—can significantly boost the few-shot performance of large language models.

In this work, we integrate these insights through dataset-aware schema prompting combined with code execution.

2.3 In-Context Learning and Prompt Engineering

The performance of large language models is significantly enhanced by in-context learning, as evidenced by works like GPT-3 (Brown et al., 2020) and chain-of-thought prompting (Wei et al., 2023). Typical strategies involve designing generic prompts that guide the model's reasoning. DeepTabCoder extends these strategies by incorporating tailored prompts enriched with structured metadata and function definitions. This targeted prompt engineering enables the model to concentrate on the essential schema characteristics of each dataset without revealing complete table representations, thereby reducing token usage and facilitating more precise code synthesis for query resolution.

2.4 Tool-Augmented Reasoning Frameworks for Tables

The TART [1] framework (Lu et al., 2024) has been influential in integrating external computational tools into table reasoning, combining table formatting, tool creation, and explanation generation. We build upon this foundation by creating dataset-specific metadata and injecting it into the prompt. DeepTabCoder leverages DeepSeek-V3 (DeepSeek-AI et al., 2025), a state-of-the-art Mixture-of-Experts (MoE) language model with a total of 671 billion parameters, of which 37 billion are activated per token for code generation and execution, borrowing TART's capabilities to better handle the nuances of the DataBench task.

3 System Overview

This section presents DeepTabCoder's system architecture and methodology for generating domain-specific prompts that enable models to synthesize Python programs to answer user queries $\mathcal{Q}$ regarding datasets $\mathcal{D}$. The complete implementation of DeepTabCoder can be found in Appendix A.

3.1 In-Context Prompt Generation

We generate tailored prompts that encapsulate key schema characteristics of each dataset while minimizing verbosity. This approach empowers the model to produce precise Python code for query resolution without exposing full table representations.

3.2 Modular Function Definitions

To support dataset manipulation, we define the following modular functions:

- **Data Loading:** `load_data` : $\mathcal{F} \rightarrow \mathcal{D}$, where $\mathcal{F}$ represents the file path space.

[1] https://github.com/XinyuanLu00/TART

- **Row Retrieval:** `get_row_by_name` : $\mathcal{D} \times \mathcal{K} \rightarrow \mathcal{V}$, where $\mathcal{K}$ is the keyspace and $\mathcal{V}$ is the value space.

3.3 Query-Conditioned Inference Pipeline

Given an input tuple $(\mathcal{D}, q)$, DeepTabCoder's inference pipeline consists of the following key components:

3.3.1 Augmented Prompt Construction

We construct an augmented prompt that concatenates structured schema features and the user query:

$$\mathcal{P}(\mathcal{D}, q) = \underbrace{f(\mathcal{D})}_{\text{Schema Features}} \oplus \underbrace{q}_{\text{Query}} \quad (1)$$

where $\oplus$ denotes the concatenation operator.

3.3.2 Inference with Query Injection

DeepTabCoder integrates dataset-specific metadata with the query to ensure the model accurately interprets the task within the dataset context. The process involves:

- **Query Integration:** The dataset-aware prompt is formulated as shown in Equation 1. Here, $f(\mathcal{D})$ encapsulates structured metadata and function definitions extracted from $\mathcal{D}$, ensuring that all pertinent schema details are provided before the model processes the query.
- **LLM Inference:** The constructed prompt $\mathcal{P}(\mathcal{D}, q)$ is passed to the large language model (LLM) $\mathcal{M}$, which generates the corresponding Python code $\mathcal{C}$:

$$\mathcal{C} = \mathcal{M}(\mathcal{P}(\mathcal{D}, q)) \quad (2)$$

  The resulting code $\mathcal{C}$ is a syntactically and semantically structured function designed to compute the answer a based on $\mathcal{D}$.

3.4 Code Execution

After the Python code $\mathcal{C}$ is generated, it is executed and validated to ensure correctness in answering the query q over the dataset $\mathcal{D}$. Code generation is performed using DeepSeek-V3.

- **Code Execution:** The function $\mathcal{C}$ is executed in a controlled runtime environment to produce the answer:

$$a = \mathcal{C}(\mathcal{D}) \quad (3)$$

Figure 1: Overview of the proposed pipeline.

4 Experimental Setup

We use the DataBench and DataBench Lite datasets provided for SemEval 2025 Task 8. Each dataset-specific prompt is constructed by extracting schema metadata (column names and the first row), defining modular utility functions such as `load_data` and `get_row_by_name`, and appending the corresponding query q. The prompts are designed to minimize verbosity while providing sufficient context for code generation, as illustrated in Template A. This is a condensed version; full prompt examples are available in the project's GitHub repository.

During inference, the structured prompt is passed to DeepSeek-V3, which generates a Python code snippet intended to answer the query. The generated code is executed in a sandboxed Python environment to produce the final prediction. The same code $\mathcal{C}$ is used for both the full DataBench datasets and their Lite versions without regeneration.

Evaluation is performed using the `databench_eval`[2] package provided by the organizers. We report overall accuracy along with per-category accuracies across Boolean, Categorical, Numerical, List of categories, and List of numbers.

5 Results

In this section, we present the evaluation results for DeepTabCoder on two datasets: *DataBench* and *DataBench Lite*. We analyze the overall accuracy as well as the category-specific performance for both datasets using databench_eval package. The tables and accompanying analysis provide a detailed overview of the model's performance across different categories.

5.1 DataBench Accuracy Results

The overall accuracy of DeepTabCoder on the *DataBench* dataset is 80.27%. The accuracy values for each category within the dataset are presented in Table 1. From this, we can observe that the model

[2] https://github.com/jorses/databench_eval

excels in the *boolean* category with an accuracy of 86.05%, which is the highest among all categories.

Category	Accuracy
list[category]	0.7639
list[number]	0.7802
category	0.7703
boolean	0.8605
number	0.8013

Table 1: Accuracy results on the DataBench dataset.

As shown in Table 1, the model demonstrates robust performance across the categories, with particularly high accuracy in the *boolean* category.

5.2 DataBench Lite Accuracy Results

When evaluated on the *DataBench Lite* dataset, the overall accuracy of the DeepTabCoder drops slightly to 79.50%, as shown in Table 2. We reuse the same code $\mathcal{C}$ without any modifications for generating answers on the DataBench Lite dataset.

Category	Accuracy
list[category]	0.7222
list[number]	0.7802
category	0.7703
boolean	0.8682
number	0.7885

Table 2: Accuracy results on the DataBench Lite dataset.

Table 2 also shows that DeepTabCoder performs best on the *boolean* category for the Lite dataset, achieving an accuracy of 86.82%.

5.3 Baseline Comparison

The official competition leaderboard reports DeepTabCoder achieving 81.42% on DataBench and 80.46% on DataBench Lite, evaluated manually by task organizers. For comparison, the baseline model, stable-code-3b-GGUF, achieved 26% and 27% respectively. DeepTabCoder outperforms stable-code-3b-GGUF by a significant margin, achieving much higher accuracy across both datasets.

5.4 Evaluation of Accuracy vs. Task Complexity

We evaluated the accuracy of DeepTabCoder using DeepSeek-V3 against the complexity of tasks in both datasets. Figure 2 presents a visual representation of the model's accuracy on the different categories across both datasets.

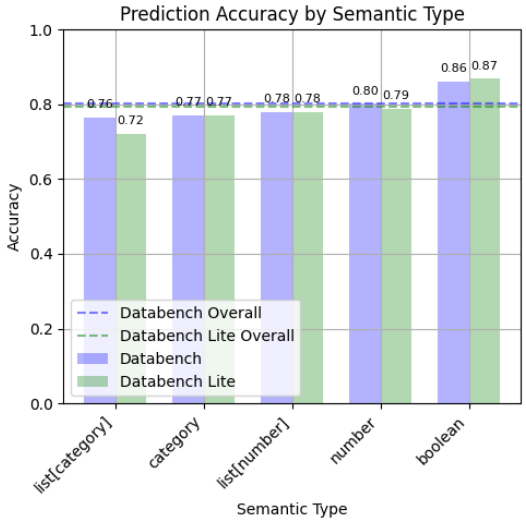

Figure 2: Accuracy of DeepSeek-V3 on different categories for the DataBench and DataBench Lite datasets.

The results highlight DeepTabCoder's strength in handling Boolean and numerical queries, where precision-based conditions and arithmetic computations are critical. The higher accuracy in these categories indicates that executing model-generated Python code offers an effective mechanism for addressing straightforward logical and statistical tasks. However, lower performance on `list[category]` and `category` outputs reveals the difficulty in generalizing over categorical aggregations, particularly when questions require selecting multiple elements or identifying non-unique patterns. In several failure cases, the model either missed entries when filtering a list or returned duplicate values instead of unique ones, suggesting an opportunity to improve aggregation handling.

Overall, while DeepTabCoder significantly outperforms the baseline by leveraging fixed schema templates and code execution, these observations emphasize the need for improvements in structured decoding, multi-hop reasoning, and aggregation strategies to further enhance performance on complex tabular reasoning tasks.

6 Limitations

Despite demonstrating strong performance in tabular question answering, DeepTabCoder still has several limitations that need to be addressed. One major limitation is the handling of complex queries. It struggles with queries that require multi-hop rea-

soning and advanced aggregation. While code execution helps with computation, the model sometimes generates incorrect logic or fails to retrieve the correct subset of data.

Another challenge arises with list-based output generation. As observed in our results, the model's accuracy on questions requiring a list of categories (e.g., `list[category]`) is significantly lower compared to other categories. This indicates difficulties in aggregating and structuring multiple categorical responses correctly.

The model faces challenges with code generation, as it is not always correct, leading to runtime errors. Although executing model-generated Python code improves precision, errors in syntax or logic occasionally occur, requiring additional checks.

7 Future Work

To address these issues, we propose several directions for future research. Enhancing multi-hop reasoning through explicit decomposition and intermediate verification could improve query resolution. For list-based outputs, structured decoding and refined prompt engineering may lead to better aggregation.

To improve code generation accuracy, future work should incorporate additional calls to smaller LLMs that verify and correct errors in the generated code after the initial output, thus enhancing execution reliability. Adaptive schema understanding could also be improved using schema-agnostic or meta-learning techniques. Furthermore, we plan to investigate domain-specific fine-tuning and sophisticated post-processing strategies to improve the handling of aggregation and multi-hop reasoning tasks. Given limited co-location of programming and other languages, special evaluations of multilingual (Aryal et al., 2023a; Aryal and Prioleau, 2023) and code-switched text (Aryal et al., 2023b,c, 2022) will also be considered, especially low-resource languages (Prioleau and Aryal, 2023; Aryal and Adhikari, 2023; Sapkota et al., 2023). These enhancements are expected to bolster the robustness and generalizability of DeepTabCoder in diverse real-world tabular reasoning scenarios

8 Conclusion

In this work, we presented DeepTabCoder to SemEval 2025 Task 8: DataBench, which combines code-based retrieval with in-context learning and dataset-specific prompt engineering for question answering over tabular data. By utilizing DeepSeek-V3 for Python code generation and execution, we achieved an improvement of approximately 3.13 times on the DataBench dataset (81.42% vs. 26%) and 2.98 times on the DataBench Lite dataset (80.46% vs. 27%) compared to the baseline.

While DeepTabCoder demonstrates strong performance in tasks such as Boolean reasoning and numerical queries, we observed challenges with tasks requiring multi-hop reasoning and list-based outputs, particularly in handling aggregation and multi-category responses. This highlights areas for further improvement, including enhanced multi-hop reasoning capabilities, more effective handling of complex aggregations, and improved code generation accuracy through additional error correction and debugging mechanisms.

Overall, our results suggest that DeepTabCoder, with future enhancements, has the potential to offer a robust solution for tabular question answering, addressing both schema diversity and complex query execution. Further work will focus on refining DeepTabCoder's capabilities through multi-hop reasoning enhancements, improved code generation accuracy, adaptive schema understanding, and domain-specific fine-tuning to ensure robustness and generalization across diverse real-world tabular reasoning tasks.

Prompt for 066_IBM_HR dataset

Task: Given a table and a question, write a Python program to answer the question.
Steps:

- Define modular, reusable functions that can be used for multiple questions.
- Create a main function `solution(table_data)` that processes the table and answers the query.
- Avoid hallucinating non-existent headers or table structures.
- Ensure no assumptions about missing or empty column headers.
- Keep the code clean, modular, and reusable across queries.

Dataset Schema

Field	Value
Age	41
Attrition	Yes
BusinessTravel	Travel_Rarely
...	...
YearsWithCurrManager	5

Question: What is the average job satisfaction for employees who have worked for more than 5 years?
Solution Example Code:

```
import pandas as pd
def load_data(file_path):
    df = pd.read_parquet(file_path)
    return df
def get_row_by_name(df, key):
    if key in df.columns:
        return df[key].iloc[0]
    return None
def solution(df):
    filtered_df = df[df['YearsAtCompany'] > 5]
   avg_job_satisfaction = filtered_df['JobSatisfaction']
                          .mean()
    return avg_job_satisfaction
df = load_data("./datasets/066_IBM_HR/all.parquet")
print(solution(df))
```

Abstract

We describe the methods used by our UAlberta team for the SemEval-2025 Task 2 on Entity-Aware Machine Translation (EA-MT). Our methods leverage large language models with prompt engineering strategies suited to this task, including retrieval augmented generation and in-context learning. Our best results overall are obtained with ensembles of multiple models, leveraging named entity knowledge in the dataset. We demonstrate that our methods work well even without gold named entity translations, by using an alternative knowledge base such as BabelNet. Finally, we provide evidence that the best translation of a given sentence is not necessarily the most literal. Our code and data are available on GitHub.

1 Introduction

This paper describes our work on SemEval 2025 Task 2: EA-MT: Entity-Aware Machine Translation (Conia et al., 2025). The EA-MT task is closely related to the well-studied task of machine translation (MT), with two key distinctions: (1) all input sentences contain a named entity, such as a location or the name of a film, and (2) the evaluation metric places a strong emphasis on the correct translation of named entities. This variant of MT is particularly challenging because named entities are often not translated literally or word-for-word (Conia et al., 2024).

The EA-MT datasets are designed to emphasize the correct translation of named entities. Each instance consists of a source English sentence, its translation in one of the target languages, a unique instance ID, the entity's Wikidata ID, the type of the entity (e.g., "Film"), and the named entity translation (NET). The data is split into four parts: training, sample, validation, and test. (As our methods are unsupervised, we do not make use of the training data.)

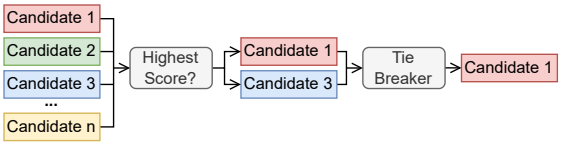

Figure 1: Our MT system ensembling template. A highest-scoring candidate translation is selected, with a tie-breaker applied if necessary.

This paper represents a further extension of our work on a comprehensive theory of lexical semantics, grounded in discrete, language-independent concepts (Hauer and Kondrak, 2020). We have applied theory-driven techniques based on multilinguality and lexical knowledge bases in our approaches to prior SemEval tasks (Hauer et al., 2020, 2021, 2022; Ogezi et al., 2023; Shi et al., 2024). The most directly relevant was the task of idiomaticity detection (Tayyar Madabushi et al., 2022), as neither idiomatic phrases nor named entities can be translated word by word (literally).

For this EA-MT task, we build upon prior work on ensembling MT systems (Figure 1). Farinhas et al. (2023) experiment with various methods for ensembling the output translations of large language models (LLMs), specifically motivated by the hallucination problem. Vernikos and Popescu-Belis (2024) leverage quality estimation systems to ensemble LLMs. However, these prior works do not specifically focus on the correct translation of named entities. Contrariwise, we incorporate NETs into both LLM prompts and ensembling systems.

In this paper, we posit and test four hypotheses: (1) Retrieval augmented generation (RAG; Lewis et al., 2020) and in-context learning (Brown et al., 2020) can improve the performance of LLMs on the EA-MT task. (2) Translation quality can be increased by ensembling the outputs of multiple MT systems via favoring NETs retrieved from a knowledge base. (3) The literalness of a sentence translation correlates with the quality of the trans-

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1709–1717

lation. (4) In the absence of gold named entities, a multilingual wordnet can serve as a source of named entity translations.

We pursue two directions in developing our systems: prompt engineering and ensembling, which can also be used in tandem. Prompt engineering involves employing techniques for instructing LLMs such as in-context learning and RAG, which we use to develop a prompt template for LLMs with a particular focus on NETs. Our second principal direction, ensembling, consists of selecting the best translation among those produced by different MT systems given the same input. We use validation set performance, named entity identification, and literalness metrics as sources of information for our various ensembling strategies.

Our results indicate that both prompt engineering and ensembling yield improvements over baseline methods. We show that a NET-based ensembler outperforms its individual component systems. Both RAG and in-context learning improve the performance of LLMs on EA-MT. Surprisingly, using literalness to select the best translation yields no consistent improvement. In the official evaluation, our best system ranks 4th overall among 27 teams, and achieves the highest reported score for Arabic. Notably, we outperform all submitted systems on the COMET metric.

2 Methods

In this section, we describe our methods for the EA-MT task.

2.1 Prompt Engineering

To address the challenges of entity identification and phonetic or semantic adaptation, our MT system integrates RAG, in-context learning, and optimized prompt design (Liu et al., 2023) with an LLM that has strong contextual awareness and multilingual capabilities (Robinson et al., 2023).

Our GPT+NET method ("WikiGPT" in the official results table) employs a prompt template which is structured to provide additional information from external sources (Table 5 in the Appendix). This prompting strategy leverages the translations of named entities retrieved from an external knowledge base (e.g., Wikidata). The intuition is that providing explicit translation candidates guides the model toward translating the entity more accurately. In our development experiments, we found that the accuracy of our system improves when we use only the first of multiple alternative translations provided in the knowledge base.

In-context learning improves entity translations produced by LLMs by providing an example of the expected input and output. By including a high-quality reference translation, the model aligns its output with verified examples, improving fluency and correctness, and improving the handling of edge cases and linguistic nuances. In addition to integrating both retrieval and in-context learning elements, we establish a role of an "expert translator" to make the LLM adopt a professional approach to translation, and produce more precise and contextually appropriate translations.

2.2 Multi-Agent Translation

In this method, we decompose the translation process into subtasks, each handled by a different LLM agent (Guo et al., 2024). First, we tokenize the input string by identifying the longest matching substrings in BabelNet to extract potential entities. Substrings that begin with capital letters and are not located at the beginning of the sentence are passed to BabelNet to obtain all possible translations. Using RAG, these potential translations are passed to the first GPT agent, which is asked to select the best translation from the list, given the context in which it is used in the source sentence, or translate the given entity itself. The output is passed to another agent which is asked to translate the whole sentence given the already translated entities. Finally, a third agent evaluates whether the generated translation accurately conveys the source sentence; if not, it translates the source independently. We refer to this method as Multi-Agent GPT.

2.3 Named Entity Ensembling

The correct translation of named entities is given significant weight by the evaluation metric for this task. Given multiple candidate sentence translations, our primary ensembling method, which we refer to as Best-First Ensembler, assigns the maximum score to all candidates that correctly translate the named entity, and a minimal score to all other candidates. For tie-breaking purposes, we rank the MT methods according to their performance on the validation set for the language pair under consideration, and choose the candidate produced by the highest-ranked method. Our NE ensembling approach method necessarily assumes access to the correct NETs, which may be given as part of the data, or derived using available tools and resources.

2.4 Literalness

In line with our literalness hypothesis, we also test an alternative approach to ensembling which prefers the most literal translation. To obtain a literalness score, we adopt the *aligned source words* (ASW) metric of Raunak et al. (2023), which computes the proportion of words in the source sentence that are aligned to at least one word in the target sentence.[1] In our implementation, we disregard both function words and named entities. Our Literal Ensembler method selects the translation with the highest ASW.

2.5 Named Entity Translation Identification

Our prompting and named-entity ensembling methods both require at least one valid translation of the source entity. While the dataset generally includes Wikidata IDs that can be used to retrieve these NETs, we aim to maximize the generality of our methods by allowing them to operate in the absence of gold NETs. To retrieve NETs, we first apply pre-trained NER models to the source sentence, and then query a semantic knowledge base to retrieve all available translations.

3 Systems, Tools, and Resources

Our methods require multiple candidate sentence translation candidates, as well as named entity translations (NETs). For the former, we use an LLM and two commercial MT systems.

3.1 Sentence Translation

LLMs can be employed for translation by prompting them to translate an input sentence. In particular, we use the most recent version of the GPT series of LLMs, gpt-4o-2024-08-06. We set the temperature parameter to 0 to maintain translation consistency. To ensure conciseness, we limit the maximum token count per translation to 200.

DeepL is a commercial MT system. We found that DeepL may fail to translate individual sentences in a large batch. In such cases, we use CometKiwi (Rei et al., 2022) to detect the misaligned translations. DeepL does not support English-to-Thai translation.

We access Google Translate (GT) via its official API. The Chinese outputs in this task are required to be in Traditional Chinese, which is supported by both GT and DeepL. Although we specify the appropriate language code when using MT systems, we further ensure consistency in the final test set submission by converting all outputs to Traditional Chinese using the Python OpenCC library.

3.2 Named Entity Translations

Wikidata (Vrandečić and Krötzsch, 2014) is a comprehensive multilingual knowledge base, created using both manual and automated procedures, which is freely accessible via a web interface or API (Nielsen, 2020). The multilingual information in Wikidata contributes to identifying and verifying the gold standard translations for named entities. As an alternative source of NETs, we experiment with BabelNet (Navigli and Ponzetto, 2012), accessed via its Python API. Where necessary, we use spaCy to identify named entities in the text. While LLMs could be employed for NER, we found spaCy to be a more practical and sufficiently effective tool.

4 Results

We present the evaluation results of our methods across all 10 English-to-target language pairs. The principal metric for this task is the harmonic mean of COMET and M-ETA. We begin by reporting the results for our official submissions, followed by an analysis of our findings explored on the provided validation set. In addition to those already described, we report the results of three baselines: GPT as run by the shared task organizers (GPT-ST), GPT prompted without NETs (GPT-Prompt), and an ensembler which randomly selects one of the candidate translations (Random Ensembler).

4.1 Official Submissions

The results of our official submissions are reported in Table 1. Among the GPT-based methods, GPT-Prompt achieves a modest score of 61.5% when operating without external information. This shows the limitations of relying solely on its existing model capabilities without additional NET knowledge. In contrast, GPT+NET achieves an average score of 91.4%, which shows that RAG with Wikidata significantly enhances translation quality. The notable increase in the M-ETA score from 46.7% to 88.1% demonstrates the impact of leveraging external knowledge sources through RAG. Our best-performing system, Best-First Ensembler with Wikidata NETs, achieves the highest overall score of 91.5%. The slight improvement is due to

[1] For word alignment, we use SimAlign (Jalili Sabet et al., 2020) with the following hyperparameter settings: XLMR as the model, word embeddings from layer 8, bpe to define tokens, the "mai" matching method, and itermax alignment.

Table 1: Our results on the test sets (in %), measured as the harmonic mean of COMET and M-ETA. All ensemblers use DeepL and GT, as well as the version of GPT which appears in that section of the table. The source of NETs may be Wikidata (WD), BabelNet (BN), or none. On the official leaderboard, "WikiEnsemble" corresponds to Best-First Ensembler with WD NETs, "WikiGPT4o" to GPT+NET, and "PromptGPT" to GPT-Prompt. *DeepL can not translate into Thai, so the average for DeepL is taken over only the other nine languages.

the higher M-ETA score of 88.3%, which shows the utility of ensembling that prioritizes accurate entity translation.

4.2 Prompt Engineering

To better understand the outstanding performance of our prompt template, we analyze the results of several variants of our prompt on the French validation set (Table 2). The final prompt template combines various established prompting strategies, effectively contributing to the success of our Best-First Ensembler. These experiments constitute an ablation study, allowing conclusions to be drawn from simpler variants of our key method.

Prompt templates are shown in Table 5. Starting from the official baseline prompt, we incrementally add information to the template. First, we test an increased emphasis on the entity in the prompt ("Entity Use"), and adding a single ("one shot") example of the task. Together, these prompting techniques improve the harmonic mean score of GPT's translations from 58.9% to 69.6%. Incorporating NETs from BabelNet further increases their scores to 79.1%. With the "soft NET" strategy, we allow the model to treat these entity translations as suggestions rather than constraints, which boosts performance to 80.1%. Replacing BabelNet NETs with Wikidata NETs produces the best score by far, 91.3%. These results prove that, unlike conventional translation services, LLMs-based translations can be refined by prompt design, demonstrating the benefits of techniques like RAG and in-context learning.

4.3 Additional Findings

In this section, we discuss the multi-agent translation method (Section 2.2), and describe some peculiarities pertaining to Wikidata.

Prompt	NETs	M-ETA	COMET	HM
GPT-ST	none	44.1	88.9	58.9

+Soft NETs	BN	70.4	92.8	80.1
+Soft NETs*	WD	88.5	94.2	91.3

Table 2: Results of different prompts on the French (fr) validation set. Methods marked with * correspond to the version used in our final submission (GPT-Prompt and GPT+NET).

We did not submit the Multi-Agent GPT results, as our implementation of this method underperforms the one-shot prompt. This is principally due to the difficulty in prompting LLMs to consistently follow instructions for intermediate steps. The issues that reduce the reliability and effectiveness of the multi-agent approach include: (1) copying the English NE instead of translating it, (2) answering the source question instead of translating it, (3) error propagation between the agents, and (4) the presence of lowercase entities in the dataset.

When analyzing our translations, we observe that the provided gold reference translations sometimes conflict with the information we retrieved from Wikidata. We found that these discrepancies are due to two factors. First, the Wikidata IDs provided in the dataset do not always match those we retrieved from the Wikidata API or web interface. For example, the Arabic entity "Andalusian Mosque" is linked to ID "Q12204195" in the task dataset, whereas its correct entry in Wikidata is "Q3324925". Second, the entity translations in the dataset have been refined manually (Conia et al.,

Table 3: Our results on the validation sets (in %), measured as the harmonic mean of COMET and M-ETA. All ensemblers use DeepL and GT, as well as the version of GPT which appears in that section of the table. For the validation sets, no conversion from Simplified to Traditional Chinese was applied.

2024), resulting in discrepancies between the gold translations and Wikidata information. For example, in Wikidata the entity "Q1761410" is translated as "Dark Night of the Soul" in both English and German, with the German entry simply copying the English name. These cases show that some errors in our translations actually arise from dependence on Wikidata. We found that 88.6% of the translations in the validation set and 88.1% of the translations in the test set were consistent with the gold translations. More details can be found in Table 4 in the Appendix.

4.4 Hypotheses and Evidence

In Section 1, we put forward four hypotheses related to the EA-MT task. In this section, we assess, for each hypothesis, what conclusions we can draw about these hypotheses based on our empirical findings. In some cases, we have carried out additional experiments after the official submission period to obtain additional data and resolve open questions. The results in Table 3 in the Appendix present our extended evaluation results on the validation set.

First, our experiments confirm that RAG and in-context learning significantly improve LLMs for the EA-MT task. Without NETs, applying prompt engineering with in-context learning improves the performance of GPT by an average of 10% over the reproduced official GPT baseline. With NETs, using either BabelNet or Wikidata further boosts performance to 82.1% and 90.7%, respectively, demonstrating the effectiveness of integrating external knowledge sources in enhancing entity translation accuracy.

Second, our results confirm that ensembling multiple translation outputs with named entity retrieval consistently improves translation quality. Using DeepL, GT, and GPT-Prompt as base translators, Best-First Ensembler increases the performance of best single translator GPT-Prompt from 65.4% to 69.4%. Even though GPT+NET already achieves a high score with access to Wikidata, our Best-First Ensembler further enhances its performance, reaching 90.8%, the highest among all our systems. This reinforces the effectiveness of prioritizing candidates that contain correct NETs.

Third, our experiments with literalness-based ensembling provide no evidence that favoring literal translations improves ensemble quality overall. In fact, we observe a drop in performance with respect to the random baseline. To further explore this surprising finding, we analyzed the literalness scores of the provided gold sentence translations. We found that many gold translations are in fact less literal than our candidate translations. On average, the ASW score of the first gold translation for each sample in the validation dataset is 82.2%, whereas the mean ASW for our candidate translations is 83.0% for GPT, 83.5% for DeepL, and 84% for GT. For example, GPT translation of *"blood sugar levels"* as *"les niveaux de sucre dans le sang"* appears more literal than the gold translation *"glycémie"*. Taken together, these experiments do not provide evidence for our third hypothesis linking literalness to translation quality; the most literal translation, we find, is not necessarily the best.

Finally, our results confirm that, in the absence of gold named entity links, using BabelNet for NETs instead of Wikidata still consistently improves performance, raising overall scores from the 60% range to approximately 80%. For the best single translator, GPT-Prompt, integrating BabelNet

significantly enhances its performance, increasing the average score from 65.4% to 82.1%. These results underline the importance of explicit entity translation and demonstrate that multilingual wordnets can serve as effective alternatives when knowledge resources like Wikidata are unavailable.

These findings validate three of the four hypotheses proposed at the outset, reinforcing the importance of prompt engineering, ensembling strategies, and external knowledge integration in improving modern entity-aware machine translation.

5 Conclusion

After extensive experimentation on the EA-MT datasets, we conclude that three of four hypotheses formulated in Section 1 are well-supported by our empirical results. Our work provides new evidence supporting the use of external knowledge bases in semantic tasks, and prompts further exploration of word-level analysis, especially as it corresponds to literalness. Finally, we note that our highest-scoring methods were ranked at or near the top of the official leaderboards for several languages and categories.

Limitations

Our system integrates several components, ensembling multiple MT systems and retrieving NETs from external knowledge bases. This design not only contributes to strong performance but also increases computational requirements. In fixed dataset settings, the process remains manageable through preprocessing and sequential execution.

Scalability is an important factor when applying our system to larger datasets or new domains. While the current setup works well for the shared task, broader use may benefit from optimizations. Leveraging multiple translation systems and external lookups can lead to increased latency and higher resource consumption, especially in high-throughput or multilingual scenarios.

Real-time or latency-sensitive applications may require further adjustments. Model ensembling and external database queries are less practical for instant translation. In addition, depending on structured resources like Wikidata or BabelNet may reduce the system effectiveness in domains or languages with limited coverage.

Oath Breakers at SemEval-2025 Task 06: Leveraging DeBERTa and Contrastive Learning for Promise Verification

Muhammad Khubaib Mukaddam[†*], **Owais Aijaz**[†], **Ayesha Enayat**[†]
[†]Habib University, School of Science & Engineering, Pakistan
Correspondence: mk07218@st.habib.edu.pk

Abstract

We present *Oath Breakers*, our system for SemEval-2025 Task 06: Promise Verification in ESG (Environmental, Social, and Governance) texts (Chen et al., 2025) which aims to identify and verify promises made within company reports. We fine-tune `microsoft/deberta-v3-base` with a contrastive loss to better separate promise vs. non-promise embeddings, and apply generative augmentation via `Mistral-7B-Instruct-v0.3`—manually validated—to balance the timeline classes. On the English official test set, we achieved F1=0.6003 (33% split, 3rd place) and F1=0.5733 (67% split, 2nd place), making our final ranking 2nd place on the English test dataset. These results validate the effectiveness of combined contrastive and generative strategies in promise verification.

1 Introduction

Recognizing the critical role of transparency and accountability, SemEval-2025 Task 6: PromiseEval aims to assess a company's commitment and adherence to its Environmental, Social, and Governance (ESG) promises. To this end, the organizers have compiled a diverse collection of ESG-related texts from company reports and news articles. This task aims to enhance enhance transparency and compel organizations and public figures to uphold their commitments. The insights derived would empower consumers, investors, and the broader public to make informed decisions grounded in verifiable actions and stated objectives. Ultimately, it aims to seek tangible progress on global sustainability, social justice, and ethical governance. Additional details about the task and dataset can be found at the official project page: `https://sites.google.com/view/promiseeval/promiseeval`.

*corresponding author

2 Problem Definition

The primary objective of this research is **Promise Verification**. Given a report or a part of a report from a company, the goal is to identify and verify promises made within that report. Specifically, we aim to determine whether a statement qualifies as a promise based on three key criteria:

- The statement must be related to Environmental, Social, and Governance (ESG) criteria **(required)**.
- The statement should outline a principle, commitment, or strategy that the company intends to uphold **(required)**.
- The statement should be supported by at least one piece of evidence (optional).

The Promise Verification process follows a pipeline approach, with multiple subtasks:

1. **Promise Classification**: Initially, we classify whether a statement constitutes a promise based on the criteria above.
2. **Evidence Verification**: If a promise is mentioned in the report, we need to evaluate whether it also contains evidence that supports the promise.
3. **Evidence Classification**: If evidence is mentioned for the promise, we evaluate its nature—whether the evidence is misleading, clear, or falls into another category.
4. **Timeline Verification**: If a promise is identified, we verify whether the timeline of the promise has been fulfilled or determine when it is expected to be fulfilled.

This structured approach allows for a comprehensive assessment of promises, ensuring that they are both identifiable and verifiable within the scope of ESG-related commitments.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1718–1723

3 Data Description

The dataset used for the Promise Verification task consists of company reports, primarily focusing on Environmental, Social, and Governance (ESG) commitments. Each entry in the dataset provides detailed information regarding specific ESG-related statements. Below is an outline of the dataset structure, including key fields and preprocessing steps undertaken.

Out of the 600 records given in the dataset, each record in the dataset includes the following fields:

- **URL**: A link to the source document, providing context and allowing for traceability.
- **page_number**: The page in the document where the statement is located.
- **data**: The textual content of the statement, which may contain potential promises.
- **promise_status**: A binary label indicating whether the statement contains a promise ("Yes") or not ("No").
- **verification_timeline**: Already, Less than 2 years, 2 to 5 years, More than 5 years, N/A
- **evidence_status**: A binary indicator of whether evidence supporting the promise is present ("Yes") or not ("No").
- **evidence_quality**: Assesses the quality of any provided evidence, categorized as "Clear," "Misleading," or "Not Clear."

This dataset provides a structured approach to assess ESG promises by capturing essential attributes related to promises, timelines, and evidence, which are critical for the Promise Verification pipeline.

4 Related Work

In recent years, several research efforts have focused on developing robust methodologies for classification and verification tasks in deep learning and natural language processing (NLP). A particularly comprehensive study by Henning et al. (2023) categorizes a wide range of techniques aimed at addressing class imbalance in NLP. Their analysis spans sampling strategies, data augmentation, staged learning, and the application of instance-level weighting, all of which are highly relevant to our work. In the context of evidence verification, we adopt oversampling methods inspired by these strategies to mitigate imbalance, especially concerning the *Misleading* class.

Another pertinent line of research by Mirzaei et al. (2023) explores the classification of implicit negative intentions in questions—an area often overlooked in mainstream NLP research. By introducing the *Question Intention Dataset*, they provide a framework for detecting both explicit and implicit negative intentions using a TF-IDF-based dictionary and Transformer models such as RoBERTa. Their emphasis on polarity classification and nuanced intention detection has informed our understanding of subtle linguistic cues, which we incorporate into the task of evidence classification within Promise Verification.

Complementary to these efforts, Heinisch et al. (2023) and Prabhu et al. (2023) demonstrate the effectiveness of contrastive learning in multilingual, multi-label framing detection tasks. Their models learn to differentiate between similar and dissimilar frame representations by employing contrastive loss functions, which draw semantically close instances together while pushing apart unrelated ones. Inspired by this technique, we integrate contrastive loss into our own model to enhance the semantic separation of misleading and accurate evidence, thereby improving verification accuracy.

Collectively, these studies lay the groundwork for our approach, which builds upon class imbalance handling, intention-aware representation, and contrastive learning. Our method synthesizes these components to address the unique challenges posed by the Promise Verification task, particularly in the classification and interpretation of evidence.

5 Methodology

The methodology section provides a detailed outlook on the progression of the task and how the baseline approach was complemented via the new methods and techniques.

5.1 Baseline

As a reference, we fine-tune `bert-base-uncased` on each subtask using only cross-entropy loss (no contrastive objective or augmentation). This establishes the baseline F1 in Table 2.

5.2 Subtask 1: Promise Classification

Initially, a `BERT`-based model was used for sequence classification, but the results were suboptimal. To improve performance, the model was upgraded to `DeBERTa`, a transformer architecture known for its superior contextual understanding and language representation. DeBERTa's robust contextual modeling capabilities outperformed BERT in handling nuanced language, making it an ideal choice for this subtask.

We fine-tune `microsoft/deberta-v3-base` with a joint classification + contrastive objective via a custom `ContrastiveTrainer`. Let $\mathcal{L}_{cls}$ be the standard cross-entropy loss on the binary labels. At each forward pass, we extract the [CLS] token embeddings

$$\mathbf{h}_i = \text{outputs.hidden\_states}[-1]_{i,0,:},$$

and build all positive pairs $(\mathbf{h}_i, \mathbf{h}_j)$ when $y_i = y_j$, and negative pairs when $y_i \neq y_j$. We then apply PyTorch's `CosineEmbeddingLoss` with margin 0.5:

$$\mathcal{L}_{contrastive} = \frac{1}{|\mathcal{P} \cup \mathcal{N}|} \sum_{(u,v)\in\mathcal{P}\cup\mathcal{N}} \ell_{\cos}(u, v,\ s_{u,v})$$

$$\text{where } s_{u,v} = \begin{cases} +1 & (u,v) \in \mathcal{P}, \\ -1 & (u,v) \in \mathcal{N}. \end{cases}$$

We weight the contrastive term by $\alpha = 0.1$:

$$\mathcal{L} = \mathcal{L}_{cls} \ + \ 0.1\, \mathcal{L}_{contrastive}.$$

Here, $\mathcal{P} = \{(u,v) \mid y_u = y_v\}$ and $\mathcal{N} = \{(u,v) \mid y_u \neq y_v\}$, with $|\mathcal{P} \cup \mathcal{N}|$ their combined count. The function $\ell_{\cos}(u, v, s)$ is implemented which for a positive pair ($s = +1$) minimizes $1 - \cos(u, v)$, and for a negative pair ($s = -1$) enforces

$$\max\big(0, \cos(u,v) - \text{margin}\big),$$

with margin $= 0.5$. Dividing by the total number of pairs balances the contributions of both positive and negative samples during training.

This formulation encourages same-label examples to cluster in embedding space and pushes apart opposite-label examples. In practice, this yields a +0.83% F1 gain over our `bert-base-uncased` baseline.

```python
def compute_loss(self, model, inputs,
    return_outputs=False,
    num_items_in_batch=None):

    labels = inputs.get("labels")
    outputs = model(**inputs,
        output_hidden_states=True)
    classification_loss = outputs.loss

    embeddings = outputs.hidden_states
        [-1][:, 0, :]
    positive_pairs, negative_pairs =
        create_pairs(embeddings, labels)
    contrastive_loss = 0

    if positive_pairs:
        pos_emb1 = torch.stack([p[0] for
            p in positive_pairs])
        pos_emb2 = torch.stack([p[1] for
            p in positive_pairs])
        cx = contrastive_loss_fn(
            pos_emb1, pos_emb2, torch.
            ones(pos_emb1.size(0)).to(
            pos_emb1.device))
        contrastive_loss += cx

    if negative_pairs:
        neg_emb1 = torch.stack([n[0] for
            n in negative_pairs])
        neg_emb2 = torch.stack([n[1] for
            n in negative_pairs])
        cp = contrastive_loss_fn(
            neg_emb1, neg_emb2, -torch.
            ones(neg_emb1.size(0)).to(
            neg_emb1.device))
        contrastive_loss += cp

    total_loss = classification_loss +
        0.1 * contrastive_loss
    return (total_loss, outputs) if
        return_outputs else total_loss
```

Listing 1: Contrastive Loss Method for Classification

5.3 Subtask 2: Evidence Verification

Given the similarity of this task to Subtask 1 in terms of task formulation, we utilized the `DeBERTa` model here as well, leveraging its contextual embedding capabilities for binary classification. We followed the same training pipeline, ensuring consistency in model optimization and hyperparameter tuning.

To preprocess the dataset, we encoded the `evidence_status` labels into numerical values, mapping `"Yes"` to `1` and `"No"` (including missing values) to `0`. The dataset had a near-balanced distribution, with **343** instances labeled as **1 (Supporting Evidence)** and **256** instances labeled as **0 (Non-Supporting Evidence)**. This balance eliminated the need for data augmentation or threshold adjustments.

Furthermore, to ensure robustness in feature

representation, we confirmed that the encoded labels were stored in `int64` format, with unique values restricted to `[0, 1]` for consistency.

This approach allowed the model to achieve strong performance on the **Evidence Verification** task, ensuring reliable classification of supporting and non-supporting evidence.

5.4 Subtask 3: Evidence Classification

Initially, we used `BERT`, but later transitioned to `DeBERTa`, which provided better results due to its disentangled attention mechanism and enhanced contextual representations. This improved our F1-scores and overall subtask accuracy, demonstrating better generalization in evidence classification.

A significant challenge in this task was **class imbalance**, particularly the underrepresentation of the `Misleading` class. To address this, we applied filtering techniques to extract instances where both `promise_status` and `evidence_status` were positive. Additionally, we utilized the `Gemini API` for data augmentation, generating synthetic samples for the `Misleading` class. This oversampling strategy increased the number of minority class samples, ensuring the model had sufficient data to learn effectively and improving its capacity to generalize across imbalanced classes.

We encoded the `clarity` labels numerically, mapping `'Clear'` to `0`, `'Not Clear'` to `1`, and `'Misleading'` to `2`, while handling missing values by assuming `'Not Clear'` as the default. This preprocessing step standardized the dataset and ensured consistency in model training.

Standard classification loss was used, along with careful validation, to ensure that the augmented data did not introduce noise or compromise the quality of predictions. The final model demonstrated improved performance in distinguishing between clear, unclear, and misleading evidence.

```
response = models.generate_content([
 f"Paraphrase the sentence: '{sentence}'"
 f"Reflect evidence status: '{evidence}',
     and quality: '{quality}'."
 f"Ensure exactly 500 characters,
     including the entity name."
 f"Do not start with a number,
     or special character." ])
```

Listing 2: Contrastive Loss Method for Classification

5.5 Subtask 4: Timeline Verification

After initial experimentation with the baseline model, we transitioned to `DeBERTa`, leveraging its superior attention mechanisms to capture subtle differences in verification timelines. Additionally, we performed preprocessing by filtering data where both `promise_status` and `evidence_status` were positive, ensuring that only relevant instances were considered. The final distribution showed dominant categories like `Already` (212 instances) and `2 to 5 years` (58 instances), ensuring a well-structured class balance.

To mitigate the class imabalances, we augmented the data to provide a more holistic data for the model to learn from. The Table 1 shows the distribution of the labels for Verification subtask. The augmentation process was carried out using the following steps:

1. Identified the class distribution and set the target count based on the majority class.
2. Determined the number of augmented samples needed per class.
3. Utilized `Mistral-7B` to generate synthetic text samples based on existing data.
4. Ensured that the generated samples maintained coherence with the dataset.
5. Incorporated the augmented samples into the training data.

We manually reviewed a random subset of 100 synthetic samples to ensure coherence and label consistency before adding them to training.

Table 1: Class Distribution: Verification Timeline

Timeline	Before	After
Already	212	212
2 to 5 years	58	212
More than 5 years	45	212
Less than 2 years	28	212

5.6 Training Arguments and Optimizations

For overall training optimization, we used a batch size of 16 (training and evaluation), with a 2e-5 learning rate under cosine decay scheduling. To maintain stability and prevent overfitting, we applied 0.01 weight decay, gradient accumulation

Table 2: F1 Score Comparison: Baseline vs Final Models

Task	Base F1	Final F1	Improv.
Subtask 1	76.67%	77.50%	+0.83%
Subtask 2	72.80%	80.00%	+7.20%
Subtask 3	59.80%	76.20%	+16.40%
Subtask 4	41.20%	72.90%	+31.70%

Table 3: Official Test Results and Leaderboard Positions (English track)

Split	F1	Rank
33% test	0.600	3rd
67% test	0.573	2nd

steps of 1, and gradient clipping with maximum norm 1.0. We enabled mixed precision (FP16) to improve memory efficiency. These optimizations ensured stable training while maximizing computational resource utilization.

6 Evaluation

We measure macro-averaged F1 on both our development split and the official test set. For all experiments, the dataset was split into **80% training, 15% validation, and 5% testing**, ensuring a robust evaluation of the models while maintaining a sufficient amount of data for generalization. The Table 2 compares the BERT baseline vs. our final DeBERTa+contrastive+augmentation system on dev. Table 3 then reports the locked leaderboard results on the English test data. Table 4 shows the task wise results on the official test dataset.

7 Analysis and Insights

- **Promise Classification:** The BERT baseline already achieved 76.67% F1, limiting room for improvement. Our final system's modest +0.83% gain indicates that promise detection primarily relies on surface cues (e.g., modal verbs, commitment phrases) which both models capture. Contrastive learning adds fine-grained separation of borderline cases, but further gains may require external world knowledge or document-level context.

- **Evidence Verification:** Here, DeBERTa's enhanced contextual embeddings, combined with contrastive loss, yield a substantial +7.20% gain. This subtask benefits from clearer signal patterns (presence/absence of explicit evidence markers), so additional representation power translates to more accurate binary judgments. Further improvements might be achievable with larger datasets and better context understanding.

Table 4: Official Subtasks F1 score on Test Leaderboard (English track)

	Promise	Evidence	Clarity	Timing
f1	0.739	0.770	0.669	0.465

- **Evidence Quality:** With a baseline of 59.80% F1, evidence-quality classification suffers from subtle semantic distinctions between "clear," "not clear," and "misleading." Data augmentation of the rare `Misleading` class closed the gap significantly, producing a +16.40% gain. This demonstrates that synthetic examples—manually validated—help the model generalize complex judgment criteria underrepresented in the original data. The use of richer annotation schemas and more robust training objectives, such as reinforcement learning with human feedback (RLHF), could further enhance performance.

- **Timeline Verification:** The largest gain (+31.70%) stems from both synthetic oversampling of underrepresented timeline categories and DeBERTa's stronger sequence modeling. Timeline inference requires understanding temporal expressions and domain-specific timeline characteristics, which benefit greatly from additional examples. Manual review of 100 augmented samples ensured no label drift occurred. Future approaches could take into account knowledge graphs to refine performance further.

- **Language Considerations:** Although we performed experiments on only the English track, we expect contrastive learning and generative augmentation to be similarly effective in other languages (French, German) provided high-quality synthetic data and language-specific pre-trained encoders. Future work should validate cross-lingual consistency and investigate whether language-specific idioms impact performance gains.

8 Discussion

- The significant improvements in **Evidence Classification**, **Evidence Quality**, and **Verification Timeline** demonstrate the value of iterative development and the inclusion of sophisticated techniques like contrastive learning, few-shot learning, and augmented datasets.

- The relatively smaller gain in **Promise Classification** may point to task saturation, where the current methods are already close to the upper performance bound for the dataset used. It could also suggest that this subtask is less sensitive to the advanced techniques applied in the final model.

- While the improvements are promising, the relatively low scores for **Evidence Quality** and **Verification Timeline** highlight areas that require further exploration, particularly in terms of data diversity, annotation quality, and advanced modeling techniques.

9 Limitations

Despite the improvements achieved, this study has several limitations. First, the dataset's size and diversity may have constrained the model's ability to generalize, particularly in subtasks such as **Evidence Quality** and **Verification Timeline**. Limited training samples and potential annotation inconsistencies could have introduced biases, affecting performance. The small size of the dataset restricted our ability to train models on a fully representative dataset that was large enough to capture all the nuances.

Second, while advanced techniques like contrastive learning and few-shot learning improved results, their effectiveness was not uniform across all subtasks. **Promise Classification** showed marginal gains, suggesting that additional refinements or task-specific adaptations might be necessary.

Finally, computational constraints limited the exploration of more complex architectures, such as large-scale transformers or graph neural networks. This hindered our experimentation and we could not try out more resource-intensive models like LLaMA.

10 Conclusion

Our participation in SemEval-2025 Task 6 showcased the effectiveness of a carefully curated methodology that integrated contrastive learning, data augmentation, and semantic-aware representations to tackle the multifaceted challenge of Promise Verification. Achieving the 2nd position overall in the leaderboard in the English dataset. The performance gains observed in the more complex subtasks affirm the importance of addressing class imbalance and leveraging semantic alignment through contrastive loss. Beyond competitive results, our model architecture and training strategy provide a strong foundation which we speculate can be used for generalizing across multilingual and multi-domain verification tasks. In summary, our system demonstrates promising strides in automated evidence verification, and we hope our insights contribute meaningfully to the broader research community working at the intersection of fact-checking, framing, and NLP-based reasoning.

Abstract

This paper describes our submission to SemEval-2025 Task-3: Mu-SHROOM, the Multilingual Shared-task on Hallucinations and Related Observable Overgeneration Mistakes, which mainly aims at detecting spans of LLM-generated text corresponding to hallucinations in multilingual and multi-model context. We explored an approach of fine-tuning pretrained language models available on Hugging Face. The results show that predictions made by a pretrained model fine-tuned on synthetic data achieve a relatively high degree of alignment with human-generated labels. We participated in 13 out of 14 available languages and reached an average ranking of 10th out of 41 participating teams, with our highest ranking reaching the top 5 place.

1 Introduction

Recent years have witnessed the rapid development of large language models (LLMs) and their applications in various fields of natural language processing (Wei et al., 2022; Zhao et al., 2023). However, content generated by LLMs occasionally contains inaccurate or fictitious information (Perković et al., 2024). The phenomenon in which natural language generation models often generate text that is nonsensical, or unfaithful to the provided source input is commonly referred to as "hallucinations" (Ji et al., 2023). It is therefore a vital task to detect and identify hallucinated content so as to improve the reliability and trustworthiness of LLM-generated content.

SemEval 2025 Task 3 (Mu-SHROOM, the Multilingual Shared-task on Hallucinations and Related Observable Overgeneration Mistakes) (Vázquez et al., 2025) proposes the task of detecting hallucination in content generated with LLMs. Different from the previous iteration, SemEval-2024 Task 6 (Mickus et al., 2024), in which the participants were asked to make binary decisions of whether a given context contains hallucination, the current task requires the participants to predict where the hallucinations occur. Specifically, the current task requires the participants to predict the spans of the hallucinated content within LLM outputs in 14 different languages.

As is shown in the results of the previous iteration of this task (Mickus et al., 2024), it is effective to fine-tune pretrained language model for hallucination detection. We therefore further extended this approach from performing binary classification tasks to predict the spans of hallucinations. We explored fine-tuning a series of Transformer-based pretrained language models (Vaswani et al., 2017), including text-to-text Transformer models (Raffel et al., 2020) and BERT-based models (Devlin, 2018), with training data created by ourselves.

Building on this method, we developed the system based and participated in 13 out of 14 languages. In addition, we also applied the approach of named entity recognition (NER) as a baseline in order to provide a more comprehensive evaluation of our system's performance. We have released our code and other relevant material on GitHub [1].

2 Background

Hallucination detection has been an extensively researched topic in recent years. One promising solution for hallucination detection is to utilize the self-evaluation ability of LLMs to judge the factual correctness of a given statement, leveraging the fact that LLMs have possessed a rich knowledge base (Li et al., 2024; Zhang et al., 2024). Many existing studies focus on the binary classification of hallucination. For instance, SelfCheckGPT (Manakul et al., 2023) is built on the idea that when an LLM is familiar with a particular concept, the responses it generates are likely to be consistent and con-

* Equal contribution, authors are listed alphabetically.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1724–1736

tain similar facts. In the HaluEval 2.0 benchmark (Li et al., 2024), the hallucination detection approach is built by first extracting factual statements from LLM responses, then determining the trustfulness of these statements with respect to world knowledge by taking advantage of the vast knowledge base of LLMs. Similarly, MIND (Su et al., 2024) introduces a similar approach that leverages the internal states of LLMs for real-time hallucination detection without requiring manual annotations. GraphEval (Sansford et al., 2024) proposes a method of detecting inconsistencies with respect to provided knowledge using a knowledge-graph approach.

Prompt engineering is a crucial technique for extending the capabilities of LLMs (Sahoo et al., 2024). A commonly used strategy is few-shot prompting, which refers to the technique of constructing prompts using a small set of demonstrative input-output examples (Lazaridou et al., 2022; Ma et al., 2023). Another method that has been proved effective is chain-of-thought (CoT) prompting, which is achieved by guiding the LLM to think step by step to perform complex reasoning tasks (Wei et al., 2022; Zhang et al., 2022; Chen et al., 2023).

Named entity recognition (NER) (Yadav and Bethard, 2019) is the task of identifying named entities such as person, location and organization in text, which are often central to factual inconsistencies in LLM-generated text. Deep learning approaches have increasingly been adopted for NER and have exhibited impressive abilities across various domains and languages (Li et al., 2020; Song et al., 2021; Liu et al., 2022). Recent research also explores the possibility of integrating prompting techniques into NER tasks by utilizing LLMs (Shen et al., 2023; Hu et al., 2024). While NER is limited to identifying predefined entity types and cannot assess the broader context or relationships between entities, it can still serve as a tool for detecting potential sources of hallucinations, making it a possible referential benchmark.

3 System Overview

3.1 Fine-tuning Procedure

The goal of this task is to detect hallucinations and identify their spans, defined by character indices, within an answer generated in response to a question. One of the ways to address this is to reformulate the problem as a token classification task, where hallucinated tokens are labeled as 1 and non-hallucinated tokens as 0.

We conducted experiments on Transformer-based models to evaluate their performance on this task. Given the limited size of the validation sets (50 labeled data points per language), all base models were trained on our self-generated data (approximately 2K data points per language).

3.1.1 Data Construction

It is crucial to have sufficient data to fine-tune pretrained language models in order to enhance their performance on specific tasks. However, the training sets provided by the organizers are unlabeled and are thus unable to be used directly for fine-tuning. Therefore, we proposed a semi-automatic approach to construct labeled data by prompting state-of-the-art generative language models, specifically GPT-4o.

In order to obtain the data in a manner similar to that of the labeled validation sets provided by the organizers, we explored a combination of few-shot prompting and chain-of-thought (CoT) prompting techniques. Specifically, we utilized several data points in the labeled validation set as learning examples and guided the LLM to infer hallucinated content based on the spans marked by human annotators in those samples.

A closer examination of the generation revealed that the LLM often misidentified the span boundaries of the hallucinated words it generated. Therefore, we optimized the pipeline of data construction by prompting the LLM to identify the hallucinated words first and subsequently convert the tokens to spans. To that end a simple algorithm was applied, which would automatically iterate through the model output text, locate each hallucinated word, and mark its start and end character indices. This additional step significantly increases the quality of generated annotations.

A number of 2,371 data points in English was constructed initially for testing purposes. In addition to those, ultimately, we constructed 2000 data points for each of the 12 other languages in which we participated. The detailed prompt is shown in Appendix C.

3.1.2 Base Models and Token Classification Setup

For fine-tuning, we experimented with a diverse set of pretrained Transformer-based models (Vaswani et al., 2017), starting with monolingual architec-

tures and later transitioning to multilingual models, which support all 13 target languages, to achieve broader language coverage. We focused on the English monolingual models to compare their performance with that of the multilingual models. Table 1 and Table 2 in the Appendix B show the details of the base models.

`AutoModelForTokenClassification` classes from the Hugging Face `transformers` library (Wolf et al., 2020) are used to load each of the base models and their tokenizers. This step attaches a randomly initialized linear classification layer on top of the Transformer encoder, ensuring the model outputs token-wise predictions for binary classes (1 or 0 for hallucination or non-hallucination, respectively). The label mappings are explicitly defined through the model's configuration using `id2label` and `label2id`. The model performs sequence labeling, where each token in the input sequence is assigned a binary label based on both its own identity and its contextual information from the entire sequence.

3.2 Performance Evaluation

A system's capability to capture hallucination spans is assessed along two main dimensions: (i) the overlap between the system's predicted hallucination spans and human annotations, and (ii) the alignment in reasoning between the system and human annotators, reflected in the correlation between the confidence of system predictions and the agreement of human annotators on hallucination spans.

These two evaluation dimensions were measured using Intersection over Union (IoU) and Correlation (Cor) scores, respectively.

The IoU score quantifies the overlap between predicted hard labels and reference hallucination spans by dividing the size of their intersection by the size of their union. If neither the prediction nor the reference contains hallucinations, the score is set to 1.0.

The Cor score quantifies the agreement between predicted soft labels and reference confidence levels, which are computed as the fraction of annotators who labeled a span as hallucinated. This agreement is measured using Spearman's rank correlation (Spearman, 1987). The score ranges from -1 to 1, where 1 indicates perfect agreement, 0 signifies no correlation, and -1 represents complete disagreement.

4 Experimental Setup

4.1 Model Fine-Tuning

The fine-tuning procedure began with preprocessing the training data, aligning tokens with binary labels to indicate hallucination. Fine-tuning Stage 1 was conducted using our auto-generated training data. This step is followed by fine-tuning Stage 2 using the labeled validation sets provided by the task's organizers, either with all available sets (for multilingual models) or the validation set corresponding to the specific test language (for both monolingual and multilingual models). Model performance was assessed for both fine-tuning stages. The experimental architecture is illustrated in Figure 1.

4.1.1 Data Preprocessing

Label Alignment In all labeled datasets used for fine-tuning, hallucination spans are provided in the format `[start_index, end_index]`. We leveraged this span information to automatically generate labels for each token before feeding the training data into the base models. After tokenization, labels are assigned based on each token's `offset_mapping`: tokens whose start and end indices fall within any hallucination span receive a label of 1, while all others are labeled 0.

Data Split We used a 9:1 training-validation split on our self-generated labeled data, resulting in approximately 1,800 training samples and 200 validation samples for each of the 13 languages. These included nine announced target languages: Arabic, German, English, Spanish, Finnish, French, Hindi, Italian, and Chinese, as well as four surprise languages: Czech, Catalan, Basque and Farsi, which were revealed only after the test set was released by the organizers.

We evaluated our models' performance using the labeled validation sets provided by the organizers after fine-tuning. We chose these sets as test data due to (i) their high-quality hallucination spans annotated by human annotators and (ii) their likely similarity to the data used by the organizers for final evaluation. In contrast, our semi-automatically generated labeled data were not reviewed by native speakers and may be of lower quality. However, since labeled validation sets were not available for the four surprise languages, we generated 50 labeled data points for each of these languages for testing purpose using the same method as for our training data.

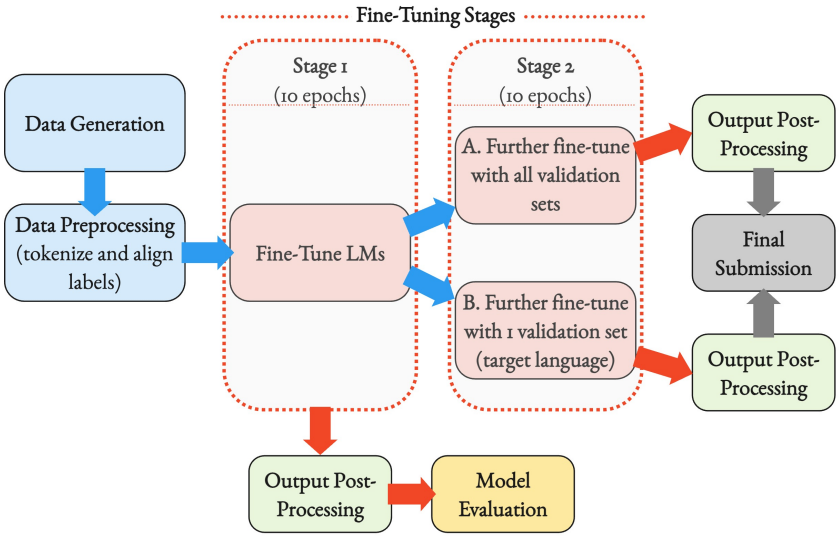

Figure 1: Fine-Tuning Pipeline.

4.1.2 Hyperparameters for Tokenization and Training

For the fine-tuning procedure, the same set of hyperparameters for both tokenization and training was applied to all base models. The same hyperparameters were applied to both fine-tuning Stage 1 and Stage 2.

Tokenizer Parameters Only the generated answers (`model_output_text`) were tokenized as input for model fine-tuning, while the inquiries (`model_input`) were not used. Tokenization included `padding` with a maximum length of `128` tokens and the application of `truncation`. Additionally, `return_offsets_mapping` was set to `True`, as the offset mapping is crucial for converting hallucination spans into token-level labels after tokenization. Details on this process are discussed in Section 4.1.1.

Training Parameters The training process was configured with a predefined set of parameters. The learning rate was set to 2e-5. Batch sizes were defined as 8 for both training and evaluation (`per_device_train_batch_size = 8` and `per_device_eval_batch_size = 8`). The number of training epochs was set to 10, as our preliminary experiments indicated that model performance plateaued around this point. Additionally, a `weight_decay` of 0.01 was applied to the training arguments.

4.1.3 Output Post-Processing

During the inference stage, the input text was tokenized and processed by the models to obtain logits for each token to be assigned to one of the two possible labels. The logits were later converted to probabilities using the softmax function, which normalized the scores along the label dimension:

$$P(y_i \mid x) = \frac{\exp(z_i)}{\sum_j \exp(z_j)}$$

In the formula above, $P(y_i \mid x)$ represents the probability of the i-th label for a given token, and z_i the corresponding logit.

To identify hallucination spans, contiguous tokens labeled as "1" (hallucinated) were grouped based on their start and end indices derived from the token offset mappings. Adjacent "1" labels with consecutive indices were treated as a single span. For each span, the average probability of the "1" labels was computed, providing a confidence score that reflects the model's uncertainty regarding the span's validity. This average probability, along with the start and end indices of each hallucination span, together form the soft labels. Hard labels are then derived by selecting spans from the soft labels with a probability of 0.5 or higher.

4.2 Benchmarks for Evaluation

To assess whether fine-tuning improves model performance in hallucination detection, we evaluate the predictions of the models from fine-tuning Stage 1 on the organizers' validation sets. This evaluation uses Cor and IoU scores and compares the results against three benchmarks: (i) the benchmark provided by the organizers and (ii) the performance of a pretrained multilingual Named Entity Recognition (NER) model.

Organizers' Benchmark The benchmark provided by the organizers was derived by fine-tuning the multilingual model `FacebookAI/xlm-roberta-base` (Conneau et al., 2019a) using the labeled validation sets they released. These validation sets contained 50 data points per language across 10 languages, excluding the four surprise languages.

Cor and IoU scores were computed for each test language. The base model was trained on validation sets from all languages except the test language, ensuring no test data leakage. This process was repeated for each language, yielding 10 fine-tuned models, each tailored to a specific test language. Fine-tuning was performed using the `model_output_text` and two label types, which classified tokens as either hallucinated or non-hallucinated.

NER Benchmark A close examination of the sample set shows that a considerable number of hallucinations involve proper nouns, such as names of people, places or organizations. We therefore proposed using a model fine-tuned for NER to make predictions without further fine-tuning, in order to serve as a comparison to the models fine-tuned specifically for this task.

This benchmark was created using the pre-trained NER model `51la5/roberta-large-NER` (Conneau et al., 2019b), a large multilingual language model supporting all 13 of our target languages. Trained on 2.5TB of filtered CommonCrawl data, this model is an XLM-RoBERTa-large variant fine-tuned on the CoNLL-2003 dataset for English NER. We used the model as-is, without any additional fine-tuning. As a result, it treated all named entities as hallucinations.

5 Results

Our submission included 21 models in total, with different combinations of models and training data used. These were the following:

- Multilingual models trained on the synthetic data only (26.3K data points, 10 epochs)
- Multilingual models trained on the synthetic data (26.3K data points, 10 epochs) and fine-tuned further with a single validation set for the target language (50 data points, 10 epochs)
- Multilingual models trained on the synthetic data (26.3K data points, 10 epochs) and fine-tuned further with all the validation sets (650 data points, 10 epochs)
- English language models trained on the synthetic data only (2.3K data points, 10 epochs)
- English language models trained on the synthetic data only (2.3K data points, 10 epochs) and fine-tuned further with a single validation set for the English language (50 data points, 10 epochs)

From all the combinations the models trained on the maximum amount of data showed superior results, with some minor exceptions (see Appendix D). Our best average performing model was based on `xlm-roberta-large`.

As opposed to the initial submission, when the models were trained on the generated answers only (`model_output_text`), we have conducted an additional test, and trained `xlm-roberta-large` base model again with the same parameters, but using a concatenation of the questions and the answers as the training input, separating them with an additional special token `'<@@>'`. We have used similar joint input for inference and adjusted the spans accordingly. The results of such training have outperformed all of our other approaches, with a significant increase of scores for all of the languages except English and Chinese. A comparative summary of the models' IoU scores is shown in Appendix A.

6 Conclusion and Limitations

As our participation in SemEval-2025 Task-3, we proposed the approach of fine-tuning language models with synthetic data for hallucination span prediction. The results demonstrate that our system achieved competitive scores across various languages. Our approach is proved effective as the scores rank as high as 5th in certain languages.

The fact that the model is exclusively fine-tuned on data constructed by LLM suggests that this approach is a feasible and effective strategy for the task of hallucination span prediction, particularly under the circumstance where human-labeled training data is absent. However, it is worth pointing out that LLM-based synthetic data are potentially more heavily subject to limitations compared with hand-crafted data. A closer examination suggests that the quality of the synthetic data does not match that of the validation and test sets provided by the organizers. Across various languages, the synthetic

data can often be shorter or significantly longer in output length, cover a narrower range of topics, and propose less sophisticated question-and-answer pairs than those in the validation and test sets. These problems can supposedly be addressed through few-shot prompting and more elaborate prompt-engineering. It is also important to mention, that although various efforts have been made in both prompting and post-processing to increase the likelihood that the spans correctly indicate the hallucinated texts, the final output is still prone to errors and may not match the accuracy of human-annotated data, although it was reported that models trained on data generated in a similar manner outperform models trained on real-world data in certain tasks (Li et al., 2023). In addition, it should also be noted that predominantly only one model, GPT-4o, is used for data synthesis. This lack of variation in model choice may limit the diversity of the synthetic data, which could in turn potentially reinforce the intrinsic biases of the model in question.

Future directions could include creating and utilizing training data in large quantities, as well as optimizing prompting techniques to obtain higher-quality training data from LLMs. Another viable approach would be to adopt more advanced state-of-the-art models for either data creation or fine-tuning.

7 Acknowledgments

We would like to express our gratitude to our supervisor, Jörg Tiedemann, for valuable suggestions and guidance throughout this work.

8 Individual Contributions

Xinyuan Mo: Model fine-tuning, including I. constructing python script for: 1) data preprocessing (tokenizing and aligning labels), 2) fine-tuning multiple base models, and 3) output generation and scoring (integrating code "`scorer.py`" from the organizers to generate scores), and II. executing the fine-tuning and scoring procedure on Puhti supercomputer.

Writing of the sections of the paper: System Overview (excluding the "Data Construction" subsection) and Experimental Setup.

Nikolay Vorontsov: Experimenting with various options for data construction, including: 1. Direct prompting with Gemini and GPT through APIs and output post-processing; 2. Generating question-answers pairs from given input texts (with AutoModelForQuestionAnswering, QuestionAnsweringPipeline) and refining them with a generative model. 3. Converting the labeled datasets into translated versions with the preserved labeling (with Google Translator API) and output post-processing.

Development of the system for labeling the datasets with LLMs through API (used as another baseline during development), automated post-processing of the output, union and intersections of the models' predictions.

Development of alternative fine-tuning strategies with different training parameters, including LoRA parameter-efficient fine-tuning of Llama 7B model with 4-bit quantization. Alternating tokenization pre-processing and post-processing to include both questions and answers during the training and inference stages. Setting up the environment on Puhti supercomputer, running training and prediction jobs.

Limited project management, including setting up shared repositories, communication channels, submitting the final predictions to the shared task.

Writing of the Results section of the paper, analysis of the results, creating figures, and formatting.

Tiankai Zang: Data construction, including 1) designing and testing various prompting techniques for optimal outputs, 2) overseeing the data generation process and making adjustments as needed, and 3) converting the data to desired format for fine-tuning.

Writing of the sections of the paper: Abstract, Introduction, Background, System Overview ("Data Construction" subsection), Conclusion and Limitations.

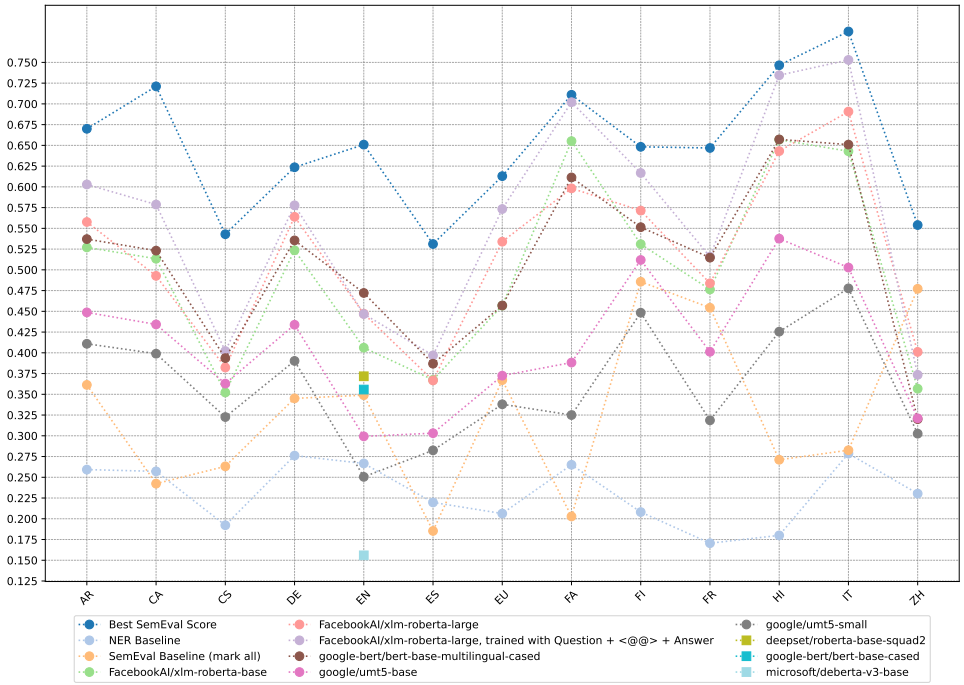
A IoU Scores for models trained on synthetic data and fine-tuned further with either: (1) all the validation sets (multilingual models); (2) single validation set (English language models)



B Base Models Used

Model	Description
`google-bert/bert-base-cased`	109M parameters, pretrained for masked language modeling (MLM) (Devlin et al., 2018).
`deepset/roberta-base-squad2`	124M parameters, a RoBERTa-base model fine-tuned for extractive question answering (deepset, 2020).
`microsoft/deberta-v3-base`	86M backbone parameters, pretrained for replaced token detection (He et al., 2021).

Table 1: Monolingual (English) base models for fine-tuning

Model	Description
`google-bert/bert-base-multilingual-cased`	179M parameters, 104 languages, pretrained for MLM and next sentence prediction (NSP) (Devlin et al., 2018)
`google/umt5-small`	179M parameters, 102 languages (Chung et al., 2023)
`google/umt5-base`	
`FacebookAI/xlm-roberta-base`	279M (base) / 561M (large) parameters, 94 languages, pretrained for MLM (Conneau et al., 2019a)
`FacebookAI/xlm-roberta-large`	

Table 2: Multilingual base models for fine-tuning

C Prompt for Data Construction

```
""Given information 1:
   "model_input": "How many genera does the
Erysiphales order contain?",
   "model_output_text": "The Elysiphale order
contains 5 genera.",
   "Model_output_text" is supposed to be the
answer to the question in "model_input" but
contains some errors (hallucinations) which
contradict the fact. Your task is to specify the
spans of the erroneous texts and mark them as
"soft_labels".
   In order to do this, firstly, you should
locate the erroneous texts based on the question
asked in "model_input" as well as the fact. For
example, in this case, Elysiphale order contains
4 genera instead of 5; the span of "4" is [31,
32]; and it has a probability of 1 to be
erroneous. Therefore, you should specify this in
the following way:
     { "start": 30, "prob": 1, "end": 31 }.
   Apply the same approach to other parts of the
text. The final result is:
     "soft_labels": [
       { "start": 4, "prob": 0.2, "end": 14 },
       { "start": 30, "prob": 1, "end": 31 },
       { "start": 31, "prob": 0.2, "end": 38 }],
     "hard_labels": [[30, 31]],
For your information, here are two more examples:
Example 1
   "model_input": "Do all arthropods have
antennae?",
   "model_output_text": "Yes, all insects and
arachnids (including spiders, scorpions, and
ticks) have at least one antenna.",
   "soft_labels": [
     { "start": 10, "prob": 0.2, "end": 12 },
     { "start": 12, "prob": 0.3, "end": 13 },
     { "start": 13, "prob": 0.2, "end": 18 },
     { "start": 25, "prob": 0.9, "end": 31 },
     { "start": 31, "prob": 0.1, "end": 37 },
     { "start": 45, "prob": 1, "end": 49 },
     { "start": 49, "prob": 0.3, "end": 65 },
     { "start": 65, "prob": 0.2, "end": 69 },
     { "start": 69, "prob": 0.9, "end": 83 }],
Example 2
   "model_input": "What did Petra van Staveren
win a gold medal for?",
   "model_output_text": "Petra van Stoveren won a
silver medal in the 2008 Summer Olympics in
Beijing, China.",
   "soft_labels": [
     { "start": 10, "prob": 0.2, "end": 12 },
     { "start": 12, "prob": 0.3, "end": 13 },
     { "start": 13, "prob": 0.2, "end": 18 },
     { "start": 25, "prob": 0.9, "end": 31 },
     { "start": 31, "prob": 0.1, "end": 37 },
     { "start": 45, "prob": 1, "end": 49 },
     { "start": 49, "prob": 0.3, "end": 65 },
     { "start": 65, "prob": 0.2, "end": 69 },
     { "start": 69, "prob": 0.9, "end": 83 }],
   "hard_labels": [ [25, 31], [45, 49], [69, 83]
],
You should:
1. Study the examples above, understand why and
how certain texts in "model_output_text" are
labeled.
2. Please generate a similar example, in which
you ask a question, answer it with one or a few
hallucinations deliberately, and label the
hallucinated words (instead of the spans and
probabilities of possible hallucinations).
3. You are encouraged to include more than two
hallucinated words in your output.
4. You do not need to explain your annotations.
5. The output format should be JSON.
The format should be:
   "model_input":
   "model_output_text":
   "hallucinated_words": <list all hallucinated
words in "model_output_text" here>
generate your response in {lang}""
```

The above prompt was used as an input for dialogue systems, with a language specified inside `{lang}`. The output was then manually copied and pasted into a .jsonl file, repetitive outputs were eliminated. Hard labels were created by running the following example code:

```python
import json

current_id = 1

with open('eu-sim-val-raw.json', 'r', encoding='utf
    -8') as file:
    data = json.load(file)

with open('eu-sim-val.jsonl', 'a', encoding='utf-8')
     as output_file:

    for entry in data:
        model_input = entry["model_input"]
        model_output_text = entry["model_output_text
            "]
        spans = []

        for word in entry["hallucinated_words"]:
            start_index = 0
            while True:
                start_index = model_output_text.find
                    (word, start_index)
                if start_index == -1:
                    break
                end_index = start_index + len(word)
                spans.append([start_index, end_index
                    ])
                start_index = end_index

        result = {
            "id": current_id,
            "created_with": "GPT4o",
            "lang": "eu",
            "model_input": model_input,
            "model_output_text": model_output_text,
            "hard_labels": [[start_index, end_index]
                for start_index, end_index in
                spans]
        }

        current_id += 1

        json.dump(result, output_file, ensure_ascii=
            False)
        output_file.write("\n")
```

Abstract

This paper presents our findings of the Multilingual Shared Task on Hallucinations and Related Observable Overgeneration Mistakes, MU-SHROOM, which focuses on identifying hallucinations and related overgeneration errors in large language models (LLMs). The shared task involves detecting specific text spans that constitute hallucinations in the outputs generated by LLMs in 14 languages. To address this task, we aim to provide a nuanced, model-aware understanding of hallucination occurrences in English. We used natural language inference and fine-tuned a ModernBERT model using a synthetic dataset of 400 samples, achieving an Intersection over Union (IoU) score of 0.032 and a correlation score of 0.422. These results indicate a moderately positive correlation between the model's confidence scores and the actual presence of hallucinations. The IoU score indicates that our model has a relatively low overlap between the predicted hallucination span and the truth annotation. The performance is unsurprising, given the intricate nature of hallucination detection. Hallucinations often manifest subtly, relying on context, making pinpointing their exact boundaries formidable.

1 Introduction

Despite the advancements in Natural Language Processing (NLP) and the development of Natural Language Generation (NLG) models, their limitations and potential risks have gained increased attention. A significant issue is that NLG models often produce unfaithful text relative to the source input, a phenomenon known as "hallucination" (Koehn and Knowles, 2017a; Rohrbach et al., 2018; Maynez et al., 2020a). Hallucinations in NLG models often result in outputs that, while fluent, lack accuracy. This issue arises because existing evaluation metrics prioritize fluency over correctness, ultimately diminishing system performance and failing to meet user expectations in practical applications (Mickus et al., 2024). For example, Dopierre et al. (2021) illustrate this phenomenon by attempting to paraphrase the statement "I am not sure where my phone is," which leads to the hallucinated output: "How can I find the location of any Android mobile."

Hallucination in NLG is concerning due to its impact on performance and safety in applications like medicine, where hallucinatory summaries or machine-translated instructions can pose risks to patient diagnosis (Ji et al., 2023). Similarly, hallucinations can lead to privacy violations by generating sensitive information not present in the source input (Carlini et al., 2021).

To address this challenge, *"SemEval-2025 Task 3 – Mu-SHROOM, a Shared-task on Hallucinations and Related Observable Overgeneration Mistakes"* (Vázquez et al., 2025) was introduced. The shared task involves detecting specific text spans that constitute hallucinations in outputs generated by LLMs. Participants compute the probability of each character being marked as a hallucination using the LLM output consisting of a character string, tokens, and logits, thus enabling a fine-grained hallucination detection.

2 Background

Numerous efforts are provided to address hallucination across various NLG tasks. Analyzing hallucinatory content and its relationships in different tasks could enhance our understanding and unify efforts across NLG fields (Ji et al., 2023). While most existing studies focus on specific tasks like abstractive summarization (Huang et al., 2021; Maynez et al., 2020b) and machine translation (Lee et al., 2018), the study of Ji et al. (2023) offer a comprehensive analysis on the phenomenon of hallucination in abstractive summarization, dialogue generation, generative question answering, data- to-text generation, and machine translation.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1737–1741

(Parikh et al., 2020) argue that hallucination problem occurs when there is very little divergence in dataset and encoder with a defective comprehension ability could influence the degree of hallucination. Similarly, (Koehn and Knowles, 2017b) show that training and modeling choices of neural models have influence for hallucination. While large pre-trained models used for downstream NLG tasks are powerful in providing generalizability and coverage, they however prioritize parametric knowledge over the provided input and can result in hallucination of excess information in the output (Longpre et al., 2021).

Recent efforts to address hallucination include the Shared Task on Hallucinations and Related Observable Overgeneration Mistakes (SHROOM), which focused on binary classification for task-specific English language models (Mickus et al., 2024). Maksimov et al. (2024); Arzt et al. (2024); Rahimi et al. (2024) identify cases of fluent overgeneration hallucinations in model-aware and model-agnostic settings. They detect grammatically sound outputs which contain incorrect or unsupported semantic information. Building on this task instead of focusing on model-agnostic and model-aware tracks, this year's task focuses on the multilingual aspect. Therefore, all data-points in this year's task are model-aware.

We present our submission for the task *Multilingual Shared-task on Hallucinations and Related Observable Overgeneration Mistakes (MU-SHROOM)* which aims to detect hallucinations in a multilingual context, providing a more nuanced understanding of their occurrence. MU-SHROOM is a SemEval-2025 shared task that focuses on detecting hallucinations and overgeneration errors in AI-generated text, a crucial challenge in improving the reliability of LLMs (Vázquez et al., 2025). Hallucinations occur when LLMs produces fluent but false or unsupported content, while overgeneration mistakes involve excessive, often misleading text (Ji et al., 2023). This task is important as language models become increasingly prevalent in various applications, where factual accuracy and reliability are essential for maintaining user trust and system integrity. Therefore, tackling these issues is essential for ensuring AI-generated text remains trustworthy and useful across various applications (Maksimov et al., 2024).

The task consists of participants detecting spans of text corresponding to hallucinations and determine which parts of the given text produced by LLMs constitute hallucinations. Annotated dataset are provided, allowing researchers to develop and benchmark models for identifying these issues in different linguistic contexts. Given the LLM output as a string of characters, a list of tokens, and a list of logits, participants calculate the probability that each character is marked as a hallucination and thus provide a fine- grained hallucination detection. Similarly, the task is held in multilingual and multi-model context as data are produced by a variety of public-weights LLM in multiple languages which includes: Arabic (Modern standard), Chinese (Mandarin), English, Finnish, French, German, Hindi, Italian, Spanish, and Swedish, along with three surprise test languages.

3 System Overview

One of the primary challenges in this task was the lack of labeled training data. To address this, we created a synthetic training dataset using ChatGPT, adhering to official annotation guidelines.

For the language selection, we used English language only and this is due to time constraint. Secondly, English language offers an extensive resource for NLP model development and evaluation. Similarly, focusing on a single language allowed us to develop deeper linguistic pattern recognition for hallucination detection.

For model selection, we fine-tuned ModernBERT (Warner et al., 2024), an advanced variant of BERT (Devlin et al., 2019) that offers significant improvements in handling long-context inputs, computational efficiency, and robustness in token classification tasks. This choice aligns with recent studies highlighting the benefits of long-context language models in detecting nuanced text errors (Sahitaj et al., 2025).

For a precise understanding of hallucination detection, we used the model-aware method. This method is based on analysing internal data of LLM during inference. One of the possible approaches is the analysis of the outputs of the hidden layers of the transformer. Using vector values of hidden layers for hallucination detection was proposed in a method called Statement Accuracy Prediction, based on Language Model Activations (SAPLMA) (Azaria and Mitchell, 2023). SAPLMA is a probing technique that utilises a feedforward neural network trained on activation values of the hidden

layers of LLM.

4 Experimental Setup

4.1 Dataset Generation

For this task, we initiated the development of a robust model for detecting hallucinations in text by generating synthetic data specifically for training purposes. Borra et al. (2024) have shown the success of using synthetic data in finetuning models for hallucination detection in LLMs. This synthetic dataset was designed to simulate a wide range of scenarios, enhancing the model's ability to generalize across various contexts. With this approach, We were able to generate 400 diverse labeled data points.

Similarly, we utilized the task-provided validation dataset to assess the model's performance during the training phase, ensuring that it effectively learned from the training data while maintaining its ability to generalize. Finally, we reserved the provided unlabeled test dataset for final evaluation, allowing us to measure the model's performance on completely unseen data.

4.2 Data Preprocessing

The text data was tokenized using the Hugging Face AutoTokenizer from the Transformers library (Wolf et al., 2020), which efficiently segmented the text into manageable units. Similarly, token labels were assigned based on entity spans identified in the dataset, ensuring that the model learned to recognize specific entities and their contexts.

4.3 Model Training

The core of our approach involved fine-tuning the ModernBert model on the synthetic dataset. During this training process, we implemented several advanced techniques to optimize performance:

- Cosine Learning Rate Scheduler: This scheduler dynamically adjust the learning rate throughout the training, promoting a smoother convergence and help avoid local minima.
- Mixed Precision Training: By utilizing both float16 and float32 data types, we enhanced computational efficiency while preserving model accuracy. This approach significantly reduced memory usage and improved training speed.
- Gradient Clipping: To maintain stability during training, we employed gradient clipping techniques that prevented gradients from exceeding a specified threshold. This safeguard helped mitigate issues related to exploding gradients, which can destabilize the training process.

4.4 Evaluation Metrics

To evaluate the model's effectiveness post-training, we utilized several key metrics: precision, recall, and F1 score. The selected evaluation metrics were implemented to facilitate a comprehensive assessment of the model's efficacy, encompassing both predictive precision and capacity to address class distribution asymmetries. The above metrics are used in addition to Intersection over Union (IoU) and Correlation Score that were used by the task organizers to assess the performance of our model.

4.5 Classification and Prediction

Once trained, the model was capable of processing unseen text to detect hallucinations effectively. The outputs of the model were converted into two formats: hard labels (binary classification) indicating the presence or absence of hallucinations, and soft labels representing confidence scores that quantify the model's certainty regarding its predictions. This dual-output approach not only enhances interpretability but also allows for flexible integration into downstream applications where varying levels of confidence may be required.

5 Results

At the end of training our model, the evaluation result showed that the model had a precision and recall score of 0.49 and 0.54 respectively. The F1 score of the model was at 0.43. The result indicates that the model correctly identifies hallucinations about half the time. The model is also able to detect slightly more than half of all hallucinations present in the text.

On the task-based evaluation of our model, our system achieved an Intersection over Union (IoU) score of 0.032 and a correlation score of 0.422. The IoU score indicates that our model has a relatively low overlap between the predicted hallucination span and the truth annotation. With the relatively low score, the model is struggling to identify the exact boundaries of the hallucinated content. Going by this result also, the model may be prone to false positives and/or false negatives.

The models correlation score of 0.422 shows a moderate positive correlation between the con-

fidence scores of the model and the actual presence of hallucinations. This result can translate to the model's ability to differentiate between hallucinated and non-hallucinated content. While this may not be the best performance, the results show that there is room for further improvement.

Our model results ranked 42nd and 24th on the IoU and correlation score indices respectively. The scores are not favourable and may not be entirely unexpected given the inherent complexity of hallucination detection,. Hallucinations can be subtle and context-dependent, making exact boundary detection particularly challenging. The model result is a promising starting point for further improvement.

6 Conclusion

This paper presents our approach to the SemEval shared task on LLM hallucination detection, focusing on a fine-grained, model-aware analysis of hallucination occurrences in the English language. We leveraged natural language inference and fine-tuned a ModernBERT model using a synthetic dataset of 400 samples. Our model achieved rankings of 42nd and 24th on the Intersection over Union (IoU) and correlation score indices, respectively. These results, while modest, underscore the inherent complexity of hallucination detection and highlights the need for continued refinement and innovation in this area. Our findings serve as a promising foundation for future improvements, emphasizing the importance of model-aware strategies in enhancing the reliability of LLM outputs.

Abstract

Media framing is a widely used technique in misinformation campaigns, where narratives are constructed through specific angles to align with political agendas. Such narrative twisting involves complex dynamics of rhetoric, topic selection, and pattern repetition, yet typically maintains coherence aligned with the intended media agenda. The SemEval-2025 Task 10 (Subtask 2) challenges participants to classify online news articles according to a pre-defined, two-level narrative taxonomy. In this paper, we present a retrieval-based approach to narrative classification using the E5 variant of the Mistral 7B language model. Rather than relying on supervised training, our method frames narrative detection as a semantic similarity task via story embeddings. This design exploits the inherent coherence across similarly framed news stories. Our system achieves a sample-level F1 score of 0.226, outperforming the official baseline. We highlight both the strengths and challenges of using retrieval-based embeddings for narrative understanding and propose future directions for improving label precision and generalizability.

1 Introduction

Media framing, an interdisciplinary area of study (Otmakhova et al., 2024), plays a central role in shaping online disinformation. SemEval-2025 Task 10 (Piskorski et al., 2025) advances this field by introducing a richly annotated multilingual dataset focused on controversial topics such as climate change and the Russia–Ukraine conflict. This paper presents our submission for Subtask 2: narrative classification of English news articles using a predefined two-level taxonomy (Stefanovitch et al., 2025). The task is framed as a multi-label, multi-class classification problem where each article can be associated with multiple narrative labels.

Prior work on narratives has primarily adopted an event-centric lens (Piper et al., 2021), which often overlooks propagandistic intent and disinformation framing. In contrast, Task 10 brings attention to narrative construction in the context of agenda-driven reporting, introducing new challenges in narrative modeling and classification.

To address these challenges, we frame narrative classification as a retrieval problem. This approach is motivated by several observations from the disinformation literature:

- News articles advancing specific media frames often rely on repetitive rhetorical patterns (Entman, 2003).
- These frames typically focus on a limited set of recurring topics (DiMaggio et al., 2013).
- Articles promoting similar disinformation narratives—particularly in crisis events—tend to exhibit semantic and thematic coherence (Baden and Stalpouskaya, 2015; Van der Meer et al., 2014).

Motivated by these insights, we propose a narrative classification system grounded in topical coherence and semantic similarity. Our system leverages story embeddings to retrieve semantically aligned training articles and transfers their narrative labels to test samples. Figure 1 provides a high-level overview of this pipeline, where narrative detection is framed as a retrieval problem based on embedding similarity rather than supervised classification. We adopt the approach proposed by Hatzel and Biemann (2024), which utilizes contrastive learning and adapter-finetuned large language models (E5 variant) (Wang et al., 2024) for robust narrative representation.

This paper details our system pipeline, experimental results, observed limitations, and future research directions.

2 System Description

To address the task of narrative classification, we adopt a retrieval-based approach inspired by story

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1742–1746

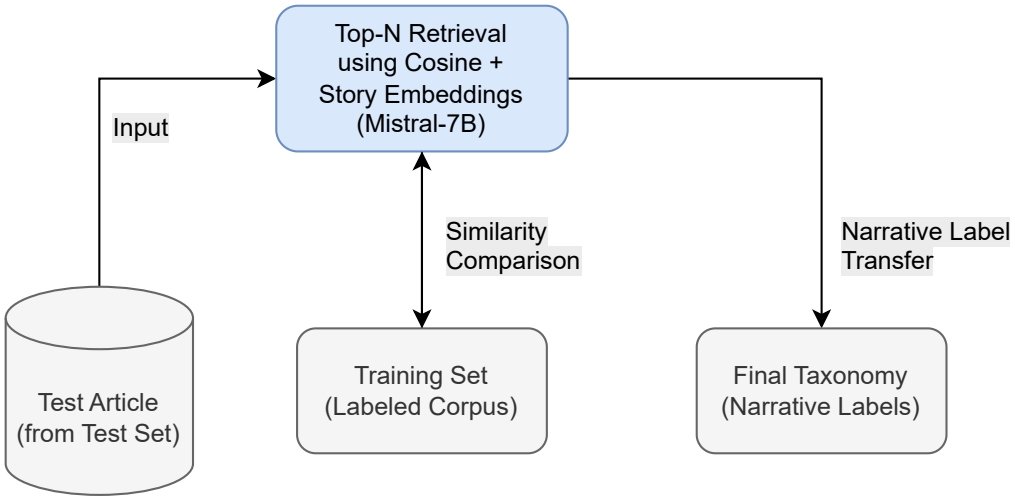

Figure 1: High-level Overview of Our Subjectivity Analysis Pipeline

embeddings proposed by Hatzel and Biemann (2024). Their method models narrative coherence through contrastive learning applied to narrative chains. We hypothesize that narrative labels in news articles can be transferred effectively based on semantic proximity in embedding space. Therefore, rather than training a supervised classifier, we treat the problem as one of story retrieval and label transfer.

Our approach is influenced by common-sense reasoning tasks such as the Story Cloze Test (Mostafazadeh et al., 2017), where systems must choose the more coherent ending from two candidates given a four-sentence story. Similarly, we embed a test article and compare it to candidate articles from the training set to identify the most semantically similar ones and inherit their labels. The overall system pipeline, previously introduced in Figure 1, proceeds through the following stages:

Given a test article, we compute cosine similarity between its embedding and those of all training articles using the E5 variant of Mistral-7B (Wang et al., 2024). The process comprises the following steps:

- **Similarity Ranking:** We first embed all articles using the story embedding model and rank training samples by their cosine similarity to the test article.
- **Candidate Selection:** The top-n most similar training articles are selected. These represent the most semantically coherent stories with respect to the test article.
- **Anchor-Based Prediction:** We treat the test article as the anchor and embed it alongside each of the top-n stories. We then compute similarity in the story embedding space to identify the closest narrative match.
- **Label Transfer:** The narrative labels from the most similar training article are directly transferred to the test article. This unsupervised strategy assumes that narrative proximity implies label relevance. However, as illustrated in Table 1, this approach may result in the transfer of excessive or irrelevant labels in cases where the semantic similarity is partial or ambiguous.

In implementation, we use the open-source story embedding model released by Hatzel and Biemann (2024) on Hugging Face.[1] No additional fine-tuning was performed on the model. The query prompt used to guide retrieval was: *"Retrieve stories with a similar narrative to the given story:"* This framing implicitly guides the model to surface coherent narrative alignments.

While this pipeline provides a simple and generalizable baseline, we recognize that direct label transfer introduces potential noise, especially in multi-label cases. We analyze this limitation and its impact on performance in the following section.

[1] https://huggingface.co/uhhlt/story-emb

Article Snippet	Excess Label Transferred
• Title: **OBEY THE GREEN: Blue states depriving rural counties of right to reject green energy community takeovers** Snippet: Each of these so-called "blue" states – Michigan is arguably a "purple" state since it appears as though Donald Trump may have won the state, minus the fraud, in the 2020 election – is controlled by far-left politicians who are in bed with the green energy industry.	CC: Hidden plots by secret schemes of powerful groups
• Title: **European Parliament members clash over support for Ukraine** Snippet:Members of the European Parliament (EP) engaged in mutual insults during debates on the need for further support to Ukraine. Several European Parliamentarians accused advocates of continuing military assistance of madness and called for an end to arms shipments during debates in the EP's plenary session in Strasbourg.	URW: Russia is the Victim

Table 1: Examples of Excess Labels' Transfer in Development Set

3 Experiments and Evaluation

3.1 Experimental Setup

We implemented our system using Google Colab with a T4 GPU. The story embedding model from Hatzel and Biemann (2024) was accessed via Hugging Face[2] without any additional fine-tuning. The dataset used was the official English subset provided by the Task 10 organizers. After computing predictions, results were exported in the required submission format for leaderboard evaluation.

3.2 Evaluation and Label Transfer Analysis

Since gold labels for the final test set are unavailable, we conducted a detailed analysis using the development set. One key insight is that the article most similar to a test sample based on cosine similarity often differs from the one closest in the story embedding space. This similarity re-ranking effect occurred in roughly 50% of the development samples, indicating that embedding-based coherence plays a critical role.

However, we also observed a limitation: direct transfer of narrative labels from the nearest training article sometimes led to excessive or irrelevant labels. This issue is particularly evident in multi-label scenarios, where overlapping but distinct narratives may coexist. Table 1 (introduced in Section 2) provides concrete examples of this phenomenon. These findings highlight the need for more precise or supervised methods for narrative label assignment.

To assess the sensitivity of our system to the number of retrieved candidates, we varied the value of n used for label transfer. Table 2 summarizes the results. We observe that increasing n beyond 2 consistently degrades performance. This drop in F1 score is likely due to added semantic noise from additional training articles, which dilutes the coherence of the narrative signal.

[2] https://huggingface.co/uhhlt/story-emb

Number of Retrieved Articles (n)	F1 Score (Sample-Level)
2	0.2260
3	0.1830
4	0.1780

Table 2: Effect of Number of Retrieved Articles on F1 Score

These results reinforce our design choice to limit label transfer to the top-$n = 2$ most similar training stories. Selecting a larger set introduces topic drift or partial matches, increasing the risk of incorrect narrative assignments.

4 Conclusion and Future Work

This paper presents our system description for narrative classification in Subtask 2 of SemEval-2025 Task 10. We approached the task through a retrieval-based perspective using story embeddings derived from a Mistral-7B model variant (E5), framing narrative detection as a similarity-driven retrieval challenge. Our method leverages the narrative coherence and topical consistency typically embedded in disinformation, enabling us to transfer narrative taxonomy labels based on content proximity in the semantic embedding space. Without any additional supervised fine-tuning, our system outperformed the competition baseline and achieved an F1 score of 0.226 on the samples.

Our analysis revealed both strengths and limitations of our pipeline. Notably, the re-ranking of similar stories using embedding-based similarity rather than raw cosine similarity led to insightful improvements. However, we also observed the challenge of excessive or inaccurate label transfer during the final inference stage, highlighting the need for a more precise mechanism for label assignment.

As part of future work, we intend to address these limitations by:

- Incorporating supervised learning components to refine the label transfer step, potentially using contrastive loss or multi-label classification heads on top of retrieved embeddings.
- Exploring narrative disambiguation strategies that can handle overlapping or competing frames within articles more robustly.
- Applying zero-shot or few-shot prompt engineering techniques to leverage large language models directly for narrative prediction, reducing reliance on nearest-neighbor heuristics.
- Investigating multilingual extensions to better support narrative detection in global contexts, given the cross-cultural framing of controversial topics.

Overall, our findings suggest that framing narrative classification as a retrieval task is a promising direction, especially when paired with pre-trained embeddings that encode structural and semantic narrative features. We hope our approach sparks further innovations in retrieval-based disinformation and narrative analysis.

Abstract

Large language models (LLMs) may retain and reproduce sensitive information learned during training, posing significant privacy and ethical concerns. Once detected, this personal information should be deleted from the model. For this reason, Machine Unlearning (MU) has risen in recent years as an emerging field of research to delete specific information from a model's knowledge efficiently. This paper presents our solution to the "Unlearning sensitive content from Large Language Models" shared task at SemEval-2025, which challenges researchers to develop effective LLM MU techniques. We adopt a Dual-Teacher framework that leverages a Competent and an Incompetent Teacher to erase unwanted information while selectively preserving model utility. Our approach adapts established computer vision unlearning methods to the sequential nature of language models through KL divergence minimization over next-token prediction probabilities. Experimental results show that our method achieves strong performance in removing information from the forget set, resisting adversarial membership inference attacks, and in the overall evaluation metric used in the shared task compared with the other methods considered.

1 Introduction

Large Language Models (LLMs) have grown considerably in recent years due to their unique ability to generate text consistent with the information learned during training (Bertetto et al., 2024). However, these models may retain and reproduce hallucinated (Borra et al., 2024), sensitive personal (Yao et al., 2024) or copyrighted information (Liu et al., 2024a), raising ethical and privacy concerns. This danger is amplified given the large amount of data collected without supervision to train these models. The model's creator should identify and remove the corresponding information from the training data in these cases. The most straightforward way would be to retrain the model from scratch on the filtered dataset. However, this approach is unfeasible due to the enormous computational costs, time requirements, and environmental impact of training these large models (Crawford, 2022). Furthermore, full retraining does not guarantee that unwanted information from correlated data still present in the training corpus will not be retained. Machine Unlearning (MU) has emerged as a challenging research area involving selectively erasing specific information from a trained model without requiring complete retraining (Golatkar et al., 2020).

The *Unlearning Sensitive Content from Large Language Models* challenge (Ramakrishna et al., 2025b) has been proposed at SemEval 2025 to investigate this field. The challenge comprises different tasks to reflect different scenarios where unlearning could be applied with varying evaluation metrics to assess the methods' efficacy.

This work[1] introduces an approach already used in the unlearning framework on other domains: using a Dual-Teacher framework to make our model forget some information while retaining the final model utility. The proposed method achieves excellent results in the evaluated task, surpassing all the other methods considered.

2 Related Works

In the unlearning framework, models are trained with a training dataset $\mathcal{D}$, which is then split into Forget Set ($\mathcal{D}_f$), which contains the information that must be forgotten, and Retain Set ($\mathcal{D}_r$), which includes the remaining part of $\mathcal{D}$ (the information that should be retained). An unlearning method aims to remove the information related to $\mathcal{D}_f$ from the model's knowledge without retraining it.

Traditional unlearning methods, initially designed for classification models, may struggle

[1]The code to replicate the experiments can be found at https://github.com/MAL-TO/Unlearning-sensitive-content-from-LLMs

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1747–1752

to generalize to generative architectures such as LLMs (Qu et al., 2024), where memorization and retrieval of training data are inherent characteristics. As shown by Eldan and Russinovich (2023), LLMs differ from standard classifiers because data deletion is more challenging to evaluate, as they are trained on vast datasets where tracking the specific concepts that should be forgotten is challenging. To overcome this problem, recent work has introduced benchmarks designed to assess unlearning in LLMs (Maini et al., 2024; Jin et al., 2024). A recent benchmark, LUME (*"LLM Unlearning with Multitask Evaluations"*) (Ramakrishna et al., 2025a), forms the foundation of this challenge and the proposed work. A detailed description of the benchmark and its dataset and evaluation methods is described in Section 3. This work adapts the Bad Teaching method (Chundawat et al., 2023) to the field of LLM unlearning. This method encapsulates the core principle of knowledge distillation, already used in LLM unlearning (Liu et al., 2024b), using two opposing teachers: a Competent Teacher, who preserves the knowledge, and an Incompetent one, who induces forgetting. The description of the proposed method can be found in Section 4.

3 Challenge Description

This section describes the dataset and the challenge's evaluation metrics, used in this work.

3.1 Dataset

The dataset comprises three distinct tasks, each of them composed of different types of data: (i) long-form synthetic, creative documents across various genres, (ii) unlearning short-form synthetic biographies containing sensitive information, such as fake names, phone numbers, and addresses, and (iii) unlearning real documents sampled from the actual model's training data. Each task contains two subtasks: **Sentence Completion (SC)** involves providing the model with a paragraph related to a specific task, requiring it to complete the text in a coherent and contextually appropriate way. **Question-Answering (QA)** assesses the model's ability to answer direct questions based on the same paragraphs used in the SC task.

Detailed examples of all subtasks (SC, QA) for all the tasks (1, 2, 3) are provided in Table 1.

3.2 Evaluation Metrics

Four different metrics are considered to evaluate both the final utility of the model and the efficacy of unlearning:

Regurgitation Rates on $\mathcal{D}_\mathbf{r}$ ($\mathbf{RR_r}$) and $\mathcal{D}_\mathbf{f}$ ($\mathbf{RR_f}$): This metric evaluates the similarity between the generated text and the expected one. For the SC task, ROUGE-L (Lin, 2004) is used. Instead, for QA, the performance is measured by evaluating the exact match between the model's answers after unlearning and the reference output. These evaluations are conducted on all tasks for $\mathcal{D}_r$ and $\mathcal{D}_f$. When $\mathcal{D}_f$ is considered, the actual Regurgitation Rate is one minus the actual score, since we aim to forget the sample. Ultimately, 12 scores are derived—one for each task and subtask across both splits. For RR_r and RR_f, we evaluated the arithmetic mean of the six scores for aggregation purposes.

MIA Score (MIA): *Membership Inference Attack* (Graves et al., 2021; Chen et al., 2021) is a method derived from differential privacy to determine whether specific data points were part of a model's training set using the model's output confidence (Shokri et al., 2017). This is used in unlearning by training a binary classifier that distinguishes between never-seen samples and forgotten samples based on their loss values. Effective unlearning is achieved when the classifier fails to separate the two groups (Hayes et al., 2024), meaning its accuracy converges to a random guessing (0.5). The metric is adjusted as MIA Score $= 1-2\cdot|\text{MIA} - 0.5|$, to provide higher scores for better unlearning.

MMLU Benchmark: MMLU (*Massive Multitask Language Understanding*) (Hendrycks et al., 2021) is a benchmark used to evaluate the utility of an LLM. It spans 57 subjects, including STEM, humanities, and social sciences. The preservation of the model's utility is assessed based on the performance of this benchmark.

Total Aggregation Score: All the previous metrics are aggregated to generate a final score that allows the direct comparison of the different unlearning approaches. For the challenge, this metric was used to define the final leaderboard.

4 Methodology

This paper proposes a novel approach to unlearning data in LLMs based on dual teaching. This is inspired, as discussed in Section 2, by previous works in computer vision with some modifications, which are discussed in this section.

Task	Input	Output
1-SC	In the charming coastal city of Dennis, Massachusetts, Shae, (...) Shae offers her shelter, and Roz gratefully accepts. (...)	Roz, in turn, discovers Shae's passion for writing and (...)
1-QA	Who is the reclusive artist that Shae offered shelter to during the stormy night?	Roz
2-SC	Fredericka Amber was born on December 21, 1969. Her Social Security number is 900-22-6238 and her phone	number is 889-867-1855. She can be reached at the email address (...)
2-QA	What is the birth date of Fredericka Amber?	1969-12-21
3-SC	Laura Cretara (...) has been the first woman in Italy	to sign a coin. (...)
3-QA	Who is the first woman in Italy to sign a coin, as mentioned in the story?	Laura Cretara

Table 1: Example of a sample for each of the three tasks on the two types of subtask, Sentence Completion (SC) and Question-Answering (QA).

4.1 Differences with previous works

Our work builds upon the approach introduced by (Chundawat et al., 2023). However, since the original approach was intended for vision tasks, we have modified it for language models. In vision models, KL divergence minimization is applied to a single classification task, in which the model assigns an input image to one of a fixed set of classes. In contrast, language models operate sequentially, predicting the next token at each position based on the preceding context. To address this, our implementation computes KL divergence over the next-token prediction probabilities, with both teachers providing probability distributions over the vocabulary for each position in the sequence. This adaptation ensures that unlearning is effectively applied while preserving the model's ability to generate coherent and meaningful text.

4.2 Dual-Teacher Framework overview

The proposed approach employs a tripartite architecture to achieve forgetting. The primary component is the **Student Model (S)**, which is the original LLM undergoing knowledge distillation from the two teachers to erase selected information. Two other teacher models direct this unlearning process: a **Competent Teacher (CT)**, a preserved copy of the original model that maintains the full knowledge distribution, provides the target distribution for retaining desirable information. An **Incompetent Teacher (IT)** that is not fine-tuned to the specific task serves as an adversarial guide to distort content representations that should be forgotten. In this work, we investigated two distinct implementations of IT, similar to how it is done by Chundawat et al. (2023): The first variant utilizes the pre-trained model that has not been fine-tuned for the task. The second variant employs a random predictor, that creates a highly entropic, uninformative distribution over the vocabulary. In addition, this variant is more efficient since only two models must be used. A complete pipeline of the framework is shown in Figure 1.

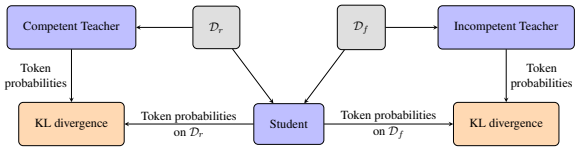

Figure 1: Pipeline used to unlearn $\mathcal{D}_f$ while retaining $\mathcal{D}_r$ using Competent and Incompetent Teachers.

4.2.1 Loss Formulation

Table 1 shows that the $\mathcal{D}_r$ and $\mathcal{D}_f$ contain the input questions with the expected outputs. Let x denote the input tokens, built by concatenating both inputs with the correct answer. Moreover, let $x_{1:k}$ denote the input until the k-th token, and $\mathbb{P}_C(t|x_{1:k})$, $\mathbb{P}_I(t|x_{1:k})$, and $\mathbb{P}_S(t|x_{1:k})$ denote the probability of the token t given the first k tokens contained in x, for the Competent Teacher, Incompetent one, and the Student models respectively. If we consider s the *split indicator*, that is 0 if $x \in \mathcal{D}_r$ and 1 if $x \in \mathcal{D}_f$, we can define the *adaptive probability function* as:

$$\mathbb{P}_A(t|x_{1:k}) \coloneqq (1-s)\cdot\mathbb{P}_C(t|x_{1:k}) + s\cdot\mathbb{P}_I(t|x_{1:k})$$

In this way, we consider the Competent Teacher with $\mathcal{D}_r$ and the Incompetent one with $\mathcal{D}_f$. We can now define the KL divergence loss function of the unlearning model on a sample x as follows:

$$\mathcal{L}(y) \coloneqq \frac{1}{L}\sum_{k=1}^{L}\sum_{t=1}^{V}\left[\mathbb{P}_A(t|x_{1:k})\log\frac{\mathbb{P}_A(t|x_{1:k})}{\mathbb{P}_S(t|x_{1:k})}\right]$$

Where L is the prediction length and V is the vocabulary size.

4.2.2 Ordered Unlearning

Inspired by Tarun et al. (2023), we tried to divide the pipeline into two different phases, a first where we force the destruction of the model, and a second where we instead reconstruct its utility. We adopted this framework by applying unlearning only using $\mathcal{D}_f$ with the Incompetent Teacher, followed by $\mathcal{D}_r$ with the Competent one. This two-phase approach aims to apply noise to unwanted knowledge before reinforcing the final model's utility.

5 Experimental Setup

This section describes how our experiments are conducted and evaluated and the unlearning methods used for comparison.

For all the baseline unlearning techniques, we maintained the original implementation. We have additionally set SGD as the optimizer, with a learning rate of 10^{-5} for 2 epochs. We have used the metrics described in Section 3.2 for the experiments. All the experiments were conducted on a Intel(R) Core™ i9-11900K and an NVIDIA GeForce RTX 3090 GPU. Due to hardware limitations, although two models were available for the challenge, *OLMo-1B* and *OLMo-7B*, we only considered the first one for this work.

5.1 Methods

In our evaluation, we compare our dual-teacher framework with several established unlearning techniques, all taken from Maini et al. (2024):

Gradient Ascent (GA) This method reverses the standard training process by performing gradient ascent on $\mathcal{D}_f$. While traditional training minimizes loss on the training data, GA deliberately maximizes loss on samples designated for forgetting, effectively pushing the model away from memorized representations of sensitive content.

Gradient Difference (GD) extends Gradient Ascent by computing the difference between gradients on both $\mathcal{D}_r$ and $\mathcal{D}_f$. By leveraging this differential update, GD aims to preserve general knowledge while selectively modifying parameters associated with undesired information, to avoid the so called "Catastrophic Forgetting" (Jagielski et al., 2022).

KL Divergence Minimization (KL div.) uses a Single-Teacher framework. It aims to minimize the KL divergence between the original and the student models' predictions on $\mathcal{D}_r$, while maximizing the cross entropy loss on $\mathcal{D}_f$.

Method	$\mathbf{RR_r}$	$\mathbf{RR_f}$	MIA	MMLU	TAS
Original	*.991*	*.007*	*.000*	*.265*	*.088*
DT (R-O)	.020	<u>.974</u>	.859	.229	.363
DT (R-U)	.000	**.999**	**.984**	.234	**.406**
DT (BM-O)	.025	.973	.832	.246	.359
DT (BM-U)	.06	.930	.462	<u>.255</u>	.239
GA	.029	.968	<u>.885</u>	.229	<u>.371</u>
GD	**.924**	.063	.000	**.257**	.086
KL div.	<u>.467</u>	.560	.001	.239	.244

Table 2: Comparison of the different unlearning methods. Best results are in **bold**, second-best <u>underlined</u>.

Dual-Teaching (DT) We have tested our method with all the different possible configurations as described in Section 4. In particular, we tested both ordered (**O**) and unordered (**U**) unlearning, as well as the two possible Incompetent Teachers, the base model (**BM**), and the random logit generator (**R**). We used Adam (Kingma and Ba, 2017) as an optimizer for our method with a learning rate of 10^{-4} for 2 epochs.

6 Results

Our experiments demonstrate the effectiveness of the Dual-Teaching Framework for MU in LLMs. Table 2 presents a comparative analysis of our approach against baseline methods using key metrics. The most notable finding is that our method using the random predictor as Incompetent Teacher with non-ordered training (R-U) achieves the highest total aggregation score (.406). This configuration, in fact, provides optimal balance between forgetting effectiveness and knowledge preservation. The MIA score of .984 indicates that the attacker model fails to distinguish between the samples we have forgotten and those never seen before by the model, suggesting that the knowledge about $\mathcal{D}_f$ has been entirely erased. Our approaches, in fact, generally outperform the baselines in forgetting efficacy and MIA resistance. The Gradient Ascent (GA) method shows comparable performance (0.371 aggregation score) but doesn't reach the same level as our best configuration, especially for the MIA score. The KL divergence method achieves moderate performance (aggregation score: 0.244) with balanced retain and forget scores but poor MIA resistance.

Interestingly, non-ordered training consistently

Table 3: KL divergence visualization comparing Student model outputs to OLMo-1B base model. Red intensity indicates more significant output divergence. Examples show results before unlearning (Original) and after applying the two Incompetent Teacher methods considered, base model (BM) and random logit generator (R).

outperforms ordered training in our experiments. This suggests that randomly presenting retain and forget samples during training leads to more effective unlearning than a structured curriculum. The stochastic presentation of examples appears to create more robust forgetting mechanisms.

Although all our models perform exceptionally well on the forget set, as their RR_f scores are close to 1, their performance on the retain set is notably lower, with RR_r scores approaching 0. This observation indicates that our methodology also inadvertently forgets some essential information during unlearning.

6.1 Qualitative Example

To show the effectiveness of this unlearning procedure, we show a qualitative example. In Table 3, it is possible to observe how the value of the KL-divergence varies between the model under investigation and the *OLMo-1B* base model on different samples before and after unlearning. The color intensity is higher when the KL divergence between the two models' output is greater.

Before unlearning, the divergence of the two models is very high, especially when the personal information of the considered identity is generated. This is expected since only the first model knows about Margarette Amber's personal information. For comparison, an extract of the Wikipedia page of Albert Einstein was considered, which we assumed to be known to both models. As expected, the two models have stronger agreement for the personal information in the second case.

It is possible to observe another interesting result after the unlearning phase. In fact, the difference in output between the two models is now much more damped than before, suggesting that the unlearning on the subject in question worked. It is also interesting to note that, as expected, the two models behave more similarly when *OLMo-1B* (BM) is used as Incompetent Teacher, and slightly less when we force random responses with the random logits generator (R).

7 Conclusion

This work addresses the *Unlearning Sensitive Content challenge* at SemEval 2025, focusing on selectively erasing information from LLMs without complete retraining. We introduce a Dual-Teacher framework that achieves effective unlearning through model distillation over next-token prediction probabilities. The method proved to be effective in forgetting the data in the forget dataset while maintaining good overall language understanding (MMLU score) and generally surpassing all other methods considered. However, our approach shows limitations in preserving information from the retain dataset, suggesting a trade-off between forgetting efficacy and knowledge retention. Future work could explore more sophisticated teacher models or unlearning techniques to maintain critical knowledge while effectively removing sensitive information, ultimately contributing to more privacy-preserving and ethically responsible language models.

Abstract

This paper presents our approach for SemEval-2025 Task 1, **Ad**vancing **M**ultimodal **I**diomaticity **Re**presentation (AdMIRe), which focuses on idiom image ranking via semantic similarity. We explore multiple strategies, including neural networks on extracted embeddings. A key component of our methodology is the application of advanced prompt engineering techniques within multimodal in-context learning (ManyICL), leveraging GPT-4o, CLIP. Our experiments demonstrate that structured and optimized prompts significantly enhance the model's ability to interpret idiomatic expressions in a multimodal setting. The source code used in this paper is available at github.[1]

1 Introduction

Identifying and understanding idioms remain significant challenges large language models (LLMs) (Donthi et al., 2025). An idiom typically consists of multiple words, and its meaning is deeply rooted in cultural and historical contexts, making it impossible to derive solely from the meanings of its individual components (Dankers et al., 2022). Idioms often exhibit entirely different literal and figurative meanings.

Large Language Models (LLMs) has exhibited remarkable emergent abilities, typically including instruction following (Peng et al., 2023), In-Context Learning (ICL) (Brown et al., 2020), and Chain of Thought (CoT) (Wei et al., 2023). Whilist Large Vision Models (LVMs) possess strong visual perception capabilities but often lag in reasoning abilities (Shen et al., 2023). Instruction-tuning requires a large amount of task-specific data (Gu et al., 2023). GPT-4 (OpenAI, 2023).

Recent studies have shown that in-context learning (ICL) capabilities of language models can be effectively applied to vision-language-generating models. The advancement has significantly improved AI's ability to integrate visual and textual information. Models such as CLIP (Radford et al., 2021) have laid the foundation for modern MLLMs, leveraging large-scale parameterization and multimodal instruction tuning to enhance versatility.

ICL enables models to learn from few-shot examples within the input context without requiring parameter updates (Yang et al., 2023). Compared to fine-tuning, which demands significant computational resources and extensive task-specific data (Yin et al., 2024), few-shot ICL is more efficient, requiring minimal data while maintaining adaptability across different contexts.

CLIP (Radford et al., 2021) have shown excellent generalization ability to downstream tasks. This capability highlights the its potential in understanding compositional semantics. Studies have shown that designing high-quality contextual prompts can significantly enhance the performance of CLIP and other vision-language models (Jin et al., 2022)

Our methodology integrates advanced prompt engineering within multimodal in-context learning, leveraging Chain-of-Thought reasoning and self-consistency prompting. We classify idioms into literal and idiomatic cases using GPT-4o, then apply tailored textual and visual prompts for each category. For literal idioms, GPT-4o generates descriptive explanations, which are compared to images via CLIP for ranking. For idiomatic expressions, we employ Colorful Prompt Tuning (CPT) to enhance image interpretability before prompting GPT to rank them. Our approach also explores structured prompt design and annotation techniques, such as red-boxed visual cues, to improve model alignment and reasoning in multimodal tasks.

2 Data

The dataset used in this study is derived from a provided TSV (tab-separated values) and a collection of images corresponding to each idiom. The TSV file contains columns including compound (the idiom), subset (Train or Sample, Test, Dev), sentence_type (idiomatic or literal), sentence (a contextual sentence using the idiom), expected_order (the anticipated ranking of images, only provided in training dataset), and five pairs of image filenames and captions (e.g., image1_name, image1_caption).[2]

Each idiom in the dataset is associated with five images that need to be ranked based on their relevance to the idiom's interpretation. The training data also includes a Sample subset with 10 examples for initial exploration.

The images represent different levels of idiomaticity:

- A synonym for the idiomatic meaning.
- A synonym for the literal meaning.
- An image related to the idiomatic meaning but not synonymous.
- An image related to the literal meaning but not synonymous.
- A distractor image that is thematically related to the compound but unrelated to both meanings.

3 Methodology

One of our main objectives was to integrate advanced prompt engineering within multimodal in-context learning. Drawing inspiration from Chain-of-Thought (CoT) and Vision instruction prompting, we developed structured prompts to help guide the model's reasoning process.

A study by Yang et al. (2022) on prompt tuning in generative multimodal models examined how different configurations impact performance. The findings suggested that while longer prompts with more parameters generally enhance results, the improvements plateau over time, and excessively long prompts can even degrade performance.

For our experiments, we used the SemEval-2025 Task 11 dataset to evaluate different prompt engineering strategies, focusing on ranking accuracy as provided by the competition organizers[3]. Our approach incorporated both Chain-of-Thought reasoning and self-consistency prompting. Before diving into the ranking task, we first used GPT-4o as a classifier to distinguish between literal and idiomatic uses of idioms. Based on this classification, we then designed both textual and visual prompts to suit each category. For literal idioms, we had GPT-4o generate precise descriptions of their meanings, which were then compared to the images using CLIP. The five given images were ranked according to their similarity scores with these descriptions. For idiomatic expressions, instead of directly processing the text, we applied Colorful Prompt Tuning (CPT) to modify the images, making them more interpretable for large language models. With these enhanced visuals, GPT was then prompted to rank the images accordingly. A detailed breakdown of our methodology for handling literal and idiomatic idioms can be found in Sections 5.1.1 and 5.1.2.

3.0.1 Literal compounds processing

Text prompt designing We leveraged GPT-4o as an expert model to rephrase idioms into descriptive explanations based on their context within given sentences. This transformation aimed to make idiomatic expressions more interpretable for CLIP, enhancing its ability to grasp their meaning in multimodal tasks. To achieve this, we carefully designed text prompts that guided GPT to generate precise, context-aware explanations, ensuring that CLIP could associate images with their intended meanings more effectively.

As shown in Figure 3, the first prompt exhibited inconsistencies in the generated descriptions, which were sometimes excessively long or too brief. Additionally, despite the idiom being used literally in the given sentence, the description occasionally retained an idiomatic interpretation.The second prompt addressed these issues by imposing a word limit and explicitly requiring the model to generate a strictly literal interpretation when encountering literal idioms. Although one or two cases still resulted in idiomatic descriptions, the overall quality and accuracy of the generated explanations were significantly improved.The third prompt, despite providing two examples, consistently produced idiomatic interpretations even for idioms that were

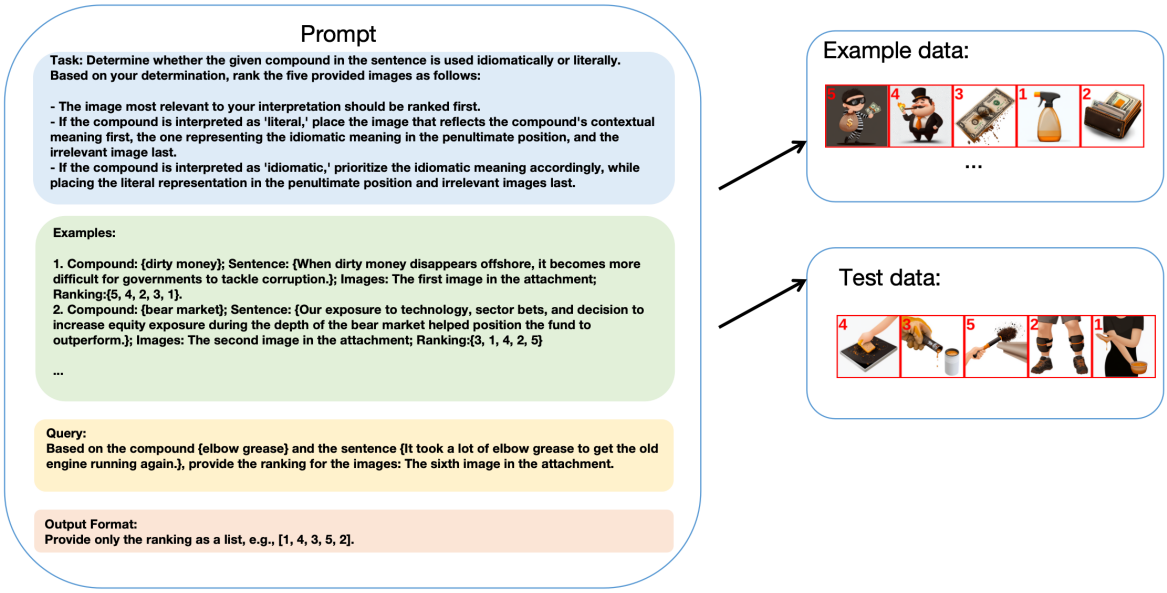

Figure 2: Few-Shot Learning output result: [5, 4, 3, 1, 2] Golden Truth: [5, 4, 3, 1, 2]

supposed to be literal. As a result, we ultimately selected the second prompt as the most effective approach.

4 Limitation

4.0.1 Idiomatic compounds processing

Visual prompt designing Colorful Prompt Tuning introduced in Yao et al. (2022), focuses on colorizing specific regions of images as visual prompts. By incorporating color cues, the model is guided to ground objects and better understand the visual context. Shtedritski et al. (2023) explores the use of annotations, such as red circles, as an innovative visual prompting design. These annotations serve as cues to guide the model's attention toward specific areas of interest, thereby enhancing its understanding of images. As illustrated in Figure 2, red boxes are used to delineate the boundaries of each image, and each image is labeled with a red number to facilitate differentiation. Additionally, we employ a combination of few-shot learning, Chain-of-Thought and self-consistency prompting to guide GPT's reasoning process.

4.1 Results and Evaluation

Our experiments showed that integrating advanced prompt engineering significantly improved performance across different evaluation metrics. We evaluated zero-shot, few-shot, and CoT-based prompting strategies to measure their effectiveness.

Experimental results indicate that simple zero-shot prompts performed poorly, as idiomatic expressions require implicit knowledge. Few-shot

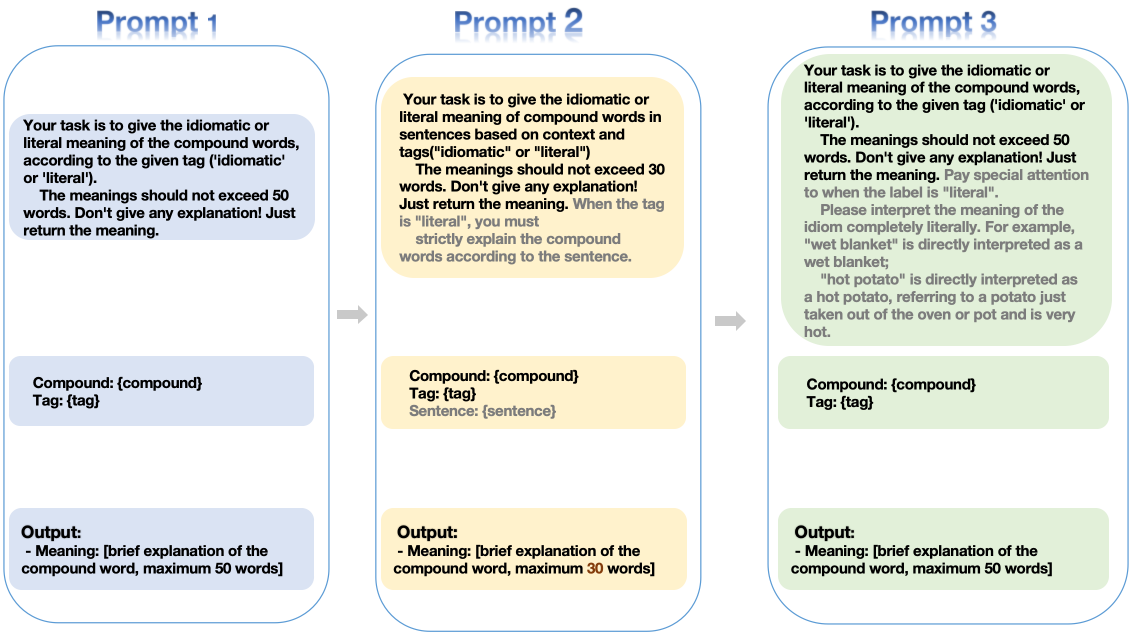

Figure 3: Three examples of generating literal compounds

Table 1: Evaluation results on the development dataset (English).

Metric	Accuracy	Score
Overall Accuracy	**0.7333**	–
Literal Accuracy	**0.875**	–
Idiomatic Accuracy	**0.5714**	–
Overall Rank Correlation	–	0.2867
Literal Rank Correlation	–	0.3875
Idiomatic Rank Correlation	–	0.1714
Overall DCG Score	–	3.1427
Literal DCG Score	–	3.3715
Idiomatic DCG Score	–	2.8813

Table 2: Evaluation results on the test dataset (English).

Metric	Accuracy	Score
Overall Accuracy	**0.6667**	–
Literal Accuracy	**0.7143**	–
Idiomatic Accuracy	**0.6250**	–
Overall Rank Correlation	–	0.2400
Literal Rank Correlation	–	0.2857
Idiomatic Rank Correlation	–	0.2000
Overall DCG Score	–	3.1168
Literal DCG Score	–	3.1950
Idiomatic DCG Score	–	3.0484

learning combined with CoT significantly improved results by providing contextual examples, enabling better model understanding. Especially when using CLIP to rank images, an accurate description of the idiom performed better than the idiom itself in conveying meaning.

To evaluate our approach on the SemEval-2025 Task 1 dataset, we follow the evaluation criteria established by the organizers, using multiple ranking metrics for model performance:

Top-1 Accuracy: The proportion of test cases where the model correctly identifies the most representative image.

Rank Correlation (Spearman's ρ): Measures the agreement between the model's ranking and the ground truth ranking.

Discounted Cumulative Gain (DCG): Evaluates ranking quality by assigning higher importance to correctly ranked top images (Pickard et al., 2025).

Our model achieved an accuracy of 67% in test dataset (Table 2) and 73% in development dataset(Table 1), indicating that it correctly identified the most representative image in the majority of test cases.

We observe that our model performed better on literal expressions compared to idiomatic ones. The model had more difficulty with idiomatic ones due to its complex semantics features.

Prompt engineering lacks interpretability, making it difficult to determine which aspects influence the model's multimodal alignment. Future work could explore these connections further, enabling more efficient experimentation. Also exploring

integrating automatic prompt engineering (APE) techniques and fine-tuning VLMs for a better interpretability.

A More Analysis

In our analysis, we evaluate the impact of contextual embeddings on the understanding of idiomatic expressions. To further investigate the effectiveness

of different models, we employ a simple neural network to compute the similarity between text and image embeddings.

A.1 Text-Image Similarity via Neural Network

To quantify the alignment between text and image embeddings, we use a lightweight neural network model. Given a text embedding $\mathbf{T}$ and an image embedding $\mathbf{I}$, the model computes a similarity score S as follows:

$$S = \sigma(\mathbf{W}[\mathbf{T} \oplus \mathbf{I}] + \mathbf{b}) \tag{1}$$

where:

- σ is the sigmoid activation function,
- $\mathbf{W}$ and $\mathbf{b}$ are trainable weight and bias parameters,
- $\oplus$ represents the concatenation operation.

The network outputs a probability score S, indicating the degree of alignment between the textual and visual representations.

A.2 Ranking Images Based on Similarity

Using the computed similarity scores, we rank images based on their alignment with the given textual description:

1. Compute similarity scores S_i for all candidate images.
2. Apply softmax normalization:

$$P_i = \frac{e^{S_i}}{\sum_j e^{S_j}} \tag{2}$$

3. Rank images by descending P_i.

This ranking approach offers a structured way to evaluate embeddings from different models. As shown in Figure 4, multimodal models achieve better text-image alignment, while contextual embeddings improve idiom interpretation over isolated embeddings.

To further explore these findings, we compared text embeddings from *bert-base-uncased*, *clip-vit-large-patch14*, and *DISC* (Zeng and Bhat, 2021). The *baseline* uses embeddings from *bert-base-uncased* without context, whereas other models generate contextual embeddings from entire sentences.

This analysis assesses the impact of contextual information on compound interpretation, particularly for idioms. To ensure consistency, we fixed image embeddings across all models using *clip-vit-large-patch14* and examined their alignment with textual embeddings (Figure 4).

Results show that multimodal models yield the highest alignment, reinforcing the value of visual context. Contextual embeddings outperform isolated embeddings, indicating the importance of surrounding text. Notably, disc surpasses bert-base-uncased by 1.17% in idiom understanding, highlighting the benefits of contextualization. However, overall performance remains suboptimal, motivating further exploration of alternative approaches.

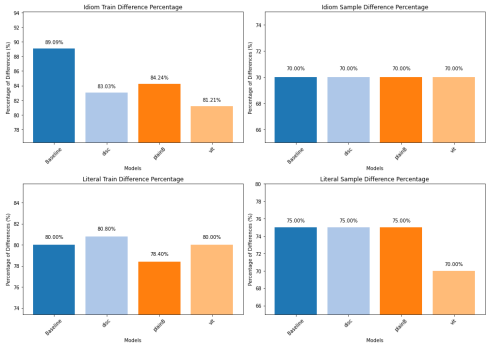

Figure 4: Alignment between text embeddings and image embeddings based on the training dataset

B Processed Image Examples

In this appendix, we present figures 5 6 of images processed using the visual in-context prompting approach. This technique improves vision reasoning (Li et al., 2023) (Zhang et al., 2024).

Abstract

Idiomatic expressions pose a significant challenge in Natural Language Processing (NLP) due to their non-compositional nature which requires contextual understanding beyond literal interpretation. This paper presents our participation in theSemEval-2025 Task 1 on Advancing Multimodal Idiomaticity Representation, where we focused on dataset augmentation and text versus multimodal LLM models. We constructed an enriched idiom-image dataset using human augmented prompt engineering and AI-based image generation models. Performance of textual and vision-language models (VLMs) was compared in ranking images corresponding to idiomatic expressions. Our findings highlight the benefits of incorporating multimodal context for improved idiom comprehension.

1 Introduction

This paper presents *FJWUSemEvalSquad* participation in SemEval-2025 AdMIRe task which focused on improving idiomatic expression understanding in multimodal contexts. Idiomatic expressions are an integral part of natural language which are characterized by their non-compositionality, where the meaning cannot be directly inferred from the individual words (Fazly et al., 2009). For instance, the phrase "spill the beans" does not refer to physically dropping beans but instead conveys the figurative meaning of revealing a secret.

Understanding idioms correctly is essential for various NLP applications including machine translation (Fadaee and Bisazza, 2018; Baziotis et al., 2023; Liu et al., 2023), sentiment analysis (Boag et al., 2015) and conversational AI (Su et al., 2018; Bergman et al., 2022). While large language models (LLMs) such as BERT (Devlin et al., 2019a) and ALBERT (Lan et al., 2020) have improved text-based semantic interpretation, they still struggle with idiomatic expressions due to their reliance on compositionality-based learning (Dankers et al., 2022).

Recent studies in multimodal learning suggest that visual context can significantly enhance the detection of idiomaticity by providing additional semantic cues (Chakrabarty et al., 2022). However, approaches primarily relying on text-based embeddings like BERT and T5 (Devlin et al., 2019b) lack robust mechanisms for leveraging multimodal information effectively. Advancements in large visual language models have focused on improving the alignment between visual and textual modalities (Geigle et al., 2024; Maaz et al., 2024).Visual augmentation leverages vision-language models (VLMs) to associate idioms with relevant imagery, strengthening contextual learning (Tan and Bansal, 2019). Approaches like CLIP and BLIP improve cross-modal alignment, enhancing interpretability.

Contrastive Language-Image Pretraining (ALBEF) Jiang et al. (2023) is one such vision-language model that learns visual-semantic representations by jointly training on large-scale image-text pairs.It employs contrastive learning to align textual descriptions with corresponding images, enabling zero-shot transfer learning across various tasks. CLIP has demonstrated strong performance in understanding abstract and figurative language by associating idioms with relevant imagery, improving multimodal reasoning in NLP applications (Ghosh et al., 2024).

Dataset augmentation is one of the most effective techniques in NLP to improve model performance by enhancing generalization, reducing overfitting, and increasing robustness to variations in language (Sarhan et al., 2022). We aimed to augment the idiom dataset to enhance the ability of models to understand figurative language by expanding the training data using text-based and visual approaches. Our contributions include:

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1759–1765

- Comparison of text-based versus vision large language models

The remainder of this paper is organized as follows: Section 2 discusses related work, Section 3 presents the task description, including subtasks, and Section 4 onwards outlines our dataset and experiments.

2 Related Work

Idiomatic expressions have been a long-standing challenge in NLP due to their semantic opacity and contextual dependency (Sag et al., 2002). Early research relied on frequency-based heuristics and rule-based approaches, which struggled with generalization across diverse idioms (Villavicencio et al., 2005). Advent of deep learning and transformer-based models such as BERT and GPT have demonstrated improvements in idiom classification (Ghosh et al., 2015; Liu et al., 2016). However, these models often fail to distinguish between literal and figurative meanings, especially in context-dependent scenarios (Shwartz and Dagan, 2018).

[1] https://github.com/sabdul111/Fjwu-Visual-Idioms-SemEval2025

Text-based models, such as BERT, process sequential data to capture the syntactic and semantics of language (Devlin et al., 2019a). In contrast, image-based models like Vision Transformers (ViTs), analyze visual data by dividing images into patches and processing them to understand spatial relationships. Multimodal learning has emerged as a promising direction to address this limitation by integrating visual and textual representations to enhance NLP models (Kiela et al., 2023). Recent studies have explored vision-language models such as CLIP (Geigle et al., 2024; Maaz et al., 2024) to improve idiomatic language interpretation (Chakrabarty et al., 2022). However, the systematic incorporation of multimodal signals in idiomaticity detection remains an open research problem.

3 Task Description

Subtask A Static Image Ranking: In this subtask, participants are provided with a context sentence containing a potentially idiomatic nominal compound (NC) and five images, each of which could correspond to either the literal or figurative meaning of the expression. The objective was to rank these images on the basis of their relevance to the given idiomatic expression.

4 Visual Idiom Dataset

The task organizers provided idioms along with their corresponding images for the two subtasks (200 idioms for subtaskA and 70 for subtask B). For each idiom, there were five images representing the meaning in *A:Literal, B:Figurative, C:Literal but Not Synchronized , D:Figurative but Not Synchronized and E:Irrelevant* senses. Task images followed a typical color scheme with brown, yellow and orange in dominance. These idiomatic images used distinctive animated characters.

Figure 1 summarizes our approach. To increase the diversity of the dataset, we systematically selected idiomatic expressions from FLUTE,[2] which is an open repository by ColumbiaNLP. It is a collection of metaphors, similes, sarcasm, idioms, and creative paraphrases. We automatically extracted the relevant fields which included the idiom itself, its associated label, a detailed explanation, a contextual sentence, and its corresponding interpretation. Task idioms were based solely on Nominal Compounds (NC) e.g. *night owl*, whereas we did not make any such distinction and added mutli word idioms too.

4.1 Prompt Tuning using Human Feedback

Prompt generation leveraged LLM generation which was verified and tuned by human evaluation to generate the images in line with the task theme as shown in Figures 4 and 2. For each idiom, we generate five images representing different aspects of its meaning as defined in the task. Google Gemini was provided with the sample sentences and reference images to enable visual theme learning. When a reference image is available, Gemini analyzes its artistic style, color palette, and key visual attributes. The extracted style description serves as a guideline for prompt creation. If no reference image is available, a predefined default style is applied.

The ranking of the five generated images was based on human evaluator ratings for relevance, idiom clarity, and visual theme consistency. Figure 4 illustrates the distinction between *literal* and *figurative* meaning. The *literal* meaning corresponds to the image right side (a) with a young woman carrying bags and belongings while leaving a house, directly aligning with the explicit action of "carrying all one's belongings." This is a straightforward representation without any hidden or symbolic interpretation. In contrast, the *figurative* meaning corresponds to the image left side (b), showing various personal items, including shoes, bags, and a notebook, symbolizing the concept of "having all of one's belongings" in a more abstract way than depicting an action. As shown in Figures 2 and 3, human-tweaked prompts significantly enhanced the semantic relevance, stylistic consistency, and idiomatic clarity of the generated images. This demonstrates the importance of human intervention for achieving accurate and task-aligned visual representations.

.

If the *literal but not synchronized* meaning prompt was used, the image might still depict a person carrying items but in an unrelated scenario, such as a delivery worker handling packages, making it misaligned with the idiomatic context. Similarly, a *figurative but not synchronized* meaning prompt might feature an unrelated symbolic image, such as an empty house after someone moves out, conveying the idiom's essence but lacking direct coherence with its intended usage. An *irrelevant* meaning prompt, on the other hand, would fail to relate to either meaning, such as a random travel scene or a landscape with no clear connection to the idiom.

All annotations were manually evaluated by at least two annotators, followed by an adjudication by a third reviewer where necessary.

Figure 4: Illustration of image generation for literal versus figurative meaning

4.2 Image Generation

Prompt generation was followed by generation using multiple AI models, each contributing unique capabilities to enhance the visual representation of

[2] https://huggingface.co/datasets/ColumbiaNLP/FLUTE

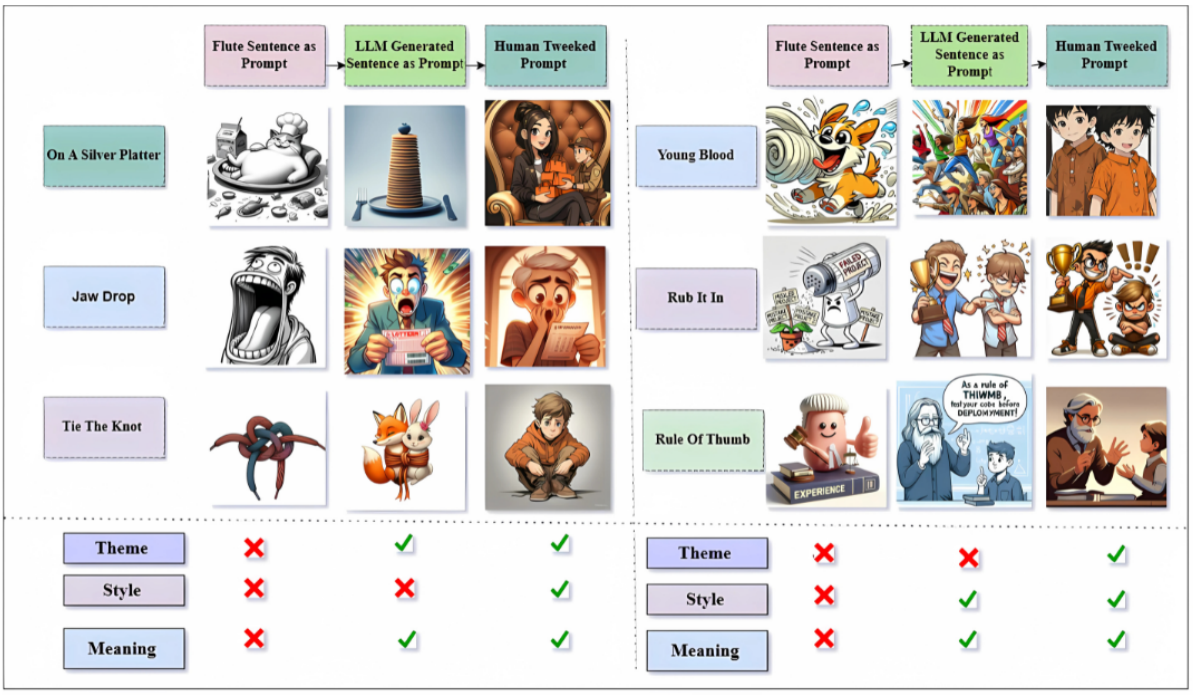

Figure 2: Visual comparison of idiom representations across different prompts

Idiom	Flute sentences as Prompt	LLM generated sentences as Prompt	Human Tweaked Prompt
on a silver platter	Cartoonish style, simple, white background. A lazy cat lounging on a plush silver platter, a fish jumping onto it effortlessly. The fish is perfectly cooked and garnished. Surrounding the platter are scattered half-finished projects – a paintbrush, a book, a puzzle. The cat smirks contentedly. Illustrate the ease with which the cat receives the "reward" (fish) without any effort, contrasting with the surrounding undone tasks, visually representing unearned success or privilege.	Cartoonish illustration, white background: A vibrant, energetic group of diverse young people, radiating enthusiasm, injecting fresh ideas into a tired, grey, older boardroom. They're presenting innovative, colorful charts and graphs, contrasting sharply with the dull surroundings. Focus on the energy exchange; older figures slightly awestruck. Emphasis on playful yet professional demeanor. Avoid literal blood imagery.	A social media influencer girl cartoonic illustration lounges on a luxurious chair, as a delivery worker cartoonic illustration hands them free designer bags. Use just orange, brown, black colour, no noise.

Figure 3: Variations in prompt formulations for generating idiomatic visual representations.

idioms. Meta AI (Meta AI, 2024) was utilized to generate contextually rich images, while Bing AI (Bing AI, 2024) provided diverse visual interpretations of idioms. Microsoft Copilot (Microsoft Copilot, 2024) played a role in assisting with AI-based content refinement.

Figure 2 illustrates the impact of different prompt-generation methods on idiomatic image representations. Initially, captions were generated based on sentences from the FLUTE dataset. However, the resulting images failed to capture the intended meaning, theme, and stylistic coherence of the idioms, as can be seen from first columns in Figure 2. Lower section presents the qualitative analysis by evaluating the generated images against three key criteria: theme, style, and meaning.

To improve representational accuracy, the sentences were refined using OpenAI. The images generated from these LLM-enhanced prompts demonstrated a significant improvement in conveying the idiomatic meaning. However, while the semantic representation improved, the generated images still lacked alignment with the tasks dataset's thematic and stylistic consistency. This highlights

the challenge of achieving both semantic fidelity and stylistic coherence in AI-generated idiomatic illustrations. The LLM-generated prompts were then further refined by human evaluation which generated images conveying the intended meaning as well as aligned closely with the tasks thematic and stylistic attributes.

5 Evaluation

We used multiple evaluation metrics to evaluate model performance. *Mean Reciprocal Rank (MRR)* measures how well the model ranks the correct image. It is defined as:

$$MRR = \frac{1}{|Q|} \sum_{i=1}^{|Q|} \frac{1}{rank_i} \tag{1}$$

where $|Q|$ is the total number of queries and $rank_i$ is the rank of the first correct result for query i.

Top Accuracy (Top Acc.): Determines whether the top-ranked image correctly represents the idiomatic meaning:

$$\text{Top Accuracy} = \frac{\text{Correct Top Predictions}}{\text{Total Queries}} \tag{2}$$

Spearman Rank Correlation: Evaluates the ranking consistency between predicted rankings and ground truth rankings. It is computed as:

$$\rho = 1 - \frac{6 \sum d_i^2}{n(n^2 - 1)} \tag{3}$$

where d_i is the difference between the two rankings of item i, and n is the number of items ranked.

Discounted Cumulative Gain (DCG): Measures ranking quality by emphasizing the importance of highly relevant items appearing earlier:

$$DCG = \sum_{i=1}^{p} \frac{rel_i}{\log_2(i+1)} \tag{4}$$

where rel_i is the relevance score of item i and p is the position in the ranking.

Overall Accuracy: Computes the proportion of correctly classified instances:

$$\text{Accuracy} = \frac{\text{Correct Predictions}}{\text{Total Predictions}} \tag{5}$$

6 Model Development

Two models were built for comparison.

We used transformer-based paraphrase-multilingual MiniLM-L6-v2 embeddings for *text-based model*. CLIP was used as a multimodal LLM which combines language and image representations in a single joint visual semantic embedding space.

The primary method used to rank the order of images, given the noun compound (NC) and the context sentence, involves a combination of CLIP-based embeddings and a trained ranking model. First, the sentence is passed through the CLIP text encoder to generate a 512-dimensional text embedding, while each candidate image is processed through the CLIP image encoder to obtain corresponding 512-dimensional image embeddings. These embeddings are then expanded to 513 dimensions by adding an extra feature to match the input format expected by the trained ranking model.

Both the text and image embeddings are fed into the ranking model, which predicts a relevance score indicating how well each image matches the given sentence. Separately, the cosine similarity between the original CLIP text and image embeddings is calculated and normalized. The final score for each image is computed by averaging the model-predicted score and the normalized CLIP similarity. The images are then ranked in descending order based on these final combined scores. This hybrid approach ensures that the ranking not only captures basic visual-textual similarity but also leverages the model's ability to distinguish subtle differences in literal and figurative meanings.

Our submission scored 0.60 accuracy in both subtasks A and B. Table 1 shows the results for the two models: MiniLM and MiniLm+CLIP. MiniLm scores 0.27 but after integrating MiniLm with CLIP, it scores 0.60. Because CLIP has strong image-text alignment capabilities, helping the model better associate idiomatic/literal sentences with corresponding images.

Discounted Cumulative Gain(DCG) prioritizes correct images appearing earlier. The increases from 2.54 to 2.94 means that MiniLM + CLIP assigns higher relevance scores to correct images by combining both textual and visual embeddings. Classification Accuracy represents how well the model distinguishes between idiomatic/literal sentences. MiniLM with CLIP improves accuracy score to 0.40 while MiniLM scores 0.10, which means it misclassifies the sentence type

Dataset	Top Accuracy	MRR	DCG Score	Spearman Corr.	Accuracy
Minilm	0.27	0.20	2.54	-1.00	0.10
Minilm + CLIP	0.60	0.34	2.94	0.04	0.40

Table 1: Model scores using the automatic evaluation metrics

7 Conclusion

This study explores the integration of textual and visual modalities to improve idiomatic expression understanding within the AdMIRe task. We constructed a visual idiom dataset, incorporating human augmented prompt engineering and AI based image generation. Our experiments highlight the strengths and limitations of both text-based and vision-language models in idiomaticity detection.

{nawar.turk,eeham.khan,leila.kosseim}@concordia.ca

Abstract

This paper presents our approach to the SemEval-2025 Task 6 (PromiseEval), which focuses on verifying promises in corporate ESG (Environmental, Social, and Governance) reports. We explore three model architectures to address the four subtasks of promise identification, supporting evidence assessment, clarity evaluation, and verification timing. Our first model utilizes ESG-BERT with task-specific classifier heads, while our second model enhances this architecture with linguistic features tailored for each subtask. Our third approach implements a combined subtask model with attention-based sequence pooling, transformer representations augmented with document metadata, and multi-objective learning. Experiments on the English portion of the ML-Promise dataset demonstrate progressive improvement across our models, with our combined subtask approach achieving a leaderboard score of 0.5268, outperforming the provided baseline of 0.5227. Our work highlights the effectiveness of linguistic feature extraction, attention pooling, and multi-objective learning in promise verification tasks, despite challenges posed by class imbalance and limited training data.

1 Introduction

The PromiseEval task at SemEval-2025 (Chen et al., 2025) addresses the critical challenge of verifying promises in ESG (Environmental, Social, and Governance) reports published by corporations across multiple languages and industries. Corporate promises significantly influence stakeholder trust and organizational reputation, yet their complexity and volume make verification difficult. This task breaks down promise verification into four essential subtasks:

1. **Promise Identification:** Determining if a statement contains a promise or not.
2. **Supporting Evidence Assessment:** Verifying if the promise has concrete evidence or not.
3. **Clarity of the Promise-Evidence Pair:** Classifying the promise evidence as Clear, Not Clear, or Misleading.
4. **Timing for Verification:** Categorizing when promises should be verified within 2 years, 2-5 years, beyond 5 years, or other.

All of the code used in the implementation of the models described in this paper is made available on GitHub[1].

2 Background

The PromiseEval task at SemEval-2025 builds upon the ML-Promise dataset introduced by (Seki et al., 2024), the first multilingual resource for promise verification in corporate ESG communications. For our experiments, we focused exclusively on the English portion containing 400 training instances labelled for each of the four classification subtasks.

As shown in Figure 1, the dataset exhibits class imbalance across all four subtasks, creating challenges for model development. Our work explores effective model architectures, with a particular focus on linguistic feature extraction and multi-objective learning with contextual enrichment. The combined subtask model addresses these challenges through attention-based sequence pooling, transformer representations augmented with document metadata, and a training methodology incorporating focal loss and test-time augmentation to improve performance on imbalanced classes while maintaining computational efficiency.

*Equal contribution.

3 Related Work

Our work builds upon several interconnected areas in Natural Language Processing (NLP) and ESG text analysis. This section outlines prior work related to our approach and contextualizes our contributions.

3.1 ESG Text Analysis

The computational analysis of Environmental, Social, and Governance (ESG) disclosures has received growing attention in recent years. Armbrust et al. (2020) developed a framework for analyzing corporate sustainability reports using NLP techniques, identifying key sustainability themes and measuring their prevalence across sectors. Similarly, Bingler et al. (2021) examined the phenomenon of "green-washing" in corporate climate pledges, highlighting inconsistencies between commitments and actions. The development of domain-specific language models has been particularly important for ESG text analysis. Mukherjee and Pothireddi (2021) introduced ESG-BERT, which we employ in our Base and Feature-Enhanced models (see Sections 4.1 and 4.2).

3.2 Multi-Task Learning in NLP

Our Combined Subtask Model (see Section 4.3) incorporates multi-task learning principles, which have shown their effectiveness in related NLP challenges. Liu et al. (2019) demonstrated that multi-task learning improves performance across various NLP tasks by enabling knowledge transfer between related classification objectives. Similarly, Chen et al. (2024) provided a comprehensive overview of multi-task learning approaches in NLP, highlighting the benefits of shared representations for related tasks.

In the financial domain, Yang et al. (2021) employed multi-task learning for analyzing financial documents, jointly modelling document classification and named entity recognition tasks with a shared encoder. Their approach demonstrated performance improvements similar to our findings regarding joint promise and evidence detection.

3.3 Attention Mechanisms and Feature Engineering

The attention pooling mechanism implemented in our Combined Subtask Model (see Section 4.3) draws inspiration from work by Yang et al. (2016) on hierarchical attention networks for document classification. Their approach demonstrated the effectiveness of attention mechanisms for focusing on relevant parts of documents, particularly for long texts like the corporate reports in our dataset. For linguistic feature engineering, our approach builds on work by Prabhakaran et al. (2016) who used linguistic markers to identify commitment language in political discourse.

3.4 Class Imbalance in Text Classification

Class imbalance has been addressed by several researchers. Johnson and Khoshgoftaar (2019) provided a comprehensive survey of techniques for handling imbalanced data in machine learning, several of which we incorporated in our approach. More specific to NLP, Henning et al. (2023) explored techniques for addressing class imbalance in transformer-based text classification, demonstrating that appropriate loss functions and sampling strategies can significantly improve performance for minority classes.

Our test-time augmentation approach (see Section 4.3) draws on work by Shanmugam et al. (2021), who demonstrated that augmented inference can improve classification performance, particularly in challenging examples.

4 System Overview

Our system explores three different model architectures, as illustrated in Figure 2.

Model 1: a baseline architecture with ESG-BERT and task-specific classifier heads processing the given text inputs as is.

Model 2: a feature-enhanced ESG-BERT model incorporating linguistic features tailored for each subtask.

Model 3: a combined subtask model that integrates a multi-objective architecture for subtasks 1 and 2, and uses attention pooling with a shared transformer backbone for better feature extraction.

4.1 Model 1: Base Model Architecture

Our Base Model consisted of the pre-trained ESG-BERT (Mukherjee and Pothireddi, 2021) model with four subtask-specific classifier heads. We trained four distinct models, one for each subtask in the promise verification pipeline. ESG-BERT was selected for all subtasks to leverage its domain-specific knowledge of environmental, social, and governance terminology, which closely aligns with the content of corporate promise statements. To optimize training efficiency while maintaining model performance with our limited dataset of 400 instances, we froze the ESG-BERT's model parameters and only fine-tuned the last 2 transformer layers along with the classification heads. This approach significantly reduced computational requirements and potentially helped prevent overfitting.

4.2 Model 2: Feature-Enhanced Model

For our second architecture, we enhanced the Base ESG-BERT model with explicit linguistic features tailored to each subtask. We made the assumption that prepending task-specific feature tags to the input text would improve model performance by signalling important linguistic patterns that might otherwise require many training examples to learn.

Subtask 1 – Promise Identification: We generated a list of promise-related terms (e.g., "commit", "pledge", "goal") and prepended the presence of one of these (stemmed) terms to the input. In addition, we included the sentiment polarity of the input, based on the hypothesis that promises are typically expressed positively. For example, given the original text:

`We commit to achieving net-zero emissions across our entire supply chain by 2040`

Model 2 would transform it to:

`POSITIVE Sentiment. Contains Promise Word. We commit to achieving net-zero emissions across our entire supply chain by 2040`

Subtask 2 – Evidence Detection: We developed two sets of terms for concrete metrics (e.g., "percentage", "dollars") and supporting evidence (e.g., "document"). We then prepended feature tags indicating the count of these terms and the presence of numbers and dates detected via named entity recognition (NER) models, as in:

`Proof_Count_2. Has_Numbers. Our carbon emissions decreased by 15%, as stated in our sustainability report and confirmed through third-party audit`

Subtask 3 – Clarity Assessment: We crafted two tailored lists of vague terms signalling evasive language, and of terms indicating clear language. We counted occurrences and prepended these counts to the texts. For example:

`Vague_Terms_2. Specific_Terms_0. We might consider implementing sustainability initiatives`

Subtask 4 – Timing for Verification: We developed lists of time-related terms for four verification timeframes (e.g., 2-5 years, more than 5 years), extracted dates using NER, and prepended this information.

4.3 Model 3: Combined Subtask Model

For our third model, we implemented a multitask learning framework, specifically focusing on Subtasks 1 and 2. The core of our system is built on the DeBERTa-v3-large transformer model (He et al., 2021), with several architectural additions:

Attention Pooling: Instead of relying on the standard [CLS] token representation, we implemented attention pooling to dynamically weight token representations across the sequence, allowing the model to better focus on relevant textual elements:

$$\alpha_i = \text{softmax}(W_{\text{attn}} h_i) \tag{1}$$

$$r = \sum_{i=1}^{n} \alpha_i h_i \tag{2}$$

where h_i represents hidden states and W_{attn} is a learnable parameter, and r is the final representation of the input.

Dual Task-Specific Heads: We designed parallel classification pathways for promise (Subtask 1) and evidence (Subtask 2) detection with identical architectures consisting of sequential layers:

$$\text{Classifier}(x) = W_2 \text{GELU}(\text{LN}(\text{Dropout}(W_1 x))) \tag{3}$$

Each classifier employs layer normalization for training stability, dropout for regularization, and GELU activation functions for improved gradient flow.

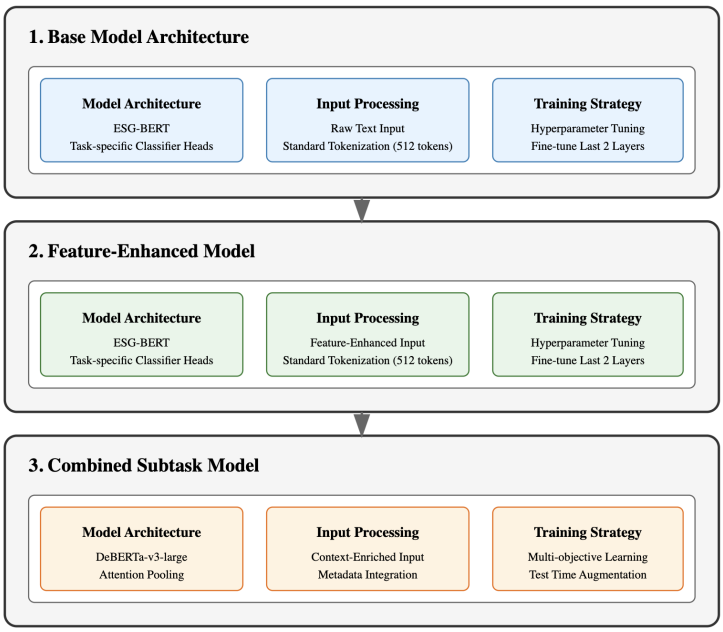

Figure 2: System architecture of the three Promise Verification models.

Context-Enriched Representation: We incorporated document metadata directly into text representations by prepending structural markers:

$$x_{\text{enriched}} = \text{"[PAGE } p\text{] [ESG REPORT] "} + x_{\text{raw}} \tag{4}$$

Here, [PAGE p] is dynamically set based on the page number of the input document, and the document-type tag ([ESG REPORT]) can vary depending on the report source, allowing the model to distinguish between different document types.

Multi-objective Weighting: The combined training objective weights the promise and evidence subtasks differently to prioritize the more foundational promise detection task:

$$\mathcal{L} = 0.6 \cdot \mathcal{L}_{\text{promise}} + 0.4 \cdot \mathcal{L}_{\text{evidence}} \tag{5}$$

Test-Time Augmentation: For prediction, we implemented multiple forward passes with different text augmentations, averaged the probabilities across ensemble predictions, and calibrated thresholds for final binary decisions.

5 Experimental Setup

5.1 Models 1 & 2: Cross-Validation and Feature-Enhanced Training

For Models 1 and 2, we implemented a 4-fold stratified cross-validation approach for data splitting during hyperparameter tuning for each subtask. The English dataset was divided using the StratifiedKFold class from the scikit-learn library[2], maintaining class distribution across folds to address class imbalance. For each trial, the data was partitioned with 75% used for training and 25% for validation. Validation loss was the sole optimization metric, averaged across all 4 folds for each of the 7 trials per subtask. We maintained consistent random seeds throughout all experiments to ensure reproducibility.

For Model 2, our preprocessing approach varied by subtask, with each designed to extract task-specific linguistic features. For promise identification, we used sentiment analysis through the `Flair` package (Akbik et al., 2019) and promise word detection. For evidence identification, we counted concrete metrics and supporting proof terms while detecting named entities using `spaCy`[3]. For clarity assessment, we analyzed the prevalence of vague versus specific terminology. For the timing for verification, we extracted dates and identified timeline indicators. All enriched features were prepended to the original text as specialized tags before tokenization.

Hyperparameter optimization was performed using Optuna with the TPE sampler. We tuned the learning rate (1e-5 to 5e-5), batch size (4, 8, 12),

[2] https://scikit-learn.org/stable/modules/generated/sklearn.model_selection.StratifiedKFold.html

[3] https://spacy.io/

and weight decay (0.01 to 0.3). We used early stopping with a patience of 2 epochs to prevent overfitting. For model architecture, we fine-tuned only the last two transformer layers and the classification head while freezing earlier layers. After determining optimal hyperparameters, the final model for each subtask was trained on the entire dataset.

5.2 Model 3: Multi-Task Learning Setup

For Model 3, we adopted a different experimental approach to leverage the multi-task learning paradigm. We divided the English dataset using stratified sampling with a 90-10 train-validation split, ensuring a balanced representation of both promise and evidence classes. This larger training proportion was selected to provide sufficient examples for the joint learning task. The model was trained with a learning rate of 1e-5, weight decay of 0.01, and a cosine learning rate scheduler with 10% warmup steps. To accommodate memory constraints while maintaining effective batch sizes, we implemented gradient accumulation with 16 steps and reduced sequence length to 256 tokens. Training proceeded for 5 epochs with evaluation on a held-out validation set after each epoch, with the best checkpoint saved based on the average F1 score across both tasks. For inference, we employed test-time augmentation (Shanmugam et al., 2021) with 3 forward passes using random word dropout (10%) and metadata variations, then ensemble-averaged the predictions with calibrated thresholds (0.5) for final classification.

6 Results and Discussions

Table 1 presents the performance of our three models on both public and private leaderboards. The public leaderboard score is computed using approximately 33% of the test set, while the private leaderboard score determines the final standings based on the remaining 67%.

Since the Combined Model only worked on Tasks 1 and 2, and Kaggle required all four subtasks for evaluation, we incorporated Task 1 and 2 predictions from our Combined Model while using our Feature-Enhanced Model for Tasks 3 and 4.

The private scores show improvement across our models. Starting with the Base Model (0.4994), we achieved better results with the Feature-Enhanced Model (0.5094), and our Combined Subtask Model reached 0.5268, surpassing the Kaggle Baseline (0.5227). While the improvements are modest, they suggest our architectural changes and feature engineering methods are effective for promise verification tasks.

Model	Public Score	Private Score
Kaggle Baseline	0.5523	0.5227
Base Model	0.5082	0.4994
Feature-Enhanced Model	0.5137	0.5094
Combined Subtask Model	0.5255	0.5268

Table 1: Performance of our models on the SemEval-2025 Task 6 leaderboard compared to the Kaggle baseline. The public score is calculated using 33% of the test set, while the private score reflects the final evaluation based on 67% of the test set.

Our Base Model and the Feature-Enhanced Model show a slight improvement of approximately 0.010 on the private leaderboard (from 0.4994 to 0.5094). Our minimal improvements in performance likely stem from ESG-BERT already implicitly capturing many of these patterns during domain-specific pre-training, creating a redundancy effect. Additionally, our prepending approach may have created a structural disconnect between features and relevant text spans, while the limited training data (400 instances) constrained the model's ability to learn optimal weightings for the introduced features.

The Combined Subtask Model yields the largest gain, achieving 0.5268, a 1.74% absolute improvement over the baseline. We attribute this improvement to three factors: (1) multitask learning benefits from shared representations between promise and evidence detection, (2) attention pooling allows the model to focus on semantically relevant tokens dynamically, and (3) test-time augmentation reduces variance in prediction by ensembling multiple augmentations. However, despite achieving our highest score, the Combined Subtask Model showed only modest gains relative to its substantially increased architectural complexity and computational requirements. The limited size of our training dataset (400 instances) may have prevented the model from fully leveraging its advanced components like attention pooling and multi-objective learning, while the potential negative transfer between promise and evidence tasks may have constrained performance gains for instances where these classifications require contradictory feature attention.

7 Conclusion

Our work explored three model architectures for promise verification in ESG reports: a baseline ESG-BERT model, a feature-enhanced model incorporating linguistic markers, and a combined subtask model with attention pooling. The combined model achieved the best performance (0.5268 on the private leaderboard), outperforming the Kaggle baseline. Despite the challenge of class imbalance across all four subtasks, our linguistic feature extraction approach and multi-objective learning framework demonstrated effectiveness in promise verification with limited training data.

Future work could explore incorporating cross-lingual promise verification through multilingual transformer models, integrating more advanced linguistic pattern recognition, and incorporating all classification tasks within a single multi-objective architecture to better capture interdependencies between promise identification, evidence assessment, clarity evaluation, and verification timing. Additionally, a systematic ablation study could quantify the contribution of each backbone pre-trained language model (PLM), such as BERT and RoBERTa, and each feature strategy (e.g., linguistic features, document metadata).

Howard University-AI4PC at SemEval-2025 Task 4: Unlearning Sensitive Content From Large Language Models Using Finetuning and Distillation for Selective Knowledge Removal

Aayush Acharya and Saurav K. Aryal
EECS, Howard University
Washington, DC 20059, USA
https://howard.edu/
saurav.aryal@howard.edu

Abstract

This paper presents our approach and submission to the SemEval 2025 task on "Unlearning Sensitive Content from Large Language Models." The task focuses on making LLMs forget specific knowledge, such as copyrighted material and personally identifiable information (PII), without needing expensive retraining from scratch. We propose a method to unlearn using fine-tuning and knowledge distillation. Our approach involves fine-tuning separate models on "retain" and "forget" datasets to preserve or suppress knowledge selectively. We then distill the model to try to suppress the data using a combine loss of $L2$, KL divergence and $cosine$ similarity while retaining knowledge from the fine-tuned model using KL divergence loss.

1 Introduction

Large language models (LLMs) have revolutionized natural language processing (NLP) by training on a vast amount of publicly available information to perform various tasks. Their ability to generate human-like responses and understand complex linguistic patterns has made them indispensable across industries. During training, they may inadvertently retain copyrighted content or personally identifiable information (PII), leading to ethical, legal, and privacy concerns. The presence of such sensitive data within an LLM raises questions about data security, user privacy, and intellectual property rights, making it crucial to develop mechanisms to selectively remove unwanted information from these models.

To foster research in the field of LLM unlearning, Ramakrishna et al. (2025) introduced SemEval-2025 Task 4: Unlearning Sensitive Contents from Large-Language Models. This task was divided into three sub-tasks:

- Unlearning long-form synthetic documents.
- Unlearning short-form synthetic biographies containing PII such as names, phone number, email, address, Social Security Number(SSN).
- Unlearning real documents sampled from the target model's training data.

The participants were provided with two sets of data: "Forget" and "Retain". As the names suggest, the goal was to ensure the model forgets the information from the "Forget" set and preserves the information from the "Retain" set. Aditionally, the organizers provided 1B and 7B parameter models pretrained on the datasets provided to facilitate the experimentation. We refer to these models as candidate models throughout this work. For the evaluation phase, participants were required to submit working Python scripts implementing the solution to the problem. The scripts were executed on privately held subsets of "Forget" and "Retain" sets for each sub-tasks to assess the effectiveness of the method.

One possible solution to solve the problem is to retrain the model from scratch using a filtered dataset, but this process is computationally expensive and requires substantial GPU hours, making it impractical for large-scale models. Moreover, complete retraining does not guarantee the complete removal of unwanted knowledge as residual traces of the information may persist due to the complex nature of LLMs.

To address these challenges, we experimented with a method to unlearn specific data from LLMs without requiring complete retraining. Our method focuses on selectively modifying the model in a way to suppress unwanted knowledge while preserving required information. We try to achieve this by fine-tuning separate models on forget and retain sets. This allows us to distill knowledge in a way where we try to suppress the forget-set information and retain the retain-set information.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1772–1776

2 Related Work

In this section, we explore prior research done in the field of unlearning in non-LLM and LLM settings.

2.1 Non-LLM settings

Ullah et al. (2021) uses gradient manipulation technique to unlearn. The paper introduces Total Variation(TV) stability as a framework for achieving unlearning. The paper proposes a TV-stable algorithm using noisy Stochastic Gradient Descent(SGD).

Setlur et al. (2022) introduces an adversarial unlearning approach to unlearn. The paper introduces Reducing Confidence along Adversarial Directions (RACD) and provides a theoretical analysis to support its effectiveness in unlearning patterns from the training data.

Fan et al. (2024) introduces parameter saliency identification for targeted knowledge removal in image generation. The paper introduces Saliency Unlearning(SalUn) which can achieve up to 100% accuracy when it comes to unlearning.

While prior methods like TV-stable SGD, RCAD, and SalUn have shown their effectiveness, they primarily target smaller-scale models or specific domains like classification and image generation. These approaches may not directly generalize to LLMs. Our approach, however, is specifically geared towards LLMs by utilizing finetuning and knowledge distillation.

2.2 LLM settings

Jang et al. (2023) introduce gradient ascent on the target token to forget information. They also highlight that sequential unlearning is better than batch unlearning. In contrast, our method involves reinforcing the knowledge to eventually retain or forget the information.

Ji et al. (2024) introduces a method that uses logit differences to suppress certain information. They use assistant models to forget the "retain" set and remember the "forget" set and eventually use the logit difference to remove forget set information from the base model. In our method, however, we use assistant models to retain both the retain and forget sets and suppress the forget set onto the candidate model while reinforcing the information from the retain set.

Kassem et al. (2023) introduces DeMem, an approach that utilizes a reinforcement learning feedback loop to unlearn. In contrast, our approach uses finetuning and knowledge distillation to unlearn.

3 Description of Our Technique

This section outlines the methodology used in our experiments.

Before detailing the technique, we establish the following notations:

- Let X represent the dataset on which the candidate LLM was initially trained.
- Let Y represent the unlearning dataset, which contains the information that has to be removed from the candidate model. Here, $Y \subset X$.
- Let Z represent the retain dataset, which contains the information that has to be retained by the candidate model. Here, $Z \subset X$.

The experiment consists of the following steps:

3.1 Fine tuning Models

In the initial phase of our approach, we focused on fine-tuning two distinct candidate models to ensure a clear separation between the information we intended to forget and that which we aimed to retain. In order to make fine-tuning less resource intensive, we quantized the models. As (Lang et al., 2024) suggest, quantization reduces the size of an LLM as we reduce the precision of the model. With the reduction in precision, we get a speedup in mathematical operations like matrix multiplication. This speedup in mathematical operations would reduce the time required for finetuning, however it comes with the cost of reduction in performance of the model.

The first candidate model was fine-tuned in the data set Y, which contains the forget-set data that we specifically seek to remove from the LLM. This fine-tuning process was essential in strengthening the model's knowledge of dataset Y, which would enable us to later suppress this information during the distillation phase. We refer to this fine-tuned model as $Model_{forget}$, as it represents the model that recognizes and remembers the data we wish to unlearn. To achieve effective fine-tuning, we utilized carefully selected hyperparameters tailored to optimize the model's performance on the forget set.

In parallel, we implemented a similar fine-tuning process on another candidate model using dataset

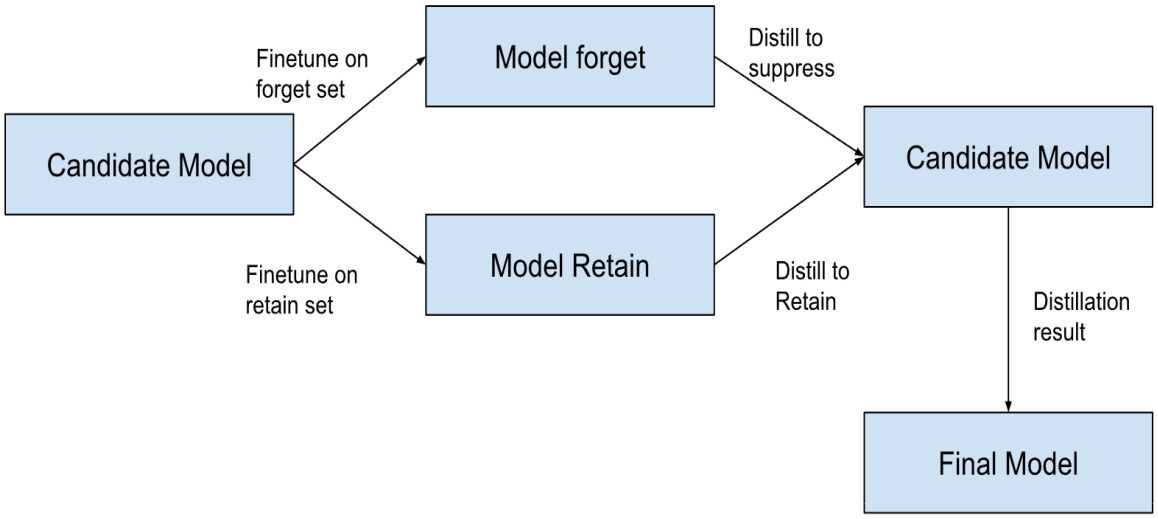

Figure 1: System implementation diagram

Z, which comprises the retain set— the information we wish to preserve and protect from being lost during the unlearning process. This model is referred to as $Model_{retain}$, representing the reinforced understanding of critical knowledge that must remain intact. Just as with $Model_{forget}$, we applied a set of appropriate hyperparameters to ensure optimal performance.

3.2 Knowledge Distillation

Following the fine-tuning of $Model_{forget}$ and $Model_{retain}$, we moved to the phase of knowledge distillation, where we aimed to transfer the insights from these fine-tuned models onto the candidate model. This process required careful attention to ensure that we achieved selective unlearning of the unwanted information while retaining essential knowledge. During the distillation of $Model_{forget}$ onto the candidate model, we implemented a negation mechanism aimed at the logits generated by the teacher model (i.e., $Model_{forget}$). This mechanism attempted to discourage the base model from aligning its outputs with the learned representations from the forget set. To discourage the alignment, we negated the result from Kullback–Leibler divergence(KL divergence), cosine similarity, and L2 loss. The combined loss function is expressed as follows:

Before expressing the loss function, we establish the following notation:

- l_2 refers to l_2 loss.
- KL refers to KL divergence loss.
- $cosine$ refers to cosine similarity.
- α is an arbitrary constant.

$$loss = Mean(-\alpha l_2, -KL, -\alpha cosine\ )$$

During the training process, the negatively weighted components in the loss function serves to encourage divergence rather than convergence between the predicted and actual values. Specifically, the negatively weighted KL divergence tries to push the predicted probability distribution to differ as much as possible from the true distribution. Similarly, the negatively weighted $cosine$ similarity tries to encourage dissimilarity in vector direction. Likewise, the negative weighted l_2 loss tries to maximize the distance between the predicted and actual output.

Conversely, when distilling knowledge from $Model_{retain}$ onto the same candidate model, we adopted a contrasting strategy. Our goal in this case was to ensure that the logits were closely aligned with those generated by $Model_{retain}$. This alignment attempted to preserve the information within the dataset Z. The loss function that we used to continue to retain the information was KL divergence loss. With KL divergence loss, we tried to bring the probability distribution of the actual and the predicted result as close as possible.

4 Result

Our approach resulted in insufficient GPU VRAM on the official test environment for the 7B parameter OLMo model. However, there was no such

issue when it came to running the algorithm on the 1B parameter OLMo model. The final 1B parameter model underperformed and ranked 24th on the leaderboard. Our final aggregate score was 0.079 with an MMLU score of 0.236.

We conducted additional experiments using the GPT-2 model with 137 million parameters. The performance of the model was evaluated using Rogue score. The scores after finetuning the models on Retain and Forget sets are as follows:

	Forget Finetuned	Retain Finetuned
Rogue-1	0.8	0.83
Rogue-L	0.8	0.83

Table 1: Rouge scores after finetuning

The results above indicate that the finetuned models retained some information from their respective training datasets. After the distillation process as discussed in section 3.2, we had the following results:

	Forget dataset	Retain dataset
Rogue-1	0.71	0.77
Rogue-L	0.71	0.77

Table 2: Comparison of Rogue-1 and Rogue-L scores between forget and retain datasets

The post-distillation results suggest that for the retain dataset, the model's output tried to move as close as possible to the actual output. While the result from forget dataset suggest that the predicted outputs shifted a bit from the actual outputs. While the negative weighted loss functions helped in somewhat suppressing the information, we still can see that the suppression was incomplete because of relatively high rogue scores. This finding suggests a potential need for an alternative or complementary loss function to enhance the effectiveness of unlearning.

5 Conclusion

In this study, we explored a fine-tuning and distillation-based approach to unlearning in large language models. Our method involved training separate models to distinguish between forget and retain sets, followed by a distillation phase to suppress unwanted knowledge while preserving critical information. Despite the effort, the results did not achieve the effective unlearning. The method struggled to fully remove the targeted knowledge and resulted in an unintended degradation to the model, highlighting the need for a modified approach to solve the problem.

6 Limitations & Future Work

Our approach of unlearning had limitations that hindered overall effectiveness. Although the negative-weighted loss function contributed to partial suppression of the forget-set, it also affected the model's effectiveness. Our method lacked a rigorous mechanism to confirm whether the targeted information was properly removed.

For future work, we propose several directions. Applying our method on larger models, may reveal whether the increase in model capacity lead to more effective suppression. Additionally, using a non-quantized model during the process could offer higher precision during training, potentially improving the outcomes. Finally, exploring alternative loss functions to suppress the knowledge may result in more robust unlearning behavior.

Howard University-AI4PC at SemEval-2025 Task 7: Crosslingual Fact-Checked Claim Retrieval-Combining Zero-Shot Claim Extraction and KNN-Based Classification for Multilingual Claim Matching

Suprabhat Rijal and **Saurav K. Aryal**
EECS, Howard University
Washington, DC 20059, USA
saurav.aryal@howard.edu

Abstract

SemEval Task 7 introduced a dataset for multilingual and cross lingual fact checking. We propose a system that leverages similarity matching, KNN, zero-shot classification and summarization to retrieve fact-checks for social media posts across multiple languages. Our approach achieves performance within the expected range, aligning with baseline results. Although competitive, the findings highlight the potential and challenges of zero-shot methods, providing a foundation for future research in cross lingual information verification.

1 Introduction

The rapid spread of misinformation on social media platforms has highlighted the urgent need for automated fact-checking systems that can operate across multiple languages. Multilingual and cross lingual fact checking pose significant challenges, as they require systems to verify claims in diverse linguistic contexts while maintaining high accuracy and scalability (Ngueajio et al., 2025; Washington et al., 2021). To address these challenges, SemEval Task 7 introduced a benchmark dataset designed to evaluate the performance of such systems, providing a platform for advancing research in this domain (Peng et al., 2025).

Our proposed approach to cross lingual fact checking leverages zero-shot classification and summarization techniques. Using zero-shot methods, our system retrieves fact checks associated with social media posts across multiple languages without requiring language-specific training data. This strategy enables the system to bridge the gap between high-resource and low-resource languages, promoting more equitable access to fact-checking tools (Aryal et al., 2023b,d). The zero-shot framework allows the system to generalize across languages, making it scalable and adaptable to diverse linguistic contexts.

Our results demonstrate that the proposed system achieves performance within the expected range, aligning with baseline results reported in prior work. Although the results are competitive, they also reveal the inherent challenges of zero-shot methods, particularly in claim classification tasks. These findings validate the feasibility of zero-shot approaches for cross lingual fact-checking and provide a foundation for future research.

To support reproducibility and further research, we have released the code for our system. The code can be found in Appendix A.

2 Background

2.1 Task Summarization

The task comprised two distinct tracks: Monolingual (Track 1) and Cross Lingual (Track 2). In the Monolingual track, the objective was to match social media posts with fact checks written in the same language across multiple languages. In contrast, the Cross Lingual track required matching social media posts with fact-checks across different languages, addressing the challenge of verifying claims in multilingual contexts. Our work aims to tackle Track 2.

2.2 Dataset

This dataset contains social media posts, each including images with extracted text (OCR) and accompanying captions, presented in both the original language and English translations. These posts were paired with fact checks that also contained claims in the source language and their English translations. The development phase covered eight languages, while the testing phase introduced two additional unseen languages.

2.3 Related Work

Cross lingual claim matching, a critical task in misinformation detection and fact checking, has

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1777–1782

received relatively limited attention in the research community, as evidenced by recent surveys (Panchendrarajan and Zubiaga, 2024). Existing approaches have predominantly relied on embedding-based representations of claims to retrieve relevant fact-checks using similarity metrics, as exemplified by the authors of the MultiClaim dataset. Furthermore, the use of fine-tuned multilingual models, such as mBERT (Devlin et al., 2019), for claim classification—as explored in the MMTweets framework(Singh et al., 2024)—has shown promise but has not yet achieved consistent performance in cross lingual settings. Existing literature indicates that claim extraction techniques using LLMs yield promising results when applied to fact-checking tasks (Sundriyal et al., 2023). Given these limitations, our work seeks to experiment with alternative approaches, combining semantic similarity and classification-based methods while incorporating zero-shot techniques to explore their potential for improving cross lingual claim matching.

3 System Overview

Our cross lingual claim matching system is composed of three main components: Text Translation, Knowledge Base Creation and Fact-Check Retrieval.

3.1 Text Translation

Both the social media post information (OCR text and caption text) and verified fact checks are translated into English. For this step, we utilize the translated social media OCR text and caption text provided by the MultiClaim Dataset which uses Google Translate API for translation.

3.2 Knowledge Base Creation

To enable efficient claim retrieval, we first generate vector embeddings for all fact-checked claims using a pre-trained language model (all-MiniLM-L6-v2). These embeddings capture the semantic representations of the claims and are stored in a vector database. The database facilitates cosine-similarity-based searches, allowing for the identification of semantically similar claims during the retrieval process.

3.3 Fact-Check Retrieval

The retrieval process involves the following steps:

- **Claim Extraction:** A large language model, Deepseek-r1:14B (DeepSeek-AI et al., 2025) quantization Q4_K_M, is employed to extract the core claim from the translated social media post. This is achieved using carefully designed prompts that ensure accurate and concise claim identification.

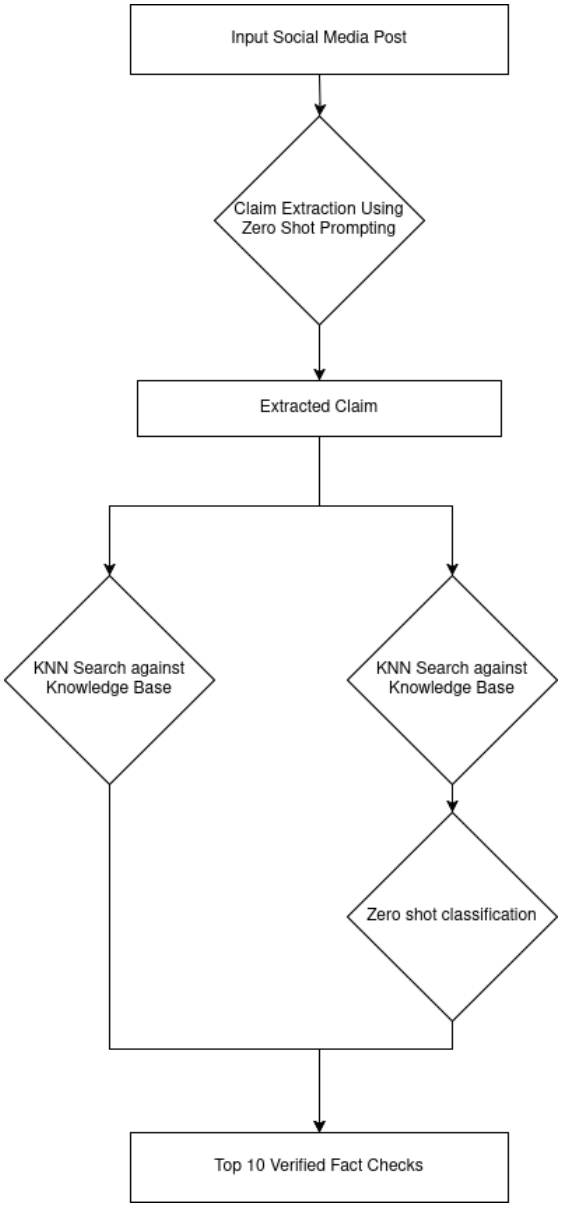

Figure 1: Crosslingual Fact Check Retrieval Pipeline

- **Knowledge Base Search:**To provide 10 fact checks for each query as required by the task, we implemented two distinct approaches:
  - **KNN Search:** The top-10 fact-check embeddings are retrieved solely based on semantic similarity to the social media claim.
  - **Zero-shot classification:** In this approach, we first retrieve the top-10 fact-

check embeddings based on cosine similarity. For each retrieved fact-check, a large language model is prompted to classify whether the social media claim and the fact-check claim are semantically equivalent. If fewer than 10 matches are identified, the process iteratively retrieves the next 20 closest vectors and repeats the classification until 10 claims are matched. This hybrid approach combines embedding-based retrieval with LLM-driven classification, significantly reducing the search space and computational overhead by avoiding classification inference over the entire "verified fact checks" search space.

4 Experimental Setup

4.1 Open Source Software used

- **Embedding Function:** To generate semantic embeddings for the claims, we utilized the `sentence-transformers` (Reimers and Gurevych, 2019). library with the `all-MiniLM-L6-v2`(Wang et al., 2020) model. This model was chosen for its efficiency and effectiveness in capturing semantic representations of text, enabling robust similarity-based retrieval (Wang et al., 2020).

- **Vector Database:** For storing and querying the embeddings, we employed `chromadb` as the vector database.

- **Hosting LLM:** The distance function we used was the standard `cosine similarity` provided by chromadb due to its invariance to magnitude.

- **Embedding Function:** The large language models (LLMs) used in our system were hosted locally using `ollama`, ensuring low-latency access and control over model configurations. We employed the structured output functionality in ollama to ensure the large language model (LLM) generated precise JSON-formatted responses.

4.2 LLM Setup for Claim Generation

For claim extraction from social media posts, we used the `deepseek-r1:14b` model with quantization `Q4_K_M`. The following prompt was designed to guide the model in generating concise and accurate claims:

```
Task: Generate a concise and
    accurate claim made by a
    social media post.

Input:
    OCR Text: {ocr}
    Social Media Caption: {text}

Output:
JSON
{
  "claim": [The claim made in the
      social media post, based on
      both the image text and the
      caption]
}

Guidelines:
    - The claim should be stated
      objectively and avoid
      subjective language.
    - If multiple claims are
      present, focus on the most
       prominent one while
      mentioning others.
    - Rephrase opinions or
      sentiments as formal
      statements.
    - Ensure grammatical
      correctness and
      professional tone.
JSON
{
  "claim": "97% of scientists
     agree climate change is real
     ."
}
```

4.3 LLM Setup for Prompt Classification

For zero-shot classification, we used the `deepseek-r1:7b` model with quantization `Q4_K_M` and the following prompt:

```
Task: Determine whether a fact-
    checked claim (Claim A) can
    verify or contradict another
    claim (Claim B).
```

```
Input:
    Claim A: {
        claim_to_check_against}
    Claim B: {claim}

Output:
JSON
{
  "can_fact_check": boolean
}

Guidelines:
    - Identify key entities and
      central themes in both
      claims.
    - Compare the claims for
      overlap, contradiction, or
       support.
    - Provide a logical
      explanation for whether
      Claim A can fact-check
      Claim B.
    - Return a boolean value
      indicating the result.
```

This prompt was designed to ensure the model could accurately assess the relationship between claims, enabling effective zero-shot classification for fact-check retrieval.

5 Results

The performance of our system was evaluated using the Success@10 (`S@10`) metric, which measures whether at least one associated fact check is successfully retrieved within the top 10 results for a given social media post.

5.1 Knowledge Base Search Results

The results for the two Knowledge Base Search methods—KNN Search and KNN + Zero-shot Classification—are presented below:

Method	S@10
KNN Search	**0.59**
KNN + Zero-shot Classification	0.47

Table 1: Results for Knowledge Base Search methods using Test dataset

The similarity search method achieves a S@10 score of **0.59** while KNN + Zero-shot classification achieves a score of **0.47** suggesting that zero-shot claim classification is ineffective.

Since we did not train any models, the dev dataset was not used.

5.2 Overall Task Leaderboard

The results for the cross lingual track are summarized in the leaderboard below:

Rank	Team Name	S@10
19	UPC-HLE	0.6385
20	JU_NLP	0.619
21	**Howard University - AI4PC**	**0.59225**
22	Word2winners	0.55425

Table 2: Leaderboard results for Crosslingual Track

Our system achieved an average (`S@10`) score of **0.59225**, securing the 21st position on the leaderboard. This result demonstrates the effectiveness of our approach in addressing the challenges of cross lingual claim matching. While there is room for improvement, our methodology shows promise, and further refinements are expected to enhance performance in future iterations.

6 Limitations and future work

Although our system combines KNN with zero-shot classification to reduce the search space, it remains computationally intensive. As highlighted in the results, simple KNN outperformed zero-shot classification, underscoring the limitations of zero-shot methods for claim matching in this context. Additionally, the translation process may lead to the loss of certain linguistic nuances and information (Sapkota et al., 2023; Aryal et al., 2023c), further contributing to the system's reduced effectiveness. Looking ahead, we aim to address these limitations by exploring multilingual embedding models and large language models (LLMs) that are better suited for cross-lingual tasks (Aryal and Prioleau, 2023; Aryal et al., 2023a). We also plan to fine-tune models specifically for claim extraction and claim matching to improve accuracy and efficiency. These refinements are expected to enhance the system's performance and scalability in multilingual fact-checking scenarios.

7 Conclusion

In this paper, we presented a system for cross lingual fact-checked claim retrieval, addressing

the challenges posed by SemEval Task 7. Our approach leveraged a combination KNN search and zero-shot classification. The results demonstrated that simple similarity search methods, such as KNN, outperformed zero-shot classification for the claim matching task, achieving an average Success@10 score of 0.59225 and securing the 21st position on the leaderboard. While this performance is competitive, it highlights the potential for further refinement, particularly in improving the precision of claim classification. Future work will focus on optimizing the classification process, and exploring more robust embedding techniques.

McGill-NLP at SemEval-2025 Task 11: Bridging the Gap in Text-Based Emotion Detection

Vivek Verma[1,2]*, **David Ifeoluwa Adelani**[2,3,4]

[1]Université de Montréal, [2]Mila - Quebec AI Institute,
[3]McGill University [4]Canada CIFAR AI Chair
vivek.verma.1@umontreal.ca

Abstract

In this paper, we present the results of our SemEval-2025 Emotion Detection Shared Task Track A which focuses on multi-label emotion detection. Our team's approach leverages prompting GPT-4o, fine-tuning NLLB-LLM2Vec encoder, and an ensemble of these two approaches to solve Track A. Our ensemble method beats the baseline method that fine-tuned RemBERT encoder in 24 of the 28 languages. Furthermore, our results shows that the average performance is much worse for under-resourced languages in the Afro-Asiatic, Niger-Congo and Austronesia with performance scores at 50 F1 points and below. Our simple approach ranked second for Kinyarwanda, and ranked in top-5 for Afrikaans, Algerian Arabic, Nigerian-Pidgin, Sundanese, and Swahili, in Track A of the Emotion Detection Shared Task. [1]

1 Introduction

Emotion detection is the task of identifying and categorizing emotions expressed in textual data (Acheampong et al., 2020). Given a piece of text, such as sentence, document, sentence, or summary, the goal could be to determine the underlying emotion conveyed by the speaker or that invoked in the listener. Emotions play an essential role human interaction and interpersonal relationships (Ekman, 1999). In actual speech, speakers often give many non-verbal cues such as facial expressions or hand gestures to convey their emotions. Even then emotions of the speaker can be hard to detect and this problem becomes even harder for text because of the subtle cues, lack of emoticons, sarcasm or satire, or complexity and ambiguity of language (Kratzwald et al., 2018; Chatterjee et al., 2019).

People use text on social media such as reddit and there is a growth of textual dialogue with growing prominence of these platforms (Chatterjee et al., 2019). Most human-LLM interaction is in text and hence Emotion detection in text is important for NLP models to respond appropriately. Nandwani and Verma (2021) describe a wide variety of cases for businesses, healthcare sector, education sector, etc. that have a need for accurate emotion detection.

Wide array of approaches have been tried to solve emotion detection. Acheampong et al. (2020) provide a list of state of the art approaches from 2015 to 2020 including rule-based, machine learning based, and hybrid approaches that combine the two. In SemEval2018 (Mohammad et al., 2018), Alhuzali and Ananiadou (2021) use BERT (Devlin et al., 2019) to learn contextualized word representation and combine it with a linear layer to get a single score for each token to solve multi-label emotion detection in English, Arabic, and Spanish. For the same task Huang et al. (2021) use bi-directional LSTMs as encoders and decoders. Das et al. (2021) experiment with various machine learning, deep learning, and transformer based architectures and get best performance from XLM-R (Conneau et al., 2020) for emotion classification on Bengali text. Plaza-del Arco et al. (2022) explore emotion classification in zero shot learning setup with Natural Language Inference (NLI). In more recent times, LLMs are being used for all sorts of NLP tasks and at SemEval-2024 Task 3 (Wang et al., 2024), a third of the teams used LLMs. Team *petkatz* (Kazakov et al., 2024) that ranked second, fine-tuned GPT-3.5 for emotion classification.

Our team used a combination of GPT-4o (OpenAI, 2024) given the success of GPT-4 (OpenAI et al., 2024), and NLLB-LLM2Vec (Schmidt et al., 2024) which integrates Machine Translation (MT) encoders into LLM backbones. MT-LLMs preserve the multilingual representation alignment from MT encoder, allowing low resource languages to tap into the knowledge of English-centric LLMs. For GPT-4o we use few-shot prompting technique

*This work was carried out during internship at Mila.
[1]Our code will be made available here

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1783–1789

(Brown et al., 2020) and with NLLB-LLM2Vec we fine-tune LoRA adapters for each language with the training and dev set of the data provided.

2 Task Description

The task (Muhammad et al., 2025b) focuses on identifying and quantifying perceived emotion of the speaker based on a given sentence or a short text snippet. This means determining the emotion that the speaker appears to express, rather than the emotions invoked in the listerner, or anyone else mentioned in the text, or the true emotion of the speaker.

The emotions being looked at for this task are from Ekman's six basic emotions (Ekman, 1992) - joy, sadness, fear, anger, surprise, or disgust. The definition of these emotions is provided in Muhammad et al. (2025a), which we present here:

- Joy: "Expressions of happiness, pleasure, or contentment."
- Sadness: " Expressions of unhappiness, sorrow, or disappointment."
- Fear: "Expressions of anxiety, apprehension, or dread."
- Anger: "Expressions of frustration, irritation, or rage."
- Surprise: "Expressions of astonishment or unexpected events."
- Disgust: "A reaction to something offensive or unpleasant."

The shared tasks has **Three Tracks** of problems - Track A, Track B, and Track C. **Track A** is for multi-label emotion detection where given a piece of text we evaluate the presence of each of the six emotions described above and give a binary classification of 0 or 1 for each of them. **Track B** is for emotion intensity detection where each of the emotions can have ordinal values from 0 to 3. 0 meaning no emotion, 1 for low degree of emotion, 2 for moderate degree of emotion, and 3 for high degree of emotion. **Track C** is for Cross-lingual emotion detection where given labeled training data in a language, predictions need to be done for text instances in another language. Some languages in all the 3 tasks include five emotions, excluding the emotion *disgust*.

We focus on a single track, so our submission is only for Track A which had 28 languages in the dataset (Muhammad et al., 2025a; Belay et al., 2025): Afrikaans (afr), Algerian Arabic (arq), Amharic (amh), Portuguese (Brazilian) (ptbr), Mandarin Chinese (chn), Emakhuwa (vmw), English (eng), German (deu), Hausa (hau), Hindi (hin), Igbo (ibo), Kinyarwanda (kin), Spanish (Latin American) (esp), Marathi (mar), Moroccan Arabic (ary), Portuguese (Mozambican) (pt-MZ), Nigerian-Pidgin (pcm), Oromo (orm), Romanian (ron), Russian (rus), Somali (som), Sundanese (sun), Swahili (swa), Swedish (swe), Tatar (tat), Tigrinya (tir), Ukrainian (ukr), Yoruba (yor).

3 System Overview

Our system for solving Track A consists of GPT-4o, NLLB-LLM2Vec and a method of ensemble to combine the best results from the two. We describe each of these below:

3.1 Prompting GPT-4o in few-shot setting

We prompt GPT-4o via API. For each language the prompt has a static context part that consists of Task description, the order of emotions, and first 50 examples from the training set. A dynamic query is added to the static context for each entry in the test set, requiring one API call for each entry.

The DEV set is used heuristically, before running on the test set, to try different prompts and prompt structures, and chose one that gives the best F1-score. For all languages, we kept the prompt in English and only use examples and test case in the target language. We stick to prompting in English since previous work already suggest that prompting in English works better on average (Lin et al., 2021).

3.2 NLLB - LLM2Vec

NLLB-LLM2Vec was developed to combine the excellent multilingual representations of MT models with LLMs that excel on English NLU, due to their language modeling training on large corpora. It fuses NLLB 600M parameter model MT encoder (Team et al., 2022) and Llama 3-8B variant (Meta AI, 2024) that underwent 'LLM2Vec process' (BehnamGhader et al., 2024)

We fine-tune LoRA adapters for each language. We train with rank r=16, alpha α=32, and use 4-bit QLoRA-style quantization (Dettmers et al., 2023). We use weight decay of 0.01, per device batch size

Language	GPT-4o	NLLB-LLM2Vec	Ensemble	Baseline
Afrikaans (afr)	60.1	32.5	**60.1**	37.1
Amharic (amh)	51.3	63.0	63.4	63.8
Algerian Arabic (arq)	57.0	41.0	**58.7**	41.4

Tatar (tat)	73.9	39.3	**73.9**	53.9
Tigrinya (tir)	42.5	44.3	**48.2**	46.3
Ukrainian (ukr)	60.0	37.5	**60.0**	53.5
Emakhuwa (vmw)	12.3	6.0	**12.6**	12.1
Yoruba (yor)	33.0	19.5	**33.0**	9.2
Average F1	**56.9**	**49.6**	**59.4**	**50.9**

Table 1: Result on test set for GPT-4o (few-shot), NLLB-LLM2Vec, and Ensemble of these two (Ranked Submission), along with the Baseline RemBERT score. Instances where our Ensemble method does better than Baseline RemBERT are marked in bold. The average macro F1 across all languages for each system is shown in the last row.

of 4, and train for 2 epochs. We use the provided train set and dev set entirely as training and validation sets. After fine-tuning we scan for a threshold between 0.3 to 0.7 in increments of 0.05 for classification so that it maximizes f1 score on validation set. We then generate predictions on test set from fine-tuned model. Fine-tuning was done on a single Nvidia V100 32GB GPU.

3.3 Ensemble of GPT-4o and NLLB-LLM2Vec

For our final submission, we use the best results from the two systems at an emotion level. This means that a submission for a single language could have a few emotions from GPT-4o and a few from NLLB-LLM2Vec based on which of the two performed better for each emotion. Ideally, this should be done looking at those results on the validation set and predecided, instead of looking at test set results and choosing the best one.

4 Results and Discussion

The results from the two approaches, and the ensemble which is our final ranked submission, are shown in the Table 1. The performance varies from 0.1256 macro F1 for Emakhuwa (vmw) being the lowest to 0.8802 for Hindi (hin) being the highest. We computed the results for all the 28 languages. Comparing our results to other teams, on 12 languages out of 28, our team is in the top 10 rankings for that language. Our ensemble method does better than the Baseline RemBERT (Chung et al., 2021) provided by the Task organizers (Muhammad et al., 2025a) on 24 languages out of 28.

Language Family	Average ranked F1 score
Afro-Asiatic	50.7
Austronesian	50.3
Creole	63.2
Indo-European	69.1
Niger-Congo	45.3
Sino-Tibetan	59.6
Turkic	73.9

Table 2: Average macro F1 score of the ranked submission, grouped by language family.

Average F1 score across language families (Muhammad et al., 2025a; Belay et al., 2025) is shown in the Table 2. We see that Turkic and Indo-European languages have the highest scores while Austronesian and Niger-Congo languages have the lowest scores. Few-shot prompting on GPT-4o performs better than NLLB-LLM2Vec on most languages in the Indo-European, Niger-Congo, Turkic, and Austronesian families, whereas NLLB-LLM2Vec performs better on languages in the Creole, and Sino-Tibetian family and half the languages in Afro-Asiatic family.

There are a few things we could've done to look for better performance. We have the same training parameters for NLLB-LLM2Vec for each language and we might have benefited from tuning parameters at a language level. We could've also increased the number of epochs of training for better performance.

4.1 Experiments Post Competition Deadline

Given our shortcomings in the fine-tuning of our NLLB-LLM2Vec, we evaluate the languages more granularly to improve performance. We introduce lora dropout of 0.05 in the LoRA parameters, we train for 5 epochs instead of 2 and chose the epoch that maximizes the F1 score on the dev set. At each epoch, we generate classification probabilities for each emotion in the dev set. To convert the probabilities to classification, we need a threshold

Language	NLLB-LLM2Vec	NLLB-LLM2Vec (Tuned)
Afrikaans (afr)	32.5	**47.1**
Amharic (amh)	63.0	66.0
Algerian Arabic (arq)	41.0	45.8
Moroccan Arabic (ary)	39.8	**47.7**
Mandarin Chinese (chn)	55.9	**62.5**
German (deu)	62.0	62.9
English (eng)	77.5	77.7
Spanish (esp)	72.1	76.1
Hausa (hau)	57.8	59.5
Hindi (hin)	87.0	87.3
Igbo (ibo)	48.7	49.0
Kinyarwanda (kin)	40.3	**47.8**
Marathi (mar)	85.4	81.9
Oromo (orm)	48.2	**55.0**
Nigerian-Pidgin (pcm)	63.2	64.1
Portuguese (Brazilian) (ptbr)	40.3	**48.8**
Portuguese (Mozambican) (ptmz)	42.2	45.2
Romanian (ron)	67.2	68.9
Russian (rus)	84.4	84.7
Somali (som)	40.7	43.2
Sundanese (sun)	26.6	**42.0**
Swahili (swa)	21.8	27.6
Swedish (swe)	42.4	**49.7**
Tatar (tat)	39.3	**60.8**
Tigrinya (tir)	44.3	**53.0**
Ukrainian (ukr)	37.5	**44.7**
Emakhuwa (vmw)	6.0	**28.4**
Yoruba (yor)	19.5	**34.5**
Average F1	**49.6**	**55.8**

Table 3: Results on test set for NLLB-LLM2Vec (Tuned) with better hyperparameter tuning (Post Competition Deadline) compared to that of the results in the ranked submission before competition deadline. We see significant performance gain on the test set compared to our previous iteration for NLLB-LLM2Vec, with macro F1 average increasing from 49.6 to 55.8. This improvement surpasses the Baseline macro F1 average of 50.9. Languages with significant improvement due to hyperparameter tuning are marked in bold.

cut-off, and we choose to have a different threshold for each emotion. We do this by sweeping through threshold values in the range [0.05, 0.7], in increments of 0.05, and selecting the one that maximizes the macro F1 score on the dev set. We use the test set prediction from the epoch with the best F1 score on dev set.

Our dedicated effort for languages improves performance for NLLB-LLM2Vec. We only fine-tune on dev set without looking at test set and score the test set a single time at the end. The new scores are shown in Table 3

We see that the average macro F1 score increased from 49.6 to 55.8 which is slightly behind GPT-4o with an average macro F1 score of 56.9. NLLB-LLM2Vec alone, without any ensemble technique, does better than Baseline RemBERT score on 19 languages out of 28 and on macro F1 average. On a few languages it does better than the previous Ensemble method, with the most noteworthy jump being on Emakhuwa (vmw) from 12.6 to 28.4. This would've placed our team on the second spot for this language. In about half of the languages there is a jump of greater than 5 points in F1 score, highlighting the importance of better hyperparameter tuning.

5 Conclusion

In this work, we present our approach for Track A of SemEval-2025 Task 11 for multi-label emotion detection in text on 28 languages. We experiment with two methods - few-shot prompting with GPT-4o and fine-tuning NLLB-LLM2Vec with LoRA adapters, and present an ensemble of these two for our best results. Our model outperforms Baseline results in most languages. We also see that average F1 scores are at 50 F1 points and below for under-resourced languages in the Afro-Asiatic, Niger-Congo and Austronesia.

We also present improvements and analysis on the performance of NLLB-LLM2Vec for this task with better hyperparameter tuning on the dev set. This leads to NLLB-LLM2Vec beating Baseline results in 19 languages, and its performance gets close to GPT-4o performance on average macro F1 score across languages. Further work can be done to improve the Ensemble technique to work more fluently and combine the results of GPT-4o and NLLB-LLM2Vec based on the dev set. This would invariably provide better results than our ranked submission.

Howard University - AI4PC at SemEval-2025 Task 3: Logit-based Supervised Token Classification for Multilingual Hallucination Span Identification Using XGBOD

Saurav K. Aryal and **Mildness Akomoize**
EECS, Howard University
Washington, DC, USA
saurav.aryal@howard.edu

Abstract

This paper describes our system for SemEval-2025 Task 3, Mu-SHROOM, which focuses on detecting hallucination spans in multilingual LLM outputs. We reframe hallucination detection as a point-wise anomaly detection problem by treating logits as time-series data. Our approach extracts features from token-level logits, addresses class imbalance with SMOTE, and trains an XGBOD model for probabilistic character-level predictions. Our system, which relies solely on information derived from the logits and token offsets (using pretrained tokenizers), achieves competitive intersection-over-union (IoU) and correlation scores on the validation and test set.

1 Introduction

SemEval-2025 Task 3, Multilingual Shared-task on Hallucinations and Related Observable Overgeneration Mistakes (Vázquez et al., 2025) addresses the critical challenge of detecting hallucinations in instruction-tuned Large Language Model (LLM) outputs. The challenge of hallucination extends beyond text-based LLMs to multimodal large language models (MLLMs) as well, posing significant obstacles to their real-world applications (BAI et al., 2025). This task is crucial for ensuring the reliability and trustworthiness of LLMs in real-world applications, especially in multilingual contexts. Mu-SHROOM encompasses 14 languages: Arabic, Basque, Catalan, Chinese, Czech, English, Farsi, Finnish, French, German, Hindi, Italian, Spanish, and Swedish, reflecting the growing need for robust multilingual LLM evaluation (Ji et al., 2022).

Our system tackles this span detection task by framing it as a point-wise anomaly detection problem. We hypothesize that hallucinated text spans exhibit anomalous patterns in the LLM's output logits compared to factual or consistent text. Inspired by recent work demonstrating the potential of Large Language Models for time series anomaly detection (Liu et al., 2024), we leverage the XGBOD (eXtreme Gradient Boosting for Outlier Detection) algorithm (Zhao, 2019), trained on features extracted directly from the LLM's logit sequences, to identify these anomalous points indicative of hallucinations. By participating in Mu-SHROOM, we discovered that a relatively simple, data-driven anomaly detection approach can achieve effective hallucination span detection across diverse languages, relying solely on model logits without prompts, text, tokens, or Retrieval-Augmented Generation (RAG).

2 Background

Recent work has also explored the use of LLMs directly for time series anomaly detection. (Liu et al., 2024) proposed LLMAD, a framework that uses LLMs for few-shot anomaly detection in time series, achieving both high accuracy and interpretability. Their work, while focused on general time series data, further motivates our exploration of anomaly detection techniques for hallucination detection in LLM text output, particularly by leveraging the LLM's own logit representations. The survey by (Luo et al., 2024) provides comprehensive overviews of various hallucination detection techniques. The field of time series anomaly detection itself is a well-established area, with extensive research into various methodologies, as highlighted in comprehensive surveys by (BLÁZQUEZ-GARCÍA et al., 2020; DARBAN et al., 2024). These surveys cover a wide range of techniques, including deep learning approaches, and discuss applications across diverse domains. Anomaly detection techniques have been successfully applied to various time-series data domains, such as system log analysis (Du et al., 2017).

The task input consists of:

1. `model_input` (instruction prompt)

2. `model_output_text` (LLM generated text)

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1790–1794

3. `model_output_logits` (logit values for each token in the output)

4. `model_output_tokens`

5. Human annotations in the form of `soft_labels` (probabilistic hallucination spans) and `hard_labels` (definite hallucination spans)

The expected output from participating systems is, for each character in the `model_output_text`, a probability indicating whether it is part of a hallucination span.

The dataset is split into Sample, Validation, Unlabeled Train, Unlabeled Test, and Labeled Test sets. We utilized the Validation set for training our anomaly detection model and the Unlabeled Test set for evaluation. The dataset covers 14 languages and utilizes outputs from various public-weight LLMs. Our submission focused on span detection across all 14 languages using a single model.

3 System Overview

Our system employs a three-stage process: feature extraction from logits, anomaly detection using XGBOD and prediction of anomaly scores for each token.

3.1 Feature Extraction

Our system extracts six features for each token in the LLM's output, including the raw logit value, its normalized position in the sequence, and the logit difference from the previous token, all derived from the `model_output_logits` sequence. We hypothesize that tokens within hallucinated spans will display distinctly anomalous logit patterns compared to tokens in non-hallucinated spans. These features are designed to capture both the individual token's logit behavior and its context within the overall logit sequence.

3.2 Anomaly Detection with XGBOD

We employ XGBOD, an efficient and effective outlier detection algorithm based on eXtreme Gradient Boosting (XGBoost), for anomaly detection. We chose XGBOD for its ability to handle complex feature interactions and robustness against data imbalance (Zhao, 2019).

The model is trained on the labeled validation set. SMOTE is used to oversample the minority class and the labels provided in the validation set are used as the ground truth for anomaly/non-anomaly classification at the token level. Specifically, if a token's character span overlaps with any hallucination span, it's labeled as anomalous (1), otherwise non-anomalous (0).

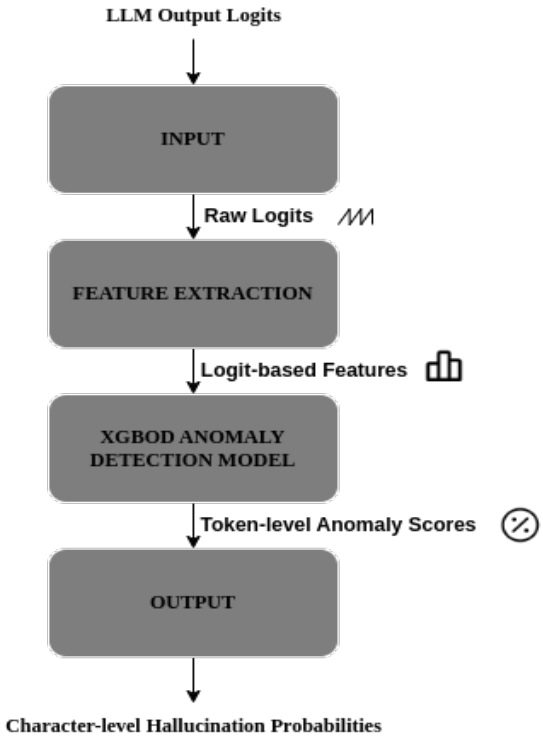

Figure 1: Overview of the system pipeline for hallucination span identification, illustrating data flow from LLM output logits to character-level probability predictions.

3.3 Inference and Prediction

For the unlabeled test set, we apply the trained XGBOD model to predict anomaly scores for each token. The process mirrors the feature extraction step used in training. For each instance in the test set:

1. Extract logits and model output text.

2. Tokenize the text to obtain token offsets.

3. Extract the same six logit-based features for each token as during training.

4. Use the trained XGBOD model to predict an anomaly score (probability) for each token.

5. Map token-level anomaly scores back to character-level probabilities.

The design choices for our system is motivated by several key considerations. First, we leverage

LLM logits as a rich internal representation, reflecting the model's predictive probabilities, confidence, and uncertainty. While hallucinations can sometimes present as linguistically plausible text, we hypothesize that these instances may still correspond to deviations from the logit patterns typically observed during factual or consistent generation. We are not necessarily looking for individual "surprising" or out-of-distribution logit values, but rather for subtle shifts in the distribution, sequence, or relationships among logits, which we aim to capture through our extracted features. This lightweight design translates to significantly reduced compute requirements for both model training and inference compared to large transformer models or methods involving extensive external knowledge bases. Training our XGBOD model is substantially faster and less resource-intensive, enabling efficient processing and potential suitability for real-time hallucination detection. This data-driven methodology, training an anomaly detection model on the validation set, allows us to learn hallucination patterns directly from the data, rather than relying on heuristics. Finally, the language-agnostic nature of logit-based features enables multilingual applicability. Drawing inspiration from the successful use of anomaly detection in time-series data (Du et al., 2017) and the recent application of LLMs to time-series anomaly detection (Liu et al., 2024), our system provides a targeted and efficient solution for multilingual hallucination span identification while utilizing a distinct gradient boosting model and focusing specifically on text hallucination.

4 Experimental Setup

4.1 Data Splits and Preprocessing

We used the validation set provided by the Mu-SHROOM task organizers to train our XGBOD model. The unlabeled test set was used to generate our predictions for the competition. We did not use any additional data or external resources beyond the provided datasets and pre-trained tokenizers.

The preprocessing steps included the following:

- Tokenization: For each language and `model_id`, we used the corresponding Hugging Face Transformers tokenizer (AutoTokenizer) (Wolf et al., 2019) to obtain token offsets for feature extraction and label alignment.

- Feature extraction: As described in Section 3.1, we extracted six logit-based features for each token.

- Label Generation: The validation set la WObels were used to generate token-level anomaly labels (0 or 1) as described in Section 3.2.

- Addressing Class Imbalance: Due to the imbalanced nature of the data, we employed SMOTE (Synthetic Minority Oversampling Technique) (Chawla et al., 2002) to oversample the minority class in the training set, improving model robustness.

4.2 Hyperparameter Tuning

We performed hyperparameter tuning for the XGBOD model using GridSearchCV with 3-fold cross-validation on the resampled training data (after SMOTE).

Parameter	Search Space
n_estimators	{100, 200, 300}
max_depth	{3, 5, 7}
learning_rate	{0.01, 0.05, 0.1}

Table 1: Hyperparameter search space for XGBOD using GridSearchCV.

4.3 Evaluation Metrics

The Mu-SHROOM task evaluates system performance using two character-level metrics:

1. Intersection-over-Union (IoU): Measures the overlap between predicted and gold hallucination spans.

2. Correlation (Cor): Measures the correlation between the system's predicted hallucination probabilities and the empirical probabilities derived from human annotations.

5 Results

As shown in Table 1, our system shows a significant improvement in intersection-over-union (IoU) scores in most languages compared to the baseline. In particular, for Arabic (AR), Spanish (ES), Finnish (FI), French (FR), and Italian (IT), our system achieves IoU scores that are substantially higher than the baseline. This indicates that our anomaly detection approach is considerably more effective in identifying and accurately delineating hallucination spans in these languages.

Moving to Correlation (Cor) scores, the comparison is more nuanced. our system generally achieves competitive or superior correlation scores, indicating a better alignment between our predicted hallucination probabilities and the human-annotated

Lang	Id	Metrics	
		IoU	Cor
AR	XGBOD	0.2138	0.3844
	Baseline	0.0001	0.2235
DE	XGBOD	0.2522	0.2763
	Baseline	0.2716	0.1288
EN	XGBOD	0.1325	0.2751
	Baseline	0.0802	0.3061
ES	XGBOD	0.1341	0.3642
	Baseline	0.0715	0.0774
FI	XGBOD	0.3996	0.3432
	Baseline	0.0843	0.2625
FR	XGBOD	0.4164	0.3990
	Baseline	0.1130	0.0911
HI	XGBOD	0.2586	0.3216
	Baseline	0.2421	0.1452
IT	XGBOD	0.2675	0.4020
	Baseline	0.0010	0.2004
SV	XGBOD	0.1109	0.0668
	Baseline	0.1893	0.1696
ZH	XGBOD	0.2152	0.1119
	Baseline	0.0776	0.1502

Table 2: Comparison of our system and baseline results on the test set (IoU and Cor)

probabilities. For languages like Arabic, Spanish, French, and Italian, our system exhibits higher correlation values. However, for English and Swedish, the baseline shows slightly higher correlation scores, suggesting it might be somewhat better at ranking the likelihood of hallucination at the character level in these languages, even if its span identification (IoU) is weaker.

Considering both IoU and Correlation metrics, our system presents a significant imporvement over the provided baseline, particularly in its ability to better identify hallucination spans (as reflected by the IoU metric) across a wide range of languages. While the baseline shows some comparable results in specific languages in terms of correlation, our anomaly detection approach provides a more robust and generally superior language-agnostic solution for the Mu-SHROOM task, especially for span detection.

6 Conclusion

In this paper, we presented our system for SemEval-2025 Task 3: Mu-SHROOM. Our approach reframes multilingual hallucination span detection as a point-wise anomaly detection problem on LLM output logits, utilizing the XGBOD algorithm (Zhao, 2019). Experimental results demonstrate the effectiveness of this simple yet powerful approach, achieving competitive performance across 14 diverse languages. While our system shows promising results, we acknowledge several limitations and directions for future work. A key limitation is that our point-wise anomaly detection with XGBOD, while effective, does not explicitly model the temporal dependencies within the logit sequence. Furthermore, accurately calculating token offsets proved challenging across diverse models due to varying tokenizer support, sometimes necessitating reliance on less precise string parsing approaches. Future research will explore directly learning from these temporal dependencies by treating logit sequences as time series, potentially using sequence models within frameworks like Ludwig. We are also actively investigating integrating Retrieval-Augmented Generation (RAG) and textual information to provide richer context for hallucination detection. This includes exploring a multimodal approach to leverage diverse data sources. Addressing the inherent data scarcity and the challenges of obtaining consistent human labels across multiple languages and models remains a crucial long-term goal for advancing research in this domain. We believe that further exploration of these directions will lead to more robust and accurate multilingual hallucination detection systems.

Abstract

Emotion detection in text is crucial for various applications, but progress, especially in multi-label scenarios, is often hampered by data scarcity, particularly for low-resource languages like Emakhuwa and Tigrinya. This lack of data limits model performance and generalizability. To address this, the NTA team developed a system for SemEval-2025 Task 11, leveraging data augmentation techniques: swap, deletion, oversampling, emotion-focused synonym insertion and synonym replacement to enhance baseline models for multilingual textual multi-label emotion detection. Our proposed system achieved significantly higher macro F1-scores compared to the baseline across multiple languages, demonstrating a robust approach to tackling data scarcity. This resulted in a 17th place overall ranking on the private leaderboard, and remarkably, we achieved the highest score and became the winner in Tigrinya language, demonstrating the effectiveness of our approach in a low-resource setting.

1 Introduction

Emotions are influential in human interactions because it affects how people relate to each other, communicate, make decisions, and even sustain mental health. Being able to notice and understand emotions expressed in language is particularly important for the development of adaptive human-machine interfaces, AI systems with emotional intelligence, and targeted mental health care though combating depression. While there has been progress in emotion recognition, it is still deficient in most languages such as English, which happens to dominate the world. Leaving the bulk of the world's ethnolinguistic diversity unattended creates gaps that cannot be automatically filled by western emotional understanding. SemEval 2025 Task 11 "Bridging the Gap In Text-Based Emotion Detection"(Muhammad et al., 2025b) attempts to solve this problem using multilanguage emotion recognition for 32 African, Asian and European languages such as Emakhuwa, Amharic, Hausa and Swahili. The task mainly focuses on the recognition of insights emotions , that is, the emotion a listener infers from the speaker's words and takes into consideration the interactions surrounding it. The participants work in three tracks. Track A: Multi-label Emotions, track B: Emotion Intensity, track C: Cross-lingual Emotion Detection. We focus on Track A, Multi-label Emotions. We identify the emotion(s) portrayed by the speaker in the given target text snippet using Transformer models such as DeBERTa, RoBERTa, and mXLM-R, as these are powerful models from different linguistic families. To mitigate the lack of training data, we deploy augmentation strategies such as synonym replacement, deletion of random words, and oversampling for the minority emotion classes. These techniques improve model performance for languages with lower availability of resources. The analysis shows positive changes in macro-F1 scores, demonstrating the benefit of large language models in combination with advanced data for cross-cultural emotion detection. This not only solves the problem of language diversity, but also enhances the availability of emotion-sensitive technologies around the world.

2 Related Work

Emotion detection has evolved rapidly, fueled by transformer models (BERT, RoBERTa) that capture context better than old lexicon-based tools or handcrafted features(Mohammad and Turney, 2013). Multilingual efforts, like XLM-R(Conneau et al., 2020), struggle with low-resource languages—African languages, for instance, still lag despite adaptations like Afro-XLM-R(Alabi et al., 2022a). Adding to the chaos, multi-label emotion tasks require tweaked models to handle overlapping feelings. Data scarcity remains a hurdle.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1795–1801

While methods like EDA(Wei and Zou, 2019) randomly swap or delete words, our hybrid approach blends tailored augmentation with model adjustments, aiming to preserve cultural and linguistic quirks often lost in translation.

3 Shared Task Description

The SemEval-2025 Task 11 focuses on text-based emotion detection, specifically identifying the perceived emotion of a speaker based on a short text snippet. It consists of three tracks, however, we only focus on **Track A: Multi-label Emotion Detection:** Given a target text snippet, predict the perceived emotion(s) of the speaker. Specifically, select whether each of the following emotions apply: joy, sadness, fear, anger, surprise, or disgust. In other words, label the text snippet with: joy (1) or no joy (0), sadness (1) or no sadness (0), anger (1) or no anger (0), surprise (1) or no surprise (0), and disgust (1) or no disgust (0). Note that for some languages such as English, the set perceived emotions includes 5 emotions: joy, sadness, fear, anger, or surprise and does not include disgust. A training dataset with gold emotion labels will be provided for this track. The dataset for this shared task(Muhammad et al., 2025a; Belay et al., 2025) is drawn from five multilingual sources: social media posts, personal narratives, talks/speeches, literary texts, and news data, including both human-written and machine-generated content. This track comprises 28 languages from various countries in Africa, Asia, and Europe, including: Afrikaans (afr), Algerian Arabic (arq), Amharic (amh), Chinese (chn), Emakhuwa (vmw), English (eng), German (deu), Hausa (hau), Hindi (hin), Igbo (ibo), Kinyarwanda (kin), Marathi (mar), Moroccan Arabic (ary), Nigerian Pidgin (pcm), Oromo (orm), Brazilian Portuguese (ptbr), Mozambican Portuguese (ptmz), Romanian (ron), Russian (rus), Somali (som), Latin American Spanish (esp), Sundanese (sun), Swahili (swa), Swedish (swe), Tatar (tat), Tigrinya (tir), Ukrainian (ukr), and Yoruba (yor).

4 System Overview

The architecture of our system is illustrated in **Figure 1**. The pipeline is divided into five main steps: preprocessing, data augmentation, fine-tuning, voting scheme and threshold optimization. The detailed structure of the pipeline is depicted in the following subsections below.

4.1 Preprocessing

The process of preparing data before training improves model results by standardizing and cleaning input data. This research involves executing the following series of preprocessing steps:

1. **Lowercasing:** The text standardization process converts every character to lowercase across all languages to maintain consistency and simplify data complexity. For example: *The Brown Fox* becomes *the brown fox*. By converting all words to lowercase the model learns to recognize words based on their meaning instead of their case.

2. **Whitespace Removal:** We eliminate all unnecessary spaces to maintain uniform spacing throughout the text. The process removes leading and trailing whitespace from the text and merges multiple spaces between words into one space. The removal of excess whitespace guarantees consistent spacing throughout the text which prevents unwanted variations as demonstrated by the transformation of *" Hello world! "* to *"Hello world! "*.

3. **Lexical Normalization:** In English processing we apply lexical normalization as a supplementary preprocessing approach. The process converts non-standard word variations into their standard forms. The process of lexical normalization expands standard English contractions into their complete forms so *you'll* turns into *you will*, *they're* becomes *they are*, and *can't* changes to *cannot*. The text conversion process replaces slang terms and abbreviated codes with their full standard language equivalents like turning *ASAP* into *As Soon As Possible*.

4.2 Data Augmentation

In attempts to train powerful models on languages that have scarce resources, we face issues with general model data quality and paraphrasing context-embedded emotions. Our model incorporates and generalizes four fundamental techniques—swapping, deleting, over-sampling, and emotion specific synonym substitution. In addition, our model uses targeted synonym substitute per sentences for English. We will explain each technique and its motivation in detail as we go along.

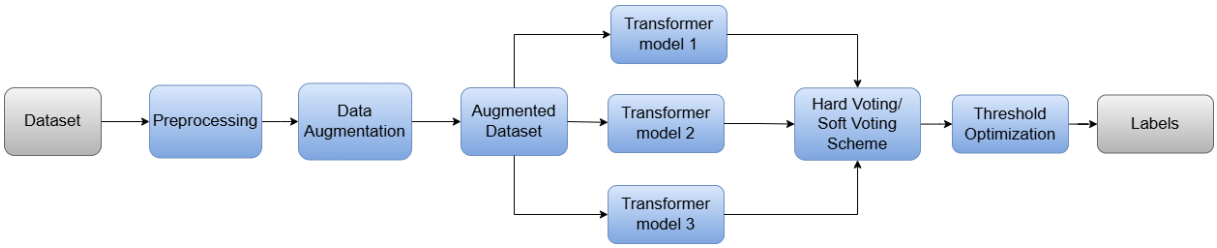

Figure 1: The architecture of the NTA team's system

4.2.1 Swap Augmentation

To address the problem of overreliance on fixed word order snares, we implement stochastic permutations, which consist of random positioning of two words in a sentence. This technique helps the model learn how to capture invariant emotional content regardless of the order of the words. For example, the sentence *"I love this beautiful place"* can be transformed to *"I beautiful this love place"*, thus, testing the ability of the model to discern emotional cues with respect to positional biases.

4.2.2 Deletion Augmentation

In most cases, real-world textual data is filled with noise or missing information. In order to recreate such conditions, we delete phrases within sentences that contain more than three words and this is where we let the model label emotions on its own. One example would be *"The weather is beautiful and sunny today"* being reduced to *"The is beautiful and today,"* and this checks capability of the model to classify accuracy when important words are absent.

4.2.3 Oversampling Augmentation

Oversampling augmentation is how we address class imbalance alongside motivating joint emotion recognition by creating new samples from existing ones. The label for the samples generated is set as the union of original sets of emotions present. For example, the combination of *"This news makes me surprised"* (surprise) and *"What a wonderful day!"* (joy) generates the sentence *"This news makes me surprised. What a wonderful day!"* with a composite label of *surprise + joy*. This technique enhances the model's ability to manage blended emotions simultaneously.

4.2.4 Emotion-Focused Synonym Insertion

To amplify emotional salience, we leverage the NRC Emotion Lexicon (Mohammad and Turney, 2013) to inject emotion-specific synonyms into sentences. For a sample labeled *anger* containing the word *"annoyed"*, we insert terms such as *"furious"* or *"enraged"* from the lexicon. This enriches emotional density without distorting the original sentiment, strengthening the model's grasp of domain-specific vocabulary.

4.2.5 Synonym Replacement

The synonym shifting process done in English is further aided by WordNet (Miller, 1994) allowing for more replacement while also being bound by emotion consistency checks via the NRC Lexicon. Consider, for example, *"I felt ecstatic after the celebration."* This text is transformed into *"I felt elated after the celebration."* Both the meaning and emotion intensity is retained. Such a technique can only be done in English because of the high availability of nuanced synonyms in WordNet that allow for generalization without losing accuracy in labels.
In conclusion, these methods expand the effective training corpus, promote robustness to syntactic variation, and sharpen the model's sensitivity to cross-lingual emotional signals—critical advantages for low-resource language processing.

4.3 Models

Our approach uses DeBERTa-v3, XLNet, and RoBERTa for processing English data. For non-English languages, we assemble an ensemble of multilingual models: mBERT, mXLM-R(for all non-English languages), and AfroXLMR-large (Alabi et al., 2022b) (for African languages). Model selection prioritized the ability to process diverse linguistic data and provide robust performance across a range of language tasks.

4.3.1 DeBERTa

DeBERTa(He et al., 2021) (Decoding-enhanced BERT with Disentangled Attention) is a model opportunity that enhances prorogation BERT and RoBERTa. In addition, it uses a disentangled attention mechanism whereby content and position addition are done separately. Thus, DeBERTa is

superior because it has successfully proven to clarify the interaction between position and content of tokens in several NLP tasks.

4.3.2 RoBERTa

RoBERTa (Robustly Optimized BERT Approach) refines BERT's architecture by training more extensively on a larger dataset and removing the next-sentence prediction mechanism, focusing solely on more robust language modeling tasks. This model has proven effective due to its optimized training approach and larger training corpus.

4.3.3 XLNet

XLNet(Yang et al., 2020) integrates Transformer-XL principles into a generalized autoregressive pre-training method. It outperforms BERT by learning on all possible permutations of the input sequence words, thus capturing a broader context and understanding the extended dependencies in text.

4.3.4 Multilingual Models

For tasks involving languages other than English, we harness the power of multilingual models:

- **mBERT**(Pires et al., 2019) (Multilingual BERT) is pretrained on a large corpus comprising text from 104 languages, which supports its capacity to understand and process multiple languages effectively.
- **mXLM-R** (XLM-RoBERTa) extends the capabilities of XLM models by training on an even more extensive multilingual dataset, further improving its effectiveness in cross-lingual settings.
- **AfroXLMR-large** was created by MLM adaptation of XLM-R-large model on 17 African languages (Afrikaans, Amharic, Hausa, Igbo, Malagasy, Chichewa, Oromo, Nigerian-Pidgin, Kinyarwanda, Kirundi, Shona, Somali, Sesotho, Swahili, isiXhosa, Yoruba, and isiZulu) covering the major African language families and 3 high-resource languages (Arabic, French, and English).

These models are pivotal in ensuring that our NLP solutions are not only efficient but also universally applicable across different linguistic backgrounds.

4.4 Ensemble Model

We experiment with two ensemble methods:

- **Soft-Voting:** Averages the prediction probabilities from each component model and selects the label with the highest average probability as the final output.
- **Hard-Voting:** Chooses the most frequently predicted label by the component models as the final output, applying a majority vote rule.

We use Hard-Voting for English and African languages and Soft-Voting for all other languages because Hard-Voting requires at least three models.

4.5 Threshold Optimization

The output logits of models are converted to probabilities using the sigmoid function. We adjust the threshold t for classification:

1. Iterate through potential threshold values from 0.40 to 0.60.
2. Compute the Binary Cross-Entropy loss for each threshold on the validation set.
3. Select the threshold t that minimizes the loss, optimizing the model's predictive accuracy.

This approach allows for fine-tuning the models to achieve optimal performance across diverse linguistic datasets and tasks.

5 Experimental Setup

- **Data and Pre-processing:** In our experiments, we utilize the training dataset provided by the organizers. We shuffle the data with a fixed random seed (42) and split it into training and validation subsets in an 80:20 ratio. This ensures a consistent and reproducible way to evaluate model performance throughout the development process.
- **Configuration Settings:** We implemented our models using the Trainer API from the Hugging Face library(Wolf et al., 2020) with the following hyperparameter settings:
  - **Learning rate**: 2e-5
  - **Optimizer**: AdamW with cosine learning rate scheduler
  - **Number of epochs**: 20
  - **Early stopping**: EarlyStoppingCallback with a patience of 3

6 Results

We present our results in two subsections. The first subsection compares results with and without augmentation, and the second compares official results and the SemEval Baseline.

6.1 Comparison of Augmented and Non-Augmented Results

The comparison of overall augmented and non-augmented results is shown in Table 1 (for the detailed results in each language, see appendix A). The augmented results achieve a better F1-Score in 21 out of 28 languages, and in the overall results, compared to the non-augmented results. These results prove that augmentation helps to increase the performance of the system, especially in low-resource languages.

Table 1: Comparison of Overall Augmented and Non-Augmented Results

Approach	F1-Score
Non-Augmented approach	0.4965
Augmented approach	0.5233
Comparison	+0.0267

6.2 Comparison of Official Results and SemEval Baseline

The official results are presented in Table 2. Our system achieves better results for the following languages: afr, amh, arq, chn, eng, hau, orm, som, sun, swe, tat, tir, vmw, and yor, compared to the SemEval baseline. Unfortunately, for the remaining languages, our system's performance was not as effective. We realized that this difference in performance is likely due to resource availability. For under-resourced languages, our augmentation learning helped the system improve performance, surpassing the baseline, remarkably, we achieved the highest score and became the winner in Tigrinya language, demonstrating the effectiveness of our approach in a low-resource setting. However, for rich-resourced languages, our augmentation learning did not significantly improve performance, and our model's performance was not as strong as the baseline's. Consequently, our results were lower than the baseline results.

Table 2: Our system's performance on private test sets

Language	F1-Score	SemEval Baseline
afr	**0.4073**	0.3714
amh	**0.6719**	0.6383
arq	**0.5063**	0.4141
ary	0.249	**0.4716**
chn	**0.5944**	0.5308
deu	0.5713	**0.6423**
eng	**0.761**	0.7083
esp	0.7528	**0.7744**
hau	**0.6783**	0.5955
hin	0.8367	**0.8551**
ibo	0.4703	**0.479**
kin	0.3798	**0.4629**

yor	**0.2188**	0.0922
Overall	**0.5233**	0.5093

7 Conclusion

In this study, we have taken on the dual challenge of multilingual emotion detection with multiple labels, specifically narrowing our focus on under-resourced languages. The hybrid approach that combined targeted data augmentation with language-specific model ensembles was found to be an effective approach, preventing further bias by the depletion of the data. The hybrid approach integrated lexical normalization, emotion-enriched synonym expansion, and adaptive threshold optimization, securing robust performance across various languages. Our system's performance beat the baseline in many languages and in overall. However, it is necessary to improve the performance in some languages. In future work, we plan to experiment more models and more augmentation techniques to increase the system's performance.

Deerlu at SemEval-2025 Task 2: Wikidata-Driven Entity-Aware Translation: Boosting LLMs with External Knowledge

Lu Xu
Sapienza NLP Group, Sapienza University of Rome
xu@diag.uniroma1.it

Abstract

This paper presents an entity-aware machine translation system that significantly improves named entity translation by integrating external knowledge from Wikidata with Large Language Models (LLMs). While LLMs demonstrate strong general translation capabilities, they struggle with named entities that require specific cultural or domain knowledge. We address this challenge through two approaches: retrieving multilingual entity representations using gold Wikidata IDs, and employing Relik, an information extraction tool, to automatically detect and link entities without gold annotations. Experiments across multiple language pairs show our system outperforms baselines by up to 63 percentage points in entity translation accuracy (m-ETA) while maintaining high overall translation quality. Our approach ranked 3rd overall and 1st among non-finetuned systems on the SemEval-2025 Task 2 leaderboard. Additionally, we introduced language-specific post-processing further enhances performance, particularly for Traditional Chinese translations.

1 Introduction

Machine translation (MT) has witnessed remarkable advancements in recent years, largely driven by neural approaches and, more recently, large language models (LLMs). Despite these improvements, the accurate translation of named entities remains a significant challenge.

Named entities—proper names referring to people, famous landmarks, and cultural artifacts, which often require specialized handling that goes beyond standard translation procedures. The challenge of named entity translation is multifaceted. Many entities demand specific localized forms in the target language (e.g., country names, famous landmarks). Some entities, particularly those relating to cultural artifacts like books, movies, and products, may have official translations or established conventions in target languages that must be adhered to for accurate communication.

Traditional MT systems typically struggle with named entities for several reasons. First, named entities are often rare in training data, leading to poor representation in the model's parameters. Second, ambiguity in entity references frequently requires contextual or world knowledge to resolve correctly. Third, domain-specific or culturally-specific entities demand specialized knowledge that general MT systems may lack.

These challenges become even more pronounced when translating between languages with different writing systems or culturally distant contexts. For instance, translating English entity names into languages like Chinese, Japanese, or Arabic involves not just semantic transfer but also phonetic adaptation and cultural localization.

To address these challenges, we explore how LLMs can be enhanced with external knowledge to better handle these challenging cases. Our approaches leverage Wikidata as an external knowledge source and demonstrate significant improvements in both entity translation accuracy and overall translation quality. Our main contributions are as follows:

- We establish baseline performance for entity-aware translation using state-of-the-art LLMs (Qwen-Plus, Qwen-Max, and GPT-4o-mini) with simple prompting strategies
- We propose a novel approach using gold Wikidata ID to retrieve multilingual entity information before translation, and leverage these information to guide the translation
- We develop a more practical approach using Relik (Orlando et al., 2024), an information extraction tool, to automatically identify entities and retrieve their multilingual represen-

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1802–1809

tations without relying on gold entity annotations

- We implement language-specific post-processing techniques to address issues such as simplified/traditional Chinese character conversion

2 Related Work

The challenge of translating named entities has been a longstanding issue in machine translation research. Our work addresses the task introduced by (Conia et al., 2025) in SemEval-2025 Task 2, which highlights the limitations of existing translation models in handling named entities that require more than literal translation.

Previous work by (Conia et al., 2024) established the foundation for this task by demonstrating the effectiveness of retrieval-augmented generation (RAG) from multilingual knowledge graphs. While (Zhao et al., 2020) showed promising results with knowledge-enhanced translation in the biomedical domain, such approaches often struggle to generalize beyond specific domains to broader translation scenarios.

The recent emergence of LLM offers a potential solution to these generalization challenges. (Zhu et al., 2024) demonstrated impressive zero-shot translation abilities with LLMs, while (Zhang et al., 2023) and (Guo et al., 2024) explored various prompting strategies to enhance their translation quality. These models show particular promise for low-resource language pairs (Dai et al., 2025) and challenging linguistic phenomena (Nicholas and Bhatia, 2023). Despite these advances, (Guerreiro et al., 2023) identified that LLMs remain prone to hallucinations when translating entities they have limited knowledge of, highlighting the need for augmentation with external knowledge sources.

To effectively integrate external knowledge, robust entity recognition and linking capabilities are essential. Existing systems like BLINK (Wu et al., 2020), GENRE (De Cao et al., 2020), and cross-lingual approaches (Botha et al., 2020) provide valuable capabilities but often require significant computational resources. Our work overcomes these constraints by leveraging ReLiK (Orlando et al., 2024), which provide en efficient method for identifying entities in text and connecting them to knowledge graph entries.

Our work builds upon these foundations, combining the strengths of LLMs with external knowledge retrieval to address the specific challenges of entity-aware machine translation. By leveraging tools like ReLiK for entity detection and Wikidata for multilingual entity information, we create a system that significantly improves named entity translation.

3 System Description

This section describes our entity-aware machine translation approach, which enhances LLMs with external knowledge to improve translation of sentences containing named entities.

3.1 Baseline Systems

We conducted experiments using three pre-trained LLMs: Qwen-plus, Qwen-max, and GPT-4o-mini. Our initial baseline used minimal prompting, instructing the model to translate from source to target language with a simple system prompt without any inspiration of entity information.

In particular, we noticed that the dataset we are worked with is composed of questions, so we implemented a second baseline with a more explicit prompt to address cases where models attempted to answer questions rather than translate them. This explicit identification of the sentence improved task adherence but did not resolve the fundamental challenge of entity translation.

3.2 Entity-Enhanced Translation

To overcome the limitations in entity translation, we developed two approaches that incorporate external knowledge:

Gold Entity Knowledge Integration. Our first approach leverages gold Wikidata IDs provided in the dataset. First we query the Wikidata API to retrieve entity names in both source and target languages, and enhance the translation prompt by including these entity mappings. Then let LLMs translate sentences with explicit knowledge of the correct entity representations. This approach significantly improves translation accuracy and overall translation quality.

Automatic Entity Detection and Knowledge Retrieval. However, gold entity annotations are impractical in real-world scenarios, so we further developed an approach free the system from gold entity annotations. We employ *Relik* (Orlando et al., 2024), an information extraction tool, to identify potential named entities in the source text. For each detected entity, we query Wikidata to retrieve

corresponding entity names in both source and target languages. These automatically retrieved entity mappings are integrated into the translation prompt to guide LLMs during the translation process. While this approach does not achieve the same level of accuracy as using gold entity data, it significantly outperforms baselines and represents a practical solution for real-world applications.

3.3 Post-Processing for Language-Specific Challenges

For Traditional Chinese (zh-TW) translations, we implemented a targeted post-processing step using the *zhconv* tool to convert any Simplified Chinese characters in the output to Traditional Chinese. This addresses the common issue where LLMs produce mixed character sets despite instructions to use Traditional Chinese.

3.4 System Components

Our entity-aware translation system integrates the following key components:

- Pre-trained LLMs: Qwen-plus, Qwen-max, and GPT-4o-mini
- *Relik* for entity extraction and linking to Wikidata
- Wikidata API for cross-lingual entity name retrieval
- *zhconv* for Traditional Chinese character conversion

The prompt templates and detailed examples of entity-enhanced prompts are provided in the Appendix. We proposed a novel approach to integrating external knowledge into LLM-based translation, specifically targeting the challenging problem of entity translation across languages.

4 Results and Analysis

In this section, we present our experimental results on the entity-aware machine translation task, comparing our system against baselines and analyzing factors affecting translation quality and entity handling across different settings.

4.1 Main Results

Table 1 summarizes the performance of our systems evaluated on m-ETA (entity translation accuracy), COMET (Rei et al., 2020) (overall translation quality), and the overall score (harmonic mean of m-ETA and COMET).

	Average across all languages		
System	**M-ETA**	**COMET**	**Overall**
GPT-4o-mini	0.317	0.903	0.469
GPT-4o-mini-relik	0.724	0.931	0.815
GPT-4o-mini-gold	0.851	0.943	0.895
Qwen-plus	0.257	0.879	0.398
Qwen-plus-relik	0.728	0.922	0.814
Qwen-plus-gold	0.880	0.940	0.909
Qwen-max-relik	0.713	0.928	0.806
Qwen-max-gold	0.883	0.947	0.914
Our system-relik	0.714	0.928	0.807
Our system-gold	**0.890**	**0.948**	**0.917**

Table 1: Performance comparison of different system configurations on the entity-aware translation task. Systems with "-relik" use automatic entity detection, while "-gold" systems use gold Wikidata entity information.

Our experiments reveal a clear performance gap between baseline LLMs without entity knowledge and our enhanced approaches. Without external entity information, models like GPT-4o-mini and Qwen-plus achieve m-ETA scores of only 0.317 and 0.257 respectively, confirming the difficulty LLMs face in correctly translating named entities using only their parametric knowledge.

Adding gold Wikidata entity information dramatically improves performance, with m-ETA scores increasing by approximately 60 percentage points across all models. More importantly, our Relik-based approach, which automatically identifies entities without relying on gold annotations, achieves m-ETA scores of 0.714-0.728, representing a practical solution for real-world scenarios.

Table 2 compares our systems with top performers on the SemEval leaderboard. Our gold-enhanced system ranked 3rd overall and achieved the highest COMET score (94.76%) among all non-finetuned systems. Notably, while not officially submitted, our Relik-based system (71.35% m-ETA, 92.82% COMET) would have outperformed the best non-gold and non-finetuned system on the leaderboard, demonstrating the effectiveness of our approach in practical scenarios.

4.2 Impact of Entity Knowledge Integration

To understand how different levels of entity information affect translation quality, we conducted a controlled experiment using GPT-4o-mini across ten language pairs. We compared three conditions: (1) no external entity information, (2) source language entity information only, and (3) complete entity information for both source and target lan-

System	Uses Gold	Finetuned	LLM Name	m-ETA	COMET	Overall score	Rank
Top System	Yes	Yes	Qwen2.5	89.10%	94.74%	91.79%	1
Top Non-gold System	No	Yes	GPT-4o-mini	77.13%	91.81%	83.63%	17
Top Non-gold & Non-finetuned System	No	No	Qwen2.5	68.24%	91.64%	78.17%	19
Ours-Gold(Top Non-finetuned System)	Yes	No	Qwen2.5-max	88.95%	**94.76%**	91.74%	3
Ours-Relik	No	No	Qwen2.5-max	71.35%	92.82%	80.68%	-

Table 2: Comparison with top systems on the SemEval-2025 Task 2 leaderboard. Our Relik-based system was not submitted to the official leaderboard.

Language	w/o Info	Source Info	Full Info
EN-ZH	32.44%	33.30%	64.61%
EN-AR	25.53%	25.45%	91.18%
EN-DE	35.11%	35.57%	84.97%
EN-IT	36.19%	38.21%	91.72%
EN-JA	31.42%	33.48%	87.43%
EN-KO	30.76%	29.59%	86.32%
EN-ES	42.19%	45.05%	89.68%
EN-TH	13.05%	12.97%	89.79%
EN-TR	35.03%	35.14%	75.45%
EN-FR	34.86%	37.44%	89.53%
Average	31.66%	32.62%	85.07%

Table 3: Entity translation accuracy (m-ETA) with varying levels of external entity information across language pairs. Language codes: Chinese (ZH), Arabic (AR), German (DE), Italian (IT), Japanese (JA), Korean (KO), Spanish (ES), Thai (TH), Turkish (TR), and French (FR).

guages.

As shown in Table 3, providing only source language entity information yields minimal improvement (31.66% to 32.62% on average), suggesting that recognizing the entity alone is insufficient. The model requires the target language entity information to perform accurate translation. When complete entity information is provided, performance improves dramatically across all language pairs, with an average increase of over 53 percentage points.

This pattern is particularly striking for language pairs with significant linguistic distance from English. For Thai, m-ETA increases from 13.05% to 89.79% when complete entity information is provided, highlighting how critical external knowledge is for translating entities into languages with different writing systems or cultural contexts.

4.3 Handling Traditional Chinese

For Chinese translations, we observed that models frequently produced a mixture of Simplified and Traditional Chinese characters despite explicit instructions to generate Traditional Chinese. This inconsistency significantly affected evaluation metrics when comparing against gold Traditional Chinese references.

Table 4 demonstrates the effectiveness of our post-processing approach using the *zhconv* tool. This simple yet effective step improved m-ETA scores by approximately 6-16 percentage points across all models, with the most significant improvement seen in GPT-4o-mini (from 64.61% to 80.64%).

Interestingly, we also observed that without additional entity information but with the same post-processing step, LLMs generally performed better when asked to translate into Simplified Chinese rather than Traditional Chinese, suggesting a potential bias in model training toward more widely used character sets.

Systems	w/o zhconv	w zhconv
GPT-4o-mini	64.61%	80.64%
Qwen2.5-plus	73.93%	80.51%
Qwen2.5-max	74.78%	80.76%

Table 4: Impact of post-processing to convert Simplified to Traditional Chinese on m-ETA scores.

4.4 Additional Findings

Our experiments revealed several additional insights about entity-aware translation:

Impact on Low-Resource Languages The benefits of entity knowledge integration are particularly pronounced for low-resource languages. For instance, Thai showed one of the most dramatic improvements (13.05% to 89.79%) when complete entity information was provided. Similar trend can

be find in Korean. Due to the scarcity of data, LLMs struggled more with low-resource languages when no entity information was provided. However, when we retrieved entity information using Relik or gold annotations and provided entity information to the model, the performance improved significantly. In some cases, the performance for low-resource languages surpassed that of rich-resource languages like German, as shown in Table 3.This suggests that external knowledge can effectively compensate for limited training data in the model's parameters.

Task Comprehension Given that all sentences in the dataset are questions, we found that explicitly indicating the sentence to be translated in the prompt improved model performance. Without this specification, models occasionally attempted to answer the question rather than translate it, particularly in baseline configurations.

Prompt Language We explored whether prompting in the target language rather than English would improve performance. Results showed minimal and inconsistent effects across language pairs, suggesting that the availability of external entity knowledge is a much stronger determinant of performance than the language of instruction.

These findings collectively underscore the importance of external knowledge integration for entity-aware translation and highlight the effectiveness of our proposed approaches in addressing this challenging aspect of machine translation.

5 Conclusion

We introduced an entity-aware machine translation system that improves the translation of named entities by integrating external knowledge from Wikidata. Using gold Wikidata IDs or the Relik tool for automatic entity extraction, our approach outperforms baseline models and ranks highly on the official leaderboard. This demonstrates the effectiveness of incorporating external knowledge to address the limitations of LLMs in handling named entities during translation tasks.

This paper presented an effective approach to entity-aware machine translation by enhancing LLMs with external knowledge retrieval. We demonstrated that while state-of-the-art LLMs possess impressive general translation capabilities, they struggle significantly with named entity translation, particularly for culturally-specific entities or those requiring specialized knowledge.

Our experimental results across multiple language pairs confirm that integrating entity knowledge from Wikidata substantially improves both entity translation accuracy and overall translation quality. The gold entity knowledge integration approach achieved near-optimal performance (m-ETA of 89.0%, COMET of 94.8%), ranking among the top systems in the SemEval-2025 Task 2 competition. More importantly, our practical Relik-based approach, which automatically identifies and links entities without requiring gold annotations, achieved competitive results (m-ETA of 71.4%, COMET of 92.8%) while being applicable to real-world translation scenarios.

Analysis of our approach revealed several key insights: (1) providing complete entity information in both source and target languages is crucial for accurate entity translation, (2) automatic entity detection with knowledge retrieval is highly effective for practical applications, and (3) targeted post-processing for specific language challenges, such as Traditional Chinese character conversion, can yield substantial gains.

Our work contributes to the ongoing efforts to make machine translation more reliable for real-world scenarios where accurate handling of named entities is essential for effective cross-cultural communication.

Limitations

While our approach significantly improves entity-aware machine translation, several limitations should be acknowledged:

First, our system's effectiveness is contingent upon the quality and coverage of Wikidata. For low-resource languages or specialized domains, Wikidata may lack comprehensive entity information or accurate translations. Furthermore, as a dynamic knowledge source that undergoes frequent updates, Wikidata's evolving nature may lead to inconsistent translations of certain entities over time, potentially affecting reproducibility.

Second, the Relik-based approach, though effective in practical scenarios, introduces potential error propagation. Inaccuracies in entity detection or linking to incorrect Wikidata entries directly impact translation quality. Our analysis shows that approximately 15-20% of translation errors with the Relik approach stem from entity linking failures rather than translation model limitations, detailed

analysis can be find in Appendix.

Third, our post-processing solutions, such as Chinese script conversion, introduce language-specific complexity that doesn't generalize well across all language pairs. This approach requires maintaining separate conversion pipelines for different writing systems, increasing implementation complexity.

Finally, despite strong performance, our approach still requires multiple API calls to external services for each sentence containing entities, introducing latency that may be problematic for real-time applications or high-volume translation services.

A Appendix A

A.1 Prompt Templates

This appendix provides the prompt templates used in our experiments and examples of how they are implemented for specific translation tasks.

A.1.1 Basic Baseline Prompt

Prompt-0 `You are an expert translator. Translate from {SOURCE_LANGUAGE} to {target_language}.`

Only provide the translation without explanations.
{sentence}

A.1.2 Enhanced Baseline Prompt (Explicitly Identifying the Sentence)

Prompt-1 You are an expert translator. Translate from {SOURCE_LANGUAGE} to {target_language}.
Only provide the translation without explanations.
The sentence is: {sentence}

A.1.3 Source Only Entity-Enhanced Prompts

Prompt-2 You are an expert translator. Translate from {SOURCE_LANGUAGE} to {target_language}.
Only provide the translation without explanations.
The sentence contains an entity, and its mention is provided.
If the mention is 'Label not found', translate the entire sentence on your own.
The sentence is: {source_text}
The mention is {source_title}

A.1.4 Full Entity-Enhanced Prompts

Prompt-3 You are an expert translator. Translate from {SOURCE_LANGUAGE} to {target_language}.
Only provide the translation without explanations.
The sentence contains an entity. The entity name is specified in both the source and target languages. When you translate the sentence, please use the specified mention in the target language.
If the mention is 'Label not found', translate it it by yourself.
The sentence is: {source_text}
The entity in {SOURCE_LANGUAGE} is {source_title}, in {target_language} is {target_title}.

A.2 Examples of Language-Specific Prompts

A.2.1 Traditional Chinese Prompt

Prompt-4-zh 您是翻譯專家。英譯漢（繁體）。只翻譯譯文，不做解釋。
句子中存在實體。實體名稱在源語言和目標語言中均已指定。您翻譯句子時，請使用目標語言中指定的提及。如果目標語言中的提及是'Label not found'，請自行翻譯。
句子：{source_text}
英文中的實體是{source_title}。
中文（繁體）中的實體是{target_title}。

A.2.2 Japanese Prompt

Prompt-4-JA あなたは熟した翻者です。英から日本に翻してください。明はせずに翻のみを翻してください。
文にはエンティティがあります。エンティティ名はソス言とタゲット言の方で指定されています。文を翻するときは、タゲット言で指定された言及を使用してください。タゲット言の言及が「Label not found」の合は、自分で翻してください
文: {source_text}
英のエンティティは {source_title} です。
日本では {target_title} です。

A.2.3 Italian Prompt

Prompt-4-IT Sei un traduttore esperto. Traduci dall'inglese all'italiano. Traduci solo la traduzione senza spiegare.
Ci sono entità nella frase. Il nome dell'entità è specificato sia nella lingua di origine che in quella di destinazione. Quando traduci la frase, usa la menzione specificata nella lingua di destinazione. Se la menzione nella lingua di destinazione è 'Label not found', traducila da solo.
Frase: {source_text} L'entità in inglese è {source_title}.
In italiano è {target_title}.

B Appendix B

B.1 Error Analysis

This appendix presents a detailed error analysis of our system outputs, focusing on Qwen2.5-Max. Through careful examination of translation errors, particularly instances of entity mismatch, we identified three primary error categories:

- **Wikidata-Dataset Misalignment**: Despite using gold Wikidata IDs provided in the dataset, entity name retrieval sometimes produces translations that differ from the gold labels. This discrepancy stems from Wikidata's continual updates since the dataset's creation. For example, the entity "Q1024181" (Pushkin House) returns "普希金屋" in Chinese from

current Wikidata, while the dataset's gold label is "普希金之家"—a subtle but evaluation-affecting difference.

As shown in Table 5, these Wikidata-dataset misalignments result in 10.8% errors on average across languages, with values ranging from 7.34% for Italian to 18.87% for Traditional Chinese. This represents an artificial evaluation penalty rather than a true translation error, as both forms may be valid translations. Further more, we observe that LLMs can fix some small misalignments, because the miss match rate dropped 1% after the LLMs translation.

- **Relik Entity Retrieval Errors**: When using Relik for automatic entity detection, the system occasionally prioritizes prominent entities over the actual target entities. For instance, in "How does Jia Jing contribute to the overall plot of Dream of the Red Chamber?", Relik identifies the famous novel "Dream of the Red Chamber" but misses the character "Jia Jing" (the actual entity of interest).

  This entity retrieval error challenge affects approximately 19.94% target labels are miss match to the dataset label, as shown in Table 5.

- **Missing Target Language Labels**: In some cases, Wikidata lacks a corresponding entity name in the target language. When this occurs, the system passes "Label not found" as the target label, leading to two typical outcomes: (1) the model produces a translation that mismatches the gold label, or (2) the model retains the source language entity name untranslated.

  As indicated in Table 5, when gold information provided, there is less than 1% instance missing target language labels, when retrive entity information uesing Relik, there is 11.93% instance missing target language labels.

Table 5 presents the miss match rate that due to these error categories across language pairs. Our analysis reveals substantial variation across languages, reflecting different challenges in entity handling for each language pair.

Additionally, we compared the performance between our gold entity system and Relik-based system. As shown in Table 6, the Relik-based system exhibits notably higher error rates across all language pairs, with an average difference of 16.93 percentage points. This gap demonstrates the significant impact of accurate entity identification on translation quality. It also illustrates the error propagation from entity linking to the final translation results.

Language	Gold Mismatch	Relik Errors	Missing Labels
EN-AR	8.23%	16.14%	11.08%

Abstract

This paper introduces a system designed for SemEval-2025 Task 3: Mu-SHROOM, which focuses on detecting hallucinations in multilingual outputs generated by large language models (LLMs). Our approach leverages the collective intelligence of multiple LLMs by prompting several models with three distinct prompts to annotate hallucinations. These individual annotations are then merged to create a comprehensive probabilistic annotation. The proposed system demonstrates strong performance, achieving high accuracy in span detection and strong correlation between predicted probabilities and ground truth annotations.

1 Introduction

Hallucinations in large language models (LLMs) are a widely-known problem critical for their trustworthiness (Hong et al., 2024; Mitrović et al., 2024). The detection of hallucinations presents a challenge due to the absence of a standardized definition (Venkit et al., 2024; Mishra et al., 2024). Moreover, different LLMs may identify different parts of the same text as hallucinations and in general, different LLMs have different hallucination rates[1](Mishra et al., 2024). Furthermore, despite some on-going research, hallucinations are still not very well explored in multilingual setups (Zhang et al., 2023; Xu et al., 2024).

In order to contribute to the research on multilingual and multimodel hallucinations, Mu-SHROOM ("Multilingual Shared-task on Hallucinations and Related Observable Overgeneration Mistakes") (Vázquez et al., 2025), a SemEval-2025 Task-3, was proposed. The task focuses on detection of hallucination spans in the outputs of instruction-tuned publicly available LLMs, covering 14 different languages: modern standard Arabic (AR), Basque (BA), Catalan (CA), Chinese Mandarin (ZH), Czech (CS), English (EN), Farsi (FA), Finnish (FI), French (FR), German (DE), Hindi (HI), Italian (IT), Spanish (ES), and Swedish (SV). The dataset is divided into validation (labelled), train and test (both unlabelled) sets (for details see Appendix, Table 7). Each data instance consists of model input (question), information about question language and model used, and model output (LLM answer) (see Fig. 1). Validation data additionally contains the list of soft and hard labels while train and test data contain, instead, list of model tokens and logits. Soft labels represents a list of hallucination spans, denoting the index of the starting and end-

Example 1
INPUT: When did Karen Percy become a Member of the Order of Canada?
OUTPUT: Karen Elizabeth Perky was made a member of Order in Canada on December 10, 2018 .

Example 2
INPUT: What was the population of Labalme, France in 1982?
OUTPUT: Inhabitants of the commune Labal e me in 1984 were 1,976 .

Example 3
INPUT: How many people were living in Valeille in 2020?
OUTPUT: In 2020, Valeille s had a population of 2,961 .

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1810–1827

ing character and the hallucination probability of each span. Hard labels are obtained by removing spans from soft labels with hallucination probability ≤ 0.5. Based on these, official task evaluation metrics were defined. One is intersection-over-union (*IoU*) of characters marked as hallucinations in the ground truth versus predicted. Another is character-level correlation (*corr*) of the empirical probabilities observed by annotators (ground truth) and the predicted probability.

We utilized two distinct approaches, referred to as System 1 (S1) and System 2 (S2), which rely on in-context learning, exploiting different prompts and underlying (mostly proprietary) models. While S1 serves as a simple baseline, with S2 we additionally aimed to harness the knowledge of different models in an ensemble-like manner, hoping that their collective intelligence would help mitigate occasional suboptimal outputs from individual models. In this context, collective intelligence refers to the emergent consistency and insight gained by combining outputs from multiple LLMs and prompt variations. Rather than relying on a single model, we leverage the diversity and statistical significance of responses to identify patterns, disagreements, and potential hallucinations. By analyzing the agreement between models and correlating it with human annotations, we explore whether this collective signal can approximate human judgment. This approach allows us to investigate how aggregated model outputs can enhance hallucination detection with respect to their correlation to human annotations.

In the remaining of the paper, due to space limitations, we mainly focus on our best performing approach S2[2], which in the official IoU ranking scored 4^{th} and 5^{th} for FR and IT, respectively, but we also provide some details on S1 in the Appendix. The ensemble strategy performs particularly well for *corr* metric (it ranked 1^{st}, 3^{rd} and 4^{th} for EN, DE and FR, respectively), but we have identified, as well, some particularly performative models and prompts for *IoU*. We provide a detailed analysis of considered closed-weight large language models' performance.

2 Related Work

This Mu-SHROOM task builds upon Semeval 2024 monolingual SHROOM task 6 (Mickus et al., 2024), which comprised three NLG tasks divided in two streams (model-agnostic vs. model-aware) but was scoped less ambitiously: participants were supposed to *only* perform binary classification to identify hallucinations, without indicating hallucination spans. Nevertheless, some ideas from 2024 edition's winning approaches were inspirational for us. In particular, we noticed that 4 out of 6 best approaches were reporting excellent results using closed-weight models (Mehta et al., 2024; Obiso et al., 2024; Liu et al., 2024; Allen et al., 2024) as well as that high performance is not readily achieved with off-the-shelf LLMs and systems (Mehta et al., 2024; Belikova and Kosenko, 2024). In particular, the best performing model (Mehta et al., 2024) resorted to a meta-regressor framework aggregating uncertainty signals from multiple LLMs, which was the motivation for models' output merging in our S2. Moreover, we draw inspiration from direct prompting strategies which have already been explored to evaluate factual consistency (Chen et al., 2023), assess the self-alignment capabilities of LLMs with respect to factuality (Zhang et al., 2024), and detect confabulations, a specific subclass of hallucinations, by eliciting multiple candidate responses (Farquhar et al., 2024; Verspoor, 2024).

3 Challenges Related to Ground Truth Annotations

We observed that the ground truth annotations for EN lack consistency: the characters included in the span of the same hallucination type differ from sentence to sentence. For example, in some cases where the names of the places used in the question were misspelled in the model outputs, ground truth annotates complete name as a hallucination (see Ex. 2 in Figure 1) while in others, only the added character ('s' in Ex. 3 in Figure 1) was annotated as such. Some other languages (e.g. IT) did not have this type of issues (or had very few which, however, have not influenced annotations).

4 System Overview

In order to facilitate the readability of our article, we use abbreviations to designate the LLMs employed (see Appendix B.1 for the list of exploited LLMs and their respective abbreviations).

Our systems have been evaluated only on the languages included in the validation set.

[2]Our code and data is available at: https://github.com/IDSIA-NLP/mushroom/

4.1 System 1 (S1) Description

As a reference system, we perform a few-shot prompting on test data for our languages of interest. More precisely, we use 3 random examples from validation data per language to perform prompting on test data. We limit ourselves to only two models, *g3.5* and *haiku-3*. For Chinese, we used *haiku-3* since *g3.5* was causing issues due to long contexts. For other languages, we noticed that *g3.5* is performing much better than *haiku-3*.

4.2 System 2 (S2) Description

In S2, we explore the capabilities of hallucination detection of the state-of-the-art service LLMs for in-context few-shot learning. Our approach simulates the original annotation process using multiple artificial annotators, each instantiated through a different LLM service combined with varying prompts. The outputs of these artificial annotators are then aggregated into a single probabilistic annotation.

To construct a diverse set of artificial annotations, we employ six different LLMs and three distinct prompting strategies, resulting in a total of 18 unique model-prompt combinations. Each model is accessed via its respective API, ensuring consistency in inference settings. The exact model identifiers are provided in Appendix B.1.

To facilitate in-context few-shot learning, we randomly select language-specific examples from the evaluation dataset. Furthermore, each example must contain at least three annotated hallucinations based on hard labels. This ensures that the models are exposed to relevant patterns in hallucination annotation.

For annotation, the models are prompted to mark hallucinations using an inline XML format with the tags "$<h>$" and "$</h>$". The provided examples are formatted in the same style to maintain consistency in the learning process.

We used the following three prompting strategies:

- Prompt V1: A general prompt with a short task description (with 2 in-context examples)
- Prompt V2: A detailed task explanation incorporating chain-of-thought reasoning (with 1 in-context example)
- Prompt V3: A general prompt with an explicit instruction to be highly sensitive to hallucinations, marking spans even if there is only a low probability (with 2 in-context examples)

Once the models generate annotations, we convert the inline XML hallucination tags into offset-based annotations. A predicted hallucination span is considered valid only if it exactly matches the corresponding portion of the original text; otherwise, it is discarded.

After collecting annotations from all artificial annotators, we aggregate them into a single probability-based annotation scheme, producing soft labels that quantify confidence in each hallucination span. First we normalize the character-level spans by extracting and sorting hallucination span boundaries predicted by different models, and pairing adjacent boundaries to define sub-spans, forming continuous intervals that maintain character-level consistency. Next, we compute for each sub-span the probability of it being a hallucination as follows:

$$P(H) = \frac{N_H}{N_A}$$

where $P(H)$ is the hallucination probability of a given sub-span. N_H is the number of annotators (LLMs) that marked the sub-span as a hallucination. N_A is the total number of annotators.

Furthermore, we included two merging variations, where we excluded the 3 and 6 worst-performing runs (model + prompt variation) with respect to *corr* score based on the English validation data—denoted as $m_{\setminus 3}$ and $m_{\setminus 6}$, respectively. To ensure diversity, we applied the constraint that at least one run from each model had to be included. This approach aimed to filter out the lowest-performing runs while maintaining variety.

S2 allows for a probabilistic measure of hallucination confidence, simulating the variability and uncertainty inherent in human annotation.

5 Quantitative Findings

We provide simple statistics in Table 1 regarding matched and mismatched annotation spans across data instances. We noticed that these statistics vary from one language to the other. For example, for IT we have 69 out of 150 instances (46%) where S2 and ground truth annotation spans completely match[3], while for EN this percentage decreases to 14.29 and eventually for ZH to only 1.33%.

[3]Note that a single instance can have multiple annotated spans both in S2 and ground truth, hence by overlapping spans we consider both coinciding in span number as well as in the start and ending character of each span.

Lang.	Match(%)		Mismatch(%)	
	full	nosp	S2-nosp	GT-nosp
EN	14.29	1.95	9.09	1.30
FR	6.67	0.00	3.33	0.00
IT	46.00	0.00	3.33	0.00
DE	13.33	1.33	8.67	1.33
FI	11.33	0.00	2.00	0.00
ES	17.11	6.58	6.58	1.97
HI	46.00	0.00	6.00	0.00

Table 2: Detailed results for S2 and different languages showing strategy (single model or merged) and prompt version providing the best IoU score. Ranks in **boldface** are official rankings, while the others represent the ranking that would have been obtained if the results were submitted within the official deadline. * : Details on included models for merging can be seen in Appendix B.2. The BL column presents the results achieved by the best baseline provided by the organizers for each language. For IoU, the baseline is always mark-all.

Additionally, we noticed that for all languages mismatches related to no-spans were far more frequent for the direction when spans were present in ground truth and missing in S2 (*S2-nosp*) than vice versa (*GT-nosp*). However, percentages of *S2-nosp* vary greatly across languages, being the best for FI, then SV, and the worst for EN and ZH. We performed yet another analysis, where together with the ratio of overlapping spans (*ol_spans*) we also looked at the ratio of overlapping characters (*ol_chars*) for each test instance, comparing the S2 annotations with those of ground truth. Comparing inter-quantile ranges (and medians) of *ol_spans* and *ol_chars* distributions (see Figure 2), we can see not only differences in scores between various languages but also that, as expected, reaching span overlap is much harder to achieve than character overlap (the latter also aligns better with *IoU*).

IoU The official rankings of the Mu-SHROOM task were provided only with respect to the *IoU* score. As showcased in the Table 2, S2 scored quite well in the official rankings (**boldface**) for FR and IT, ranking 4^{th} out of 30 teams and 5^{th} out of 28 teams, respectively. In the same table, we provide, as well, post-deadline to-be rankings[4] for other languages, generated using the official Mu-SHROOM evaluation scripts. Looking at model and prompt comparisons, we observe that among single models *g4o* and *sonnet* are consistently outperforming competitors on all languages (see Figure 3) while prompt *v3* among prompts performs the best (see Figure 3, right).

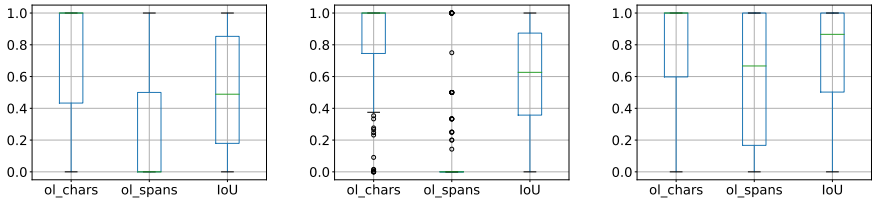
Results for less performing S1 can be seen in Appendix (Table 8).

Corr Our merged configuration demonstrated particular effectiveness in measuring correlation, yielding the best results across all languages, with performance on *corr* surpassing even that of *IoU*. Specifically, the $m_{\setminus 6}$ configuration achieved the highest performance for eight languages, compared to $m_{\setminus 3}$ and m, which were the bests for only one language each. Furthermore, these configurations proved highly effective relative to other teams, allowing us to achieve the best results for three languages (SV, EN, and ES) and rank within the top five for eight out of the ten languages evaluated (see also mean *corr* plots in Appendix D). However, Chinese remains challenging due to annotation difficulties, resulting in a correlation value below 0.5 and performance significantly lower than that of the top-performing teams (ranking 11^{th} out of 20).

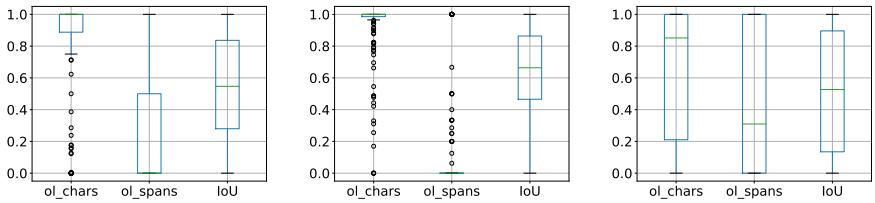
6 Qualitative Analysis

We performed qualitative analysis for IT and FR comparing our best S2 models for these languages with ground truth. Some of the observed patterns in annotation discrepancies between S2 and ground truth are reported in (Table 3 and Appendix Table 9 for IT and FR, respectively). Even though some

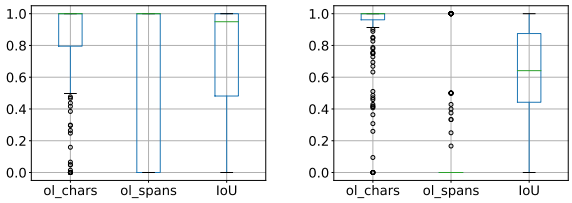
[4]We have not managed to apply our system to all languages during the allotted period for this shared task. Therefore, by "post-deadline to-be rankings" we refer to the rankings which would have been obtained for FI, ES, HI, SV, AR, ZH have we had submitted our system output within the deadline.



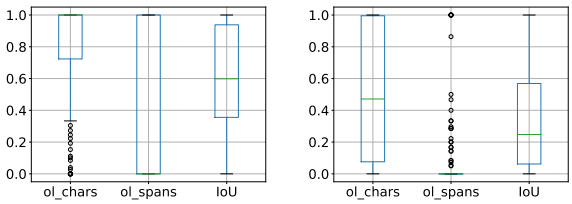
(a) English (b) French (c) Italian



(d) German (e) Finnish (f) Spanish



(g) Hindi (h) Swedish



(i) Arabic (j) Chinese

Figure 2: Boxplots for the ratio of overlapping chars (*ol_chars*), the ratio of overlapping spans (*ol_spans*) and IoU (*IoU*), all calculated on instance-level between S2 and ground truth, per language.

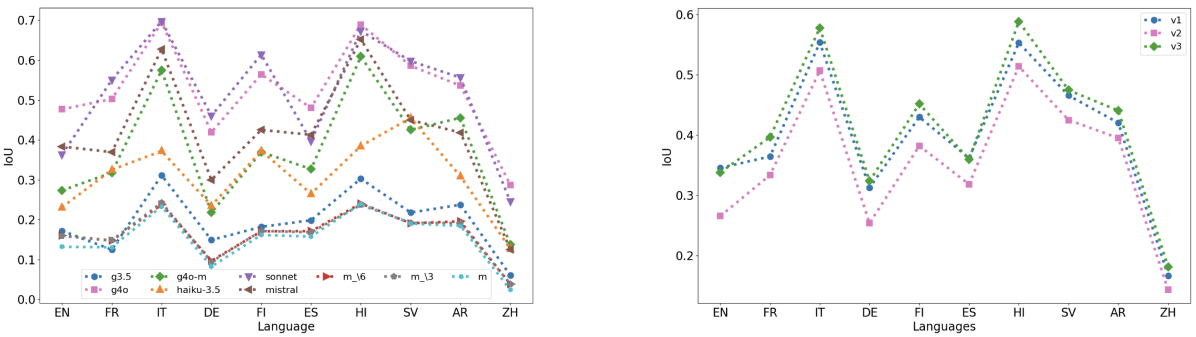


Figure 3: Mean IoU scores by LLM (left) and by version of prompt (right). For the mean by LLM, each model was tested with three versions of the prompt, and the mean IoU score across these versions is reported for each model. For the mean by version, each version of prompt was tested with 6 different LLM, and the mean IoU score across these LLMs is reported for each version.

ID	S2 span(s)	Ground truth span(s)	Comment
1	"nel 1952"	"1952" (1)	S2 involves prepositions and connectors
2	"Jelgava, in Lettonia"	"Jelgava", "Lettonia" (2)	
3	"ottobre del 1991"	"ottobre", "1991" (2)	
4	"Jamie Jones e Sean Tyas"	"Jamie Jones", "Sean Tyas" (2)	
5	"due medaglie d'oro olimpiche nel 1952"	"due", "d'oro", "1952" (3)	S2 encompasses larger context
6	"fu campione panamericano di nuoto"	"panamericano" and "nuoto" (2)	
7	"Neuchâtel, nella regione della Svizzera occidentale"	"Neuchâtel", "Svizzera occidentale"(2)	
8	"5 febbraio 1942"	"5" and "1942"	S2 is less precise than ground truth ("febbraio" and "Mary" are correct)
9	"Dr. Mary Blakiston"	"Blakiston"	
10	"Jomsland, che è un'isola situata nel Mar Baltico"	"Jomsland"	S2 annotates an extra information
11	"100°F (38°C)"	"100°F (38°C"	imperfection of ground truth annotation

Table 3: Some minor problems observed for IT when comparing S2 with ground truth. For ID=10, IoU=0.16.

of these look trivial, their repercussion on the final result can be immense (see ex. 10 in Table 3 for IT). We have also noticed that S2 for IT performs quite well in recognizing named entities (NE) which participate in hallucination spans. On 150 observations, it missed to recognize only 18 NE in 14 different observations compared to ground truth, while it had perfect precision. For FR, S2 was making much more errors for NE. Details about all NE errors of S2 for IT and FR can be seen in the Appendix (Table 10).

INPUT: Chi era raffigurato nel simbolo del partito Fronte Democratico Popolare?

OUTPUT (sonnet): Il simbolo del partito Fronte Democratico Popolare raffigurava la testa di una donna.
OUTPUT (g4o): Il simbolo del partito Fronte Democratico Popolare raffigurava la testa di una donna.
OUTPUT (haiku-3.5 and g3.5): Il simbolo del partito Fronte Democratico Popolare raffigurava la testa di una donna.

Figure 4: An example of how different underlying models lead to different S2 annotations for IT. In red, S2 annotations, top to bottom from best performing (*sonnet* and *g4o*, second best) to worst performing models (*haiku-3.5* and *g3.5*) for IT. Annotation spans are shorter for better performing models.

When comparing different model hallucination annotation, we perceived that models performing worse for IT were tending to annotate more hallucination spans than best performing models (see Figure 4). The contrary of this behavior was noticed for FR. We also noted that observations with shorter length tend to have higher IoU scores. This tendency is particularly pronounced for IT while it is less evident for other languages (see Appendix, Figure 8).

Additionally, Figure 7 in Appendix shows two examples (in IT and FR) of more drastic annotation problems.

6.1 Open-Weight Model Comparison

To assess whether the task could be effectively performed using only Open-Weight LLMs (OWMs), we reused the S2 prompts with a dozen OWMs (for details see Appendix, Table 5).

The results were significantly poorer compared to those obtained with service models. IoU scores were 1.7 to 3.5 times higher for closed-weight models than for OWMs, with a maximum IoU of 0.486 for Italian. Notably, substantial variation was observed across both models and prompts. For each language, the highest IoU scores were consistently achieved by either *ministral-8B* or *mistral-7B*, particularly with the V1 or V3 prompts. Conversely, certain models, like Gemma and Qwen rarely produced annotations.

Correlation measurements, however, exhibited better performance. In all languages, correlations surpassed those obtained by the best baseline models, further supporting the reliability of these metrics. The highest correlations were consistently achieved by a merged model, reinforcing the effectiveness of collective intelligence in addressing the task.

7 Conclusion

This paper outlines our system for Mu-SHROOM, a shared task with key challenges, such as multilingualism, hallucination span detection without annotated training data, inconsistencies in human annotations. Despite all these, our collective intelligence approach exploiting annotation potential of diverse close-weight LLMs and accompanying prompts, demonstrated strong effectiveness, particularly in achieving high correlation with the ground truth annotations. Our future work will focus on investigating noted imbalances varying across different languages and inputs, as well as more refined comparison exploiting the Open-Weight Models.

A Limitations

Our data annotations rely extensively on the output of proprietary large language models (LLMs) accessed via API-based services. These models have a limited lifespan and are frequently updated, deprecated, or replaced on their respective platforms. Consequently, our results are strictly applicable to the specific versions of the LLMs used at the time of annotation and may not generalize to future iterations.

Additionally, due to time constraints, we were unable to submit results for all languages before the official deadline. Instead, we ran our systems after

the deadline and subsequently integrated our results into the official rankings. This approach assumes that the rankings remained stable and that no other teams were in a similar situation. However, it is likely that other teams also faced similar challenges. As a result, the rankings we assigned ourselves may be optimistic, as no other team's score increase placed them above ours in the updated standings.

B Details on used models

B.1 Models used and abbreviations

A list of all the LLMs used and the respective abbreviations we have used to designate them is available in Table 4.

LLM	Abbreviation
gpt-3.5-turbo	g3.5
gpt-4o-2024-08-06	g4o
gpt-4o-mini-2024-07-1	g4o-m
claude-3-haiku-20240307	haiku-3
claude-3-5-haiku-20241022	haiku-3.5
claude-3-5-sonnet-20241022	sonnet
mistral-large	mistral

Table 4: List of used close-weight models and their corresponding abbreviations.

LLM	Abbreviation	Quantization
Llama-3.1-8B-Instruct	Llama-3.1-8B	4Bit QLoRA
Llama-3.2-1B-Instruct	Llama-3.2-1B	-
Llama-3.2-3B-Instruct	Llama-3.2-3B	4Bit QLoRA
Mistral-7B-Instruct-v0.3	mistral-7B	4Bit QLoRA
Ministral-8B-Instruct-2410	ministral-8B	4Bit QLoRA
DeepSeek-R1-Distill-Llama-8B	DS-R1-L	4Bit QLoRA
DeepSeek-R1-Distill-Qwen-1.5B	DS-R1-Q	-
gemma-2-9b-it	gemma-2-9B	4Bit QLoRA
gemma-2-2b-it	gemma-2-2B	-
Qwen2.5-7B-Instruct-1M	Qwen-2.5-7B	4Bit QLoRA
Qwen2.5-1.5B-Instruct	Qwen-2.5-1.5B	-

Table 5: List of Open-Weight Models (OWM) used locally, their corresponding abbreviations and the quantization used for the inference.

B.2 Merged models

This section displays the details for merging approaches used in System 2. Table 6 shows the runs excluded from the merging without the worst performing n ($m_{\setminus n}$) runs, where each run is a combination of a model and prompt version. The performance is measured based on the Corr score and English validation dataset.

S2 $m_{\setminus 3}$	S2 $m_{\setminus 6}$	OWM $m_{\setminus 3}$	OWM $m_{\setminus 6}$
g3.5 – v2	g3.5 – v2	DS-R1-Q – v2	DS-R1-Q – v2
haiku – v2	haiku – v2	Qwen-2.5-7B – v2	Qwen-2.5-7B – v2
sonnet – v2	sonnet – v2	Qwen-2.5-7B – v3	Qwen-2.5-7B – v3
-	haiku – v1	-	gemma-2-2B – v2
-	g3.5 – v1	-	gemma-2-9B – v1
-	g4o-m – v2	-	gemma-2-2B – v3

Table 6: List of the models excluded from the merging without the worst performing n ($m_{\setminus n}$) runs (model – prompt version) with regard to the Corr score for System 2 (S2) and System 2 with Open-Weight Models (OWMs).

C Dataset statistics

Basic statistic of dataset with respect to language and validation/train/test sets is provided in Table 7.

Lang	Validation data					Train data			Test data				
	# inst.	# LLMs	$\bar{m}$ soft sp.	$\bar{m}$ hard sp.	$\bar{m}$ out. len.	# inst.	# LLMs	$\bar{m}$ out. len.	# inst.	# LLMs	$\bar{m}$ soft sp.	$\bar{m}$ hard sp.	$\bar{m}$ out. len.

SV	49	3	6	2	157	-	-	-	147	3	5	2	130
ZH	50	4	49	10	406	200	5	375	150	5	47	11	320

Table 7: Basic statistics showing per language and validation/train/test set: number of instances, number of different models used, average number of soft and hard spans per instance, average model output length (in chars). Average numbers are rounded for better readability. Train data is not labelled, hence information on spans is missing for all languages. Some languages are additionally left out from validation and train data.

D Additional results

System	En	It	Fi	Fr	De	Es	Sv	Ar	Hi	Zh
S1	0.24	0.47	0.50	0.29	0.36	0.25	0.35	0.30	0.45	0.20*

E Prompts

Prompt : System 1

```
You are tasked with identifying and marking hallucinations in the following answers. A hallucination in this context
      refers to an answer that provides incorrect or fabricated information. Your goal is to review each answer
      relative to the question and highlight any incorrect or unsupported parts of the response using an <h> tag at
      the beginning of a span and a </h> tag at the end. If the answer is factually correct, return it without any
      highlighting.

        For each example, provide only the response sentence (R) with the highlighted hallucinations if present. Do
             not provide explanations or commentary.
        Example 1:
        Q: \colorbox{blue_position_prompt}{\{example\_1\_q\}}
        A: \colorbox{blue_position_prompt}{\{example\_1\_a\}}
        R: \colorbox{blue_position_prompt}{\{example\_1\_r\}}

        Example 2:
        Q: \colorbox{blue_position_prompt}{\{example\_2\_q\}}
        A: \colorbox{blue_position_prompt}{\{example\_2\_a\}}
        R: \colorbox{blue_position_prompt}{\{example\_2\_r\}}

        Example 3:
        Q: \colorbox{blue_position_prompt}{\{example\_3\_q\}}
        A: \colorbox{blue_position_prompt}{\{example\_3\_a\}}
        R: \colorbox{blue_position_prompt}{\{example\_3\_r\}}

        New Question and Answer:
        Q: \colorbox{blue_position_prompt}{\{input\_q\}}
        A: \colorbox{blue_position_prompt}{\{input\_a\}}
        R:\\
```

S2 Prompt: V1 - Brief instruction with in-context learning

```
You are tasked with identifying and marking hallucinations in the following large language model (LLM) answers
      . A hallucination in this context refers to an answer that provides incorrect or fabricated information.
       Your goal is to review each LLM answer (provided in <LLM_Answer>[llm_answer]</LLM_Answer>) relative to
      the question (provided in <Question>[question]</Question>) and highlight any incorrect or unsupported
      parts of the response using ***h>** tags. If the answer is factually correct, return it without any
      highlighting.

For each example, provide only the response sentence (R) with the highlighted hallucinations if present. Do
      not provide explanations or commentary. For structured extraction  use the following format/tags for the
       response: <<<START>>>[final_response_with_hallucinations_marked]<<<END>>>

Important: Ensure that the text remains exactly the same length as the original text, don't change any amount
      of whitespace or newline characters. You should only add tags and not delete any characters. To this end
       a token list is provided for the LLM answer (provided in  <LLM_Answer_in_tokens>[
      LLM_Answer_in_token_list]</LLM_Answer_in_tokens>).

---

Example 1:
<Question> {example_1_q} </Question>
<LLM_Answer> {example_1_a} </LLM_Answer>
<LLM_Answer_in_tokens> {example_1_a_tokens} </LLM_Answer_in_tokens>
<<<START>>> {example_1_r} <<<END>>>

Example 2:
<Question> {example_2_q} </Question>
<LLM_Answer> {example_2_a} </LLM_Answer>
<LLM_Answer_in_tokens> {example_2_a_tokens} </LLM_Answer_in_tokens>
<<<START>>> {example_2_r} <<<END>>>

New Question and Answer:
<Question> {input_q} </Question>
<LLM_Answer> {input_a} </LLM_Answer>
<LLM_Answer_in_tokens> {input_a_tokens} </LLM_Answer_in_tokens>
```

S2 Prompt: V2 - Brief instruction with in-context learning and chain of thought reasoning

```
You are tasked with identifying and marking hallucinations in the following large language model (LLM) answers
      . A hallucination in this context refers to an answer that provides incorrect or fabricated information.
       Your goal is to review each LLM answer (provided in <LLM_Answer>[llm_answer]</LLM_Answer>) relative to
      the question (provided in <Question>[question]</Question>) and highlight any incorrect or unsupported
      parts of the response using **<h>** tags. If the LLM answer contains no hallucinations, return it
      without any highlighting.

In short:
- Carefully read the answer text.
- Highlight each span of text in the answer text that is an overgeneration or hallucination (factual
      distortion, excessive and unsupported output, typographic hallucination, nonexistent entities,
      contradictory statements)
- Your annotations should include only the minimum number of characters in the text that should be edited/
      deleted to provide a correct answer (in the case of Chinese, these will be "character components").
- You are encouraged to annotate conservatively and focus on content words rather than function words. This is
       not a strict guideline, and you should rely on your best judgments.
- Ensure that you double-check your annotations.
- Important: Ensure that the text remains exactly the same length as the original text, don't change any
      amount of whitespace or newline characters. You should only add tags and not delete any characters. To
      this end a token list is provided for the LLM answer (provided in  <LLM_Answer_in_tokens>[
      LLM_Answer_in_token_list]</LLM_Answer_in_tokens>).

To ensure accuracy, follow and write down ALWAYS these reasoning steps first and than provide the final
      response with hallucinations marked:
1. Understand the Question: Analyze the intent and scope of the question. What information does it seek?
2. LLM Answer Break Down: Identify distinct factual claims or statements in the response.
3. Claim Verification:
    - Cross-check with reliable knowledge sources.
    - Determine if the claim is logically consistent with known facts.
    - If a claim is unverifiable or fabricated, it is a hallucination.
4. Identify Other Hallucinations and Overgenerations:
    - Check for typographic errors
    - Identify contradictions.
    - Look for unsupported or excessive information.
5. Final Response:
    - Output only the final response for structured extraction in the format: <<<START>>>[
          final_response_with_hallucinations_marked]<<<END>>>
    - Mark Hallucinations: Surround incorrect or unsupported parts with **<h>** tags.
    - Do not provide explanations or extra formatting.
    - If no hallucinations are found, return the LLM answer as is inside the <<<START>>> and <<<END>>> tags.

---
Example of Question, LLM Answer and Final Response with Hallucinations Marked (but without the reasoning steps
      ):

<Question> {example_1_q} </Question>

<LLM_Answer> {example_1_a} </LLM_Answer>

<LLM_Answer_in_tokens> {example_1_a_tokens} </LLM_Answer_in_tokens>

Response:
    1. Understand the Question: [Here, you would provide a brief analysis of the question's intent and scope.]
    2. LLM Answer Break Down: [Here, you would identify distinct factual claims or statements in the response
          .]
    3. Claim Verification: [Here, you would cross-check each claim with reliable knowledge sources and
          determine if they are logically consistent with known facts.]
    4. Identify Other Hallucinations and Overgenerations: [Here, you would check for typographic errors,
          contradictions, and unsupported or excessive information.]
    5. Final Response: <<<START>>> {example_1_r} <<<END>>>

---
Remember, first provide the reasoning steps and then the final response with hallucinations marked.

<Question> {input_q} </Question>

<LLM_Answer> {input_a} </LLM_Answer>

<LLM_Answer_in_tokens> {input_a_tokens} </LLM_Answer_in_tokens>

Response:
    1. Understand the Question:
```

S2 Prompt: V3 - Brief instruction with in-context learning + be sensitive

```
You are tasked with identifying and marking hallucinations in the following large language model (LLM) answers
      . A hallucination in this context refers to an answer that provides incorrect or fabricated information.
       Your goal is to review each LLM answer (provided in <LLM_Answer>[llm_answer]</LLM_Answer>) relative to
      the question (provided in <Question>[question]</Question>) and highlight any incorrect or unsupported
      parts of the response using **<h>** tags. If the answer is factually correct, return it without any
      highlighting.

For each example, provide only the response sentence (R) with the highlighted hallucinations if present. Do
      not provide explanations or commentary. For structured extraction  use the following format/tags for the
       response: <<<START>>>[final_response_with_hallucinations_marked]<<<END>>>

Important: Ensure that the text remains exactly the same length as the original text, don't change any amount
      of whitespace or newline characters. You should only add tags and not delete any characters. To this end
       a token list is provided for the LLM answer (provided in  <LLM_Answer_in_tokens>[
      LLM_Answer_in_token_list]</LLM_Answer_in_tokens>).

Note: Your should be extremely critical in identifying hallucinations in the LLM answers. This means any
      character span that has the slightest chance of being incorrect should be marked as a hallucination.

---

Example 1:
<Question> {example_1_q} </Question>
<LLM_Answer> {example_1_a} </LLM_Answer>
<LLM_Answer_in_tokens> {example_1_a_tokens} </LLM_Answer_in_tokens>
<<<START>>> {example_1_r} <<<END>>>

Example 2:
<Question> {example_2_q} </Question>
<LLM_Answer> {example_2_a} </LLM_Answer>
<LLM_Answer_in_tokens> {example_2_a_tokens} </LLM_Answer_in_tokens>
<<<START>>> {example_2_r} <<<END>>>

New Question and Answer:
<Question> {input_q} </Question>
<LLM_Answer> {input_a} </LLM_Answer>
<LLM_Answer_in_tokens> {input_a_tokens} </LLM_Answer_in_tokens>
```

TeleAI at SemEval-2025 Task 8: Advancing Table Reasoning Framework with Large Language Models

Abstract

The paper presents our system developed for SemEval-2025 Task 8, which focuses on table question answering (TQA). TQA tasks face challenges due to the characteristics of real-world tabular data, such as large size, incomplete column semantics, and entity ambiguity. To address these issues, we propose a large language model (LLM)-powered and programming-based table reasoning framework, named TableReasoner. It models a table using the schema that combines structural and semantic representations, enabling holistic understanding and efficient processing of large tables. We design a multi-step schema linking plan to derive a focused table schema that retains only query-relevant information, eliminating ambiguity and alleviating hallucinations. This focused table schema provides precise and sufficient table details for query refinement and programming. Furthermore, we integrate the reasoning workflow into an iterative thinking architecture, allowing incremental cycles of thinking, reasoning and reflection. Our system achieves first place on both subtasks[1].

1 Introduction

Table Question Answering is a spin-off Question Answering (QA) task, aiming at responding to natural language questions based on table data that feature heterogeneous and complex two-dimensional structure (Lu et al., 2025). Compared to tasks involving unstructured or plain text, TQA faces greater challenges and emphasizes the model's reasoning abilities. The primary challenges encompass large size, incomplete semantics, and entity ambiguity. To advance research on table understanding by applying language models, SemEval-2025 introduces Task 8: Question Answering on Tabular Data (Osés-Grijalba et al., 2025).

In this paper, we present TableReasoner, a systematic LLM-powered and programming-based framework for TQA. We introduce the table schema as the table representation, instead of entire or truncated table text in conventional format (such as CSV or Markdown), enabling our framework capable of processing large tables. TableReasoner employs a programming module to solve questions using the table schema to understand the table content from a holistic perspective. To ensure precise scheduling for query decomposition and programming, we design a "parsing-linking-refinement" action flow. It refines the global table schema into a focused one only associated with the original query, to some extent alleviating model hallucinations. In addition, inspired by the ReAct (Yao et al., 2023) paradigm, we incorporate the reasoning workflow into a "thought-action-observation" architecture, facilitating iterative cycles of thinking, reasoning and reflection within our system.

TableReasoner is flexible to any advanced language model. It delivers excellent results even without fine-tuning, while further performance enhancements can be achieved through fine-tuning and majority voting. Our system wins first place on both subtasks, validating the superiority and scalability of our framework.

2 Background

2.1 DataBench Dataset

DataBench (Osés Grijalba et al., 2024) is an English benchmark comprising 80 real-world tables, with splits of 49/16/15 for training, development, and testing for TQA task. It contains five types of question-answer pair: boolean, category, number, list[category], and list[number]. The test set contains 522 human-annotated question-answer pairs. We categorize the tables of test set into large, medium, and small sets based on the number of cells. The distribution of QA types and the divi-

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1828–1841

sion of size are detailed in Appendix A. DataBench offers a reduced version called DataBench Lite, where each table retains the first 20 rows of data. Correspondingly, the competition includes two subtasks: subtask A on DataBench and subtask B on DataBench Lite.

2.2 Related works

TableLlama (Zhang et al., 2024a), TableGPT (Zha et al., 2023), and StructLM (Zhuang et al., 2024) continue to pre-train models with the decoder-only architecture like Llama(Touvron et al., 2023) towards various table-related tasks. However, table tuning demands a substantial amount of high-quality labeled data, which may be difficult to obtain in certain domains.

With the progress of LLMs, the paradigm has increasingly shifted from traditional models pre-trained from scratch or task-specific modules designed for narrow applications (Liu et al., 2023; Xiong et al., 2024) to leveraging LLMs' strong reasoning and emergent abilities for adapting to downstream tasks (Ruan et al., 2024; Wu et al.; Li et al., 2024b; Shao and Li, 2025). LEVER (Ni et al., 2023), Binder (Cheng et al., 2023), PoTable (Mao et al., 2024) and OpenTab (Kong et al., 2024) are programming-based methods, solving questions with the assistance of SQL or Python codes. However, these methods exhibit limitations in fully comprehending the relationships between questions and table data. Dater (Ye et al., 2023), Chain-of-Table (Wang et al., 2024) and ReActTable (Zhang et al., 2024b) prompt LLMs iteratively to locate critical rows and columns. These methods feed the entire table text into the model, which are usually not applicable for larger tables due to inherent context length constraint. TableRAG (Chen et al., 2024) introduces a million-token table understanding framework, while the encoding and matching operations result in accuracy loss and additional budget.

3 System Overview

Our system is implemented using TableReasoner, an LLM-powered and programming-based framework, as shown in Figure 1. It's designed to integrate a reasoning workflow into an iterative thinking process.

3.1 Reasoning Workflow

Table Schema Generation. We utilize the table schema to describe and provide table information to LLMs. Firstly, we use Python to read the spreadsheet file. Each column is considered as a distinct feature, characterized by data type and meta statistical attributes (e.g., the maximum, minimum, mean and median values of numerical data; unique categories and the most frequently occurring items of categorical data). Additionally, K random rows are selected as example values. Then, to disambiguate specific column names (such as abbreviations), we incorporate the latent semantics of column names into the table schema. In detail, we treat the above table metadata as a preliminary schema to prompt the LLM to generate descriptions of the table and each column. The global table schema is structured as JSON format, an illustrative example is provided in Appendix B.

This table representation method expands the capacity of TableReasoner in processing large-sized tables. The token complexity of a table schema is approximately $O(N)$, which is significantly lower than the complexity $O(M \times N)$ of the entire table when M is very large, where M and N denote the number of rows and columns respectively.

Table Schema Linking. We propose a "parsing-linking-refinement" action flow to refine the global table schema into a focused schema strongly associated with the query. (i) Parsing. We prompt LLM to parse the query based on the table schema, decoupling it into specific sequential sub-queries. (ii) Linking. During parsing, the LLM is also prompted to extract relevant columns for each sub-query, a process referred to as *column linking*. To align the entities mentioned in the query with the values in the table, an *entity linking* step is employed. Specifically, the LLM is used to identify whether the query contains entities, extract them, and suggest belonging table columns. Next, Python is utilized to read all elements of the corresponding columns, and the Longest Common Subsequence algorithm is applied to retrieve elements from column entries whose overlap rate with the query entity exceeds 0.6. Finally, we use the LLM to precisely select the aligned value from these recalled elements. For instance, "*Mr Harari*" in the query is linked to "*Yuval Noah Harari*" in the table. (iii) Refinement. At last, we prune irrelevant columns from the global table schema and integrate entity alignment information as needed, yielding a focused table schema. This module effectively reduces token consumption and noise input.

Query Refinement. To enhance comprehension of complex reasoning tasks, we further decompose

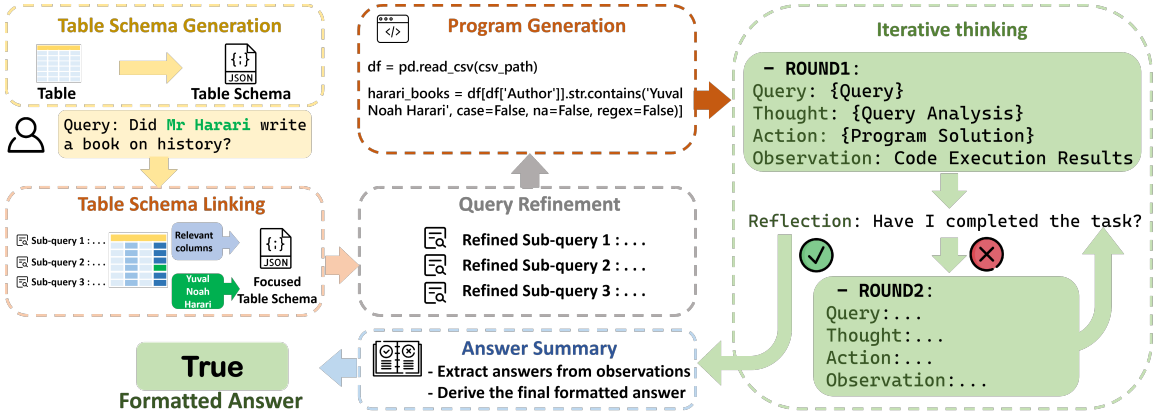

Figure 1: Architecture of TableReasoner framework. The table is firstly converted into a table schema containing global features and example values. The table schema and query go through a reasoning workflow which comprising 5 core sequential modules to obtain observations. The reasoning process and observations are then fed into an iterative thinking framework. It's repeated until expectations are met.

the query into S progressive sub-queries along with associated column names using Chain-of-Thought (CoT) prompting (Wei et al., 2022). The sole distinction from query parsing in table schema linking stage lies in employing the focused table schema which is more information-dense and de-noised.

Program-assisted Solution Generation. The TableReasoner framework centers on programming to derive precise results. Specifically, we guide the LLM to generate a Program-of-Thoughts (PoT) (Chen et al., 2023) solution, utilizing the focused table schema and refined queries from prior steps. The generated codes are subsequently executed in isolated environments (e.g., Python interpreter) to produce verifiable results. Compared to only textual reasoning approach, the program-assisted solution can effectively mitigate numerical hallucinations in multi-step data acquisition and processing.

Answer Summary. Due to the strict answer format requirements of DataBench, we introduce an answer summary module at the end of the workflow. This module generates the final formatted answer by summarizing intermediate thoughts and observations derived from Python executions during the iterative reasoning process.

3.2 Iterative Thinking Paradigm

Inspired by the ReAct, we design the iterative thinking paradigm, integrating the reasoning workflow into a "*thought-action-observation*" architecture, with the goal of bringing incremental self-reflection and decision-making mechanisms into the framework. "*Thought*" corresponds to the decomposed sub-queries from the Query Refinement stage; "*action*" represents the program ideas and codes generated during the Program-assisted Solution Generation stage; and "*observation*" is the feedback from code execution. This creates a reasoning cycle in our workflow. Upon completion of each cycle, the system evaluates whether the query can be answered with the current reasoning state. If yes, it proceeds to the Answer Summary stage; otherwise, it generates a new follow-up query and repeats the process.

3.3 Supervised Fine-tuning

For the purpose of boosting the QA ability on DataBench dataset, we fine-tune the LLMs deployed in Query Refinement and Program-assisted Solution Generation stages. We adopt rejection sampling (Yuan et al., 2023) method on DataBench train and development datasets to synthetize training data. Please refer to Appendix C for details.

4 Experimental setup

Model[2]. We conduct extensive experiments on popular LLMs, including the open-sourced Qwen2.5 series (Yang et al., 2024; Hui et al., 2024), Llama3 series (Dubey et al., 2024), TeleChat2-35B (He et al., 2024; Li et al., 2024a), Mistral-Large[3] and close-sourced GPT-4o (OpenAI, 2023). GPT-4o is invoked via the official API interface, and other models are deployed and invoked locally.

[2]Unless stated otherwise, all models employed in the experiments are the Instruct versions.

Table 1: Performance comparison of Accuracy(%) on DataBench / DataBench Lite test sets. △ means the combination of Mistral-Large for Program-assisted Solution Generation and Qwen2.5-32B for other modules.

Implementation. We fine-tune the Qwen2.5-32B-Instruct and Mistral-Large models for the Query Refinement and Program-assisted Solution Generation stages respectively, applying Low-Rank Adaptation method (Hu et al., 2022). Each model is trained for 5 epochs, with learning rate of 5e-6, lora rank of 8 and total batch size of 32. We set the temperature to 0 to ensure stable output during inference. If majority-voting strategy is adopted, the temperature is configured according to the default values. Within the iterative thinking framework, the maximum round of reasoning cycle is set to 5. We design delicate prompts combining few-shot learning, structured output and CoT strategies to mitigate model bias and address intricate details. Some prompts can be found in Appendix E.

Baseline. We compare 2 common prompting approaches with our TableReasoner. **(i) Zero-shot In-Context Learning** (Z-ICL), which provides the task description and table data in the prompt for textual reasoning. **(ii) Code-based**, which directly answers queries by generating PoT solution leveraging a single LLM and executing codes. For the sake of fairness, we format program execution results through the Answer Summary module to produce final answers. In these cases, we represent tables in Markdown format, which is one of the most common verbalized types of tabular data.

5 Results and Analysis

5.1 Main Results

The main results are shown in Table 1. For the code-based approach, Mistral-Large and GPT-4o show superior performance. A consistent trend of performance enhancement is observed as the model parameters increased in Qwen model series. The results of the Z-ICL method are provided in Appendix D.

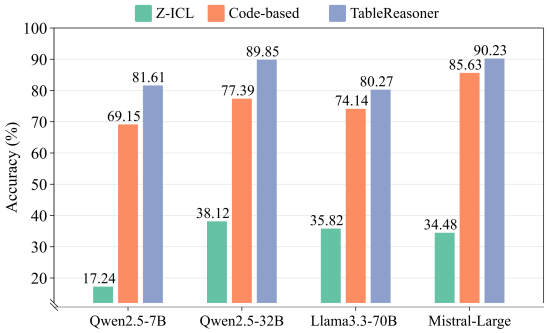

Figure 2: Accuracy comparison with baselines on DataBench test set.

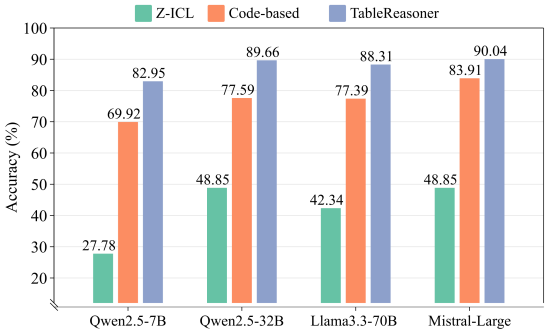

Figure 3: Accuracy comparison with baselines on DataBench Lite test set.

Improvements brought by TableReasoner. TableReasoner consistently enhances the performance across both DataBench and DataBench Lite without fine-tuning. As evidenced in Figure 2 and

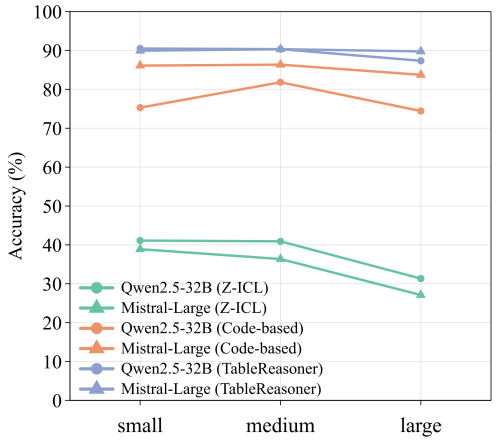

Figure 4: Accuracy comparison between tables of different sizes on DataBench test set.

3, it brings remarkable improvements in accuracy, with absolute increases of 40%+ under the configurations of various backbone models, when compared to the Z-ICL approach. It also realizes substantial improvements to the code-based approach. Moreover, TableReasoner narrows the performance gap between models of small and large parameter size. Notably, integrating Qwen2.5-7B into TableReasoner achieves high accuracy scores, surpassing the top performer in the small-scale model competition rankings (fewer than 8B parameters).

Analysis on different QA types. Table 1 shows that models perform well on Boolean but struggle with list[category] QA types. These complex queries require the model to have a profound understanding of user intent and possess a deep comprehension of tabular data, including deduplication and multi-column correlation analysis. The proposed TableReasoner exhibits more balanced performance advantages across various QA types.

Analysis on table size. We explore the performance on small, medium and large size of tables. As depicted in Figure 4, the Z-ICL approach experiences a sharp performance decline as the table size increases. The code-based approach consistently outperforms Z-ICL and maintain relatively stable performance on tables of different sizes. It not only validates the efficacy of the PoT method but also highlights its great potential for handling large-scale tabular data. Remarkably, TableReasoner exhibits outstanding scalability and robustness, showing minimal degradation as the table size expands.

5.2 Ablation Study

We perform ablation study to verify the effectiveness of each component of TableReasoner workflow. The experiments are conducted on the framework that embeds Qwen2.5-32B model, and results are shown in Table 2. The accuracy shows a drastic deterioration when removing table schema generation and schema linking modules and replacing table schema with the markdown-format text in other remaining stages. The accuracy decreases by 5.37% on the test set and 1.92% on the Lite test set, strongly demonstrating the superiority of applying table schema as the representation, especially for large-sized tables. It is suggested that the specific data in each row is of lesser importance compared to comprehending table's overall structure and column features for programming-based solutions. Removing the schema linking or query refinement module leads to a drop in accuracy, highlighting the importance of the focused table schema and refined sub-queries.

Method	Test	Lite Test
TableReasoner	89.85	89.66
- table schema	84.48 (↓ 5.37)	87.74 (↓ 1.92)
- schema linking	87.55 (↓ 2.30)	88.31 (↓ 1.35)
- query refinement	88.51 (↓ 1.34)	89.27 (↓ 0.39)

Table 2: Ablation results on DataBench and DataBench Lite test sets.

Method	Test	Lite Test
TableReasoner	90.61	90.04
+ Fine-tuning	92.53	91.19
+ Majority-voting (k=5)	93.87	91.76

Table 3: Results of useful strategies.

5.3 Effects of Strategies

LLM Combination. We observe Mistral performs better in code generation tasks. Building upon this finding, we design a hybrid architecture: employing Mistral-Large in Program-assisted Solution Generation stage, while retaining Qwen2.5-32B for other functional modules. The experimental results shown in Table 1 indicate that this hybrid architecture slightly improves accuracy by 0.76% on DataBench test set compared to the architecture using solely Qwen2.5-32B.

Fine-tuning & Majority-voting. To further improve the accuracy on DataBench, we employ the fine-tuned LLMs described in Section 4 within the hybrid architecture. As demonstrated in Table 3, coupled with majority voting based on the self-consistency principle, our system achieves state-of-the-art accuracy of 93.87% and 91.76% on test and Lite test sets, respectively.

6 Conclusion

In this paper, we introduce an LLM-powered and programming-based table easoning framework — TableReasoner, which achieves first place in both subtasks of SemEval-2025 Task 8. We utilize the table schema as a representation, understanding the table from a holistic perspective and addressing the context length constraint. A comprehensive schema linking is implemented in TableReasoner, which provides a focused and precise table schema for query refinement and programming. Besides, we propose an iterative thinking paradigm, incorporating the reasoning workflow to facilitate incremental thinking and reflection. We further enhance performance through fine-tuning and majority voting. Extensive experiments indicate our system is of high scalability and performance across real-world table datasets and has a greater advantage on large-sized tables.

Limitations

For Z-ICL and Code-based methods using LLMs without fine-tuning, prompt design plays a critical role in influencing model performance. For instance, representing tabular data in different formats, such as JSON, CSV or Markdown, can lead to varying results, as different LLMs may exhibit format preferences. Due to time constraints, we were unable to comprehensively evaluate the effects of prompt variations on the comparative experimental outcomes. We will further investigate the impact of different prompt designs.

In this study, we focus on the domain of reasoning over tabular data. Our proposed TableReasoner framework achieves high accuracy by encouraging deliberate reasoning steps. However, it requires numerous inference iterations which are time-consuming. In future work, We will explore adaptive action flow to balance inference times with accuracy.

A Distribution of DataBench Test Set

The distribution of QA-pair types is depicted in Figure 5. We split tables in DataBench test set into large, medium, and small groups based on the number of cells, as shown in Table 4. The small tables include 069_Taxonomy, 071_COL, 072_Admissions, 075_Mortality and 080_Books, total 180 questions; the medium tables include 066_IBM_HR, 073_Med_Cost, 074_Lift, 077_Gestational and 078_Fires, total 176 questions; and the large tables include 067_TripAdvisor, 068_WorldBank_Awards, 070_OpenFoodFacts, 076_NBA and 079_Coffee, total 166 questions.

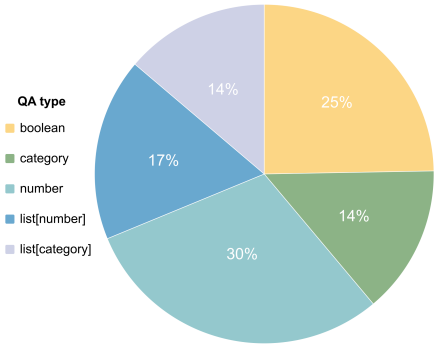

Figure 5: The distribution of Question-Answer pair types on test set.

Type	Dataset Number	Average Cells
Large	5	1519065
Medium	5	18131
Small	5	2882

Table 4: The split of table size on DataBench test set.

C Preparation of Fine-tuning Dataset

The preparation of our fine-tuning dataset involves the following steps: (1) **Reasoning Path Collection**. Within our pipeline, we utilize multiple advanced LLMs—such as GPT-4o, Qwen2.5-72B-Instruct, and Mistral-Large—to perform five rounds of inference on both the training and development sets of DataBench (excluding the DataBench Lite subset), with the temperature parameter set to its default value (not 0). The inputs and outputs of the Query Refinement and Program-assisted Solution Generation modules are recorded for each inference round. Consequently, for each question q, we obtain two sets of reasoning paths: $G[q, (u_i, u_o), (c_i, c_o)]$, where u_i and u_o denote the input and output of Query Refinement step, c_i and c_o denote the input and output of Program-assisted Solution Generation step. (2) **Filtering Incorrect Reasoning Paths**. We verify the correctness of the final reasoning results against ground truth answers and discard any reasoning paths that lead to incorrect results.(3) **Reasoning Path Selection**. We employ a rule-based reward mechanism to select the optimal reasoning paths. For the Query Refinement model, we prioritize paths (u_i, u_o) that correctly associate column names with more subqueries. For the Program-assisted Solution Generation model, we select paths (c_i, c_o) with greater code length. If multiple candidates remain, one is chosen randomly.

For questions that have never been answered correctly, we manually remove ambiguous ones and annotate the others with hints. Specifically, we provide one to three key clues to guide the LLMs toward correctly interpreting and answering the question. The question and its corresponding hints are then concatenated and reprocessed following the aforementioned steps.

After filtering and annotating as described above, the fine-tuning dataset consists of 1184 out of 1308 training samples,

D Performance of Z-ICL approach

As shown in Table 5, the performance of Z-ICL approach falls short on both DataBench test and Lite test sets, with the highest scores being 41.38/56.70, achieved by leveraging GPT-4o. This Z-ICL paradigm confronts several intractable challenges, including text truncation due to length limitations, potential hallucination phenomena, and the absence of explicit reasoning processes.

E Prompts

E.1 Table Description Prompt

Given a database schema regarding "{table_name}", your task is to analyse all columns in the database and add detailed explanations for database and each column.

Requirements:
1.Response should include column names and the specific meanings of each column to help users better understand the data content.
2.Response format example:
{
"Table_Description":...,
"Column_Description": [
{"column_name": "Age", "specific_meaning": "Represents User's Age."},
{"column_name": "Joined Date", "specific_meaning": "The date on which the user joined."},
{"column_name": "Gender", "specific_meaning": "User's Gender, with 2 categories."},
{"column_name": "City", "specific_meaning": "City where the user resides, with 32 categories and only one category example displayed."}]
}

Definition of fields:
Table_Description: Explain the main content and possible uses of the table.
Column_Description: Explain the meaning of each column.
Ensure that the response format is a compact and valid JSON format without any additional explanations, escape characters, line breaks, or backslashes.

Database Schema
{table_schema}

Please response in **JSON** format complying with the above requirements.

E.2 Query Refinement Prompt

As an experienced and professional data analysis assistant, your goal is to analyze a user's question and identify the relevant columns that might contain the necessary data to answer user's question based on the table schema. The table schema consists of table descriptions and multiple column descriptions.

Specifically, you need to complete two sub tasks:
`[task1]`
Thoroughly understand and analyze user's question. You should orient your approach towards resolving user query by referencing the information provided in the table schema, and break down the original query into more specific, complete and executable sub-queries.

`[task2]`
For each query to be answered, identify and extract the relevant columns from the 'column_list' field in the table schema that are necessary to answer the query.

Instruction
`[task1 Instruction]`
- You should attempt to decompose the original query into more specific, progressively detailed, step-by-step sub-queries. Ensure the sub-queries maintain high relevance to the original query and executability to table retrieval, and confirm that no critical information is omitted.
- You can recognize key entities, intentions, special reminder, and specific objects from user's question, which can help you accurately analyze user issues.
- Ensure that each query can be answered by retrieving relevant values from the table.
- Pay attention to the expression of the maximum value (maximum/top/highest/most/lowest/smallest/last, etc) in user's query.

`[task2 Instruction]`
- Identify one or more relevant columns from the 'column_list' field in the table schema that are necessary to answer each query.
- Distinguish between easily confused column names, and refer to column descriptions and example values if necessary, to ensure the accuracy of the relevant columns extracted.
- The user's terminology may have multiple meanings or their expression might be ambiguous. In such cases, try to infer the most likely intent from the user's query and provide all potentially relevant columns.
- When queries are vague or ambiguous, attempt to infer the most likely intent based on the user's question and the table description, and provide all potentially relevant columns as comprehensively as possible.

- Ensure no necessary columns are omitted.
- Please reflect and ensure that the extracted column names must exist in the table schema(‘Field: column_list‘). Prohibit modification and avoid any illusions to ensure that the relevant values can be read from the table.

Output format
Please answer with a list of sub_queries in JSON format **without any additional explanation**.

Examples:
Question: What are the average sales, cost, and profit per order for children’s food?
Response:[
{"Query1": "Filter the data to include only orders related to children’s food.", "relevant_column_list": ["product_category"]},
{"Query2": "Calculate the average sales per order for children’s food.", "relevant_column_list": ["sales"]},
{"Query3": "Calculate the average cost per order for children’s food.", "relevant_column_list": ["cost"]},
{"Query4": "Calculate the average profit per order for children’s food.", "relevant_column_list": ["profit"]}
]
Question: What is the average concentration of PM2.5 in Sichuan Province in January 2015?
Response: [
{"Query1": "Select data from January 2015.", "relevant_column_list": ["date<the Gregorian calendar>"]},
{"Query2": "Further filter the data of Sichuan Province from the results of Query1.", "relevant_column_list": ["province"]},
{"Query3": "Calculate the average concentration of PM2.5.", "relevant_column_list": ["PM2.5"]}]
Let’s begin!
Table Schema
{table_schema}

Response the user’s question ‘{query}‘ strictly follow the above guidelines.
Question: {query}
Response:

E.3 Answer Summary Prompt

Based on the following thought process records, generate the Final Answer of the user query "{query}" to the table.
Rules
1. Thoroughly analyze the connection between the query and the thought process, and extract the correct Final Answer.
2. Determine the data type of Final Answer based on the understanding of user question. The data type of Final Answer must be one of the following:
- Boolean: Valid answers include "True" or "False"(must be string).
- Category: A catgory value (e.g., "Bryin", "try your best!").
- Number: A numerical value, which may represent a computed statistic (e.g., average, maximum).
- List: A list containing number or categories. The expected format example is: [’real estate’, ’investments’, ’pharmaceuticals’, ’software’].
3. Output the Final Answer directly without any prefix words or explanations. Your Final Answer’s data type must be a number, a category, or a list. Answer with a complete sentences in Final Answer is strictly prohibited.

Attention! The data type is just for reference to help you provide the correct format of the Final Answer. The Final Answer content should be derived from the information in the thought process records. Here are your thought process records:
{thought_process}

=========

User Query

Query: {query}

Final Answer:

E.4 Iterative Thinking Prompt

As an intelligent assistant for table analysis, your primary task is to analyze the table schema and assist in answering questions based on the data. To perform this, follow these guidelines:
1.You cannot view the table directly. However, you are provided with schema details and some sample cell values.
2.Use these schema details to frame relevant Python queries that progressively solve the user’s question.
3.Strictly adhere to the structured format below to document your thought process, actions, observations, and responses.

Provided Information:
Schema Retrieval Results:
{table_schema}

Thinking Format:
- Query: Input question that need to be answered.
- Thought: You should always think about what to do and clearly state that.
- Action: Generate concrete Python-based ideas based on table schema retrieval results to get the observation or answer.
- Observation: Provide observations or results from the action. If unavailable, note the missing information or ambiguities.
(Repeat the Thought/Action/Observation steps as needed)
- Thought: After sufficient observations, decide if the original input question can be answered. If so, articulate the response based on the findings.
- Response: Present a concise and accurate answer to the original input question.

Task:
Given the table schema retrieval results above, analyze the input question and generate the thought or response in the structured format.

Input Question:
{query}

Thinking Process Records:
{history_thinking}

(Remember! Make sure your brief output always adheres to one of the following two formats:
A. If the answer to the question can be obtained or inferred from thinking process records, indicating you have completed the task, please output:
Thought: 'I have completed the task'
Response:

B. Otherwise, please further rewrite and generate an **improved and clearer query** of the user's target question '{query}' based on previous thinking without explanation, and point out potential considerations and error prone points that neeed to be noted, making it easier for LLMs to uderstand and analyse, please output:

Query:
)

E.5 Z-ICL Prompt

You are an assistant tasked to response the question asked of a given Table in markdown format. Before providing your response, you need to fully understand and utilize the information contained in the Table. You must response in a single JSON with your answer to the question and your explanation:
* "answer": answer using information from the provided Table only.
* "explanation": A short explanation on why you gave that answer.

Answer Requirements:
1. Determine the data type of answer based on the understanding of user question. The data type of answer must be one of the following:
- Boolean: Valid answers include "True" or "False"(must be string).
- Category: A catgory value.
- Number: A numerical value, which may represent a computed statistic (e.g., average, maximum).
- List: A list containing number or categories. The expected format example is: ['real estate', 'investments', 'pharmaceuticals', 'software'].
2. Output the response directly without any prefix words or explanations.
3. The answer value in response must be derived from the values extracted from the provided data, and any unnecessary rewriting, expansion or format conversion is not allowed.

Response Format:
Question: What is the name of the richest passenger?
Table:
```
"""
| passenger | wealth($) |
| ————— | ————— |
| value1 | value2 |
"""
```
Response: {
"answer": "value1",

```
    "explanation": ""
    }

Now let's start!

Question: {question}
Table:
"""
{table_data}
"""
Response:
```

E.6 Code-based Prompt

```
You are a professional programming assistant designed to utilize the Python package 'pandas' to analyze the table and Response efficient and robust Python code for answering user's Question. The code will read the file from the given 'Table_path' and perform data extraction.
You should act in accordance with the following requirements:
1. Generate chain-of-thought execution ideas based on the understanding of the table content and the user's Question. Describe in detail the algorithm steps as much as possible, including Question analysis, table data format parsing method and code logic description.
2. Then write Python codes according to your approach to solve the question. The codes need to be concise and easy to understand, and if necessary, add comments for clarification.
3. Note that your analysis must be based entirely on the Table data, with special attention to the content and format of the table cells.

You should deliberately go through the user's Question, Table_path and Table and strictly follow the guidelines to appropriately answer the user's Question. You can only output a standardized JSON object, including "code_thought" and "code", and you are prohibited from outputting any other unnecessary thought processes. Ensure that your Response can be read by json.loads().

### Guidelines:
**Thought generation**: With the goal of addressing the user's Question, refer to table_data to generate step-by-step code writing ideas.

**File Reading**: Depending on the table file format and size, efficiently read data from the given 'Table_path' (supporting formats such as CSV, Excel) and load it into a Pandas DataFrame. For larger datasets, choose an appropriate method to ensure performance.

**String Matching**:
- When performing string matching, it is best to use the '.contains()' method instead of a completely strict equal match ('=='). When using '.contains()' function, set the 'regex=False'. Usage Example: filtered_df = df[df['Publication'].str.contains('Harpercollins Publishers (India)', case=False, na=False, regex=False)]

**Sorting and Ranking**:
- If the query involves rankings, top/bottom N, max/min, higher/lower than, etc, please sort the data using 'sort_values()'. If one or more columns of data to be sorted may have the same value, they should be sorted twice in index order. Usage Example: 'df.sort_values(by='value', ascending=False, kind='mesort')'.
- Ensure that the DataFrame is sorted by index even if the values are the same.
- When sorting string type numbers, first convert the data type of the numbers from string to float. Usage Example: 'sorted_unique_ids = sorted([float(u) for u in unique_supplier_ids if not pd.isna(u)])\n earliest_5_suppliers = sorted_unique_ids[:5]'
- Use unique operation with caution when sorting and ranking.

**Special reminders**:
- The generated code should be robust, including error handling and file format compatibility. It should strictly match the column names mentioned in the user's Question, avoiding irrelevant or mismatched columns.
- Unless otherwise specified, please ignore null or empty values.
- Pay attention to the wording of the question to determine if uniqueness is required or if repeated values are allowed. Unless otherwise specified, the unique operation ('.unique()') is not necessary when sorting or finding the maximum/top/highest/-most/lowest/smallest/last (etc) N values in most cases.
- Pay attention to **the format of example values** before you manipulate the data in a certain column. Deeply think about how to correctly parse and extract ill-formed data, Not JUST anomaly capture.
- For Boolean problems, it is not necessary to output all elements, only obtain True or False answers, or obtain the first few elements to avoid too much unnecessary output.
- The results of mathematical operations must be specific number values, and Scientific notation cannot be used.
```

Code Instruction:
Your code must be like:
"import pandas as pd\n def parse_labels(s):\n if s == '[]':\n return []\n return [label.strip() for label in s.strip('[]').split(',')]\n df = pd.read_csv('all.csv')\n # Explode the labels into individual rows\n labels = df['labels_en'].apply(parse_labels).explode()\n # Count occurrences of each label\n label_counts = labels.value_counts()\n # Find the label with the highest number\n most_common_label = label_counts.idxmax()\n print('the label with the highest number of products', most_common_label)"

- Ensure the final answer is the last line in python code.
- Note that "Answer" is just the placeholder in the code. You should replce it with a entity name or a specific description derived from the user's input, as short as possible. Note that when single quotes are included in the answer description, please use double slashes: 'print('Alice's score')'

Response Format:
User's Question: Which label has the highest number of products?
Response:
{
"code_thought":" To find the single label with the highest number of associated products, we'll: 1. Parse the <labels_en> column to extract individual labels; 2. Handle empty lists and string formatting issues; 3. Count occurrences of each label; 4. Identify the label with the highest count.",
"code": "import pandas as pd\n def parse_labels(s):\n if s == '[]':\n return []\n return [label.strip() for label in s.strip('[]').split(',')]\n df = pd.read_csv('all.csv')\n # Explode the labels into individual rows\n labels = df['labels_en'].apply(parse_labels).explode()\n # Count occurrences of each label\n label_counts = labels.value_counts()\n # Find the label with the highest number\n most_common_label = label_counts.idxmax()\n print('the label with the highest number of products', most_common_label)"
}

Let's begin!
Now please deliberately go through the following user's Question, Table_path and Table word by word and strictly follow the above guidelines to appropriately answer the question. You can only output a standardized JSON object, including "code_thought" and "code", and you are prohibited from responsing without any prefix words or explanations. Ensure that your Response can be read by json.loads().

User's Question: {question}

"""
Response:

Howard University-AI4PC at SemEval-2025 Task 1: Using GPT-4o and CLIP-ViT to Decode Figurative Language Across Text and Images.

Saurav K. Aryal and **Abdulmujeeb Lawal**
Electrical Engineering & Computer Science
Howard University

Abstract

Correctly identifying idiomatic expressions remains a major challenge in Natural Language Processing (NLP), as these expressions often have meanings that cannot be directly inferred from their individual words. The SemEval-2025 Task 1 introduces two subtasks, A and B, designed to test models' ability to interpret idioms using multimodal data, including both text and images. This paper focuses on Subtask A, where systems were given a context sentence that contains a potentially idiomatic nominal compound, with the goal being to rank the images based on how accurately they represent the meaning of the nominal compound used in the sentences. To address this, we employed a two-stage approach. First, we used GPT-4o to analyze sentences, extracting relevant keywords and sentiments to better understand the idiomatic usage. This processed information was then passed to a CLIP-ViT model, which ranked the available images based on their relevance to the idiomatic expression. Our results showed that this approach performed significantly better than directly feeding sentences and idiomatic compounds into the models without preprocessing. Specifically, our method achieved a Top-1 accuracy of 0.67 in English, whereas performance in Portuguese was notably lower at 0.23. These findings highlight both the promise of multimodal approaches for idiom interpretation and the challenges posed by language-specific differences in model performance.

1 Introduction

Deep learning and language models have substantially improved multilingual language understanding, as well as content and sentiment classification across domains (Aryal et al., 2023b,a), at both the sentence and token levels (Prioleau and Aryal, 2023; Aryal and Prioleau, 2023). However, idiomatic words and compounds pose a huge challenge for Large Language models. While humans can easily discern figurative usage from literal usage of words, models trained predominantly on idiomatic usage of words tend to "overlook" their literal meaning and assume idiomatic usage as long as such a word or compound is spotted. The SemEval-2025 Task 1, AdMIRe, aims to address this problem by trying to examine how image and textual modalities, similar to humans, can help improve idiom interpretations.

The dataset provided consists of potentially idiomatic nominal compounds and target sentences in which the compound is used, in both English and Brazilian Portuguese. It also includes five candidate images, which are to be ranked according to how closely they capture the intended meaning, be it either literal or idiomatic (Pickard et al., 2025).

While the task comprises two Sub tasks, A and B, this paper focuses solely on Subtask-A where systems are given a context sentence that contains a potentially idiomatic nominal compound and the goal is to then rank the images based on how accurately they represent the meaning of the nominal compound used in the sentences (Pickard et al., 2025). For example, given the image in Figure 1 below and the phrase *bad apple*, if the phrase is used literally in the target sentence, then the spoiled fruit depicted on the right would be more relevant and thus should be ranked higher, and if the phrase is used idiomatically in the target sentence, the more figurative illustration on the left should be ranked higher.

Our approach aims to capture the high-level semantic nuances and keywords of each compound in the given sentences and then compare the images using a vision-language model. Also, this approach does not involve training models on any data; rather, we just focus on leveraging large language model prompts and visual-textual alignment to allow us to correctly identify idiomatic nominal compounds.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1842–1848

Figure 1: Bad-apple Illustration from task description document

2 Related Work

Recent research on idiom detection has highlighted the challenge of modeling both the compositional and non-compositional aspects of idiomatic expressions. A fairly recent study introduced a multilingual dataset and evaluation framework, demonstrating that current models struggle to capture the dual nature of idioms (Tayyar Madabushi et al., 2022). Another study proposed IBERT, a BERT-based model for cloze-style idiom comprehension (Qin et al., 2021). Although this approach differs from ours, it underscores the importance of incorporating both local (immediate surrounding words) and global context (whole sentence/document). This aligns with our prompting strategy, which encourages models to focus not just on the word but on how it's used.

Also, while the aforementioned studies have mostly focused on textual data, recent developments, especially in multimodal models, do show that visual information can offer much. Greater contextual grounding has the potential to improve model performance. This idea is also supported by the embodied cognition framework, which posits that real-world imagery aids in semantic interpretation (Lakoff and Johnson, 1980). Extending on this, our work uses a vision-language model, combined with careful prompt engineering, to enable us to align visual and textual representations for more effective detection of literal versus idiomatic usage of certain nominal compounds.

3 System Overview

We designed our system to work on the idiomatic ranking without any fine-tuning. We describe each part of our pipeline in detail.

3.1 Data Preparation

The dataset provided by the organizers required minimal processing on our end. As such, our initial step involved extracting the given nominal compound and its corresponding sentence.

3.2 Textual Analysis and Nominal Compound Interpretation

We then analyzed the nominal compounds and their sentences. Here, we employed GPT-4o to assess the context and then determine whether the compound is used idiomatically or literally in the given sentence. The model evaluates the surrounding text and then classifies the usage accordingly. We also generate some sentiment cues and keywords related to the compound based on the usage. These cues are very important and helpful as they serve as the descriptors that inform the next stage of visual matching.

3.3 Visual Matching and Image Selection

Taking the sentiment cues and the keywords generated from GPT-4o, we then focus on the next stage, which is to select and rank the most representative image. Here, we make use of CLIP-ViT to extract visual features from each candidate image. Rather than just comparing the original sentence to the 5 candidate images, our approach compares the sentiment descriptors and keywords generated by GPT-4o with the visual features of the images. This makes sure that the selected image best represents the intended literal or figurative meaning of the nominal compound.

3.4 Final Output

The final output, which consists of the expected order of the ranked candidate images and the compound name, is then formatted according to the task requirements and stored as tab-separated files. This output is then submitted as our system's final result.

4 Implementation Details

All code was written using Python with a focus on integrating pre-trained models through API interfaces as opposed to training.

4.1 Infrastructure and Model Integration

The models integrated into our pipeline were CLIP-ViT (openai/clip-vit-base-patch32) and GPT4o.

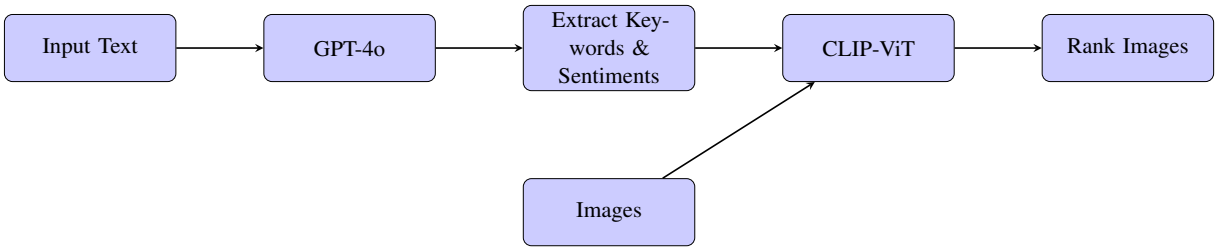

Figure 2: Diagram Illustrating the System Overview

As for the programming language, we used Python 3.10. Also, there were little to no storage concerns, and it was all stored on a MacBook Pro with 512GB storage space and 18GB RAM without CUDA support. There were also no performance concerns since all the models, aside from CLIP, were accessed through their respective APIs. The CLIP-ViT model was accessed through the Hugging Face transformers library and was downloaded locally for use.

4.2 Prompt Engineering

Our method of prompt engineering was very critical to the system's performance. We made sure to include in our prompts:

- Clear instructions to distinguish between literal and idiomatic usage of the compounds.
- Some examples of both types of usage to help guide the model's reasoning.
- Clear and explicit requests for sentiment cues and descriptive keywords based on the global context.
- Formatting requirements for the output to ensure proper parsing when getting results.

The final prompts utilized can be found in the Appendix.

4.3 Data Processing Pipeline

The Portuguese data was first translated into English to work with. After that, both the English and the now-translated Portuguese datasets had their compounds and sentences extracted. The next step was to then prompt the GPT4o model to extract the literal meaning, literal keywords, literal sentiments, as well as the idiomatic meaning, idiomatic keywords, and idiomatic sentiments of the nominal compound. The images were then loaded, opened, and prepped for comparisons. Another prompt then took in the sentence and the compound, and after reasoning, decided whether the word usage was idiomatic or literal. If the usage was literal, then the images were compared against the literal sentiments and keywords and then ranked. If the usage happened to be idiomatic, then the images were compared against the idiomatic keywords and sentiments and then ranked. Then the output data was processed in the submission format required by the task organizers.

5 Evaluation

We evaluated our system using Top-Image Accuracy and Discounted Cumulative Gain (DCG) scores, which were provided upon submission by the Coda bench platform. The Top-Image Accuracy reflects only whether the single most representative image – the one that should be ranked first – is correctly identified, as opposed to the DCG, which accounts for the entire ranking of images according to the weighting scheme detailed in the task description paper. Our approach showed a relatively strong performance with our latest submission averaging a Top Image Accuracy of 0.67 in English. Further experimentation, particularly with a higher temperature setting in the GPT4 model, did achieve a submission with up to 0.8. While we do recognize that this could be due to chance, it still does highlight the impact of varying temperatures alongside prompting.

Language	Top-1 Accuracy	DCG Score
English	0.67	3.13
Portuguese	0.23	2.64

Table 1: Final ranking scores for English and Portuguese.

To further give some context to the importance of our results, we note that the task organizers involved human annotators, who were all self-described fluent English Speakers, to work on an extended English dataset. The human annotators

achieved a Top-image accuracy score of 0.71 and a DCG of 3.22 in English, which indicates that our system, while simple, approaches human-level accuracy and ranking quality. (Pickard et al., 2025).

Furthermore, the clear performance gap between English and Portuguese in our results highlights the need for improved adaptability and better models in different languages, as some information or context could have been lost during the translation process.

6 Limitations

While our approach demonstrates some decent performance on the SemEval-2025 Task 1, there are some limitations we need to mention.

Making our system rely on out-of-the-box models like GPT4 and CLIP-ViT could limit the performance on the task. This doesn't mean the models aren't very good in their own right, but the fact that we didn't include any fine-tuning could potentially limit how well they can perform when they meet certain words for the first time

Also, there was a notable gap in performance between the English and Portuguese datasets. We believe this could have been caused by the translation process, as the Portuguese texts were automatically translated into English without any additional quality control. This could have resulted in a loss of important contextual or semantic information. Consequently, we do recognize the need for better models that understand more languages to allow them to natively handle multiple languages without relying solely on translation.

Additionally, since we didn't use a traditional classifier but relied on the model's outputs, we were unable to explicitly validate the accuracy of the classifier step due to the absence of ground truth labels. This was done to avoid introducing bias into the work. As such, while the GPT classifiers' outputs might have been qualitatively useful, we do acknowledge that this would limit our ability to report standalone metrics on that.

Lastly, given that our GPT model was accessed primarily through API's, there's the possibility that the model could be updated and hence do better or even worse on certain tasks, and this means that moving forward, we could have less control over some of the model's behaviors using the prompts.

7 Conclusion

In this paper, we presented a multimodal system that used GPT4o to extract important context information from text and then used CLIP-ViT to rank the images based on that. Our approach relied very heavily on prompting as opposed to training models on new data, and this showed that it was possible to get cues from text which could help in image idiomatic image identification. Our system also revealed a very important limitation when working without finetuning any models - a lot of context information could be lost when translating from one language to another. Looking to the future, we think it's important that future research should focus on creating more datasets for idiomatic training in other languages and also focus on refining prompting strategies to ensure the models are always guided.

A Appendix

Figure A: Prompt for Sentiments and Keywords

Analyze the given term: "{idiomatic_word}".
1. Literal Meaning:
- Provide a short and descriptive explanation of the literal meaning of "{idiomatic_word}". Include things that can help an AI model find it
- Then, generate 5 strongly associated keywords that could strongly describe the literal meaning of the word. Focus on the most relevant and descriptive words.
- Also generate 3 sentiments that could relate strongly to it based on the sentence given.
2. Idiomatic Meaning:
- Provide a short and descriptive explanation of the idiomatic meaning of "{idiomatic_word}" including "{idiomatic_word}" in the explanation. Include things that can help an AI model find it.
- Then, generate 5 descriptive keywords that strongly describe the idiomatic meaning based on the sentence, focusing on its core essence and usage.
- Also generate 3 sentiments or emotions that relate strongly to it based on the sentence given.

Return the result in the following JSON format:
"literal_meaning": "<brief explanation of the literal meaning>",
"literal_keywords": ["<word1>", "<word2>", "<word3>", ...],
"literal_sentiments" : ["<word1>", "<word2>", "<word3>", ...],
"idiomatic_meaning": "<brief explanation of the idiomatic meaning>",
"idiomatic_keywords": ["<word1>", "<word2>", "<word3>", ...]
"idiomatic_sentiments" : ["<word1>", "<word2>", "<word3>", ...],

This is important to me

Figure B: Classification Prompt

"Determine whether the usage of the word '{word}' in the following sentence is idiomatic or literal. This is important to me: \n"
"Sentence: {sentence}\n"
"Respond with 'idiomatic' or 'literal' and don't give an explanation"

CSECU-DSG at SemEval-2025 Task 6: Exploiting Multilingual Feature Fusion-based Approach for Corporate Promise Verification

Tashin Hossain[1], Abu Nowshed Chy[2],
[1,2]Department of Computer Science and Engineering,
University of Chittagong, Chattogram-4331, Bangladesh
[1]tashin.hossain.cu@gmail.com, [2] nowshed@cu.ac.bd

Abstract

Trust and commitment are fundamental to personal, professional, and legal interactions, particularly in an era where digital platforms facilitate communication and transactions. Ensuring the authenticity and fulfillment of promises has become a critical concern for individuals and organizations, necessitating a robust verification mechanism. To address this challenge, SemEval-2025 Task 6 introduced a promise verification task, encompassing five different languages, which involves analyzing multi-industrial reports, including corporate disclosures, ESG reports, and legal contracts etc. In response to this challenge, we propose a multilingual promise verification framework that integrates textual analysis, contextual understanding, and probabilistic assessment to evaluate the validity and fulfillment of given promises. Our approach leverages a feature fusion of LASER and USE, employing a Bi-LSTM neural network architecture combined with an MLP for the identification of promises and supporting evidence within documents. Experimental evaluations conducted using the ML-Promise dataset demonstrate that our system achieves competitive performance across multiple languages.

1 Introduction

In today's society, corporate, governmental, and public personalities' pledges have the power to shape public perception, influence stakeholder trust, and determine institutional reputation. These organizations' promises of social responsibility, environmental responsibility, and ethical governance are important markers of their legitimacy and accountability. However, the quantity and magnitude of such commitments make it extremely difficult to confirm whether they are actually being fulfilled. It is now more important than ever to be able to verify a promise, especially in the world of business, where corporations commonly make grand claims about their impact on Environmental, Social, and Governance (ESG) measures.

In order to tackle this problem, SemEval-2025 introduces ML-Promise, the first multilingual dataset created especially for promise verification (Chen et al., 2025). This dataset allows for a cross-cultural analysis of corporate promises verifying four different evaluation criteria, described in Table 1.

In recent years, the application of Natural Language Processing (NLP) in ESG analysis and sustainability reporting has become increasingly common. For instance, Gutierrez-Bustamante et al. (Gutierrez-Bustamante and Espinosa-Leal, 2022) employed Latent Semantic Analysis (LSA) and Global Vectors (GloVe) for word representation to assess the alignment of sustainability reports with the Global Reporting Initiatives (GRI) framework. Gorovaia et al. (Gorovaia and Makrominas, 2024) employed text analysis of corporate social responsibility (CSR) reports to identify reporting inconsistency between violator companies that violate environmental infractions and non-violator companies. Moreover, the ESGReveal system, introduced by Zou et al. (Zou et al., 2025), blends large language models (LLMs) with retrieval-augmented generation (RAG) to retrieve structured ESG details from ESG reports.

In this paper, we illustrate our insights accumulated from experimenting on this task. We proposed feature fusion based neural architecture, to identify the promise and evidence statements. Here, we utilized the Language-Agnostic SEntence Representations (LASER) and Universal Sentence Encoder (USE) embedding for the feature fusion.

The structure of this paper is as follows: Section 2 provides a detailed explanation of our proposed framework. In Section 3, we present the experimental setup along with a comparative performance analysis. In Section 4, we provide our insights and explanability of the models on the task. Lastly, we conclude the paper in Section 5, discussing poten-

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1849–1858

Label	Description	Possible Values
Promise Identification	Does the statement contain a promise?	Yes / No
Supporting Evidence	Is there evidence backing the claim?	Yes / No
Clarity of Promise	Is the promise clear, unclear, or misleading?	Clear / Not Clear / Misleading
Timeline Verification	When can the promise be verified?	<2 years, 2-5 years, >5 years, Other

Table 1: Promise Evaluation Criteria

tial future directions.

2 System Overview

We shape the corporate promise verification task as a sequence classification task and employ an ensemble of embedding models, LASER, and USE for the feature extraction process, then combine these two embedding layers, and feed them into the Bi-LSTM + MLP layer to get the desired label. The framework of our system is depicted in Figure 1.

2.1 Data Preprocessing Techniques

Preparing documents for analysis is an essential part of NLP, which turns unstructured text data into understandable text. First, we extract the text from documents using PyPDF2 (Li et al., 2023). Following that, we eliminating noise, such as extraneous punctuation, special characters, HTML tags, or unrelated information, that could impair model performance.

2.2 LASER Embedding

Laser (Language-Agnostic SEntence Representations) (Schwenk and Douze, 2017; Artetxe and Schwenk, 2019; Schwenk and Li, 2018) is a unified model that generates high-quality sentence embeddings for over 90 languages. We utilized this multilingual feature embedding model for the feature extraction. After text preprocessing, we gather the 1024-dimensional feature embedding from this model to feed into our final system.

2.2.1 Universal Sentence Encoder (USE)

Universal Sentence Encoder (Cer et al., 2018) is a language-independent, fixed-dimensional vector form of representing text that embeds semantic meaning in a language-independent, domain-independent, and task-independent manner. We extracted the 1024-dimensional feature embedding from the sentence encoder to feed into our system.

2.3 Bi-LSTM + MLP

Bidirectional Long Short-Term Memory (Bi-LSTM) (Liu and Guo, 2019; Zhang and Rao, 2020; Deng et al., 2021) is a complex form of LSTM for improving sequential information processing with both past and future contextual information capture. Unlike a traditional LSTM, processing one direction sequentially, BiLSTM consists of two LSTM layers in parallel, one processing in sequence direction and one in the reverse direction. Output of both directions is then combined, and both past and future context can be utilized in prediction by the model. For our proposed framework, we concatenate features coming from the LASER and USE model, feed them into the Bi-LSTM layer for training, and then go through the MLP layer before getting the final predictions.

2.4 Model's Prediction

Following the process of feature fusion, the model is subsequently directed towards an additional feed-forward layer, which ultimately results in the generation of probabilities for each distinct category. Finally, we utilize Equation 1 to get the final predictions.

$$argmax(f(x)) = x \in X \tag{1}$$

where $f(x)$ denotes the probabilities of the output layer, X denotes the number of classes and x is the highest probability index.

3 Experiments and Evaluations

3.1 Dataset Description

In the following subsections, we will overview the dataset for the promise verification task.

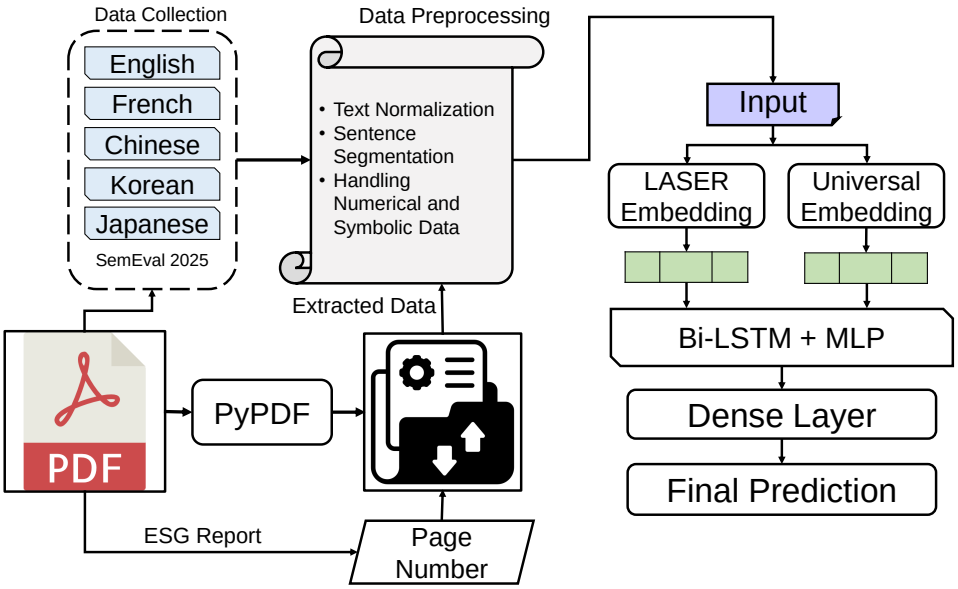

Figure 1: Proposed Framework.

3.1.1 Dataset Overview

SemEval 2025 Promise Verification Task (Chen et al., 2025) The ML-Promise dataset is a multilingual dataset designed to analyze and verify corporate promises made in ESG reports. These reports often contain commitments related to sustainability, ethical governance, and social responsibility. However, companies may exaggerate or misrepresent their claims (a practice known as greenwashing). The ML-Promise dataset aims to provide structured data to assess the credibility of such corporate commitments.

The dataset consists of 3,010 instances collected from ESG reports published in five different languages which are depicted in Figure 2.

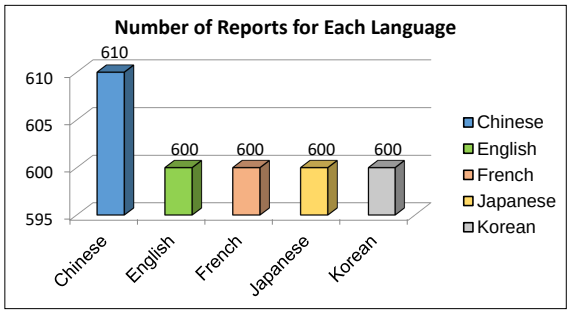

Figure 2: Data distribution among different languages.

3.1.2 Statistical Analysis of Dataset Labels

A quantitative analysis of the dataset reveals key trends in corporate ESG reporting among different countries and different industries.

Promise Identification Rates The proportion of statements identified as corporate promises varies significantly across languages, as shown in Figure 3.

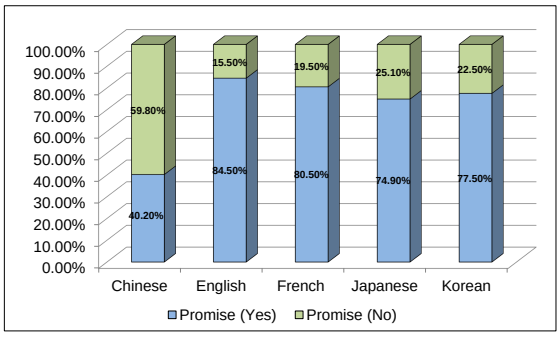

Figure 3: Promise identification rate among different languages.

English and French companies tend to make more explicit promises than Chinese firms. Notably, the Chinese dataset has the lowest promise rate at 40.2%, suggesting that Chinese reports may be more vague or general in nature, potentially lacking clear commitments or measurable objectives.

Supporting Evidence Availability The availability of supporting evidence varies significantly across languages, as depicted in Figure 4. English and Chinese companies rarely provide supporting evidence, with only 20.1% of statements backed by tangible proof. In contrast, French, Japanese, and Korean firms are more likely to include supporting documents, with Korean companies leading at 75.6%, followed by French (71.6%) and Japanese

(66.4%).

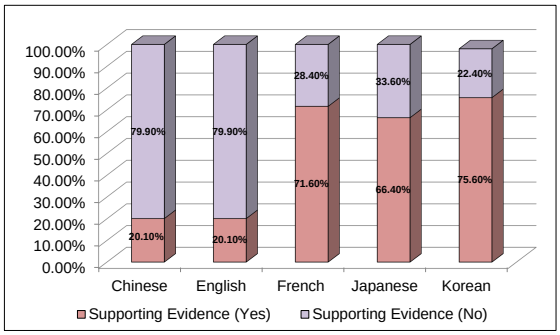

Figure 4: Evidence availability rate among different languages.

Clarity of Promise-Evidence Pair The clarity of the promise-evidence pair varies across languages, as shown in Figure 5. Korean corporate reports demonstrate the highest clarity, with 94.8% of statements being clearly supported and almost no misleading claims. In contrast, English and Japanese reports have a relatively higher rate of misleading claims, around 4%. While Chinese reports show a strong clarity rate (64.7%), they contain no misleading statements, whereas French reports exhibit a lower misleading rate of 1.5%, maintaining a balanced level of clarity.

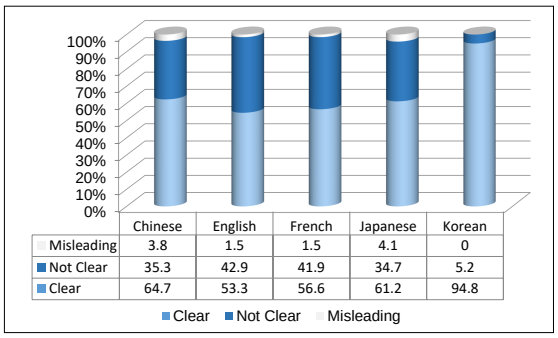

Figure 5: Clarity of promise-evidence rate among different languages.

Differences in Short-Term vs. Long-Term Promises The distribution of short-term and long-term promises varies across languages, as shown in Figure 6. Korean (45.5%) and Chinese (37.5%) firms make the most short-term commitments (<2 years), indicating a stronger focus on immediate actions. In contrast, English reports have the highest proportion of unclear timelines (75%), suggesting a tendency toward vague or long-term commitments without specific verification periods. French and Japanese firms demonstrate a more balanced distribution across different timeframes, while Korean reports contain the fewest long-term (>5 years) commitments. Overall, English and French firms

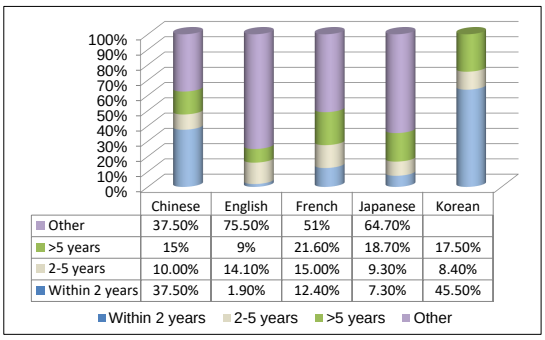

Figure 6: Promise verification timeline among different languages.

offer more specific commitments, whereas Chinese reports are less expected to include detailed commitments. Korean firms are the highest in both supporting evidence and clarity, whereas English and Japanese reports include more misleading information. Taiwanese and Korean firms focus on short-term action in their commitment timelines, whereas English firms have the largest proportion of unclear or unverifiable timelines.

3.2 Experimental Setup

For our system, we employ the feature fusion based neural network architecture. The configuration of the system is provided in Table 2.

Settings of the Proposed System
1. *Sentence Embedding*: LASER, USE
2. *Embedding Dimension*: 1024
3. *Optimizer*: Adam, AdamW
4. *Learning_rate*: 1e-7 to 7e-5
5. *Epochs*: 10 to 30
6. *Batch Size*: 16, 32, 64

Table 2: System settings.

3.3 Result Analysis

This section includes some experimental analysis to support our proposed Fused Bi-LSTM+MLP system. Before finalizing the methods architecture, we first conducted several tests based on the training data of the promise verification dataset. However, to estimate the performance of our promise verification system, we utilized the F1-score as a primary evaluation measure. The results of our proposed model's performance on two tasks are displayed

in Table 3 and the detailed experimental baseline score are shown in Figure 7.

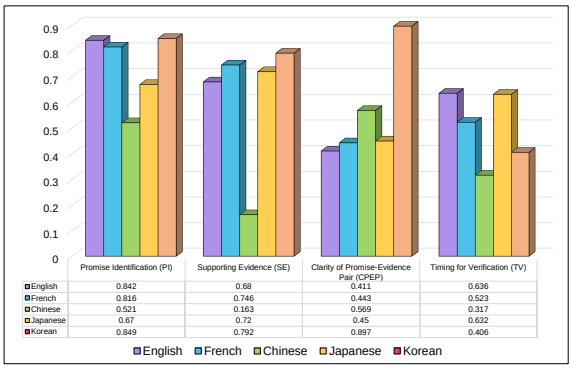

Figure 7: Experimental results on different languages.

We have shown the performance of our experimented models on the SemEval 2025 promise verification dataset. The Figure 7 demonstrates the results on four different categories in five different languages.

While doing experimental analysis, it is evident that the scoring pattern among different languages, such as English, Chinese, Korean, French, and Japanese also matches the data analysis pattern for the promise identification and evidence verification task. In the dataset overview section, we noticed that English and French language ESG reports had a greater ratio of promise which was also reflected in the scoring. Furthermore, our system shows competitive performance for each of the languages except Korean language.

4 Discussion

To maintain clarity and focus, supplementary analyses—including topic modeling to identify key themes in corporate promises, sentiment analysis aimed at detecting greenwashing in ESG reports, and word frequency analysis for promise detection—are provided in Appendix 5. In this section, we focus on core evaluation aspects, including explainability analysis using SHAP and a detailed error analysis of the evidence identification task, to further interpret model performance and understand its limitations.

4.1 Explainability Analysis using SHAP

To better understand the decision-making process of the model, we apply SHAP (SHapley Additive exPlanations) (Lundberg, 2017) to describe feature contributions. SHAP dissects the effect of individual words or phrases on the prediction of the model, making it transparent to decisions. The bar chart in Figure 8 illustrates the top 20 most important words influencing the evidence prediction model, ranked by their mean absolute SHAP values. The higher the SHAP value, the greater the word's impact on the model's decision-making process. Words like "risk", "employees", "group", and "2022" have the strongest influence, suggesting they play a crucial role in determining whether a piece of text contains supporting evidence. Other significant terms, such as "burberry", "emissions", "ethics", and "supply," indicate the model's focus on themes related to corporate responsibility, financial matters, and ethical concerns. This visualization helps in understanding which words contribute most to the model's predictions, providing insights into its decision logic.

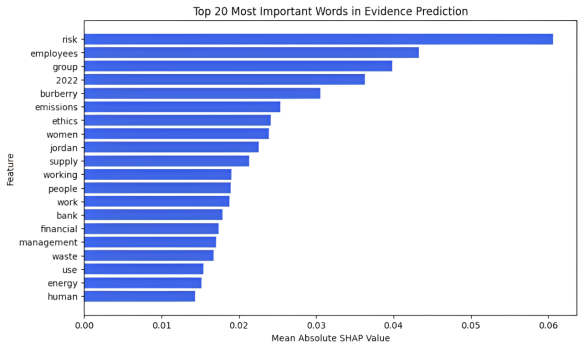

Figure 8: Word impact toward evidence prediction.

4.2 Error Analysis

4.2.1 Error Analysis for Promise Identificatin Task

The Table A6 presents an error analysis for the promise identification task, comparing sample texts with their predicted and true labels. The second prediction is correct, as the model accurately identified the commitment to reducing energy intensity and decarbonizing electricity usage, making it a valid promise. The presence of explicit terms like "We will reduce our energy intensity" strengthens the model's decision.

However, the first prediction is incorrect, as the model classified a disclaimer about forward-looking statements as a promise. The statement contains phrases like "we cannot guarantee their realization" and "undertakes no duty to update such information except as required under applicable law", which indicate caution rather than a commitment. The misclassification suggests that the model might have mistaken forward-looking language for

Language	PromiseVerification	EvidenceVerification
English	0.8113	0.7114
Chinese	0.6360	0.6973
French	0.7225	0.5850
Japanese	0.9300	0.5650
Korean	0.2340	0.2160

Table 3: Task scores for different languages.

a definitive obligation, leading to an overestimation.

This error highlights a key challenge in promise verification—distinguishing between actual commitments and general disclaimers or legal protections. Future improvements should focus on context-aware training, refining the model's ability to differentiate between legally binding statements and non-committal language, thereby improving classification accuracy.

4.2.2 Error Analysis for Evidence Idenfication Task

The Table A7 presents an error analysis for the evidence identification task, where the model determines whether a given text contains supporting evidence for a claim or commitment. Among the three examples, two were correctly classified, while one was misclassified. The first sample, discussing collaboration and environmental reporting, was correctly classified as evidence since it explicitly mentions engagement with stakeholders, regulators, and Indigenous communities. Additionally, it provides quantifiable data, stating that in 2022, Canada Nickel had zero instances of environmental non-compliance, fines, or violations, making it a strong supporting evidence statement. The second sample, detailing the risk assessment process, was also correctly classified as not containing evidence since it describes a procedure rather than providing specific data or verifiable reports. However, the third sample, outlining the responsibilities of the ESG Committee, was misclassified as containing evidence when it actually does not. While the text discusses accountability in areas such as health and safety, climate change, and social matters, it does not present concrete proof, such as compliance data or measurable outcomes. The misclassification suggests that the model may be over-relying on governance-related terms rather than distinguishing between general policy descriptions and verifiable evidence. Future improvements should focus on refining the model's ability to differentiate between commitments, procedural descriptions, and factual evidence, ensuring more accurate classification.

5 Conclusion and Future Work

In this paper, we introduced a feature fusion based neural architecture framework for corporate promise verification. Among them, for the feature fusion, we levaraged the feature embedding coming from LASER and Universal Sentence Encoder. Then, the Bi-LSTM with MLP framework trained with after the feature integration to get the predictions for promise and evidence identification subtasks.

Our future plan amalgamates working with the clarity of promise and verification timeline subtasks, as well as focus on the better model by incorporating multilingual Retrieval-Augmented Generation (RAG) with Large Language Model (LLM) based framework for the corporate promise verification task.

A Supplementary Analyses

A.1 Topic Modeling: Identifying Key Themes in Corporate Promises

Corporate ESG reports encompass a range of diverse themes, ranging from climate change to social responsibility. To reveal the dominant subjects of corporate commitments, **Latent Dirichlet Allocation (LDA)** is applied, which identifies key themes underlying the text. Table A4 presents the five most salient topics from the English dataset. Each topic comprises key terms that provide a hint of the primary areas of emphasis of corporate commitments, enabling a systematic interpretation of ESG priorities across industries.

Topic	Top Keywords
Topic 1	Equality, fashion, commitments, liquidity, Arabi, 500, LVMH, Kering, SMEs, care
Topic 2	Energy, term, low, products, circular, supply, fashion, waste, carbon, emissions
Topic 3	Staff, disability, men, like, LVMH, heritage, European, spill, pragmatic, collaborate
Topic 4	Middle, emergency, East, dialogue, year, trade, create, bank, best, Jordan
Topic 5	Impact, environmental, safety, business, bank, management, information, employees, group, risk

Table A4: Identified topics and keywords from Topic Modeling.

- **Topic 1 (Equality and Corporate Commitments):** This topic is centered around fashion industry commitments, corporate liquidity, and equality. The presence of terms like LVMH, Kering (major fashion companies), and SMEs suggests a focus on sustainability and inclusivity in the fashion sector.
- **Topic 2 (Energy and Sustainability):** The words carbon, waste, emissions, and circular supply indicate that this topic deals with environmental sustainability, particularly in reducing carbon footprints, managing waste, and promoting circular economies.
- **Topic 3 (Workforce and Inclusion):** This topic relates to diversity, disability inclusion, and employee well-being, as seen through words like staff, disability, heritage, and collaborate. The presence of LVMH again suggests a connection to the fashion industry's employment policies.
- **Topic 4 (Crisis Response and Economic Stability):** The keywords Middle East, emer-

gency, trade, and bank suggest a focus on corporate responses to crises, possibly related to humanitarian aid, financial support, or economic stability in specific regions.

- **Topic 5 (Risk and Environmental Impact):** This theme revolves around corporate risk management, environmental responsibility, and workplace safety, as indicated by words like impact, safety, business, employees, and risk management.

Thus, the LDA key ESG theme analysis reveals that corporate commitments are centered around sustainability, social responsibility, crisis management, and labor inclusion. Certain industries, like fashion and finance, seem to be prominent in these commitments. Further, though some of the topics prioritize long-term sustainability objectives, others prioritize short-term economic and social issues.

A.2 Sentiment Analysis: Detecting Greenwashing in ESG Reports

The analysis seeks to identify greenwashing behavior in ESG reports through the sentiment of corporate commitments. Greenwashing is said to happen when firms utilize excessively positive language to present a false picture of their sustainability initiatives without the presence of considerable evidence. This was evaluated by using the VADER (Valence Aware Dictionary and Sentiment Reasoner) tool to measure the sentiment polarity of statements. Every statement was given a sentiment score from -1 (most negative) to +1 (most positive). Statements scoring above 0.8 on the sentiment scale and having no evidence to support them were considered possible instances of greenwashing. The sentiment distribution, as the Figure 9 shows, indicates that the majority of statements are concentrated towards the positive side of the scale, specifically towards a sentiment score of 1. This shows that firms tend to use very optimistic language in their ESG commitments. Yet, the existence of some neutral and negative statements indicates variability in the sentiment tone. The clustering of statements with high positive sentiment scores identifies the potential risk of greenwashing, particularly if such statements are not supported by concrete evidence, calling for a more critical analysis of firms' ESG commitments.

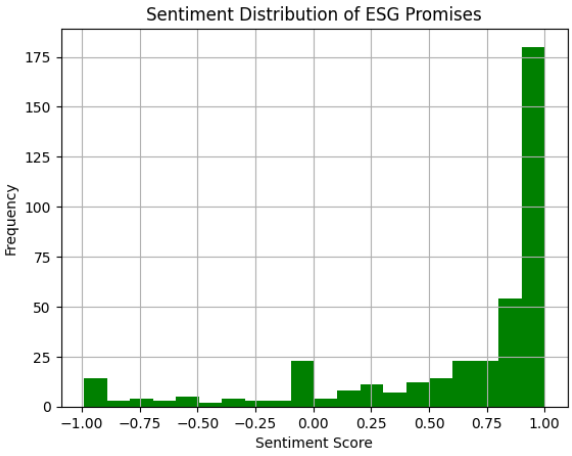

Figure 9: Sentiment analysis in detecting greenwashing in ESG reports.

A.3 Word Frequency Analysis for Promise Detection

The word frequency Table A5 for the promise detection english dataset shows the main differences between promise and non-promise statements.

In promise statements, the most common words are risk (231), employee (190), impact (130), business (128), information (125), emission (115), support (108), and program (104). These words indicate a strong focus on commitment, responsibility, and organized actions, especially in risk management, environmental impact, and business programs. Words such as training (89), community (89), and opportunity (83) also point to a commitment to employee development and corporate social responsibility (CSR).

In contrast, in non-promise statements, although risk (137) remains the most frequent word, other high-frequency words such as management (64), governance (24), compliance (22), report (19), and policy (32) suggest a more regulatory or descriptive rather than commitment-oriented tone. In addition, the occurrence of words such as privacy (16), client (15), and chief (15) suggests a focus on general policy and leadership arrangements rather than specific action. The occurrence of impact (17) in both groups suggests that impact assessment is addressed in both promise-driven and neutral contexts, but with different implications.

This analysis points out that promise language often involves active words like support, program, training, and action, whereas non-promise language is more policy-oriented or descriptive and focuses on management, compliance, and gover-

Promise	Frequency	Non-Promise	Frequency
Risk	231	Risk	137
Employee	190	Management	64
Impact	130	Information	40
Business	128	Policy	32
Information	125	Data	30
Emission	115	Business	26
Support	108	Governance	24
Program	104	ESG	23
Work	93	Compliance	22
Community	89	Employee	20
Training	89	Report	19
Management	88	Group's	19
Environmental	87	Conduct	18
Service	85	Climate	18

Abstract

This paper presents our approach to SemEval-2025 Task 11 (Track A): Bridging the Gap in Text-Based Emotion Detection, focusing on multilabel emotion classification for the English dataset. Our methodology leverages an ensemble of transformer-based models, incorporating full fine-tuning along with additional classification layers to enhance predictive performance. Through extensive experimentation, we demonstrate that fine-tuning significantly improves emotion classification accuracy compared to baseline models. In addition, we provide an in-depth analysis of the dataset, highlighting key patterns and challenges. The study also evaluates the impact of ensemble modeling on performance, demonstrating its effectiveness in capturing nuanced emotional expressions. Finally, we outline potential directions for further refinement and domain-specific adaptations to enhance model robustness. Our submission was officially ranked 34th in Track A (multilabel emotion detection) leaderboard for English language.

1 Introduction

The increasing availability of electronic documents in the digital era has provided a valuable resource for analyzing human expressions and improving various applications. Understanding this plays a crucial role in multiple domains, including user experience enhancement, social media analysis, mental health monitoring, and market research. Increasing scholarly attention has been directed toward extracting user perspectives on various events by analyzing textual content. The computational identification and classification of opinions within text has been recognized as a fundamental step in data mining. Researchers have traditionally focused on determining whether a given text conveys a positive, negative, or neutral stance toward a specific subject or product (Feng et al., 2021). More recently, studies have expanded to incorporate multidimensional emotional annotations (Hu and Flaxman, 2018; Tasmin, 2018; Acheampong et al., 2020) capturing sentiments such as joy, fear, anger, etc.

Emotion expression in language is inherently nuanced and complex, presenting challenges for emotion recognition. Despite its significance, research in this field has predominantly focused on high-resource languages, leading to significant disparities in dataset availability and model performance for low-resource languages. To address this gap, the organizers of SemEval-2025 Task 11 have curated a specialized dataset, BRIGHTER (Muhammad et al., 2025a) to bridge further the gap in emotion recognition research in underrepresented languages, facilitating more inclusive and effective NLP models. It is a collection of multilabel emotion-annotated datasets spanning 28 languages. This dataset emphasizes low-resource languages from Africa, Asia, Eastern Europe, and Latin America, incorporating diverse textual sources annotated by fluent speakers. The shared task consists of three tracks: multi-label emotion classification (track A), emotion intensity prediction (track B), and text cross-lingual emotion detection (track C).

In this paper, we present our system developed for track A of the task (Muhammad et al., 2025b), multilabel emotion classification. Transformers have been proven to be the most successful in understanding the contextual and semantic information of the text (Acheampong et al., 2021; Gillioz et al., 2020). We selected top-performing models from preliminary experiments, including cardiffnlp/twitter-roberta-large-emotion-latest (Antypas et al., 2023), SamLowe/roberta-base-goemotions (Lowe, 2022) and Emanuel/twitter-emotion-deberta-v3-base (Huber, 2021), to build an ensemble leveraging these models, combining their strengths for improved emotion classification,

* All Authors have equal contribution.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1859–1865

and performed full fine-tuning. Since these models had more emotion categories than our dataset, we incorporated additional classifier layers, adapting to our task.

Our system demonstrated good performance across track A. We achieved competitive results, ranking 42 on the English dataset among the 75 participating teams. Dataset imbalance presents a challenge in these methods. Robust methods using undersampling and oversampling techniques need to be used to overcome this challenge. Further, extensive data analysis is always beneficial. Please find the code here- https://github.com/Tafazzul-Nadeem/TBED-CS779-IITK.

2 Background

The landscape of human emotions has been described through various taxonomies and frameworks. Ekman (Ekman and Friesen, 1971) identified six core emotions expressed through facial expressions that are universally recognized across cultures: joy, sadness, anger, surprise, disgust, and fear. Later, finer-grained taxonomies have been developed, capturing a broader range of up to 600 emotions and employing machine learning to cluster emotion concepts (Cowen and Keltner, 2019). These frameworks highlight the complex, culturally influenced nature of emotions expressed through vocalization (Cowen and Keltner, 2018), music, and facial expressions.

Previous approaches to text-based emotion detection have primarily utilized machine learning (ML) techniques. For instance, Wikarsa et al. and Ameer et al. (Ameer et al., 2021) focused on multi-label emotion classification for code-mixed SMS messages in Roman Urdu and English, employing classical ML methods (SVM, J48, Naive Bayes, etc.) and deep learning models (LSTM, CNN, etc.) on a new dataset. Their results indicated that classical ML methods outperformed both ML and deep learning models. Similarly, Polignano et al. (Polignano et al., 2020) developed a model combining Bi-LSTM, Self-Attention, and CNN for emotion detection, finding that word embeddings significantly improved performance. Their experiments in the ISEAR, SemEval-2018 (Mohammad et al., 2018), and SemEval-2019 datasets demonstrated that the ISEAR dataset produced the best precision and recall.

In recent years, research on text-based emotion detection has increasingly utilized transformer-based pre-trained language models. For instance, Acheampong et al. (Acheampong et al., 2020) conducted comparative analyses of models such as BERT (Devlin et al., 2019), RoBERTa (Liu et al., 2019), DistilBERT (Sanh et al., 2019), and XLNet (Yang et al., 2019) for emotion recognition using the ISEAR dataset. Asalah et al. (Thiab et al., 2024) proposed an ensemble deep learning approach for emotion detection in textual conversations, CNN-based model and transformer-based models, including BERT, RoBERTa, and XLNet. They utilize hard and weighted majority voting methods to enhance prediction accuracy. Their method demonstrates superior performance, achieving a micro-averaged F1-score of 77.07% on the SemEval-2019 Task 3: EmoContext dataset (Chatterjee et al., 2019), outperforming previous baseline results.

We performed experiments with the track A dataset (Muhammad et al., 2025a), where the training set contains 2768 samples with five binary emotion labels (joy, sadness, fear, anger, and surprise). Dev set contains 116 samples, and 2767 samples are available for inference.

3 Analysis

The co-occurrence matrix of the labels for the English dataset is plotted to gain insights about the correlation between the labels, as shown in Figure 1. We have also visualized the box plot for

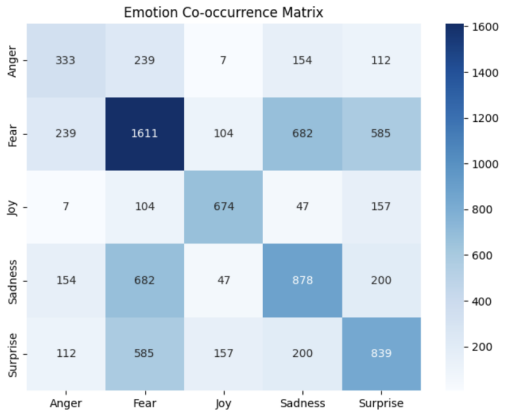

Figure 1: Co-occurrence matrix of emotion labels

length of the text snippets showing the interquartile range (Q1, Q2, etc.) in Figure 2 to gain insights about the context length or prompt length we require while selecting a transformer model. The maximum length is found to be 94 words. Hence, any model with a 512 token size can be used since

the number of tokens = 4 x the number of words (widely used estimate).

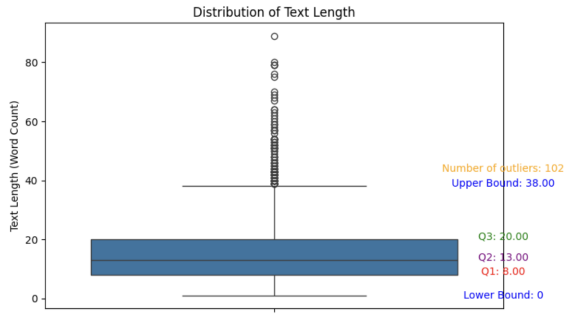

Figure 2: Boxplot of text snippet length

4 Proposed Approach

Since transformer-based models have shown promising results in classification tasks lately, we decided to first find some suitable models for the multilabel classification task. From recent works (Lowe, 2022; Barbieri et al., 2022; Antypas et al., 2023; Huber, 2021; Grattafiori et al., 2024), we shortlisted the following huggingface models, ensembled them, and fully fine-tuned the ensemble: cardiffnlp/twitter-roberta-large-emotion-latest (Antypas et al., 2023), SamLowe/roberta-base-go_emotions (Lowe, 2022) and Emanuel/twitter-emotion-deberta-v3-base (Huber, 2021). The ensemble model, along with the standalone parts, was evaluated on the training data for the English language with full fine-tuning. The results are shown in Table 1.

5 Experiments

The following sections provide a comprehensive overview of our model development process and the final model used for multi-label emotion detection. The first section traces the evolution of our approach, detailing the various models and fine-tuning strategies we experimented with. This includes trials with both smaller and larger models, full fine-tuning, classifier adaptations, and specialized training settings such as entailment-based approaches. The second section focuses on our final approach, which represents the culmination of our iterative experimentation. We describe its architecture, training methodology, and the rationale behind selecting this configuration as our best performing system. The final model integrates insights gained from our earlier experiments, leveraging an ensemble of fine-tuned models to achieve optimal performance.

5.1 Evolution of our approach

We selected some of the best performing models from preliminary experimentation, cardiffnlp/twitter-roberta-large-emotion-latest (Antypas et al., 2023), SamLowe/roberta-base-go_emotions (Lowe, 2022), and Emanuel/twitter-emotion-deberta-v3-base (Huber, 2021), and evaluated them on the validation set to get baseline results. Then, full fine-tuning was performed on these models.

We then tried training adapter models by adding a classifier layer. Since the off-the-shelf models have more emotion categories than our dataset, we added an extra fully connected (FC) layer with five neurons (equal to emotion labels in the dataset). The base model is frozen, and only the FC layer is trained. The Macro F1 score is 0.69 for cardiffnlp/twitter-roberta-large-emotion-latest with this approach.

We also experimented with the entailment approach, in which the dataset was converted to a premise-hypothesis pair dataset with a label '0' or '1'. '0' for hypothesis being in contradiction/neutrality of the premise and '1' for hypothesis being entailment of the premise, respectively, for every emotion.

Example:

Input Sample: "But not very happy."

	Anger	**Fear**	**Joy**	**Sadness**	**Surprise**
Emotions	0	0	1	1	0

Converted to five different samples:

Premise	But not very happy.
Hypothesis	The speaker is feeling Anger.
Labels	[0] (Neutral or Contradiction)
Premise	But not very happy.
Hypothesis	The speaker is feeling Fear.
Labels	[0] (Neutral or Contradiction)
Premise	But not very happy.
Hypothesis	The speaker is feeling Joy.
Labels	[1] (Entailment)
Premise	But not very happy.
Hypothesis	The speaker is feeling Sadness.
Labels	[1] (Entailment)
Premise	But not very happy.
Hypothesis	The speaker is feeling Surprise.
Labels	[0] (Neutral or Contradiction)

Model Name	Track	Accuracy	Micro F1	Macro F1
SamLowe/roberta-base-go_emotions	A	0.21	0.45	0.44
cardiffnlp/twitter-roberta-large-emotion-latest	A	0.29	0.54	0.53
Emanuel/twitter-emotion-deberta-v3-base	A	0.16	0.45	0.40
meta-llama/Meta-Llama-3-8B-Instruct	A	0.24	0.58	0.59
cardiffnlp/twitter-roberta-large-emotion-latest (Full Fine-tuning)	A	0.43	0.60	0.49
SamLowe/roberta-base-go_emotions (Full Fine-tuning)	A	0.44	0.61	0.49
cardiffnlp/twitter-roberta-large-emotion-latest (Added Classifier Layer Only)	A	0.57	0.73	0.69
cardiffnlp/twitter-roberta-large-emotion-latest (Entailment Approach)	A	0.60	0.73	0.73
Fully fine-tuned Ensemble (final system evaluated on test set)	A	-	**0.7636**	**0.7344**

Table 1: Results of all the experiments conducted for Track A on Dev Set

The Premise and Hypothesis are then appended and given to a laguange model with an added final layer of single neuron to predict 0 or 1 for Contradiction and Entailment respectively.

All results are presented in Section-6.

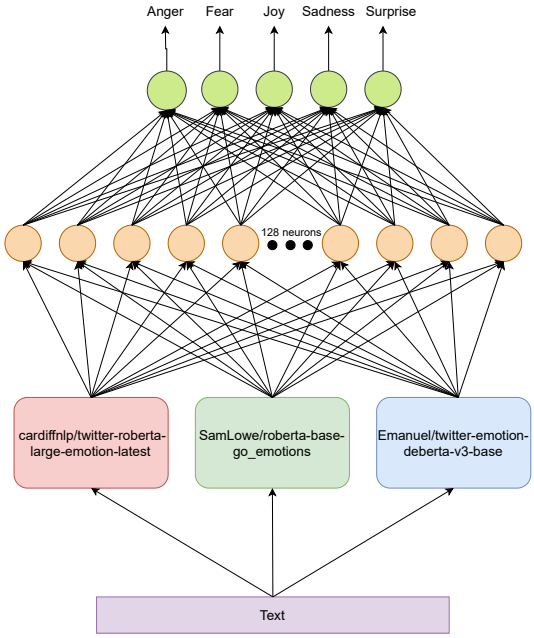

Figure 3: Model architecture of our system

5.2 Final Approach: Ensemble of Three Transformer Models

An ensemble using three transformer models: cardiffnlp/twitter-roberta-large-emotion-latest, SamLowe/roberta-base-go_emotions, and Emanuel/twitter-emotion-deberta-v3-base is created as shown in Figure-3. First, we tokenized the training, validation, and test datasets using the tokenizer for each model. A custom ensemble dataset was created to combine the inputs from all three models. While training, output of each model (logits) are concatenated together. The concatenated outputs were passed through two fully connected layers of 128 and 5 neurons for multi-label classification. Binary cross-entropy loss is used for training the model. The ensemble was trained for five epochs using a batch size of 8.

The training is done on an A30 24 GB GPU card. AdamW optimizer with a learning rate of 2e-5 and a weight decay of 0.01 is employed. A linear learning rate scheduler with no warm-up steps is used for training. The models are trained with a maximum sequence length of 256 tokens. For regularization, dropout is set to 0.1 in the fully connected layers. The total training time for five epochs is approximately 30 minutes.

The results are analyzed in Section-6.

6 Results

The results of our experiments are summarized in Table 1. We began by evaluating several transformer-based pre-trained models without fine-tuning. We shortlisted models listed in for initial experiments and found that the macro-F1 score hovered between 0.40 to 0.50. To get a comparative understanding, we also evaluated a big model, meta-llama/Meta-Llama-3-8B-Instruct model, but could not achieve significant gains in the scores.

Afterward, we focused on smaller models and fine-tuned the cardiffnlp/twitter-roberta-

large-emotion-latest and SamLowe/roberta-base-go_emotions model. A fully fine-tuned version achieved a marginal improvement over the baseline. We also experimented with partial fine-tuning by adding only a classifier layer on top of twitter-roberta-large-emotion-latest, which resulted in the best performance among individual models and a 0.69 mmacro-F1 score. Employing an entailment-based approach with the cardiffnlp/twitter-roberta-large-emotion-latest model resulted in notable performance improvements, achieving a macro-F1 score of 0.73.

In our final approach, to further boost performance, we created an ensemble of pre-trained models trained on different emotion datasets and fully fine-tuned the ensemble with added classifier layers at the top. The models used were cardiffnlp/twitter-roberta-large-emotion-latest, SamLowe/roberta-base-go_emotions, and Emanuel/twitter-emotion-deberta-v3-base. The ensemble achieved the best overall performance with a Macro-F1 of 0.7344 in the test dataset, demonstrating the advantage of leveraging multiple models for emotion classification.

7 Conclusion

In this challenge, we explored various transformer-based models for multi-label emotion detection, evaluating their performance on Track A using multiple fine-tuning strategies and model ensembles. Our results demonstrate that model architecture and fine-tuning approach significantly impact performance. Our findings highlight the advantages of leveraging multiple pre-trained models and ensembling techniques for emotion classification tasks. Future work could explore additional architectures, data augmentation methods, and domain adaptation techniques to further enhance model performance and generalizability across different datasets. Our findings show that fine-tuning smaller models can sometimes perform as well as, or even better than, larger models. This means it is possible to improve accuracy without the requirement of very big models like LLMs.

Future Work

In the future, there are several ways we can improve the performance of our model. One important area is making these methods work for low-resource languages, where pre-trained models are not available. This might require new techniques like transfer learning or data augmentation techniques. We propose investigating cross-lingual transfer learning, e.g., XLM-R (Conneau et al., 2020), mBERT (Devlin et al., 2019) adaptations and back-translation-based data augmentation (Sennrich et al., 2016) to synthetically expand training data. Another challenge we face is class imbalance, where some emotions are harder to detect because they appear less often in the data. Future research could look at better ways to deal with this, such as creating more data for rare emotions e.g., SMOTE, Chawla et al. (2002) or using different loss functions, such as focal loss, Lin et al. (2018). Lastly, combining text with other types of data, like speech or images, as in multimodal fusion (Baltrušaitis et al., 2019) could make the model even better at understanding and classifying emotions. This could help create a more complete system for emotion detection.

Limitations

One of the key limitations of our approach is the lack of extensive focus on data augmentation strategies, which could have further enhanced model performance. While we explored an entailment-based reformulation to expand the dataset, we did not experiment with other augmentation techniques such as back-translation, synonym replacement, or adversarial data augmentation, which might have introduced greater diversity in training examples. The high computational cost of full fine-tuning is another constraint, as large transformer models require significant GPU resources, making scalability an issue. Better optimization techniques can mitigate the issue to a significant level.

Acknowledgments

This work was carried out at the Exploration Lab, IITK. We are thankful to the organisers of the competition for their contribution to the research community.

Stanford MLab at SemEval-2025 Task 11: Track B–Emotion Intensity Detection

Joseph Le and Hannah Cui and James Zhang
Stanford University

Abstract

We here outline our SemEval 2025 Track B: Emotion Intensity Prediction submission, for which the objective is to predict the intensity of six primary emotions—anger, disgust, fear, joy, sadness, and surprise—between 0 and 3, with 0 being none and 3 being very strong. We used a regression fine-tuned BERT-based model that makes use of pretrained embeddings in order to sense subtle emotional wordings in text.

We include tokenization with a BERT tokenizer, training with AdamW optimization, and an ExponentialLR scheduler used for learning rate modification. Performance is monitored based on validation loss and accuracy through closeness of model outputs to gold labels.

Our best-performing model is 68.97% accurate in validation and has a validation loss of 0.373, demonstrating BERT's capability in fine-grained emotion intensity prediction. Key findings include that fine-tuning transformer models with regression loss improves prediction accuracy and that early stopping and learning rate scheduling avoid overfitting. Future improvements can include larger datasets, ensemble models, or other architectures such as RoBERTa and T5. This paper shows the potential of pretrained transformers for emotion intensity estimation and lays the groundwork for future computational emotion analysis research.

1 Introduction

The SemEval 2025 Task 11 Track B: Emotion Intensity Prediction seeks to create models that make predictions about the perceived intensity of six emotions—joy, sadness, fear, anger, surprise, and disgust—in a sentence. The intensity is on an ordinal scale of 0 (no emotion) to 3 (strong emotion), which allows us to have a more nuanced view of emotional expression. This task is essential to the creation of emotion-aware NLP applications, such as sentiment analysis, mental health tracking, and human-computer interaction, by identifying not just the presence of emotion, but also its intensities. The dataset comprises eleven languages—Amharic, Algerian Arabic, Mandarin Chinese, German, English, Spanish, Hausa, Portuguese, Romanian, Russian, and Ukrainian—and covers a multilingual range of emotion detection. For the full description of the task, dataset, and evaluation setup, refer to the SemEval 2025 Task 11 Track B overview paper (Muhammad et al., 2025b).

Our approach employs a transformer-based model, which depends on multilingual pre-trained language models (PLMs) such as XLM-RoBERTa to acquire semantic and contextualized representations across languages. Because the task is ordinal, we experiment with both regression-based and ordinal classification approaches, complementing data augmentation and fine-tuning methods for improving generalization. We also explore language-specific and multilingual training settings, balancing the trade-offs of cross-lingual knowledge transfer and fine-tuning particular to languages. To further enhance our predictions, we integrate ensemble learning techniques and utilize different model outputs in combination to reduce variance and increase robustness. Through this assignment, we gained valuable lessons in multilingual emotion intensity prediction tasks. Our system performed well with high-resource languages like English and Spanish, performing within the top 60% of submissions. It declined for low-resource languages such as Hausa and Amharic, revealing the limitations of PLMs to handle underrepresented languages. Additionally, our model struggled with subtle distinctions between moderate and high emotion intensities, suggesting directions for future optimization in label calibration. Contrastive learning and emotion-aware embeddings are directions of future work that can enhance the degree of granularity in emotion intensity predictions.

Our code has been publicly released and can be

2 Background

For Task 11 Track B, the main aim is to create a model that could predict the perceived intensity of emotions within a sentence, across different languages. More specifically, each language had 5-6 major emotions that could be detected in a sentence– joy, sadness, fear, anger, surprise, and disgust. The predictions are a perceived intensity on a scale of 0-3 of each emotion within a sentence, with 0 being no emotion at all and 3 being strong emotion. The datasets provided for this algorithm included the languages Amharic, Algerian Arabic, Mandarin Chinese, German, English, Spanish, Hausa, Portuguese, Romanian, Russian, and Ukrainian. There were separate datasets for dev, test, and train, with varying amounts of data between each language (usually a couple thousand sentences for each dataset).

3 System Overview

Our detection system is built using PyTorch and the HuggingFace transformers library. First for preprocessing, the dataset will be tokenized using the AutoTokenizer from HuggingFace transformers and padded to the default max_length for the model. The labels(emotions) are also converted to tensors for training.

We used the Bidirectional Encoder Representations from Transformers, or BERT, base model (uncased) from Hugging Face as a pre-trained model that we then fine-tuned for a regression task on the provided emotion intensity dataset. We set the tokenizer to the BERT tokenizer, and ran each of the datasets (train, val, test) through our preprocessing pipeline.

For the model itself, we used the BERT model for sequence classification with 5 labels for the emotions (6 for languages with 6 emotions), and set the problem type to regression for this task. We used an AdamW optimizer with a learning rate of 5e-5. In the training loop, we iterated over each batch of data and evaluated the output of the model given tokenized input ids and attention masks that allows the model to differentiate between actual tokens and padding. The loss was then calculated in each iteration using mean squared error, which is the default for a regression task. At the end of the loop, gradients are calculated with loss.backward() and model weights are updated.

4 4 Experimental Setup and Methods

4.1 Data Splits

We use the given dataset for SemEval 2025 Task 11 Track B, dividing it into training, validation, and test sets:

- Training Set: It is used to train the model.
- Validation Set: It is utilized for hyperparameter tuning and early stopping.
- Test Set: It is utilized for final performance evaluation.

The data set consists of text snippets with annotated perceived emotion intensities (anger, disgust, fear, joy, sadness, surprise) on an ordinal scale from 0 to 3. The data is read from CSV files:

- track_b_data/train/[language].csv
- track_b_data/dev/[language].csv
- track_b_data/test/[language].csv

4.2 Preprocessing

Tokenization: We tokenize text data with the Hugging Face AutoTokenizer and the bert-base-uncased model. Sequences are padded or truncated to a maximum of 128 tokens. Dataset Formatting: We define a custom PyTorch Dataset class (EmotionDataset) to handle tokenized input and corresponding labels. Batching: The data is batched with DataLoader for training and testing with batch size 16.

4.3 Model and Training Configuration

Model: BERT-base-uncased is fine-tuned for regression using AutoModelForSequenceClassification with num_labels=1 to return emotion intensity scores. Loss Function: Mean Squared Error (MSE) loss is used to train the regression model. Optimizer: AdamW optimizer with 1e-5 learning rate and weight decay of 0.001. Scheduler: Learning rate is adjusted dynamically with an exponential scheduler (gamma=0.99).

4.4 Training Strategy

Epochs: 15 epochs with early stopping when validation loss does not show improvement for 3 consecutive epochs. Gradient Updates: Backpropagation through loss.backward() and optimization steps through optimizer.step(). Validation Checkpoints: The model is validated at the end of every epoch on the validation set and the best performing model (according to validation loss) is stored.

4.5 Evaluation Metrics

Loss: At validation time, Mean Squared Error (MSE) loss is tracked. Accuracy Proxy: A prediction is considered to be correct if its absolute deviation from ground truth is less than 0.5. Final Output Processing: Prediction is rounded and clamped in the interval [0,3] prior to submission.

4.6 Tools and Libraries

PyTorch (torch==2.x) - Model training and testing. Transformers (transformers==4.x) - Tokenization and model loading. Pandas (pandas==1.x) - Data management and CSV operations.

4.7 Model Saving and Inference

The best model according to validation loss is saved as model_best_weights.pt. Predictions on the test set are saved in [language]_predictions_rounded.csv. This setup ensures reproducibility and effective model training for emotion intensity prediction in the SemEval 2025 Track B task.

5 Results

The proposed model achieved a validation accuracy of 68.97% and a validation loss of 0.373, indicating robust performance in emotion intensity prediction. These results affirm that regression-based fine-tuning of BERT effectively captures subtle variations in emotional expression. Our system ranked within the top 60% overall, demonstrating competitive performance across multiple languages. The model performed well in high-resource languages such as English and Spanish but exhibited limitations in low-resource languages like Hausa and Amharic, suggesting potential constraints in cross-lingual transfer learning.

6 Analysis

6.1 Quantitative Analysis and Ablation Studies

The choice of model architecture played a crucial role in performance. The use of bert-base-uncased provided a strong baseline, but alternative models such as roberta-base and deberta-v3-base could offer enhanced contextual representations. Training on a merged multilingual dataset proved beneficial for high-resource languages, yet it provided limited advantages for low-resource languages, suggesting that improved cross-lingual learning strategies are necessary. The implementation of AdamW with an ExponentialLR scheduler contributed to training stability. Experiments with various batch sizes and learning rates confirmed that our chosen hyperparameters struck an optimal balance between convergence speed and generalization.

6.2 Error Analysis and Limitations

The model encountered challenges in distinguishing moderate from strong emotion intensities, particularly in emotions such as sadness and fear, where contextual subtleties are crucial. False positives and negatives were more frequent in ambiguous cases where multiple emotions co-occurred, indicating the need for more sophisticated emotion-aware embeddings. Overfitting risks were observed, with superior performance on high-resource languages compared to low-resource ones, likely due to dataset imbalances and domain mismatches. While formal human evaluation was not conducted, manual inspection suggested that the model occasionally exhibited bias toward the dominant emotion present in the training data.

7 Conclusion

This study demonstrates that transformer-based models, particularly BERT, are effective for emotion intensity prediction. However, challenges remain in handling low-resource languages and refining distinctions between emotion intensities. Future work will explore alternative architectures such as roberta-base and deberta-v3-base, as well as incorporating contrastive learning techniques to improve representation learning. Expanding dataset diversity is essential to enhance generalization across languages. Furthermore, conducting human evaluations will provide deeper insights into model predictions and refine calibration strategies. Despite these limitations, our approach con-

tributes to the growing field of computational emotion analysis, underscoring the value of pretrained transformers in emotion intensity estimation. The findings provide a strong foundation for future advancements in emotion-aware natural language processing applications.

Abstract

This paper presents a system developed for SemEval 2025 Task 8: Question Answering (QA) over tabular data. Our approach integrates several key components: text-to-SQL and text-to-code generation modules, a self-correction mechanism, and a retrieval-augmented generation (RAG). Additionally, it includes an end-to-end (E2E) module, all orchestrated by a large language model (LLM). Through ablation studies, we analyzed the effects of different parts of our pipeline and identified the challenges that are still present in this field. During the evaluation phase of the competition, our solution achieved an accuracy of 80%, resulting in a top-13 ranking among the 38 participating teams. Our pipeline demonstrates a significant improvement in accuracy for open-source models and achieves a performance comparable to proprietary LLMs in QA tasks over tables. The code is available at this GitHub repository.

1 Introduction

Accessing structured data through natural language (NL) queries is crucial in various fields. However, converting NL into operations that retrieve outputs such as strings, numbers, booleans, or lists continues to be a significant challenge.

This paper outlines our team's participation in SemEval 2025 Task 8: DataBench (Osés Grijalba et al., 2024). This competition assesses question-answering (QA) systems working with tabular data, taking into account various formats, data quality issues, and complex question types. Our aim is to develop a system that accurately retrieves answers from tables, despite challenges such as missing values, inconsistencies, and ambiguous queries.

We focus on improving Large Language Models (LLMs) using Chain-of-Thought (CoT) reasoning (Wang et al., 2023; Cui et al., 2024). By integrating reasoning-inducing prompts, we enhance LLM-based code generation and decision-making. Additionally, our approach includes an end-to-end (E2E) pipeline and an LLM orchestrator to improve accuracy. To further refine performance, we implement several techniques aimed at reducing model forgetfulness. We introduce structured checklists to help the model verify each step, reducing errors in multi-hop reasoning. By combining prompt engineering, structured reasoning, and workflow optimizations, our system aims to achieve high exact-match accuracy. This paper details our system's architecture and key techniques (Sec. 3), dataset overview (Sec. 4), and experimental results (Sec. 5).

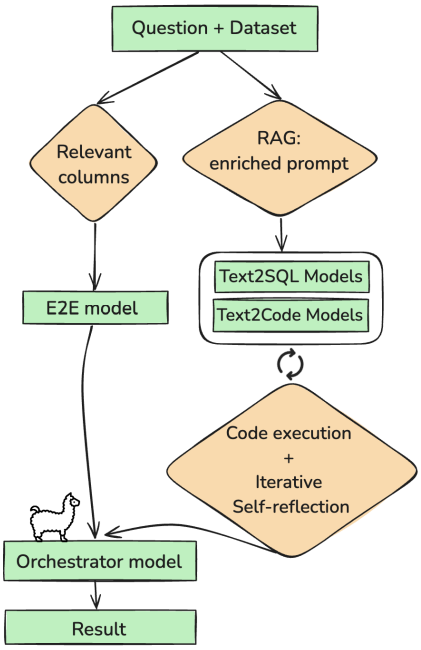

Figure 1: Overview of our system, featuring two solutions: end-to-end (E2E) and code-based. The code-based solution utilizes a self-correction mechanism and retrieval-augmented generation (RAG), with the final decision made by the orchestrator model.

Our findings offer key insights for enhancing LLM-driven QA for structured data, bridging the gap between open-source and proprietary models. Notably, our development set results showed that open-source LLMs achieved an accuracy of 88%, surpassing GPT-4o's 74%.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1870–1884

2 Related work

Question Answering (QA) over tabular data has gained significant attention due to the growing need for structured information retrieval (Sui et al., 2024; Liu et al., 2023; Singh and Bedathur, 2023; Ruan et al., 2024; R. et al., 2024). Research in this field has progressed with key datasets, such as FeTaQA (Nan et al., 2021) and ChartQA (Masry et al., 2022), as well as a large Wikipedia-based dataset, OpenWikiTable (Kweon et al., 2023). Various methodologies have been explored in recent surveys (Fang et al., 2024; Jin et al., 2022), including reinforcement learning and selective classification for text-to-SQL (Zhong et al., 2017; Somov et al., 2024; Somov and Tutubalina, 2025), pre-trained deep learning models (Abraham et al., 2022; Mouravieff et al., 2024), and few-shot prompting techniques (Guan et al., 2024). Building on previous work, we introduce a hybrid LLM-based pipeline that combines multiple techniques to improve performance.

3 System Description

Our system, as shown in Fig. 3, leverages LLMs and consists of the following key elements:

1. Text-to-SQL and Text-to-Code models to translate NL questions into code executable against tabular data (Sec. 3.2; Sec. 3.3)

2. RAG used to enrich prompts with relevant rows and delete irrelevant columns (Sec. 3.4);

3. Self-correction mechanism used to correct potential errors during execution (Sec. 3.5);

4. An E2E answering model to answer questions that target semantic understanding (Sec. 3.7);

5. An orchestrator model to make the final decision between provided solutions (Sec. 3.8).

3.1 Models

We used state-of-the-art instruction-tuned models featuring various model families: Llama (Grattafiori et al., 2024) (version 3.3 with 70b parameters as an orchestrator and 3.2 version with 3b for retrieval), Codestral (20.51 version) (Mistral AI Team, 2025) and Qwen Coder Instruct (2.5 version with 32b parameters) (Hui et al., 2024) for SQL and Code generation, also MiniMax-01 (MiniMax et al., 2025) for E2E solution. The selection of the models was driven by their outstanding performance in various benchmarks and the fact that they are open-source.

3.2 SQL code generation

Here the system resorts to generating SQL queries while using a carefully crafted prompt with a few relevant rows injected in it (Sec. 3.4) and with a suggested list of relevant columns to use (Sec. 5.5). The query is executed against the in-memory database (SQLite database via the SQLAlchemy package in our case), and the result is formatted and returned as a potential solution.

3.3 Pandas code generation

Here we prompt LLM to generate Python code with the use of Pandas library. The code is then executed against a Pandas Dataframe within a sandboxed environment with a timeout to prevent indefinite loops. The result of the execution is recorded as a potential solution. Along with the result, we record query success status and error text (if present) for possible future error correction (Sec. 3.5).

3.4 Retrieval

The Databench dataset contains data similar to what you might find in the real world, which presents certain challenges. One of these challenges is accurately filtering data based on specific properties, which often requires contextual knowledge. For example, to answer the question "How many customers are from Japan?", the model needs to know that "japan" is spelled in lowercase in the dataset. To tackle this challenge, we implemented a retrieval step (Gao et al., 2024). We first created sentence embeddings for each relevant column (previously identified in Sec. 5.5) and stored them for efficient searching. When a question was asked, we searched these embeddings to find the top three rows that were most semantically similar. The retrieved data was then used to enrich the LLM's context, enabling the model to answer such questions more accurately and efficiently.

3.5 Self-correction

The system incorporates a self-correction mechanism (Deng et al., 2025) that attempts to refine solutions that have failed execution attempts. After the failure of the Pandas solution, the system passes meta-info (schema, error message), along with the question back to LLM. Then new solu-

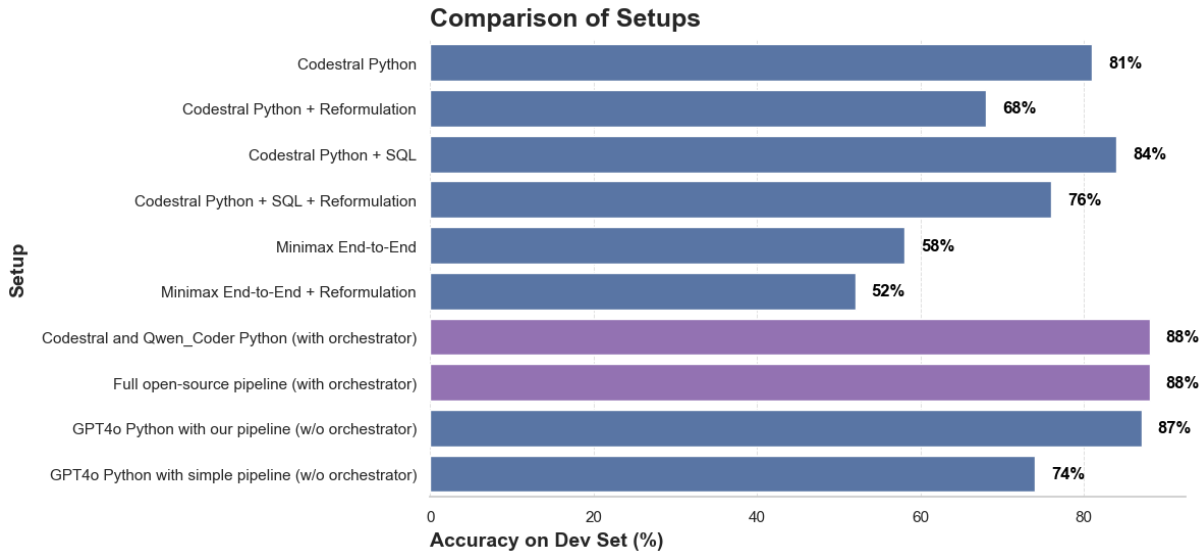

Figure 2: System performance on the dev set. Llama3.3-70b-instruct is used as an orchestrator. As a full pipeline, we're using: Codestral and Qwen Coder for Python and SQL, with Minimax E2E, managed through an orchestrator.

tion is generated. The same rules apply to SQL solutions.

3.6 Reasoning step

Recent advancements in prompting techniques, such as chain-of-thought prompting (Wei et al., 2022), have demonstrated that large language models (LLMs) can be guided to perform complex reasoning by structuring prompts to include intermediate reasoning steps. In our approach, we leverage this technique by explicitly instructing the LLM to reason extensively before providing its final answer. To extract only the relevant answer from the model's response, we employ fuzzy matching, which allows us to identify and isolate the desired output even when the response contains additional explanatory text or reasoning steps.

3.7 E2E answer generation

This method completely skips the code generation. The dataset is converted into human-readable text (markdown), then given to the LLM along with the underlying question. The model generates a direct answer. Model must put solution into one of the following data formats: Boolean, List, Number or String. The method is used to take advantage of LLM's ability to understand text and, therefore, answer questions about text data from the dataset.

Unlike code-generation, an E2E solution may only work well in a limited context: that is why we use the Retrieval step (see Sec. 3.4) and combine E2E with code-generation approaches to further increase performance.

3.8 Orchestrator

We use Llama (3.3 instruct version with 70b parameters) to choose the most probable solution among all presented. The model is provided with several solutions that were successfully executed. Each solution has code and a text-formatted result. Prompt (See Appendix prompt) has specific recommendations on how to choose the most probable solution. The model is incapable of generating new solution on the fly and only chooses between the presented options. Further orchestrator's performance analysis is in Sec. 5.3.

4 Dataset

The dataset comprises 65 publicly available tables across five domains: Health, Business, Social Networks & Surveys, Sports & Entertainment, and Travel & Locations. It retains real-world noise to enhance robustness and includes **1300** manually curated QA pairs **in English**, with 500 used for the test set across five answer types: boolean, category, number, list[category], and list[number]. DataBench is provided in two versions: the full dataset and DataBench lite, a smaller subset containing the first 20 rows per dataset. Key dataset statistics are summarized in Tab. 4. To illustrate dataset diversity, Fig. 5 presents five representative question types. Our **dev set** consists of the first 100 QA pairs, designated for hypothesis testing.

A notable challenge was handling emojis in col-

umn names and textual data, as exact answer matching was required per competition rules, but LLMs struggle with emojis (Qiu et al., 2024). They often insert spaces or omit them, leading to inaccuracies. We mitigated this issue by:

a) Replacing emojis in column names with unique symbols (hashes) for easier query generation.

b) Restricting the orchestrator to selecting answers from SQL or Python outputs rather than generating responses, ensuring accuracy.

4.1 Accuracy Calculation

The evaluation was conducted using the framework provided in the repository. The evaluation metric was calculated by the rules presented in Fig. 4.1. The approach is flexible and provides a fair metric calculation for different pipelines.

Comparison Rules

Numbers: Truncated to two decimals.

Categories: Compared directly as-is.

Lists: Order is ignored.

5 Experiments and Evaluation

This section details the experiments conducted to evaluate our system's performance in Table QA. More experiments are in Appx. A.1 and A.2.

As shown in Fig. 2, reformulating the question generally decreases accuracy (we discuss why in Sec. 5.4), as seen in setups like "Codetral Python + Reformulation" (68%) and "Minimax End-to-End + Reformulation" (52%), both of which perform worse than their non-reformulated counterparts. Whereas, adding SQL capabilities tends to increase accuracy, with "Codetral Python + SQL" reaching 84%. The highest accuracy is achieved when multiple models are combined and orchestrated, such as "Codetral and Qwen Coder Python (with orchestrator)" and "Full open-source pipeline (with orchestrator)", both achieving 88%, surpassing single-model approaches.

5.1 Performance of Code-Generation

Text-to-SQL and text-to-code generation performed well on structured queries but struggled with ambiguous questions that lack explicit context. The self-correction mechanism improved accuracy by refining failed queries. However, unclear queries, such as "Provide the median number of claims for B2 and S1 kinds" could lead to misinterpretations, whether computing a single median or separate medians, resulting in incorrect outputs.

5.2 Effectiveness of E2E Processing

The E2E approach, which skips code generation and directly answers questions using a textual representation of the table, performed well on questions requiring semantic understanding. For instance, it excelled at answering non-exact questions like "Is there a patent related to 'communication' in the title?". Furthermore, models were given the task of answering the question: "How many distinct male participants took part in the competition?" based solely on participants' names. This required the models to infer the participants' sex from their names that is a task that LLMs typically excel at. However, solving this problem using SQL or Python alone would be quite challenging. In such cases, both systems complemented each other, leveraging the strengths of LLMs for context understanding and the structured data processing power of SQL and Python.

5.3 Orchestrator Performance

The orchestrator model, which selects the most probable solution from multiple candidates, generally performed well. However, its accuracy depended heavily on the quality of the candidate solutions. If all candidates were incorrect, the model couldn't generate a correct answer on its own. Additionally, when the majority of candidate answers were incorrect, the orchestrator sometimes failed to select the correct solution, instead favoring the most frequent or popular response.

We propose, for future research, exploring automatic methods to determine whether a given question is better suited for SQL or Python-based querying. This could help the orchestrator make more informed decisions, leading to improved accuracy and efficiency in selecting the correct answer.

5.4 Question Reformulation

Handling ambiguous or under-specified queries is a key challenge in structured data QA with LLMs (Zhao et al., 2024). We tested LLM-based question reformulation to make queries more explicit, but it proved counterproductive (as seen in Fig. 2). Errors in reformulation at the pipeline's start led to failures without any recovery mechanism. Conversely, without reformulation, some models inferred intent correctly, enabling the orchestrator to choose the

Original Name	Renamed Column
DMC	Duff Moisture Code
DC	Drought Code
ISI	Fire Spread Index
RH	Relative Humidity

Table 1: Renaming ambiguous column names for clarity using context and LLM insights.

right response even if others failed. While reformulation may be less effective with multiple models (e.g., in our case: two SQL, two Python, one E2E), further research is needed to confirm this.

5.5 Predicting Useful Columns

E2E models often encounter challenges when working with long-context data, a difficulty sometimes referred to as "The Needle In a Haystack problem" (Laban et al., 2024). To address this problem, we introduced LLM-driven column selection. The separate model is given a description of the query and asked to select the most relevant columns before attempting to generate an answer. This method ensures that only the useful parts of the dataset are provided to the E2E model, reducing context length and minimizing the risk of hallucinations.

5.6 Column name explanation

Structured datasets often have ambiguous or abbreviated column names, making LLM comprehension challenging. To address this, we introduced column reformulation. For example, given the table "078 Fires" and initial data rows, LLMs effectively generated clearer column names.

Tab. 1 highlights the ambiguity of original column names, which were clarified through renaming for better usability. However, this poses challenges, as users may refer to original names, necessitating entity recognition for query adjustments, which is beyond the scope of our study. Misinterpretation is also a risk: abbreviations like DC and DMC have multiple meanings, and even strong models can generate incorrect names (e.g., GPT-4o renamed ISI as Fire Spread Index instead of Initial Spread Index). Further research is needed to refine this strategy for effective QA pipeline integration.

6 Comparison with proprietary models

The integration of multiple components showcased the potential of open-source LLMs for solving QA tasks over tabular data. As Fig. 4 illustrates, we compared Codestral against GPT-4o (OpenAI et al., 2024), both utilizing our pipeline. While GPT-4o outperformed Codestral, the performance gap remained within a reasonable range. However, the best results were achieved by a two-model system, which combined Codestral and Qwen Coder for Python code generation, managed by an orchestrator. This setup reached 88% accuracy, surpassing GPT-4o. By leveraging an orchestrator to optimize the strengths of multiple models, our approach demonstrates that open-source solutions can achieve accuracy levels comparable to proprietary models. Our pipeline applied to GPT4o (w/o orchestrator) also performs well (87%), resulting in a noticeable improvement over a simpler pipeline, showing the effectiveness of such an approach even for already strong proprietary models.

Rank	Codabench ID	Team	Score
1	xiongsishi	TeleAI	95.02
2	pbujno	SRPOL AIS	89.66
13	**anotheroption**	**anotheroption**	**80.08**
	baseline	stable-code-3b-GGUF	26.00

Table 2: Official results among open source models

7 Official results

We ranked in the top 13 out of 38 teams in the competition's OpenSource-models-only section (Osés-Grijalba et al., 2025), achieving an accuracy score of 80% on the Databench evaluation as well as on a lite part of the benchmark. Our official results on Databench part of the task are presented in Tab. 2, showing that we significantly outperformed the baseline by 54 points. The best solution achieved a score of 95.20. In the global ranking presented in Tab. 3, which includes proprietary models, we placed in the top 20 out of 53 teams while exclusively using open-source models.

8 Error Analysis

8.1 Orchestrator decisions

In Fig. 3, the distribution of orchestrator decision types is shown. Most cases (63.4%) involved simple confirmation of consensus among identical outputs ('Agreement'). However, in 36.6% of scenarios, the orchestrator took a more active role: filtering out logically flawed responses (14.6%), rejecting answers with mismatched data formats (12.2%), or resolving conflicts between divergent yet seemingly valid outputs (9.8%).

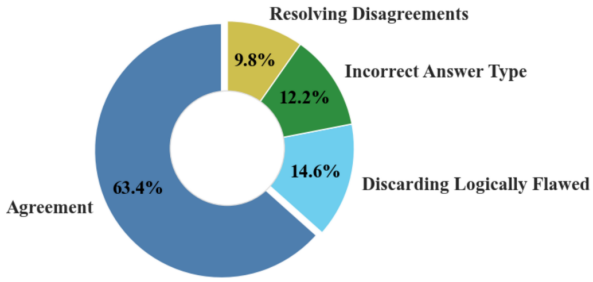

Figure 3: Distribution of LLM orchestrator decision scenarios (based on 41 questions from the dev set).

8.2 Code-based solution failure analysis

Some code-based solutions had incorrect syntax. There are several common patterns in which this occurred.

- Incorrect aggregation: queries with broken logical chains, incorrect applications of aggregation functions or "group by" operation.
- Type unaware operations: the system would often make syntax errors due to incorrect handling, such as trying to retrieve properties over int objects.
- Flawed code understanding: errors included attempts to call Pandas methods with incorrect or omitted arguments.

And when the code syntactically was correct, there were several common failure patterns.

- Subtle logical errors: this often manifests syntactically correct code that nonetheless employs incorrect aggregation, filtering, or sorting logic for the specific dataset. *Example: Incorrect identification of the most retweeted author due to flawed aggregation.*
- Query misinterpretation: in these cases, the generated code fails to capture the full intent of the query. *Example: Returning pokemon name instead of total stats when asked for the "lowest total stats of pokemon".*
- Data-specific edge cases: generated code struggles with particular data characteristics, such as incorrectly handling null values, emojis, timestamps, or failing to provide a robust approach to tied rankings in sorting or max/min operations. *Example: Failure to correctly identify authors of shortest posts due to inaccurate word count.*

Identifying these distinct failure types is crucial for improving the overall reliability of the Q&A system.

8.3 Self-correction

The self-correction mechanism was largely ineffective due to the system design involving multiple LLM agents: two for Python and two for SQL. In the vast majority of cases, at least one Python and one SQL agent a runnable solution. As a result, the orchestrator could select a valid answer without having to rely on self-correction.

9 Conclusion

We introduced a comprehensive system for QA over tables, showcasing that well-orchestrated open-source models can rival proprietary solutions. We tested various methods: some risked errors, while others improved accuracy and reliability of the system. Our system ranked among the top 13 teams with 80% accuracy. Future work could explore dynamic pipeline selection — automatically determining whether a question requires code-based execution, semantic analysis, or hybrid approaches — to optimize efficiency and accuracy. Additionally, enhancing the orchestrator's capacity to detect and correct logical inconsistencies in candidate answers could further improve robustness.

10 Limitations

The performance of the system exhibits significant variability across different model sizes. Additionally, retrieval systems often encounter challenges when the terms in a query do not align well with the tabular data being searched, and embedding models do not completely address this issue. A notable limitation lies in the generation of candidates for orchestration, where it is possible for all generated responses to be incorrect. This represents a well-known challenge, as identified in prior work (Bradley, 2024), highlighting how certain tasks can prove difficult even for comprehensive groups of large language models (LLMs). In these instances, the system is inherently designed without a mechanism to independently generate a correct answer. Future research could explore potential strategies to address such scenarios effectively.

11 Ethics Statement

All models and datasets used are publicly available. We honor and support the ACL Code of Ethics.

A Appendix

A.1 Checklists and Dialogue-Inducing Prompts

During testing, models often skipped crucial instructions, leading to incorrect code generation. To enhance reliability, we implemented checklist-based prompts (Cook et al., 2024), enforcing constraints like type matching, entity verification, and logical consistency for more accurate outputs. We also tested dialogue-inducing prompts, where the model simulated a specialist discussion to clarify queries, but this proved superficial, as the model did not actively use the dialogue to correct mistakes.

A.2 Few-shot Prompting

LLMs perform better with contextual examples (Liu et al., 2022), a phenomenon often referred to as few-shot prompting (Reynolds and McDonell, 2021; Brown et al., 2020). This approach involves providing the model with a small number of task-specific examples before asking it to perform the desired task. We also experimented with dynamic few-shot prompting (R, 2024), where the model selects relevant examples based on their similarity

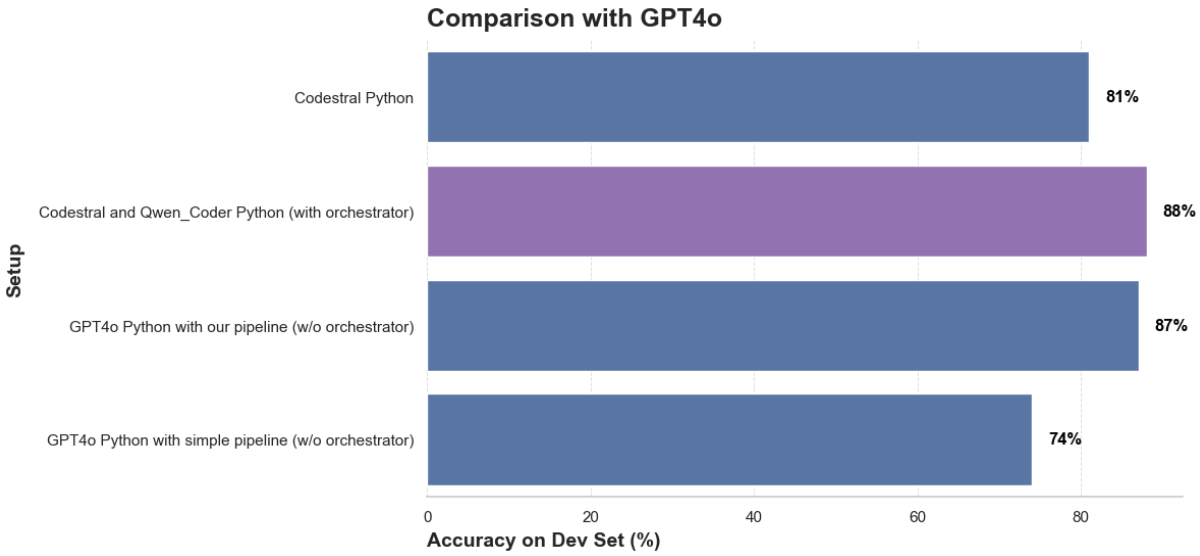

Figure 4: GPT4o comparison with and w/o our pipeline. Llama3.3-70b-instruct used as orchestrator.

to the given question. However, this approach requires generating a large number of high-quality examples for each question type, which is both labor-intensive and time-consuming. Additionally, scaling this method could be challenging, as the number of question types may become too large to manage effectively. Due to these limitations, we consider it beyond the scope of our current work.

Rank	Codabench ID	Team	Accuracy
1	xiongsishi	TeleAI	95.01

Boolean answers (T/F)	65% / 35%
Avg. columns per question	2.47
Most common answer types	
Category / Boolean	199 / 198
List[Num] / List[Cat]	198 / 197
Number	196
Columns per dataset (avg./std)	25.98 / 22.74
Question length (avg./std)	61.36 / 18.01

Table 4: Core statistics illustrating the distribution of questions and answers in DataBench.

Data Questions and Formats

Data Type: Number
Q: What is the average age of our employees?
Format: Single numerical value (e.g., 35.2).

Data Type: List[Category]
Q: Unique classifications for employees' education fields?
Format: List of categories (e.g., ["Life Sciences", "Marketing"]).

Data Type: List[Number]
Q: Lowest 5 monthly incomes?
Format: List of numbers (e.g., [2000, 2100, 2200]).

Data Type: Category
Q: Most common role?
Format: Single category (e.g., "Manager").

Data Type: Boolean
Q: Is the highest DailyRate 1499?
Format: `True` or `False`.

Figure 5: Structured data questions and formats.

prompt for python generation (dialogue)

```
1. You are two of the most esteemed Pandas DataScientists engaged in a heated
     and truth-seeking debate. You are presented with a dataframe and a
    question. Begin dialogue by rigorously discussing your reasoning step by
    step, ensuring to address all aspects of the checklist. In your discourse,
     meticulously articulate the variable type necessary to derive the answer
     and confirm that each column referenced is indeed present in the
    dataframe. Conclude your debate by providing the code to answer the
    question, ensuring that the variable result is explicitly assigned to the
     answer. Remember, all code must be presented in a single line, with
    statements separated by semicolons.
2. Refrain from importing any additional libraries beyond pandas and numpy.
3. The dataframe, df, is already populated with data for your analysis; do
    not initialize it, but focus solely on manipulating df to arrive at the
    answer.
4. If the question requires multiple entries, always utilize .tolist() to
    present the results.
5. If the question seeks a single entry, ensure that only one value is output
    , even if multiple entries meet the criteria.

You MUST FOLLOW THE CHECKLIST, ANSWER EACH OF ITS QUESTIONS (REASONING STEP),
     AND ONLY THEN OUTPUT THE FINAL ANSWER BASED ON THOSE ANSWERS:
1) How many values should be in the output?
2) Values (or one value) from which column (only one!) should the answer
    consist of?
3) What should be the type of value in the answer?

Example of a task:
Question: Identify the top 3 departments with the most employees.
<Columns> = ['department', 'employee_id']
<First_row> = ('department': 'HR', 'employee_id': 101)
Reasoning: Count the number of employees in each department, sort, and get
    the top 3. The result should be a list of department names.
Checklist:
1) The output should consist of 3 values.
2) The values should come from the 'department' column.
3) The type of value in the answer should be a list of strings.
Code: result = df['department'].value_counts().nlargest(3).index.tolist()

Your data to process:
<question> = {question}

- Make absolute sure that all columns used in query are present in the table.
<columns_in_the_table> = {[col for col in df.columns]}
<first_rows_of_table> = {df.head(3).to_string()}
YOUR Reasoning through dialogue and Code (Start final code part by "Code:"):
```

Figure 6: Prompt for python generation (dialogue)

prompt for python generation

```
1. You are a best in the field Pandas DataScientist. You are given a
    dataframe and a question. You should spell out your reasoning step by
    step and only then provide code to answer the question. In the reasoning
    state it is essentianl to spell out the answers' variable type that
    should be sufficient to answer the question. Also spell out that each
    column used is indeed presented in the table. In the end of your code the
     variable result must be assigned to the answer to the question. One
    trick: all code should be in one line separated by ; (semi-columns) but
    it is no problem for you.
2. Avoid importing any additional libraries than pandas and numpy.
3. All data is already loaded into df dataframe for you, you MUST NOT
    initialise it, rather present only manipulations on df to calculate the
    answer.
4. If the question ask for several entries alsways use .tolist().
5. If the question ask for one entry, make sure to output only one, even if
    multiple qualify.

<...> (same as previous prompt)
```

Figure 7: Prompt for python generation (without dialogue)

prompt for self-correction

```
"The following solutions failed for the task: \"{question}\"\n\n"
        + '\n'.join([f'Solution {i+1} Error:\n{traceback}\n' for i, traceback
     in enumerate(tracebacks)])
        + "\nDF info: \n"
        + "<columns_to_use> = " + str([(col, str(df[col].dtype)) for col in
    df.columns]) + "\n"
        + "<first_row_of_table> = " + str(df.head(1).to_dict(orient='records
    ')[0]) + "\n"
        + "YOUR answer in a single line of pandas code:\n"
        + "Please craft a new solution considering these tracebacks. Output
    only fixed solution in one line:\n"
```

Figure 8: Prompt for self-correction

prompt for orchestrator

```
Examples of deducing answer types:
1. If the question is "Do we have respondents who have shifted their voting
    preference?" the answer type is **Boolean** because the response should
    be True/False.
2. If the question is "How many respondents participated in the survey?" the
    answer type is **Integer**
3. If the question is "List the respondents who preferred candidate X?" the
    answer type is **List** because the response requires a collection of
    values.
4. If the question is "What is the average age of respondents?" the answer
    type is **Number** because the response should be a decimal value.
5. If the question is "What is the name of the candidate with the highest
    votes?" the answer type is **String** because the response is a single
    textual value.

Given the following solutions and their results for the task: "{question}"

{'   '.join([f'Solution Number {i+1}:  Code: {r["code"]} Answer: {str(r["
    result"])[:50]} (may be truncated) ' for i, r in enumerate(solutions)])}

Instructions:
- Deduce the most probable and logical result to answer the given question.
    Then output the number of the chosen answer.
- If you are presented with end-to-end solution, it should not be trusted for
     numerical questions, but it is okay for other questions.
- Make absolute sure that all columns used in solutions are present in the
    table. SQL query may use additional double quotes around column names, it'
    s okay, always put them. Real Tables columns are: {df.columns}
- If the column name contain emoji or unicode character make sure to also
    include it in the column names in the query.
- If several solutions are correct, return the lowest number of the correct
    solution.
- Otherwise, return the solution number that is most likely correct.
- If the question ask for one entry, make sure to output only one, even if
    multiple qualify.

You should spell out your reasoning step by step and only then provide code
    to answer the question. In the reasoning state it is essentianl to spell
    out the answers' variable type that should be sufficient to answer the
    question. Also spell out that each column used is indeed presented in the
     table. The most important part in your reasoning should be dedicated to
    comparing answers(results) from models and deducing which result is the
    most likely to be correct, then choose the model having this answer.
First, predict the answer type for the question. Then give your answer which
    is just number of correct answer with predicted variable type.  Start
    reasoning part with "REASONING:" and final answer with "ANSWER:".
```

Figure 9: Prompt for orchestrator

prompt for SQL generation

```
The task is: {question}
Here are some examples of SQL queries for similar tasks:
Example 1:
Task: Is there any entry where age is greater than 30?
REASONING:
1. Identify the column of interest, which is 'age'.
2. Determine the condition to check, which is 'age > 30'.
3. Use the SELECT statement to retrieve a boolean result indicating the
    presence of such entries.
4. Apply the WHERE clause to filter rows based on the condition 'age > 30'.
5. Use the EXISTS clause to ensure the query outputs 'True' if any row
    matches the condition, otherwise 'False'.
6. Verify that the query outputs 'True' or 'False' when presented with a yes
    or no question.
CODE: ```SELECT CASE WHEN EXISTS(SELECT 1 FROM temp_table WHERE "age" > 30)
    THEN 'True' ELSE 'False' END;```
Example 2:
Task: Count the number of entries with a salary above 50000.
REASONING:
1. Identify the column of interest, which is 'salary'.
2. Determine the condition to filter the data, which is 'salary > 50000'.
3. Use the SELECT COUNT(*) statement to count the number of rows that meet
    the condition.
4. Apply the WHERE clause to filter rows based on the condition 'salary >
    50000'.
5. Ensure the table name is 'temp_table' and the column name is enclosed in
    double quotes to handle any spaces or special characters.
CODE: ```SELECT COUNT(*) FROM temp_table WHERE [salary] > 50000;```
Write a correct fault-proof SQL SELECT query that solves this precise task.
Rules:
- Your SQL query should be simple with just SELECT statement, without WITH
    clauses.
- Your SQL query should output the answer, without a need to make any
    intermediate calculations after its finish
- Make sure not to use "TOP" operation as it is not presented in SQLite
- If present with YES or NO question, Query MUST return 'True' or 'False'
- If the question asks about several values, your query should return a list
- Equip each string literal into double quotes
- Use COALESCE( ..., 0) to answer with 0 if no rows are found and the
    question asks for the number of something.
Table name is 'temp_table'.
Available columns and types: {', '.join([f"{col}: {str(type(df[col].iloc[0]))
    }" for col in column_names])}
Top 3 rows with highest cosine similarity: {
    get_relevant_rows_by_cosine_similarity(df, question, ai_client).head(3).
    to_markdown()}
YOUR RESPONSE:
```

Figure 10: Prompt for SQL-generation

prompt for E2E model

```
Question: {question}
    Dataset: {dataset_text}

    Analyze the data. Provide your final answer to the question based on the
    data.
    If the question assumes several answers, use a list. Your answer should
    be in the form of one of the following:
    1. Boolean (True/False)
    2. List (e.g., ['Tree', 'Stone'])
    3. Number (e.g., 5)
    4. String (e.g., 'Spanish')

    Give extensive reasoning and then fianlly provide the answer starting
    with string "Final Answer:" in one of the four formats presented above (
    Boolean, List, Number, String). Your response should then be finished.
```

Howard University-AI4PC at SemEval-2025 Task 2: Improving Machine Translation With Context-Aware Entity-Only Pre-translations with GPT4o

Saurav K. Aryal and **Jabez Agyemang-Prempeh**
EECS, Howard University
Washington, DC 20059, USA
https://howard.edu/
saurav.aryal@howard.edu, jabez.agyemang-prem@bison.howard.edu

Abstract

This paper presents our work on a 3-Step GPT translation system developed for SemEval-2025 Task 2 to enhance the translation of named entities within machine translation. Our approach integrates (1) entity extraction via wikidata, (2) GPT-based refinement of entity translations, and (3) final context-aware GPT translation. Results from the original dataset of six languages show significant improvements in the handling of named entities compared to direct GPT-based translation baselines. We further discuss replicability, observed challenges, and outline future research directions.

1 Introduction

Modern translation technologies have enabled cross-cultural communication at scale. Additionally, machine translations are the initial step considered in tackling multilingual problems in natural language processing and understanding (Aryal et al., 2023). However, translations may lead to the loss of certain linguistic nuances and cultural information (Sapkota et al., 2023; Aryal and Adhikari, 2023), further contributing to the system's reduced effectiveness. In particular, Machine translation (MT) systems often struggle with named entities, particularly rare, ambiguous, or unknown to the translation model. Proper handling of names of people, organizations, locations, and products is crucial to maintaining correctness and cultural relevance across different languages.

SemEval-2025 Task 2 (Conia et al., 2025) challenges participants to improve named entity translation from English into multiple target languages. We propose a 3-Step GPT Translation pipeline that integrates external knowledge from wikidata to enrich named entity contexts, combined with carefully constructed GPT prompts. Our main contributions include:

1. A modular pipeline that leverages wikidata to retrieve accurate entity labels and descriptions for the target language.
2. A three-step approach, featuring (a) entity extraction from wikidata, (b) GPT-based refinement of entity translations, and (c) context-aware GPT translation of full sentences.

2 Task Description

SemEval-2025 Task 2 focuses on accurately translating sentences that contain named entities from English to a set of target languages. These include Italian (it), Spanish (es), French (fr), German (de), Arabic (ar), Japanese (ja), Chinese (zh), Korean (ko), Thai (th), and Turkish (tr). The task's official scoring metric is the harmonic mean of COMET and M-ETA.[1]

3 Related Work

Recent advances in retrieval-augmented machine translation further support our methodology. For instance, Conia et al. (2024) introduced KG-MT, a system that leverages knowledge graphs to incorporate structured external information into the translation process, while Zeng et al. (2023) proposed the "Extract and Attend" framework, which aligns entity representations with their surrounding context to improve named entity translation accuracy. In addition, work on entity pre-training, such as that by Hu et al. (2022), demonstrates that denoising strategies can boost translation accuracy for entities. Resources such as ParaNames (Sälevä and Lignos, 2022) have also established the value of extensive multilingual corpora derived from Wikidata. Unlike KG-MT, which integrates knowledge graph embeddings directly into the translation model, our approach leverages GPT's context-aware generative capabilities, systematically refining individual

[1]Final Score is defined as the harmonic mean of the M-ETA score (Manual Entity Translation Accuracy) and the COMET score.

entity translations through explicit prompts before final translation. This design choice prioritizes precise entity contextualization and improved handling of sparse or ambiguous data that might be inadequately captured by traditional embedding-based KG methods

4 System Overview: 3-Step GPT Translation

4.1 Step 1: Wikidata Entity Extraction

Our entity extraction process originally employed spaCy's `en_core_web_sm` model for named entity recognition. However, through experimentation, we found GPT-based entity recognition to be both faster (given our hardware and runtime environment constraints) and more accurate, especially in recognizing novel or domain-specific entities that spaCy struggled with. For instance, spaCy frequently failed to recognize rare or uniquely constructed proper nouns, whereas GPT succeeded due to its contextual reasoning capabilities. Consider a hypothetical example sentence: Consider the following hypothetical example sentence: "I recently visited Takunville to watch the grand opening performance by Awetu Tesfaye." Here, spaCy may fail to detect entities like "Takunville" or "Awetu Tesfaye," whereas GPT typically recognizes these from context. Consequently, we transitioned entirely to GPT for entity detection. We then query Wikidata using `wikidata.client` (a Python library for accessing wikidata) for entity metadata: short description, aliases (if present) and label in the target language. If Wikidata lacks relevant information for any of the entities identified for a given source sentence, our fallback strategy is to trust GPT to provide either transliteration or its best guess at an accurate translation from the context of the source sentence in the next step.

4.2 Step 2: GPT-Based Entity Translation Refinement

This step directly yields an entity translation result guided by context retrieved from wikidata information. Using this prompt, we make a query to obtain a refined entity translation:

```
You are an advanced translation service.
Translate the entity name in the input from English
to target_locale.
In the input, there's extra information to help you
translate the entity.
Input: label_info_input
Return only the entity translation.
```

Each entity translation refinement step results in a structured JSON-like object containing the following fields for every named entity:

- `label`: The entity name in the source language.
- `description`: A short description providing contextual information about the entity.
- `target_reference`: The refined translation of the entity into the target language.
- `entity_group`: A category abbreviation (e.g., "PER" for person, "LOC" for location).

We pass a list of these structured objects to the final GPT translation step (Section 4.3). This detailed structured representation ensures precise handling and consistent naming of entities in the translated output.

4.3 Step 3: Context-Aware GPT Translation

Finally, we combine:

1. The source sentence in English.
2. The target language (e.g., German).
3. The list of refined entity translations from Step 2.

The final translation prompt instructs GPT to incorporate the previously refined entity names into the resulting translation, ensuring consistency and accuracy:

```
You are an advanced translation service.
Given:
1. 'source': A sentence in English.
2. 'target_locale': The target language.
3. 'processed_wiki_entities': A list of refined
entity translations.
Task: Translate 'source' to target_locale using
'processed_wiki_entities'.
Return ONLY the translated sentence as a string.
```

By explicitly referencing the refined entity names, we mitigate GPT's tendency to guess or alter named entities.

5 Validation and Results

5.1 Validation Setup

We first conducted experiments on the initial 6 languages from the SemEval-2025 Task 2 validation dataset: Arabic (ar), German (de), Spanish (es), French (fr), Italian (it), and Japanese (ja). Using the harmonic mean of COMET and M-ETA as specified by the task organizers, we compared our proposed approach to both GPT-4o mini with no special entity handling or context beyond requesting a translation of the source text to the target language.

5.2 Results

The experimental results of our validation that are in Table 3 show that we outperformed our baseline models with no entity-associated context. This approach was then applied to the test set and submitted to the official leaderboard.

Table 1 presents non-metric system details and overall scores for leaderboard entries (ranks 14 to 20), while Table 2 summarizes the language-specific final scores for these entries.

On the official leaderboard by the organizers of SemEval, under the name Howard University-AI4PC, our system *DoubleGPT* was ranked 16th overall with an overall final score of 84.44, an overall M-ETA score of 77.93, and a COMET score of 93.63.[2] Notably, we achieved our highest per-language performance in Korean (90.15), Japanese (89.90), and Spanish (89.73), suggesting that our entity-refinement pipeline can excel in languages with strong tokenization or ample external resources. In contrast, our system struggled with Chinese (57.84), reflecting the need for further adaptation when wikidata coverage is sparse or script complexity is high. Despite this gap, our multi-step GPT approach remained competitive relative to single-pass LLM-based methods, demonstrating that targeted named entity handling and retrieval-augmented generation can yield robust improvements across a diverse range of languages.

5.3 Real-World Viability

While our multi-step GPT-based pipeline delivers notable improvements in entity translation, it introduces significant computational overhead due to multiple GPT interactions at both the entity-level and sentence-level. Each translated sentence requires multiple GPT calls, potentially causing latency and increased runtime costs in real-world or real-time translation scenarios. Moreover, our current prompt engineering strategy employs uniform prompt templates across all languages, potentially missing opportunities for language-specific optimizations that could further enhance performance, especially for languages that differ substantially in linguistic structures or available resources.

5.4 Omission of Additional Languages

We recognized that the official dataset was later updated to include Chinese, Korean, Thai, and Turkish. Although they were included in our official submission, we discovered these additions too late in our research cycle to fully evaluate or compute official metrics. We plan to incorporate these languages in a future version of this work.

6 Conclusion and Future Work

We presented a 3-Step GPT Translation system for SemEval-2025 Task 2, emphasizing named entity accuracy. By integrating external Wikidata and employing carefully engineered GPT prompts across two stages (entity translation refinement and final context-aware translation), our approach achieved notable improvements over baseline GPT-4o miniGPT-4o direct translations.

[2]Final Score is defined as the harmonic mean of the M-ETA score (Manual Entity Translation Accuracy) and the COMET score.

Despite these promising results, our method still exhibits certain limitations. Primarily, our system's performance heavily depends on Wikidata coverage; thus, entities without sufficient Wikidata entries risk incorrect or incomplete translations. Additionally, we identified notably lower performance for languages like Chinese due to sparse Wikidata coverage and unique script complexities. Future research will address these issues by exploring supplementary multilingual knowledge resources or custom lexical databases specifically targeted at improving performance in these languages.

We also recognize missed opportunities for prompt customization tailored explicitly to linguistic nuances and specific entity types. Therefore, future work will involve developing and testing language-specific and entity-type-specific prompts, aiming to further enhance translation accuracy.

Finally, addressing computational efficiency remains a critical component of future improvements. We plan to investigate optimization strategies such as single-pass GPT prompts or selectively triggered GPT calls, dynamically invoking GPT only when entity translations are uncertain or when comprehensive Wikidata coverage is lacking. These optimizations will aim to sustain high accuracy while significantly reducing computational resources and translation latency.

Ethics Statement

Our work depends on pretrained LLMs (GPT-4o mini / GPT-4o) and a publicly available knowledge base (wikidata). While these technologies can improve named entity translation, we note that wiki data entries might be incomplete or skewed toward certain languages or cultures, leading to uneven performances. Mistranslations of personal or place names have cultural and ethical implications. Users should verify correctness when translating culturally sensitive content.

Abstract

Language is a rich medium employed to convey emotions subtly and intricately, as abundant as human emotional experiences themselves. Emotion recognition in natural language processing (NLP) is now a core element in facilitating human-computer interaction and interpreting intricate human behavior via text. It has potential applications in every sector i.e., sentiment analysis, mental health surveillance. However, prior research on emotion recognition is primarily from high-resource languages while low-resource languages (LRLs) are not well represented. This disparity has been a limitation to the development of universally applicable emotion detection models. To address this, the SemEval-2025 Shared Task 11 focused on perceived emotions, aiming to identify the emotions conveyed by a text snippet. It includes three tracks: Multi-label Emotion Detection (Track A), Emotion Intensity (Track B), and Cross-lingual Emotion Detection (Track C). This paper explores various models, including machine learning (LR, SVM, RF, NB), deep learning (BiLSTM+CNN, BiLSTM+BiGRU), and transformer-based models (XLM-R, mBERT, ModernBERT). The results showed that XLM-R outperformed other models in Tracks A and B, while BiLSTM+CNN performed better for Track C across most languages.

1 Introduction

Language, as a means of communication, plays a central role in the conveyance and perception of emotions (Mohammad et al., 2018). Emotions are an intrinsic part of human communication, affecting how we perceive and respond to others' messages. Although we all feel and deal with emotions daily, the detection of emotions in text remains a challenging task in NLP (Muhammad et al., 2025a). Emotions are difficult to convey explicitly, and the ways people perceive and express emotions vary greatly, with differences in culture, context, and personality (Wiebe et al., 2005; Mohammad and Kiritchenko, 2018; Acheampong et al., 2020). Therefore, emotion detection from text is one of the most difficult tasks in NLP. The ability to detect emotions from text is increasingly crucial for applications such as virtual assistants, mental health monitoring systems, and social media analytics (Acheampong et al., 2020). The majority of existing studies on emotion detection have focused on high-resource languages, which are supported by large datasets and extensive research. This focus has created an enormous research gap in terms of low-resource languages, which lack high-quality annotated data (Tafreshi et al., 2024; Muhammad et al., 2025a). To address these challenges, the SemEval-2025 Shared Task 11 titled *Bridging the Gap in Text-Based Emotion Detection*[1] focused on approximately 32 low-resource languages, including Afrikaans (afr), Amharic (amh), Oromo (Orm), Hausa (Hau), among others (Muhammad et al., 2025b). The task includes three tracks: multi-label and cross-lingual emotion detection, and detection of emotion intensity. These challenges involve processing textual features to grasp the hidden meaning in cultural and linguistic contexts and classify the text into 6 classes i.e., *joy, sadness, fear, anger, surprise, or disgust* simultaneously in track A, detecting emotion intensity as *no emotion, low, moderate, or high* in track B, and adapting the model to multiple languages in track C. Therefore, the contributions of this work are as follows:

- Developed deep learning and transformer-based approaches that effectively process textual features to detect emotion in low-resource languages.
- Investigated various ML, DL, and transformer-

*Authors contributed equally to this work.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1890–1904

based models to identify the emotion and its intensity while evaluating performance metrics and conducting error analysis to determine the best strategy.

The implementation details of the tasks will be found in the GitHub repository[2]. The rest of the paper is organized as follows: Section 2 discusses related work, Section 3 describes the dataset and task, Section 4 outlines the system overview, Section 5 presents the results analysis, Section 6 summarizes insights and future research directions, and Section 7 outlines the limitations of our research.

2 Related Work

Multi-label emotion detection is essential for discerning complex emotional states from text, where instances may display multiple emotions concurrently.

2.1 Multi-label Emotion Detection

The emotion detection task is challenging due to the nuanced and context-sensitive nature of the text. Jabreel and Moreno (2019) enhanced emotion classification in tweets by using deep learning in the SemEval-2018 Task 1 dataset, achieving a 59% accuracy. Another work focused on improving recognition accuracy in contextual settings using multi-task learning and the EMOTIC dataset (Bendjoudi et al., 2020). A framework was developed for multimodal emotion detection, showing superior results on the CMU-MOSEI dataset (Zhang et al., 2020). Le et al. (2023) employed transformer-based techniques for video content, using IEMOCAP and CMU-MOSEI datasets, and showing significant advancements. Abdul-Mageed and Ungar (2017) created EmoNet for fine-grained emotion detection on Twitter, achieving high accuracies. Mansy et al. (2022) introduced an ensemble model for Arabic tweets, outperforming previous methods.

2.2 Multi-label Emotion Intensity Detection

Ganesh and Kamarason (2020) developed a CNN-based model for multi-labeled emotion intensity analysis on Twitter, emphasizing the need for refined emotion analysis in social media. Mashal and Asnani (2017) and Rodríguez and Garza (2019) further explored algorithms to accurately measure and predict emotion intensities in informal texts and social networks, respectively. Firdaus et al. (2020) introduced the MEISD dataset for multimodal emotion and sentiment analysis, catering to the demand for sophisticated emotion detection systems. Additionally, Singh et al. (2022) created EmoInHindi, an annotated Hindi dataset, to facilitate multi-label emotion recognition in resource-scarce languages. Another study discussed the use of machine learning for classifying emotions in tweets, highlighting the challenges in less-researched linguistic contexts like Urdu (Ashraf et al., 2022; Mashal and Asnani, 2020).

2.3 Cross-lingual Emotion Detection

Neumann and Vu (2018) explored multilingual speech emotion recognition using CNNs for English and French, evaluating the cross-language adaptability of emotional indicators. Another work proposed a novel approach for estimating sentiment prevalence across languages without target language data (Esuli et al., 2020). Transfer learning evaluated for speech emotion recognition across languages and corpora, emphasizing multi-task learning to boost model versatility (Goel and Beigi, 2020). Their models show improved accuracy in cross-lingual recognition, particularly when incorporating auxiliary tasks like language identification. Navas Alejo et al. (2020) investigated emotion intensity prediction across languages using translation and embedding techniques. Kanclerz et al. (2020) showed deep transfer learning's efficacy in sentiment analysis, using language-agnostic representations to effectively predict sentiments in low-resource languages.

3 Dataset and Task Description

The shared task on emotion detection consists of three tracks, namely Track A (multi-label emotion classification), Track B (emotion intensity prediction), and Track C (cross-lingual emotion detection). Track A predicts perceived emotions (*joy, sadness, fear, anger, surprise, disgust*) in a text, with *disgust* excluded for some languages. Track B assigns an intensity level (*no, low, moderate, high*) to each emotion. The dataset (Muhammad et al., 2025a; Belay et al., 2025) for this track provides labeled instances indicating the degree of emotion expressed in the text. Finally, Track C focuses on cross-lingual emotion detection, requiring models to classify emotions in a target language using a labeled dataset from another language. It lacks a labeled training corpus as compared to other tracks.

[2] https://github.com/RJ-Hossan/SemEval_2025_T11

The dataset structure remains consistent across tracks, allowing exploration of multi-label classification, intensity prediction, and cross-lingual generalization. Tables A.1, A.2, and A.3 in Appendix A show the class-wise distribution of train, validation, and test set for these tasks.

4 System Overview

Figure 1 illustrates the exploration of various ML, DL, and transformer-based models to develop a framework for detecting multi-label and cross-lingual emotion, along with emotion intensity estimation.

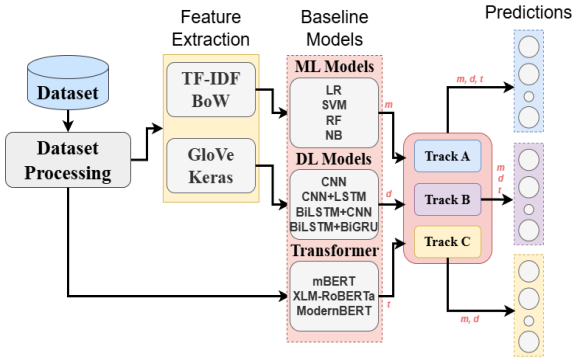

Figure 1: Schematic process of multi-label emotion classification, emotion intensity prediction, and cross-lingual emotion detection.

4.1 Data Preprocessing

The text preprocessing pipeline entailed several crucial steps toward cleaning and normalizing the data. Emojis were removed using *emoji.replace_emoji*, which replaced them with an empty string, while special characters were eliminated with `re.sub(r'[\w\s]', '', text)` without retaining anything but alphanumeric content. Subsequently, the text was lowercase for consistency and then tokenized using *.split()*. The removal of stopwords was done using the *nltk* library. Finally, cleaned tokens were reconstructed into sentences so that there would be a uniform text format for the model to perform better in cross-lingual sentiment analysis.

4.2 Feature Extraction

Feature extraction is necessary for ML and DL models to learn from text. We utilized TF-IDF (Takenobu, 1994) to extract features for various ML algorithms. For DL models, we employed GloVe (Pennington et al., 2014) and Keras-based embeddings to obtain features.

4.3 ML Models

Several machine learning (ML) models were explored to identify multi-label and cross-lingual emotions. Specifically, we used LR, SVM, NB, and RF classifiers for emotion detection in different languages. Furthermore, we applied hyperparameter tuning to enhance model performance, such as experimenting with *linear* and *RBF* kernels for SVM, varying *max_iter* for LR, and optimizing the value *alpha* for NB. GridSearchCV[3] was used to systematically explore the optimal hyperparameters, ensuring improved classification accuracy in detecting multi-label and cross-lingual emotion. Table 1 provides the tuned hyperparameters used in the experiments for ML models for Track C.

Model	Hyperparameters
Logistic Regression	max_iter = 256
Random Forest Classifier	n_estimators = 120, max_depth = 12
Support Vector Machine	kernel = rbf, C = 2
Naive Bayes	alpha = 1.0

Table 1: Tuned hyperparameters used for ML models (Track C).

4.4 DL Models

Several deep learning models were explored for these emotion detection tasks, including CNN, BiLSTM+CNN, and BiLSTM+BiGRU, among others, to effectively capture the sequential dependencies in textual data. To detect emotion in a cross-lingual setting, the BiLSTM+CNN model begins by transforming tokenized input text into dense vectors using an embedding layer with a vocabulary size of 10,000, an embedding dimension of 128. The text is processed through a Bidirectional LSTM layer of 128 units to capture sequential dependencies, followed by a dropout layer of 0.3. The model includes two Conv1D layers with 128 and 64 filters, kernel sizes 5 and 3, MaxPooling1D layers, and BatchNormalization for stable learning. The output is flattened and passed through a Dense layer (128 units, ReLU), with a final output layer of 6 units using sigmoid activation for multi-label classification. The tuned hyperparameters for this task are presented in Table 2.

Table 2: Tuned hyperparameters used for DL models (Track C).

4.5 Transformer-based Models

Various transformer-based models such as XLM-R, mBERT, and ModernBERT were employed to leverage their powerful attention mechanisms for multi-label emotion detection and intensity prediction tasks. By fine-tuning these models on our specific datasets, we aimed to achieve better performances in these tasks. We set up the multi-label emotion classification pipeline with the *FacebookAI/xlm-roberta-base*[4] and *google-bert/bert-base-multilingual-uncased*[5] models. The *EmotionsDataset* class was created to tokenize text inputs using *AutoTokenizer* and get corresponding emotion labels. Details about the tuned hyperparameters for these tasks are presented in Tables 3 and 4.

Hyperparameter	Value
Learning Rate	2e-5
Per Device Batch Size	8
Number of Epochs	5
Max Sequence Length	128
Loss Function	Binary Cross-Entropy
Optimizer	AdamW
Weight Decay	0.01

Table 3: Tuned hyperparameters used for multi-label emotion classification task (Track A) using XLM-R.

The hyperparameters were selected based on standard fine-tuning practices, i.e., a learning rate of 2e-5 for observed stable convergence, a batch size of 8 to avoid overfitting on small datasets, 5 training epochs for balanced performance, Binary Cross-Entropy for multi-label classification (Track A), and Cross-Entropy Loss for intensity estimation (Track B). We chose transformer-based models like XLM-R for Tracks A and B due to their proven multilingual contextual understanding, as XLM-R excels in handling nuanced emotional expressions across diverse linguistic structures.

Hyperparameter	Value
Learning Rate	2e-5
Per Device Batch Size	8
Number of Epochs	5
Max Sequence Length	128
Loss Function	Cross-Entropy Loss
Optimizer	AdamW
Weight Decay	0.01

Table 4: Hyperparameters used for emotion intensity detection task (Track B) using XLM-R.

4.6 System Requirements

The BiLSTM+CNN model for cross-lingual emotion detection and the XLM-R model for multi-label emotion and emotion intensity recognition were trained on a dual-GPU setup (NVIDIA Tesla T4x2), utilizing parallel processing for enhanced performance. The BiLSTM+CNN model utilized approximately 5-7 GB of GPU memory, whereas the XLM-R model utilized approximately 8-10 GB of GPU memory. Overall, the BiLSTM+CNN, along with other DL models, were trained for 45 epochs for 90-100 minutes, depending on training time by the number of data sets and computation of class weights. It enabled the efficient execution of challenging tasks to achieve flawless output for any language and the objectives of emotion detection.

5 Result Analysis

Table 5 presents the evaluation results of ML, DL, and transformer-based models for multi-label emotion detection across five languages: Amharic, Hindi, Igbo, Marathi, and Russian. Among ML models, SVM demonstrates the highest F1 scores in most cases, particularly excelling in Russian (60.85), Marathi (50.33), and Hindi (48.78), while Random Forest (RF) performs slightly better for Igbo (41.81). In DL models, CNN consistently outperforms other architectures, achieving the best results across all languages, with the highest F1 score in Marathi (51.70). However, transformer models significantly surpass both ML and DL models, with XLM-R achieving the highest F1 scores in four out of five languages, including Hindi (84.60), Marathi (78.74), and Russian (84.38), while m-BERT performs best for Igbo (49.35).

Table 5: Performance of the employed models for detecting multi-label emotion in several languages where P, R, F1, and A denote precision, recall, F1 score (macro), and accuracy, respectively.

Table 6 presents the evaluation results of ML, DL, and transformer-based models for multi-label emotion intensity detection in four languages: Algerian Arabic, Chinese, Hausa, and Russian. Among ML models, LR and SVM show competitive performance, with LR achieving the highest F1 scores in Chinese (27.83) and Russian (29.19), while SVM performs best in Hausa (28.94), but all ML models, including RF and NB, struggle in Algerian Arabic (F1 around 23.10). In DL models, CNN+BiLSTM consistently outperforms CNN+GRU, with the highest F1 scores across all languages, peaking at 35.04 in Hausa. However, the transformer-based model XLM-RoBERTa significantly surpasses both ML and DL models, achieving the highest F1 scores in all four languages: Algerian Arabic (29.17), Chinese (46.71), Hausa (57.34), and an outstanding 83.74 in Russian. These results underscore the superior effectiveness of transformer-based models, particularly XLM-RoBERTa, for both multi-label emotion detection and intensity detection, delivering markedly better performance across diverse linguistic contexts.

Table 6: Performance of the employed models for detecting multi-label emotion intensity in several languages where P, R, F1, and A denote precision, recall, F1 score (macro), and exact match accuracy, respectively.

Table 7 demonstrates the evaluation results of ML and DL models to detect cross-lingual emotion across five languages, i.e., Amharic, Algerian Arabic, Hausa, Oromo, and Somali. Among machine learning (ML) models, SVM consistently achieves the highest F1 scores, performing best for Amharic (41.37), Hausa (47.80), Oromo (32.04), and Somali (20.39). In contrast, Random Forest (RF) and Naïve Bayes (NB) show poor performance. For deep learning (DL) models, BiLSTM+BiGRU outperforms other architectures in most cases, achieving the highest F1 scores for Hausa (53.48) and Oromo (42.62). CNN-based models also perform

competitively, particularly in Amharic (40.25). Overall, transformer models were not implemented for this task, but BiLSTM+BiGRU emerges as the strongest deep learning model, while SVM remains the best-performing ML model across most languages. Appendix B presents an in-depth error analysis of the employed models, whereas Appendix C outlines a comparative performance ranking between our proposed system and the baseline model (RemBERT), evaluated using F1 scores.

Table 7: Performance of the employed models for detecting cross-lingual emotion in several languages where P, R, F1, and A denote precision, recall, F1 score (macro), and accuracy, respectively.

6 Conclusion

This paper demonstrated a multi-label emotion classification and intensity prediction model with the best performance for Task A (multi-label emotion classification) and Task B (emotion intensity prediction) through XLM-RoBERTa, while a BiLSTM+CNN model was found superior in Task C (cross-lingual emotion detection) across different LRLs. The outcome of our work demonstrates the capabilities of transformer models for structured emotion prediction and hybrid deep learning models for cross-lingual transfer learning. Future work will explore enhancing model generalizability across languages with scarce labeled data by merging self-supervised learning and contrastive learning techniques. We also plan to research domain adaptation methods and data augmentation strategies to improve emotion recognition in low-resource languages and multi-lingual social media settings.

7 Limitations

Although the study presents valuable information on emotion detection in LRLs, certain limitations inevitably affect the generalizability and robustness of its findings.

- The emotion intensity prediction task faces challenges due to subjective labeling, leading to inconsistencies in the dataset.
- The model struggles with capturing fine-grained emotion variations and overlapping emotions, particularly in multilingual and code-mixed scenarios, where expressions of emotions vary across languages and cultures.
- The cross-lingual emotion detection task is constrained by the absence of a labeled training dataset, making it heavily dependent on transfer learning techniques, which may not generalize well across distant language pairs.
- The study is affected by class imbalance, where certain emotions are underrepresented, limiting the model's ability to learn and predict rare emotions effectively. Advanced data augmentation strategies could help mitigate this issue.

Acknowledgments

We thank the SemEval-2025 shared task organizers for running this task. This work was supported by the Directorate of Research & Extension (DRE), Chittagong University of Engineering & Technology (CUET).

	Sadness	290	44	73	2860
	Surprise	231	34	56	1879
	Total	1737	274	488	16078

Table A.2: Class-wise distribution of train, validation, and test set for Track B, where W_T denotes class-wise total words in the train set.

Language	Classes	Train	Valid	Test	W_T
Amharic	Anger	1188	207	582	28987
	Disgust	1268	209	628	27307
	Fear	109	22	54	1975
	Joy	549	93	276	10329
	Sadness	771	127	355	15657
	Surprise	151	27	82	2828
	Total	3549	592	1774	69926
Algerian Arabic	Anger	296	31	293	4060
	Disgust	206	28	202	3140
	Fear	223	26	216	3442
	Joy	153	13	160	2403
	Sadness	404	40	405	6552
	Surprise	313	32	305	4663
	Total	901	100	902	12914
Hausa	Anger	408	67	209	7207
	Disgust	329	55	168	4290
	Fear	327	53	169	4577
	Joy	320	53	162	4320
	Sadness	647	109	328	10390
	Surprise	349	57	177	4078
	Total	2145	356	1080	29279
Oromo	Anger	646	108	323	18533
	Disgust	557	94	275	11338
	Fear	123	21	65	2911
	Joy	1091	183	547	18403
	Sadness	298	52	159	6631
	Surprise	129	27	69	2357
	Total	3442	574	1721	67780
Somali	Anger	328	55	163	9611
	Disgust	477	83	241	12816
	Fear	305	50	149	7167
	Joy	595	99	297	12073
	Sadness	391	67	194	10151
	Surprise	179	28	88	3462
	Total	3392	566	1696	78451

Table A.3: Class-wise distribution of train, validation, and the test set for track C, where W_T denotes class-wise total words in the train set.

Table A.1 and A.2 show data for languages like Marathi, Hindi, Russian, Amharic, Igbo, and Algerian Arabic, and large imbalances in class distribution. For example, in Amharic, there are 1268 samples for *Disgust* but only 109 for the *Fear* class. Furthermore, Table A.3 is extended to include *Surprise* as an additional emotion class and covers Amharic, Algerian Arabic, Hausa, Oromo, and Somali. Class imbalance is particularly evident in languages like Oromo, where *Joy* (547 samples) dwarfs *Fear* (65 samples). The tables also contain W_T values that are the total number of words in the training set, higher for more-resourced languages (e.g., 69926 for Amharic in Table A.3) than lower-resourced languages (e.g., 2911 for *Fear* in Oromo).

B Error Analysis

Both quantitative and qualitative error analyses were conducted to gain a deeper understanding of the performance of the best-performing model.

B.1 Quantitative Analysis

This section offers a detailed quantitative error analysis of the results from the best-implemented model across different languages for the subtasks.

Multi-label Emotion Detection

Figures B.1, B.2, B.3, B.4, and B.5 present the label-wise confusion matrices for five languages (Amharic, Igbo, Marathi, Russian, and Hindi, respectively). In comparison, the true positive detection for the joy class is significantly higher in Marathi (138) compared to Amharic (169), indicating better performance in detecting joy-related expressions in Marathi.

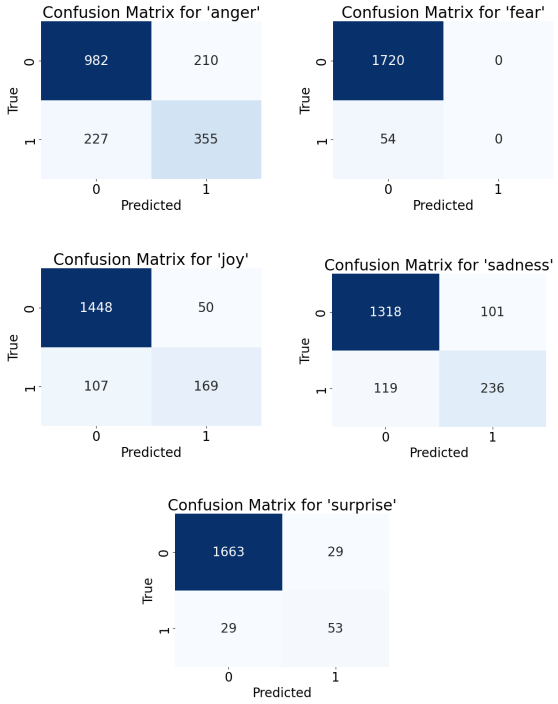

Figure B.1: Confusion matrix of the proposed model (XLM-R) for Amharic language in Track A.

For instance, in Amharic, the model predicts 1720 non-fear instances but fails to detect any actual fear cases, which indicates a severe class imbalance issue. The relatively improved joy detection in Marathi may suggest better linguistic features for identifying joy in the Marathi dataset or better representation in training data. The poor performance in detecting fear class can be attributed to fear being expressed implicitly or contextually, making it difficult for models to detect. Moreover, cultural differences in how fear is expressed might have played a role. The fear class had fewer labeled instances,

limiting the model's ability to learn features associated with it, and model bias in multi-label settings favored more frequent emotions, further suppressing fear detection.

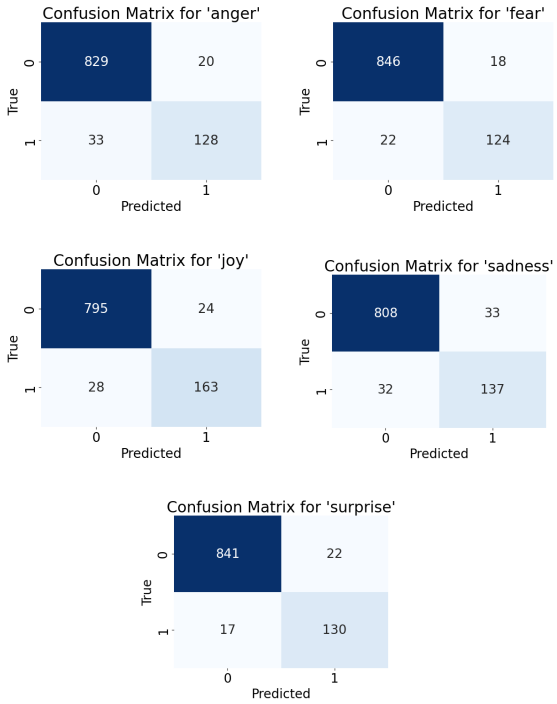

Figure B.2: Confusion matrix of the proposed model (XLM-R) for Hindi language in Track A.

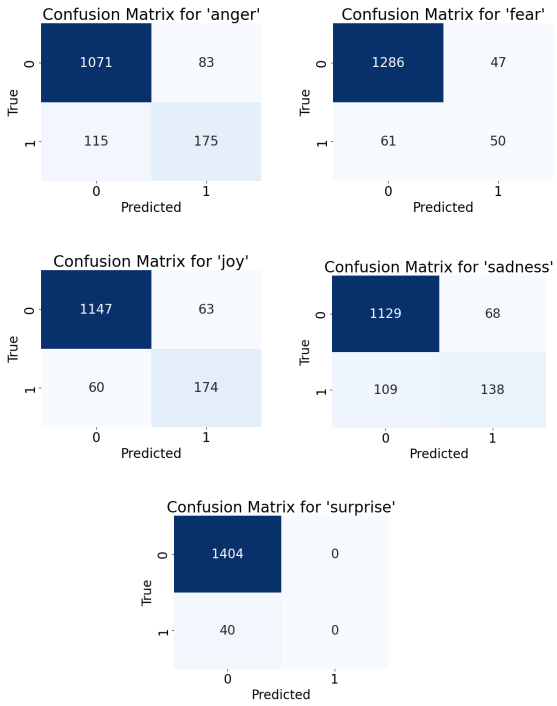

Figure B.3: Confusion matrix of the proposed model (m-BERT) for Igbo language in Track A.

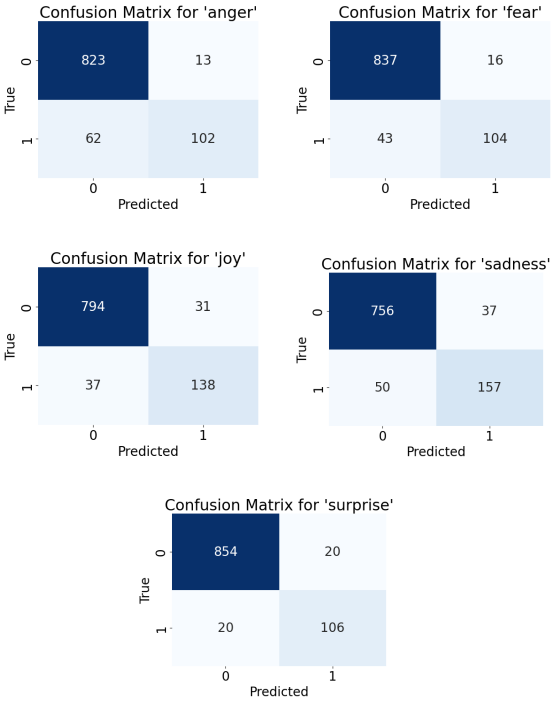

Figure B.4: Confusion matrix of the proposed model (XLM-R) for Marathi language in Track A.

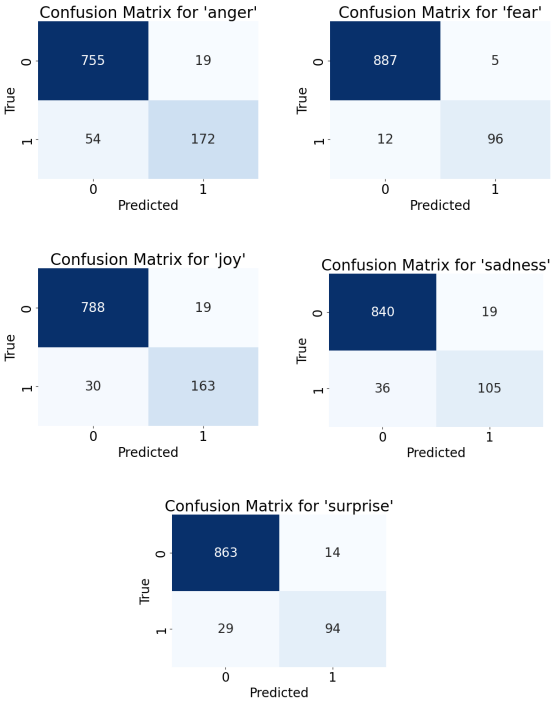

Figure B.5: Confusion matrix of the proposed model (XLM-R) for Russian language in Track A.

On the other hand, anger detection performs better in Amharic (355) than in Marathi (102). Fear detection remains notably poor across all languages, with very low true positive values (0 for Amharic, 50 for Igbo, 104 for Marathi, 96 for

Russian, and 124 for Hindi). The model appears to be biased towards predicting negative instances (class 0), as evidenced by the consistently high true negative values across all languages.

Multi-label Emotion Intensity Detection

Figures B.6, B.7, B.8, and B.9 illustrate the label-wise confusion matrices for four languages: Russian, Algerian Arabic, Chinese, and Hausa. Each demonstrated varied performance in detecting six emotions: *anger, disgust, fear, joy, sadness, and surprise*. In Russian, the model exhibits high accuracy in recognizing *anger* and *disgust*, with 275 and 311 true positives and no false negatives, but it shows limitations in detecting *joy* and *fear*, with 52 and 44 false negatives, respectively. Algerian Arabic performs well in accurately detecting *anger* and *disgust*, with 69 and 72 true positives and no false negatives for both, yet struggles with the identification of *joy* and *fear*, as evidenced by 13 and 26 false negatives. The Chinese model is proficient in distinguishing *sadness* and *disgust* but has difficulties with *fear* and *surprise*, where false negatives are noticeable at 5 and 17.

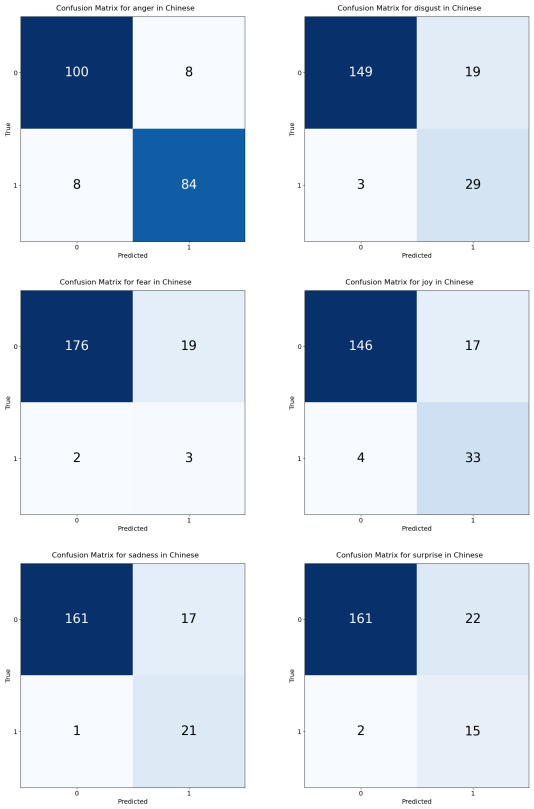

Figure B.7: Confusion matrix of the proposed model (XLM-RoBERTa) for Chinese language in Track B.

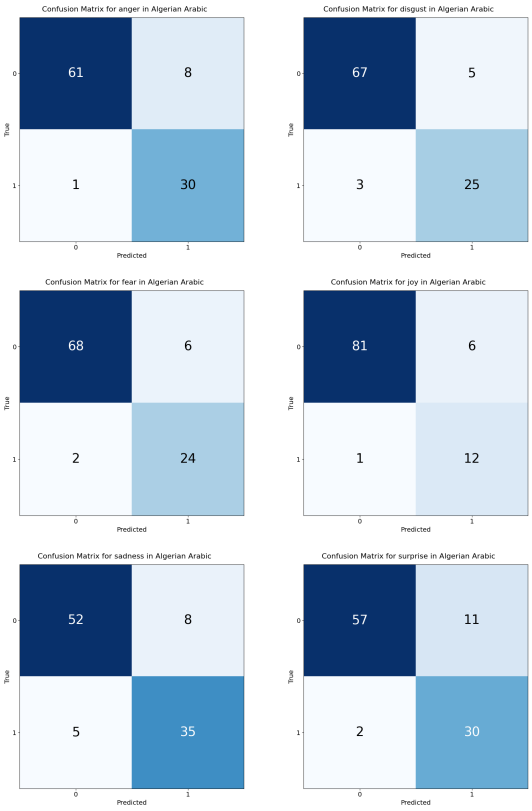

Figure B.6: Confusion matrix of the proposed model (XLM-R) for Algerian Arabic language in Track B.

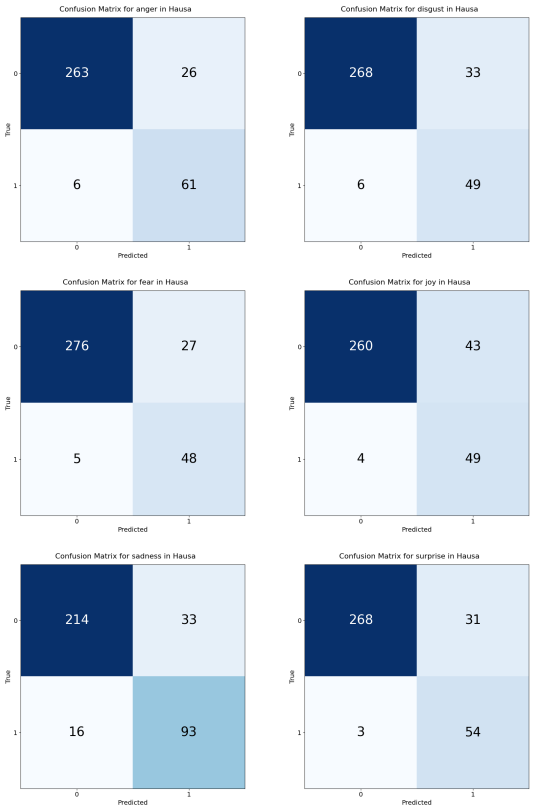

Figure B.8: Confusion matrix of the proposed model (XLM-RoBERTa) for Hausa language in Track B.

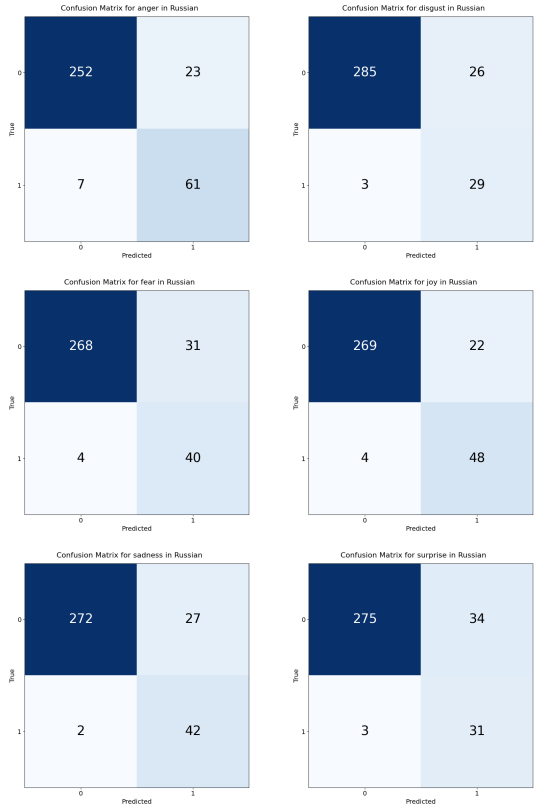

Figure B.9: Confusion matrix of the proposed model (XLM-RoBERTa) for the Russian language in Track B.

However, Hausa shows robust classification in *disgust* and *sadness* with 301 and 247 true positives, respectively, but faces challenges in *joy* and *surprise*. These matrices show the effectiveness of the model in recognizing certain emotions while pointing out specific areas of improvement, which may be affected by cultural or linguistic factors in the training data.

Cross-lingual Emotion Detection

Figures B.10, B.11, B.12, B.13, and B.14 illustrate the confusion matrix on the label for five languages (Amharic, Algerian Arabic, Hausa, Oromo, and Somali, respectively). However, between Oromo and Amharic languages, true positive detection (class 1 predicted correct as 1), *joy* performs significantly better in Oromo (409) compared to Amharic (146), showing that the model is better used to detect Oromo expressions of *joy*. *Anger* detection, however, is better in Amharic (333) than in Oromo (150). Detection of *fear* is extremely poor for both languages, with extremely low true positive values (5 for Amharic, 17 for Oromo). The model is highly biased towards predicting negative instances (class 0) for both languages, as evident from the consistently high true negative scores (class 0 predicted as 0). This suggests the likelihood of training data skewness or model calibration issues.

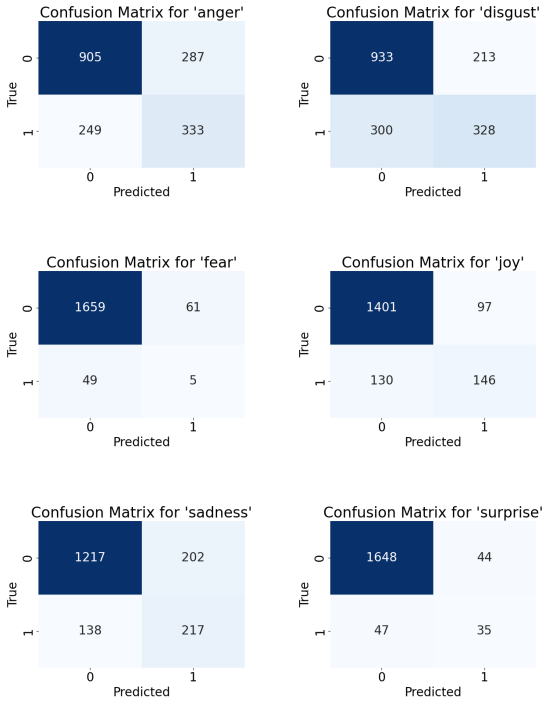

Figure B.10: Confusion matrix of the proposed model (BiLSTM+CNN) for Amharic language in Track C.

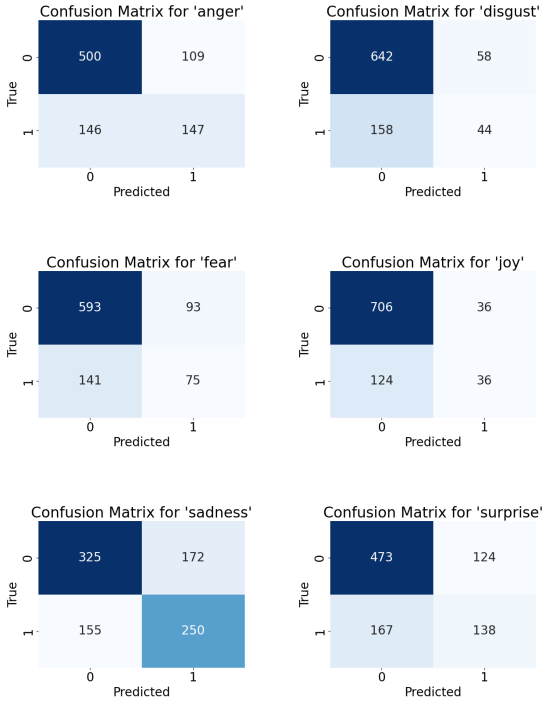

Figure B.11: Confusion matrix of the proposed model (BiLSTM+CNN) for Algerian Arabic language in Track C.

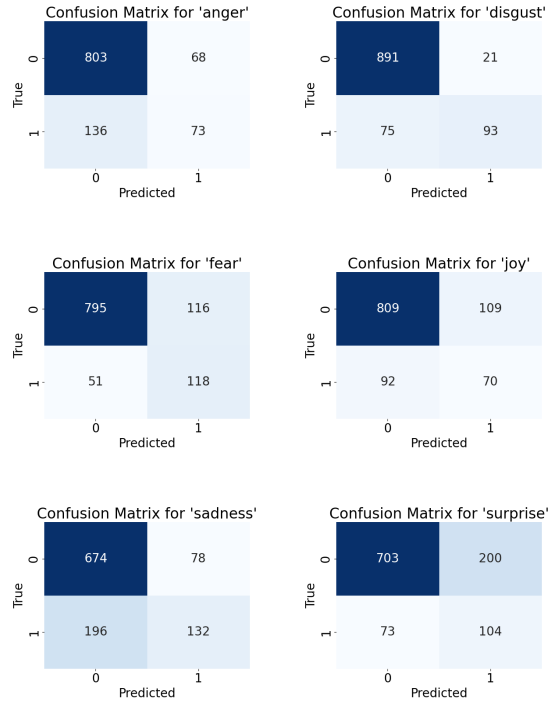

Figure B.12: Confusion matrix of the proposed model (BiLSTM+CNN) for Hausa language in Track C.

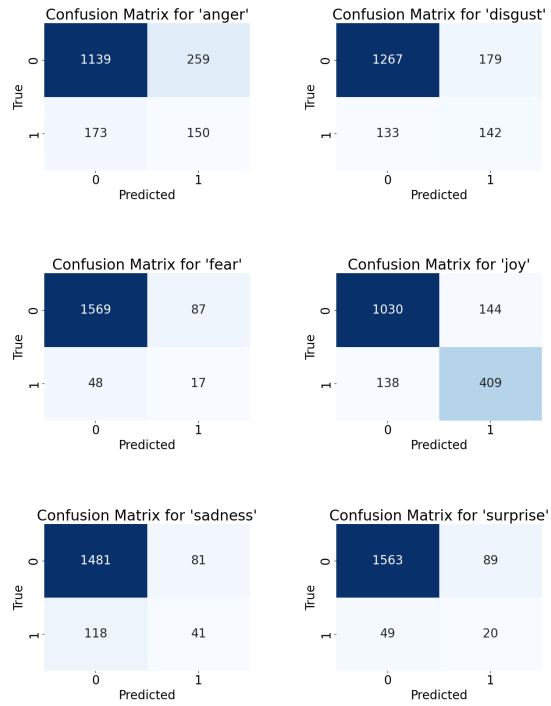

Figure B.13: Confusion matrix of the proposed model (BiLSTM+CNN) for Oromo language in Track C.

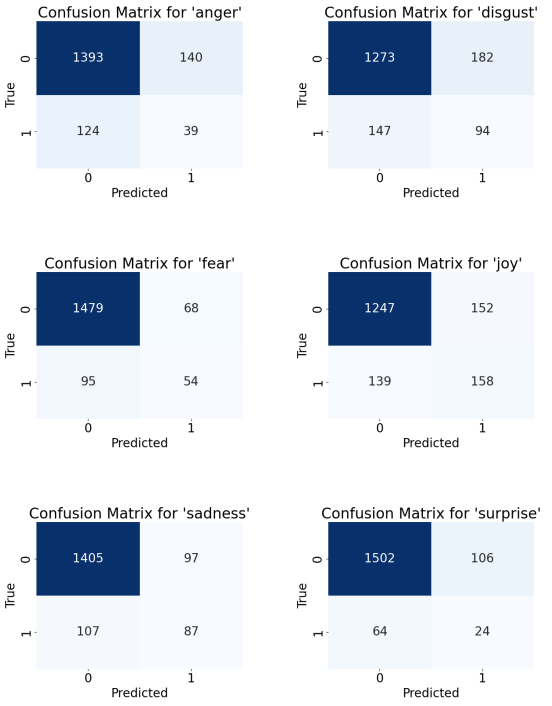

Figure B.14: Confusion matrix of the proposed model (BiLSTM+CNN) for Somali language in Track C.

For instance, for Amharic, the model predicts 1659 *non-fear* instances but only 5 actual *fear* instances, which is a case of extreme class skewness. The relatively improved performance for *joy* detection in Oromo may be explained by more discriminated linguistic features for *joy* in this language or even greater coverage in the training data. The consistently poor performance in detecting *fear* in both languages shows that expressions of *fear* may be more culturally coded or context-bound and hence more challenging to identify in a cross-lingual setting.

B.2 Qualitative Analysis

This section offers a detailed qualitative error analysis of the results of the best-implemented model in different languages for the subtasks.

Multi-label Emotion Detection

Figures B.15 and B.16 illustrate the multi-label emotion detection results, highlighting both strengths and weaknesses in the model's ability to identify emotions in Russian and Amharic text. The model demonstrates strong accuracy in cases where emotions are clearly stated, as seen in Russian Sample 1 and Amharic Sample 2, where the

predicted emotions align perfectly with the actual labels.

Sample Text	Actual Label	Predicted Label
Sample 1: ጦርነት ሲጀመር ቀላል ይመስላ። እግዚያብሔር ለሁለቱም ወገን ሠላሙን ያምጣ። ኢትዮጲያውያን ግን ጉዳዩን ከሀይማኖት ጋር አያይዛችሁ ሀገራችሁን ለመበጥበጥ አጀንዳ አትፍጠሩ። ይህ ጦርነት የድንበር የይዞታ ጉዳይ እንጂ ሀይማኖታዊ አይደለም (When a war starts, it seems easy. May God bring peace to both parties. But Ethiopians, do not link the issue with religion and create an agenda to destroy your country. This war is a border issue, not a religious one)	Anger, Sadness	Anger
Sample 2: አንድን ህዝብ በጅምላ እየሰደብክ ነገ ጉራጌን እንደማትሰድብ ምን ማስተማመኛ አለ?ጉራጌ እጅግ ከሚጠላቸው ነገሮች አንዱ ዘረኝነት ነው።የኦሮሞንም ሆነ የአማራን ህዝብ እኩል ህዝቤ ብሎ (What is the assurance that you will not insult Gurage while mass insulting a nation? One of the things Gurage hates the most is racism.)	Anger	Anger
Sample 3: በእውነት መሳይ መኮንን እዚህ መካከል ሳየው ህፃን መንሱርን መርሳታቸው ገርሞኛል የሚገርም መንግስት! (When I see a really handsome officer here, I am surprised that they forgot baby Mansoor. Amazing government!)	Surprise	Surprise

Figure B.15: Few sample predictions by the XLM-R for the Amharic language in Track A.

Sample Text	Actual Label	Predicted Label
Sample 1: у меня не было этой игры, но чет немного страшно .-. #анжелапедофил (I didn't have this game, but it's a little scary.-. #angelapedophile)	Fear	Fear
Sample 2: наконец то у нас всё хорошо (finally everything is fine with us)	Joy	Joy
Sample 3: Выходные они такие...КОРОТКИЕ!Ужасно короткие! (Weekends are so...SHORT! Terribly short!)	Sadness	Sadness

Figure B.16: Few sample predictions by the XLM-R for the Russian language in Track A.

However, it struggles with complex or nuanced expressions, particularly in cases of mixed emotions. For instance, in Amharic Sample 1, the actual emotions include both *Anger* and *Sadness*, but the model predicts only *Anger*, suggesting difficulty in capturing layered emotional content. Similarly, the model's ability to differentiate emotional intensity varies, as seen in Russian (Sample 3), where the sentiment is correctly classified as *Sadness*, but subtleties in emotional expression may require further refinement. These findings highlight the challenges of multilingual emotion detection, particularly for languages with unique linguistic structures and cultural expressions of emotions. Improving contextual sensitivity could enhance the robustness of such models for diverse languages.

Multi-label Emotion Intensity Detection

Figure B.17 illustrates the results of an emotion intensity detection task in Hausa language samples with rich qualitative data. For Sample 1, which describes the definition of terrorists and bandits (with crying emojis), the model correctly detects *Anger* but at a lower intensity (1) compared to the ground truth (2), correctly detecting *Sadness* as well. Notably, the model also predicts *Fear (1)*, which, in the case of the threatening content, is to be expected but was not annotated by humans.

Sample Text	Actual Label	Predicted Label
Sample 1: Ga manyan Yan ta'ada can da Yan bindiga suna holewa abanza Sai wadanda suke kokarin neman yancin kansu😭😭😭 (There are big terrorists and bandits who are trying to find their freedom 😭😭😭)	Anger (2), Sadness (2), The rest are (0)	Anger (1), Fear (1), Sadness (1), The rest are (0)
Sample 2: Yana shiga cikin gonar ya taka kashin mutun seda ya koma bakin gari ya wanke. (He went into the garden and stepped on the dead man's bone and went back to the city to wash.)	Disgust (2), The rest are (0)	Disgust (3), The rest are (0)
Sample 3: wasu yan takarar pdp na kyamar hoto da jonathan (some pdp candidates hate jonathan's image)	All emotions (0)	All emotions (0)

Figure B.17: Few sample predictions by the Bi-LSTM+CNN for the Hausa language in Track B.

Sample 2, a disturbing account of treading upon human bodies, shows the model correctly detecting *Disgust* as the most prominent emotion but overestimating its strength (3 versus the ground truth of 2). This suggests that the model might be more sensitive to *Disgust*-fostering content than humans are. Sample 3, about political candidates hating someone's picture, was correctly labeled as having no emotions (0) in all categories, which indicated the model's ability to differentiate between emotive content and factual information. These results indicate the model's strengths in emotion type detection but not intensity estimation, which highlights the subtle challenge in multilin-

gual emotion intensity detection, particularly for resource-scarce languages.

Cross-lingual Emotion Detection

Figures B.18 and B.19 illustrate the cross-lingual emotion detection results with strengths and weaknesses to detect emotions between the Hausa and Oromo languages.

Sample Text	Actual Label	Predicted Label
Sample 1: Allah yarabamu da corona ka h bamu Corola🙏🚗 (God bless us with corona and give us Corola 🙏🚗)	Fear	Fear, Sadness
Sample 2: Ministar Tinubu Ta Bayyana Malamin Addinin da Ya Mata Addu'a Ta Samu Mukami, Ta Yi Godiya (Minister Tinubu Explained The Religious Teacher Who Prayed For Her To Get The Position, She Was Thankful)	Joy	Joy, Surprise
Sample 3: Akatambayi buzu ko ya Iya s allah Sai yace ah ah Sai akace to ko kokas an rasulullah Sai yace 😁😁😁😁😁😁😁😁m Kun Kara badda ni. (He asked Buzu if he can pray and he said ah ah. Then he was asked if he was prayin g. Then he said 😁😁😁😁😁😁😁😁m Kun Kara badda me.)	Joy	Anger
Sample 4: Ibrahim ya bata kayan sa da kashin alade (Abraham lost his clothes with a pig's bone)	Disgust	Disgust

Figure B.18: Few sample predictions by the Bi-LSTM+CNN for the Hausa language in Track C.

Sample Text	Actual Label	Predicted Label
Sample 1: Bakar Waaree sodaa nafxenyaa f xiqqollee hin suukannooyne. Arra garuu Warra Sodaa Nafxenyaaf iyyuutu Goota. N afxenyaan awwalamte akka lammada hin d eebinetti. Isii irraanfadhaa. Qalbii takkaan r afaa. Warri biyya harkaa qabu oromoodha. *(Bakar Waaree was not the least bit terrified of the fear of the Nazis. Today, however, even those who are afraid of the Nazis are Heroes. Nafxanya was buried so that she would neve r come back. Forget about her. Sleep with on e heart. Those in charge of the country are O romo.)*	Anger	Anger, Disgust
Sample 2: This team work make the great re sult which broud us.Galatoomaa ijoollee biyy aa nu boonsitan nutis hojii gaarii hojjettaniin baay'ee gammaneerra. *(This team work make t he great result which broud us.Thank you guy s for making us proud and we are very happy with the good work you have done.)*	Joy	Joy
Sample 3: Halkan edaaKonya Horro Guduru u wallaggaa Ona Amuuruu Araddaa oborraatt iIrree fi gaachanni oromoo WBO waan ajaa'ib aa hojjetee jira injifannoon goolabeeraas.Um manni horro Guduruu wallaggaa baga Gamm addan kanaaf tumsa barbaachisu gochuun bira dhaabbadhaa WBO bira. *(The WBO has done a wonderful job in the village of Amuuruu in t he district of Horro Guduruu Wallagga last ni ght.)*	Joy	Disgust, Joy

Figure B.19: Few sample predictions by the Bi-LSTM+CNN for the Oromo language in Track C.

While the model performs flawlessly for certain emotions (perfect accuracy for *Disgust* in Hausa Sample 4), it falls short at more subtly expressed emotions, particularly where emojis are used (misclassifying *Joy* as *Anger* in Hausa Sample 3 despite numerous smiling emojis). The model tends to predict more than a single emotion, showing uncertainty in its prediction, as seen in predictions like *Fear, Sadness* and *Joy, Surprise.* There are language-specific tendencies where Oromo samples have mixed emotion predictions (like Sample 3 with *Disgust, Joy*), echoing potential challenges with the contextual understanding of this language. These findings highlight the need for improved cultural and contextual sensitivities in multilingual emotion detection systems, particularly for low-resource African languages, whose emotional expressions may be very different from those of high-resource languages on which the models are typically trained.

C Performance Ranking

Table C.1 outlines the F1 scores and rankings of the proposed framework compared to the baseline model (RemBERT) across corresponding languages and tracks.

Language	Models	F1 Score	Rank
Track A			
Marathi	Proposed Framework	0.807	22
	Baseline (RemBERT)	0.822	18
Hindi	Proposed Framework	0.838	23
	Baseline (RemBERT)	0.855	17
Russian	Proposed Framework	0.843	22
	Baseline (RemBERT)	0.838	25
Amharic	Proposed Framework	0.542	25
	Baseline (RemBERT)	0.638	15
Igbo	Proposed Framework	0.470	20
	Baseline (RemBERT)	0.479	15
Track B			
Algerian Arabic	Proposed Framework	0.292	18
	Baseline (RemBERT)	0.016	23
Chinese	Proposed Framework	0.4671	20
	Baseline (RemBERT)	0.4053	21
Hausa	Proposed Framework	0.573	14
	Baseline (RemBERT)	0.270	23
Russian	Proposed Framework	0.837	14
	Baseline (RemBERT)	0.876	9
Track C			
Amharic	Proposed Framework	0.459	8
	Baseline (RemBERT)	0.486	6
Algerian Arabic	Proposed Framework	0.436	8
	Baseline (RemBERT)	0.338	12
Hausa	Proposed Framework	0.499	8
	Baseline (RemBERT)	0.319	11
Oromo	Proposed Framework	0.391	4
	Baseline (RemBERT)	0.262	8
Somali	Proposed Framework	0.365	5
	Baseline (RemBERT)	0.273	9

YNU-HPCC at SemEval-2025 Task 6: Using BERT Model with R-drop for Promise Verification

Dehui Deng, You Zhang*, Jin Wang, Dan Xu and **Xuejie Zhang**
School of Information Science and Engineering
Yunnan University
Kunming, China
Contact: dehuideng@stu.ynu.edu.cn, yzhang0202@ynu.edu.cn

Abstract

This paper presents our participation in the SemEval-2025 task 6: multinational, multilingual, multi-industry promise verification. The SemEval-2025 Task 6 aims to extract Promise Identification, Supporting Evidence, Clarity of the Promise-Evidence Pair, and Timing for Verification from the promises made to businesses and governments. Using these data to verify whether companies and governments have fulfilled their promises. In this task, we focus on the English dataset. Our model introduces regularization dropout based on the BERT-base model to focus on the stability of non-target classes, improve the robustness of the model, and ultimately improve the indicators. Our approach obtained competitive results in task. The code of the paper is available at: https://github.com/xxkaras/SemEval-2025-Task-6.

1 Introduction

Tracking and verifying promises made by businesses and governments is essential for fostering accountability and trust. However, assessing whether these promises are upheld is often hindered by the complexities of different industries, languages, and countries. SemEval-2025 Task 6 (Chen et al., 2025) introduces a novel approach to multilingual, multi-industry promise verification to tackle this challenge. This task is designed to extract key information from promises made to businesses and governments, such as identifying supporting evidence for the promise, evaluating the clarity of the promise-evidence relationship, and determining the appropriate timing for verification. By leveraging this data, the goal is to assess the degree to which these promises have been honored.

The subtasks of SemEval-2025 Task 6 can be divided into binary classification and multi-classification tasks. Text classification is an important task in natural language processing (NLP) (Cambria and White, 2014) that aims to organize text into predefined categories automatically. According to the different types of tasks, text classification can be divided into binary, multi-class, and multi-label. In binary classification tasks, the text is divided into two mutually exclusive categories, such as spam and non-spam; multi-class classification tasks divide the text into multiple mutually exclusive categories, such as classified news; and multi-label classification tasks allow each text to belong to multiple categories at the same time, such as multi-label sentiment analysis. This process usually includes data reconstruction, feature extraction, model training, and evaluation. The text must be cleaned and segmented in the data reconstruction stage to convert it into a machine-processable format. Next, the feature extraction step converts the text into a numerical vector. Commonly used methods include the bag-of-words model, TF-IDF, Word2Vec, and BERT (Koroteev, 2021). The labeled data trains the machine learning or deep learning model in the model training phase. Common models include support vector machine (SVM) (Wang and Hu, 2005) and naive Bayes (Naive) (Webb et al., 2010). After the training is completed, the model needs to be evaluated on the test set, and the performance is evaluated using indicators such as accuracy, precision, recall, and F_1-score. Text classification (Gasparetto et al., 2022) has many applications, including sentiment analysis, spam filtering, topic classification, public opinion monitoring, etc. With the development of deep learning technology, pre-trained language models (Min et al., 2023) (such as BERT and GPT (Achiam et al., 2023)) have performed well in text classification tasks, especially for large-scale data sets (Bzdok et al., 2019) and complex tasks.

SemEval-2025 Task 6 contains the following four subtasks:

- Subtask 1 Promise Status (PS): Identify

*Corresponding author.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1905–1911

whether there is a promisein the sentence

- Subtask 2 Evidence Status (ES): Identify whether there is supporting evidence for the promise in the sentence
- Subtask 3 Verification Timeline (VT): Identify whether there is a verification time for the supporting evidence in the sentence
- Subtask 4 Evidence Quality (EQ): Identify the clarity of the evidence related to the promise in the sentence

Subtask 1 and subtask 2 are binary classification tasks, and subtask 3 and subtask 4 are multi-classification tasks.

SemEval-2025 Task 6: PromiseEvalMultinational, Multilingual, MultiIndustry Promise Verification competition features a novel multilingual dataset comprising English, French, Chinese, Japanese, and Korean, designed to evaluate corporate ESG promises and their implementation. Our team has participated in this competition and focus on English datasets. To improve the robustness of our model, we introduced a regularization dropout mechanism based on BERT-base. This method focuses on enhancing the stability of non-target classes, ultimately boosting the model's performance and generalizability. Our approach delivered competitive results in this task, showcasing the potential of incorporating regularization techniques into promise verification tasks. This paper discusses our methodology, results, and insights into how these advancements contribute to more effective promise verification.

The rest of this paper is organized as follows. Section 2 introduces the related work before our study for this task. Section 3 gives an overview of our system for this task. Section 4 presents the specific details of our system and discusses the experimental results. The conclusions are drawn in Section 5.

2 Ralated Work

Some companies use misleading information to create an overly positive environmental image, a practice known as greenwashing. To address the greenwashing phenomenon and the challenge of evaluating corporate promises, Seki et al. (2024) proposed ML-Promise, the first multilingual dataset for deep promise verification, including Chinese, English, French, Japanese, and Korean. The dataset provides key training samples for related technologies in the field of natural language processing (NLP) to verify corporate promises in environmental, social, and governance (ESG) reports. The dataset contains promise data from different countries and companies, with structured labels to facilitate the identification and evaluation of corporate promises, supporting evidence, supporting evidence quality, and verification time of the promise. The labels are divided into four main aspects to ensure a comprehensive assessment of corporate promises.

Hillebrand et al. (2023) proposed a recommendation system based on natural language processing (NLP) to automatically analyze the credibility and substantive content of corporate sustainability reports. The study adopted a BERT-based multi-task learning framework, combined with rule matching and attention mechanism, to extract promise statements from reports and classify their credibility, and external data was used for cross-validation. The traditional manual review process was enhanced through multimodal analysis, explainable recommendations, and cross-domain adaptation. Experiments show that the system achieves excellent results in the task of sustainability report detection. The study provides a technical reference for the automated verification of corporate promises.

To promote in-depth verification of promises, this paper aims to apply models in the field of natural language processing to promise verification, and to monitor corporate promises and their compliance with ESG promises, as well as the promises and compliance of public figures.

3 System Overview

Our system is based on the BERT-based model, and the regularization technology RDrop (Regularized Dropout) (Wu et al., 2021) has been added to implement it. The overall structure of our system consists of four modules, which are described below.

Input layer. In this layer, we build text processing tools for performing text preprocessing and word embedding (Jiao and Zhang, 2021). The input is a data frame containing text data (obtained from the train data test set). The text data is converted to the BERT input format (token IDs) using functions provided by BERT. The input is padded to ensure consistent input length within a batch. The dataset

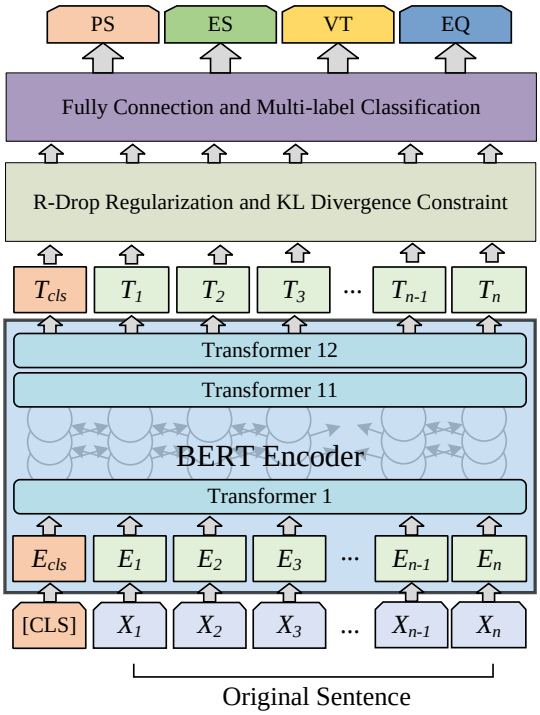

Figure 1: Multi-label classification system

is converted to the Hugging Face dataset format using API provided by Hugging Face.

Context encoder. BERT (Devlin et al., 2019) is a natural language processing (NLP) model proposed by Devlin et al. in 2018. The main novelty of BERT lies in its bidirectional encoder structure, which can simultaneously model text from left to right and from right to left, allowing it to better capture contextual information in the text. BERT uses a pre-training method and can handle various text-processing tasks through fine-tuning. BERT is based on the Transformer (Zheng et al., 2022) architecture and adopts bidirectional. This means that when learning context, BERT considers the information before and after the word and simultaneously analyzes the relationship between the left and right sides. Hence, it has a stronger ability to understand semantics. BERT first pre-trains with large-scale corpus to learn general language knowledge. On this basis, BERT can adapt to specific tasks (such as text classification, question answering, named entity recognition, etc.) through fine-tuning (Wang et al., 2024) to achieve excellent performance. In the pre-training stage, BERT uses static masking to process text. In each training cycle, BERT randomly masks some words in the input text and trains the model to predict these masked words. In this way, BERT can learn the deep relationship between words. This module mainly uses the pre-trained BERT model to complete the context encoder (Pathak et al., 2016).

Dropout Layer. Dropout (Srivastava et al., 2014) is a common regularization technique used in the training process of neural network models to prevent overfitting of the model. It was proposed by Geoffrey Hinton et al. in 2014 and is widely used in deep learning. The core idea of Dropout is to discard some neurons in the neural network randomly. In each training, randomly select some neurons and their connections to make them *invalid* or *not involved in the calculation* in the current iteration. This operation helps to reduce the complex dependencies between neurons and forces each part of the model to learn features independently, thereby improving the model's generalization ability.

Linear Classifier. In our model, the linear classifier (Bai et al., 2022) maps the context information extracted by BERT to the target label space, such as promise status, evidence status, verification time, and evidence quality. It classifies label through the fully connected layer. The classifier combines the dropout layer (regularization) to avoid overfitting and trains the model through the cross-entropy loss so that the model can predict the score of each label based on the input text.

The input size of this layer is 768 (the hidden layer size of BERT-BASE), and the output size is 4 (the number of labels)

Loss Function. In our model, the calculation of the loss function includes the following parts: Cross-Entropy Loss (Mao et al., 2023), which is used to calculate the gap between logits and labels. Kullback-Leibler (KL) divergence (Van Erven and Harremos, 2014) calculates the consistency between model outputs. As a regularization term, It encourages the model to produce similar predictions in different training cycles. Cross-entropy loss measures the difference between the probability distribution predicted by the model and the distribution of the true label. The calculation formula for Cross-Entropy Loss is as follows:

$$CrossEntropyLoss = -\sum y_i log(p_i) \quad (1)$$

Kullback-Leibler Divergence is a measure of the difference between two probability distributions. Our model uses KL divergence to calculate the difference between logits and kl_logits (logits calculated by BERT for the second time), which is added to the loss function as a regularization term. The calculation formula for KL divergence is as follows:

$$KL\,Divergence(P||Q) = \sum P(x) log(\frac{P(x)}{Q(x)}) \quad (2)$$

KL Divergence Loss (Cui et al., 2025) calculates the KL divergence between logits and kl_logits and the KL divergence between kl_logits and logits. The final KL Divergence Loss is the average of the two, encouraging the model's output to be consistent across different training steps. The total loss of the model is a weighted sum of the cross-entropy loss, the KL divergence loss, and another cross-entropy loss.

The application of our model in SemEval-2025 Task 6 is discussed below. The first part of this task is extracting semantic information from a given tweet text. We call it sentence classification. In the upstream task, we used a pre-trained BERT model for the upstream sentence information extraction task. In the downstream task, we used BERT for multi-label classification, where the model's goal is to predict multiple labels based on the input text (such as a promise statement or a business text). Specifically, the model needs to predict the following labels: promise_status, verification_timeline, evidence_status, and evidence_quality. The prediction of each label is independent, and the output features of BERT, i.e., the pooled output of [CLS] token, are mapped to the logits of each label. These scores are converted into probability values for each label through the sigmoid activation function, indicating whether the label exists.

4 Experiments

Datasets. SemEval-2025 Task 6 uses the Multilingual Dataset for Corporate Promise Verification as the dataset that needs to extract from the promise text whether there is a promise, supporting evidence, the quality of the promise and the time limit for the verification of the promise. Table 1 shows the labels of each subtask. The dataset is in JSON format and Parquet format. Because the TSV format is more convenient for data processing, we convert both the training set and the dataset to the TSV format.

Evaluation Methods. The evaluation metric for SemEval-2025 Task 6 is accuracy. Each subtask in the task is evaluated for accuracy. Leaderboard scores are aggregated scores for all subtasks.

Implementation Details. To evaluate the effectiveness of our proposed method, we conducted a series of experiments. All experiments were performed under identical conditions to ensure consistency and comparability of results. Our model was separately trained and tested for label prediction across four subtasks. We split the training data into training and validation sets at an 8:2 ratio. For label encoding, we employed LabelEncoder to convert textual category labels into numerical values (e.g., encoding "No" as 0 and "Yes" as 1 in the promise status task). We constructed a custom BERT classification model based on BertPreTrainedModel. The model architecture incorporates a dropout layer and a linear classification layer (with output dimensions corresponding to the number of label categories) on top of the pooled BERT representations. The number of labels varied across tasks (e.g., binary classification for promise status and evidence status with 2 labels, 5 labels for verification timeline, and 4 labels for evidence quality). To enhance model robustness, we combined cross-entropy loss with KL-divergence loss, computing consistency regularization through dual forward propagation. Train-

Subtask	Label
Promise Status	Yes/No
Evidence Status	Yes/No
Verification Timeline	within 2 years/2-5 years/longer than 5 years/other/nan
Evidence Quality	Clear/Not Clear/Misleading/nan

Table 1: Label in each subtask

	Learning Rate	Train Epochs	Train Batch Size	Warmup Steps	Weight Decay
Promise Status	3.6672	4	4	200	0.0881
Evidence Status	7.2486	4	8	200	0.0156
Verification Timeline	4.2965	4	4	500	0.0442
Evidence Quality	3.9092	2	4	1000	0.03

Table 2: The optimal parameters after fine-tuning

	w/ optimal params	w/o optimal params
Promise Status	0.7875	0.7625
Evidence Status	0.6753	0.625
Verification Timeline	0.4252	0.3875
Evidence Quality	0.3	0.2125

Table 3: performance comparison of model in promise verification with and without optimal parameters

ing was conducted using optimized hyperparameters. Upon completion of training, predictions were made on the test set by selecting the class with the maximum logit value. Finally, the numerical predictions were converted back to their corresponding textual labels. This approach ensures both task adaptability and improved generalization performance through our loss design.

Hyperparameters Finetuning. We train and evaluate the model with different hyperparameters in the objective function.Our hyperparameter tuning employs Bayesian optimization through Optuna, systematically exploring the learning rate (1e-5 to 5e-5), batch sizes during training (4, 8, 16), total number of training epochs (2 to 5), number of warmup steps for the learning rate scheduler (100 to 1000, in steps of 100), and strength of weight decay (0.0 to 0.1). The optimization goal is to maximize validation accuracy over 10 trials, each performing complete model training using Hugging Face's Trainer API. It determines the optimal hyperparameter combination through multiple experiments, as shown in Table 2.

Ablation Study. To evaluate the impact of regularized dropout in ESG promise verification, we conducted ablation study by systematically removing regularized dropout from parts of the model and deeply analyzed the contribution of regularized dropout to the experimental results. The Table 4 compares the performance of the BERT-BASE model combined with R-drop and the Bert-Base model after fine-tuning in each subtask. To ensure the accuracy and fairness of the experiment, both models use the parameters fine-tuned by Optuna. The results prove that R-drop is effective in improving the accuracy in ESG promise verification.

	w/ R-drop	w/o R-drop
Promise Status	0.7875	0.75
Evidence Status	0.6753	0.6125
Verification Timeline	0.4252	0.3756
Evidence Quality	0.3	0.2752

Table 4: performance comparison of BERT model in promise verification with and without R-drop

Results and Analysis. In the competition leaderboard, our system ranked 9 in the English leaderboard. As indicated, our method is effective.This is mainly because BERT is combined with R-Drop to improve generalization ability, enhance robustness, optimize training process, improve task performance and reduce overfitting.Our model has an accuracy of 0.7875 in the promise status subtask and0.6753 in the evidence status subtask. The model performs well in the binary classification task and can judge the existence of the promise and the existence of evidence in the text with high accuracy.However, the accuracy in the verification timeline and evidence quality subtasks is only 0.4252 and 0.3 respectively, which means that the model has difficulty in clearly judging the clarity of the given evidence in relation to the promise and specific deadline for promise verification completion.

5 Conclusions

This paper proposes a promise verification label classification model base BERT with R-drop for SemEval-2025 Task 6. The model successfully solves the classification problems of commitment existence status, evidence existence status, evidence quality and commitment verification timeline.In the promise verification task, R-Drop simulates different sub-networks by randomly dropping neurons, making the model more robust to input perturbations and making the final output labels of each sub-task more accurate. Although small models combined with few-shot learning can effectively solve binary classification tasks such as promise status and evidence status, the effect on verification timeline and evidence quality tasks is not ideal. Future works will apply, text data augmentation, such as using synonym replacement, random insertion or back-translation techniques, to expand the training set. Moreover, weighted loss functions or oversampling/undersampling techniques to balance the distribution of labels and avoid the model being biased towards the majority class label.

Abstract

This paper introduces the approach we adopted for the SemEval-2025 "Food Hazard Detection" task, which aims to predict coarse-grained categories (such as "product category" and "hazard category") and fine-grained vectors (such as specific products like "ice cream" or hazards like "salmonella") from noisy, long-tailed text data. To address the issues of dirty data, as well as the severe long-tail distribution of text labels and length in the data, we proposed a pipeline system. This system combines data cleaning, LLM-based enhancement, label resampling, and ensemble learning to tackle data sparsity and label imbalance problems. The two subtasks have strong semantic relatedness. By integrating them into a unified multiturn dialogue framework, we fine-tuned five models using a bagging approach. Ultimately, we achieved notable results on both subtasks, with F1 scores of 80.17% (ranked 4th) for Subtask 1 (ST1) and 52.66% (ranked 3rd) for Subtask 2 (ST2).

1 Introduction

Food safety incidents pose significant risks to public health and economic stability, necessitating rapid detection and transparent decision-making systems. The SemEval 2025 Task on Food Hazard Detection addresses this challenge by evaluating systems that classify food incident reports from web resources into predefined categories and specific vectors for "product" and "hazard." This task focuses on English-language reports, aiming to automate the discovery of food-related risks from social media and news platforms, where timely and interpretable predictions are critical for mitigating economic and health impacts. The task requires dual subtasks: ST1 for predicting hazard and product categories (e.g., "meat, eggs, and dairy" or "pathogenic bacteria") and ST2 for identifying exact hazard and product entities (e.g., "Salmonella" or "ice cream"). With 1,142 unique products and 128 hazards distributed across imbalanced categories, the task demands robustness against long-tail distributions and noisy text, reflecting real-world complexities in food safety monitoring (Randl et al., 2025, 2024).

Our system integrates data augmentation, label resampling, and ensemble learning to tackle these challenges. Inspired by advances in NLP for low-resource scenarios, (Wei and Zou, 2019) proposed some traditional data augmentation methods: Synonym Replacement, Random Insertion, Random Swap, and Random Deletion. In addition to these, advanced strategies like metadata-aware data augmentation (Zhang et al., 2021) (e.g., substituting similar products from a food ontology) and prototypical networks (Snell et al., 2017) show promise but remain untested in multi-task food safety contexts. Against this backdrop, we employed large language models (LLMs) to generate synthetic summaries of raw incident reports. This approach not only enhanced the diversity of the dataset but also preserved its semantic integrity.

To address the severe class imbalance in our dataset, we employed a combination of oversampling techniques for minority classes (Chawla et al., 2002) and a bagging ensemble (Breiman, 1996) comprising five fine-tuned models with Low-Rank Adaptation (LoRA) (Hu et al., 2022). This approach effectively mitigated the imbalance and enhanced model performance. MTLN (Multi-dimensional Type-slot label interaction Network) (Wan et al., 2023) is a neural network-based MTL framework designed to handle multiple natural language processing tasks through a unified architecture. Compared with single-task learning, multi-task learning (MTL) demonstrates enhanced generalization capabilities by leveraging task correlations and complementarity, which has been theoretically validated. Given that ST1 and ST2 in our challenge are both focused on food hazard detection and are highly related, we integrated Large

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1912–1918

Language Models (LLMs) to combine ST1 and ST2 into a multi-turn dialogue framework. This framework enables the model to effectively utilize data from multiple tasks, leading to improved generalization and adaptability, while also mitigating issues such as underfitting or overfitting (Guo et al., 2018).

Our experiments yielded competitive results: 80.17% F1-score (4th rank) for ST1 and 52.66% F1-score (3rd rank) for ST2. Quantitative analysis demonstrated that, compared to single-model predictions, employing bagging voting with five models boosted performance by 1.09% for Subtask 1 and 3.14% for Subtask 2. This indicates the effectiveness of the bagging voting approach, especially in significantly enhancing the model's generalization ability when dealing with long-tailed label distributions. However, the system encountered difficulties in handling ambiguous hazard descriptions (for example, distinguishing between "listeria monocytogenes" and "listeria spp"). This reflects the limitations of fine-grained entity recognition observed in the food safety literature. Qualitative errors further highlighted the need for context-aware disambiguation, particularly for overlapping hazard categories such as "sulphur dioxide and sulphites" versus "sulphates/sulphites." These findings align with the broader challenges in interpretable AI for food risk assessment (Ribeiro et al., 2016), emphasizing the trade-off between model complexity and explainability.

This paper demonstrates the following contributions:

- Through text summarization based on prompt engineering, we enhanced the diversity of the data, which helps to improve the model's generalization ability.
- Given the correlation between the two subtasks, we constructed them into a multi-turn dialogue format, which improved the model's performance.
- On the validation set leaderboard, ST1 and ST2 achieved scores of 86.41% (ranked 1th) and 54.32% (ranked 4th), respectively. On the test set leaderboard, we were ranked 4th for ST1 and 3rd for ST2.

2 System Overview

As illustrated in Figure 1, our experimental workflow begins with a dataset sourced from web scraping, which contains noisy data and suffers from severe label imbalance as well as a pronounced long-tail distribution of text lengths. To mitigate these issues, we first applied regular expressions to clean the data by removing elements such as hyperlinks, HTML formatting, and email addresses. Following this, we utilized a large language model with prompt engineering to generate textual summaries of the cleaned data, aiming to augment our dataset and enhance its diversity. This was achieved by concatenating the original texts with their generated summaries to form an enriched dataset.

To address the label imbalance problem within this enhanced dataset, we implemented label resampling techniques. Subsequently, using a Bagging approach, we sampled five subsets of data with replacement. Considering the strong interrelation between the two subtasks (ST1: food hazard prediction; ST2: precise vector detection), we combined them into a unified framework through a multi-turn dialogue format. Specifically, we performed Supervised Fine-Tuning (SFT) using the LoRA method across these five subsets. This process resulted in the training of five distinct models, whose outputs were aggregated through voting to determine the final predictions, thereby achieving improved performance and robustness.

2.1 Supervised Fine-Tuning (SFT)

The main approach employed across all two subtasks was Supervised Fine-Tuning (SFT) (Ouyang et al., 2022). In this training phase, model parameters are optimized through a supervised learning objective designed to enhance predictive performance on annotated datasets.

The standard formulation of the SFT loss function can be expressed as:

$$\mathcal{L}_{SFT} = \frac{1}{N} \sum_{i=1}^{N} \mathcal{L}_{\text{cross-entropy}}(y_i, \hat{y}_i) \quad (1)$$

where $\mathcal{L}_{\text{crossentropy}}$ is the cross-entropy loss between the true label y_i and the predicted label $\hat{y}_i$, and N is the number of training samples.

2.2 LoRA

LoRA was implemented for adjusting large pretrained models. This methodology deploys trainable low-rank decomposition matrices A and B to approximate parameter adjustments, thereby minimizing trainable parameters while preserving the

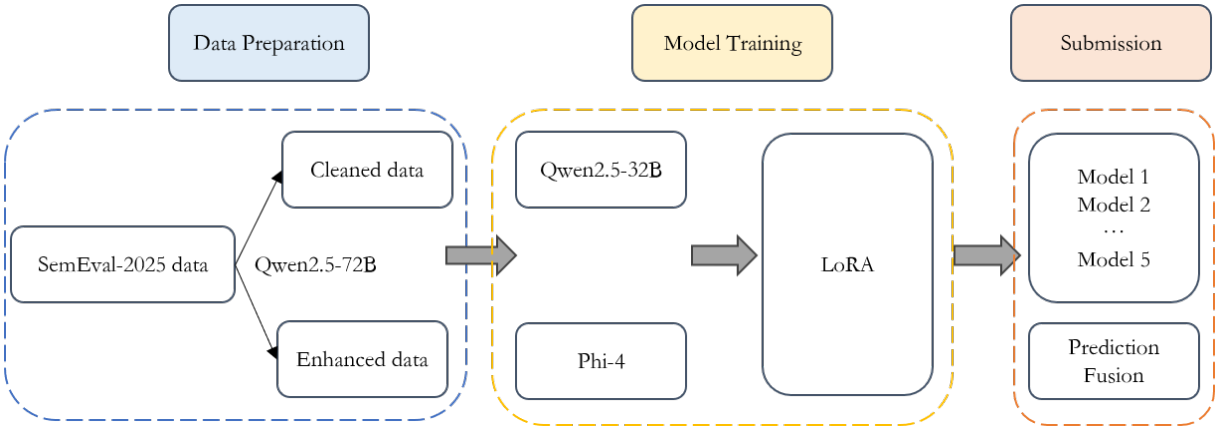

Figure 1: Task experimental progress

base model's capabilities. The adaptation process for a given weight matrix W operates through additive low-rank projections:

In addition to the techniques above, LoRA was implemented for adjusting large pre-trained models. This methodology deploys trainable low-rank decomposition matrices A and B to approximate parameter adjustments, thereby minimizing trainable parameters while preserving the base model's capabilities. The adaptation process for a given weight matrix W operates through additive low-rank projections:

$$W_{\text{new}} = W + \Delta W = W + AB^T \quad (2)$$

where A and B are low-rank matrices that are learned during fine-tuning. This approach allows the model to adapt to new tasks with fewer trainable parameters, making it computationally efficient.

The LoRA loss function is typically added to the standard SFT loss:

$$\mathcal{L}_{\text{LoRA}} = \mathcal{L}_{SFT} + \lambda \|A\|_F^2 + \lambda \|B\|_F^2 \quad (3)$$

where $\|\cdot\|_F$ denotes the Frobenius norm and λ is a regularization parameter that controls the strength of the low-rank adaptation.

2.3 Data Preprocessing

The data provided for this task is sourced from web pages. Through data analysis, we identified the presence of unwanted elements such as hyperlinks, HTML formatting, and email addresses. To address this, we applied regular expression preprocessing to remove these components.

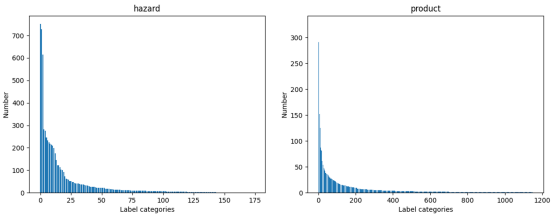

Figure 2: Distribution of labels for hazard and product in Subtask 2.

2.4 Data Augmentation

In our approach, we address the challenges posed by noisy data and imbalanced label distributions through robust data augmentation and resampling strategies. Initially, we generate concise summaries of cleaned texts using a large language model based on prompt-based summarization. These summaries are then concatenated with their original texts to form an augmented dataset. This enhancement strategy serves multiple purposes:

- Summarization aids in standardizing text representation by distilling essential information, thereby reducing noise and improving model interpretability.
- It boosts data diversity by introducing alternative phrasings and sentence structures, which helps mitigate the risk of overfitting.
- It accentuates crucial contextual elements, particularly beneficial for tackling label imbalance. By explicitly highlighting key information related to product categories and hazard classes, the model receives clearer classification signals.

Figure 2 illustrates the label distribution for haz-

ard and product classes, revealing a severe long-tail distribution. To further mitigate this inherent issue, we employed resampling techniques on the augmented dataset. Specifically, for underrepresented categories (e.g., 74.2% of product categories have fewer than five samples), we performed resampling to ensure each category had at least five samples. Through multiple experimental validations, we found that augmenting small sample categories to a minimum of five entries yielded the best performance on the validation set. This balanced representation enabled our models to learn more robust and generalizable features, significantly improving overall performance.

2.5 Ensemble

After undergoing data preprocessing, data augmentation, and label resampling, the original dataset was transformed into a more balanced, diverse, and clean augmented dataset. Based on this enhanced dataset, we employed a bagging approach to perform bootstrapping, generating five subsets of data for training five Phi-4 models. For each model, we selected the weights that achieved the best performance on the validation set to evaluate the models on the official test set provided by the competition organizers. Finally, we integrated the predictions from all five models using an ensemble voting mechanism to produce our final submission for the test leaderboard.

2.6 Metrics

This task evaluates the joint marco-F1 for hazard and product. The composite evaluation metric is defined as:

$$\text{Composite-F1} = \frac{1}{2}\left(\text{F1}_{\text{h}} + \text{F1}_{\text{p|h}}\right) \tag{4}$$

Where the component metrics are calculated as:

$$\text{F1}_{\text{h}} = \frac{2 \cdot \text{Precision}_{\text{h}} \cdot \text{Recall}_{\text{h}}}{\text{Precision}_{\text{h}} + \text{Recall}_{\text{h}}} \tag{5}$$

$$\text{F1}_{\text{p|h}} = \frac{2 \cdot \text{Precision}_{\text{p}|C} \cdot \text{Recall}_{\text{p}|C}}{\text{Precision}_{\text{p}|C} + \text{Recall}_{\text{p}|C}} \tag{6}$$

The conditional set C is formally defined as:

$$C = \{\, i \mid \hat{y}_{\text{h},i} = y_{\text{h},i} \,\} \tag{7}$$

Where the subscripts h and p represent hazard and product, respectively.

3 Experimental Setup

This section describes various experiments conducted on model fine-tuning and inference, aimed at exploring the impact of different approaches on the model's F1-score. We applied the LoRA method to fine-tune the Phi-4 models, using a rank of 4, an alpha of 8, and targeting all layers. The Phi-4 model parameters were frozen, with only the low-rank adapter parameters being trained.

During the LoRA-based domain fine-tuning, we trained large models using the Llama-Factory (Zheng et al., 2024) framework and the Adam (Kingma and Ba, 2014) optimization algorithm. The training included a warm-up step of 10% and a learning rate of 5e-5. Additionally, we performed distributed training using Deepspeed Zero-3 (Rajbhandari et al., 2020) on two NVIDIA A100 GPUs (80GB), with a batch size of 1 per GPU and gradient accumulation of 12, for a total of 5 epochs.

In this study, we employed various techniques and used bagging to sample five subsets of data, training five distinct models. We then evaluated their performance on the SemEval-2025 official dataset by aggregating the predictions from the five LoRA-fine-tuned LLMs. The best checkpoints were selected based on the highest F1-score on the validation set, and a voting mechanism was used to make final predictions.

4 Results

4.1 Main Quantitative Findings

As can be seen from Table 1, our system performed robustly on both subtasks of the SemEval 2025 Food Hazard Detection Challenge. For ST1, which involves the prediction of food hazard categories, our model achieved an F1 score of 80.17%, ranking 4th among all participants. For ST2, which involves the prediction of the exact product and hazard vectors, our model achieved an F1 score of 52.66%, also ranking 3rd. These results highlight the effectiveness of our approach in tackling the challenges of class imbalance and long-tail distribution in the dataset.

Task name	F1(%)	Rank
ST1	80.17	4
ST2	52.66	3

Table 1: Results of Phi-4 on the test leaderboards.

4.2 Ablation Analysis

We conducted an ablation study to evaluate the contributions of various components in our system, as shown in the table 2. The experiments were conducted on the official test split.

Method	ST1 F1 (%)	ST2 F1(%)
Single-turn	61.52	35.43
multi-turn	63.97	37.52
multi-turn + Data Augmentation	79.08	49.52
multi-turn + Data Augmentation + Bagging	80.17	52.66

Table 2: Ablation results on Phi-4.

Single-turn: The model is tasked with completing both ST1 and ST2 predictions simultaneously. The baseline approach, which did not incorporate multi-turn dialogue or data augmentation, achieved an F1 score of 61.52% on ST1 and 35.43% on ST2.

Multi-turn: First, the model predicts the hazard-category and product-category in ST1. Then, based on these initial predictions, it proceeds to predict the results for ST2. Detailed prompt information can be found in Appendix A.1. By incorporating multi-turn dialogue, the system showed improvement with F1 scores of 63.97% (ST1) and 37.52% (ST2), demonstrating that the use of contextual dialogue helps in better capturing task-specific information.

Multi-turn + Data Augmentation: Adding data augmentation through text summarization further boosted the system's performance, with F1 reaching 79.08% (ST1) and F1 increasing to 49.52% (ST2). This indicates that data augmentation effectively enhanced model generalization by introducing more diverse training examples.

Multi-turn + Data Augmentation + Bagging: The final system, which included data augmentation and Bagging for model ensembling, showed the highest performance with F1 of 80.17% (ST1) and F1 of 52.66% (ST2). This demonstrates the benefits of combining multiple models to improve robustness and reduce variance in predictions.

These results underscore the effectiveness of our approach, where multi-turn dialogue, data augmentation, and ensemble learning via Bagging were key contributors to the performance improvements.

4.3 Error Analysis

To gain insights into the types of errors made by our system, we analyzed a sample of the predictions. While the system performed well overall, it tended to struggle with highly imbalanced classes, particularly in ST2 where the task requires predicting specific product and hazard vectors. In some cases, the model incorrectly predicted the exact hazard or product due to the complexity of distinguishing between similar categories in long-tail distributions. Further investigation and manual tagging of errors revealed that the most common mistakes were due to ambiguous or noisy text data, which is a challenge inherent in web-scraped datasets.

5 Conclusion

In this work, we proposed a multi-turn dialogue modeling approach combined with data cleaning, prompt-based data augmentation, label resampling, and a bagging strategy to tackle the SemEval 2025 food hazard detection challenge. Our final system achieved F1 scores of 80.17% and 52.66% on Subtask 1 and Subtask 2, respectively, securing 4th place in ST1 and 3rd place in ST2. From the ablation experiments, we observed that combining multi-turn modeling with data augmentation and ensemble methods can effectively mitigate the long-tail distribution and noise issues in real-world datasets. For future work, we plan to explore more advanced model interpretability techniques, domain-specific knowledge incorporation, and automated sampling strategies to further improve both the robustness and explainability of food hazard detection systems.

6 Limitations

Despite the promising results achieved by our multi-turn approach with data augmentation and bagging, several limitations remain. First, our reliance on large language models for text summarization and augmentation introduces potential biases in the generated data. Since these models are trained on broad corpora, they may inadvertently produce content that is contextually inconsistent or irrelevant for specific food hazard scenarios, thereby influencing both model training and evaluation outcomes.

Second, although label resampling and bagging helped address class imbalance, rare classes remain challenging. In real-world applications, novel or extremely infrequent hazards and products may not be

adequately represented, leading to degraded performance when encountering such cases. Furthermore, the final system relies on multiple model ensembles and LoRA-based fine-tuning, which can be computationally expensive, making the approach less feasible for teams with limited resources.

Finally, while we integrated ST1 (hazard-category, product-category) and ST2 (hazard, product) within a multi-turn framework, our current interpretability methods are still somewhat simplistic. Generating "vector" explanations offers initial transparency, yet deeper domain-specific insights—such as causal chains or uncertainty estimates—are not thoroughly explored. Future work could incorporate more advanced explanation mechanisms to provide richer, more reliable interpretability in real-world food safety applications.

7 Acknowledgments

This task has been accomplished with the funding of *Ping An Life Insurance Company of China, Ltd*. All research presented in this paper was conducted during the Semeval-2025 competition. The opinions and conclusions expressed herein are solely those of the authors. We would also like to thank the task organizers and anonymous reviewers for their valuable feedback and constructive comments.

A Appendix

A.1 Fine-tuning Prompt

In Figure 3, the upper part shows the prompt for the first dialogue round and the lower part shows the prompt for the second dialogue round. The red numbers indicate the required input information:① represents the input title;② represents the input text after cleaning it using regular expressions;③ represents the summary of the input text generated by LLM;④ represents the product-category predicted in the previous round;⑤ represents the hazard-category predicted in the previous round.

By constructing two-round dialogue fine-tuning prompts in this manner, the model can focus on both coarse-grained food and hazard categories, as well as the relationships between finer-grained food and hazard details. This approach enhances the model's performance by allowing it to better capture the nuances between different levels of categorization.

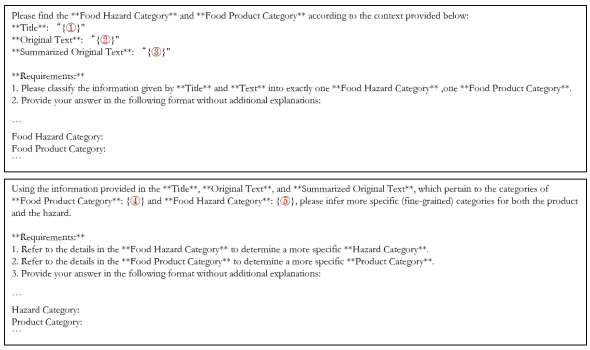

Figure 3: An Example of Prompt Engineering for Multi-turn Dialogue Based on LoRA Fine-tuning.

Howard University-AI4PC at SemEval-2025 Task 9: Using Open-weight BART-MNLI for Zero Shot Classification of Food Recall Documents

Abstract

We present our system for SemEval-2025 Task 9: Food Hazard Detection, a shared task focused on the explainable classification of food-incident reports. The task involves predicting hazard and product categories (ST1) and their exact vectors (ST2) from short texts. Our approach leverages zero-shot classification using the BART-large-MNLI model, which allows classification without task-specific fine-tuning. Our model achieves competitive performance, emphasizing hazard prediction accuracy, as evaluated by the macro-F1 score.

1 Introduction

Food safety is a critical global concern, with foodborne illnesses affecting millions annually and causing significant economic losses. Rapid and accurate detection of food hazards is essential to mitigate these risks, but the sheer volume of food-incident reports makes manual monitoring challenging. Automated systems that identify and classify food hazards from textual data, such as recall notices or social media posts, offer a promising solution. However, these systems must be accurate since it is crucial for building trust and enabling human oversight in food safety applications.

Recent advancements have enabled the development of systems that can automatically detect food hazards from textual data. For example, previous work has focused on identifying foodborne illnesses from social media posts or analyzing food recall reports from official agencies. (Poisoned, 2025)

Despite the progress in automated food safety systems, there is a lack of systems that provide exact predictions for food hazards. Additionally, the imbalanced and ambiguous nature of food-incident data poses significant challenges for traditional supervised learning approaches.In this paper, we aim to address these challenges by developing a system for food hazard detection using zero-shot classification. Our approach leverages the BART-large-MNLI model to predict hazard and product categories (ST1) and their exact vectors (ST2) from short food recall related texts.

The key contribution of our work evaluate the effectiveness of zero-shot classification using a well-studied pre-trained open-weight model as part of SemEval-2025 Task 9 (Randl et al., 2025).

2 Related Work

Utilizing advancements in deep learning and large language models to categorize and classify text is standard practice in research literature across multiple domains and languages (Prioleau and Aryal, 2025; Aryal and Prioleau, 2024; Aryal et al., 2023a,b; Prioleau and Aryal, 2023). Recently, the detection of food hazards from textual data, such as food incidents reports, has gained significant attention due to its potential to improve public health and reduce economic losses. Traditional methods for identifying food hazards often rely on manual analysis of reports from official sources, which can be time-consuming and prone to delays. To address these limitations, recent research has focused on developing automated systems that can efficiently process and classify food-incident reports collected from the web. For example, studies have explored the use of machine learning (ML) techniques to analyze social media posts and web-based reports for early detection of food borne illnesses, demonstrating the potential of these systems to identify unreported events and enhance outbreak response (Radford et al., 2018; Tao et al., 2023). Additionally, systems like FINDER have leveraged aggregated web search and location data to detect food borne illnesses in real-time, showcasing the value of integrating diverse data sources for timely hazard identification (Tao et al., 2023). However, many existing systems lack explainability, which is crucial for ensuring transparency and enabling human

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1919–1923

oversight in food safety applications. Our work addresses this gap by introducing classification system that uses zero-shot classification to predict hazard and product categories (ST1) and their exact vectors (ST2) from food-incident reports which supports the development of automated crawlers that can efficiently extract and classify food hazards from web sources like social media. (Poisoned, 2025)

3 Methodology

The task involves two subtasks:

- **ST1:** Hazard and Product Category Classification – Systems are required to predict the general category of the hazard (e.g., "biological hazards") and the product category (e.g., "meat, egg, and dairy products") from the input text.
- **ST2:** Hazard and Product Vector Detection – Systems must predict the exact hazard (e.g., "salmonella") and product (e.g., "ice cream") from the input text.

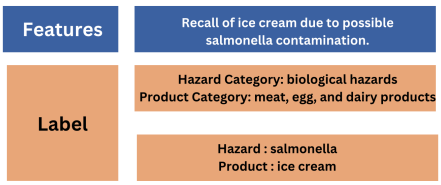

Figure 1: Model inputs in Blue and ground truth in Orange.

The dataset is primarily in English and includes a variety of genres, such as recall notices, social media posts, and news articles. The size and diversity of the dataset make it a challenging benchmark for evaluating the performance of automated systems in real-world scenarios. (Randl et al., 2025)

3.1 Key Algorithms and Modeling Decisions

Our approach focuses on classifying input text into categories by identifying exacts hazards and products along with their respective category. To achieve this, we leverage zero-shot learning using a powerful language model, combined with labels derived from the training dataset. The overall process consists of four key components:

- **Data Preprocessing:** We start with cleaning and formatting the input text from the testing dataset which involves removing additional whitespace and newline characters to form one continuous input text.
- **Label Extraction:**From the training dataset, we extract candidate labels from the datafield —such as categories like hazards and products—along with their corresponding classifications. These labels are then passed to the model alongside the text field from the test dataset. Number of hazards and products extracted:

```
Number of hazards and products extracted:
hazards = 128
products = 1022
hazards category = 10
products category = 22
```

- **Zero-Shot Classification:** To classify the input text, we employ the BART-large-MNLI model, a powerful transformer-based architecture designed for natural language inference. This model allows us to predict hazard and product along their categories by:
  - Assessing whether the input text of testing dataset aligns with a set of predefined candidate labels retrieved from the training dataset.
  - Each label is reformatted as a natural language hypothesis whereas the input text is treated as a premise.
  - Evaluating the relationship between the text and each label in terms of entailment (true), neutral, or contradiction (false).
- **Prediction Generation:** Selecting the label with the highest probability as the final classification result and saving it in a file.

3.2 Core Model:Why BART-large MNLI for zero-shot classification

We selected the BART-large MNLI model as the core of our system because it has shown strong performance in zero-shot classification tasks, particularly in scenarios where labeled training data is limited or unbalanced. The model is pre-trained on the Multi-Genre Natural Language Inference (MNLI) dataset, which enables it to generalize well to unseen tasks by leveraging its understanding of textual entailment and semantic relationships. This makes it highly suitable for our task, where we need

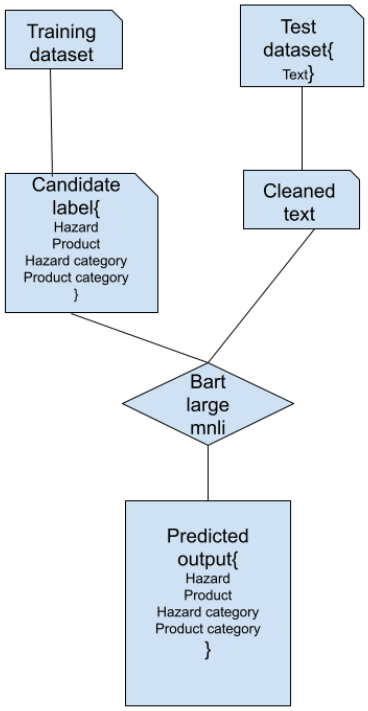

Figure 2: Proposed model approach

to classify food hazards and products from short, unstructured texts without task-specific fine-tuning.

Unlike T5, which is optimized for text-to-text generation and excels in tasks where output generation is necessary (Face, 2025), BART-MNLI is directly aligned with classification tasks, allowing us to leverage its structure without additional task-specific formatting or training. While GPT-based classifiers are powerful, they often require complex prompt engineering and tend to be more computationally intensive.(Hugging Face, 2024) In contrast, BART-MNLI offers a strong balance between performance, interpretability, and resource efficiency.

Furthermore, its zero-shot capability allows it to handle unbalanced datasets effectively without requiring training, making it a robust and scalable choice for food-hazard detection in real-world applications.

4 Experimental Setup

4.1 Data Splits

The dataset for the Food Hazard Detection Task is divided into three main splits: training, development, and test sets. Each split serves a specific purpose in the development and evaluation of our system.

- **Training Set:** This set is used to extract candidate labels for hazards and products. These labels are essential for the zero-shot classification process, as they provide the model with a predefined set of options to choose from.
- **Test set:** This set is used for the final evaluation of the system. It provides an unbiased measure of the system's performance on completely unseen data, simulating real-world conditions.

Figure 3: Example of test dataset

4.2 External Tools and Libraries

Our system relies on several external tools and libraries for data manipulation, text pre-processing, and model inference. Below, we provide a summary of these resources.

- **Transformers:** Used for loading the BART-large-MNLI model and performing zero-shot classification. (Wolf et al., 2020)
- **Pandas:** Used for data manipulation, such as loading the dataset and extracting candidate labels. (Paszke et al., 2019)
- **Torch:** Used for GPU acceleration during model inference. (pandas development team, 2020)

4.3 Evaluation Measures

The task is evaluated using the macro-F1 score, which is calculated separately for hazard and product predictions. The final score is the average of the two F1 scores, with a higher weight given to the accuracy of the prediction of hazards. This evaluation metric ensures that the system performs well on both tasks while prioritizing the correct identification of hazards.

5 Limitation

A key limitation of our approach is that relying on candidate labels extracted from the training set guarantees we will miss unseen or novel labels, limiting the system's ability to generalize to new hazards or products. Additionally, while our approach is preliminary, there may be better-performing models or techniques, such as fine-tuning, few-shot learning, or testing alternative architectures, that could yield improved results. Furthermore, our system only utilizes text data, which could overlook valuable context from other data fields that could enhance performance. Finally, the model is only English, which restricts its applicability to multilingual contexts, highlighting the need for future work to address language diversity and incorporate additional data sources for more robust and generalizable food hazard detection.

Our system underperforms compared to other participants, but we lack a thorough error analysis to understand why. Future work should include a detailed breakdown of performance across different subcategories (e.g., biological vs. chemical hazards) and confusion matrices to identify specific areas of model weakness and common failure patterns in hazard versus product classification.

6 Result

The intention behind the submission was to evaluate the feasibility of using a zero-shot model for food-hazard and product classification from short, unstructured texts—without relying on task-specific fine-tuning or annotated training data, which is often scarce or unbalanced in real-world applications.Our model performed better than random chance, indicating that it captures some meaningful semantic distinctions between hazards and products and score between two of them has been mentioned below:

Model	**Naive Random Classifier**	**BART-MNLI (Zero-shot)**
Task 1	0.0043	0.2426
Task 2	0.07275	0.1380

However, we agree that the performance is not sufficient for deployment and that more extensive work is needed.

For all the tasks where the shared task organizers released a test data and , we used the test data for the results reported in this section (for the and the score was evaluated by calculating the macro-F1-score on the participants' predicted labels using the annotated labels as ground truth.The leaderboard can be found below:

ID	Username	Organization	Score

49	hanguanghui	QF_CS	0.1529
50	kritikapant2003	**"ours"**	0.1380

Table 2: Leaderboard results for ST2

7 Conclusion

Key contributions of our work include the use of zero-shot classification to handle imbalanced data and the integration of multi-task learning and ensemble methods to improve robustness. We recognize that a more thorough error analysis would provide deeper insights, and we plan to include this in future iterations of our work.We also acknowledge the importance of comparing our zero-shot baseline to fine-tuned transformer models or few-shot learning approaches, which are likely to yield better results by leveraging task-specific supervision. While our current focus was to establish a simple yet meaningful baseline, we plan to explore and benchmark fine-tuned models and other machine learning baselines in future work to better contextualize performance.

Abstract

Understanding how news narratives frame entities is crucial for studying media's impact on societal perceptions of events. In this paper, we evaluate the zero-shot capabilities of large language models (LLMs) in classifying framing roles. Through systematic experimentation, we assess the effects of input context, prompting strategies, and task decomposition. Our findings show that a hierarchical approach of first identifying broad roles and then fine-grained roles, outperforms single-step classification. We also demonstrate that optimal input contexts and prompts vary across task levels, highlighting the need for subtask-specific strategies. We achieve a Main Role Accuracy of 89.4% and an Exact Match Ratio of 34.5%, demonstrating the effectiveness of our approach. Our findings emphasize the importance of tailored prompt design and input context optimization for improving LLM performance in entity framing.

1 Introduction

News is produced and consumed at an unprecedented scale, yet the expectation of neutrality and objectivity in journalism (Schudson, 2001) often contrasts with the reality that media selectively determines what is newsworthy (Eliaz and Spiegler, 2024). Through inclusion, omission, or emphasis of specific details, journalists shape public interpretation of events (Iyengar, 1990), promoting particular recommendations (Entman, 1993), which in turn influences public opinion and policy decisions (Ziems and Yang, 2021).

When such selective framing is used to shape perceptions of an entity, it is known as entity framing (van den Berg et al., 2020). SemEval-2025 Task 10 introduces a benchmark for analyzing entity framing (Piskorski et al., 2025; Stefanovitch et al., 2025), examining how linguistic choices from word selection to narrative structure affect perception.

Example in Figure 1 demonstrates how strategic language choices portray the entity *Bill Gates* as an Antagonist. Despite mentioning his substantial investments in climate change initiatives, the narrative emphasizes his high carbon footprint, highlighting hypocrisy. Phrases such as "carefully constructed interview" and references to his connections with Epstein further reinforce an image of deception and evading accountability. This selective emphasis shapes the reader's perception of Gates as a Deceiver and Corrupt figure, demonstrating how framing subtly influences interpretation.

> Gates *claimed* that because he continues to spend billions of dollars on climate change activism, his *carbon footprint* isn't an issue [...] Elsewhere during the *carefully constructed interview*, Gates said he was surprised that he was *targeted by 'conspiracy theorists' for pushing vaccines* during the pandemic [...] While the BBC interview *was set up* to look like Gates was being challenged or grilled, he wasn't asked about his *close friendship with the elite pedophile Jeffrey Epstein*

Figure 1: An example document excerpt from the dataset. The author strategically uses loaded language, contrastive framing, and selective emphasis to shape the reader's perception of Bill Gates as corrupt and deceptive. By highlighting contradictions in his public advocacy, casting doubt on the authenticity of his media appearances, and referencing controversial associations, the text reinforces a negative framing.

Recent advances in large language models (LLMs) have demonstrated superior performance in text classification, frequently outperforming traditional machine learning approaches on complex tasks (Kostina et al., 2025). In this paper, we explore if this extends to entity framing. Relying solely on prompting, we ask whether LLMs accurately identify the framing roles assigned to entities in news articles. Given the sensitivity of LLM predictions to prompt variability (Zhuo et al., 2024), we assess how prompt engineering strategies such as role-based prompting, incorporating task related information such as label definitions, and rationale generation shape classification performance.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1924–1934

To this end, we develop a modular zero-shot approach that relies exclusively on prompting. Our method decomposes the task into two stages, first predicting broad narrative roles (Protagonist, Antagonist, Innocent), and then refining into fine-grained roles. We systematically vary the input context comparing full articles, entity-centered excerpts, and framing-preserving summaries and design prompt templates incorporating expert personas and task related information.

The main contributions of this paper are:

(1) *Systematic evaluation of LLMs for zero-shot entity framing:* We assess how well LLMs infer framing roles from implicit narrative cues without fine-tuning.

(2) *A multi-step prompting strategy:* We show that decomposing the task into two stages, predicting broad roles first, then fine-grained roles, yields better results than a single-step approach.

(3) *Strategic prompt design:* We demonstrate that effective prompt design, incorporating role-based guidance and task definitions, improves classification. A carefully engineered prompt enables a smaller model to perform comparably to a larger one.

We report a Main Role Accuracy of 89.4% and an Exact Match Ratio of 34.5% on the SemEval 2025 Task 10 Subtask 1 for English, placing sixth on among the participating teams. We make our codebase and associated prompts publicly available.[1]

2 Background: Task & Dataset

The SemEval 2025 Task 10: *Multilingual Characterization and Extraction of Narratives from Online News* introduces three subtasks for analyzing narrative elements in news articles across five languages: Bulgarian, English, Hindi, European Portuguese, and Russian. This paper focuses on *Subtask 1: Entity Framing* for *English*.

The goal of *Entity Framing* is to determine how a named entity is framed within a news article. Framing is represented at two levels: *Main Role* and *Fine-Grained Roles*. The main role broadly categorizes the entity as a Protagonist, Antagonist, or Innocent, while fine-grained roles provide more detailed labels.[2] An entity may be framed with multiple fine-grained labels, making this a multi-class, multi-label classification problem.

For further details on the dataset, including domain coverage, corpus statistics, and annotation methodology, see (Piskorski et al., 2025; Stefanovitch et al., 2025). We now describe our approach to leveraging large language models (LLMs) for entity framing classification.

3 Related Work

Language shapes interpretation by selectively emphasizing aspects of reality (Entman, 1993). Prior research identifies two key linguistic mechanisms underlying framing effects: *naming conventions*, where respectful or formal titles correlate strongly with positive sentiment (van den Berg et al., 2019, 2020); and *narrative framing*, reflecting partisan differences in media portrayals of events (Ziems and Yang, 2021). However, these studies primarily treat framing as an implicit phenomenon correlating with other tasks, rather than explicitly classifying or predicting specific framing roles or labels.

Beyond text, in the multimodal domain, Sharma et al. (2022) introduce HVVMemes, a meme dataset covering COVID-19 and US politics, annotated with coarse-grained framing roles: *hero*, *villain*, *victim*, or *none*. In contrast, our work focuses on news text and classifies entities at a more fine-grained, hierarchical roles.

Large language models (LLMs) have recently achieved strong performance in text classification tasks, often surpassing traditional machine learning methods on complex datasets (Kostina et al., 2025). However, significant challenges remain, particularly concerning sensitivity to prompt phrasing and input structure (Zhuo et al., 2024). Structured prompting strategies, such as role conditioning (Kong et al., 2024) and instruction reframing (Mishra et al., 2022), have been proposed. Nevertheless, the effectiveness of these strategies remains highly task-dependent and often requires careful adaptation to specific problem settings (Atreja et al., 2024).

Guided by these insights, we develop and systematically experiment with multiple prompting strategies for hierarchical entity framing, aiming to improve both coarse and fine-grained entity framing classification.

{input_context}
```

Figure 2: Structure of the prompt template. Curly-bracketed content is dynamically replaced based on the experimental setting (see Appendix D for exact phrasing). The template is designed to minimize variability, ensuring that observed differences arise solely from targeted prompt modifications.

4 Prompting for Framing Classification

To systematically evaluate the impact of different prompting strategies on framing classification, we adopt a structured, template-based approach (Figure 2). LLM decision-making is often opaque. By using a fixed template, we ensure any variation in outputs comes from our controlled prompt modifications rather than randomness.The template consists of modular components that adapt to different experimental conditions.

Our approach is structured around three key components: *(1) Input Context* which determines the textual context provided for classification, specified in `input_context`. *(2) Prompt Design*, which examines prompting strategies, such as persona prompting, structured within `task_definition`, `task_instructions`, and `output_format_with_example`. *(3) Inference Strategy*, which defines whether classification is performed as a single task or decomposed into two steps, reflecting the hierarchical nature of framing. The following sections provide a detailed discussion of each component.

4.1 Input Context Variation

Framing involves selectively emphasizing certain details while omitting others to highlight specific aspects of perceived reality (Entman, 1993). Thus, optimizing context is crucial for maximizing narrative signals. To assess the impact of context granularity on framing classification, we define five input settings encompassing both extractive and summarization-based approaches,[3] each varying in the amount of contextual information available for classification.

- *Full Text* (FT): The entire article.
- *Entity-Sentences* (Ent-Sent): Only sentences mentioning the entity.
- *Entity-Sentences Neighbors* (Ent-Neigh): Entity-mentioning sentences plus one preceding and one following sentence.
- *Neutral Summary* (Neutral-Sum): A summary generated by an LLM prompted to focus neutrally on the entity's involvement, actions, and framing.
- *Framing-Preserved Summary* (FP-Sum): A summary generated by an LLM prompted to preserve the article's original framing, emphasizing positive or negative actions.

[3] See Appendix C for details on summarization.

4.2 Prompt Design

While various prompting strategies have been proposed (Gu et al., 2023), we focus on the following:

(1) *Role/Persona Prompting:* Assigning a role or persona in an LLM prompt may shape its performance. While one study finds that role-based prompting improves task performance (Kong et al., 2024), another suggests its effectiveness is highly task-dependent and varies across settings (Zheng et al., 2024). To assess its impact on entity framing, we compare a neutral prompt with one explicitly assigning an expert persona.

(2) *Task-Related Information:* We test two configurations: one providing only the task definition and another including both task and label definitions.

(3) *Output Rationale:* We compare predictions with and without model-generated explanations to assess whether requiring justifications improves or degrades classification accuracy.

4.3 Inference Strategy

We compare two inference strategies that determine whether classification is performed as a single task or decomposed into two stages, reflecting the hierarchical structure of framing. *Single-Step Prediction* jointly predicts both the main and fine-grained roles within a single inference step, whereas *Multi-Step Prediction* first infers the main role, which is then incorporated into the prompt to predict the fine-grained role.

Having established our prompting strategies, we now present the experimental setup used to systematically evaluate their effectiveness.

5 Experimental Setup

We first discuss a key assumption in our study, followed by evaluation metrics, and LLM setup.

Single-Label Approximation for Fine-Grained Role Classification Although the SemEval task defines Entity Framing as a multi-label classification problem, we observe that entity mentions typically receive only one fine-grained role, averaging 1.08 fine-grained roles per mention in the English training split, a trend consistent across languages and main roles (Appendix B). Additionally, in our experiments, we observed that the model in our study consistently predicts two main roles even when allowed to predict only one. Given these patterns, we adopt a single-label approximation, assigning each mention a single fine-grained role.

Evaluation Metrics We assess performance using two metrics: *Main Role Accuracy (MRA)*, the proportion of instances where the predicted main role matches the gold label, and *Exact Match Ratio (EMR)*, the proportion of instances where both the main and fine-grained roles match exactly, with no partial credit.

Model and API We use GPT-4o (gpt-4o-2024-08-06) via the OpenAI API.[4]

We next examine the results obtained using different prompting strategies and input contexts across both inference setups.

6 Results

We present results from our prompting experiments on the development set, followed by the official SemEval results and post-SemEval analyses. Key findings are discussed in Section 7.

6.1 Development

We systematically assess the impact of individual prompt modifications across different input contexts in both single-step and multi-step settings, using the baseline prompt detailed in Appendix D. To ensure precise attribution of effects, we isolate prompt modifications rather than evaluating combined strategies. While one combination setting is included in Section 6.2, systematic evaluation of prompt strategy combinations is beyond the scope of this paper.

[4]https://github.com/openai/openai-python, Temperature set to 0 and all other parameters at their default values. A fixed random seed (42) is specified, though deterministic outputs are not guaranteed.

Metric	Baseline	+ EP	+ LD	+ RA
Main Role Accuracy				
FT	0.93	0.92	0.89	0.91
Ent-Sent	0.90	0.93	0.92	0.91
Ent-Neigh	0.92	0.93	0.92	0.93
Neutral-Sum	0.69	0.73	0.69	0.71
FP-Sum	**0.95**	**0.95**	0.93	0.93
Exact Match Ratio				
FT	0.29	**0.35**	0.30	0.29
Ent-Sent	0.32	0.33	**0.35**	0.31
Ent-Neigh	0.30	0.34	0.32	0.31
Neutral-Sum	0.22	0.21	0.21	0.24
FP-Sum	0.33	0.32	0.34	0.33

Table 1: Performance comparison of different input contexts and prompt engineering strategies when jointly prompting for main role and fine-grained roles. EP = Expert Persona, LD = Label Definitions, RA = Rationale. For main roles, Framing-Preserved summaries are the strongest input context, achieving the highest accuracy (0.95). For fine-grained roles, full text, and only sentences containing entity are strongest when used with a prompting strategy.

Single-Step Approach Table 1 shows the performance of different input contexts and prompt engineering strategies in the Single Step Setup. Main role accuracy is highest with Framing-Preserved Summaries (0.95), where additional prompt strategies yield no further gains. In contrast, fine-grained role classification benefits from prompting strategies, with Full Text + Expert Persona and Entity-Only Sentences + Label Definitions achieving the highest Exact Match Ratio (0.35).

These findings suggest that a single input strategy may not optimally support both tasks, motivating further exploration of a multi-step approach, where main and fine-grained roles are predicted separately. Additionally, due to consistently lower performance, the Neutral Summary setting is excluded from subsequent experiments.

Multi-Step Approach In the multi-step setting, the model first predicts the main role, which is then used to guide fine-grained classification.

Main Role Prediction: Table 2 reports main role accuracy when predicted independently. Framing-Preserved Summaries remain the strongest setting, achieving 0.96 accuracy.

Fine-grained roles: Main role predictions from the best-performing setup are used to inform the prompt for fine-grained role classification. Additionally, we restrict the set of possible output labels to only those fine-grained roles valid for the predicted main role. This reduces ambiguity and

Metric	Baseline	+ EP	+ LD	+ RA
FT	0.89	0.91	0.91	0.87
Ent-Sent	0.84	0.86	0.87	0.82
Ent-Neigh	0.91	0.92	0.91	0.88
FP-Sum	0.92	0.93	**0.96**	0.93

Table 2: Performance comparison of different input contexts and prompt engineering strategies in the Multi-Step Setup for Main Role Prediction, reported with accuracy. EP = Expert Persona, LD = Label Definitions, RA = Rationale. Framing-Preserved Summaries remain the strongest input context, achieving the highest accuracy (0.96), now benefiting from the Label Definitions (LD) strategy, unlike in the single-step setting.

Metric	Baseline	+ EP	+ LD	+ RA
FT	0.33	0.36	0.31	0.35
Ent-Sent	0.36	**0.44**	0.35	0.37
Ent-Neigh	0.36	0.38	0.34	0.37
FP-Sum	0.29	0.29	0.35	0.31

Table 3: Performance comparison of different input contexts and prompt engineering strategies in the Multi-Step Setup for fine-grained role classification using Exact Match Ratio metric. EP = Expert Persona, LD = Label Definitions, RA = Rationale. The multi-step approach improves EMR across most settings compared to single-step prediction, with Entity-Sentences + Expert Persona (EP) achieving the highest EMR (0.44).

improves classification accuracy.

As shown in Table 3, the multi-step approach outperforms single-step prediction across most settings. The best-performing strategy is Entity-Sentences + Expert Persona (EP), which achieves an Exact Match Ratio (EMR) of 0.44, a substantial improvement over the best single-step result (0.35). Entity-Sentences remains the strongest input context for fine-grained roles(0.44 EMR), whereas full text falls behind.

These findings further support the effectiveness of separating main and fine-grained role prediction and constraining valid role labels to enhance classification accuracy.

6.2 Official SemEval Results

The findings from our development experiments highlight the effectiveness of different input contexts and prompting strategies. However, for our official SemEval submission, we employed a Full-Text + Expert Persona + Multi-Step setup using O1(o1-2024-12-17) as our model, as this configuration was selected based on our pre-competition experiments.

Rank	Team	EMR (Δ)	MRA (Δ)
1	DUTIR	0.41	0.95
2	PATeam	0.38 (-0.03)	0.89 (-0.06)
3	DEMON	0.37 (-0.04)	0.92 (-0.03)
4	gowithnlp	0.37 (-0.04)	0.94 (-0.01)
5	TartanTritons	0.36 (-0.05)	0.72 (-0.23)
6	**Ours**	**0.34 (-0.07)**	**0.89 (-0.06)**
27	Baseline	0.04 (-0.37)	0.29 (-0.66)

Table 4: Official SemEval test set results. Teams are ranked by Exact Match Ratio (EMR), with Main Role Accuracy (MRA) also reported. Our system ranked 6th, achieving an EMR of 0.34, just 0.07 behind the top system (DUTIR). Δ values indicate the difference from the top-ranked system.

Approach	EMR	MRA	Model	Price/1M Tokens	
				Input	Output
SemEval	0.345	0.894	O1	$15.00	$60.00
Improved	**0.349**	**0.894**	GPT-4o	$2.50	$10.00

Table 5: Comparison of our official SemEval submission and the refined approach. Although the performance is nearly identical, the refined approach is notable because it achieves these results using GPT-4o, a significantly smaller and more cost-effective model. This highlights the importance of optimized prompt design, which allows a more compact model to match or exceed the performance of larger, more expensive alternatives.

As shown in Table 4, our system ranked 6th overall, achieving an Exact Match Ratio (EMR) of 0.34, placing 0.07 behind the top-performing system (DUTIR). While competitive, our post-SemEval ablation studies revealed a more effective strategy, which we discuss in the next section.

6.3 Post-SemEval

After the SemEval submission, we conducted structured ablation studies to refine our approach, as discussed in Section 6.1. As shown in Table 5, the new approach achieves an EMR of 0.349, compared to 0.345 in our official submission, with MRA remaining unchanged at 0.894. This result is significant because it was achieved using GPT-4o, a smaller and significantly cheaper model.

7 Insights

We present key findings from our experiments, examining the impact of different approaches.

Framing and emphasis: selective highlighting shapes interpretation As shown in Table 1, neutral summaries which present entities in a factual, impartial manner, consistently underperformed

compared to framing-preserved summaries. This aligns with existing framing theory, reinforcing that framing is not only about fact selection but also about selective emphasis to shape interpretation (Entman, 1993).

Justifications do not improve classification performance Our experiments show that requiring models to justify their predictions does not improve classification accuracy. Performance is primarily determined by the information in the prompt.

More information isn't always better Longer contexts aren't always useful. Main role classification benefits from broad context that establishes overarching narratives, whereas fine-grained roles require focused, entity-specific details. Excessive input, such as full-text context, can dilute key framing signals, whereas condensed, framing-preserved summaries improve accuracy. This highlights the importance of tailoring context granularity to the specific classification task.

Multi-Step Approach Improves Performance We find that a structured, multi-step classification approach substantially improves performance. By first predicting the main role and then refining fine-grained classification based on that prediction, the model benefits from clearer context at each stage. This approach reduces ambiguity and ensures that each classification step is optimized for its specific level of framing.

Prompt Design Enables Small Models to Rival Larger Ones Finally, our experiments highlight the effectiveness of carefully engineered prompts. Carefully crafted prompts allow smaller models to rival larger ones. A well-optimized prompt for GPT-4o matches or exceeds a less-tuned prompt on the larger, costlier o1 model. These results suggest that before scaling to larger architectures, improving prompt design for smaller models can yield substantial gains in both efficiency and accuracy.

8 Conclusion

In this paper, we explore the effectiveness of large language models (LLMs) for Entity Framing Classification in a zero-shot setting. While LLMs perform well in broad role classification, fine-grained classification remains challenging. Our multi-step approach, incorporating distinct input contexts and prompt strategies at each stage, significantly improves overall performance.

A Entity Framing Labels

The entity framing taxonomy consists of three main roles and 22 fine-grained roles. For detailed definitions and annotation guidelines, see (Piskorski et al., 2025; Stefanovitch et al., 2025).

- **Protagonist:** Guardian, Martyr, Peacemaker, Rebel, Underdog, Virtuous.
- **Antagonist:** Instigator, Conspirator, Tyrant, Foreign Adversary, Traitor, Spy, Saboteur, Corrupt, Incompetent, Terrorist, Deceiver, Bigot.
- **Innocent:** Forgotten, Exploited, Victim, Scapegoat.

B Average Sub Roles across Language

	EN	BG	PT	HI	RU
All	1.08	1.13	1.05	1.16	1.06
Protagonist	1.06	1.02	1.01	1.24	1.00
Antagonist	1.10	1.19	1.09	1.12	1.11
Innocent	1.02	1.01	1.00	1.06	1.01

Table 6: The average number of sub-roles per instance across different languages (English (EN), Bulgarian(BG), European Portuguese(PT), Hindi(HI), and Russian(RU)) and main roles in the training split. The values remain close to one, justifying our single-label approximation for fine-grained classification.

C Prompts for Summary Generation

C.1 Neutral Summary

```
Summarize the following article with a specific focus on { entity }. Write the summary as a standalone description, ensuring that the entity and its role are clearly introduced without referring to 'the article' or assuming prior context. Clearly state their involvement, actions, and framing within the event. Maintain a factual and neutral tone.
```

Figure 3: Prompt used to generate neutral summaries. The instructions guide the LLM to ensure that that the entity's role is explicitly introduced while maintaining a factual and impartial tone.

C.2 Framing-Preserved Summary

```
Write a standalone summary that clearly reflects how the author of the article frames entity and their actions. Do not present the entity neutrally—mirror the language and implicit bias of the article itself. If the author portrays the entity favorably, highlight their positive actions, successes, and beneficial impact. If the author is critical, emphasize the entity's negative actions, failures, or harmful consequences.
If the framing is mixed or subtle, encode the contrast in tone and nuance.Strongly reflect the author's framing through:
- Loaded or emotionally charged language (if present in the article)
- Emphasis on the entity's perceived intentions and motivations
- Who is affected by their actions and how the consequences are framed
- Any direct or implied judgments made by the author.
Maintain the style and tone of the article, ensuring the framing is explicit in how the entity's role and impact are described. Do not add external information or neutralize the bias. The summary should feel as though it was written by the original author.
```

Table 7: Prompt used to generate framing-preserved summaries. The instructions guide the model to reflect the article's original framing, emphasizing bias and tone while avoiding neutrality or external information.

D Prompt Template Details

Our system prompt follows the structured format introduced earlier. The input context is provided in the user prompt, while the rest remains part of the system prompt.

Prompt Type	Template
System Prompt	{expert_phrasing} You will be provided with {input_format_phrase}. Your task is to {task_definition}. {task_instructions} {output_format_with_example}
User Prompt	{input_context}

Table 8: Structure of the system and user prompts. The system prompt provides instructions, while the user prompt supplies contextual input for the model.

We outline the values these elements take in different settings below.

D.1 Input Format Phrase & Input Context

The input context is formatted as `DOCUMENT:{content}` Note that in the `Entity-Sentences` and `Entity-Sentences Neighbors` settings, the individual sentences or sentence groups are separated by `[...]`.

In the system prompt, the input format phrase specifies the type of input context provided to the model. The format follows this structure:`a {document_type_str} in the following format-`

DOCUMENT:{document_type_str}. The corresponding document_type_str for each input context type is provided in the table below:

Input Context Type	document_type_str
Full Text	news article
Entity-Sentences or Entity-Sentences Neighbors	excerpt of a news article
Neutral Summary or Framing-Preserved Summary	news article summary

Table 9: Mapping between input context types and corresponding input phrases.

D.2 Prompt Design

D.2.1 Expert Persona

In the context of role/persona prompting, if no specific persona is assigned, {expert_phrasing} remains empty. Otherwise, it is replaced with the following text:

> You are an expert in analyzing how a specific named entity is portrayed in a given text. Read the text carefully and focus on everything said about {entity}.

D.2.2 Output Rationale

In the template below, we incorporate prompting for justification by including three variables:

- {ask_reasoning}: "with a reasoning for your prediction"
- {reasoning_in_json}: ', "reasoning" : "your reasoning here"
- {reasoning_example}: , "reasoning" : "The article frames Kremlin propagandists as instigators and deceivers, highlighting their role in spreading falsehoods and promoting extreme measures."

When the setting does not require justification with the output label, these variables remain empty.

D.2.3 Task Related Information

Setting	task_definition	task_instructions	output_format_with_example
Single Step	classify the narrative framing of the {entity} in the document based on the taxonomy that follows in the format [(broad role,[list of valid fine grained roles/])]. The taxonomy is {taxonomy}.	Instructions: 1. Assign exactly one broad role from: Protagonist, Antagonist, or Innocent. 2. Determine one or a maximum of two corresponding fine grained role from the taxonomy. 3. Order the sub-roles by likelihood, with the most likely fine-grained role listed first.{label_definitions}	4. Finally, return your conclusion {ask_reasoning} as a single JSON object with no extra text, in this format: { "main_role": "<most_likely_main_role>", "fine_grained_roles": ["<Most likely sub-role>", "<Second most likely sub-role if relevant>"] {reasoning_in_json}} Example Output: {"main_role": "Antagonist", "fine_grained_roles": ["Conspirator"] {reasoning_example}
Multi-Step : Main Role	classify the narrative framing of the entity in the document as either Protagonist, Antagonist or Innocent.	Instructions: 1. Assign exactly one main role from: Protagonist, Antagonist, or Innocent.{label_definitions}	2.Return your conclusion {ask_reasoning} as a single JSON object with no extra text, in this JSON format: { "main_role": "<most_likely_main_role>" {reasoning_in_json}} Example Output: {"main_role": "Antagonist" {reasoning_example}}
Multi-Step : Fine-grained Role	classify the narrative framing of the {entity} in the document. The taxonomy is {taxonomy}. {label_definitions}	You have previously identified the broader narrative frame to be main_role_candidate. Instructions: 1. Determine one or a maximum of two corresponding fine grained role from the taxonomy. 2. Order the sub-roles by likelihood, with the most likely fine-grained role listed first.	3. Finally, return your conclusion {ask_reasoning} as a single JSON object with no extra text, in this format: { "fine_grained_roles": ["<Most likely sub-role>", "<Second most likely sub-role if relevant>"] {reasoning_in_json}} Example Output: {"fine_grained_roles": ["Conspirator"] {reasoning_example} }

Table 10: Mapping between different settings, task definitions, and corresponding instructions for narrative framing classification.

Taxonomy The taxonomy shared in the prompt is the same as in Appendix A. The label definitions provided are from the official paper and is shared in Table 11.

Role Level	{label_definitions}
Main Role	Protagonist: The central figure or party in a news article, often portrayed as a hero or positive force driving the narrative. Antagonist: The opposing figure or force in a news article, often depicted as the source of conflict or challenge to the protagonist. Innocent: An individual or group portrayed as untainted or blameless in the context of the news, typically victimized or wronged.
Fine Grained Roles Protagonist	Guardians: Heroes or guardians who protect values or communities, ensuring safety and upholding justice. They often take on roles such as law enforcement officers, soldiers, or community leaders (e.g., climate change advocacy community leaders). Martyr: Martyrs or saviors who sacrifice their well being, or even their lives, for a greater good or cause. These individuals are often celebrated for their selflessness and dedication. This is mostly in politics, not in Climate Change. Peacemaker: Individuals who advocate for harmony, working tirelessly to resolve conflicts and bring about peace. They often engage in diplomacy, negotiations, and mediation. This is mostly in politics, not in Climate Change. Rebel: Rebels, revolutionaries, or freedom fighters who challenge the status quo and fight for significant change or liberation from oppression. They are often seen as champions of justice and freedom. Underdog: Entities who are considered unlikely to succeed due to their disadvantaged position but strive against greater forces and obstacles. Their stories often inspire others. Virtuous: Individuals portrayed as virtuous, righteous, or noble, who are seen as fair, just, and upholding high moral standards. They are often role models and figures of integrity.
Fine Grained Roles Antagonist	Conspirator: Those involved in plots and secret plans, often working behind the scenes to undermine or deceive others. They engage in covert activities to achieve their goals. Instigator: Individuals or groups initiating conflict, often seen as the primary cause of tension and discord. They may provoke violence or unrest. Deceiver: Deceivers, manipulators, or propagandists who twist the truth, spread misinformation, and manipulate public perception for their own benefit. They undermine trust and truth. Incompetent: Entities causing harm through ignorance, lack of skill, or incompetence. This includes people committing foolish acts or making poor decisions due to lack of understanding or expertise. Their actions, often unintentional, result in significant negative consequences. Corrupt: Individuals or entities that engage in unethical or illegal activities for personal gain, prioritizing profit or power over ethics. This includes corrupt politicians, business leaders, and officials. Tyrant: Tyrants and corrupt officials who abuse their power, ruling unjustly and oppressing those under their control. They are often characterized by their authoritarian rule and exploitation. Foreign Adversary: Entities from other nations or regions creating geopolitical tension and acting against the interests of another country. They are often depicted as threats to national security. This is mostly in politics, not in Climate Change. Terrorist: Terrorists, mercenaries, insurgents, fanatics, or extremists engaging in violence and terror to further ideological ends, often targeting civilians. They are viewed as significant threats to peace and security. This is mostly in politics, not in Climate Change. Bigot: Individuals accused of hostility or discrimination against specific groups. This includes entities committing acts falling under racism, sexism, homophobia, Antisemitism, Islamophobia, or any kind of hate speech. This is mostly in politics, not in Climate Change. Saboteur: Saboteurs who deliberately damage or obstruct systems, processes, or organizations to cause disruption or failure. They aim to weaken or destroy targets from within. Traitor: Individuals who betray a cause or country, often seen as disloyal and treacherous. Their actions are viewed as a significant breach of trust. This is mostly in politics, not in Climate Change. Spy: Spies or double agents accused of espionage, gathering and transmitting sensitive information to a rival or enemy. They operate in secrecy and deception. This is mostly in politics, not in Climate Change.
Fine Grained Roles Innocent	Victim: People cast as victims due to circumstances beyond their control, specifically in two categories: (1) victims of physical harm, including natural disasters, acts of war, terrorism, mugging, physical assault, etc., and (2) victims of economic harm, such as sanctions, blockades, and boycotts. Their experiences evoke sympathy and calls for justice, focusing on either physical or economic suffering. Scapegoat: Entities blamed unjustly for problems or failures, often to divert attention from the real causes or culprits. They are made to bear the brunt of criticism and punishment without just cause. Exploited: Individuals or groups used for others' gain, often without their consent and with significant detriment to their wellbeing. They are often victims of labor exploitation, trafficking, or economic manipulation. Forgotten: Marginalized or overlooked groups who are often ignored by society and do not receive the attention or support they need. This includes refugees, who face systemic neglect and exclusion.

Table 11: Label Definitions shared in the prompt. These are from the task definitions (Piskorski et al., 2025).

CSCU at SemEval-2025 Task 6: Enhancing Promise Verification with Paraphrase and Synthesis Augmentation: Effects on Model Performance

Kittiphat Leesombatwathana, Wisarut Tangtemjit, Dittaya Wanwaree
Department of Mathematics and Computer Science, Faculty of Science,
Chulalongkorn University, Bangkok, Thailand

Abstract

The Promise Verification task involves classifying corporate commitments and their supporting evidence into multiple categories, and this study presents significant findings in machine learning and environmental, social, and governance (ESG) evaluation. We compared various approaches, including zero-shot and six-shot GPT-4o, Support Vector Machine (SVM) with Multilingual E5 text embeddings, and fine-tuned DistilBERT. Six-shot GPT-4o achieved the best performance, while zero-shot GPT-4o struggled due to a lack of in-context examples, with both models demanding considerable computational resources and reliance on external APIs. In contrast, SVM proved to be an economical alternative, effective in binary classification tasks especially when enhanced by data augmentation techniques. Although DistilBERT is more resource-intensive, it offers a scalable solution balancing efficiency and accuracy. Our experiments show that data augmentation, utilizing paraphrasing and synthesis techniques, generally improves performance, though it has limitations in clarity evaluation. These findings emphasize the trade-offs between performance, cost, and efficiency in selecting models for the Promise Verification task, offering valuable insights for the field.

1 Introduction

In recent years, the significance of environmental, social, and governance (ESG) commitments has increased, with stakeholders demanding greater corporate transparency and accountability. Accurately assessing these commitments is essential for evaluating a company's dedication to sustainable practices and ethical standards. However, the complexity and volume of these commitments present significant challenges in verification, highlighting the urgent need for effective evaluation methods.

One major obstacle in this area is the lack of comprehensive datasets designed for training models in promise verification tasks. This deficiency hampers the development of robust systems capable of effectively evaluating ESG commitments, emphasizing the need for further research and data collection. This gap presents a potential avenue for future work.

To address this issue, we have employed text augmentation techniques to improve the quality of promise verification tasks. Our approach involves synthesizing data using large language models to generate augmented datasets that maintain the original semantics while enhancing the training corpus. This strategy is not just a tool; it is a necessity aimed at improving the model's ability to accurately classify ESG-related promises.

Our focus is on English-language reports, specifically targeting the following classification tasks:

1. Promise Identification (PI): Detecting explicit commitments made by corporations.

2. Supporting Evidence (SE): Linking promises to corroborative actions or statements.

3. Clarity of Promise-Evidence Pair (CPEP): Evaluating the transparency and comprehensibility of the promise and its supporting evidence.

4. Timing for Verification (TV): Determining the specified time frame for fulfilling the promise.

By implementing text augmentation techniques, we aim to enhance the performance of promise verification systems and contribute to more reliable assessments of corporate ESG commitments.

2 Related Work

The BERT family of models has become a cornerstone for text classification tasks due to its high performance and efficiency. Devlin et al. introduced BERT (Devlin et al., 2019), which has since been adapted into variants such as DistilBERT, which

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1935–1947

maintains 97% of BERT's performance while using fewer parameters (Sanh et al., 2020). Domain-specific adaptations, like ClimateBERT, highlight the benefits of pretraining on specialized datasets (Webersinke, 2022). Our approach utilizes DistilBERT as the base model, capitalizing on its efficiency while achieving comparable performance improvements through targeted data augmentation.

In recent years, large pre-trained models like GPT-4o[1] have been widely utilized for text classification tasks, including zero-shot and few-shot learning. A study by (Seki et al., 2024) demonstrated the effectiveness of GPT-4o for multi-task classification. They proposed a retrieval-augmented generation (RAG) approach that incorporates Multilingual E5 embeddings (Wang et al., 2024).

To help rating institutions assess the ESG scores of target companies, it is essential to categorize company-related documents into the corresponding ESG categories: Environment (E), Social (S), and Governance (G). However, not all company documents are relevant to these ESG topics. ESG-BERT (Goel et al., 2022), a BERT model that has been fine-tuned on ESG reports, has demonstrated superior performance in ESG-related classification tasks compared to the original BERT model. Additionally, this fine-tuned model shows strong results in ESG sentiment analysis (Kannan and Seki, 2023).

Although fine-tuning models like ESG-BERT can yield high performance, this process can be computationally expensive and resource-intensive. As a more cost-effective alternative, recent approaches employ in-context learning and few-shot prompting with large GPT models. These methods eliminate the need for extensive retraining. They have been successfully used to classify the impact of ESG initiatives, evaluate the credibility of ESG claims, and track the timelines of corporate promises (Tian and Chen, 2024; Chen et al., 2025).

Data augmentation is widely used to enhance dataset size and diversity, improving model generalization, particularly in low-resource settings. Wei and Zou demonstrated that training on a dataset with 50% augmented data can achieve performance comparable to using the entire dataset (Wei and Zou, 2019).

[1]GPT-4o is a state-of-the-art language model developed by OpenAI.

3 System overview

3.1 Dataset Description

The dataset includes five languages: English, French, Korean, Japanese, and Traditional Chinese. For this study, we will focus exclusively on the English dataset. The training and test sets contain a total of 400 instances, addressing the tasks of Promise Identification, Supporting Evidence, Clarity of the Promise-Evidence Pair, and Timing for Verification. The distribution of classes and additional details can be found in the overview paper (Chen et al., 2025).

3.2 Baselines

We implement few-shot learning baselines using Multilingual E5 Embeddings (Wang et al., 2024). First, we convert all training samples into embeddings with the Multilingual E5 model and store them in a vector database[2]. Next, we conduct zero-shot inference and six-shot retrieval-augmented generation (RAG). In this approach, we retrieve the six most similar training samples along with their corresponding answers and include them in a prompt for GPT-4o. These baselines were initially proposed in (Seki et al., 2024) and serve as our primary comparison points when evaluating our proposed approaches (see Appendix A for the prompts used).

3.3 Support Vector Machine Approach

We use text embeddings from the Multilingual E5 model as input for a Support Vector Machine (SVM) classifier, implemented with the scikit-learn library[3]. SVMs are particularly well-suited for high-dimensional data, such as text embeddings, as they can effectively handle large feature spaces and capture non-linear relationships.

The model is configured with `kernel="rbf"` to model non-linear patterns, `class_weight="balanced"` to address class imbalance, and `random_state=0` to ensure reproducibility. To further mitigate class imbalance, we use the RandomOverSampler from the imbalanced-learn library[4], which oversamples the minority class by duplicating existing samples.

[2]We utilize ChromaDB, an open-source vector database optimized for efficient embedding storage and retrieval. https://www.trychroma.com/

[3]scikit-learn: https://scikit-learn.org/stable/

[4]imbalanced-learn: https://imbalanced-learn.org/stable/

Although this approach may not outperform more complex models, it offers a computationally efficient and cost-effective solution for text classification tasks, making it a viable option when resources are limited.

3.4 Fine-tuned BERT Approach

In this study, we use DistilBERT, a smaller and more efficient variant of the Bidirectional Encoder Representations from Transformers (BERT) model. DistilBERT is specifically designed to maintain the language understanding capabilities of the original BERT architecture while significantly reducing computational complexity. For each task, we initialize a separate DistilBERT model with pre-trained weights from the `distilbert-base-uncased` and fine-tune it independently by optimizing the classification head for sequence classification.

To ensure consistency and reproducibility in our experiments, we systematically fix key hyperparameters, including the learning rate, batch size, and weight decay. This approach minimizes variability that could arise from hyperparameter tuning. Each model is fine-tuned for 10 epochs to achieve sufficient convergence while keeping computational efficiency in mind.

A comprehensive overview of the hyperparameter settings and training configuration can be found in Appendix E. The fine-tuning process is implemented using the *Hugging Face Transformers* library.[5]

4 Experiments

4.1 Dataset and Preprocessing

We utilize the PromiseEval 2025 Task 6 dataset (Chen et al., 2025), which consists of textual instances annotated for four classification tasks: Promise Identification (PI), Supporting Evidence (SE), Clarity of Promise-Evidence Pair (CPEP), and Timing for Verification (TV). To maintain experimental consistency, we randomly select 80% of the training data (320 instances) to create five independent training splits.

In addition to the original dataset, we implement a data synthesis process using Gemini-2.0-Flash[6] to generate augmented samples. We employ two distinct augmentation strategies:

- Paraphrase Augmentation: Large language models (LLMs) create paraphrased versions of the original text while preserving the labels.
- Synthesis Augmentation: LLMs produce new text that may alter the label as long as the synthesized content remains semantically aligned.

For the augmented training data, we combine 320 original samples with 320 augmented samples, maintaining a 1:1 ratio. Text preprocessing is conducted using the DistilBERT tokenizer, which incorporates fixed truncation and padding (with a maximum sequence length of 512 tokens) to ensure compatibility with transformer-based architectures.

4.2 Implementation Details

In our fine-tuned BERT approach[7], we employ cross-entropy loss as the objective function for training the classification models. This loss function is well-suited for both multi-class and binary classification tasks, as it quantifies the difference between the predicted probability distribution and the actual labels. Mathematically, the cross-entropy loss is defined as follows:

$$\mathcal{L} = -\sum_{i=1}^{N} y_i \log(\hat{y}_i) \tag{1}$$

where y_i represents the ground-truth label for the i-th sample, $\hat{y}_i$ is the model's predicted probability for the correct class, and N denotes the total number of samples in the dataset.

4.3 Evaluation Metrics

Following the protocol in Seki et al. (2024), we employ macro F1-score as the primary evaluation metric. The macro F1-score is computed for each task independently before averaging, providing a balanced measure in the presence of imbalanced class distributions. All experimental configurations are evaluated on a fixed test dataset, and results are aggregated over five runs.

5 Results

5.1 Variability in GPT-4o Responses

Our experiments showed slight variations in the results of the zero- and six-shot GPT-4o baselines in five runs. While the overall trend remained consistent, each API call yielded slightly different responses. We attribute this variability to the inherent

$DistilBert_{syn}$	0.6704 ± 0.0209	0.4252 ± 0.0369	**0.7835 ± 0.0152**	0.4103 ± 0.0222

Table 2: Overall Model Ranking by Average Performance Across All Tasks

Model	Average Score
GPT six-shot	0.6140
GPT zero-shot	0.5846
$DistilBert_{para}$	0.5730
$DistilBert_{syn}$	0.5724
DistilBert	0.5654
SVM_{syn}	0.5640
SVM_{para}	0.5603
SVM	0.5502

randomness in the GPT-4o model, which can produce different outputs for the same input due to the nondeterministic nature of the model. Additionally, we suspect that the default `temperature=1.0` parameter, which controls the level of randomness in the generation process, may contribute to these differences. When the temperature increases, the model generates more diverse and less predictable responses, which can explain the minor discrepancies observed in our results.

These variations, while minor, highlight the challenges of working with large language models in production environments, where outputs may not always be perfectly consistent. However, this behavior is expected and does not significantly affect the overall conclusions drawn from the experiments.

5.2 Overall Performance Comparison

Table 1 summarizes the mean and standard deviation of macro F1-scores across all models for four promise detection tasks, while Table 2 ranks the models by average performance. The models evaluated include GPT in zero- and six-shot configurations (averaged over five runs) and SVM/DistilBERT trained on an 80% split with three augmentation conditions: none, paraphrase, and synthesis. GPT-based methods show strong zero- and few-shot results, and data augmentation slightly improves SVM and DistilBERT performance.

As indicated in Table 1, GPT zero-shot excels in Promise Identification (PI), while GPT six-shot leads in Timing for Verification (TV), Supporting Evidence (SE), and Clarity of the Promise-Evidence Pair (CPEP).

Data augmentation consistently enhances SVM performance compared to non-augmented baselines. Synthesis augmentation produces the best results for PI and SE, while paraphrase augmentation shines in TV. DistilBERT with paraphrase augmentation ranks highest among non-GPT methods, followed closely by synthesis-augmented DistilBERT.

GPT-based approaches exhibit consistent performance with low standard deviations, while fine-tuned models show greater variability, indicating that augmentation can enhance performance but may also introduce inconsistencies. The CPEP task remains challenging for all models, with the best performance struggling to exceed an F1 score of

0.43. Additionally, synthesis-based augmentation ($\text{Group}_{\text{syn}}$) leads to higher variability, likely due to label noise, as shown in Table 1.

5.3 Data Augmentation Analysis

To better understand the reliability of the augmented datasets, we manually inspected the examples generated by the LLM (Gemini-2.0-Flash). For the Paraphrase Augmentation, where the goal was to rephrase the original text without altering its label, we observed that the LLM inadvertently changed the label in 14 out of 400 entries. This indicates that despite instructions to preserve labels during paraphrasing, some label noise was introduced, which could impact model training.

Conversely, for the Synthesis Augmentation, where the language model was allowed to both paraphrase and modify the label to balance class distributions, we found that only six entries had their labels changed. Ideally, we expected a greater number of label changes to better address the class imbalance. This suggests that the synthesis prompts might not have been sufficiently aggressive in encouraging label shifts.

Overall, these observations highlight that while LLM-based augmentation is a powerful tool, it introduces a degree of noise that must be carefully managed. In future work, improving the augmentation prompts or implementing post-processing strategies, such as rule-based filtering (e.g., if-else conditions to detect unintended label changes), could enhance the quality and reliability of the augmented data.

6 Conclusion

In this study, we explored several approaches to the Promise Verification tasks, including zero-and six-shot GPT-4o, SVM, and fine-tuned DistilBERT, with varying settings for data augmentation. Our results show that data augmentation generally improves performance for SVM and fine-tuned DistilBERT across tasks, with synthesis augmentation performing best for Promise Identification (PI) and Supporting Evidence (SE), while paraphrase augmentation yielded better results for Timing for Verification (TV). However, both augmentation techniques demonstrated mixed results for the Clarity of the Promise-Evidence Pair (CPEP) task, with paraphrase augmentation showing slight improvements but still remaining challenging overall, likely due to its multiclass nature and sensitivity to subtle semantic changes.

Among the models tested, six-shot GPT-4o outperformed all other approaches, establishing itself as a strong baseline for the Promise Verification task. Nevertheless, SVM and fine-tuned DistilBERT provide valuable alternatives, especially when computational efficiency or resource constraints are important. DistilBERT, in particular, offers a good balance between performance and efficiency, demonstrating that fine-tuning smaller models can achieve competitive results while being more resource-friendly than larger models like GPT-4o. Additionally, SVM provides a more economical solution for specific tasks, even if its performance is not always at the level of the more complex models.

These findings highlight the potential of combining synthesis augmentation with models like DistilBERT and SVM, suggesting that with further refinement, these models can be competitive alternatives to more significant, more resource-intensive approaches like GPT-4o. Future research could explore improving augmentation techniques, fine-tuning different models for better task-specific performance, and investigating more efficient strategies for multi-task text classification.

7 Future Work

Several directions could further enhance the findings of this study. First, exploring domain-specific language models such as FinBERT could be beneficial, as ESG-related texts often overlap with financial contexts. Fine-tuning FinBERT (Huang et al., 2023) for these tasks might lead to better representations and improved classification performance in finance.

Additionally, refining the prompting strategies for both paraphrase and synthesis augmentation is necessary to reduce the noise in generated data. In particular, improving prompts for paraphrase augmentation could help ensure that the original labels are preserved more reliably. Finally, developing a filtering system (e.g., rule-based validation mechanisms) to detect and correct label changes during paraphrase augmentation would be valuable for maintaining data quality and improving model robustness.

A Prompts Used in Baselines

A.1 Zero-Shot GPT-4o Prompt

You are an AI model that classifies paragraphs into four categories based on predefined labels.
Categories and Labels:
1. **Promise Status**: 'Yes' or 'No'
2. **Verification Timeline**: 'Already', 'Less than 2 years', '2 to 5 years', 'More than 5 years', 'N/A'
3. **Evidence Status**: 'Yes' or 'No'
4. **Evidence Quality**: 'Clear', 'Not Clear', 'Misleading', 'N/A'

Task:
Classify the following paragraph into these four categories. Respond in JSON format.

Paragraph: {paragraph}

Output Format (JSON example):

```
{
"promise_status": "Yes or No",
"verification_timeline": "Already, Less than 2 years, 2 to 5 years, More than
5 years, or N/A",
"evidence_status": "Yes or No",
"evidence_quality": "Clear, Not Clear, Misleading, or N/A"
}
```

A.2 Six-Shot GPT-4o Prompt

You are an AI model that classifies paragraphs into four categories based on predefined labels.
Categories and Labels:
1. **Promise Status**: 'Yes' or 'No'
2. **Verification Timeline**: 'Already', 'Less than 2 years', '2 to 5 years', 'More than 5 years', 'N/A'
3. **Evidence Status**: 'Yes' or 'No'
4. **Evidence Quality**: 'Clear', 'Not Clear', 'Misleading', 'N/A'

Examples:

Paragraph: {paragraph1}
- Promise Status: {label1_promise}
- Verification Timeline: {label1_verification}
- Evidence Status: {label1_evidence}
- Evidence Quality: {label1_quality}

Paragraph: {paragraph2}
- Promise Status: {label2_promise}
- Verification Timeline: {label2_verification}
- Evidence Status: {label2_evidence}
- Evidence Quality: {label2_quality}

⋮

Paragraph: {paragraph6}
- Promise Status: {label6_promise}
- Verification Timeline: {label6_verification}
- Evidence Status: {label6_evidence}
- Evidence Quality: {label6_quality}

Now classify the following paragraph:
{paragraph}

Output Format (JSON example):

```
{
"promise_status": "Yes or No",
"verification_timeline": "Already, Less than 2 years, 2 to 5 years, More than
5 years, or N/A",
"evidence_status": "Yes or No",
"evidence_quality": "Clear, Not Clear, Misleading, or N/A"
}
```

B Prompt Used in Data Augmentation

B.1 Paraphrase Augmentation Instruction

You're an ESG data synthesis and augmentation assistant. Your task is to **paraphrase** ESG-related text data while ensuring semantic meaning, logical structure, and contextual accuracy remain intact. The rewritten text must be diverse, realistic, and naturally aligned with the provided metrics.
Context of Metrics:

- **Verification Timeline**
  - "Already": ESG measures applied and with results that can already be verified.
  - "Less than 2 years": ESG measures whose results can be verified within 2 years.
  - "2 to 5 years": ESG measures whose results can be verified in 2 to 5 years.
  - "More than 5 years": ESG measures whose results can be verified in more than 5 years.
  - "N/A": Absence of promise removes the need for timeline verification.
- **Evidence Quality**
  - "Clear": Complete, logical, and intelligible evidence.
  - "Not Clear": Missing information, ranging from intelligible to superficial.
  - "Misleading": Irrelevant evidence used to distract.
  - "N/A": Absence of evidence negates the need for quality assessment.
- **Evidence Status**
  - "Yes": Evidence exists to back the promise.
  - "No": Evidence is absent.
- **Promise Status**
  - Binary classification of whether a segment qualifies as a promise ("Yes" or "No").

Paraphrasing Task:

1. **Rewrite and Maintain Semantic Meaning**
   - Generate a 1:1 paraphrased dataset while preserving the original meaning, logical structure, and assigned metrics.
   - Ensure natural variations in phrasing, word choice, and sentence structure while keeping the content consistent with ESG-related communications.
   - Include realistic company or agency names that align with the ESG context, such as "GreenFuture Initiative," "EcoFleet Logistics," or "Global Sustainability Group."
2. **Output Format**
   - Export the paraphrased dataset in a JSON file structured as follows:
   - `"URL"` and `"page_number"` fields must remain masked as `"xxx"`.
   - The `"data"` field should contain paraphrased text between 100-300 tokens, ensuring coherence and contextual accuracy.

3. **Guidelines**

   - Avoid altering the core intent or meaning of the original text.
   - Maintain consistency in tone, vocabulary, and language style used for ESG-related communications.
   - Do not introduce new information or change the original classification of any metric.
   - Ensure company or agency names fit naturally within the context of the ESG topic.

4. **Evaluation and Consistency**

   - Ensure that the paraphrased dataset aligns with the provided ESG classification metrics without modifying the dataset's original balance.
   - Include a summary in the output describing:
     - The paraphrasing strategy used.
     - Examples of rewritten company or agency names.
     - Any notable challenges in maintaining semantic accuracy.

Example: Input (Original):

```
[{
    "URL": "[URL]",
    "page_number": "[Page Number]",
    "data": "[Data]",
    "promise_status": "Yes",
    "verification_timeline": "2 to 5 years",
    "evidence_status": "Yes",
    "evidence_quality": "Clear"
}]
```

Output (Paraphrased Example):

```
[{
    "URL": "xxx",
    "page_number": "xxx",
    "data": "[Data]",
    "promise_status": "Yes",
    "verification_timeline": "2 to 5 years",
    "evidence_status": "Yes",
    "evidence_quality": "Clear"
}]
```

B.2 Synthesis Augmentation Instruction

You're an ESG data synthesis and augmentation assistant. Your task is to **generate diverse, realistic, and contextually accurate ESG-related text data** while balancing all target classes across four tasks. Ensure that the names of agencies and companies included in the data align naturally with the context and the described metrics.
Context of Metrics:

- **Verification Timeline**
  - "Already": ESG measures applied and with results that can already be verified.
  - "Less than 2 years": ESG measures whose results can be verified within 2 years.
  - "2 to 5 years": ESG measures whose results can be verified in 2 to 5 years.
  - "More than 5 years": ESG measures whose results can be verified in more than 5 years.
  - "N/A": Absence of promise removes the need for timeline verification.
- **Evidence Quality**
  - "Clear": Complete, logical, and intelligible evidence.
  - "Not Clear": Missing information, ranging from intelligible to superficial.
  - "Misleading": Irrelevant evidence used to distract.
  - "N/A": Absence of evidence negates the need for quality assessment.
- **Evidence Status**
  - "Yes": Evidence exists to back the promise.
  - "No": Evidence is absent.
- **Promise Status**
  - Binary classification of whether a segment qualifies as a promise ("Yes" or "No").

Synthesis Task:

1. **Rewrite and Paraphrase**
   - Generate a 1:1 dataset for each class, ensuring semantic meaning and logical structure remain intact.
   - Include realistic company or agency names that naturally fit the ESG context and metrics. For example, names like "GreenFuture Initiative," "EcoFleet Logistics," or "Global Sustainability Group" should align with the subject matter.
2. **Augment Across All Tasks**
   - Modify the dataset proportionally to balance positive and negative samples for **evidence_status** and **promise_status**.
   - Generate diverse examples for each class of **verification_timeline** and **evidence_quality**, avoiding over-representation of any class.

3. **Output Format**

   - Export data to a JSON file structured as follows:
   - "URL" and "page_number" fields must remain masked as "xxx".
   - Ensure the "data" field contains text between 100-300 tokens, maintaining coherence and relevance.
   - The generated dataset must include realistic agency and company names to enrich contextual accuracy.

4. **Guidelines**

   - Retain the logical connections between the promise, evidence, and timeline metrics.
   - Maintain consistency in tone, vocabulary, and language style used for ESG-related communications.
   - Avoid introducing ambiguous, contradictory, or overly generic names or concepts.
   - Use the provided metrics exclusively for synthesis; do not introduce external or new metrics.

5. **Evaluation and Balance**

   - After synthesis, analyze the class proportions across tasks to ensure a balanced representation in the training data.
   - Include a summary in the output describing:
     - How class balance was achieved.
     - Examples of generated company or agency names.
     - Any discrepancies observed and the steps taken to address them.

Example: Input (Original):

```
[{
    "URL": "[URL]",
    "page_number": "[Page Number]",
    "data": "[DATA]",
    "promise_status": "Yes",
    "verification_timeline": "2 to 5 years",
    "evidence_status": "Yes",
    "evidence_quality": "Clear"
}]
```

Output (Paraphrased Example):

```
[{
    "URL": "xxx",
    "page_number": "xxx",
    "data": "[Data]",
    "promise_status": "Yes",
    "verification_timeline": "2 to 5 years",
    "evidence_status": "Yes",
    "evidence_quality": "Clear"
}]
```

C Examples of Data Augmentation and Synthetic Data

C.1 Original Data Sample

Reliability of digital transaction channels 2022 highlights. We made structural and process changes in response to material system outages in the first half of 2022, enabling us to improve system stability and resilience. We experienced no material incidents in the second half of the year. No client-impacting cyber incidents or cyber-related losses were experienced in 2022. Our response and recovery times significantly improved in the second half of the year. We can successfully fail over (switch to a standby system) in the event of near misses, mitigating the risk of outages and impacts to the client. In South Africa, our customer NPS scores across all digital channels showed improvement in the second half of 2022. We improved our communications approach in the event of outages experienced, to ensure that we can effectively and timeously engage impacted customers. Group technology had positive engagements with the group board, regulators, and investors, to ensure clear understanding of what caused the outages in early 2022, and what we have done to improve system resilience.

C.2 Paraphrase Augmentation Example

Standard Bank Group enhanced system stability and resilience through structural and process adjustments following significant system outages in early 2022, resulting in no material incidents in the latter half of the year. There were no client-impacting cyber incidents or losses in 2022. Response and recovery times improved significantly, with successful failover capabilities to mitigate outage risks. Customer NPS scores improved across digital channels in South Africa. The bank improved communications during outages to effectively engage impacted customers. Group technology engaged with the board, regulators, and investors to ensure understanding of the outages and implemented improvements.

C.3 Synthetic Data Generation Example

Following significant system failures in early 2022, DigitalTrust Bank implemented structural and process improvements to enhance system stability. By the latter half of the year, no major incidents were reported, and cyber incidents were avoided. Recovery times improved significantly, and the bank enhanced its communication strategies during outages to keep customers informed. These efforts led to improved customer satisfaction scores across all digital channels, with positive feedback from regulators and investors.

D Data Splitting Procedure

To ensure a robust evaluation, we performed five different train-test splits of the data set using the scikit-learn train_test_split function. Each split allocated 80% of the data for training and 20% for testing, with a different random_state for each split (random_state = 0, 21, 42, 63, 84) to introduce variability while maintaining reproducibility.

Note: Only the training portion (80%) was used for model training and evaluation. The test portion (20%) was not utilized in this study.

E Hyperparameters and Training Configuration

For training the fine-tuned DistilBERT models, we use a consistent setup across all tasks. The training arguments include `logging_strategy="epoch"` and `save_strategy="epoch"` to ensure checkpoint and performance tracking at the end of each epoch. The hyperparameters for each task are listed in Table 3.

Table 3: Hyperparameter settings for fine-tuning DistilBERT on each task. LR refers to the learning rate, BS denotes the batch size, and WD represents weight decay. These values were selected to ensure stable convergence and optimal performance across tasks.

Task	LR	BS	WD
Promise Identification	0.0001	8	0.01
Timing for Verification	0.00005	8	0.01
Supporting Evidence	0.00002	8	0.1
Clarity of Promise-Evidence Pair	0.0001	8	0.01

UB_Tel-U at SemEval-2025 Task 11: Emotions Without Borders - A Unified Framework for Multilingual Classification Using Augmentation and Ensemble

Abstract

This paper presents UB_Tel-U's submission to SemEval 2025 Task 11, which addresses three tracks: Multi-label Emotion Detection, Emotion Intensity, and Cross-lingual Emotion Detection. Our approach leverages a unified multilingual training strategy enriched by diverse external corpora and data augmentation techniques, enhancing both the diversity and robustness of the dataset. Rather than building separate models for each language, we consolidate all data into a single multilingual dataset, allowing the model to learn cross-lingual emotional patterns effectively. Our ensemble framework combines the multilingual capacity of BERT, DistilBERT, XLM-RoBERTa, the zero-shot generalization capabilities of LLaMA 3.3, and an English-specific model fine-tuned for emotion classification. The proposed system achieved competitive results, ranking 11th for Afrikaans (afr) in Track A, 9th for Ukrainian (ukr) in Track B, and 3rd for Amharic (amh), Chinese (chn), Hindi (hin), Marathi (mar), Brazilian Portuguese (ptbr), Russian (rus), and Ukrainian (ukr) in Track C.

1 Introduction

This paper presents UB_Tel-U's submission to SemEval 2025 Task 11, addressing three tracks: Multi-label Emotion Detection, Emotion Intensity, and Cross-lingual Emotion Detection (Muhammad et al., 2025b). While emotion recognition plays a critical role in various NLP applications, existing research has predominantly focused on high-resource languages, leaving a significant performance gap for low-resource languages that often lack sufficient annotated data (Muhammad et al., 2025a,b). The shared task provides a large multilingual dataset (Muhammad et al., 2025a; Belay et al., 2025a), offering an opportunity to explore scalable and cross-lingual emotion detection systems.

To address the multilingual challenge, we adopt a unified modeling strategy by merging data across all languages into a single multilingual training set, enabling the model to learn language-agnostic emotional representations. The UB_Tel-U system incorporates a combination of data preprocessing, data augmentation, and ensemble learning to enhance robustness and generalization. We leverage multiple transformer-based models, including multilingual, zero-shot, and English-specific architectures, and enrich the training data with external corpora such as SemEval 2018 Task 1. Final predictions are generated using ensemble methods, which help integrate complementary model outputs and mitigate individual weaknesses.

Our system demonstrated strong performance in Track C (Cross-lingual Emotion Detection), ranking third for several languages, including Amharic (amh), Chinese (chn), Hindi (hin), Marathi (mar), Brazilian Portuguese (ptbr), Russian (rus), and Ukrainian (ukr). In Track A, our best performance was in Spanish (esp) with a score of 0.7083, while in Track B, Russian (rus) achieved the highest Pearson correlation (0.7817). Despite these successes, the system struggled with certain low-resource languages, such as Emakhuwa (vmw) and Yoruba (yor), highlighting the limitations of current techniques in the absence of sufficient training data. Moreover, emotion intensity prediction (Track B) remained particularly challenging, with considerable variance across languages.

In summary, this paper presents a comprehensive multilingual approach to emotion detection. Our system aims to deliver scalable and adaptable performance across both high- and low-resource languages by unifying multilingual data, employing augmentation, and leveraging model ensembling. The results of our approach highlight both the strengths and limitations of current approaches while pointing toward future directions for improving the understanding of cross-lingual emotions.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1948–1956

2 Background

2.1 Task Description

The SemEval 2025 Task 11 competition comprises three subtasks, each with distinct input and output formats (Muhammad et al., 2025a; Belay et al., 2025a). Track A: Multi-label Emotion Detection requires detecting the presence of six emotions—joy, sadness, fear, anger, surprise, and disgust—from a given text snippet. The output consists of binary labels indicating whether each emotion is present (1) or absent (0). For example, the input "I can't believe he forgot my birthday." might produce the output {'anger': 1, 'sadness': 1, 'joy': 0, 'fear': 0, 'surprise': 0, 'disgust': 0}.

Track B: Emotion Intensity Prediction focuses on quantifying the strength of an expressed emotion. Given a text snippet, the system outputs a numerical value between 0 and 3, where 0 indicates no emotion and 3 represents strong emotion. For instance, the input "I am thrilled about my new job!" could result in the output {'joy': 3}.

Track C: Cross-lingual Emotion Detection extends emotion classification to unseen languages. The input is a text snippet in a target language without available training data, and the output follows the same format as Track A, predicting emotion labels in a multilingual context.

2.2 Related Work

Recent advancements in multilingual NLP have significantly improved multi-label emotion detection, emotion intensity prediction, and cross-lingual emotion classification. Transformer-based architectures, such as BERT and RoBERTa, combined with domain-specific preprocessing, have enhanced the accuracy of emotion classification in social media text (Ying et al., 2019). The development of multilingual transformers like mBERT has also led to improved sentiment analysis for code-mixed and low-resource languages (Nazir et al., 2025).

Additionally, dynamic weighting frameworks have been introduced to address label imbalance in large-scale multilingual datasets (Yilmaz et al., 2023), while comprehensive multilingual datasets provide valuable benchmarks for evaluating emotion detection models (Augustyniak et al., 2023). However, emotion intensity detection remains particularly challenging in low-resource languages, where labeled data is scarce, and models struggle to generalize (Plisiecki et al., 2024; Zhang et al., 2024; Belay et al., 2025b).

Supervised models often outperform general-purpose LLMs in accuracy, but LLMs provide a viable alternative when labeled data is limited (Plisiecki et al., 2024). Fine-tuned models demonstrate superior performance in multi-label emotion classification, underscoring the importance of language-specific adaptation (Belay et al., 2025b). Similarly, in multilingual machine translation, fine-tuning has been shown to enhance model performance across diverse languages (Budiwati et al., 2021). In parallel, advancements in Affective Computing (AC) emphasize the roles of instruction tuning, prompt engineering, and hybrid AI frameworks as promising strategies for improving emotion intensity detection (Zhang et al., 2024).

Cross-lingual emotion detection aims to transfer emotion classification models across languages while addressing challenges such as limited labeled data, linguistic variation, and cultural influences on emotion expression (Zhao et al., 2024; Cheng et al., 2024; Barnes, 2023; Navas Alejo et al., 2020). Existing approaches include machine translation-based methods, embedding-based models, and transfer learning strategies to enhance multilingual sentiment adaptation (Zhao et al., 2024).

Ensemble methods combining LLMs with traditional classifiers have shown promising results, outperforming baselines in multilingual emotion detection tasks (Cheng et al., 2024). While rule-based methods remain effective in low-resource settings (Barnes, 2023), hybrid approaches that integrate linguistic features with deep learning present the most robust solutions for diverse language contexts (Navas Alejo et al., 2020).

3 System Overview

3.1 Transformer-Based Model Comparison

Transformer-based models leverage self-attention mechanisms to discern intricate contextual relationships within text. In this study, we examine four prominent transformer-based models for multilingual and emotion-specific tasks: *bert-base-multilingual-cased* (Devlin et al., 2019), *distilbert-base-multilingual-cased* (Sanh et al., 2019), *xlm-roberta-base* (Conneau et al., 2020), and *j-hartmann/emotion-english-distilroberta-base* (Hartmann, 2021).

We fine-tune each model using a multi-label classification setup. Each model's output layer was configured with a sigmoid activation function and the number of output neurons equal to the number

of emotion labels. This setup allows the model to independently predict the presence of each emotion per input instance. We used binary cross-entropy loss as the objective function, appropriate for multi-label tasks. A threshold of 0.5 was applied to the sigmoid outputs during evaluation to determine label assignment. Evaluation metrics included macro-averaged F1-score and overall accuracy. Models were trained for five epochs using the AdamW optimizer with a batch size of 32 and model checkpoints saved at each epoch.

3.2 Data Preprocessing

Our data preprocessing involves three key steps: lowercasing the text, merging all languages into a single dataset, and converting emoticons and emojis into standardized tokens. First, we convert all text to lowercase to reduce variability. Then, to simplify training, we merge data from multiple languages into one unified dataset. Next, we create a dictionary mapping common emoticons (e.g., ":)", ":-D") to specific emotion labels (e.g., "happy", "very happy") and replace each occurrence in the text with its corresponding label. Finally, we convert emojis into standardized textual descriptions.

3.3 Data Augmentation

To boost our model's multilingual emotion classification capabilities, we applied corpus-based data augmentation by incorporating external datasets that closely align with our original data. Specifically, we enrich our training set with data from SemEval 2018 Task 1, which includes content in English, Spanish, and Arabic (Mohammad et al., 2018). Previous research (Wei and Zou, 2019; Ma, 2019) has demonstrated that adding both real and synthetic training data can substantially improve model performance. Therefore, we applied corpus-based data augmentation to enrich the training data and enhance the model's generalization.

3.4 Zero-shot Classification

We utilize a zero-shot classification to automatically detect emotion from the given text. This zero-shot classification is based on LlaMa 3.3. We use a specific prompt and try multiple prompts as part of prompt engineering (Appendix A). Since the model is mostly trained using English dataset, we ask the model in English to make a prediction. The response of the prompt must concise and should only output the labels: 'anger', 'disgust', 'fear', 'joy', 'sadness', 'surprise'. However, sometimes the response can be a sentence or even a paragraph, so we add a post-processing step. The post-processing takes only the last sentence and filter out other words and leave only the expected labels. Furthermore, since this is a multilingual task emotion detection and not only in English, we ask the model to predict the language of the given text first, if the text is not in English, translate the text to English first, if the the model cannot directly translate to English, the model may translate it to another language transitively to English. As an illustration, the text may be translated first from African, to French, and from French to English. However, due to a difference in cultures and languages, some idioms or other cultural expressions, especially that have emotions, maybe lost in translation when translated to English.

3.5 Model Ensemble

We explore two ensemble techniques: majority voting and the OR rule ensemble. Majority voting is a widely used ensemble method where each classifier casts a vote for a class label, and the label with the most votes is selected as the final prediction. Majority voting is particularly effective when classifiers are diverse and independent (Zhu, 2013), and can be implemented in two forms: hard voting (based on predicted labels) or soft voting (based on predicted probabilities). In this work, we adopt the hard voting approach.

In contrast, the OR rule ensemble (also known as disjunctive ensemble) follows a more inclusive strategy, where the final decision is made if at least one classifier predicts a positive outcome. Rather than relying on the majority, it applies a logical "OR" operation across classifiers' outputs to maximize label coverage.

Specifically for Track B, where predictions involve emotion intensity values, we adapt the ensembling by selecting the maximum predicted intensity across models for each emotion. For example, if Model 1 predicts an intensity of 1 and Model 2 predicts an intensity of 3 for the same emotion, the final ensemble prediction will choose the higher value, 3.

4 Experimental Setup

For model comparison, we use the development (dev) set as the test set and split the training set into the training and validation sets using *Multilabel-*

StratifiedShuffleSplit from *iterative-stratification* library (Sechidis et al., 2011) with 'n_splits=1', we allocate 20% of the data as the validation set (test_size=0.2) and set 'random_state=42' for reproducibility. The label columns include {'anger', 'disgust', 'fear', 'joy', 'sadness', 'surprise', 'lang'}, with the addition of the 'lang' label to ensure stratification preserves the language distribution in the training and validation sets.

The evaluation metric for Track A and Track C is the average F1-score (macro), computed by first calculating the macro-averaged F1-score for each language and then averaging these scores across all languages. For Track B, where emotion intensities are continuous values ranging from 0 to 3, the evaluation metric is the Pearson correlation coefficient, also averaged across all languages.

Our research utilizes a comprehensive set of Python libraries to support data preprocessing, model training, and evaluation within our multilingual emotion classification system. For data manipulation and processing, we employ emoji (Carreira, 2017) and pandas (Reback et al., 2020) to handle text data. Dataset management and preparation are supported by the Hugging Face Datasets library (Lhoest et al., 2021) for efficient data loading and augmentation, and by the *iterative-stratification* library (Sechidis et al., 2011) for performing stratified splitting on multi-label datasets.

For model development, we leverage the Hugging Face transformers library (Wolf et al., 2020) alongside PyTorch (Paszke et al., 2019) as the deep learning framework, enabling seamless integration of pre-trained models and efficient training processes. Finally, for model evaluation, we use scikit-learn (Pedregosa et al., 2011) to compute various performance metrics. Our code is publicly available on GitHub.[1]

5 Results

5.1 Transformer-based Model Comparison

Table 1 presents a comparison of transformer-based models across three evaluation tracks, where Tracks A and C are assessed using macro-averaged F1 scores, and Track B is evaluated using Pearson correlation. Among the models, *xlm-roberta-base* consistently achieves the best performance across all tracks, highlighting its effectiveness in multilingual emotion classification tasks.

LLaMA 3.3 also demonstrates strong performance, suggesting its ability to generalize effectively across tasks. In contrast, *bert-base-multilingual-cased* and *distilbert-base-multilingual-cased* achieve moderate results. Meanwhile, *emotion-english-distilroberta-base*, which is trained specifically on English data, falls behind when evaluated in the multilingual setting. These findings highlight the importance of cross-lingual pretraining and multilingual model design in achieving robust performance in emotion classification tasks.

5.2 Effectiveness of Ensemble Methods

We compare the performance of two ensemble strategies, majority voting and the OR rule, across all tracks, as shown in Table 2. The OR Rule achieves the best results in Track A and Track C, with average F1 macro scores of 0.4997 and 0.4619, respectively, indicating improved sensitivity in detecting multiple emotion labels. Meanwhile, majority voting yields the highest Pearson correlation in Track B (0.5827), suggesting stronger performance in predicting emotion intensity. These findings indicate that while the OR rule is more effective for multi-label classification tasks, majority voting may be better suited for capturing continuous emotional dimensions.

Moreover, Table 3 shows that the ensemble consistently performs best on the 'joy' label across all tracks, achieving the highest average F1 Macro scores in Track A (0.7554) and Track C (0.7263), and the highest average Pearson correlation in Track B (0.6889). Emotions such as 'sadness', 'anger', and 'fear' also yield strong results, while 'disgust' and especially 'surprise' show relatively lower scores, particularly in Track B. These results indicate the ensemble's strength in detecting prominent emotions like 'joy' and 'sadness', but highlight challenges in handling emotions with more subtle or ambiguous expressions.

5.3 Overall System Performance

Table 4 demonstrates the progressive impact of each method on the overall system performance across all three tracks. We observe that incorporat-

4 - j-hartmann/emotion-english-distilroberta-base[5]	0.3346	0.3547	0.3065
5 - llama3.3[6]	0.4328	0.5447	0.4201

Table 2: Model ensemble results.

Ensemble Type	Track A		Track B		Track C	
	Best Combinations	Average F1 Macro	Best Combinations	Average Pearson	Best Combinations	Average F1 Macro
Majority Voting	1, 3, 5	0.4767	3, 5	**0.5827**	1, 3, 5	0.4397
OR Rule	1, 3, 4	**0.4997**	3, 5	0.5782	1, 3, 4	**0.4619**

Table 3: Ensemble performance per emotion label.

Label	Track A	Track B	Track C
anger	0.6849	0.6302	0.6644
disgust	0.6784	0.5477	0.6569
fear	0.6811	0.5464	0.6594
joy	**0.7554**	**0.6889**	**0.7263**
sadness	0.7232	0.6083	0.7073
surprise	0.6782	0.4696	0.6538

ing data preprocessing alone yields only marginal improvements. In contrast, data augmentation leads to a more notable and consistent performance boost across all tracks. The combination of preprocessing and data augmentation results in further performance gains, demonstrating the effectiveness of enriched and diversified training inputs. This combination proves particularly useful in multilingual settings, where the variation in text quality and structure across languages can be significant.

The highest scores are achieved through the ensemble approach, reaching 0.4997 in Track A, 0.5827 in Track B, and 0.4619 in Track C. Ensemble learning effectively leverages the complementary strengths of each individual model, compensating for their weaknesses and reducing the risk of overfitting to specific languages or emotion labels.

5.4 Submission

Due to time constraints and submission limitations, we were unable to submit the best-performing model identified in this study. It is important to note that all submitted models were trained using the combined train + dev set, whereas the models reported in our analysis were trained on the train set and evaluated on the dev set solely for comparison purposes.

All submitted models utilized both preprocessing and augmentation techniques. For Track A, we submitted an OR Rule ensemble consisting of *xlm-roberta-base* (Conneau et al., 2020), *j-hartmann/emotion-english-distilroberta-base* (Hartmann, 2021), and *llama3.3* (Meta AI, 2024). For Track B and Track C, we submitted *xlm-roberta-base* individually as our final model.

The results in Table 5 reveal varied performance across all three tasks and multiple languages, highlighting both the strengths and limitations of our multilingual emotion classification system. In Track A, the system achieved scores ranging from 0.1399 to 0.7083. Notably, Afrikaans (afr) attained a score of 0.5512, securing a relatively high rank of 11, which places it among the top-performing languages. In contrast, some languages like Emakhuwa (vmw) and Yoruba (yor) exhibited lower performance, with scores of 0.1399 and 0.225, respectively. These results highlight the system's strong capability in high-resource or moderately supported languages, while also emphasizing ongoing challenges in achieving robust performance for low-resource languages.

In this track, the system achieved Pearson correlation scores ranging from 0.3321 to 0.7817. Notably, Ukrainian (ukr) obtained a score of 0.5365, achieving a high rank of 9 among the participating languages. Russian (rus) achieved the highest score of 0.7817, showcasing the system's strong capability in handling emotion intensity tasks for certain languages. However, performance varied significantly across languages, suggesting that accurately modeling continuous emotion intensities remains more challenging compared to multi-label classification.

Table 4: Overall system performance on dev set.

In Track C, our cross-lingual approach is tested on languages that lack direct training data. The performance in this track shows a promising range, with scores from 0.0423 to 0.8578. Notably, Amharic (amh), Chinese (chn), Hindi (hin), Marathi (mar), Brazilian Portuguese (ptbr), Russian (rus), and Ukrainian (ukr) ranked third in Track C, demonstrating the strength of our model in transferring emotion labels across languages.

6 Conclusion

In this study, we presented a unified multilingual framework for emotion classification, evaluated across three diverse tracks: multi-label classification, emotion intensity regression, and cross-lingual generalization. Our experimental results show that combining multiple transformer-based models with strategic data preprocessing, augmentation, and ensemble learning substantially enhances system performance. Among these components, the ensemble approach proved particularly effective, consistently outperforming individual models by leveraging their complementary strengths. This integration improved robustness across languages and highlighted the importance of model diversity and data enrichment for multilingual emotion recognition.

Despite these advancements, several challenges remain. Emotion intensity prediction continues to exhibit variability across languages, and performance in low-resource settings is still limited by data scarcity and linguistic diversity. To address these issues, future research could explore more sophisticated data augmentation strategies such as back-translation across related languages, generative paraphrasing, or adversarial training. Finally, incorporating domain-adaptive pretraining or language-specific adapters could further refine model sensitivity to cultural and linguistic nuances.

A Appendix

The zero-shot prompt used for all tracks is presented in Table 6. The two prompts differ in classification detail and output format. The first prompt (Track A and C) assigns only emotion labels, producing a simple comma-separated list, while the second (Track B) includes intensity scores (0-3) for each detected emotion. The first provides binary classification (emotion present or not), whereas the second captures emotion intensity, offering finer sentiment analysis. As a result, the first prompt is suited for general emotion detection, while the second focuses on detailed sentiment analysis, capturing both the type and intensity of emotions.

Table 6: Zero-prompt used in all tracks.

Track	Prompt
Track A and C	Classify emotion from the given text into one or more: Joy, Fear, Anger, Sadness, Disgust, Surprise. The output is only the multilabel classes (Joy, Fear, Anger, Sadness, Disgust, Surprise) and separated by a comma. Do not use other unspecified classes. Do not output the reasoning statement or unnecessary sentences. If you don't know or unsure, translate into English first. If you cannot translate directly to English, translate it first to another known language, and from that another known language to English. The translation can be transitive through more than one language.
Track B	Classify the given text into one or more emotion categories: Joy, Sadness, Fear, Anger, Surprise, or Disgust. Each emotion should be assigned an intensity score between 0 and 3, where 0 means no intensity and 3 means the highest intensity. The output format should be a comma-separated list of emotions with their intensity scores in parentheses, e.g., 'Joy(2), Fear(1), Anger(0)'. Do not include emotions that are not specified. Do not add any reasoning, explanation, or extra sentences. If the text is not in English, translate it first to English. If a direct English translation is not possible, use an intermediate language before translating to English. The translation can be transitive through multiple languages if necessary.

Deepwave at SemEval-2025 Task 11: Emotion Analysis in Low-Resource Settings Using LLM and Data Augmentation

Shenpo Dong[1], **Zhilong Ji**[1],
[1]Tomorrow Advancing Life
Correspondence: dongshenpo@tal.com , jizhilong@tal.com

Abstract

This paper introduces a new emotion detection method designed for low-resource languages, specifically for the SemEval-2025 Task 11 challenge. The approach fine-tunes Google's Gemma 2 model using Chain-of-Thought prompting augmentation data. The methodology integrates supervised fine-tuning and model ensembling, leading to substantial improvements in multi-label emotion recognition, emotion intensity prediction, and cross-lingual performance. The results demonstrate robust performance across various low-resource language scenarios. On task A, our method achieves an average improvement of 6.96 F1. On task B, it yields an average increase of 23.3 F1. For task c, the proposed approach improves metrics for low-resource language families by 50% to 70%.

1 Introduction

Text sentiment analysis, a cornerstone of natural language processing (NLP), aims to computationally identify and extract subjective information from text, such as opinions, emotions, and attitudes. Over the years, this field has evolved significantly, driven by the need to understand human sentiment in various domains, including customer feedback, social networks, and product reviews (Liu and Chen, 2015). Traditional methods, such as lexicon-based approaches and machine learning models, have laid the foundation for sentiment analysis (Wiebe et al., 2005; Salam and Gupta, 2018). However, the advent of large language models (LLMs) has revolutionized this field, offering new capabilities and challenges.

Early sentiment analysis methods relied heavily on lexicon-based techniques, where predefined sentiment scores were assigned to words, and heuristic rules were applied to aggregate these scores for an overall sentiment judgment. While these methods are computationally efficient, they often struggle with complex linguistic phenomena such as sarcasm, negation, and context-dependent sentiment. Machine learning models, like Naive Bayes, Support Vector Machines (SVM) , introduced a data-driven approach to sentiment analysis (Liu et al., 2017; Islam et al., 2022). These models were trained on labeled datasets to classify text into positive, negative, or neutral categories. However, their performance was limited by the need for extensive labeled data and their inability to capture deep semantic relationships within the text.

Large Language Models (LLMs) like BERT (Devlin et al., 2019) and ChatGPT (Ouyang et al., 2022) have revolutionized sentiment analysis, particularly in high-resource languages such as English. This advancement is largely attributed to their ability to achieve superior contextual understanding and facilitate zero-shot and few-shot learning through fine-tuning (Ameer et al., 2023) and prompt-based methods (Yu et al., 2022). Specifically: (1) Zero-Shot and Few-Shot Learning: LLMs' pre-trained language understanding enables them to perform sentiment analysis with minimal or no labeled data (Kuila and Sarkar, 2024). (2) Cross-Lingual Transfer: Multilingual pre-training (Yang et al., 2025) allows LLMs to transfer knowledge from high-resource to low-resource languages. (3) Prompt Engineering: Well-designed prompts guide LLMs to better interpret emotional expressions, particularly in low-resource languages.

However, despite their success in high-resource scenarios, LLMs face significant challenges when applied to low-resource languages (Barnes, 2023), particularly those in Africa and Southeast Asia. These challenges include: (1) Data Scarcity: The limited availability of labeled data in low-resource languages hinders the training of traditional supervised learning methods (Belay et al., 2025). (2) Linguistic Diversity: The complex syntax and diverse dialects present in these languages complicate model understanding and generalization. (3) Cul-

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1957–1963

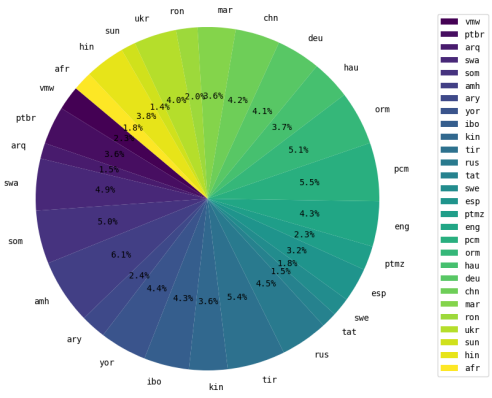

Figure 1: BRIGHTER languages distribution

tural Differences: The variations in emotional expression across cultures necessitate cross-cultural understanding, which is often challenging for models trained primarily on high-resource language data (Tafreshi et al., 2024).

In analogous event extraction tasks, the classical pipeline approach is divided into two stages, event argument extraction and event relation extraction, to enhance end-to-end accuracy (Dong et al., 2022). Consequently, for low-resource scenarios, we draw upon this concept and propose a two-stage augmented data-based sentiment extraction method.

The main contributions are summarized as: 1. We introduce a two-stage CoT-enhanced data pipeline, which generates interpretable and diverse English augmented data for low-resource languages to assist in model training. 2. We employ techniques such as supervised fine-tuning (SFT), K-fold cross-validation, model ensembling, and specialized LoRA adaptations. Across all three tasks, our approach achieves substantially higher performance compared to the baselines.

2 BRIGHTER Dataset

Understanding how emotions are expressed differently across languages is crucial for building inclusive digital tools. Muhammad et al. (2025a); Belay et al. (2025) have developed BRIGHTER, a comprehensive dataset encompassing 28 languages. BRIGHTER consists of 28 distinct datasets , each tailored to a specific language, designed to capture the nuanced expressions of emotions in text. These datasets are derived from a variety of sources, including social media posts, speeches, literary works, and news articles, ensuring a diverse representation of language usage. For some languages, new datasets were created, while existing ones were enhanced with automatically translated or generated data.

Each text instance within BRIGHTER is multi-labeled, indicating the presence of one or more of six core emotions, along with a neutral category. Furthermore, each emotion label is accompanied by an intensity rating on a 4-point scale, providing a more granular understanding of emotional expression. Analysis of BRIGHTER revealed that emotion recognition remains a significant challenge for Large Language Models (LLMs), particularly for languages with limited resources.

SemEval Task 11 contains three tasks for emotion analysis (Muhammad et al., 2025b): Task A focuses on multi-label emotion detection, classifying text snippets into six emotions (joy, sadness, fear, anger, surprise, disgust), with varying presence of the "disgust" label across languages. Task B involves emotion intensity prediction, assigning ordinal intensity levels (0-3) to given text and emotion pairs. Task C tackles cross-lingual emotion detection, requiring prediction of emotion labels in a target language using training data from a different language.

3 System Overview

In this study, we propose a novel approach for text sentiment analysis using large language models through Supervised Fine-Tuning (SFT), Chain-of-Thought (CoT) prompting (Wei et al., 2022), data augmentation and model ensemble techniques. Our methodology integrates advanced LLM capabilities with traditional sentiment analysis frameworks to achieve higher accuracy and robustness in sentiment classification tasks.

3.1 Chain-of-Thought

To enhance the model's capacity for sentiment analysis, particularly in cross-lingual settings, we employed Chain-of-Thought (CoT) prompting to generate explicit intermediate reasoning steps. This approach facilitates a more nuanced understanding of sentiment, especially in contexts where it is implicitly conveyed.

Initial pilot experiments were conducted on high-resource languages, specifically English and Chinese, to validate the efficacy of CoT in this domain. The Gemma 2 27B IT (Team, 2024) model was utilized to implement the CoT framework, decomposing the sentiment analysis task into two distinct sub-tasks:

Speaker	I can't move, my hand is stuck, I'm making weird noises and my mom is screaming.
Keyword Identification	"can't move": helplessness, fear, panic, entrapment; "stuck": helplessness, frustration, panic, entrapment; "weird noises": fear (of the unknown, of one's own body), confusion, distress; "mom is screaming": fear, alarm, panic, distress
Sentiment Recognition	Let's classify the emotions based on the given categories, allowing for multiple options: "can't move": Fear: A very strong primary emotion here, due to the physical inability and potential danger. Surprise: The sudden inability to move could certainly evoke surprise...

(i) sentiment keyword identification. *Prompt: "What emotional keywords are included in this sentence and output them in JSON format."* Like entity recognition, the LLM first analyzes sentence to identify emotionally expressive words. Without predefined category knowledge, the LLM generates varied emotional expressions, like alarm, panic, resulting in what we term coarse-grained data.

(ii) sentiment polarity recognition. *Prompt: "Summarize these emotions, with candidates including 'anger', 'fear', 'joy', 'sadness',' surprise', and' disgust'. You can choose from multiple options."* In this task, we utilize the LLM to map the previously extracted emotional terms to five predefined labels. The emotional labels in this data now perfectly align with BRIGHTER's label taxonomy, where each emotion category has one and only one standardized description. We therefore classify this as fine-grained data.

This augmented data was designed to provide the model with a granular understanding of the intricate relationship between specific keywords and their associated sentiments, thereby improving the model's overall sentiment analysis performance. We performed the same procedure on low-resource languages to generate augmented data. Notably, in our augmented dataset, all responses were strictly required to be in English except for the keywords.

We keep data matching ground truth after Task i and ii. For mismatches, we raise sample temperature and re-run the tasks iteratively until 80% of data has both coarse- and fine-grained data. This iterative process aimed to enhance the quality and diversity of the augmented dataset. For subsequent tasks, we consistently train the models using both the augmented data and the original data in combination.

3.2 Fine-Tuning

To maintain computational efficiency during the supervised fine-tuning (SFT) phase, we selected the Gemma 2 9B IT model as our base model. This decision was driven by the model's balance of performance and resource requirements, enabling us to conduct extensive experimentation within feasible time constraints.

Addressing the challenge of limited data availability, which is particularly prevalent in Tasks 1 and 2 and often leads to suboptimal model performance, we implemented a K-fold cross-validation training strategy. Specifically, we set K to 5, dividing our dataset into five equal partitions. This dataset comprised a mixture of coarse-grained sentiment data from Task 1 and fine-grained sentiment data from Task 2, effectively creating a unified training corpus. We then iteratively trained five distinct models, with each model trained on four partitions and validated on the remaining partition. This cross-validation approach allowed us to maximize the utilization of our limited data while simultaneously providing a robust estimate of model performance and mitigating the risk of overfitting.

During the training process within each fold of the cross-validation, we employed the macro-averaged F1-score as the primary evaluation metric for each language. This metric provided a comprehensive assessment of the model's performance across all classes within a given language.

$$F1_{macro}(l) = \frac{1}{|C|} \sum_{c \in C} \frac{2 \cdot p_c \cdot r_c}{p_c + r_c}$$

where: $|C|$ represents the number of classes in the language. p_c and r_c are the precision and recall for class c, respectively. To select the optimal checkpoint for each fold, we calculated the average of the macro-averaged F1-scores across all languages. This average score served as the criterion for checkpoint selection.

$$Score = \frac{1}{|L|} \sum_{l \in L} F1_{macro}(l)$$

3.3 Model Ensemble

To further enhance the performance of our sentiment analysis model, we employed a model ensembling technique. Specifically, we utilized LLM merging (Goddard et al., 2024), a strategy that combines the predictions of multiple LLM to achieve improved generalization. Given that the five models generated through our K-fold cross-validation were derived from the same base architecture and exhibited comparable performance on their respective validation sets, we opted for a linear weighted merging approach.

We perform a linear fusion of the five models into a single unified model to achieve an optimal tradeoff between inference speed and model performance. As such, each model was assigned a merge weight of 0.2, ensuring an equal contribution to the final ensemble prediction. This straightforward yet effective technique was chosen for its ability to reduce variance and mitigate the risk of overfitting, ultimately leading to a more robust and reliable sentiment analysis system.

3.4 Crosslingual Recognition

To achieve the objective of cross-lingual detection in Task C, we employed a straightforward yet effective strategy involving the training of multiple Low-Rank Adaptation (LoRA) modules. Specifically, for each target language l_i, a dedicated LoRA (Hu et al., 2022) module was trained. The training dataset for this module comprised data from all other languages within Task A, excluding the target language l_i. This approach facilitated the model's ability to discern subtle linguistic nuances and patterns characteristic of languages distinct from l_i.

Given the inherent time-intensive nature of training individual LoRA modules for each language, we abstained from employing model fusion techniques in Task C.

4 Experimental Setup

To maximize coverage for multilingual tasks, we selected the Gemma 2 multilingual model (Team, 2024) as the base model for augmenting and training. We employed bfloat16 precision and Adam optimizer was configured with beta values of 0.9 and 0.999, and an epsilon of 1e-8. To optimize the training process, we set the learning rate to 7e-6. The batch size was configured to 64, which allowed for efficient utilization of computational resources while maintaining reasonable training speed. To ensure robust evaluation and mitigate overfitting, we adopted a 5-fold cross-validation strategy. For both Task A and Task B, we trained the models using the complete set of original data along with the augmented data, and employed Mergekit (Goddard et al., 2024) for linear model fusion. For Task C, we continue to employ mixed data while training dedicated LoRA heads for each individual language.

5 Results

Our proposed work demonstrates significant improvements across three tasks, leveraging Gemma's cross-lingual capabilities enhanced through chain-of-thought reasoning, data augmentation, and model-ensembling strategies.

In task A Multi-label Emotion Recognition (Table 1), Deep achieves superior performance with an average F1-macro score of 56.42, outperforming all comparable systems by +6.96 points over the strongest baseline (Deepseek R1-70B: 49.46). Notably, in certain low-resource language scenarios, the performance metrics substantially surpass those of the English context: +13.21 in Hindi (90.13 vs. 76.91), +11.13 in Marathi (87.81 vs. 76.68) and +10.28 in Russian (87.25 vs. 76.97). However, there are also some scenes that perform poorly like Emakhuwa.

For Task B Emotion Intensity, which requires simultaneous prediction of both emotion categories and intensity levels, our method demonstrates superior performance in Table 2. Our method attaining 73.43 average F1-score +23.3 points higher than DeepSeek-R1-70B (50.13). Our method demonstrates superior performance over the baseline across nearly all language scenarios, as exemplified by the following cases: achieving 91.64 in Russian and 79.21.

For task C, Crosslingual Multi-Label Classification (Table 3), we establishe a new state-of-the-art performance with 52.85 average F1-score, surpassing previous best results by +18.76 points (LaBSE*: 34.09). As observed in Table 4, our method achieves nearly 60-70% improvements for low-resource language families (e.g., Niger-Congo and Semitic), demonstrating remarkable effectiveness in data-scarce scenarios.

As shown in Tables Table 1- 4, we conducted an additional experiment using identical training configurations to our final approach, with the sole variation being the training data. Model marked with † were trained exclusively on the original data, while final model utilized both original and augmented data. The results demonstrate that the hybrid data approach (original + augmented) consistently outperforms the original-data-only by an average margin of 6-10 percentage points. This also indicates that our augmented data underwent rigorous quality filtering, and its integration during training did not excessively interfere with the original data. On the contrary, by more explicitly highlighting the relationships between sentiment keywords and sentiment categories/intensities, it contributed to improved final performance.

6 Limitations

Our cross-lingual sentiment detection approach showed strong performance in Task 3, but its effectiveness was notably reduced in Tasks 1 and 2. This disparity is likely due to the training process involving datasets with both coarse and fine-grained sentiment annotations. The inherent differences in annotation granularity introduced inconsistencies, hindering the model's ability to accurately capture the subtle nuances of sentiment in these tasks.

Furthermore, the model performance in certain low-resource scenarios, particularly with Javanese, fell significantly below acceptable levels. This underscores the persistent challenge of adapting large language models to languages with limited available data. Future research should prioritize strategies for data augmentation in low-resource settings, such as back-translation and synthetic data generation, as well as the integration of language-specific linguistic resources. Additionally, exploring methods for efficient knowledge transfer and adaptation from high-resource to low-resource languages is crucial for bridging the performance gap.

7 Conclusion

This study investigated text-based emotion detection in low-resource languages, utilizing the Google Gemma 2 large language model. The research employed data augmentation, Chain-of-Thought (CoT) prompting, and model ensembling techniques. The proposed approach achieved substantial performance gains across multilingual emotion detection and emotion intensity prediction task, outperforming state-of-the-art baselines. Further research is needed to explore more effective knowledge transfer methods from high-resource to low-resource languages.

Overall, this work highlights the potential of large language models to bridge the gap in text-based emotion detection, particularly through data augmentation for resource-scarce language families.

Abstract

In today's era of abundant online news, tackling the spread of deceptive content and manipulative narratives has become crucial. This paper details our system for SemEval-2025 Task 10, focusing on Subtasks 1 (Entity Framing) and 3 (Narrative Extraction). We instruct-tuned quantized Microsoft's Phi-4 model, incorporating prompt engineering techniques to enhance performance. Our approach involved experimenting with various LLMs, including LLaMA, Phi-4, RoBERTa, and XLM-R, utilizing both quantized large models and non-quantized small models. To improve accuracy, we employed structured prompts, iterative refinement with retry mechanisms, and integrated label taxonomy information. For subtask 1, we also fine-tuned a RoBERTa classifier to predict main entity roles before classifying the fine-grained roles with Phi-4 for the English language. For subtask 3, we instruct-tuned Phi-4 to generate structured explanations, incorporating details about the article and its dominant narrative. Our system achieves competitive results in Hindi and Russian for Subtask 1.

1 Introduction

The internet has facilitated direct communication between information producers and consumers, making it easier for deceptive content and manipulative narratives to spread. To address this challenge, SemEval-2025 Task 10 (Piskorski et al., 2025) introduces the "Multilingual Characterization and Extraction of Narratives from Online News". The task spans over five languages - Bulgarian, English, Portuguese, Hindi, and Russian. The task has three subtasks - Entity Framing, Narrative Classification and Narrative Extraction.

In subtask 1, the dataset has news articles which have entities that need classification into main roles and then further into corresponding fine-grained roles. Each article may have multiple instances of the entity but the task entails classification on a specific occurence. Similar to Subtask 1, Subtask 2 focuses on assigning a single dominant narrative and one or more associated sub-narratives to a given news article. Subtask 3 involves generating a concise explanation that supports the dominant narrative of a news article, given the article and the narratives.

Language	Subtask 1		Subtask 3	
	Baseline	System	Baseline	System
Bulgarian	0.04	0.41 (5^{th})	0.63	0.67 (4^{th})
English	0.03	0.36 (5^{th})	0.67	0.72 (9^{th})
Portuguese	0.05	0.33 (8^{th})	0.68	0.70 (5^{th})
Hindi	0.06	0.45 (2^{nd})	0.67	0.70 (4^{th})
Russian	0.05	0.47 (3^{rd})	0.64	0.68 (3^{rd})

Table 1: Leaderboard scores and rankings on the test set. Rankings are against 34 and 17 teams in Subtask 1 and 3 respectively across languages

We participated in Subtasks 1 and 3, by instruct-tuning Microsoft's Phi-4 (Abdin et al., 2024) model and various prompt engineering techniques specific to these subtasks. Our approach experimented with multiple Large Language Models (LLMs), specifically LLaMA (Touvron et al., 2023), Phi-4, RoBERTa (Liu et al., 2019), and XLM-R (Conneau et al., 2019). We utilized both quantized large models and non-quantized small models, discovering that the former performed better. To enhance classification accuracy, we structured prompts to enforce output format consistency, used an iterative refinement methodology with retry mechanisms to reduce LLM generation errors, and incorporated label taxonomy information in prompts to improve performance. For Subtask 1, we also fine-tuned a RoBERTa classifier to predict main entity roles (with 72% accuracy) before refining for fine-grained role classification with Phi-4 for the English language. For other languages, prompt engineering with instruction tuning to generate

[*]Equal contribution

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1964–1973

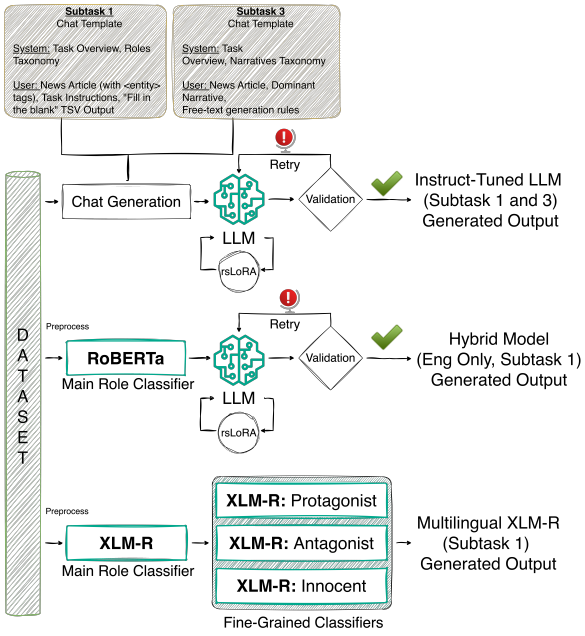

Figure 1: Schematic representation delineating the data preprocessing and model execution pipeline for Subtasks 1 and 3

both main and fine-grained roles performed best. For Subtask 3, we instruct-tuned Phi-4 to generate structured explanations, incorporating details about the article and its dominant narrative. The need for scalable solutions capable of processing millions of articles daily necessitates an approach that prioritizes efficiency and minimizes resource consumption. We aim to build a system that effectively addresses the challenges of the task while maintaining computational efficiency.

Table 1 captures the performance of our system against the baseline and other teams in the competition[1]. Our system performance is particularly competitive against the competition in Hindi (2^{nd}) and Russian (3^{rd}) for Subtask 1. We observed that few-shot prompting was suboptimal compared to LoRA-based parameter-efficient fine-tuning of the quantized Phi-4 model. RoBERTa models struggled with fine-grained role classification, necessitating an LLM-based approach. Our work is publicly available[2] for reproducibility.

2 Background

The Table 2 and Table 3 illustrate the distribution of news articles for each subtask and language, across training, validation, and test splits. Our approach is highlighted in Figure 1 and elucidated in section 3.

Table 3: Statistics on the Training Data - Subtask 1

2.1 Subtask 1 - Entity Framing

The subtask involves the classification of entity mentions within news articles, using a hierarchical taxonomy of roles. This presents a multi-label, multi-class text-span classification problem, as each entity mention can be assigned multiple fine-grained roles from a predefined set. The dataset exhibits complexities such as multiple entities per article, repeated occurrences of the same entity, and even multiple annotations of the same entity within a single article, potentially with varying roles. These nuances require careful consideration when developing and evaluating classification models for this task. For each annotated entity, the system must assign a single main role, followed by one or more fine-grained roles based on the main role. The complete set of main and fine-grained roles was provided as a predefined taxonomy[3] (Stefanovitch et al., 2025).

2.2 Subtask 2 - Narrative Classification

The subtask follows a hierarchical classification structure similar to Subtask 1, having coarse-grained and fine-grained narratives which was provided as a predefined taxonomy[4] (Stefanovitch et al., 2025) by the task. Finally, one of the narratives or sub-narratives is assigned as a dominant narrative at the article level. While this setup presents several interesting challenges, it falls outside the scope of the present work and is left as a

[3] https://propaganda.math.unipd.it/semeval2025task10/ENTITY-ROLE-TAXONOMY.pdf

[4] https://propaganda.math.unipd.it/semeval2025task10/NARRATIVE-TAXONOMIES.pdf

potential direction for future research.

2.3 Subtask 3 - Narrative Extraction

This subtask involves generating a concise free-text explanation that supports the dominant narrative of a news article, making it a text-to-text generation task. The explanation is based on the text fragments that justifies the claims of the dominant narrative which is essentially an output from Subtask 2.

2.4 Related Work

Various datasets have been developed to analyze narratives and sentiment in text across different domains. (Sharma et al., 2023) presents a dataset for identifying heroes, villains, and victims in memes, employing broad categories similar to the Subtask 1 dataset. In (Coan et al., 2021), a dataset is introduced for classifying Climate Change denial claims, which applies a narrative taxonomy similar to Subtask 2. Additionally, (Amanatullah et al., 2023) offers a detailed examination of narratives in the context of the Ukraine-Russia war.

Our approach primarily focuses on instruct-tuning quantized LLMs, particularly Phi-4, along with comprehensive prompt engineering. Instruct tuning, a form of supervised fine-tuning, significantly enhances LLM capabilities by aligning them with human instructions and downstream tasks (Zhang et al., 2023). Emerging techniques such as Parameter Efficient Fine Tuning (PEFT) (Fu et al., 2023), especially Low Rank Adaptation (LoRA) (Hu et al., 2022; Kalajdzievski, 2023), have made it significantly easier to instruct-tune LLMs with limited computational resources.

Recent advancements emphasize the effectiveness of instruction tuning and few-shot prompting. (Brown et al., 2020) demonstrated that few-shot prompting in LLMs (In-Context Learning paradigm) could generalize to a variety of tasks with minimal fine-tuning. Moreover, the benefits of instruction tuning for improving multilingual capabilities have been highlighted by (Chirkova and Nikoulina, 2024; Ming et al., 2024), suggesting that future LLM development should prioritize multilingual training. In addition, LLMs can tackle diverse and challenging tasks, including specialized domain understanding and complex zero-shot reasoning (Raghav et al., 2023, 2025). Furthermore, ongoing research explores critical aspects of modern models to enhance robustness (Carragher et al., 2025a,b).

Before the advent of large-scale LLMs, encoder-decoder models such as T5 and BART (Raffel et al., 2020; Lewis et al., 2019) were effective across a variety of NLP tasks (Raghav et al., 2022). Prior work in specialized domains (Mullick et al., 2022b,a, 2023) has explored fine-grained classification tasks closely related to our objectives. In our work, we explored RoBERTa for role classification in Subtask 1, as its effectiveness in text classification tasks is well-documented (Liu et al., 2019).

3 System Overview

This section presents the key algorithmic and modeling decisions behind our system. We rely exclusively on the dataset provided by the organizers and systematically examine a range of approaches, including large and small language models, In-Context Learning (ICL) paradigms (zero-shot and one-shot), and instruction-tuning methods. Due to compute constraints, we were unable to use large non-quantized models and instead relied on quantized large models and non-quantized small models. We observed that the quantized large models consistently outperformed their smaller non-quantized counterparts. Our approach leverages specialized instruct-tuned quantized LLMs, where well-crafted prompts guide the LLM, followed by lightweight fine-tuning using rsLoRA. We address challenges such as multilingual training, long-document parsing, and robust text generation through targeted strategies.

3.1 Instruct-Tuned LLM Approach

We employed instruct tuning across several LLMs, including LLaMA and Phi-4. Through experimentation, we found that Phi-4 achieved the best performance when tuned using rsLoRA. To address key challenges, we adopted the following strategies:

- **Entity Tagging:** We explicitly marked entity mentions in the text using `<entity>` tags to help the model focus on relevant spans. This helps the model distinguish between multiple occurrences of the same entity in the same news article.

- **Structured Output Format:** Instead of free-text predictions, we guided the model to produce structured Tab Separated Values (TSV) outputs of the form:

```
Entity \t Main_Role \t Fine_Grained_Role(s)
```

As we need to generate multiple fine-grained roles, we allow for generation in a comma seperated format. This prevented the model from overfitting to format structure (like JSON) rather than meaningful content. This helps optimise the loss function efficiently which can be quantitatively seen in Table 6.

- **Error Correction via Iterative Refinement:** For Subtask 1, we implement an iterative feedback mechanism in which errors from incorrect or unparsable outputs were fed back to the LLM for up to three retries, refining predictions dynamically. This process was triggered whenever the output did not conform to the expected TSV/JSON format or when the predicted fine-grained role was not consistent with the corresponding main role. Similarly for Subtask 3, to ensure clarity and control length, we imposed structural constraints and implemented an iterative retry mechanism for generated outputs exceeding 80 words.

- **Prompt Engineering:** We explored various prompt formulation strategies and adopted a System-User-Assistant chat template that yielded the best results for our task. The *System* message included the task introduction and a detailed taxonomy, while the *User* message contained the input article and generation instructions. Both zero-shot and instruction tuning approaches followed the same template. In the one-shot setting, we additionally provide an illustrative input-output example within the *User* message. A detailed illustration of the prompt can be found at subsection A.1 and subsection A.2.

3.2 Hybrid Model: RoBERTa for English Role Classification

RoBERTa works well on text classification in NLP tasks in the English language, especially when we have limited number of classes. We incorporated a RoBERTa-based classifier for main-role prediction. This model achieved a validation classification accuracy of 71.1% when distinguishing amongst the main roles ($\sim$2% improvement over LLMs). The predicted main roles were then fed into Phi-4 for fine-grained role classification.

We address RoBERTa's token limit by adopting a windowed-context approach, extracting 300 characters before and 200 after the target entity to retain critical surrounding context.

3.3 Multilingual Training with XLM-R

For multilingual support, we adopt a two-stage windowed-context based classification. First, we train a three-way classifier to predict the main role of an entity. Based on this prediction, the input is routed to one of three fine-grained multi-class classifiers, each specializing in a specific main role. While this approach beat the baseline, it achieved an exact match ratio of only 0.24 for English. Further, we observed lower performance for other languages.

4 Experimental Setup

Our approach for Subtasks 1 and 3 (Figure 1) focused on instruct-tuning quantized LLMs, enhanced by prompt engineering. We utilized the provided training split for systematic instruction tuning, the validation split for model selection and performance assessment, and the blind test split to generate predictions. To address the multilingual nature of the task, we adopt a combined training strategy, leveraging data from all languages to create a unified instruct-tuned model.

4.1 Instruct Tuning Setup

We leverage Unsloth's (Daniel Han and team, 2023) dynamic 4-bit quantized Phi-4 model[5] (8.48B parameters) as our base model for efficient LLM training. We use the Supervised Fine-Tuning Trainer (SFTT) from the Hugging Face TRL Library (von Werra et al., 2020) for instruct tuning. We also experimented with LLaMA-3.2 3B[6] and 4-bit dynamic quantized LLaMA-3.2 3B Instruct[7] from Unsloth.

We limit training to one epoch, as further training led to performance degradation. Furthermore, we integrated rsLoRA ($rank = 8$) and utilized Unsloth's gradient checkpointing. Our experiments (training and data storage) were conducted using a single T4 GPU on Google Colab and Kaggle.

4.2 Evaluation Metrics

Subtask 1 employs Exact Match Ratio, assessing the proportion of samples with perfect agreement between predicted and ground truth labels for both main and fine-grained roles. Subtask 2 utilizes samples F1 calculated per document. Subtask 3 leverages the F1 metric from BERTScore (Zhang

et al., 2019) to measure the similarity between generated and gold explanations.

5 Results

Our results (Table 1) demonstrate the effectiveness of prompt engineering and instruct-tuned LLMs for multilingual entity framing and narrative extraction.

We conduct two sets of ablations for Subtask 1: model variant combined with output format (TSV vs. JSON) as in Table 6, and model variant combined with training strategy (ICL zero-shot, ICL one-shot, and instruct tuning) as in Table 4. For Subtask 3, we similarly evaluated model variants with different training strategies to systematically improve performance as in Table 5. These studies helped isolate the effects of output format, training methodology and model variant effectiveness. Our key findings include:

- **LLaMA 3.2** models perform poorly for both entity classification and free-text generation. Overall, instruct tuning with **Phi-4** yields the best results.
- The instruct model variants (such as LLaMA 3.2 - 3B Instruct), consistently outperform their base counterparts (such as LLaMA 3.2 3B) even after instruct-tuning.
- We tried out zero-shot and one-shot ICL prompting methods but both these methods were worse than instruct tuning.
- Iterative **retry methodologies** reduced unparsable outputs and hallucinations, while improving response validity.
- For entity framing in English, our RoBERTa+LLM model achieved an **37% exact match**. However, multilingual generalization posed a serious challenge.
- **TSV-based outputs** improved accuracy over JSON outputs, as loss values were no longer artificially lowered by structural correctness.

6 Conclusion

Our system demonstrates the effectiveness of prompt engineering and instruct-tuned quantized LLMs for multilingual entity framing and narrative extraction. We highlight the superior performance of quantized LLMs and the benefits of incorporating a hybrid model with RoBERTa for main role

prediction in English. Additionally, we emphasize the positive impact of iterative refinement and structured output formats on overall accuracy.

Future research will focus on incorporating Subtask 2 as pre-training for Subtask 3, to refine narrative extraction quality. Investigation into the impact of model size and alternative efficient fine-tuning techniques could also yield valuable insights. Finally, enhancing multilingual generalization for RoBERTa and XLM-R may yield better results.

A Appendix

A.1 Prompt Template - Subtask 1

In Subtask 1, our strategy follows the system-user-assistant chat paradigm, a structured format to ensure accurate entity classification. In the 'System' prompt, we provide a taxonomy defining the main and fine-grained roles. This is essential as the task definitions of these entities are slightly different than what they may mean in general settings. In the 'User' prompt, goes the article text, modified with <entity> tags to identify entity instances that need classification. We add clear instructions to the model for generating classifications at both role levels, along with a reiteration to emphasize on the target main and fine-grained roles. We provide a fill-in-the-blank structure for every instance of entities using a tab-separated format to improve model consistency and generation accuracy.

System

```
You are an expert assistant trained for fine-grained entity classification. Your purpose is to
assign accurate roles to tagged entities in an article based on predefined categories.
For each tagged entity, there can be one main role from this list - ['Protagonist', 'Antagonist',
'Innocent']

Here are the fine-grained roles for Protagonist
<fine-grained roles and its descriptions for Protagonist>

Here are the fine-grained roles for Antagonist
<fine-grained roles and its descriptions for Antagonist>

Here are the fine-grained roles for Innocent
<fine-grained roles and its descriptions for Innocent>
```

User

```
User Prompt
### Task Instructions

#### Article:
<the news article, with <entity> tags>

For every tagged entity phrase, you must:
1. Assign *one main role* from the list: ['Protagonist', 'Antagonist', 'Innocent'].
2. Assign *one or more fine-grained roles* based on the predefined taxonomy for each main role:
   - *Protagonist*: Guardian, Martyr, Peacemaker, Rebel, Underdog, Virtuous.
   - *Antagonist*: Instigator, Conspirator, Tyrant, Foreign Adversary, Traitor, Spy, Saboteur,
   Corrupt, Incompetent, Terrorist, Deceiver, Bigot.
   - *Innocent*: Forgotten, Exploited, Victim, Scapegoat.
3. The output should contain tab 3 sets separated values - entity, main role and fine grained roles
4. Fine grained roles should be separated by comma if there are multiple fine grained roles for the
entity

Fill in the missing information in the following structure:
<A TSV/JSON structure containing the actual entity name, along with placeholders such as
`main_role`, and `fine_grained_role1, fine_grained_role2` to represent the main and fine-grained
roles, respectively>
The output should be the filled up.
```

Assistant

The 'Assistant' role is the output of the model, which was provided during training. Below is an example of the assistant output for one of the training examples (the news article `EN_UA_300009.txt`) in English, presented in TSV format.

```
Fail Alsynov    Protagonist   Rebel, Martyr
Bashkir people  Innocent      Victim
Bashkort        Protagonist   Rebel, Guardian
```

Here is the same assistant output in JSON format.

```
{
    'Fail Alsynov':{
        'main_role': 'Protagonist',
        'fine_grained_role': ['Rebel', 'Martyr']
    },
    'Bashkir people':{
        'main_role': 'Innocent',
        'fine_grained_role': ['Victim']
    },
    'Bashkort':{
        'main_role': 'Protagonist',
        'fine_grained_role': ['Rebel', 'Guardian']
    }
}
```

A.2 Prompt Template - Subtask 3

In Subtask 3, the tiered taxonomy is included in the System prompt, while the User prompt contains the topic label (e.g., 'Climate Change', 'Ukraine–Russia War', or 'Other'), the coarse and fine-grained narratives, and the article text. We also provide clear instructions to generate free-text explanations for generating justifications of the narratives.

System

```
You are an expert assistant trained for generating a free text explanation given the narrative and
the subnarrative of the article.
Given a news article and a dominant narrative of the text of this article, you should generate a
free-text explanation supporting the choice of this dominant narrative. The to-be-generated
explanation should be grounded in the text
fragments that provide evidence of the claims of the dominant narrative.

These are the definitions for narratives and subnarratives which you will encounter for the text:
<coarse narratives, their fine-grained narratives and their descriptions listed respectively
```

User

```
### Task Instructions

#### Article:
This is the article from which you need to extract the explanation of why the narrative and
subnarrative make sense.
<the raw news article>

Here are the categories, dominant narratives and subnarratives from the text that need an
explanation of why they are so.
Category: <`Climate Change`, `Ukraine Russia War` or `Other`>
Narrative: <coarse-grained narrative>
Subnarrative: <fine-grained narrative, if present>

Generate a one-paragraph explanation in the same language as the provided article, strictly limited
to **three sentences or 60 words**, whichever comes first. This requirement is **absolute and
non-negotiable**.
```

Assistant

The 'Assistant' role is the output of the model, which was provided during training. Below is an example of the assistant prompt for one of the training examples (the news article `EN_CC_100013.txt`) in English.

```
The text accuses climate activist Bill Gates for his alleged hypocritical behavior as he flies in
private jets that pollute the environment while advocating for the climate cause.
```

A.3 Ablation Results

Model	Output Format	Bulgarian	English	Portuguese	Hindi	Russian
LLaMA 3.2 3B	JSON	0.00	0.02	0.01	0.01	0.02
	TSV	0.00	0.02	0.02	0.01	0.03
LLaMA 3.2 - 3B Instruct	JSON	0.02	0.02	0.03	0.02	0.05
	TSV	0.03	0.03	0.04	0.02	0.07
Phi-4 Instruct	JSON	0.18	0.20	0.33	0.23	0.22
	TSV	0.25	0.22	0.40	0.31	0.32

Table 6: Ablation study on the validation set for Subtask 1 to compare output formats (JSON vs. TSV). All models were evaluated using Exact Match Ratio. While LLaMA models showed negligible differences across formats, Phi-4 demonstrated a significant improvement with TSV, leading us to adopt TSV as the preferred output format.

TreeSearch at SemEval-2025 Task 8: Monte Carlo Tree Search for Question-Answering over Tabular Data

Aakarsh Nair and Huixin Yang
Seminar für Sprachwissenschaft
Eberhard Karls Universität Tübingen, Germany
{aakarsh.nair, huixin.yang}@student.uni-tuebingen.de

Abstract

Large Language Models (LLMs) can answer diverse questions but often generate factually incorrect responses. SemEval-2025 Task 8 focuses on table-based question-answering, providing 65 real-world tabular datasets and 1,300 questions that require precise filtering and summarization of underlying tables.

We approach this problem as a neuro-symbolic code generation task, translating natural language queries into executable Python code to ensure contextually relevant and factually accurate answers. We formulate LLM decoding as a Markov Decision Process, enabling Monte Carlo Tree Search (MCTS) as a lookahead-based planning algorithm while decoding from the underlying code-generating LLM, instead of standard beam-search.

Execution success on synthetic tests and real datasets serves as a reward signal, allowing MCTS to explore multiple code-generation paths, validate outcomes, assign value to partial solutions, and refine code iteratively rather than merely maximizing sequence likelihood in a single step. Our approach improves accuracy by 2.38x compared to standard decoding.[1]

1 Introduction

Transformer-based LLMs (Vaswani et al., 2023) excel at question answering (QA) (OpenAI, 2024; Aaron Grattafiori, 2024) but frequently generate plausible yet factually incorrect responses (hallucinations) (Ji et al., 2023). Mitigating these errors is crucial for applications requiring precise, structured answers (Farquhar et al., 2024).

One domain where factual consistency is critical is table-based QA, where answers must be derived from structured tabular data. SemEval-2025 Task 8 (Osés Grijalba et al., 2024) provides a benchmark for evaluating LLMs in this setting, requiring models to generate accurate answers from real-world datasets. Table 1 lists sample questions from the SemEval-2025 Task 8 training set of questions along with their expected answer types.

Type	Dataset ID	Example Question
Boolean	072_Admissions	Is there an applicant with a chance above 95 per cent of getting into the university they applied to ?
Category	068_WorldBank_Awards	Which region has the most contracts?
Number	075_Mortality	What is the total sum of all death rate values ?
List[Category]	080_Books	List the categories of the first five books.
List[Number]	078_Fires	What are the 3 hottest temperatures recorded?

Table 1: Sample questions from the Semeval Task-8 training set along with their expected answer types.[2]

While databases have long relied on structured query languages (SQL) for precise data retrieval (Codd, 1970), translating natural language questions into executable queries remains a challenging task (Nan et al., 2022; Zhong et al., 2017).

In this task, we aim to leverage code-generating Large Language Models (Rozière et al., 2024) to query tabular data. That is, given a natural language query and the underlying table schema, we attempt to generate a concise Pandas Python code (Wes McKinney, 2010) to answer questions regarding the given table dataframe. This allows us to leverage existing code generation models like CodeLlama-7b-Python [3] model, which are extensively trained on Python code generation.

For reference, the organizers provide training data consisting of 1.3k data points, each of which includes a natural language question, the target answer, its data type, and relevant columns in the dataframe useful for answering the query. (Grijalba et al., 2024). Queries are run in either *lite* mode using the first 20 rows of the table or full mode using the entire table, with target answers for both modes provided. The organizers additionally provide a baseline decoder-only code LLM, based on Stable Code 3b (Pinnaparaju et al., 2024), which tries to generate Python-Pandas code to be run against the

[1] Our code is available at: https://github.com/HuixinYang/SemEval25-Task8-Adrianna-Aakarsh-Yang

[3] CodeLlama-7b-Python is openly available at: https://huggingface.co/codellama/CodeLlama-7b-Python-hf

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1974–1980

underlying dataframe. Using a simple beam-search-based decoder, the LLM can achieve an accuracy of 27% in lite querying mode and 26% on full table querying mode on the task's test set.

Standard beam-search decoders maximize sequence likelihood but ignore program quality for planning. We therefore propose an MCTS-based planning decoder (Zhang et al., 2023) for CodeLlama-7b-Python, grounding table-QA in the runtime behavior of generated queries.

During the decoding process, the MCTS Planner can take advantage of a reward signal from terminal states to backpropagate and value intermediate decodings of the underlying Transformer model. The MCTS planner can balance exploration and exploitation in the token decoding process to generate a higher-quality set of possible Python-Pandas completions, running them against the dataframe and automatically generated test-cases to weigh possible next tokens through a look-ahead process, while the transformer's next token probabilities serve as a good heuristic to constrain the planner's search space. Moreover, the flexibility of the reward function allows us to use a variety of much larger models to inform our judgments of the generated program solutions. For example, we can use automatically generated test-cases from a `Qwen2.5-Coder-32B-Instruct` (Hui et al., 2024) model on synthetic data following the underlying table schema to validate and generate a reward signal for our decoding process.

2 Related Work

Reinforcement Learning (RL) planning, particularly Monte Carlo Tree Search (MCTS) (Sutton et al., 1998; Silver et al., 2016), has shown success in complex domains such as games and SQL generation from natural language (Zhong et al., 2017).

While LLMs exhibit inherent reasoning capabilities (OpenAI, 2024), incorporating explicit planning into their generation process is an active research area. Approaches range from prompting strategies like Chain-of-Thought (Wei et al., 2023) to models with dedicated search, reward, and reasoning components (Hao et al., 2024).

3 Our Approach

Our approach applies planning-based transformer decoding (Zhang et al., 2023) to table-question answering. Novel query program code synthesis is formulated as a Markov Decision Process (Sutton et al., 1998). A partial program along with its prompting description is considered to be a *state* s. The act of selecting a next-token from the underlying Transformer vocabulary is considered an *action* a. Thus *transition function* moves from one partial program to another by concatenating a selected token to one partial program to form another until a terminal token is appended. The *reward* for a program is a function of the validity of the program, along with the number of synthetic test-cases the generated program passes. The aim is to use the LLM to search for a path which maximizes expected future reward: $\sum_{t=0}^{n} r(s_t, a_t)$.

3.1 Monte-Carlo Tree Search Decoding

A *Monte-Carlo Tree Search (MCTS)*-based planner maximizes the accumulated reward of the generated program, replacing beam-search, which prioritizes similarity to reference solutions but cannot explicitly optimize execution quality, making it sample-inefficient.

MCTS (Silver et al., 2016) treats planning as a look-ahead search through a tree of *actions* to find a path to terminal nodes with the highest rewards. Search proceeds from the root node, with child nodes representing next-token actions selected by the planning algorithm in phases meant to balance *exploration* and *exploitation*. The four phases are: *Selection*: A process of selecting which of the root's child node to examine, *Expansion*: A process of adding child nodes for the top-k most likely next tokens for given node (as guided by the Transformer model), *Evaluation*: Expanding greedily using beam-search on Transformer model to the terminal node to estimate program reward and *Backpropagation*: Updating a node's ancestor's with visit counts and ground truth observed rewards. Throughout its execution for each node, the planning algorithm maintains a node-visit count and $Q(s, a)$, which is the average reward for the algorithm taking action a when starting from state s. A *rollout* consists of a one full generation of a sample program and its final computed *reward*. All four phases are run as part of every full rollout. The algorithm maintains a search tree of tokens till the required number of rollouts are processed.

Selection: This process starts at the root node and recursively selects its child node until a leaf node is reached. The root node consists of the full prompt up until the slotted location for query generation. Its children represent the possible next tokens in

the generation. The selection phase recursively traverses and selects actions a down till it reaches an unexpanded node using a variant of the Predictive Upper Confidence Bound(P-UCB) (Silver et al., 2016; Zhang et al., 2023) action selection criterion, which balances *exploration* with *exploitation*, when selecting next token a to explore.

$$\text{argmax}_a \text{P-UCB}(s,a) = Q(s,a) + C \cdot P_{\text{LLM}}(a|s) \cdot \frac{\sqrt{\ln N(s)}}{1+N(s')}$$

Where $Q(s,a)$ is the reward of the best program generated from this node, $P_{\text{LLM}}(a|s)$ is the transformer's predicted probability that a is the next token and $N(s)$ and $N(s')$ are the prior visit counts of states s and the state s' achieved when we transition from state s to state s' by taking the token-concatenation action a, C is a ucb-constant which is used to control the scaling of the *exploration* term.

Expansion: Once we reach an unexpanded/unexplored node, we discover its possible succeeding children by using the Code LLM *Top-k* next tokens. Thus, the language model constrains the search paths of next tokens, reducing the probability that we will sample a syntactically invalid next token. The k represents the maximum child count of a node. It determines the fan-out size of our tree. Nodes for each of the sampled next tokens are created and added to the search tree.

Evaluation/Simulation: As the node added to the tree may be a partial program, LLM *beam-search* is used to generate a possible full completion of the program till a terminal node. The full-suite test-cases are run on this greedily generated program, if the program generated by this default policy is executable, the observed reward is recorded along with the rollout.

Success in compiling and executing the program against the underlying dataframe and the number of test-cases passed on a synthetic dataframe contributes to the reward for this rollout.

Backpropagation: In the final phase, the observed reward and visitation count are populated up through the ancestors of the current node to contribute to future look-ahead searches and the ancestor's P-UCB criterion, leading to refining the tree exploration policy over each subsequent rollout.

Answer Selection: The final results of running all rollouts are a dictionary of all programs generated and their corresponding observed rewards from the evaluation phases. The chosen program is one that achieves the maximum rewards, with the majority computed answer used to break tied rewards.

4 Experimental Setup

4.1 MCTS Decoder Configuration

We run the MCTS decoder (Zhang et al., 2023) for the base model `CodeLlama-7b-Python-hf` (Rozière et al., 2024), using a *horizon* of 32, which controls the maximum number of steps taken or tokens produced. 100 *rollouts* are performed, determining the number of programs generated for each question in the test set.

We use *P-UCB* as the *node selection algorithm* during the selection phase, with an expansion *width* of 5, which specifies the number of children each node can expand into. No *temporal discounting* is applied ($\gamma = 1$), meaning rewards are not penalized based on the number of steps taken to achieve them.

The base model is sampled using $\text{top}_k = 3$ and $\text{top}_p = 0.9$, with a *temperature* of 0.2 during the simulation/evaluation phase. Extensive hyperparameter tuning will be considered in future work on this task.

4.2 Enriched Prompting

We enrich the root prompt used by the base decoder to contain contextually relevant information that might be helpful during the MCTS decoding. Thus, our root prompt contains: (1) Entire dataframe *schema* for the table, we are generating our prompt, including column names and types (2) A *predicted return type* depending on the question we are answering. We recognize 5 output categories for the task. *boolean*, *category*, *number*, *list[category]* (for lists of categories), and *list[number]* (for lists of numbers). (3) *predicted columns used*, our prediction of the columns most relevant for answering the question.

We use the open source code LLM `Llama-3.1-Nemotron-70B-Instruct` (Wang et al., 2024), to predict the question category, and `Qwen2.5-Coder-32B-Instruct` (Hui et al., 2024) to predict the columns to be used for answering user's natural language query.

4.3 Reward Function

The MCTS function is highly sensitive to the design of the reward function, as the presence or absence of rewards guides the tree search procedure. As user questions are open-ended, it can often be hard to verify whether the generated code and responses are indeed accurate.

We use a three-pronged approach to guessing at the user's intent. (1) First, we use a strictly larger model to predict from the user's query the most probable output type. This probable output type is used to inform both the prompt used during the decoding process, as well as *type-check* the generated responses. (2) Additionally, the generated code is evaluated using a Python interpreter with the dataframe in question in the context of the interpreter. The executable section of the code is *parsed* and extracted from the generated model response. (3) Thirdly, the executable code fragment is run against a synthetic *test-suite* to verify that it passes multiple tests.

Sanity Type Checking and Malformed Code Detection We extract the completion's Pandas query as a single line following the prompt's return statement, truncating any additional extraneous tokens. While currently no explicit token penalty is applied, the short *horizon* biases the model toward concise outputs. The extracted code is then executed against the relevant dataframe, which is added to the interpreter context, and if a runtime error occurs *or* the resulting semantic data type differs from the expected output type, a single error penalty of -1 is imposed. This combination of execution-based feedback and type validation ensures that completions align with each query's requirements.

Test Set Generation In the spirit of *test-driven development*, we leverage large open-source models (`Llama-3.1-Nemotron-70B-Instruct`, `Qwen2.5-Coder-32B-Instruct`) to generate test-cases for a given query. Specifically, we prompt these models with the table schema and instruct them to generate randomized data, parameterized by a *random seed*, while ensuring compliance with the dataframe schema. Since these models have access to the table schema, sample data, and the user's query, they can produce meaningful assertions for validating Python Pandas queries.

During the *evaluation phase*, we run the MCTS- decoder's generated Pandas on the dummy dataframe and verify that all assertions hold. Using different random seeds allows us to execute the query multiple times with varying dummy data, increasing robustness. Additionally, leveraging a diverse ensemble of models for test-case generation enhances confidence in the correctness of a query that satisfies multiple test-cases, rather than relying on any single test instance. A total of five tests are run for each query, with each passing test contributing 0.1 to the final reward value. [4]

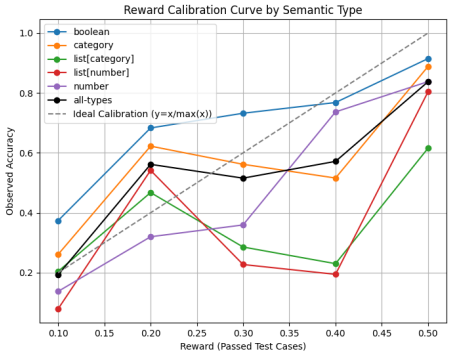

Figure 1: Plot shows the reward calibration for rollouts that passed at least one of the test-cases. We note that boolean, category, and number show good calibration, while list[category], list[number] show relatively poorer calibration, indicating that further testing is required during rollout computation to ensure their accuracy. A maximum of 5 tests are run for each rollout with a random seed. With a reward of 0.1 for each successfully passed test.

Reward Value We use a mixture of penalties for faulty generation and rewards based on the number of tests passed to evaluate MCTS rollouts.

$$r(\text{Query}) = -1 \cdot \mathbb{I}_{\text{error}} + 0.1 \cdot p \cdot (1 - \mathbb{I}_{\text{error}})$$

Where p is the number of test-cases passed by the completion, and $\mathbb{I}_{\text{error}}$ is binary indicator function with values 0 or 1 where 1 indicates the program encounters and error during execution.

5 Results

Table 2 shows the results of running the MCTS decoder with our reward function; we also compare these results by output type category. We note that the use of a reward function leads to substantial

[4] Set of generated tests for training set for competition are available at: https://huggingface.co/datasets/aakarsh-nair/semeval-2025-task-8-test-cases-competition

Approach / Output Type Detail	Base Accuracy (%)	Lite Accuracy (%)
Stable Code-3b-GGUF + Beam Search (Baseline Overall)	26 %	27 %
CodeLlama-7b Python + MCTS Decoding (Our Approach)		
Overall	**61.68**	**64.36**
Breakdown by Output Type:		
Boolean	**76.74**	**74.41**
Category	64.86	67.57
Number	62.82	66.02
List [Category]	50.00	52.77
List [Number]	45.05	53.84

Table 2: Overall numerical accuracy comparison between our MCTS-based approach (CodeLlama-7b Python + MCTS decoding) and the baseline (Stable Code-3b-GGUF + Beam Search). The table also provides a detailed breakdown of the MCTS approach's accuracy by output type. Our method significantly outperforms the baseline, with boolean questions yielding the highest accuracy.

improvement over the baseline. Figure 1 shows that for atomic return types such as *boolean*, *category*, and *number*, rewards are well calibrated. That is, passing a higher number of tests in the synthetic test suite corresponds to higher observed accuracy on the evaluation benchmark.

As the MCTS decoder does not rely on in-context learning, accuracy for both lite and base strategies is roughly equivalent. We note that the results requiring list outputs tend to have the worst performance. While boolean outputs have the highest accuracy level. Table 2 we note that MCTS decoding has a baseline accuracy of 61.68% on base tests and 64.36% on lite tests, compared to the baseline provided by the host on the test set which is 27% base and 26% on the lite dataset, corresponding to a relative improvement of 128.44% on the base test set and 147.54% on the lite test set compared to the baseline.

Output Type	Category Prediction (%)
Boolean	**100.00**
Category	**100.00**
Number	96.79
List [Category]	98.61
List [Number]	82.41
Overall	**95.78**

Table 3: Category prediction accuracy by output type, used in the reward signal. Boolean and Category types showed 100% prediction accuracy.

6 Conclusion

We applied an MCTS-based decoder (Zhang et al., 2023) for code generation in SemEval-2025 Task 8 table-QA.

Unlike conventional autoregressive methods that rely on greedy decoding or single-step chain-of-thought, our approach generates multiple candidate programs and refines them through look-ahead planning. Experimental results show that MCTS decoding achieves a substantial accuracy improvement (61.68% vs. 26% baseline decoding), demonstrating the effectiveness of search-based reasoning for code generation tasks.

Our techniques leverage strong open-source models to guide a smaller local model's decoding, enabling diverse solution generation. Tree search with partial reward signals (e.g., passed tests, semantic type checks) refined solutions by balancing exploration and exploitation. Experiments also revealed that list output types require more robust checks than atomic types, where rewards were better calibrated to accuracy.

This work highlights tree-based planning's potential in code generation for table-centric QA, suggesting avenues for advanced reasoning techniques.

7 Limitation and Future Work

While our MCTS-based approach for table-centric QA significantly boosts accuracy, several limitations remain. First, we frequently observe *semantically identical but syntactically distinct* programs,

resulting in unnecessary redundancy. This is compounded by occasional *extraneous tokens* at the end of generated completions, which we trim to prevent run-time errors but consequently reduce program diversity. Developing more robust code filters or pruning heuristics could improve the uniqueness and readability of generated solutions.

Second, although MCTS captures partial credit via our reward function, *reward design* remains imperfect. For example, incomplete or slightly incorrect solutions may pass partial tests without reflecting deeper logical errors. Future work could explore more fine-grained reward signals, such as dynamic coverage metrics or adversarial test generation, to improve the fidelity of feedback.

Third, we currently *do not fine-tune the model* on the MCTS rollouts or incorporate reward signals into a specialized training loop. Integrating *Expert Iteration* (Anthony et al., 2017) or iterative feedback mechanisms could further refine the policy beyond what standard prompting achieves. Additionally, we have not conducted extensive *hyperparameter searches* for aspects such as number of rollouts or maximum program length, potentially leaving performance gains on the table. These ablations and their performance tradeoffs will be explored in future works.

Lastly, our experiments focus on single-table question answering. Many real-world tasks involve *multiple tables* and heterogeneous data sources, requiring more advanced data integration strategies. Future iterations of our system could merge or join multiple dataframes, broadening its applicability to multi-step queries.

8 Acknowledgments

We would like to thank Dr. Çagrı Çöltekin for his guidance, feedback, and boundless optimism, which helped in the completion of this project. The authors also acknowledge support by the state of Baden-Württemberg through the bwHPC cluster on which most of the experiments were run.

Abstract

Hallucinations pose a significant challenge for large language models when answering knowledge-intensive queries. As LLMs become more widely adopted, it is crucial not only to detect **if** hallucinations occur but also to pinpoint exactly **where** in the LLM output they occur. SemEval 2025 Task 3, Mu-SHROOM: *Multilingual Shared-task on Hallucinations and Related Observable Overgeneration Mistakes*, is a recent effort in this direction. This paper describes the UCSC system submission to the shared Mu-SHROOM task. We introduce a framework that first retrieves relevant context, next identifies false content from the answer, and finally maps them back to spans in the LLM output. The process is further enhanced by automatically optimizing prompts. Our system achieves the highest overall performance, ranking #1 in average position across all languages. We release our code and experiment results.[1]

1 Introduction

Hallucinations in Large Language Model (LLM) outputs remain a significant concern (Sahoo et al., 2024; Huang et al., 2025), undermining user trust in knowledge-intensive tasks. In question answering, hallucinations manifest when models generate false or unverified information given world knowledge while maintaining a coherent response structure (Mishra et al., 2024).

While previous research has developed metrics and benchmarks to detect the presence of hallucinations (Lin et al., 2022; Min et al., 2023), most approaches provide only binary or scalar outputs. These measurements, though valuable, offer limited insight into the specific locations of hallucinated content, despite precise localization being crucial for fact-checking and model improvement.

[1] https://github.com/nlp-ucsc/semeval-2025-task3

The SemEval 2025 Task 3, Mu-SHROOM: *Multilingual Shared-task on Hallucinations and Related Observable Overgeneration Mistakes* (Vázquez et al., 2025), addresses this gap by challenging participants to identify both the spans of hallucinated text and the associated confidence. The task encompasses 14 languages and evaluates system performance on Intersection-over-Union (IoU) and spearman correlation (Corr) on LLM outputs with human-annotated ground truth labels.

The UCSC team approached this challenge using a multi-step framework consisting of: *(i)* context retrieval from external knowledge sources, *(ii)* detection of false or unverifiable content, and *(iii)* mapping error contents back to text spans. Additionally, we explored the use of automatic prompt optimization in step *(ii)* and showed this further improved system performance. The proposed pipeline grounds LLM responses in the retrieved context to distinguish true from fabricated content, while prompt optimization enhances detection reliability and span labeling accuracy.

Our systems rank highly among the submitted systems, achieving a win in 5 languages and a top two position in 11 of the 14 languages on IoU and 10 of the 14 languages on Corr. Our participation in Mu-SHROOM revealed an important insight: when paired with "good context," a simple prompting-based approach can reliably detect hallucinations with better-than-human accuracy.

2 Background

2.1 Related work

Recent efforts aiming at span-level hallucination detection for question answering, such as HaluQuestQA (Sachdeva et al., 2024) and RAGTruth (Niu et al., 2024) provide fine-grained annotations of hallucinated spans, enabling the development of error informed refinement and retrieval-augmented fact-checking systems. For

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 1981–1992

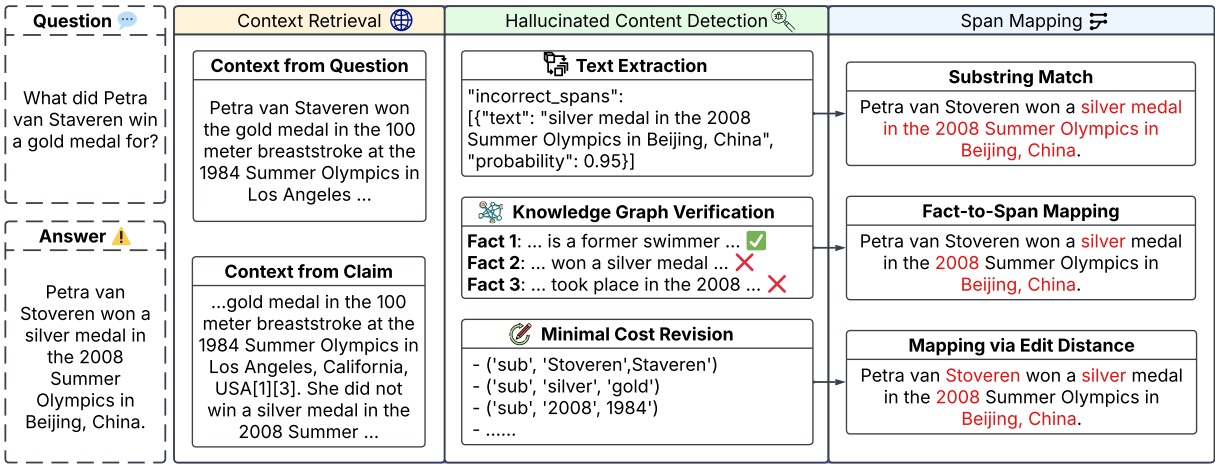

Figure 1: The UCSC hallucination detection framework. We retrieve context from external sources, identify false content in the answer, and then map these errors back to specific spans in the LLM output. In multilingual settings, we explore retrieving context either in the original language or in English by translating the question. In all cases the hallucinated content generated in the second step remains in the original language and is mapped to the answer.

summarization, Zhou et al. (2021) proposes a token-level hallucinations prediction task and introduce a method for learning to solve the task using models fine-tuned on synthetic data. Marfurt and Henderson (2022) proposes to detect hallucinations in an unsupervised fashion from the transformer's self-attentions. Min et al. (2023) proposes to break generations down to atomic facts and assign a binary label to each fact, indicating its truthfulness. However, despite these advances, recent benchmarks, e.g. FaithBench (Bao et al., 2024) highlight persistent challenges, as even state-of-the-art systems struggle at reliably detecting hallucinations. The SemEval-2025 Task 3 (Mu-SHROOM) builds upon these efforts by introducing a multilingual, span-level hallucination detection benchmark, pushing research toward more fine-grained, cross-lingual, and context-aware hallucination localization.

2.2 Task Description

The Mu-SHROOM task aims to identify hallucinated spans in LLM-generated answers across 14 languages. Human annotators provide ground truth labels: a span is a soft label if at least one annotator marks it as hallucinated and a hard label if more than half do. Participants must predict both soft and hard label spans. Hard labels are evaluated using the character-level Intersection-of-Union metric (IoU), while soft labels are evaluated using Spearman correlation (Corr).

3 System Overview

Our main system adopts a three-stage pipeline (see Figure 1), consisting of **context retrieval**, **hallucinated content detection**, and **span mapping**. On top of the three-stage pipeline, we use **prompt optimization** to automatically search for an optimal prompt to perform hallucinated content detection. In addition, we also explored a **system combination** technique where we treated each system as an individual labeler and aggregated the results together to further increase system performance.

3.1 Context Retrieval

Retrieval augmented generation (RAG) (Lewis et al., 2020) has been shown effective at reducing hallucination at knowledge-intensive tasks (Jiang et al., 2023; Gao et al., 2024). We argue it is equally crucial to include relevant context when verifying generated text. Step one in our pipeline is to gather information that should be helpful at either answering the input question or at confirming or refuting claims in the given answer.

Context from Questions Here we use the question directly as the the search query which is passed to an external search API. The returned content is used as the context. We assume that the returned content will contain all information required to answer the input question and thus should be sufficient to verify another answer to the same question.

Context from Claims In this approach, we construct a set of queries from the claims in the answer. The resulting context can then be used to fact-check all claims in the answer, not just those directly related to the question. This approach will help verify claims in the answer that are missing from the context obtained from querying a search API with just the question.

3.2 Hallucinated Content Detection

In step two, we identify content in the answer unverifiable by the retrieved context. Here we compare three distinct implementations.

Direct Text Extraction We prompt the LLM to analyze the answer text and identify specific segments not verifiable from the retrieved context. The LLM compares text in the answer against the context, extracting any text spans that contain information absent from or contradicting the context.

Verification with Knowledge Graph In this approach the context is parsed into a knowledge graph comprising entities and relations, while the answer is decomposed into individual facts. The LLM is then used to verify each fact by querying information about entities, checking for accuracy against the knowledge graph. This method ensures each fact is cross-verified with structured data, with the goal to enhance the reliability of the hallucination detection process.

Minimal Cost Revision In this approach, we use a reasoning LLM to correct the provided answer by making the fewest possible changes. This method ensures that corrections are limited to only the necessary parts of the text, with the differences between the original and corrected answer being deemed hallucinated.

3.3 Span Mapping

After identifying the hallucinated content in the answer, we convert these broad segments into character-level spans. This conversion uses three specific methods, each corresponding to one of the three hallucinated content detection techniques:

Substring Match Match the exact substring to locate the hallucinated spans within the answer. This approach is used with direct text extraction in step 2, where specific segments of text are identified as hallucinated.

Fact-to-Span Mapping We prompt an LLM to map the identified false facts back to the specific spans of the answer text that generated those facts. This method is applied following verification with knowledge graph in step 2, ensuring that each false fact is accurately traced to its source text.

Mapping via Edit Distance Calculate the minimum edit distance required to transform the original answer into the corrected version. During this process, all deletions and substitutions of words are identified, with these words being labeled as hallucinations. This method ensures the precise identification of unnecessary or incorrect information in the text.

3.4 Prompt Optimization with MiPROv2

To refine the hallucinated content detection step, we employed MiPROv2 (Opsahl-Ong et al., 2024), a systematic framework for optimizing prompts in language model programs. MiPROv2 leverages Bayesian search to explore candidate prompts to optimize task metrics (e.g. IoU or Corr). In each iteration, MiPROv2 proposes updates to both the instructions and few-shot demonstrations, evaluates them on a subset of data, and uses those results to guide the next round of proposals. This process systematically discovers prompts that yield strong performance, improving the reliability of step 2.

3.5 Multilingual Systems

Our framework design was motivated by the assumption that the pre-trained LLMs we employed might perform better in English, given the abundance of English-language training data that is generally available. For hallucination detection of non-English text use used exactly the same methods as described above. We did however explore one specific variation: we compared the use of English context vs. target-language (i.e. non-English) context for the 13 other languages within the MuSHROOM task. The English-language context is obtained by translating the given questions or claims into English before retrieval. For the target-language contexts we used the question or claims in the original language to retreive the required context. In both these cases, the unverifiable content is labeled in the original language and then mapped back to the answer.

Table 1: Multilingual test IoU and Corr results. **Opt.** indicates that prompt optimization was performed and **Trans.** indicates if the input was translated into English before performing context retrieval. All contexts are sourced from Perplexity Sonar Pro. IoU is used as the prompt optimization metric for all languages except English, where Corr was applied. We underline the best-performing individual system, and **bold** the overall best.

3.6 Multi-System Combination

Our focus in this work has been to generate hard labels for hallucinated segments with the goal to maximize IoU score. We believe this approach is best if the goal is to provide explicit feedback to users of such systems. For example when we want to highlight which segments in an LLM output could be incorrect or non-factual. When considering the probability of a specific token in an LLM output being a hallucination or not, prior methods largely rely on the language model itself to generate a "likelihood of correctness score." Such scores are found to always be too high, as the models are overly confident of their own output. Additionally, the resulting scores do not align well with the definition of soft labels in the Mu-SHROOM task, i.e., labels based on the proportion of annotators who agree on whether certain spans are hallucinated.

In the Mu-SHROOM challenge task, we attempted to replicate the human labeling process by having multiple different systems output hard-labels. We then combined these sets of hard-labels to generate the soft-labels based on label agreement. The expectation is that like human annotators, systems will vary in which specific tokens they label in the LLM output. For system combination in our submission systems, we combined the output of five different systems together. By treating each system as an annotator, we calculate the proportion of systems that labeled a specific span as hallucinated.

4 Experimental Setup

4.1 Models and Tools

For context retrieval, we use the `sonar-pro` model via the Perplexity API[2] (more details can be found in Appendix C). For the detection of hallucinated content, we generally use OpenAI's `GPT-4o` and `GPT-4o-mini` (OpenAI et al., 2024). For the task of correcting answers with minimal changes, i.e. Minimal Cost Revision as described in section 3.2, we found that the OpenAI `o1` reasoning model (OpenAI, 2024) out-performed the GPT-4 models. For the multilingual systems, we also evaluated the performance of `DeepSeek-R1` (DeepSeek-AI et al., 2025) and when performing system combination, we also included Llama3.3-70B (Grattafiori et al., 2024) as one of the 5 systems that was combined.

We used LangChain[3] to build the pipeline for our submission system and to also construct the knowledge graphs[4] used for the verification with knowledge-graph + fact-to-span mapping approach. DSPy (Khattab et al., 2024) was used to perform prompt optimization. When performing prompt optimization on the validation set we perform 2-fold cross-validation to ensure reliability.

eu	2	1	zh	9	9
Avg IoU rank: 2.6; Avg Corr rank: 2.4					

Table 2: System rankings across all languages.

4.2 Annotations and Alternative Metrics

To better understand the challenges of the hallucination span-labeling task, we manually labeled the English validation set ourselves. When we evaluated our internal annotations against the hard and soft annotations provided by the organizers, we found that our average IoU was 0.43, and the average Corr was 0.40. The best annotator in the group obtained an IoU of 0.48 and a Corr of 0.48 and the annotator with the lowest scores obtained an IoU of 0.37 and a Corr or 0.34. We found that even our best individual annotator performed significantly worse than all of our LLM-based systems. For comparison our best performing system on the validation set obtained an IoU of 0.57 and a Corr of 0.55. We hypothesize that two factors limited our overlap with the ground truth: (*i*) lack of exact reference contexts, leading to discrepancies in verification, and (*ii*) potential differences in labeling guidelines.

Due to the low agreement among our internal annotators, to better guide system development, we introduced a new metric MaxIoU, inspired by the maximum average Jaccard index (Cronin et al., 2017). MaxIoU mitigates human labeling inconsistencies by identifying the IoU with the single annotation that provides the highest IoU, rather than aggregating results into soft or hard labels. The details of the metric are provided in appendix A.

5 Results & Analyses

5.1 Main Results

Across 43 participant groups, the UCSC systems consistently achieve strong performance across almost all languages. Table 2 shows our systems rank in the top two positions in 11 of the 14 languages on IoU and 10 of the 14 languages on Corr. Furthermore, we rank the highest in average position across all 14 languages. As our system development was focused only on English, these results demonstrate the effectiveness and generalization of our approach.

Context	Method	Val		Test	
		IoU	Corr	IoU	Corr
None	Text Extr.+ Substr. Match	0.41	0.45	0.44	0.43
From Q	Text Extr.+ Substr. Match	**0.55**	0.46	**0.56**	0.52
	KG Verif.+ Fact-to-Span	0.23	0.24	0.22	0.19
	Min-cost Revi.+ Edit Dist.	0.52	0.40	0.53	0.49
From C	Text Extr.+ Substr. Match	0.46	**0.48**	0.55	**0.53**
	KG Verif.+ Fact-to-Span	0.22	0.24	0.20	0.14
	Min-cost Revi.+ Edit Dist.	**0.55**	0.46	0.53	0.49

Table 3: English results of different system flows. Text extraction and knowledge graph verification use `gpt-4o-mini` and minimum cost revision uses o1.

Our multilingual results are presented in Table 1. Among single-system results with no prompt optimization or translation, DeepSeek-R1 performs the best in terms of both IoU (0.59) and Corr (0.60). However, when prompt optimization is involved, GPT-4o becomes the overall best model, although not all languages benefit from prompt optimization. Table 1 also compares the effect of translating the question to English before retrieval, and the results indicate it slightly lowers performance: from 0.58 to 0.56 IoU and from 0.54 to 0.53 Corr.

Table 1 further includes the best performing combined system from a diverse set of individual systems. System combination improves Corr score, by 5% on average (between 0% and 12% across the 14 languages) but it generally also incurs a -5% degradation (between 0% and -16% across the 14 languages) in IoU.

5.2 Analysis of Results

System Flow Table 3 compares the performance for different system flows. We found that including retrieved context boosts performance by a considerable margin. Increasing IoU by 27% from 0.44 to 0.56 and Corr by 23% from 0.43 to 0.53. Creating context from questions works slightly better than creating from claims in terms of IoU for text extraction and knowledge graph verification, but for minimum-cost revision, creating context from claims is more effective. We suspect that the reason is that the o1 model can make better use of the fact-checking information because of its reasoning abilities. The knowledge graph-based method performs significantly worse than other approaches, with IoU and Corr scores approximately 1/2 that of the other methods. Upon manual inspection,

Opt. Target	Valid.		Test	
	IoU	Corr	IoU	Corr
✗	0.44	0.51	0.55	0.51
IoU	**0.57**	0.55	0.60	**0.55**
Corr	0.54	0.54	**0.61**	**0.55**
MaxIoU	0.55	**0.57**	0.60	**0.55**
IoU + Corr	0.53	0.56	0.57	0.53

Table 4: English results of GPT-4o on text extraction pipeline with different prompt optimization targets.

we found the knowledge graph verification step can reasonably identify false facts by querying the knowledge graph, but fact-to-span mapping is extremely unreliable, resulting in a high amount of noise in labeled spans. This results in significantly lower overall system performance. Minimum cost revision stands out as a competitive approach, although it has a significantly higher computational cost due to the reasoning required during inference.

Prompt Optimization Table 4 shows the performance of GPT-4o with different prompt optimization targets. The performance gains from prompt optimization are evident. However, no single optimization target consistently outperforms the others across both the validation and test sets. This is likely because we use the same prompting model to propose prompts, despite optimizing different targets.

System Combination As discussed in 3.6, we explored combining predictions from multiple systems to improve correlation scores. We carefully selected a group of high-performing models that differ in architecture, context handling, and optimization strategies. We found that system combination improves Corr score, by 5% on average (between 0% and 12% across the 14 languages) but it generally also incurs a -5% degradation (between 0% and -16% across the 14 languages) in IoU. Details of the multilingual combination systems, including their configurations and methodologies, are provided in Appendix B.

5.3 Error Analysis

Despite achieving remarkable performance, some limitations exist. The system underperforms in Chinese, likely due to the high complexity of Chinese datasets and the models' limited familiarity with this knowledge in Chinese. Upon inspecting the system, we find that it performs well in context retrieval and hallucinated content detection, particularly through the knowledge graph verification approach. This aligns with the observations of inconsistencies in human labeling. Moreover, our system is heavily dependent on the context and the generative labeling capabilities of the LM. Obtaining the extremely high performance of the best-performing system in this paper may not be cost effective in a real-world use case.

6 Conclusion

In this paper we described our system architecture, exploration and submission systems to SemEval 2025 Task 3 (Mu-SHROOM) for multilingual hallucination span labeling in LLM output. Our multi-stage framework, which combines context retrieval, hallucination detection, and span mapping with prompt optimization, achieves strong performance, ranking in the top two positions in 11 of the 14 languages in the evaluation set. Through our work, we discovered that (*i*) retrieving relevant context is crucial for hallucination detection, (*ii*) simple text-extraction often outperforms more complex approaches, and (*iii*) prompt optimization improves system performance. Moreover, we find significant variations in annotated spans among human annotators, even when agreeing on underlying facts, suggesting that a more well-defined framework for annotation could benefit both automatic and human labeling of hallucinated spans.

A MaxIoU

$$\text{MaxIoU} = \max_i \frac{|A \cap B_i|}{|A \cup B_i|}$$

where A is the predicted annotation, B_i represents individual human annotations.

B System Combination

- **`Llama` + Substring Match:** A system using Llama 3.3-70B with maximum substring matching,
- **`o1` + Minimum Edit Distance:** A system based on a reasoning model, `o1`, utilizing minimum edit distance,
- **Prompt Optimization Targeting IoU and Corr:** A system with prompt optimization using MiPROv2 on `gpt-4o` targeting IoU and correlation,
- **Prompt Optimization Targeting MaxIoU:** A system utilizing prompt optimization with MiPROv2 trained on MaxIoU in validation dataset,
- **`gpt-4o-mini` Reasoning**: A system using `gpt-4o-mini` to reason and map via edit distance.

System	IoU	Cor
`Llama` + Substr. Match	0.54	0.51
`o1` + Edit Dist.	0.53	0.49
Prompt Opt. (IoU & Corr)	0.59	0.54
Prompt Opt. (MaxIoU)	<u>0.60</u>	<u>0.55</u>
`gpt-4o-mini` Reasoning	0.54	0.51
Multi-System Combination	**0.61**	**0.65**

Table 5: Performance of individual systems, and the system combination. Among these systems, the combination achieves the highest IoU and significantly improves the correlation.

C Performance Evaluation By Context

In Table 6, we present the performance of the text extraction system across different context sources. This evaluation is conducted on the validation dataset, focusing on the English language. We find context generated by `perplexity-sonar-pro` provides the most performance boost on IoU, thus we conduct all subsequent experiments using `perplexity-sonar-pro` context.

D Prompts

The detail of the prompt used for hallucinated content detection can be also found in the code repository.

D.1 Text Extraction System Prompt

```
Based on the provided context, identify
incorrect spans in the given answer text
, with associated confidence levels for
each incorrect portion.

You will be provided a context with a
question and its corresponding answer.
Your task is to identify any specific
parts of the answer that describes facts
 that are not supported by the context.
If there are multiple incorrect segments
, report each one separately. Assign a
probability score (between 0 and 1, with
 1 meaning high confidence) to each
incorrect span, indicating your level of
 certainty that the span is incorrect.

# Steps
1. **Read the Context**: Carefully read
the provided context.
2. **Analyze the Answer**: Carefully
evaluate the given answer for accuracy
regarding the question and the context.
3. **Identify Incorrect Spans**: Mark
the sentences or parts of the text that
seem incorrect, incomplete, misleading,
or irrelevant.
4. **Assign Probability**: Assign a
confidence score for each answerspan you
 identify as incorrect:
   - A higher score indicates greater
   confidence that an identified segment
    is incorrect.
   - Provide a score for each span
   between 0 and 1.

# Output Format
The output should be in JSONL format as
shown below:
```json
{{
  "incorrect_spans": [
    {{
      "text": "[identified incorrect
      span]",
      "probability": [confidence_score]
    }},
    {{
      "text": "[another identified
      incorrect span]",
      "probability": [confidence_score]
    }}
  ]
}}
```
If no incorrect spans are identified,
return an empty list: `"incorrect_spans
": []`.

Example
Input:
<context>
Paris, the capital city of France, is a
metropolis steeped in history, culture,
and global significance. This
comprehensive analysis will delve into
the city's current status, basic
information, and historical importance,
providing a thorough understanding of
```

Model	Context Source	Method	IoU	Corr
gpt-4o-mini	you.com	Text Extraction + String Match	0.5235	**0.5270**
gpt-4o-mini	perplexity	Text Extraction + String Match	0.5022	0.4774
gpt-4o-mini	perplexity-Llama-3.1-sonar-small	Text Extraction + String Match	0.5133	0.5058
gpt-4o-mini	perplexity-sonar-pro	Text Extraction + String Match	**0.5295**	0.4554

Table 6: Performance evaluation by context in English in validation dataset.

````
why Paris is not just the capital of
France, but also one of the world's most
 influential cities.
</context>

<question>
What is the capital of France?
</question>

<answer>
The capital of France is Berlin.
</answer>

**Output**:
```json
{{
  "incorrect_spans": [
    {{
      "text": "Berlin",
      "probability": 0.99
    }}
  ]
}}
```

# Notes
- Ensure that the probability reflects
your confidence. If unsure about the
degree of incorrectness, use a lower
value.
- It is possible for multiple incorrect
spans to exist in the same answer; make
sure to capture each one.
- If the answer is fully correct, return
 `"incorrect_spans": []`.
- Try to identify the spans as short as
possible.
- The spans should appear in the same
order as they appear in the original
answer.
````

D.2 Knowledge Graph Verification System Prompt

````
Identify incorrect spans in the given
answer text, with associated confidence
levels for each incorrect portion.

You will be provided with a question and
 its corresponding answer. Your task is
to identify any specific parts of the
answer that are factually incorrect,
incomplete, or misleading. If there are
multiple incorrect segments, report each
 one separately. Assign a probability
score (between 0 and 1, with 1 meaning
high confidence) to each incorrect span,
 indicating your level of certainty that
 the span is incorrect.

# Steps
1. **Analyze the Answer**: Carefully
evaluate the given answer for accuracy
regarding the question context.
2. **Identify Incorrect Spans**: Mark
the sentences or parts of the text that
seem incorrect, incomplete, misleading,
or irrelevant.
3. **Assign Probability**: Assign a
confidence score for each span you
identify as incorrect:
  - A higher score indicates greater
  confidence that an identified segment
  is incorrect.
  - Provide a score for each span
  between 0 and 1.

# Output Format
The output should be in JSON format as
shown below:

```json
{{
    "incorrect_spans": [
    {{
        "text": "[identified incorrect
        span]",
        "probability": [confidence_score
        ]
    }},
    {{
        "text": "[another identified
        incorrect span]",
        "probability": [confidence_score
        ]
    }}
    ]
}}
```
- If no incorrect spans are identified,
return an empty list: `"incorrect_spans
": []`

# Example
**Input**:
Question: "What is the capital of France
?"
Answer: "The capital of France is Berlin
."

**Output**:
```json
{{
    "incorrect_spans": [
    {{
        "text": "Berlin",
        "probability": 0.99
    }}
    ]
}}
```

# Notes
- Ensure that the probability reflects
your confidence. If unsure about the
degree of incorrectness, use a lower
value.
- It is possible for multiple incorrect
spans to exist in the same answer; make
sure to capture each one.
- If the answer is fully correct, return
 `"incorrect_spans": []`.
````

```
- Try to identify the spans as short as
possible.
- The spans should appear in the same
order as they appear in the original
answer.
```

D.3 Minimum Cost Revision System Prompt

```
Use the given context, correct the
answer to the question with the minimum
number of changes.

You will be given a context, a question
and an answer to the question. The
answer may not be correct. You need to
make the minimum number of changes to
the answer to make it correct.

Return the corrected answer wrapped in <
corrected_answer> tags.

Note: Do not correct for spelling
mistakes.

<context>
{context}
</context>

<question>
{question}
</question>

<answer>
{answer}
</answer>
```

YNU-HPCC at SemEval-2025 Task 10: A Two-Stage Approach to Solving Multi-Label and Multi-Class Role Classification Based on DeBERTa

Ning Li, You Zhang*, Jin Wang, Dan Xu, and Xuejie Zhang
School of Information Science and Engineering
Yunnan University
Kunming, China
Contact: lining@stu.ynu.edu.cn, yzhang0202@ynu.edu.cn

Abstract

A two-stage role classification model based on DeBERTa is proposed for the Entity Framework task in SemEval 2025 Task 10. The task is confronted with challenges such as multi-labeling, multi-category, and category imbalance, particularly in the semantic overlap and data sparsity of fine-grained roles. Existing methods primarily rely on rules, traditional machine learning, or deep learning, but the accurate classification of fine-grained roles is difficult to achieve. To address this, the proposed model integrates the deep semantic representation of the DeBERTa pre-trained language model through two sub-models: main role classification and sub-role classification, and utilizes Focal Loss to optimize the category imbalance issue. Experimental results indicate that the model achieves an accuracy of 75.32% in predicting the main role, while the exact matching rate for the sub-role is 8.94%. This is mainly limited by the strict matching standard and semantic overlap of fine-grained roles in the multi-label task. Compared to the baseline's sub-role exact matching rate of 3.83%, the proposed model significantly improves this metric. The model ultimately ranked 23rd on the leaderboard. The code of this paper is available at: https://github.com/jiyuaner/YNU-HPCC-at-SemEval-2025-Task10.

1 Introduction

In subtask 1, given a news article and all named entity mentions (NEs) in that article, each mention is required to be assigned one or more role tags (Piskorski et al., 2025; Stefanovitch et al., 2025). Two levels of characters are defined: one for the main characters (protagonist, villain, innocent), and the other for the fine-grained characters. The evaluation criterion of the task is primarily the exact match rate, which measures the consistency between the main role and the fine-grained role of the evaluation prediction and the gold standard.

Semantic overlap (Kumar and Toshniwal, 2024) and ambiguity between fine-grained roles may occur (Peng et al., 2019), making it easy for models to be confused when differentiating. Entity roles are often determined based on the information in the context in which they are located. In news texts, the context in which entities appear may involve various metaphors, sarcasm, or indirect expressions, requiring the system to deeply understand and capture the details of the context. In real data, some roles (especially fine-grained roles) may have small sample sizes, leading to overfitting of common categories and under-identification of rare categories during model training.

In the past, rule-based methods (Grishman, 1996), traditional machine learning methods, or deep learning methods such as BERT (Devlin et al., 2019) and its variant DeBERTa (He et al., 2021), have often been used to solve similar entity character annotation tasks.

The two-stage classification model based on DeBERTa proposed in this paper utilizes the deep semantic representation of the pre-trained language model, combines the entity context, adopts Focal Loss (Lin et al., 2018) to address the category imbalance problem, and employs Optuna (Akiba et al., 2019) to fine-tune hyperparameters for handling entity role labeling tasks with multiple labels and categories.

Although the fine-grained role matching accuracy still has room for improvement, the model demonstrates effectiveness in main role recognition, with an accuracy rate of 75.32%.

The rest of the paper is organized as follows: Section 2 details the two-stage DeBERTa-based role classification model, including the main role and sub-role classification sub-models, and Focal Loss optimization for addressing class imbalance. Section 3 introduces the experimental setup, results analysis, and case study, covering dataset specifications, evaluation metrics, comparisons with base-

line methods, implementation details, and a discussion of the limitations and challenges encountered in both experiments and real-world scenarios. Section 4 concludes the paper by summarizing the experimental outcomes and key findings.

2 DeBERTa-based Two-Stage Role Classification Model

In this paper, a two-stage classification model (Ruder, 2017) based on DeBERTa (Decoded Enhanced BERT with a Decoupled Attention Mechanism) is proposed to handle the complex task of character labeling of named entities in text. The overall architecture of the model is divided into two main sub-models: main role classification and sub-role classification. Each sub-model is designed to predict character labels at different granularities. The main role refers to a more macro category (e.g., protagonist, villain, and innocent), while the sub-role is a more granular category that describes the specific characteristics of an entity. Additionally, Focal Loss is employed to address the category imbalance issue.

2.1 Main Role Classification Sub-model

The main role classification sub-model is responsible for identifying the main role of an entity. Its primary task is to determine whether the entity belongs to the Protagonist, Antagonist, or Innocent category. The sub-model is based on the DeBERTa architecture and utilizes the powerful language representation capabilities learned from pre-training on a large-scale corpus. Through decoding enhancement and decoupling attention mechanisms (Zhang et al., 2021), deep contextual information in text can be effectively captured, and rich semantic representations can be generated by DeBERTa. The input entity mentions are processed by the DeBERTa tokenizer, which encodes the text sequence into a continuous contextual representation. This representation is then fed into the model. Based on these representations, logits values are calculated and output for each category, reflecting the probability distribution of an entity belonging to the Protagonist, Antagonist, or Innocent. The sub-model addresses the category imbalance issue (Buda et al., 2018) through the optimization of the Focal Loss function, improving recognition performance on rare categories.

2.2 Sub-role Classification Sub-model

The sub-role classification sub-model further refines the role labels of entities based on the main role classification. This sub-model is also based on the DeBERTa architecture but is optimized for more sub-role categories, such as *Guardian*, *Tyrant*, *Victim*, etc. The goal of sub-role classification is to identify the specific sub-roles of an entity within the main role category to which it belongs, providing a more granular role label for each entity.

2.3 Focal Loss Layer for Category Imbalance

The Focal Loss layer is integrated into the main role classification and sub-role classification models to address the category imbalance issue (Johnson and Khoshgoftaar, 2019). On unbalanced datasets, traditional loss functions (such as binary cross-entropy) (Zhang and Sabuncu, 2018) are often unable to effectively distinguish between different classes, resulting in excessive learning from samples of common categories and insufficient learning from rare classes during training. By introducing a tuning factor, Focal Loss reduces the focus on easy-to-classify samples and increases the learning of hard-to-classify samples, improving the model's performance on difficult-to-classify low-frequency classes. The formula for Focal Loss is as follows:

$$FL(p_t) = -\alpha(1-p_t)^{\gamma}\log(p_t) \quad (1)$$

where p_t is the predicted probability of the model for the correct class. α is a weight factor that adjusts the importance of different categories. γ is a focused parameter that reduces the relative loss to a correctly classified sample.

The loss function is applied to both the main role and sub-role classification models to ensure that more attention is given to hard-to-classify samples during training. This improves model performance

Type	Learning Rate	Focal Loss α	Focal Loss γ	Batch Size	Epochs
Value	4.86e-05	0.5202	2.9722	8	2

Table 1: Experimental results at each stage of model optimization

Method	Exact Match Ratio	micro P	micro R	micro F1	Main Role Acc.
Baseline	0.0383	0.0468	0.0415	0.0440	0.2581
Ours	0.0894	0.1149	0.1019	0.1080	0.7532

Table 2: Comparison of final results between our method and the baseline

on category-imbalanced datasets. By adopting a two-stage classification architecture and incorporating Focal Loss, the model effectively handles multi-label and multi-class role classification tasks, especially in cases of category imbalance. Experimental results demonstrate that this method achieves good results in both main and sub-role classification tasks, particularly in identifying minority classes (Byrd and Lipton, 2019).

3 Experimental Details

Datasets. The dataset is sourced from SemEval 2025 Task 10, Subtask 1 (role recognition task) and is only studied for the English part. The dataset contains the following: Training: Consists of multiple English-language news articles, each stored in plain text, with the start and end of entity mentions. Development: Serves as the basis for training the final model, which is ultimately used for predicting on the test set. Test: The final test dataset to be submitted for evaluation, the label of which will not be published until submitted. The number of entity mentions, the number of articles, and the distribution of tags for each role (e.g., main role and fine-grained sub-role) in the dataset bring challenges of multi-label, multi-category, and category imbalance to this task.

Evaluation Metrics. To fully evaluate the model's performance on entity character annotation tasks, the following metrics were used: Exact Match Ratio: Measure the accuracy of the label (fine-grained subpersona) predicted by the model versus the gold standard (Tsoumakas and Katakis, 2007). Micro Precision / Recall / F1: In multi-label, multi-category scenarios, micro-average precision, recall, and F1 scores are calculated from the prediction results of all sub-character samples (Sokolova and Lapalme, 2009). Main Role Accuracy: Specifically measures the accuracy of the model in predicting the main characters (Protagonist, Antagonist, Innocent). In this task, the official evaluation metrics are mainly based on the accuracy of fine-grained roles, etc., and the accuracy of the main roles is evaluated to reflect the system's ability to capture information about core characters.

Baselines. The official dev set provides two baseline prediction methods: random prediction and majority voting prediction. In random prediction, a role from the lists of main roles and sub-roles is chosen randomly. In majority voting prediction, the most frequently occurring main and sub-roles in the training data are selected as the predicted output. On the final test set, the baseline achieved a sub-role exact match rate of only 0.0383, and the main role accuracy was only 0.2851.

Implementation Details. In the final submission, the microsoft/deberta-base PLM was used as the text feature extractor and encoder, with its built-in tokenizer (DeBERTa Tokenizer) applied for text tokenization. SpaCy (Albade and Salisbury, 2022) was utilized for basic text cleaning and punctuation processing. For each entity mention, context of 100 characters before and after its start and end positions in the original text was extracted to ensure sufficient semantic information. The maximum token length was limited to 128 to meet the model's input requirements, and samples exceeding the length limit were checked.

Parameters Fine-tuning. In the Dev set, the Optuna tuning tool is used in this paper, and the optimal hyperparameter combination is shown in Table 1.

Result. Experimental results show that an accuracy of about 75.32% is achieved in the prediction of the main role, verifying the effectiveness of the proposed two-stage classification method in capturing core role information. Compared to the baseline's Main Role Acc of 25.81%, our method shows a significant improvement of approximately 49.51 percentage points. However, the exact match rate for sub-roles is low, at only 8.94%, mainly due to the strict matching requirements of multi-tag and

Method	Exact Match Ratio	micro P	micro R	micro F1	Main Role Acc.

Table 4: Parametric sensitivity experimental results for focal loss

multi-category tasks and the ambiguity between fine-grained roles. The low micro-average metric further indicates that fine-grained persona prediction remains challenging, particularly in terms of handling persona segmentation. Comparison with the benchmark model shows that, while the proposed method demonstrates clear advantages in predicting main roles, significant improvement is still needed for fine-grained role matching.

However, after the competition ended, the model was further optimized, resulting in significant performance improvements.

Firstly, an incremental approach was adopted to explore effective solutions for the role recognition task, and the experimental results at each stage are shown in Table 3:

- **Zero-shot learning baseline**: An unsupervised zero-shot learning method (Xian et al., 2020; Yin et al., 2019) was used, which performed poorly on the test set. The exact match rate was only 0.85%, and the main role accuracy was 16.17%. This confirmed the limitations of the unsupervised paradigm for this task.

- **Semantic enhancement method**: After introducing a BERT-based semantic similarity matching, the model performance improved significantly. The exact match rate increased to 2.55%, and the main role accuracy reached 39.15%. However, the micro F1 score remained below 3%, indicating that relying solely on surface-level semantic matching failed to capture the deeper role relationships.

- **Description enhancement strategy**: By adding role description information, the precision of sub-role prediction increased to 3.4%, and the F1 score reached 4.4%. However, the main role accuracy showed no significant change, suggesting that description information has a specific enhancement effect on fine-grained classification.

- **End-to-end classification model**: A BERT-based sequence classification model was built, with a 128-token length truncation strategy. MultiLabelBinarizer was used for label vectorization. Binary cross-entropy loss (BCEWithLogitsLoss) and the AdamW optimizer (learning rate 2e-5) were used, and the model was trained for 3 epochs with a batch size of 32. This approach led to an exact match rate of 0.34% and a main role accuracy of 73.62%, confirming the effectiveness of the end-to-end deep learning method for this task.

Subsequently, an end-to-end Transformer architecture based on DeBERTa-v3 was adopted, with dynamic context window extraction (extract_entity_context) employed to enable context-aware modeling. The model jointly learns the main role (forced constraint as Antagonist) and sub-role classification tasks, and a probabilistic filtering mechanism is introduced to constrain the sub-role candidate space. The loss function uses the improved binary cross-entropy Focal Loss (Equation 2), and the parameter sensitivity experiment results are shown in Table 4.

$$L = -\frac{1}{C}\sum_{c=1}^{C}\alpha_c(1-p_c)^{\gamma}y_c\log(p_c) \qquad (2)$$

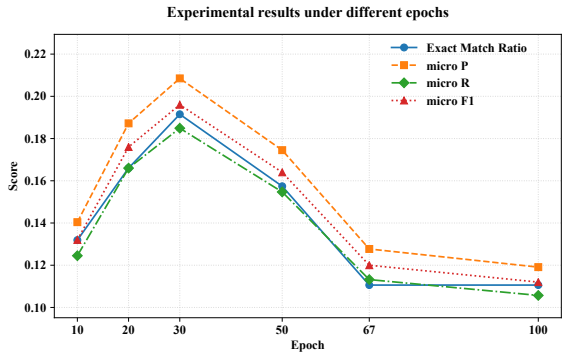

Figure 2: Experimental results under different epochs

The experiment shows that when α = 0.4 and γ = 1.5, the sub-role exact match rate reaches the optimal value of 11.49%. This parameter combination effectively alleviates the class imbalance issue by reducing the weight of the majority class ($\alpha <$ 1) and increasing the attention on difficult samples ($\gamma >$ 1).A contrastive learning framework based on Sentence-BERT (Reimers and Gurevych, 2019) was constructed, with the first 500 characters of the text directly extracted to generate embedding vectors (Wang et al., 2022). Sub-role classification was performed using a fully connected network (with the main role constrained to Antagonist). Standard cross-entropy loss (Equation 3) was used, and the training dynamics are shown in Figure 2.

$$L = -\sum_{c=1}^{C} y_c \log(\text{softmax}(z_c)) \qquad (3)$$

It can be observed that the sub-role exact match rate reaches its highest value of 0.1915 at epoch 30. As shown in the table, with the increase in training epochs, the model's performance on the minor categories first improved and then declined. The Exact Match Ratio and micro F1 peaked at epoch 30 (19.15% and 19.6%, respectively), and then gradually decreased due to overfitting (dropping to 11.06% and 11.2% at epoch 100).

Discussion. The overall exact match rate and other metrics for fine-grained role prediction are low, reflecting issues such as semantic overlap, data sparsity, and class imbalance between fine-grained roles in multi-label, multi-class scenarios. The model still requires further optimization.

Future work may explore the introduction of additional data augmentation strategies, deeper model architectures, and more advanced balancing techniques to further improve sub-role identification accuracy and the overall performance of the model.

Case Analysis. This study investigates the dynamic learning mechanisms and limitations of semantic models in complex moral categorization through a text-based entity classification task analyzing the role of *Washington* in the text fragment (EN_UA_DEV_100012.txt).

Zero-shot learning misclassifies the entity as *Protagonist/Virtuous* due to reliance on generalized narrative patterns, exposing how pre-trained knowledge obscures contextually critical semantics. Similarity matching and rule-based models generate biased labels like *Forgotten/Exploited* through shallow lexical associations (e.g., passive voice, resource-related conflict terms), confirming the failure of heuristic methods in decoding power-dynamic behaviors. While the BERT baseline captures the *Antagonist* primary category via pre-trained semantic understanding, its misattribution of systemic corruption to an individualized *Conspirator* reflects pre-trained models' inability to disentangle institutional power alienation mechanisms.

Parameter sensitivity tests (α/γ adjustments causing *Tyrant/Instigator* misclassifications) confirm that loss function design must balance explicit conflict terms and morally ambiguous representations to prevent attention mechanisms from fragmenting compound semantic features.

Experiments show that models need over 30 epochs to overcome initial stereotypical categorizations like *Foreign Adversary,* gradually forming stable correlations between *Corrupt* and implicit textual features (e.g., policy-embedded benefits, metaphors of power abuse). This hysteresis highlights moral categorization's reliance on deep contextual interdependencies.

The case underscores two challenges in entity classification: mitigating narrative biases while refining perception of power-ethics interactions. Future improvements via domain-specific knowledge graphs and adaptive attention could enhance models' ability to decode complex institutional semantics like systemic corruption.

4 Conclusions

In this paper, a DeBERTa-based two-stage role classification model is proposed for the role recognition task in SemEval 2025 Task 10, Subtask 1. The model successfully addresses the multi-label, multi-class role classification problem through a main

role classification layer and a fine-grained sub-role classification layer, and Focal Loss is used to optimize the class imbalance issue. This two-stage structure allows the model to not only accurately predict the main roles in news texts but also further identify fine-grained sub-roles, improving the precision of role categorization. Experimental results show that the model outperforms the baseline methods in all evaluation metrics. Main role accuracy reached 75.32%, but the exact match rate for sub-roles were low, at 0.0894, mainly due to the strict matching criteria in the multi-label task and semantic overlap in fine-grained roles.

Empaths at SemEval-2025 Task 11: Retrieval-Augmented Approach to Perceived Emotions Prediction

Lev Morozov[1], **Aleksandr Mogilevskii**[2], **Alexander Shirnin**[1]
[1]HSE University, [2]Independent researcher
Correspondence: ashirnin@hse.ru

Abstract

This paper describes EmoRAG, a system designed to detect perceived emotions in text for SemEval-2025 Task 11, Subtask A: Multi-label Emotion Detection. We focus on predicting the perceived emotions of the speaker from a given text snippet, labeling it with emotions such as joy, sadness, fear, anger, surprise, and disgust. Our approach does not require additional model training and only uses an ensemble of models to predict emotions. EmoRAG achieves results comparable to the best performing systems, while being more efficient, scalable, and easier to implement.

1 Introduction

SemEval-2025 Task 11 (Muhammad et al., 2025b) introduces a new task and a multilingual, multi-label, emotion-annotated dataset of texts. This task focuses on perceived emotion detection, aiming to determine the emotions that most readers would infer a speaker is experiencing based on a given text snippet. It does not concern the emotions evoked in the reader or the speaker's true emotions. Instead, it addresses how emotions are commonly interpreted, recognizing that perception may be influenced by cultural context, individual expression differences, and the nuances of text-based communication. The shared task consists of three subtasks: (A) **Multi-label Emotion Detection**, that involves predicting which emotions are perceived in the speaker's words; (B) **Emotion Intensity Prediction**, which quantifies the strength of an expressed emotion on an ordinal scale; and (C) **Cross-lingual Emotion Detection**, which assesses how well models generalize perceived emotion detection across languages using training data from a single language.

This paper proposes EmoRAG, a Retrieval-Augmented Generation (RAG) system (Lewis et al., 2020) for the Subtask A, Multi-label Emotion Detection. However, its flexible design allows for seamless adaptation to the other subtasks, Emotion Intensity Prediction (Subtask B) and Cross-lingual Emotion Detection (Subtask C), with minimal modifications. This versatility makes EmoRAG a robust solution for the diverse challenges posed by SemEval 2025 Task 11.

2 Background

Related work A common approach to multi-label emotion classification involves fine-tuning a pre-trained transformer model with a linear classification head (Kulkarni et al., 2021; Kane et al., 2022), often with minor architectural modifications to adapt to the specific task. Although such methods have shown strong performance in monolingual settings, emotion classification in a multilingual context presents additional challenges due to linguistic variability and cultural nuances in emotional expression (Kadiyala, 2024). To address these issues, we propose an alternative framework based on RAG. Unlike standard systems that rely solely on encoded representations, our method leverages the annotated training data as a retrieval corpus, enabling the model to draw on relevant emotional instances during inference, and thereby improve its robustness across languages and cultures.

Datasets The BRIGHTER dataset (Muhammad et al., 2025a) is a multilingual, multi-labeled collection of textual data annotated for emotion recognition in 28 languages. The dataset primarily addresses the disparity in emotion recognition resources, particularly for low-resource languages spoken in Africa, Asia, Eastern Europe, and Latin America.

The data is drawn from diverse sources, including social media posts, personal narratives, speeches, literary texts, and news articles, ensuring a broad representation of emotional expression across different cultural and linguistic contexts.

Each instance in the BRIGHTER dataset is man-

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2000–2007

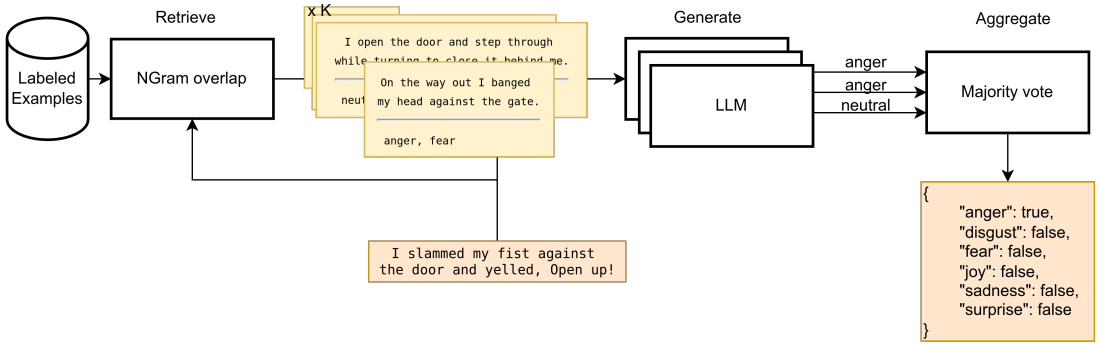

Figure 1: The EmoRAG pipeline involves a database, a retriever, a generator, and an aggregation model.

ually curated and annotated by fluent speakers to capture six primary emotions: *joy, sadness, anger, fear, surprise, disgust*, and a *neutral* category. The annotations are multi-labeled, allowing each text snippet to be associated with multiple emotions.

The dataset encompasses both high-resource languages such as English and German and predominantly low-resource languages, including Hausa, Kinyarwanda, Emakhuwa, and isiZulu. The distribution of data sources varies across languages, with some relying on re-annotated sentiment datasets, human-written and machine-generated texts, and translated literary works. Notably, some datasets, such as Algerian Arabic, include translated excerpts from literary texts like *La Grande Maison* by Mohammed Dib, whereas others, such as Hindi and Marathi, incorporate sentences generated by native speakers based on given prompts.

Some examples of the BRIGHTER dataset are shown below:

- "I can't believe this happened! I'm so excited and grateful!" (Emotion labels: Joy, Surprise, Intensity: 3)
- "Why do people always have to be so cruel? This is heartbreaking." (Emotion labels: Sadness, Anger, Intensity: 2)
- "Walking through the dark alley gave me chills. I couldn't shake off the fear." (Emotion labels: Fear, Surprise, Intensity: 3)

Track A of the SemEval 2025 focuses on prediction emotions, ignoring intensity.

In addition, the EthioEmo dataset (Belay et al., 2025), introduced in a separate study, expands multilingual emotion recognition by incorporating four Ethiopian languages: Amharic, Afan Oromo, Somali, and Tigrinya. This extension further improves coverage for underrepresented languages, providing valuable benchmarks for evaluating large language models in multi-label emotion classification tasks.

It is important to note that the languages Zulu (zul), Xhosa (xho), Javanese (jav), and Indonesian (ind) were not part of the competition; therefore, the results for these languages are not presented in this paper.

3 EmoRAG

First, we overview the EmoRAG pipeline. Next, we detail the procedures for the database, retriever, generators, and aggregation model.

Overview The EmoRAG pipeline consists of several components designed for emotion recognition:

(a) The database is created using labeled training examples.

(b) A retriever is used to fetch the top-K most similar examples from the training data.

(c) The retrieved examples are used as few-shot prompts for the decoders, which are a collection of large language models (LLMs).

(d) An aggregation model combines the predictions from the generators to produce the final output.

The overview of the EmoRAG pipeline is shown in Figure 1.

To make a prediction for a new entry in a known language, the system first uses the retriever to obtain the most similar examples from the database.

Once the most similar examples are retrieved, these examples are used as few-shot prompts for the decoder models. Models utilize these prompts to predict the perceived emotions in the new text entry.

Each decoder model produces a set of emotion predictions, which are then aggregated to form the final prediction.

The aggregation model combines the outputs from the different decoder models. This can be done using various strategies, such as majority voting or weighted averaging based on model performance metrics. The final output is a multi-label prediction indicating the perceived emotions present in the text.

4 Experiments

The main three components of EmoRAG are the retriever, the generator models, and the aggregation model.

Retrievers We experimented with an n-gram based retriever and a sentence embedder-based retriever *BGE-M3* [1] (Chen et al., 2024). The n-gram based retriever is hypothesized to perform better for low-resource languages due to its reliance on surface-level text features. We have used the n-gram retriever from the `LangChain module` [2] (Chase, 2022).

The number of retrieved examples (K) is fixed to 30 for low-resource languages and 100 for high-resource languages. The reason for this is that low-resource languages consume more tokens and thus more compute.

Decoder Models The EmoRAG system employed four different LLMs: *Llama-3.1-70B* [3] (Grattafiori et al., 2024), *Qwen2.5-72B-Instruct* [4] (Yang et al., 2024), *gpt-4o-mini-2024-07-18* (hereafter referred to as gpt-4o-mini), and *gemma-2-27b-it* [5] (Team et al., 2024). The LLM system prompt is in English and only specifies the language of the input text. We experimented with prompts in the target language for which predictions were made but found that English prompts yielded better results. We provide the whole system prompt in the appendix A.

Aggregation Strategies We tested five aggregation strategies to combine predictions from different models:

- **Single Model**: Outputs the prediction of a fixed model, such as gpt-4o-mini.
- **Majority Vote**: Each label's prediction is the majority vote across all LLM predictions.
- **Macro/Micro Majority Vote**: Weighted averages of predictions from different LLMs, with weights based on macro/micro F1 scores on the dev data.
- **Label-F1 Majority Vote**: Weighted averages for each label, with weights based on macro/micro F1 scores for each label and model.
- **GPT-4o Aggregation**: Provides results from different models to gpt-4o-mini, along with few-shot examples, to aggregate a response.

5 Results

The results of our experiments are summarized in the Table 1. More detailed results are provided in Table 2, which includes the performance of each model separately on the development set. The EmoRAG system demonstrated strong performance across a wide range of languages, with the majority_vote_by_label_f1 aggregation strategy generally yielding the best results.

Performance Across Languages The system achieved high F1-micro and F1-macro scores in high-resource languages such as English, Spanish, and Russian, with scores exceeding 0.80. In low-resource languages, the performance was more variable, but the system still achieved competitive results, particularly with the use of the n-gram retriever.

Best Models For each language, the best-performing model and aggregation strategy were selected based on the development set results. The majority_vote_by_label_f1 strategy was often the best choice, indicating the effectiveness of leveraging label-specific F1 scores for aggregation.

General Observations The experiments highlighted the importance of selecting appropriate retrievers and aggregation strategies based on the language and resource availability. The EmoRAG system's flexibility in adapting to different languages and tasks makes it a robust solution for multilingual emotion detection.

Overall, the EmoRAG system achieved an average test F1-micro score of 0.638 and an F1-macro score of 0.590 across all languages, demonstrating its effectiveness in the SemEval-2025 Task 11.

6 Conclusion

This paper presents the EmoRAG system submitted to SemEval-2025 Task 11. Our system achieved strong performance across multiple languages, demonstrating its effectiveness in multilingual emotion recognition. EmoRAG introduces a novel pipeline that integrates RAG with LLMs and an adaptive aggregation mechanism. The combination of diverse retrievers and model-specific aggregation strategies enables flexible and robust emotion detection, particularly for low-resource languages. We believe this approach holds significant potential for improving multilingual NLP tasks by leveraging retrieved examples to enhance model predictions. Our Future research will be focused on refining retrieval methods, exploring alternative RAG techniques, and investigating the use of smaller, more efficient models to improve scalability and accessibility across different com-

putational environments.

Acknowledgments

LM's and AS's work results from a research project implemented in the Basic Research Program at the National Research University Higher School of Economics (HSE University). We acknowledge the computational resources of HSE University's HPC facilities.

Limitations

While EmoRAG demonstrates strong performance, it has certain limitations. The current dataset includes a limited set of emotions, making it unclear how the method would generalize to a broader range of emotions. Additionally, the approach may struggle with highly imbalanced class distributions or significant distribution shifts in the data. Future work will focus on addressing these challenges by testing on more diverse datasets and improving robustness to class imbalance and domain shifts.

A LLM Prompt for Emotion Detection

The following prompt is used to instruct the language model for perceived emotion detection:

Emotion Detection Prompt

```
You are an expert at detecting emotions in
text. The texts are given in {language}
language.
Please classify the text into one of the
following categories:
Anger, Fear, Joy, Sadness, Surprise, Disgust
Your response should be a JSON object with
the following format:
{
    "anger": bool,
    "fear": bool,
    "joy": bool,
    "sadness": bool,
    "surprise": bool,
    "disgust": bool
}
Do not give explanations. Just return the
JSON object.
```

IUST_Champs at SemEval-2025 Task 8: Structured Prompting and Retry Policy for Tabular Question Answering

Abstract

This paper presents a novel approach to the task of Question Answering over Tabular Data, as part of SemEval-2025 Task 8. Our system generates executable Python code to derive answers directly from structured data, leveraging open-source large language models. Key innovations include structured prompting, semantic column filtering, and a one-time retry mechanism to enhance accuracy and robustness.
We evaluate our approach on the DataBench and DataBench_Lite datasets, significantly outperforming the baseline accuracy (26-27%) with our best system achieving 70.49% accuracy on the test set. Ablation studies confirm that few-shot prompting and rule-based type classification are crucial for improved performance. Despite these advancements, challenges remain in handling complex table structures and ambiguous queries. Our findings highlight the effectiveness of code-generation-based methods for tabular question answering and provide insights for further research in this area.

1 Introduction

Question answering is to generate precise answers by efficiently interacting with unstructured, structured, or heterogeneous contexts, such as paragraphs, knowledge bases, tables, images, and their combinations. Among these, question answering over tabular data or Tabular Question Answering (TQA) is a challenging task that requireserstanding of table semantics, as well as the ability to reason and infer over relevant table cells (Jin et al., 2022; Wang et al., 2024; Zhao et al., 2023). TQA has been studied with a specific focus as it allows conveniently querying the table in natural language to extract desired information (Patnaik et al., 2024).

Recently, Large Language Models (LLMs) have demonstrated their effectiveness and versatility across diverse tasks, leading to significant advances in natural language processing. This success has spurred researchers to investigate the application of LLMs to table-related tasks (Lu et al., 2025). Many text-related tasks, particularly in the domains of science, technology, engineering and mathematics (STEM), often require intricate reasoning and the use of external tools. However, table processing tasks differ in nature due to the inherent structure of tables and the specific user intent of extracting knowledge from them. For example, LLMs must comprehend table schemas, navigate data within two-dimensional tables, and execute SQL queries to retrieve relevant information. The distinct challenges associated with table processing underscore the importance of adapting LLMs to meet these specialized requirements. Early research, such as TaBERT (Yin et al., 2020), TaPas (Herzig et al., 2020), TURL (Deng et al., 2022), and TaPEx (Liu et al., 2021), adheres to the paradigm of pre-training or fine-tuning neural language models for tables.

DataBench (Os'es Grijalba et al., 2025) is a comprehensive benchmark designed for TQA. Its primary objective is to provide a standardized framework for evaluating and comparing LLMs as tabular reasoners, while also offering flexibility for the comparison of other types of question answering models.

The main strategy of our system for TQA is executable Python code generation to compute answers directly from the provided tabular data. Instead of relying on in-context learning, which struggles with long-table contexts, our approach ensures accurate execution by generating and running Python functions over the dataset. Key techniques include column filtering using semantic similarity to reduce prompt length while retaining relevant information, few-shot prompting to guide concise function generation, and a one-time retry mechanism to handle execution failures. The system employs Qwen2.5-Coder-32B as the primary model for function generation, enhancing accuracy and

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2008–2013

robustness.

Additionally, we discovered that structured prompting, column filtering, and a one-time retry mechanism significantly enhance accuracy. Our system outperformed the baseline accuracy reported in the original DataBench paper (26% for DataBench and 27% for DataBench_Lite). Empirical analysis demonstrated that few-shot prompting improved response consistency, while the retry mechanism reduced execution failures by enabling the model to regenerate more robust code. Column filtering effectively minimized ambiguity by restricting input to the most relevant attributes. However, our system struggled with complex multi-column reasoning, particularly when implicit relationships between columns needed to be inferred. These findings highlight both the strengths of our approach and areas for future improvement in handling more intricate tabular reasoning tasks. Our code is publicly available at https://github.com/Arshia-HZ/DataBench-TQA

2 Related Work

Tabular question answering task requires both the ability to reason over structured data and to understand textual contents in the table. Traditional methods utilize semantic parsing to convert the natural language question into executable commands, which retrieve and process data in the table to obtain answers (Liu et al., 2024). LLMs can learn from a few samples as prompts through in-context learning. This strategy is widely used to give models additional instructions to better solve downstream tasks (Wang et al., 2024)

- **Table Tuning** (Wang et al., 2024; Lei et al., 2023) focuses on LLMs' understanding of tables. This type of research utilizes general-purpose foundation LLMs (e.g., Llama) and a substantial volume of table-related data for instruction tuning. Table tuning examples include Dater (Ye et al., 2023) is the only model that modifies the tabular context while solving table-based tasks. However, the table decomposition in Dater is motivated by the idea that tables could be too large for LLMs to conduct reasoning. It is, therefore, more similar to an LLM-aided data pre-processing than to a part of the reasoning chain since the tabular operations are limited to column and row selections, and fixed for all tables and questions.

- **Code Tuning** (Liu et al., 2024; Kweon et al., 2023; Wang et al., 2025; He et al., 2024) To better solve table-based tasks with LLMs, researchers go beyond general text and resort to using external tools. Propose solving reasoning tasks by generating Python programs and executing them using the Python interpreter. This approach greatly improves the performance of arithmetic reasoning. To further push the limits of programs, Binder (Cheng et al., 2022) generates SQL or Python programs and extends their capabilities by calling LLMs as APIs in the programs.

- **Hybrid of table and code** research reveals that table instruction tuning based on code LLMs is more effective, i.e., code LLMs are tuned using table instruction datasets (Liu et al., 2024).

In this study, we utilize DataBench, a benchmark consisting of 65 real world datasets, with 3,269,975 and 1615 columns in total from different domains, widely different numbers of rows and columns and heterogeneous data types. Moreover, DataBench has 20 hand-made questions per dataset, with a total number of 1300 questions. Questions are further split in different types depending on the type of answer (i.e., true/false, categories from the dataset, numbers or lists), and each question is accompanied by their corresponding gold standard answer. The dataset is entirely in English. The benchmark consists of two subtasks:

- Subtask A: Utilizes the original DataBench dataset.

- Subtask B: Employs a sample of 20 rows extracted from the original DataBench dataset, referred to as DataBench_Lite.

3 System Overview

Our Tabular Question Answering (TQA) system generates and executes concise Python functions to answer natural language queries over structured tables. By leveraging code execution, we guarantee both accuracy and interpretability, avoiding common failures of pure language-model-based approaches on long or wide tables.

3.1 Column Selection

To reduce prompt length and noise, we filter the most relevant columns for each question:

1. **Semantic Similarity Scoring**: We embed column names and the input question using a pre-trained sentence embedding model (e.g., SBERT) and compute cosine similarity.

2. **Top-k Selection**: We select the top-k columns with highest similarity scores, ensuring key attributes are retained while minimizing context size.

3.2 Answer Type Classifier

Inferring the expected output type guides structured responses:

- **Heuristic Analysis**: We parse question tokens (e.g., How many", What is the average") to predict return types such as `integer`, `float`, `string`, or `list`.

- **Template Enforcement**: The predicted type constrains the generated function signature and final `return` statement, reducing malformed outputs.

3.3 Code Generation via Few-Shot Prompting

Our system uses a few-shot prompting strategy to generate Python functions that return the final answer in a single line. Each prompt includes a number of carefully selected demonstrations that cover a range of typical operations. All examples follow a consistent format, using minimal syntax and a simple `def answer(table):` signature to guide the model toward generating clean and executable code.

To maintain output quality and reliability, we employ Qwen2.5-Coder-32B, a high-performance language model optimized for code generation. Rather than relying on rigid templates, we organize the examples in a coherent, narrative format that exposes the model to diverse query styles and computational needs. This approach helps the model identify and apply the right patterns when faced with new questions.

This strategy enhances the model's ability to generalize across diverse queries and tabular structures. Compared to a templated baseline, our method achieves a noticeable improvement in robustness and code quality (see Table 1).

A high-level overview of the code generation workflow is shown in Figure 1.

3.4 Execution and Retry Mechanism

To handle occasional generation errors:

- **Automatic Execution**: We run each function in an isolated Python environment with the filtered DataFrame.

- **One-Time Retry**: If execution fails (e.g., `KeyError`, `TypeError`), we append the error message to our prompt and request a corrected function.

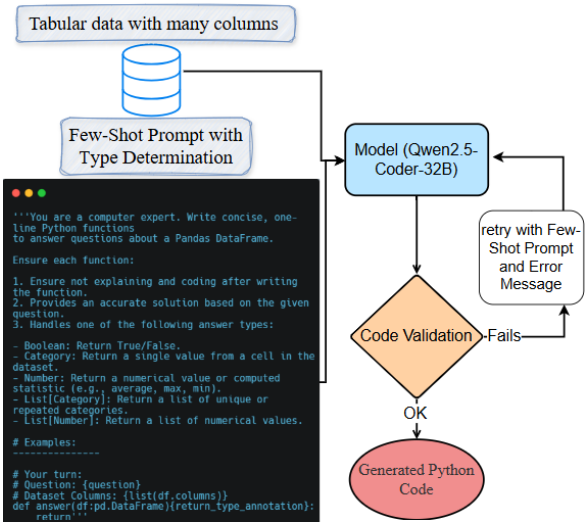

Figure 1: Tabular Question Answering Workflow Using Few-Shot Prompting and Retry Mechanism for Robust Code Generation.

4 Experimental Setup

All experiments utilize the official train/dev/test splits provided in DataBench and DataBench_Lite. DataBench_Lite consists of tables with a maximum of 20 rows, while DataBench includes tables with significantly larger numbers of rows. Accuracy is used as the primary evaluation metric, computed using the databench_eval package.
During development, we tested different few-shot strategies, varying the number of examples between 1 and 5, and validated their effectiveness on the dev set. The final configuration was determined through manual tuning, selecting the number of examples that maximized accuracy without exceeding context limits. No additional text preprocessing was applied beyond standard column filtering, ensuring fair evaluations across datasets. The following definitions differentiate between model configurations:

- Baseline: Standard prompting without column filtering or retry mechanisms.
- Few-shot: Incorporates in-context examples for improved generalization.
- Retry-enabled: Implements a one-time retry policy for execution failures.

Experiments were conducted in two parts:

1. Code generation using Qwen2.5-Coder-32B with structured few-shot prompting.
2. Error handling through execution retry strategies.

Hyperparameter tuning focused on key parameters such as temperature (0.7), max tokens (512), and prompt format variations. These were manually adjusted based on dev set performance. Since execution failures were a significant concern, our retry mechanism involves resubmitting the prompt with error details when execution fails, enabling the model to generate more robust solutions.
The databench_eval package is used to compute accuracy, ensuring automated comparison against gold-standard answers. The original DataBench paper reported a baseline accuracy of 26% for both DataBench and 27% for DataBench_Lite. Our best-performing system, which leverages open-source models alongside structured prompting and retry mechanisms, significantly improves upon this baseline. Through systematic preprocessing, prompt engineering, and controlled error handling, our system achieves substantial accuracy gains over the benchmark.

5 Results

Our system demonstrates substantial improvements over the baseline accuracy reported in the original DataBench paper. The baseline accuracy for DataBench and DataBench_Lite was 26% and 27%, respectively, whereas our best-performing configuration, utilizing structured prompting and a one-time retry mechanism, achieves significantly higher accuracy on both benchmarks (see Table 1).
To analyze the impact of different design choices, we did some research. Few-shot prompting resulted in a noticeable improvement over zero-shot prompting, as it provided structured examples that guided the model toward more accurate predictions. The retry mechanism contributed to further accuracy gains by allowing the model to regenerate more robust code when execution failures occurred. We also evaluated the effect of column filtering, observing that restricting the input to the most relevant columns reduced ambiguity and improved performance.Figure 2.
Error analysis reveals that the system still struggles with complex multi-column reasoning, especially when implicit relationships between columns must be inferred.

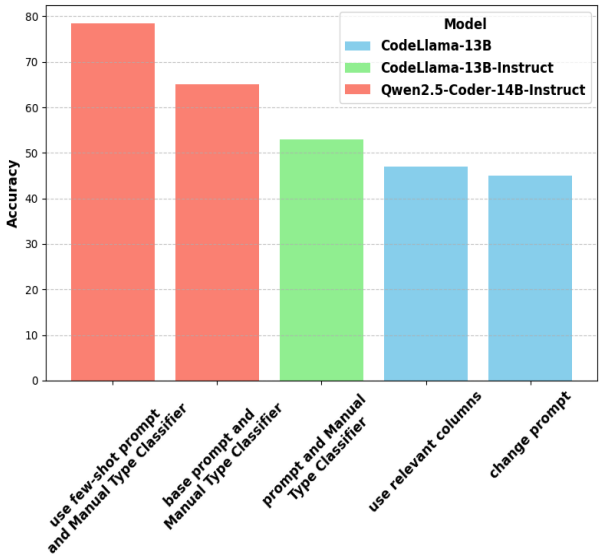

Figure 2: Accuracy of different model configurations and prompting strategies on the development set.

6 Conclusion

In this work, we introduced a Tabular Question Answering (TQA) system that generates executable Python code to compute answers directly from tabular data. Our approach incorporates structured prompting, semantic column filtering, and a retry mechanism to enhance robustness. We evaluated our system on the DataBench and DataBench_Lite datasets, achieving significant improvements over the reported baselines. Experimental results demonstrate that few-shot prompting combined with a manual type classifier leads to the highest accuracy, with Qwen2.5-Coder-32B achieving 70.49% accuracy on the test set. Table 1.

Future work includes refining the column selection process by incorporating adaptive filtering strategies, integrating more advanced program synthesis techniques to improve code reliability, and expanding the system to handle more complex table structures. Additionally, exploring alternative

Experiment	Model	Databench	Databench_lite
Zero-shot prompt + Type Classifier	CodeLlama-13b-Instruct	53.26	54.40
Few-shot prompt + Type Classifier	Qwen2.5-Coder-14B-Instruct	65.33	68.96
Few-shot prompt + Type Classifier + Retry mechanism	Qwen2.5-Coder-14B-Instruct	68.77	69.73
Few-shot prompt + Type Classifier + Retry mechanism	Qwen2.5-Coder-32B	**70.49**	**69.73**

models and optimizing inference efficiency will further enhance the system's practicality for real-world applications.

Abstract

This paper presents our approach to multi-label emotion detection in Hausa, a low-resource African language, as part of SemEval Track A. We fine-tuned AfriBERTa, a transformer-based model pre-trained on African languages, to classify Hausa text into six emotions: anger, disgust, fear, joy, sadness, and surprise. Our methodology involved data preprocessing, tokenization, and model fine-tuning using the Hugging Face Trainer API. The system achieved a validation accuracy of 74.00%, with an F1-score of 73.50%, demonstrating the effectiveness of transformer-based models for emotion detection in low-resource languages.

1 Introduction

Emotion detection in text is a fundamental Natural Language Processing (NLP) task with far-reaching applications in sentiment analysis, social media monitoring, and mental health support. While significant progress has been made in high-resource languages, low-resource languages like Hausa remain underrepresented in the NLP landscape. One of the key challenges is the limited availability of annotated Hausa datasets for emotion detection, which hinders the development of robust models. This work aims to bridge this gap by leveraging a newly available dataset called BRIGHTER by (Muhammad et al., 2025a) and fine-tuning a transformer-based model for multi-label emotion detection in Hausa.

The scarcity of comprehensive emotion lexicons and annotated corpora makes it difficult to develop and evaluate emotion detection systems for low-resource languages (Kabir et al., 2023; Al-Wesabi et al., 2023; Raychawdhary et al., 2023a). Additionally, these languages exhibit rich morphological variations, syntax, and semantic differences that are not well-captured by models trained on high-resource languages (Marreddy et al., 2022; V R et al., 2023). The phenomenon of code-mixing, where multiple languages are used within the same text, adds another layer of complexity to emotion detection in linguistically diverse contexts (Raychawdhary et al., 2023a; Sonu et al., 2022).

Our approach leverages AfriBERTa, a transformer model specifically trained on African languages, fine-tuned for multi-class emotion classification. The text data is preprocessed, tokenized using the AfriBERTa tokenizer, and the model is fine-tuned on the BRIGHTER Hausa dataset. This work contributes to the growing body of research on emotion detection in low-resource languages by demonstrating effective methods for adapting transformer models to Hausa. Our findings highlight the potential of leveraging pre-trained models like AfriBERTa (Ogueji et al., 2021) for emotion detection tasks in low-resource African languages.

2 Background

2.1 Task Setup

The SemEval-2024 Track A, which is the Multi-label Emotion Detection task under Task 11: Bridging the Gap in Text-Based Emotion Detection (Muhammad et al., 2025b) focuses on classifying text from multiple languages into six emotion categories: anger, disgust, fear, joy, sadness, and surprise. While the task encompasses a wide range of languages, our team (HausaNLP) chose to focus on Hausa, a Chadic language widely spoken across West and Central Africa by approximately 88 million people, including 54 million native speakers and 34 million second-language users primarily in Nigeria, Niger, and neighboring countries (Wolff, 2024; Eberhard et al., 2024). The input to the system is a text sample in Hausa, and the output is a one-hot encoded vector indicating the presence or absence of each emotion. This task is particularly challenging due to the nuances of emotion expression in Hausa, as well as the limited availability of annotated data for low-resource languages.

2.2 Datasets

The Hausa dataset is divided into three splits: train, validation, and test. The training set contains approximately 2,145 samples, the validation set con-

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2014–2019

tains 356 samples, and the test set contains 1,080 samples. The complete distribution of the dataset is shown in Figure 1. Each sample is annotated with one or more emotion labels, represented as a one-hot encoded vector as shown in 1. The dataset exhibits some class imbalance, with certain emotions (e.g., joy and sadness) being more prevalent than others (e.g., fear and disgust). This imbalance posed a challenge during model training and evaluation.

3 Related Work

Several researchers have proposed innovative approaches to address the challenges of emotion detection in low-resource settings. Efforts to create and annotate datasets for low-resource languages include the AfriSenti-SemEval 2023 Shared Task, which provided annotated datasets for languages like Hausa and Igbo (Raychawdhary et al., 2023a). Techniques such as few-shot and zero-shot learning have been employed to augment datasets and improve model performance in data-scarce environments (Agarwal and Abbas, 2025; Hasan et al., 2024).

Pre-trained models like mBERT, XLM-R, and BanglaBERT have been fine-tuned for specific low-resource languages, showing improved performance in emotion detection tasks (Raychawdhary et al., 2023b; Kabir et al., 2023; Raychawdhary et al., 2024). Hybrid models combining lexicon features with transformers have also been explored to enhance emotion classification accuracy (Kabir et al., 2023). Advanced methods such as the use of deep learning models (e.g., CNNs, DNNs) and hybrid approaches (e.g., TCSO-DGNN) have been proposed to better capture the emotional nuances in text (Jadon and Kumar, 2023; Bao and Su, 0).

AfriBERTa, a transformer model pre-trained on a diverse corpus of African languages, has shown promising results for tasks like text classification and named entity recognition in Hausa and other African languages (Ogueji et al., 2021). Our work builds on these advancements by fine-tuning AfriBERTa for emotion detection in Hausa, addressing the unique challenges of low-resource language processing.

Future directions in this field include multimodal emotion detection that incorporates additional data modalities (e.g., audio, video) to complement textual analysis (Sarbazi-Azad et al., 2021; Wang and Zhang, 2025), developing cross-lingual and multilingual models that can generalize across multiple low-resource languages (Raychawdhary et al., 2023b, 2024), and addressing ethical considerations related to data privacy, bias, and the deployment of emotion detection systems in diverse cultural contexts (Agarwal and Abbas, 2025).

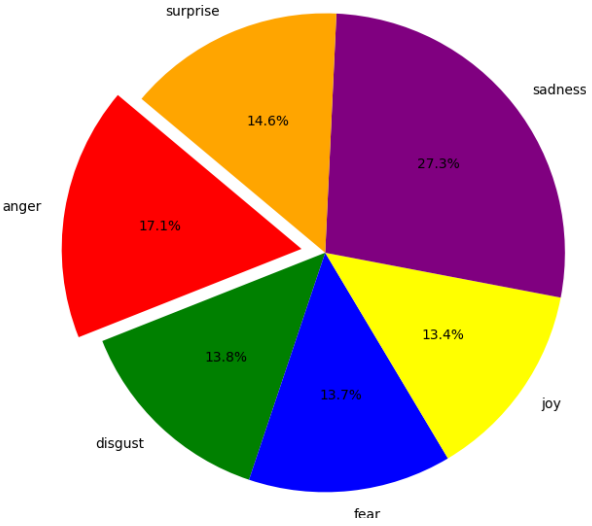

Figure 1: Distribution of Emotions in the Hausa Dataset

4 Methodology - Experimental Setup

4.1 Data Preparation and Preprocessing

To prepare the data for training, a preprocessing pipeline was implemented. First, the text data was cleaned by converting it to lowercase and stripping extra spaces. This step ensured consistency in the text format and improved tokenization. Next, the one-hot encoded labels were mapped to a single integer label representing the dominant emotion for each text sample. This transformation simplified the classification task into a multi-class problem with six classes.

4.2 Tokenization and Dataset Formatting

The preprocessed text data was tokenized using the AfriBERTa tokenizer, a pre-trained tokenizer specifically designed for African languages, including Hausa. The tokenizer was configured to truncate sequences longer than 128 tokens and pad shorter sequences to ensure uniform input sizes. The tokenized dataset was then formatted into PyTorch tensors, containing the input_ids, attention_mask, and label columns. This step prepared the data for input into the transformer model.

Table 1: Sample Entries from the Hausa Emotion Detection Dataset

ID	Text	Anger	Disgust	Fear	Joy	Sadness	Surprise
1	Kotu Ta Yi Hukunci Kan Shari'ar Zaben Dan Majalisar PDP, Ta Yi Hukuncin Bazata	0	0	0	0	0	1
2	Toh fah inji 'yan magana suka ce "ana wata ga wata"	0	0	0	0	0	1
3	Bincike ya nuna yan Najeriya sun fi damuwa da rashin tsaro da talauci fiye da korona	0	0	1	0	1	0

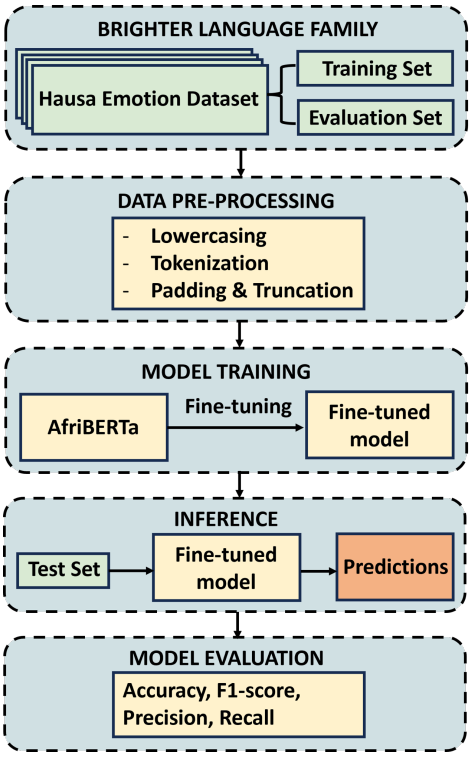

Figure 2: Multi-label Emotion Detection - System Overview

4.3 Model Selection and Fine-Tuning

The AfriBERTa Small model, a compact version of the AfriBERTa architecture, was selected for this task mainly for compute limitation. The model was fine-tuned for sequence classification with six output labels corresponding to the six emotions.

The fine-tuning process was conducted using the Hugging Face Trainer API. The training arguments were configured with a learning rate of 2e-5, a batch size of 8, and 5 epochs. To optimize training, mixed precision (fp16) was enabled, and a warmup schedule with 500 steps was applied to gradually increase the learning rate at the start of training. The model was evaluated on the validation set after each epoch, and the best model was saved based on validation accuracy.

4.4 Evaluation Metrics

During training, the model's performance was evaluated using standard classification metrics: accuracy, precision, recall, and F1-score. These metrics were computed using the classification_report function from the sklearn.metrics library. The evaluation was performed on the validation set after each epoch to monitor the model's progress and ensure it was learning effectively.

4.5 Model Saving and Inference

After fine-tuning, the best-performing model was saved to disk for future use. The model and tokenizer were saved. For inference, the model was loaded using the Hugging Face pipeline API, which simplified the process of making predictions on new text samples. The model was tested on a sample Hausa text, and the predicted emotion was displayed.

4.6 Test Set Predictions

To evaluate the model's performance on unseen data and submit to the SemEval 2025 Task 11, predictions were made on the test set. The test set was loaded from a CSV file, and the model predicted the dominant emotion for each text sample. The predictions were converted into one-hot encoded labels and saved back to a new CSV file. This file contained the original text samples along with the predicted emotion labels, allowing for further analysis and evaluation.

Table 2: Training and Validation Metrics for the Fine-Tuned AfriBERTa Model

	Accuracy	Precision	Recall	F1-Score
Train	0.7416 ± 0.02	0.7515 ± 0.02	0.7348 ± 0.02	0.7393 ± 0.02
Val	0.7400 ± 0.02	0.7500 ± 0.02	0.7300 ± 0.02	0.7350 ± 0.02

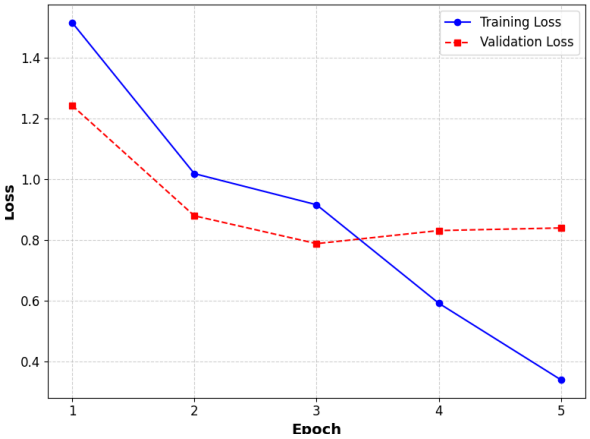

Figure 3: Comparison of Training and Validation Loss Across Epochs: The plot illustrates the progression of training and validation loss over five epochs. The training loss steadily decreases, indicating that the model is learning from the data. However, the validation loss initially decreases but later fluctuates, suggesting potential overfitting or variations in generalization performance.

5 Results and Discussion

The fine-tuned AfriBERTa model demonstrated consistent improvement over the training epochs, as shown in Table 2. The model achieved its best performance in the fifth epoch, with a training accuracy of **74.16%** and an F1-score of **73.93%**. Precision and recall scores were also strong, at **75.15%** and **73.48%**, respectively. These results indicate that the model effectively learned to classify emotions in Hausa text, despite the challenges posed by class imbalance and noisy data.

Additionally, the model showed steady progress, with the training loss decreasing from **1.5168** in the first epoch to **0.3385** in the fifth epoch. The validation loss also decreased initially but stabilized around **0.8393** in the final epoch, suggesting that the model reached a point of convergence. The model's performance on the validation set was consistent with the training results, achieving an accuracy of **74.00%** and an F1-score of **73.50%**, demonstrating its ability to generalize to unseen data.

The model performed particularly well on emotions like **joy** and **sadness**, which were more prevalent in the dataset. However, it struggled slightly with underrepresented emotions such as **fear** and **disgust**, likely due to their limited representation in the training data. This highlights the importance of addressing class imbalance in future work, potentially through techniques like data augmentation or weighted loss functions. Overall, the results underscore the effectiveness of AfriBERTa for emotion detection in low-resource languages and provide a strong baseline for future research in this domain.

6 Conclusion

In this work, we fine-tuned AfriBERTa for multi-label emotion detection in Hausa text, achieving an accuracy of 74.00% and an F1-score of 73.50%. The model performed well on prevalent emotions like joy and sadness but struggled with underrepresented emotions such as fear and disgust, highlighting the challenge of class imbalance. Our approach demonstrates the effectiveness of transformer-based models for low-resource language tasks. Future work could address class imbalance through data augmentation or weighted loss functions and extend this work to other African languages. This study provides a strong baseline for emotion detection in Hausa and contributes to the development of inclusive NLP systems.

7 Limitation

One major limitation of this work is the variability in Hausa dialects. The dataset primarily represents standard Hausa, which may not generalize well to regional dialects or informal variations commonly used in social media and conversational settings. This could lead to misclassification of emotions when processing text from underrepresented dialects.

Another challenge is the generality of the dataset. While the dataset is carefully curated, it may not fully capture the diversity of emotions expressed in different contexts, such as sarcasm, code-mixing with English or Arabic, and cultural-specific ex-

pressions. This limits the robustness of the model when applied to unseen, real-world data.

Additionally, computational constraints influenced the choice of AfriBERTa-small instead of larger transformer models. While this ensures efficiency, it may come at the cost of lower accuracy compared to models with higher capacity. The trade-off between computational efficiency and model performance is a key consideration for practical deployment.

Lastly, deep learning models often lack interpretability, making it difficult to explain why a particular emotion was predicted. This could pose challenges in high-stakes applications, such as mental health monitoring or crisis detection, where transparency is crucial.

Abstract

Emotion detection is essential for applications like mental health monitoring and social media analysis, yet remains underexplored for Indian languages. This paper presents our system for SemEval-2025 Task 11 (Track A), focusing on multilabel emotion detection in Hindi and Marathi, two widely spoken Indian languages. We fine-tune IndicBERT v2 on the BRIGHTER dataset, achieving F1 scores of 87.37 (Hindi) and 88.32 (Marathi), outperforming baseline models. Our results highlight the effectiveness of fine-tuning a language-specific pretrained model for emotion detection, contributing to advancements in multilingual NLP research.

1 Introduction

Emotion detection has garnered significant interest among researchers due to its psychological, social, and commercial importance. People express emotions explicitly through words like Happy or Angry and implicitly through context, tone, or figurative language (Garg and Lobiyal, 2020a). The complexity and subjectivity of human emotions make their accurate identification challenging, especially in text-based scenarios. Moreover, emotional expression varies significantly across languages and cultures, making it difficult to develop models that generalize well across linguistic boundaries (Wiebe et al., 2005; Mohammad and Kiritchenko, 2018).

While extensive research has been conducted on emotion detection in high-resource languages such as English, Spanish, German, and Arabic (Strapparava and Mihalcea, 2007; Chatterjee et al., 2019; Nandwani and Verma, 2021; Maruf et al., 2024), many low-resource languages, including those spoken in India, remain largely underexplored. Recognizing this gap, Muhammad et al. (2025a) introduced the BRIGHTER dataset, which covers 28 languages, primarily low-resource, spoken across Africa, Asia, Eastern Europe, and Latin America. This dataset also includes two widely spoken Indian languages, Hindi and Marathi.

Given India's rich linguistic diversity, understanding emotional expression in its various languages is essential for advancing multilingual NLP applications. This paper introduces our proposed approach and provides a comprehensive analysis of the task of SemEval-2025 Task 11[1] (Track A): *Bridging the Gap in Text-Based Emotion Detection* (Muhammad et al., 2025b). Although this task involves multilabel emotion detection across 28 widely used languages from diverse regions of the world, our system is specifically designed for emotion detection in Hindi and Marathi. Since emotions are language-dependent, we leverage a pre-trained model specifically designed for Indian languages. We fine-tune the IndicBERT v2 (Doddapaneni et al., 2023), a pre-trained model specifically trained on 23 Indian languages to detect and classify emotions in Hindi and Marathi. Our contributions focus on enhancing emotion detection for underrepresented languages to advance research in multilingual NLP. Additionally, we investigate the effectiveness of pre-trained multilingual language models in emotion detection for the Indian languages, including Hindi and Marathi languages.

We conduct our experiments using the datasets provided by the organizers of SemEval-2025 Task 11 for Track A. Our results show that the proposed system achieves an F1 score of 87.37 for Hindi and 88.32 for Marathi, outperforming the baseline models. Additionally, we perform an error analysis to evaluate the effectiveness of our system in detecting emotions in Hindi and Marathi.

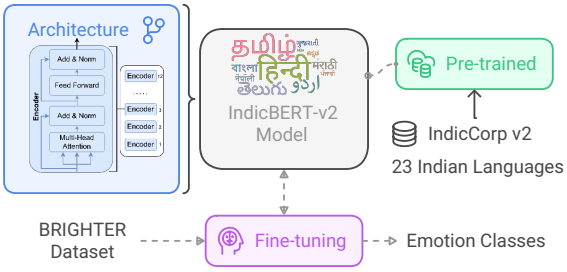

Figure 1: Model architecture and the fine-tuning process of the proposed sytem.

Early studies highlighted the impact of emotions in written communication, similar to face-to-face interactions (Wiebe et al., 2005). Emotion recognition has since been applied in healthcare, social media analysis, and conversational AI (Khanpour and Caragea, 2018; Saffar et al., 2023; Kang and Cho, 2024).

A major challenge in emotion classification lies in distinguishing between expressed and perceived emotions (Mohammad, 2022). Previous work explored multi-label classification of emotions in personal writings (Luyckx et al., 2012), using approaches like the Multi-label Maximum Entropy model (Li et al., 2016) and rule-based methods with affect lexicons (Al Masum et al., 2007). Deep learning advancements, including CNNs with self-attention (Kim et al., 2018) and CNN-LSTM models (Khanpour and Caragea, 2018), have improved fine-grained emotion detection. Transformer-based models have further enhanced performance, especially in textual conversations (Zhong et al., 2019; Jian et al., 2024).

Emotion Detection for Indian Languages: Most early research focused on high-resource languages such as English and Spanish. However, emotion recognition in Indian languages is gaining momentum. Given India's linguistic diversity, this task presents challenges due to script variations and cultural nuances.

For Hindi, lexicon-based methods like Hindi EmotionNet (Garg and Lobiyal, 2020b) and LSTM-based sentiment analysis on tweets (Gupta et al., 2021) have been explored. In Marathi, studies have applied TF-IDF-based supervised classifiers (Patil and Kolhe, 2022) and deep learning models for sentiment classification (Divate, 2021). Other Indian languages, such as Telugu and Bangla, have seen annotation efforts in sentiment analysis (Mukku and Mamidi, 2017; Kabir et al., 2023; Kumar et al., 2024). Despite progress, multi-label emotion detection for Indian languages remains underexplored, motivating our work.

3 System Overview and Experimental Setup

We fine-tune and evaluate IndicBERT-v2 (Doddapaneni et al., 2023) on the BRIGHTER dataset, using F1 Score as the primary performance metric. Additionally, to gain deeper insights into the model's performance across different emotions, we compute Accuracy (Acc), Precision (Prec), Recall, and F1 Score for each emotion.

3.1 Dataset

We focus on multi-label emotion classification for Hindi and Marathi, two Indian languages, using the BRIGHTER dataset—a human-annotated corpus designed for emotion detection across 28 languages, including Hindi and Marathi (Muhammad et al., 2025a). Each text sample in this dataset is labeled for the presence or absence of six emotions: joy, sadness, fear, anger, surprise, and disgust. This

means that each snippet is annotated as joy (1) or no joy (0), sadness (1) or no sadness (0), and so on for all six emotions. Notably, the English subset of the dataset includes annotations for only five emotions joy, sadness, fear, anger, and surprise, excluding disgust. A few samples from the Dataset for Hindi (hin) and Marathi (mar) are listed in Table 1. The dataset statistics for Train, Dev, and Test sets are presented in Table 2. We also deep-dived into the dataset to get the count of each emotion present in the dataset. Most of the sample has a single emotion label in both languages. In the training set for Hindi, almost 24% and for Marathi, almost 17% of the sample is not having any emotion. More details are in the Appendix. We have used only the train set to train the model, and all the performance metrics are calculated with the test set.

3.2 Model Architecture and Training

One of the key challenges in developing emotion detection models for Indian languages is the limited support offered by most large language models (LLMs) and pre-trained language models, which are predominantly focused on English languages. Although models such as XLM-R (Conneau et al., 2020), mT5 (Xue et al., 2021), MuRIL (Khanuja et al., 2021), IndiSocialFT (Kumar et al., 2023), and IndicBERT-v2 (Doddapaneni et al., 2023) provide some level of support for Indian languages, they often fall short in handling the full spectrum of linguistic diversity. Among these, IndicBERT-v2 stands out as the state-of-the-art for many NLP tasks in Indian languages (Doddapaneni et al., 2023), making it the ideal choice for our emotion detection model.

The model architecture and the fine-tuning process of the proposed system are shown in Figure 1. To adapt IndicBERT-v2 for emotion detection, we fine-tune it using the BERTForSequenceClassification framework, treating the task as multi-label classification where a single text can express multiple emotions simultaneously, such as anger, fear, joy, sadness, or surprise. We employ binary cross-entropy loss (BCEWithLogitsLoss), which enables independent probability estimation for each emotion, ensuring a more flexible and accurate classification. The Adam optimizer is applied with a learning rate of 2×10^{-5}. The model is trained for 15 epochs with a batch size of 32. During training, logits from the classification head are converted to probabilities using the sigmoid activation function, and a threshold of 0.5 is applied during inference to determine emotion labels.

Model	Hindi	Marathi	English
LaBSE	75.25	80.76	64.24
RemBERT	85.51	82.20	**70.83**
XLM-R	33.71	78.95	67.30
mBERT	54.11	60.01	58.26
mDeBERTa	54.34	66.01	58.94
IndicBERT	**87.37**	**88.32**	66.32

Table 3: Performance of models in terms of F1 Score.

4 Result and Analysis

We evaluate the performance of our fine-tuned emotion detection model for both Hindi and Marathi and compare it against several baseline multilingual language models, including LaBSE, RemBERT, XLM-R, mBERT, and mDeBERTa. The evaluation is based on the F1-score, which serves as the primary metric. The baseline model scores are directly taken from the BRIGHTER paper (Muhammad et al., 2025a).

Table 3 presents the overall F1-scores for different models across Hindi, Marathi, and English. The scores, except for the Proposed model, are taken from Paper (Muhammad et al., 2025a). Our proposed model achieved the highest F1-scores for Hindi (87.37) and Marathi (88.32), outperforming all baseline models. For English, the proposed model attained an F1-score of 66.32, which is competitive but slightly lower than RemBERT (70.83). The superior performance of our model for Hindi and Marathi can be attributed to IndicBERT, a language-specific model trained for Indian languages, indicating that emotion recognition is highly influenced by language characteristics.

To gain deeper insights into the performance of our proposed system across different emotions, we analyzed the F1 scores for each emotion. Table 4 provides a detailed breakdown of performance of our system across all emotions in Hindi and Marathi. In Hindi, it achieved the highest F1-score for Fear (91.17), followed by Joy (89.66). Similarly, in Marathi, the best performance was observed for Disgust (92.86), followed by Fear (91.03) and Surprise (90.70). The consistently high accuracy across different emotions demonstrates the robustness of our approach. Since the test set also contains non-emotional samples, we evaluate the model's ability to detect non-emotional sen-

Emotion	Hindi				Marathi			
	Acc	Prec	Recall	F1	Acc	Prec	Recall	F1
Anger	94.75	80.00	89.44	84.46	95.90	**93.01**	81.10	86.64
Disgust	96.83	82.64	**90.09**	86.21	**98.60**	92.86	92.86	**92.86**
Fear	**97.52**	**94.16**	88.36	**91.17**	97.40	92.31	89.80	91.03
Joy	96.14	90.86	88.48	89.66	93.70	77.72	89.71	83.29
Sadness	94.16	78.35	89.94	83.75	93.90	84.76	85.99	85.37
Surprise	96.83	90.21	87.76	88.97	97.60	88.64	**92.86**	90.70
No-Emotion	97.03	87.58	92.41	89.93	94.70	90.80	79.57	84.81

Table 4: Performance of IndicBERT-based system across all emotions for Hindi and Marathi

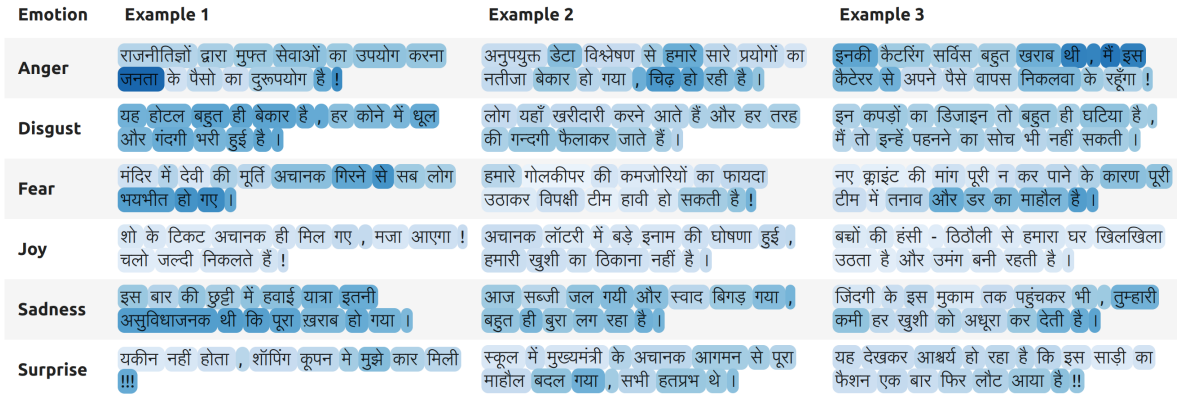

Figure 2: Heat map of the attention while predicting the emotion for some Hindi text.

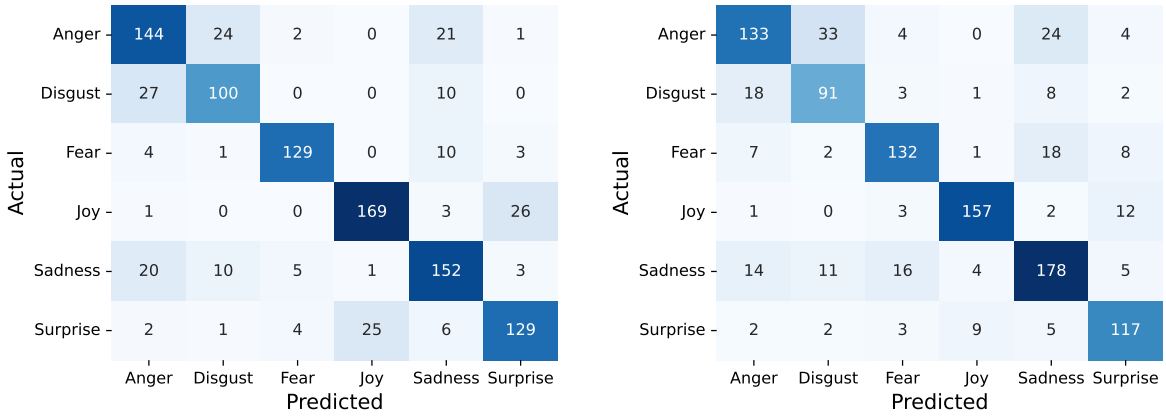
tences in both languages. Our observations indicate that the model performs slightly better for Hindi in recognizing such neutral sentences.

To determine the interpretability of the system, we performed an attention heatmap analysis. We take three samples from each emotion class and visualize the attention weights to highlight the most influential words in the sentence. This helps in understanding how the model makes predictions by identifying keywords that contribute to each emotion classification. Attention heatmap visualization for the Hindi model is presented in Figure 2. By visualizing these attention weights, we verify that the model focuses on meaningful words while predicting emotions. Due to space constraints, the attention heatmap visualization for the Marathi model is provided in Appendix Figure 5.

4.1 Error Analysis

We conduct several error analyses to understand the error in the prediction of the emotion label by plotting the confusion matrix and manually examining misclassified samples. We plot a confusion matrix to analyze misclassifications between emotions categories. Figure 3 presents the confusion matrix for emotions categories of Hindi and Marathi languages. To construct these matrices, we expand multi-label samples and treat each label independently. The confusion matrix for Hindi reveals that while Joy is detected reliably it confuses with Surprise. Similarly, the model confuses among Anger, Disgust, and Sadness categories. In the case of the Marathi language, frequent misclassifications occur among Anger, Disgust, and Sadness, as well as between Fear and Sadness and Joy and Surprise. Notably, these confusing emotions share similar affective characteristics, explaining the overlap in classification. We also manually examine some of the misclassified samples to understand pattern misclassification. Table 5 presents a few selected samples of misclassified models. Our manual inspections of misclassified samples reveal that the model struggles with context-dependent interpretation, idiomatic expressions, and subtle emotional cues. For instance, in the case of *The Conjuring* movie, the model misclassifies fear as sadness due to a lack of awareness of the genre of the movie and its expected psychological impact. Similarly,



(a) Hindi (b) Marathi

Figure 3: Confusion matrix of the emotion prediction for both Hindi and Marathi model on Test data set

		text	Actual	Predicted
Hindi	1	"दा कंजूरिंग " फिल्म देखकर घर लौटने के बाद, रात भर नींद नहीं आई !	fear	sadness
		(After returning home from watching the movie "The Conjuring", I couldn't sleep the whole night!)		
	2	जब मैंने आईना देखा तो उसमे मेरा प्रतिबिम्ब ही नहीं था। मेरे तो हाथ-पांव फूल गए।	fear	sadness
		(When I looked in the mirror, my reflection was not there. I was completely terrified.)		
	3	हर चुनौती के बाद, मेरी उम्मीदों का दायरा धीरे-धीरे सिमटता जा रहा था, इस जीत का मिलना किसी चमत्कार सा लग रहा है !	surprise	joy
		(After every challenge, the scope of my expectations was gradually narrowing, getting this victory feels like a miracle!)		
	4	तुम कीचड़ में कैसे खेल लेते हो ??	disgust	anger
		(How do you play in the mud??)		
Marathi	5	कुटुंबातील नातेसंबंध जसेच्या तसे राहिले पाहिजे, अन्यथा कोणत्याही बदलामुळे तणाव वाढू शकतो.	fear	sadness
		(Relationships in the family should remain as they are, otherwise any change may increase tension.)		
	6	शाळेतील सहलींमुळे विद्यार्थ्यांमध्ये सहकार्याची भावना वाढते.	joy	no-emotion
		(School trips increase the sense of cooperation among students.)		
	7	घराच्या नवीन रेमोडेलिंगसाठी खूपच जास्त पैसे गेले, त्यामुळे तो आर्किटेक्ट माझ्या डोक्यात गेलाय.	anger	sadness
		(The new remodeling of the house cost a lot of money, so the architect went over my head.)		
	8	टिफिनमध्ये कुजलेले अन्न सापडले.	disgust	sadness
		(Rotten food found in tiffin.)		

Table 5: Examples of Misclassified Samples.

idiomatic expressions like *haath-pawn fool gaye*, which indicate fear, are misinterpreted as sadness. The model also confuses closely related emotions, such as joy and surprise, where unexpectedness plays a key role. Additionally, implicit emotions requiring external context, such as fear of change in a family setting, are often mistaken for sadness. The misinterpretation of figurative language, sarcasm, and cultural expressions further contributes to the misclassification of emotions, as seen in Marathi sentences, where frustration is classified as sadness. From such observations from misclassification and our annual inspection, we can conclude the need for contextual understanding improvements, idiomatic knowledge incorporation, and better differentiation between overlapping emotions to enhance the model's interpretability and accuracy.

5 Conclusion and Future Work

This study proposes a system for multilabel emotion detection in Hindi and Marathi languages. Our proposed system fine-tuning IndicBERT v2 on the BRIGHTER dataset provided organize of SemEval-2025 Task 11. Our experimental results suggest that our proposed systems outperformed baseline models. We also have several ablation studies to understand the misclassification of emotions between different emotion categories by plotting a confusion matrix and manual inspections of misclassified samples. Our error analysis revealed that misclassification among emotion categories is due to confusion between similar emotions, misinterpretation of idiomatic expressions, and difficulty in capturing context-dependent emotions. To address these issues, future research will explore integrating knowledge extraction and narrative extraction, improving idiomatic phrase understanding, and incorporating multimodal cues to enhance emotion detection. Additionally, we aim to extend this work beyond Hindi and Marathi to include other widely used Indian languages such as Tamil, Bengali, Telugu, and Kannada.

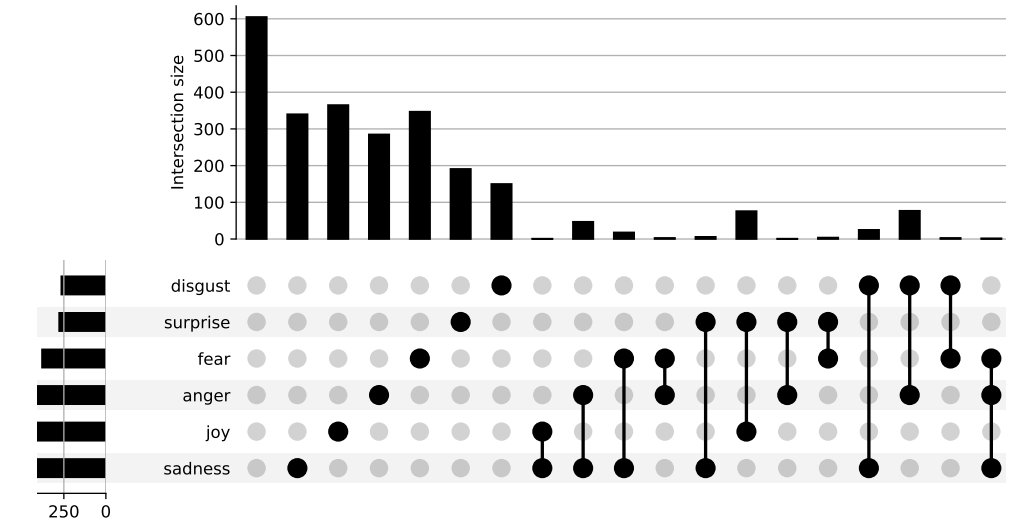
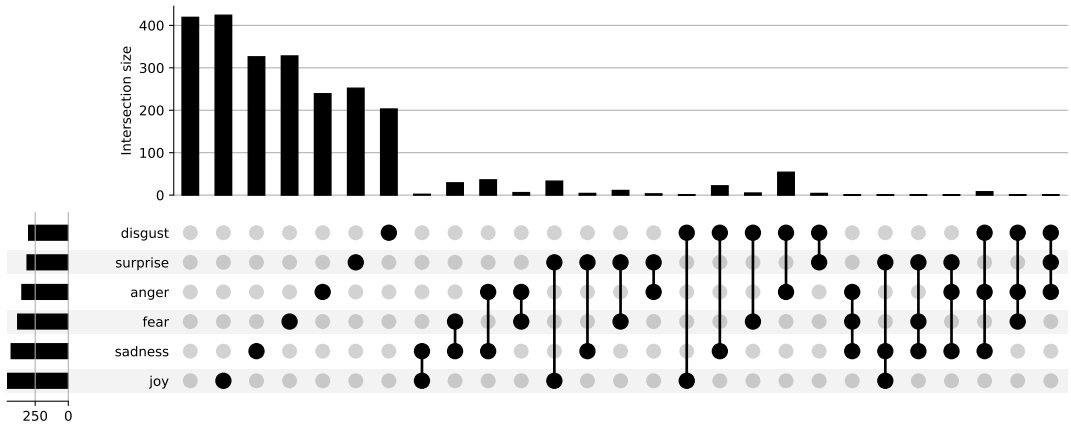
A Insights of the Dataset

The majority of samples in the training set for both Hindi and Marathi contain a single emotion label. Figure 4 provides a visualization of the dataset statistics for both languages using an UpSet plot. From this, we observe that the most frequent multi-label emotion combinations in Hindi include (joy, surprise), (anger, disgust), (anger, sadness), and (sadness, disgust). Additionally, some samples exhibit less common combinations such as (joy, sadness), (anger, surprise), and (fear, anger, sadness). Similarly, in Marathi, multilabel instances frequently appear in (disgust, anger), (sadness, anger), (fear, sadness), (anger, sadness), (surprise, joy), and (disgust, anger, sadness).

Similar to the training set, most samples in the test set for both Hindi and Marathi contain a single emotion label. For Hindi, frequent multilabel emotion combinations include (anger, disgust), (anger, sadness), (sadness, disgust), and (joy, surprise). Additionally, a few instances exhibit rare combinations such as (anger, surprise), (joy, sadness), and (fear, anger, sadness). In Marathi, the most common multilabel occurrences are (disgust, anger), (sadness, anger), (fear, sadness), (anger, sadness), (surprise, joy), and (disgust, anger, sadness). These findings indicate that overlapping emotions in both languages often share affective similarities, making classification more challenging.



(a) Hindi



(b) Marathi

Figure 4: Emotion Wise Distribution of Training Data

Emotion	Example 1	Example 2	Example 3
Anger	यावेळच्या परदेशातील प्रवासातल्या अखंड अडथळ्यांमुळे माझा संयम सुटत चालला आहे .	राष्ट्राच्या सीमांचे रक्षण करण्यात अपयशी ठरलेल्या नेत्यांवर माझा प्रचंड रोष आहे .	माझे पैसे खाल्ले आणि काम केलंच नाही , या रिअल इस्टेट एजंटला शिक्षा झालीच पाहिजे !
Disgust	माझ्या आवडत्या व्यक्तीच्या या घृणास्पद कृत्याने माझे मन उबगले आहे .	ही चिकट , तेलकट भांडी पाहून माझ्या मनात आत्यंतिक तिटकारा उत्पन्न होतो आहे .	छंदाला अत्यधिक महत्त्व देऊन घरच्या जबाबदाऱ्या टाळणे मला खूपच घृणास्पद वाटते आहे .
Fear	आयुष्यातल्या या कठीण अडचणींना सामोरे जाताना मला घाबरून गेल्यासारखे झाले आहे .	आवडत्या लेखकाच्या पुस्तकातील नकारात्मक घटना वाचून मनात प्रचंड भीती निर्माण झाली .	माझा मुलगा फॅशनच्या नादात आणखी काय काय करेल , याचीच भीती वाटते .
Joy	माझ्या आयुष्यात माझी बहीण असल्याने जीवन खूप रंगीबेरंगी आणि सुंदर झाले आहे .	नवीन रोपांची वाढ आणि फुलांची देखभाल करताना मला प्रसन्न वाटते आहे .	ही सुंदर कथा माझ्या रोजच्या जीवनातील छोट्या आनंदांना जागृत करते आहे .
Sadness	माझी स्वयंपाकाची आवड आता कायमची हरवली आहे असेच वाटतंय .	घराच्या सजावटीसाठी खूप खर्च केला तरीही मनाला समाधान मिळाले नाही .	आजाराने माझ्या क्षमतांवर बंधन घातले आहे , त्यामुळे मला असहाय्यता वाटते आहे .
Surprise	चित्रपटाच्या कथेतील अचानक बदलाने मला भांबावून टाकले आहे .	व्वा , हा पाटी मेनू अविश्वसनीय आहे ! मला ते इतके चांगले असेल अशी अपेक्षा नव्हती .	मार्केटिंग ट्रेंड्स इतक्या वेगाने बदलत आहेत की , मी खूप आश्चर्यचकित झालो आहे .

Abstract

Emotion recognition is a crucial task in natural language processing, particularly in the domain of multi-label emotion classification, where a single text can express multiple emotions with varying intensities. In this work, we participated in Task 11, Track A and Track B of the SemEval-2025 competition, focusing on emotion detection in low-resource languages. Our approach leverages transformer-based models combined with parameter-efficient fine-tuning (PEFT) techniques to effectively address the challenges posed by data scarcity. We specifically applied our method to multiple languages and achieved 9^{th} place in the Arabic Algerian track among 40 competing teams. Our results demonstrate the effectiveness of PEFT in improving emotion recognition performance for low-resource languages. The implementation code is publicly available in our GitHub repository[1].

1 Introduction

Sentiment analysis plays a crucial role in understanding human emotions in text, impacting various applications such as customer feedback analysis, social media monitoring, healthcare, and finance. Assigning weights to emotions enhances the precision of sentiment classification, enabling more nuanced decision-making (Jim et al., 2024). With the advancement of deep learning and transformer-based models, sentiment analysis has become more efficient (Cañete et al., 2023; Baziotis et al., 2018; Yu et al., 2018). However, achieving robust accuracy in emotion recognition remains a challenge, especially for low-resource languages, where data scarcity and linguistic diversity hinder model performance.

We focus on categorical emotion classification, where emotions are assigned to discrete categories. Early approaches to textual emotion classification primarily relied on handcrafted features, such as lexicons and rule-based methods (Stone et al., 1966; Strapparava et al., 2004). While modern deep learning models have significantly improved performance (Xu et al., 2020), they are highly dependent on large-scale datasets. When trained on limited data, these models often struggle with overfitting and poor generalization (Tian et al., 2024), making emotion recognition in low-resource settings particularly challenging (Yusuf et al., 2024).

Furthermore, we focus on weighted multi-label text classification, a more complex task where multiple emotions are assigned with varying intensities. While weighting mechanisms enhance emotion modeling, they also come with challenges such as data sparsity, label imbalance, and the difficulty of handling overlapping emotions effectively (Kementchedjhieva and Chalkidis, 2023).

We focus on low-resource languages by leveraging Transformer-based models, evaluating various architectures, including multilingual models. To mitigate overfitting and enhance generalization, we employ parameter-efficient fine-tuning (PEFT) techniques such as LoRA (Low-Rank Adaptation) (Hu et al., 2022), enabling efficient adaptation while maintaining model robustness.

To summarize, we conducted the following experiments on the SemEval 2024 Task 11 dataset:

- Utilizing Transformer-based models to enhance sentiment classification performance.
- Applying PEFT techniques, such as LoRA, to improve efficiency and generalization.
- Assigning density values to each emotion for better sentiment representation.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2028–2037

such as Bag-of-Words (BoW) and TF-IDF for feature extraction, using classifiers like Naive Bayes, Support Vector Machines (SVM), and Logistic Regression (Joachims, 1998; Zhang and Zhou, 2005). These approaches represented text as sparse vectors and utilized statistical patterns for classification.

With the rise of deep learning, models like Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs) became popular for text classification (Kim, 2019; Liu et al., 2016). CNNs captured local patterns, while Long Short-Term Memory (LSTM) networks in RNNs excelled in modeling sequential dependencies. Although these methods improved performance by learning dense representations, they struggled with large datasets and long-range dependencies.

The introduction of attention mechanisms and Transformer architectures represented a major advancement (Vaswani et al., 2017; Devlin et al., 2019). Models like BERT and GPT utilized self-attention to capture contextual relationships across documents, surpassing traditional methods in multi-label classification. However, their high computational costs remain a challenge.

To mitigate these issues, Parameter-Efficient Fine-Tuning (PEFT) techniques have emerged, allowing large models to be fine-tuned with reduced computational and memory overhead (Houlsby et al., 2019). Techniques such as LoRA (Low-Rank Adaptation) (Hu et al., 2022), adapters (Houlsby et al., 2019), and prefix tuning (Li and Liang, 2021) facilitate efficient adaptation of pre-trained models to specific tasks, making them more feasible for resource-constrained environments.

3 Task

This SemEval-2025 Task 11: Bridging the Gap in Text-based Emotion Detection (Muhammad et al., 2025a; Belay et al., 2025; Muhammad et al., 2025b) comprises three distinct tracks: Multi-label Emotion Detection (Track A), Emotion Intensity Prediction (Track B), and Cross-lingual Emotion Detection (Track C). Our team participated in the first two tracks. Figure 1 illustrates an overview of the task description.

3.1 Track A

Given a text snippet, the goal is to identify the emotions expressed by the speaker. Specifically, each snippet must be labeled to indicate whether it conveys any of the following emotions: joy, sadness, fear, anger, surprise, or disgust. That is, for each emotion, the snippet is assigned either a positive label (1) if the emotion is present or a negative label (0) if it is absent.

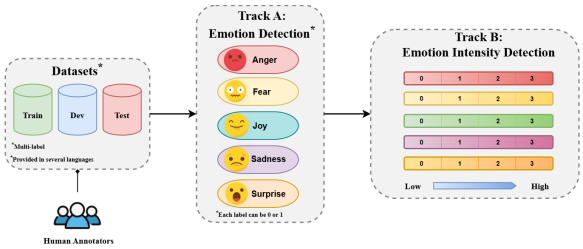

Figure 1: Task Overview for Track A and Track B

For certain languages, such as English, the set of detectable emotions is limited to five—joy, sadness, fear, anger, and surprise—excluding disgust. Table 1 is a sample of the English training data for the first track.

3.2 Track B

For a given text snippet and a specified target emotion, the objective is to predict the intensity level of that emotion.

The possible emotions under consideration include: joy, sadness, fear, anger, surprise, and disgust.

The emotion intensity levels are categorized into the following ordinal classes:

- 0: No emotion present
- 1: Low intensity
- 2: Moderate intensity
- 3: High intensity

Table 2 is a sample of the English training data for the second track.

4 Methodology

Our main focus in the first track was on Afrikaans (AFR), Arabic Algerian (ARQ), Hindi (HIN), and Swedish (SWE) languages. For the second track, we worked on Russian (RUS) and Romanian (RON). To tackle this task, we employ several transformer-based architectures, which are detailed in the Results section. In our experiments, we utilized a consistent set of hyperparameters, including a learning rate of $1e-5$, 100 training epochs, a batch size of 8 for both training and evaluation, and a weight decay of 0.01.

id	text	Joy	Fear	Anger	Sadness	Surprise
eng_train_track1_001	None of us has mentioned the incident since.	0	1	0	1	1

Table 2: Sample of the English training data for Track B

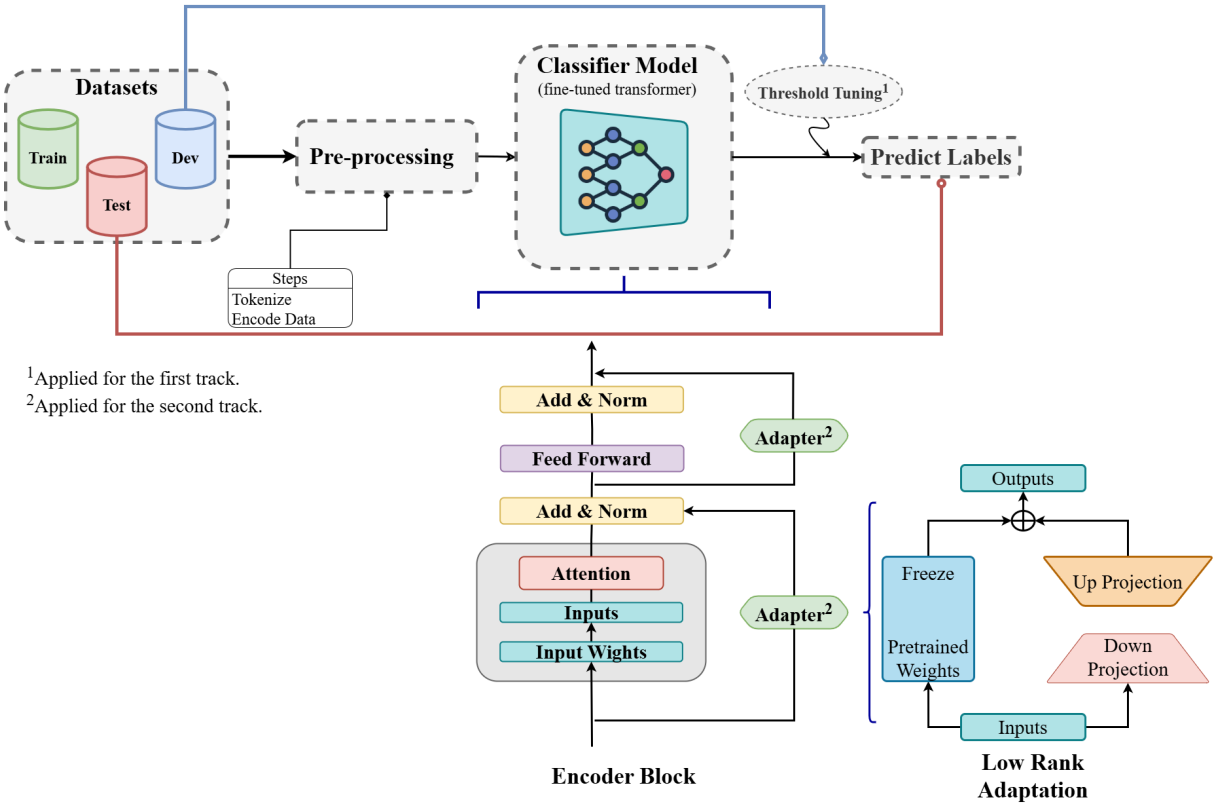

Figure 2: Methodology Overview for Track A and Track B

Figure 2 represents the methodology of our work.

We provide more information about the methodology for each task in separate subsections.

4.1 Track A

For the first track, our approach to multi-label classification involved fine-tuning pretrained transformer models on the training datasets and assessing their performance using the F1 score. During training, we initially set the label threshold in the sigmoid function to 0.3. However, after completing the training process, we applied a threshold tuning strategy to determine the optimal threshold that maximized the F1 score.

4.2 Track B

Our approach to multi-label density prediction (with labels ranging 0–3) combines transformer-based architectures with parameter-efficient fine-tuning strategies.

4.2.1 Parameter-Efficient Fine-Tuning

Since our focus is on low-resource languages, fine-tuning all parameters of large transformer models is computationally expensive and impractical. To

mitigate this, we adopt LoRA (Low-Rank Adaptation), a parameter-efficient fine-tuning method that reduces the number of trainable parameters while maintaining performance. LoRA injects trainable low-rank matrices into transformer layers, enabling efficient adaptation to new tasks without modifying the entire model. This approach is particularly beneficial in low-resource scenarios where full fine-tuning would require extensive labeled data and computational resources.

4.2.2 Training Strategy

Loss Function: To optimize our model for the density prediction task, we employ the **Mean Squared Error (MSE)** loss:

$$\mathcal{L} = \frac{1}{N}\sum_{i=1}^{N}(y_i - \hat{y}_i)^2$$

where y_i represents the ground-truth density score (0–3) and $\hat{y}_i$ denotes the predicted value. MSE is chosen for its sensitivity to large deviations, ensuring precise calibration of predicted intensities.

Post-Processing: To enforce annotation guidelines, we apply **floor clipping** to all predictions:

$$\hat{y}_i = \max\left(0, \min\left(3, \hat{y}_i\right)\right)$$

This guarantees outputs remain within the valid range [0, 3].

Evaluation Metric: We measure performance using **Pearson Correlation** for each label:

$$r = \frac{\sum(y_i - \bar{y})(\hat{y}_i - \bar{\hat{y}})}{\sqrt{\sum(y_i - \bar{y})^2}\sqrt{\sum(\hat{y}_i - \bar{\hat{y}})^2}}$$

This metric evaluates the linear alignment between predictions and ground truth, prioritizing trend consistency over absolute error.

5 Results

The output of confusion matrices and AUC curves on the development datasets are in the appendix section. Performance metrics in Tables 3,4 reveal varying effectiveness of models across languages for emotion detection. The XLM-RoBERTa-Base model (Conneau et al., 2019) scored 0.53 in Afrikaans, while T-XLM-RoBERTa (Barbieri et al., 2022) achieved 0.54. In Hindi, XLM-RoBERTa-Base excelled with 0.84, outperforming T-XLM-RoBERTa (Barbieri et al., 2022) (0.83) and BERT-Multilingual (Devlin et al., 2019) (0.69). For Arabic (Algerian), DiziBERT-Sent. (Abdaoui et al., 2021) scored 0.58, slightly higher than BERT-Multilingual (Devlin et al., 2019) (0.57). In Swedish, BERT-Base-Swedish-Cased-Sent. (Wang et al., 2020) led with 0.72, followed by XLM-RoBERTa-Base (Conneau et al., 2019) (0.71) and T-XLM-RoBERTa (Barbieri et al., 2022) (0.67). Overall, models like XLM-RoBERTa and BERT demonstrate strong performance in emotion detection across multiple languages.

Table 3: Model Performance for Language Emotion on Track A

Language	Model	Micro F1

6 Conclusion

Emotion detection and sentiment analysis remain challenging tasks in NLP, particularly for low-resource languages. In this paper, we presented our work and the performance of our models on six low-resource languages in a multi-label classification task using text-based data. Our approach, which leveraged both multilingual and monolingual transformer-based classifiers, demonstrated that these models can achieve notable success. For future work, we aim to explore various hyperparameter settings and investigate the potential of generative models through prompting techniques.

Acknowledgments

We sincerely thank the SemEval-2025 Task 11 organizers for the opportunity to participate in this

valuable experience. We appreciate the chance to work with the provided data, expand our knowledge, and contribute to the field. We also acknowledge the support and encouragement from all those who contributed to our success.

Limitations

Our experiments were constrained by limited hardware resources, preventing us from utilizing models with a higher number of parameters. Additionally, the high cost of certain generative models restricted our ability to explore them further. While some no-cost generative models were available, they often produced outputs in incorrect formats, making them time-consuming to work with for our team.

Abstract

This paper describes our system submitted to SemEval-2025 Task 4, which introduces the Synthetic Token Alternative Training (STAT) algorithm for efficient unlearning in large language models (LLMs). The proposed method aims to enable pretrained models to selectively forget designated data (the forget set) while preserving performance on the remaining data (the retain set). The STAT framework adopts a dual-stage process. In the first stage, pseudo tokens are generated through random sampling and applied to the forget set, facilitating more effective targeted unlearning. In the second stage, the model undergoes gradient-based optimization using an alternative training scheme that alternates between pseudo-token-augmented samples from the forget set and unmodified samples from the retain set. This design promotes stable unlearning of the specified data while accelerating convergence and preserving the model's general performance. Our system achieved 3rd place in the 7B model track (OLMo-7B) and 7th place in the 1B model track (OLMo-1B), demonstrating substantial improvements over the official baselines, exhibiting superior stability in knowledge retention and more effective targeted forgetting compared to existing approaches. Code is available at https://github.com/carbonatedbeverages/Synthetic-Token-Alternative-Training-for-LLM-Unlearning.

1 Introduction

The task of large language model (LLM) unlearning(Yao et al., 2024) holds significant importance in the context of data privacy and regulatory compliance. In today's data-driven landscape, enabling models to effectively forget specific data is crucial for safeguarding user privacy(Carlini et al., 2022)(Huang et al., 2022) and meeting legal requirements like the right to be forgotten(Dang, 2021). The goal of this task is to make a pretrained model forget data from a specified forget set while retaining its performance on a retain set, to promote research on enabling LLMs to unlearn certain information or behaviors as needed. A detailed description can be found in the shared task description papers(Ramakrishna et al., 2025a)(Ramakrishna et al., 2025b).

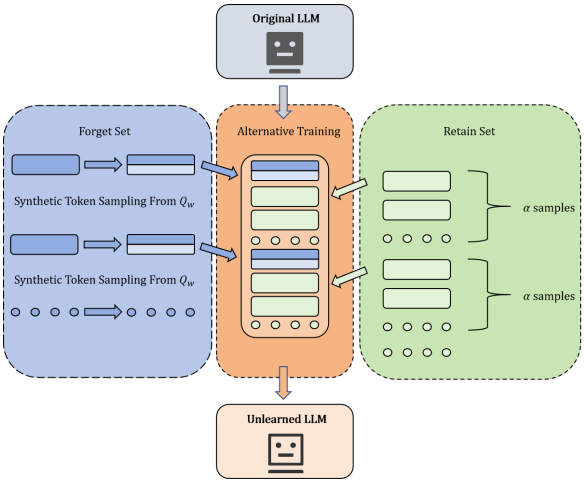

Figure 1: Overview of STAT for LLM Unlearning. Assume a Uniform distribution Q_w across all possible token sets w, and the alternation ratio α.

We propose Synthetic Token Alternative Training (STAT), a framework that enables controlled knowledge removal through synthetic data generation and alternating optimization. As shown in Figure 1, the method operates through two complementary mechanisms: (1) creating pseudo tokens to avoid destructive gradient updates, and (2) implementing alternative training to prevent catastrophic knowledge conflicts.

First, to circumvent instability caused by gradient ascent on original forget samples (Golatkar et al., 2020)(Jia et al., 2023)(Jang et al., 2022), STAT synthesizes token sequences by randomly sampling from the full vocabulary. This synthetic generation erases specific knowledge associations through token recombination. Second, unlike con-

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2038–2043

ventional approaches that complete full passes through one dataset before switching (e.g., process all forget data then all retain data), STAT alternates at sample level-updating parameters through gradient descent on synthetic forget tokens, then immediately applying prediction loss minimization (Zhang et al., 2024)(Maini et al., 2024) on actual retain samples. This alternation frequency prevents over-optimization toward either objective while accelerating convergence through coordinated parameter updates.

The task evaluation yields several critical observations that substantiate our methodological design:

- Our system achieved third place among 7B-scale models (OLMo-7B) and seventh place among 1B-scale models (OLMo-1B) in the official evaluation, demonstrating STAT's effectiveness across different model capacities.
- The synthetic token-driven gradient descent approach in STAT exhibits greater training stability and final task performance compared to gradient ascent unlearning baselines.
- Among various synthetic token generation strategies implemented in STAT, the uniform random sampling method establishes the most reliable foundation for unlearning operations.
- STAT's alternating optimization protocol demonstrates faster convergence than conventional approaches that process the forget set and retain set in separate complete phases, while fully preserving model capabilities on the retain set.

2 Background

We establish the notation that serves to formalize the process of LLM unlearning and we provide a concise overview of the baseline methods.

2.1 Notation

Given an initial model $\pi(y|x;\theta)$ that is already trained on a dataset $D = \{(x_i, y_i)\}_{i\in[n]}$ which is divided into two different data collections, namely the forget set D_{FG} and the retain set D_{RT}. The objective of LLM unlearning is to ensure that the model $\pi(y|x;\theta)$ effectively forget the data on the forget set D_{FG} while still preserving its performance on the retain set D_{RT}.

2.2 Related Work

Current research on machine unlearning in the realm of LLMs has been predominantly confined to the fine-tuned model(Chen and Yang, 2023)(Kumar et al., 2022), while retraining the pre-trained model from scratch is impractical. LLM unlearning via model fine-tuning modifies the internal mechanism of the model without preserving the original parameters, which enables more cost-effective and rapid removal of sensitive data without the need for retraining.

One category includes Gradient Ascent (GA), Gradient Difference (GD)(Liu et al., 2022). GA only focuses on the loss $\ell(y|x;\theta)$ of the forget set part within the dataset and perform an optimization on the model by maximizing the loss that is opposite to the general training objective. GD is an improved method of GA. It not only aims to maximize the loss on the forget set D_{FG}, but also strives to maintain performance on the retain set D_{RT}. Our method will not adopt this gradient ascent unlearning approach on the forget set. Nevertheless, we retain the prediction loss on the retain set in GD to enhance the stability of the training and the balance of the changes in the model's utility.

Another category is to regard the LLM unlearning task as a preference optimization problem(Ouyang et al., 2022)(Stiennon et al., 2020)(Bai et al., 2022). IDK Fine-tune(Maini et al., 2024) relabels the question in the forget set with a random response from D_{IDK}, which contains 100 rejection templates like "I don't know."(IDK). Negative Preference Optimization (NPO)(Zhang et al., 2024) draws inspiration from the framework of reinforcement learning from human feedback (RLHF)(Ouyang et al., 2022), particularly the Direct Policy Optimization (DPO) method(Rafailov et al., 2023). NPO only treats answers in the forget set as negative samples that do not match preferences but ignores positive terms in the DPO loss. Our inspiration for synthesizing pseduo tokens also stems from this preference optimization. However, our approach to constructing preference data differs from theirs and produces better results.

3 System Overview

We introduce the Synthetic Token Alternative Training (STAT) for LLM Unlearning, which addresses the instability and potential catastrophic collapse issues associated with gradient ascent unlearning methods and effectively accelerates the

model's convergence speed.

3.1 Synthetic Token Generation

To overcome the drawbacks associated with gradient ascent methods, we adopt a method inspired by the work of Golatkar(Golatkar et al., 2020) on classification problems, which involves fine-tuning with randomly replaced labels. The underlying principle of this method is that, if a model has not been exposed to the forget set D_{FG}, its behavior should mimic random predictions. Although randomly generating different classifications is straightforward and intuitive, adapting this concept to the token sequences used for model training requires specific adjustments. In STAT, we assume that Q_{W} represents a uniform distribution across all possible token sets W. We then perform synthetic sequence replacement by sampling tokens from this uniform distribution Q_{w} for all target sequences in the forget set. The complete algorithm can be found in Algorithm 1.

Algorithm 1 Generating Synthetic Token with Uniform Sampling

Require: Original forget set D_{FG}, original retain set D_{RT}, alternating ratio α
Ensure: Synthetic data set D
Set Q_w as a Uniform distribution.
Initialize the sythetic data set D as an empty set.
Let $original\_D_{RT} = D_{RT}$.
for each sample $(x, y) \in D_{FG}$ **do**
    Sample a value s from the Uniform distribution Q_w.
    Create a new sample $new\_sample = (x, s)$.
    Add new_sample to D.
    if length$(D_{RT}) \geq \alpha$ **then**
        Randomly select α samples from D_{RT} to form $selected\_samples$.
        Update $D_{RT} \leftarrow D_{RT} - selected\_samples$.
        for each sample in $selected\_samples$ **do**
            Add the sample to D.
        end for
    else
        for each sample in D_{RT} **do**
            Add the sample to D.
        end for
        Reset $D_{RT} \leftarrow original\_D_{RT}$.
    end if
end for
Return D.

3.2 Alternative Training Mechanism

Conventional unlearning methods (e.g., gradient difference) employ a strict sequential protocol: full optimization on the forget set precedes retain set processing within each epoch. This rigid phase separation induces learning rate sensitivity and gradient conflicts, culminating in complete breakdown of knowledge management capabilities.

To surmount these challenges, we introduce the Alternative Training Mechanism as part of the Synthetic Token Alternative Training (STAT) framework. The core idea of this mechanism is to alternate between the forget data and the retain data in a randomized way during training, rather than processing the entire sets one after another. This approach is designed to enhance the stability of the model training process and prevent an excessive drop in the model's generalization ability.

Different datasets can generate gradients in varying directions. The Alternative Training Mechanism is analogous to introducing dynamic perturbations during the optimization process. By constantly switching between datasets, the model is more likely to break free from local optima and find a flatter loss surface. This implicit regularization helps reduce the risk of over-fitting on specific data subsets, ensuring that the model can perform well on unseen data.

The alternation ratio α between the forget data and the retain data is usually determined by the relative sizes of the two datasets and the total number of training epochs.

3.3 Overall optimization objective

Since the alternative training mechanism does not change the final optimization objective, we combine the loss functions on the forget set and the retain set. The ultimate optimization objective is to minimize L:

$$L = \mathbb{E}_{\substack{(x,y)\sim D_{\text{FG}} \\ s\sim Q_{\text{w}}}}[\ell(s|x;\theta)] + \mathbb{E}_{(x,y)\sim D_{\text{RT}}}[\ell(y|x;\theta)] \tag{1}$$

4 Experimental Setup

4.1 Models, Datasets and Metrics

We conduct our experiments using OLMo-7B and OLMo-1B which have been fine-tuned to memorize the dataset in our unlearning benchmark.The dataset we use in our unlearning benchmark covers three LLM unlearning subtasks spanning different document types: 1) Long form synthetic creative documents spanning different genres. 2) Short form synthetic biographies containing personally identifiable information (PII), including fake names, phone number, SSN, email and home addresses. 3) Real documents sampled from the target model's training dataset.

System	Final Score	Task Aggregate	MIA Score	MMLU Avg.
Gradient Ascent	0.394	0	0.912	0.269
Gradient Difference	0.243	0	0.382	0.348
KL Minimization	0.395	0	0.916	0.269
NPO	0.188	0.021	0.080	0.463

The official evaluation metrics of this task include : 1) Task Aggregate Score; 2) MIA Score; 3) MMLU Average Score.

4.2 Experimental Details

All experiments are conducted with 8 A100 GPUs. We use AdamW with a weight decay of 0.01 and a learning rate of $2e-6$ in all unlearning experiments. We use the batch size of 4 and 10 unlearning epochs for all experiments. In the training of OLMo-7B LLM, a cosine annealing scheduler is adopted with a warmup ratio set to 0.03. The mixed-precision training technique is employed. Meanwhile, tensor parallelism is used with its degree set to 8, and the number of stages in pipeline parallelism is set to 8. Additionally, the third stage of the ZeRO optimization strategy is utilized. Since the number of data entries in the forget set and the retain set in the dataset is approximately the same, the alternation ratio for all experiments was set to 1.

5 Results

5.1 Main Results

Table 1 presents the performance of OLMo-7B LLM at the task according to official metrics. The first four systems are the baselines provided by the task organizers. The others are the systems with relatively excellent performance among the participants, including ours. As shown in Table 1, the final score of our system greatly outperforms the official baselines. Additionally, when pitted against other participants using 7B models, our system secured the third-place position. Notably, our system stood out at the forefront in terms of the task aggregate metric. Table 2 presents the performance of OLMo-1B LLM at the task. Our system ranks seventh among the participants. Similar to its performance with 7B model, our system demonstrates excellent performance in the task aggregate metric.

5.2 Ablation Studies

We conducted the abalation studies on the validation set using OLMo-1B model.

5.2.1 Real Data or Synthetic Data

We conducted experiments to compare the difference between gradient ascent unlearning with real data and gradient descent with synthetic data. We found that the method based on gradient ascent unlearning is highly sensitive to the learning rate and it often encounters catastrophic forgetting due to unstable training, which requires delicate design and adjustment of parameters. In contrast,

System	Final Score	Task Aggregate	MIA Score	MMLU Avg.
Gradient Difference	0.340	0.612	0.138	0.270
Top-k/p STS	0.412	0.922	0.046	0.267
LLM-based PSTG	0.298	0.632	0	0.263
STAT	0.430	0.952	0.064	0.273

Table 3: Performance on different systems. Top-k/p STS represents Top-k/p Synthetic Token Sampling and LLM-based PSTG represents LLM-based Prompt Synthetic Token Generation.

the method of gradient descent with synthetic data tends to be more stable, and the experimental results it finally shows are also superior to those of the former method. As shown in the experimental results in Table 3, gradient descent with synthetic data is a more stable and efficient approach.

5.2.2 Comparison of Different Synthetic Token Generation Methods

Our framework evaluates three token generation strategies for forget set construction:1) Uniform sampling (the proposed method), 2) Top-k/p STS(Cha et al., 2024), and 3) Prompted Synthetic Token Generation (PSTG) for constrained generation. The Top-k/p method implements cascaded filtering: initial Top-k ($k = 50$) selection of high-probability tokens followed by Top-p ($p = 0.95$) cumulative probability thresholding, with final random sampling from the truncated distribution. While uniform sampling offers theoretical simplicity, its syntactic-semantic deficiencies motivated our PSTG solution, which leverages the Qwen2.5-14B architecture for structurally coherent generation through prompt-based constraints.

Table 3 shows that the Top-k/Top-p STS method exhibits negligible performance gains over the STAT baseline. Although the target sequence generated by LLM-based PSTG method have significantly enhanced readability and grammaticality, there is a sharp decline in the scores on the task aggregate metric (determined by ROUGE-L). This paradoxical phenomenon likely stems from fundamental limitations of the ROUGE-L metric when applied to unlearning evaluation: its dependence on longest common subsequence alignment disproportionately rewards surface-level lexical overlaps between generated sequences and original training data. Consequently, PSTG-generated sequences—despite achieving grammatical validity—may inadvertently preserve excessive structural patterns from the forget set through their improved fluency, thereby inflating ROUGE-L scores while simultaneously undermining actual knowledge removal efficacy.

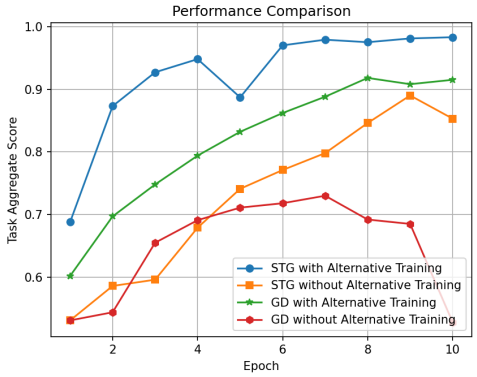

Figure 2: Effectiveness of alternative training mechanism in STAT. STG represents Synthetic Token Generation and GD represents Gradient Difference.

5.2.3 Effectiveness of Alternative Training

We have also verified the effectiveness of Alternative Training Mechanism on OLMo-1B in accelerating model convergence through experiments. As shown in Figure 2, under the same other experimental conditions, using alternative training mechanism enables the model to reach convergence state faster.

6 Conclusion

This work proposes the Synthetic Token Alternative Training (STAT) framework for precise LLM knowledge unlearning. STAT enables controlled knowledge removal through synthetic token generation and alternating gradient descent optimization between forget-set perturbations and retain-set fidelity preservation. Empirical evaluations demonstrate STAT's superior efficacy over baseline methods in official benchmarks.

Abstract

We present our approach to tackle the Sentiment Classification Task. The task was divided into 3 categories: 1) Track A: Multi-label Emotion Detection 2) Track B: Emotion Intensity, and 3) Cross-lingual Emotion Detection. We participate in subtasks 1 and 2 for the Russian language. Our main approach is summarized as using pre-trained language models and afterwords working with fine-tuning aside the corpora provided. During the development phase, we had promising outcomes. Later during the test phase, we got similar scores to the Semeval baseline. Our approach is easy to replicate and we proportionate every detail of the process performed.

1 Introduction

Nowadays, a significant portion of human communication takes place through text-based platforms such as social media, emails, and messaging applications. Understanding the emotions embedded in these interactions is crucial for enhancing user experience, analyzing public opinion, and even detecting mental health issues. Text-Based Emotion Detection (TBED) is a field within Natural Language Processing (NLP) that aims to identify and classify emotions in written text using machine learning and artificial intelligence techniques. This technology has diverse applications, ranging from sentiment analysis in social media to personalized content recommendations and customer service improvement. However, accurately detecting emotions in text remains a challenging task due to the inherent ambiguity of language, subjectivity in emotional expression, and cultural differences (Alswaidan and Menai, 2020).

SemEval-2025 Task 11 seeks to identify the perceived emotion most people would associate with a speaker based on a given sentence or short text snippet. This task prioritizes interpreting emotions rather than the speaker's actual emotional state, the emotions elicited in the reader, or those of other individuals referenced in the text. Its significance lies in enhancing the understanding of how emotions are conveyed and perceived in written language, considering the influence of cultural context, individual variations in emotional expression, and the inherent constraints of text-based communication (Muhammad et al., 2025b). This task consists of three tracks:

- Track A: Multi-label emotion detection
- Track B: Emotion intensity
- Track C: Cross-lingual emotion detection

TILeN group participated in tracks A and B for the Russian language, using in both tracks the pre-trained model RuBERT (Kuratov and Arkhipov, 2019) fine-tuned with the task data (Muhammad et al., 2025a). Due to the intensity of the classes for emotions included in track B, we pre-processed the corpora, transforming all classes into a binary classification with three intensity levels for emotions applying multi-label classification.

In the final ranking, our results were below the SemEval base score in both tracks, but the differences were within hundredths of a unit. Our approach demonstrated improved performance when employing a language-specific pre-trained model for multi-label classification predictions.

2 Related work

2.1 BERT Model

Language models pre-training has been shown to be effective for improving many natural language processing tasks, such as, sentence-level task (Williams et al., 2018) and paraphrasis (Dolan and Brockett, 2005).

A downstream task depends on the output of a previous task, and it allow us to use pre-trained models for various applications. Two strategies

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2044–2049

for applying pre-trained language representations to downstream tasks are: feature-based and fine-tuning.

- The feature-based strategy uses the pre-trained representations as additional features, such as ELMo (Peters et al., 2018).
- The fine-tuning is trained on the downstream tasks by simply fine-tuning all pre-trained parameters such as Generative Pre-trained Transformer (OpenAI GPT) (Radford and Narasimhan, 2018).

The two approaches use unidirectional language models to learn general language representations during pre-training and this limits the choice of architectures. Here is where BERT model comes in.

BERT which stands for Bidirectional Encoder Representation from Transformers is a natural language processing model based on the Transformer architecture. It was developed by Google AI in 2018 and revolutionized the field of NLP because it allows bidirectional learning of texts, which improves understanding of context in both directions (left and right).

BERT alleviates the unidirectionality constraint and use two steps, pre-training, and fine-tuning. In the pre-training step, the model is trained on unlabeled data over different pre-training task, on the other hand, for fine-tuning, the BERT model is first initialized with pre-trained parameters, and all of them are fine-tuned using labeled data from the downstream task (Devlin et al., 2019). BERT shows state-of-the-art results on a wide range of NLP tasks in English.

BERT has two multilingual models currently available.

- BERT-Base, Multilingual Cased: with 104 languages, 12-layer, 768-hidden, 12-heads, 110M parameters
- BERT-Base, Chinese: Chinese Simplified and Traditional, 12-layer, 768-hidden, 12-heads, 110M parameters

2.1.1 BERT Architecture

Before a text is fed into the model, it must be split into tokens. BERT uses a special tokenization called WordPiece (Wu et al., 2016), which splits words into subwords or fragments.

The BERT's architecture is described below

The Transformer Network processes the text in two phases: one for encoding, which is responsible for processing the input text and numerically encoding it by extracting its most relevant information, and a decoding phase that is responsible for generating a new text sequence.

The input text is encoded as two sentences:

At the beginning, a classification token (CLS) is always included and to separate one sentence from another, the separation token (SEP) is included. For each token, three representations are obtained:

- Token Embeddings: Representation of each word or subword.
- Segment Embeddings: Indicate which sentence each token belongs to.
- Positional Embeddings: Add information about the position of each token in the sequence.

BERT is trained with two main goals:

- Masked Language Model (MLM): Some tokens in the input are randomly masked and the model must predict them.
- Next Sentence Prediction (NSP): Two sentences are given and the model must predict whether the second sentence follows the first.

2.2 RuBERT Model

There are two ways to train pre-trained bidirectional language models monolingual and multilingual. Language specific models have shown greater performance than multilingual models, but these last ones allow to perform a transfer from one language to another and solve task for different language simultaneously.

This work (Kuratov and Arkhipov, 2019) shows several methods of adaptation of multilingual masked language models for a specific language, it's a Transformer encoder where the basic building blocks are Self-Attention.

This model was trained on the Masked Language Modeling and next sentence prediction tasks and considered from multilingual to monolingual using Russian as a target language for transfer. It demonstrated that the monolingual model could be trained using multilingual initialization.

The main idea is to use knowledge about target language that already captured during multilingual training. So, training model using data from multiple languages can significantly improve the performance of the model.

3 System Overview

We participated in Tracks, A and B for the Russian Language since we got promising results during the development phase. Both tracks were tackled using the same approach. We used the pretrainned model RuBERT based on Bert for the Russian Language (Kuratov and Arkhipov, 2019). This model is cased and it was trained with 12-layer, 768-hidden, 12-heads and 180m parameters. The corpora used for training consist of the Russian part of Wikipedia and news data. The authors used the training data to build a vocabulary of Russian subtokens and took a multilingual version of BERT-base as an initialization for RuBERT.

After loading the pre-trained model, we fine-tuned it using the task data (Muhammad et al., 2025a) provided by the organizers.

3.1 Track A. Multi-label Emotion Detection

This task is intended to predict the perceived emotion(s) of the speaker given a target text. The emotions to detect are: joy, sadness, fear, anger, surprise, or disgust. In other words, label the text snippet with the emotion (1) or the absence of it (0). In the task it's possible to have the presence of two or more emotions in the same text.

For example, the text: *You know what happens when I get one of these stupid ideas in my head.* Is labeled as anger and fear in the training corpus.

Additionally, the task includes a large number of languages with many predominantly spoken in regions characterized by a relatively limited availability of NLP resources (e.g., Africa, Asia, Eastern Europe and Latin America): Afrikaans, Algerian Arabic, Amharic, Hausa, Igbo, Kinyarwanda, Moroccan Arabic, Mozambican Portuguese, Nigerian-Pidgin, Oromo, Setswana, Somali, Swahili, Tigrinya,Xitsonga, isiXhosa, Yoruba, isiZulu Arabic, Chinese, Hindi, Indonesian, Javanese, Marathi English, German, Romanian, Russian, Latin American Spanish, Tatar, Ukrainian, Swedish Brazilian Portuguese

Our team only participates in the predictions of texts written in Russian. The process used is described on algorithm 1. To obtain a larger amount of data we joined the training and development corpora. So we could have more text which is essential for this approach. This algorithm was devised as a simple way to achieve good results in multi label classification.

Algorithm 1 Training a BERT-based model for multi-label sentiment classification

Require: Corpora with texts and binarized labels, pretrained `RuBERT` model
Require: Learning rate $\eta = 1e-5$, batch size $B = 2$, epochs $E = 10$
Load and preprocess data
Read dataset and convert labels to multi-label binary format
Tokenize texts using `BertTokenizer` (max length = 128)
Create `DataLoader` with batch size B
Initialize model and training setup
Load `BertForSequenceClassification` with $num\_labels = |labels|$
Define Adam optimizer and `BCEWithLogitsLoss` for multi-label classification
Train model for $E = 10$ **epochs**
for $epoch = 1$ **to** 10 **do**
    for each batch in `DataLoader` **do**
        Perform forward pass and compute logits
        Compute loss and update model weights via backpropagation
    end for
    Print epoch loss
end for

Due to hardware restrictions we couldn't add more epochs to our training. We didn't perform any additional pre-process to the corpora provided, so in this manner the data used were introduced to the algorithm without any changes.

3.2 Track B: Emotion Intensity

This track is designed to predict the intensity of each emotion class. Given a target text and a target perceived emotion.

The set of perceived emotions is the same for Track A, including: joy, sadness, fear, anger, surprise, or disgust.

The set of intensity classes are:

- 0: No emotion
- 1: Low degree of emotion

- 2: Moderate degree of emotion
- 3: High degree of emotion

Additionally, Track B also contains text snippets that could have multi-degree sentiment classes. For example:

I can't believe it! I won the scholarship! This is amazing!

Having a value of 3 for joy and a value of 3 for surprise, i.e., high degrees of joy and surprise.

The process used to predict Track B was the same as used in Track A, with some additional pre-processing in the corpora. Due to the intensity classes in this Track B, we didn't have binary values assigned to each text snippets. However, we transform all the classes into a binary classification task. All the sentiment class were divided into 3 different classes. For example, the class joy was transformed into joy_low, joy_med, and joy_hig. Therefore, if the joy class value was set to 3, only the class joy_hig was set to 1 and the other two had 0. The same logic was applied to all sentiments and emotion degrees in the corpora. The algorithm 2 describes the transform we made to pre-process all the corpora used in this Track.

Algorithm 2 Preprocessing Emotion Labels in a Sentiment Dataset

Require: CSV file containing text data with emotion intensity levels (1 = low, 2 = medium, 3 = high)

Load dataset from CSV file into a dataframe df
Define emotion labels: {"anger", "disgust", "fear", "joy", "sadness", "surprise"}
Transform emotion levels
for each emotion e in the emotion list **do**
    Create new columns:
        $e\_low \leftarrow 1$ if $e = 1$, else 0
        $e\_med \leftarrow 1$ if $e = 2$, else 0
        $e\_hig \leftarrow 1$ if $e = 3$, else 0
end for
Select relevant columns
Keep only {"id", "text"} and transformed emotion columns
Save processed dataset as a new CSV file

Finally, after performing the prediction for this Track, we need to return the corpora to the original distribution format. As described in the Algorithm 3.

Algorithm 3 Transform Emotion Labels in a Sentiment Dataset

Require: CSV file with separate columns for low, medium, and high emotion intensity

Load dataset from input CSV file into a dataframe df
Define emotion labels: {"anger", "disgust", "fear", "joy", "sadness", "surprise"}
Aggregate emotion intensity levels
for each emotion e in the emotion list **do**
    Compute aggregated emotion value:
        $e \leftarrow e\_low \times 1 + e\_med \times 2 + e\_hig \times 3$
    Clip values to a maximum of 3
end for
Select final columns
Keep only {"id"} and the transformed emotion columns
Save transformed dataset to output CSV file

4 Experimental Setup

As mentioned in the previous section, we consider the new corpora for training the text snippets of train + dev to train our models.

- **Track A.** The training corpus used for this Track in Russian language consists of 2878 (2679 train / 199 dev) text snippets. Table 1 shows the classes distribution of the corpus.

Emotion	Count
Anger	590
Disgust	299
Fear	349
Joy	589
Sadness	460
Surprise	381

Table 1: Emotion distribution in dataset

Even though, the corpus it's not perfectly balanced, we can appreciate that all classes have at least 299 elements, which is helpful for the Algorithm 1 .

- **Track B.** Applying the same criteria to add train(2220)+ dev(343) we had a total of 2563 snippet texts with the sentiment intensity distribution as shown in Table 2.

Table 2 shows that emotion intensity 1 is the least represented of all emotions and the most is intensity 2.

Emotion	Emotion Intensity		
	1	2	3
Anger	28	218	171
Disgust	24	125	17
Fear	89	197	42
Joy	77	252	152
Sadness	33	215	86
Surprise	43	164	58

Table 2: Emotion distribution across intensity levels

The main Algorithm 1 is established in the previous section. We only made additional adjustments to the Track B corpus as mentioned before.

5 Results

After the Test stage, we had the following results.

- **Track A.**

Language	Emotion	Score
Russian	Macro F1	0.8209
	Micro F1	0.8196
	Anger	0.8131
	Disgust	0.8070
	Fear	**0.9254**
	Joy	0.8624
	Sadness	0.7589
	Surprise	0.7583

Table 3: Emotion classification scores for Russian

For the official ranking, organizers used the Macro F1 score and we were positioned in the 31st place on the final ranking for this task.

- **Track B.**

Language	Emotion	Score
Russian	Anger	0.7654
	Disgust	0.8053
	Fear	**0.8919**
	Joy	0.7678
	Sadness	0.8580
	Surprise	0.7540
	Average Pearson r	0.8071

Table 4: Emotion intensity classification scores for Russian

The average Pearson r was the score used by the organizers to rank official results. The position obtained for this Task was 17.

The model A exhibited rapid convergence throughout training. Starting with an initial loss of 0.1192 in Epoch 1, the loss quickly decreased to 0.0315 by Epoch 2 and further to 0.0199 in Epoch 3, demonstrating efficient early learning. Minor fluctuations were observed in subsequent epochs, but the overall trend remained strongly downward. Notably, after Epoch 5, the model consistently achieved very low loss values, reaching as low as 0.0054 by Epoch 10. These results highlight the model's ability to effectively capture the data distribution and maintain stable performance throughout the later stages of training. In Model B, the training loss shows a general trend of effective learning, especially in the early epochs. Initially, there is a significant decrease in loss from 0.15 to 0.08 by the second epoch and further to 0.018 by the third, indicating rapid model convergence at the start. Although some fluctuations are observed in later epochs (e.g., an increase at epoch 4 and a notable spike at epoch 7), the overall trend suggests that the model adapts well and corrects itself quickly, as seen by the drop to 0.031 at epoch 8 and reaching a near-zero loss of 0.0006 at epoch 9. The final loss at epoch 10 (0.062) remains low, demonstrating that the model maintains good performance and stability across training.

Both ranking results were positioned below the Semeval baseline scores. However, we were closer to this baseline in Track A. The distance from the baseline was short, i.e. 0.0168 for Track A and 0.0695 for Track B.

6 Conclusion

We present a simple way to make predictions having multilabel classification for sentiment analysis. The system approach, actually uses the same process applied to both Tasks, changes were made on the Track B corpus to be considered as a multi-label binary classification Task. The approach is based on a pre-trained language model for a specific idiom, and after performing some fine tuning we adjust the weights for the predictions. In this way, we consider that our approach is easy to replicate when you have some specific resources, especially on the pre-trained fact. Considering this, we tried to participate in some other languages and due to the low digital resources we couldn't get good results. This problem is also visible in the baseline results provided by the organizers, for example in Afrikaans language the baseline score is 0.3741.

Even though we couldn't overcome the Semeval baseline, the results weren't disappointing.

As a future work, we will perform additional aggregation to the corpus by applying paraphrasing, or even adding the Track B corpus to Track A, affirming the fact that all the intensity classes marked with values different from zero, means the presence of that sentiment as a value of 1 in Track A.

Abstract

Table question answering (Table QA) remains challenging due to the varied structures of tables and the complexity of queries, which often require specialized reasoning. We introduce a system that leverages large language models (LLMs) to generate executable code as an intermediate step for answering questions on tabular data. The methodology uniformly represents tables as dataframes and prompts an LLM to translate natural-language questions into code that can be executed on these tables. This approach addresses key challenges by handling diverse table formats, enhancing interpretability through code execution. Experimental results on the DataBench benchmarks demonstrate that the proposed code-then-execute approach achieves high accuracy. Moreover, by offloading computation to code execution, the system requires fewer LLM invocations, thereby improving efficiency. These findings highlight the effectiveness of an LLM-based coding approach for reliable, scalable, and interpretable Table QA. [1]

1 Introduction

As structured data becomes increasingly prevalent across a wide range of domains—such as finance, healthcare, scientific research, and business—the task of answering questions over tabular data (Table QA) has emerged as a critical challenge in natural language processing (NLP) (Jin et al., 2022). Despite recent advancements in large language models (LLMs) and retrieval-augmented generation (RAG) (Liu et al., 2023), the inherent complexity of table structures continues to pose significant difficulties. Many tables contain nested headers, multi-row dependencies, and implicit relationships, which collectively complicate reasoning and information retrieval processes (Raja et al., 2021).

To address these challenges, the DataBench benchmark provides a structured framework for evaluating Table QA models (Osés Grijalba et al., 2024). However, achieving high performance on DataBench remains difficult, as existing models often struggle to reason over extensive tables, handle intricate queries, and produce clear, interpretable answers. In this study, we propose a system that harnesses the coding capabilities of large language models (LLMs) to autonomously generate, validate, and execute code for extracting precise answers from designated datasets (Ye et al., 2025). By providing the LLM with a given question and an initial preview of the dataset, we prompt it to generate code that retrieves the relevant information. Furthermore, we implement both immediate and post-execution verification mechanisms to enhance the accuracy of the generated responses.

Our evaluation examines multiple models, including `LLAMA3-8b` (Grattafiori et al., 2024), `GPT-4o-mini` (OpenAI et al., 2024b), and `o1-mini` (OpenAI et al., 2024a). Although the transition to GPT-based models yields substantial improvements in test set accuracy, certain challenges persist—particularly the system's limited capacity for self-reflection and self-error-identification. This paper provides an in-depth analysis of the system architecture, presents detailed ablation studies, and evaluates model performance, thereby highlighting both the strengths and limitations of the proposed approach.

2 Background

2.1 Dataset: DataBench

For our experiments, we use DataBench, a benchmark for Question Answering over Tabular Data. It consists of structured tables paired with natural language questions and their answers. The dataset covers diverse domains such as finance, healthcare, and sports, incorporating complex queries

[1] Our code can be found here https://github.com/NengWan/TabularQA2024

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2050–2058

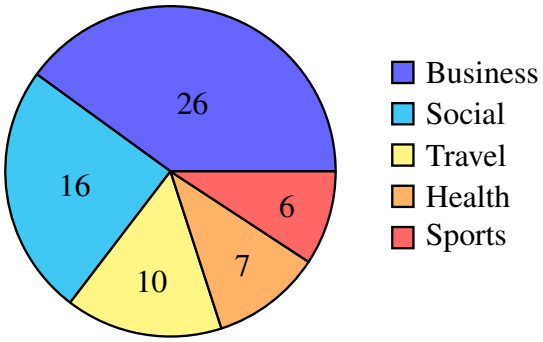

Figure 1: Proportion of datasets across different domains in the DataBench dataset.

that require aggregation, filtering, and multi-hop reasoning. Gold-standard annotations ensure reliable evaluation.

During development, we were provided with training and development sets, each containing seven columns: *question, answer, type, column used, column type, sample answer,* and *dataset*. The test set, in contrast, includes only *question* and *dataset* columns for answer generation. The train-dev datasets comprise 65 source tables, ranging from celebrity tweets, Forbes billionaire lists, and Billboard lyrics. The distribution of different dataset domains is illustrated in Figure 1

The test set consists of 15 datasets, each available in two versions: a full dataset and a lite version. Task *Test_All* contains **1468 rows**, whereas Task *Test_Lite* is a significantly smaller subset with only **18 rows** (approximately **1%** of the full dataset). This reduction in data volume significantly impacts answer accuracy, as discussed in later sections. We participated in both tracks.

2.2 Related Work

Extracting insights from complex tables is a growing challenge in data science and information retrieval. Table QA integrates structured data querying with natural language understanding, addressing difficulties in retrieving precise answers from large databases. Unlike traditional text-based QA, table QA requires reasoning over diverse structures, fine-grained cell information, and contextual dependencies (Jin et al., 2022).

Early methods relied on SQL-based models like **SQLNet** (Xu et al., 2017), which mapped natural language to SQL queries using sequence-to-sequence architectures. While effective for simple databases, these models struggled with complex multi-table schemas and schema dependencies. Neural approaches have since improved table QA by directly mapping questions to table semantics without explicit schema encoding. Transformer-based models such as **TAPAS** (Herzig et al., 2020) and **TaBERT** (Yin and Neubig, 2020) jointly encode natural language and tabular data, leveraging cell-aware and column-level embeddings.

Further advancements, including **Tuta** (Wang et al., 2021) and **TabFact** (Chen et al., 2020), enhance table representation for fact verification and comprehension, though they often require domain-specific fine-tuning. Schema-linking and retrieval-augmented generation (RAG) have also shown promise: **Zhu** (Zhu et al., 2021) improved complex query answering by integrating schema knowledge, while **Duncan** (Duncan et al., 2022) demonstrated that RAG clarifies ambiguous queries by retrieving external context.

Despite progress, challenges persist, including handling noisy data, adapting to unseen table schemas, and efficiently processing large-scale tables. Our approach seeks to address these gaps by improving generalizability, enhancing interpretability through transparent execution, and preserving data privacy via schema-based reasoning.

3 System Overview

We utilize the coding capabilities of large language models (LLMs) to generate code to query the data. Initially, we provide the model with the given question along with the first five rows of the designated dataset. In the initial prompt, we instruct the LLM to generate code capable of extracting the necessary information to produce the correct answer.

Once the code is generated, we employ two verification approaches. (i) immediate validation of the generated code, allowing the LLM to make corrections if necessary. (ii) correct the code after execution: if the execution fails, we provide the LLM with the error message, prompting it to generate a revised, executable version of the code. Finally, we obtain and output the results derived from the corrected code.

3.1 Challenges

Our objective is to develop a fully automated pipeline capable of processing a given question, comprehending its intent, generating the corresponding code, executing it, and obtaining the results. Additionally, the system incorporates an automated verification mechanism to assess the cor-

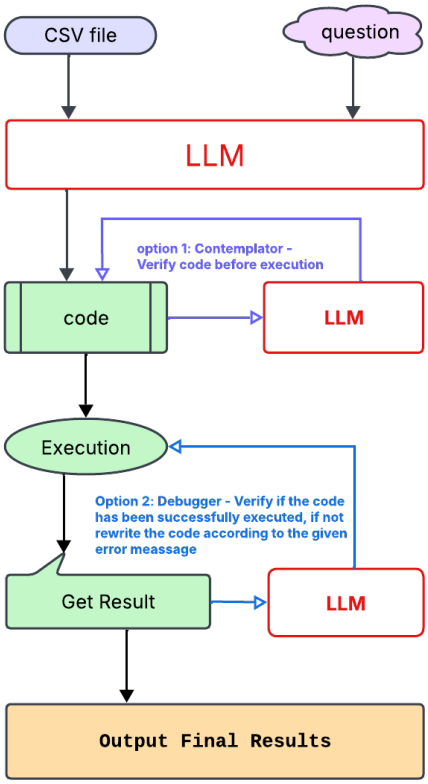

Figure 2: System overview

rectness of the generated code based on the given question.

A fundamental limitation of the system is its inability to engage in self-reflection, which has impeded further model improvement.

As detailed in the following sections, we have introduced two optional self-reflection mechanisms for the model. The first approach involves prompting the model to enter a **Contemplative** mode after code generation before the code execution, where it is explicitly instructed to assess the feasibility and correctness of the generated code. After that we feed the code into the model to get the final results.

The second approach involves an iterative refinement process, wherein, if the generated code fails to execute, the error message is fed back to the LLM. This enables the model to systematically diagnose and correct the errors until a fully executable version of the code is produced.

3.2 Methodology

The overall configuration of our system is defined by a system prompt that specifies the role and responsibilities of the LLM. In particular, the LLM is tasked with understanding the dataset and generate code that can extract answer to the question from the dataset. The prompt also delineates the required output style; for instance, the generated code should output answers as 'raw' strings.

Algorithm 1 Contemplator

Require: A question q, and a dataset preview D_5 (the first five lines of the designated dataset)
Ensure: Final answer a

Input: Question q, Dataset preview D_5
Output: Final answer a
for each q and D_5:
    LLM generate code $\rightarrow C_1$
    LLM verify C_1:
        if error: Regenerate C_2
        else: C_1
    return C^*
Execute the final corrected code C^*:
        Output the final answer a.

In addition to the system prompt, a detailed user prompt is provided. In our experiments, we evaluate two types of user prompts. In the first type, the prompt instructs the LLM to generate code that, given a specific question and the first five rows of the corresponding dataset, is capable of extracting the correct answer from the complete dataset. The prompt also includes a starter code snippet, shown in Appendix A. In the second experimental condition, the desired output format is explicitly defined (shown in Appendix B. We expect that these measures will significantly enhance the accuracy of the answers produced by the system.

Our initial approach entails returning the generated code to the LLM alongside the query:

> "Given the question, can this code produce the correct answer?"

In essence, this procedure prompts the LLM to engage in a form of self-assessment regarding its own output. The details of this methodology are presented in Algorithm 1 - the *Contemplator* .

Our second approach involves enabling the model to assess and rectify its own errors. We refer to this method as the *Debugger* approach. Essentially, the debugger prompt provides the original question along with the corresponding error message, and instructs the LLM to regenerate code that incorporates this feedback (Algorithm 2).

Algorithm 2 Debugger

Require: A question q, and a dataset preview D_5 (the first five lines of the designated dataset)
Ensure: Final answer a

Input: Question q, Dataset preview D_5
Output: Final answer a
for each q and D_5:
    LLM generate code $\rightarrow C_1$
    Execute C_1:
        while error:
            error message $\rightarrow LLM$
            Regenerate C_2
    Execute C^*:
        Output the final answer a.

3.3 Evaluation Metrics

We employed the evaluation metrics provided by the organizers. For results in boolean or numeric formats, the evaluation involves counting the number of exact matches. In the case of list-type answers, the procedure first verifies whether the lengths of the lists are identical; if so, it further assesses whether the individual elements match exactly. Ultimately, the overall accuracy score is computed by dividing the number of correct answers by the total number of answers.

3.4 Experimental Setup:

Initially, we evaluated the system using `LLAMA3-8b`; however, due to a marked improvement in performance, we promptly transitioned to `GPT-4o-mini`. While the majority of our experiments were executed with `GPT-4o-mini`, we also conducted tests using `o1-mini`, which yielded a significant enhancement in answer accuracy on the test dataset. Nonetheless, given that running `o1-mini` requires considerably more time, the competition results were produced exclusively with `GPT-4o-mini`.

4 Results

4.1 Ablation and Model Performance Analysis

We examine the effectiveness of specifying answer format. Our findings indicate that, in most cases, providing an explicit answer format results in improved accuracy. Additionally, we compared the model's performance under the contemplative mode versus the debugger mode. The results reveal that deferring code verification until an error occurs leads to better performance, whereas a double-checking approach—where the model is queried on whether it has produced the correct answer—appears to obscure the model's judgment and substantially diminish performance. In the most extreme case, this approach resulted in a 20% reduction in the performance score on the development set (from 0.909 to 0.706); see Table 2 for further details.

We observed that transitioning from `GPT-4o-mini` to `o1-mini` resulted in a significant improvement in accuracy on both test sets, with an increase of 0.09 on the full test set and 0.05 on the test lite set. Interestingly, this switch was accompanied by a reduction in accuracy on the development set.

As presented in Table 1, our models, configured with the optimal settings discussed previously, demonstrate a significant performance improvement over the state-of-the-art model reported in the original DataBench paper(Grijalba et al., 2024). The average scores across all our models improved by 13% to 28%. Notably, our model demonstrates consistently high accuracy on Boolean questions when provided with a substantial amount of table data. The highest observed accuracy, 95.3%, was achieved by GPT-4o-mini on Boolean questions within the validation set. Furthermore, the accuracy for categorical answers approaches that of boolean questions, indicating robust performance across different answer types.

Conversely, numerical answer accuracy is comparatively lower, which may be attributed to discrepancies arising from the model generating precise floating-point numbers, whereas the reference answers are rounded to two decimal places. This observation aligns with known issues related to floating-point precision and rounding errors in computational systems . Additionally, a reduction in table size correlates with a marked decline in answer accuracy, a reduction in table size is associated with a significant decline in answer accuracy, particularly affecting numerical responses, as evidenced by the performance on the Test Lite dataset.

4.2 Study on different *top_p* values

Table 3 shows the effect of varying *top_p*. *top_p* is a hyperparameter employed in nucleus sampling (Holtzman et al., 2020), a technique used for text generation in language models. It establishes a cumulative probability threshold, ensuring that only the minimal set of tokens whose combined probability is at least *top_p* is considered during sam-

Table 1: Model Accuracy by Answer Type

Prompt	Model	Avg	Boolean	Category	Number	List[Category]	List[Number]
Code Prompt 1	chatgpt3.5	63.0	52.7	73.3	75.9	56.7	56.5
Provided format Prompt (Validation set)	GPT-4o-mini	**91.3**	95.3	95.3	89.1	92.2	84.4
	o1-mini	88.1	92.2	93.8	92.2	76.6	85.9
Provided format Prompt (Test set)	GPT-4o-mini	75.1	93.8	75.7	70.5	58.3	69.2
	o1-mini	83.1	93.8	82.4	80.1	75.0	80.2
Provided format Prompt (Test Lite set)	GPT-4o-mini	78.7	71.3	39.2	16.0	25.0	15.4
	o1-mini	84.2	70.5	45.9	17.3	26.4	17.6

model	Code Correction	Prompts	Val	Test	Test_lite
4o-mini	before	Naive	0.762	0.651	0.672
4o-mini	before	Provided format	0.706	0.661	0.695
4o-mini	after	Naive	0.9	0.718	0.764
4o-mini	after	Provided format	0.909	0.743	0.795
o1-mini	after	Provided format	0.881	0.831	0.843

Table 2: Activating debugger mode after an error, rather than before, significantly improved answer accuracy. Providing answer formats for all datasets slightly boosted accuracy. (*top_p* = 0.7, temperature = 0.1)

Top_p	Val	Test	Test_lite
0.1	0.906	0.751	0.782
0.4	0.913	0.741	0.780
0.7	0.906	0.743	0.795
0.9	0.897	0.747	0.789
1.0	0.9	0.745	0.787

Table 3: Comparison on different *top_p* values for all datasets with temperature = 0.1 and with answer format provided

Temperature	Val	Test	Test_lite
0.1	0.897	0.747	0.795
0.5	0.9	0.749	0.787
1.0	0.894	0.741	0.789

Table 4: Comparison on different temperature values for all datasets with *top_p* = 0.9 and with answer format provided

pling. Our experiments, which varied the *top_p* parameter, indicate that its impact on model performance is minimal. In this section, all temperature values are set to the empirically determined optimum of 0.1.

4.3 Study on different temperature values

Table 4 shows the effect if varying temperature. Temperature is a hyperparameter that adjusts the randomness in the sampling process of language models. It operates by scaling the model's logits prior to applying the softmax function; consequently, lower temperature values yield outputs that are more deterministic and focused, whereas higher temperature values engender increased variability and creativity in the generated responses. Our empirical evaluations in Table 4 demonstrate that the model exhibits optimal and stable performance when the temperature is set to 0.5. Accordingly, in this section, all *top_p* values have been fixed at 0.9.

We can conclude that the temperature value does impact the model performance. The best temperature should be set to 0.5.

4.4 Error Analysis

One frequently encountered error arises from the inherent instability of OpenAI's API, which can result in no code being generated and an output of "None/Error." Another prevalent issue occurs when the answer is numerical: while the correct value is rounded to two decimal places, the code produced by the LLM returns a float with full precision. For instance, consider the query:

> "What is the standard deviation of the 'ISI' column?"

The correct answer is 4.55, whereas the LLM-generated answer is 4.5594771752160375

In addition, ambiguities in natural language can lead to errors, especially when the LLMs process

complex or lengthy sentences. For example, consider the query:

> "List the usernames of the authors who provided a username and wrote more than 4 reviews. If there are none, answer with an empty list."

The model might focus only on the initial instruction to "list the usernames" and overlook the condition about authors who wrote more than four reviews. As a result, it may generate code that lists all usernames, ignoring the specified criteria.

To address such issues, we implemented a rewriter function designed to clarify complex questions. This approach improved performance on some intricate queries but negatively impacted simpler Boolean questions, leading to an overall decrease in accuracy.

Moreover, upon reviewing the answer comparisons, it appears that the LLM's response may sometimes be correct, even if it doesn't exactly match the expected answer; for example:

> **Query:** List the 2 players with the most steals overall.
> **LLM Answer:** {'Chris Paul', 'James Harden'}
> **Ground Truth:** {'Chris Paul', 'Russell Westbrook', 'James Harden'}

Nonetheless, certain discrepancies can be attributed to model hallucinations.

5 Conclusion

In this study, we introduced a code-generation-based approach to Table Question Answering (Table QA) using large language models (LLMs). By translating natural language questions into executable code, our method improves interpretability, reduces LLM invocations, and ensures high accuracy across diverse table formats. Evaluation on the DataBench benchmark demonstrated its effectiveness, with explicit answer formatting and deferred code validation enhancing performance. While `o1-mini` achieved the best test set accuracy, trade-offs in computational efficiency were observed. Despite challenges like ambiguous queries and occasional hallucinations. Our findings highlight the promise of LLM-driven code execution for scalable and interpretable Table QA.

A Starter Code

The code should begin with:

```
import pandas as pd

def get_result(csv_file):
    ...
    return result
```

B Result Output Format

The acceptable outputs include:

- Boolean values (e.g., `True`, `False`);
- A categorical value (e.g., `Flat`);
- An integer or a floating-point number (e.g., `77` or `198.7995642701525`);
- A list of categories (e.g., `[Central, Northern, Mission, Southern]`);
- A list of numbers (e.g., `[2018, 2019, 2022, 2021]`).

JU-CSE-NLP'25 at SemEval-2025 Task 4: Learning to Unlearn LLMs

Arkajyoti Naskar, Samitinjaya, Dipankar Das, Sivaji Bandyopadhyay

Abstract

Large Language Models (LLMs) have achieved enormous success recently due to their ability to understand and solve various non-trivial tasks in natural language. However, they have been shown to memorize their training data which, among other concerns, increases the risk of the model regurgitating creative or private content, potentially leading to legal issues for the model developer and/or vendors. Such issues are often discovered post-model training during testing or red teaming. While unlearning has been studied for some time in classification problems, it is still a relatively underdeveloped area of study in LLM research since the latter operates in a potentially unbounded output label space. Specifically, robust evaluation frameworks are lacking to assess the accuracy of these unlearning strategies. In this challenge, we aim to bridge this gap by developing a comprehensive evaluation challenge for unlearning sensitive datasets in LLMs.

1 Introduction

Large Language Model (LLM) unlearning is selectively removing specific knowledge from a trained model while retaining its general capabilities. This is crucial in scenarios where models inadvertently memorize sensitive information, contain outdated or incorrect data, or need to comply with user requests for data removal under regulations like GDPR. Unlike traditional model retraining, which is computationally expensive and impractical for large-scale models, efficient unlearning methods seek to erase targeted knowledge with minimal computational overhead.

Our system employs a two-pronged approach to tackle this challenge: ***Normalized Gradient Difference*** (NGDiff) for selective unlearning and ***AutoLR*** for dynamic learning rate adaptation. NGDiff modifies model parameters by computing the gradient differences between retain and forget datasets, ensuring targeted forgetting while minimizing unintended knowledge loss. This method allows the model to maintain critical learned information while efficiently removing specific instances.

AutoLR enhances this process by optimizing the learning rate through quadratic loss fitting. This allows the system to dynamically adapt its updates for faster convergence and stability. For every 10 iteration, AutoLR evaluates the model's loss behavior with different learning rates and selects the optimal value to ensure stable and effective parameter updates. The combination of NGDiff and AutoLR makes our system an efficient and scalable solution for the problem of selective unlearning.

Through our participation in this task, we observed that applying NGDiff with AutoLR significantly improved unlearning efficiency compared to static learning rate approaches.

However, challenges remained, particularly in handling complex QA examples where forgetting was less effective. Instances involving long-context dependencies or indirect knowledge retrieval were harder to unlearn, suggesting that additional refinements to the gradient normalization process could further enhance performance. Additionally, we noted that aggressively tuning AutoLR in early epochs sometimes led to instability, indicating the need for more adaptive thresholding techniques.

2 Task Description

The challenge covered three sub-tasks spanning different document types:

1. **Subtask 1:** Long-form synthetic creative documents spanning different genres.

2. **Subtask 2:** Short-form synthetic biographies containing *personally identifiable information* (PII), including fake names, phone numbers, SSNs, email, and home addresses.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2059–2064

3. **Subtask 3:** Real documents sampled from the target model's training dataset.

For each task,[Ramakrishna et al., 2025b] there were two types of evaluation - Sentence Completion and Question Answering (QA). A trained Large Language Model (LLM) was provided to memorize documents from all three tasks. For each subtask, there were specific **Retain** (i.e., documents the model should retain in memory) and **Forget** sets (i.e., documents the model should forget) along with the target model. The primary task was to develop an algorithm to unlearn the information present in the Forget set without affecting the information present in the Retain set.

3 Related Work

Several unlearning methods have been explored, each addressing different challenges in forgetting specific information while maintaining generalizability.

3.1 Gradient Difference

Gradient difference methods compute the difference between gradients from the retain and forget datasets to selectively adjust model parameters. The core idea is to reduce the model's reliance on forget-set data while ensuring minimal impact on retain-set performance. The standard gradient difference formulation is given by:

$$g_{diff} = g_R - g_F \tag{1}$$

where g_R and g_F are the gradients computed from the retain and forget datasets, respectively. This method updates the model parameters by applying the computed gradient difference, effectively counteracting the influence of the forget set.[Bu et al., 2024]

3.2 Gradient Ascent

Gradient ascent unlearning reverses the learning process by updating model parameters in the opposite direction of gradients computed on the forget set. While effective for aggressive forgetting, this method risks instability and can cause model divergence if not carefully controlled.

$$\theta_{t+1} = \theta_t + \eta \nabla_\theta L_F(\theta_t) \tag{2}$$

where $L_F(\theta_t)$ is the loss on the forget dataset, η is the learning rate, and ∇_θ represents the gradient with respect to model parameters.[Ginart et al., 2019]

3.3 KL Minimization

Kullback-Leibler (KL) divergence minimization unlearning aims at aligning the model's output distribution after unlearning with a desired target distribution. This method is particularly effective in reducing the dependence of the model on forgotten data while preserving generalization.

$$\min_\theta D_{KL}(P_{forget}(x) \parallel P_{model}(x;\theta)) \tag{3}$$

where $D_{KL}(P \parallel Q)$ is the KL divergence between two probability distributions.[Guo et al., 2020]

3.4 Negative Preference Optimization

By modifying the loss function, negative preference optimization enforces lower confidence in specific outputs associated with forgotten information. This method selectively reduces the likelihood of forgotten data appearing in model predictions without significantly affecting other learned knowledge.

$$L_{neg} = -\sum_i w_i \log(1 - P_\theta(y_i|x_i)) \tag{4}$$

where $P_\theta(y_i|x_i)$ is the probability the model assigns to a forgotten instance and w_i is a weighting factor.[Yao et al., 2024]

3.5 Preference Optimization

Preference optimization techniques adjust the model's training objective to explicitly reduce reliance on undesired information while strengthening important knowledge. This approach ensures a structured forgetting process without excessive performance degradation.

$$L_{pref} = \alpha L_{retain} + (1 - \alpha) L_{forget} \tag{5}$$

where α controls the trade-off between forgetting and retention objectives.[Bourtoule et al., 2021]

4 System Overview

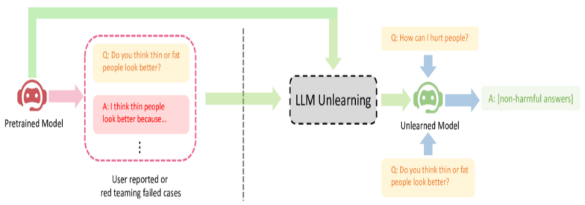

Figure 1: General Block Diagram of LLM Unlearning Process [Yao et al., 2024]

4.1 Datasets

The following datasets have been provided to us:

1. Retain Train Set
2. Forget Train Set
3. Retain Validation Set
4. Forget Validation Set

Figure 1 and Figure 2 give us some insight into the data that was given to us for our task. [Ramakrishna et al., 2025b]

The data sets used were spread across the three subtasks given, the details of which are provided in Section 2. Also, to compare our algorithm with existing algorithms, our task organizers used the ***TOFU*** [1] dataset to run those existing algorithms and provide us with a baseline score of the said algorithms. This dataset comprises question-answer pairs based on autobiographies of 200 different authors that do not exist and are completely fictitiously generated by the GPT-4 [2] model. In addition, during the evaluation phase, along with the data gathered from the organizers, the data set is used to evaluate the algorithm on various evaluation metrics.

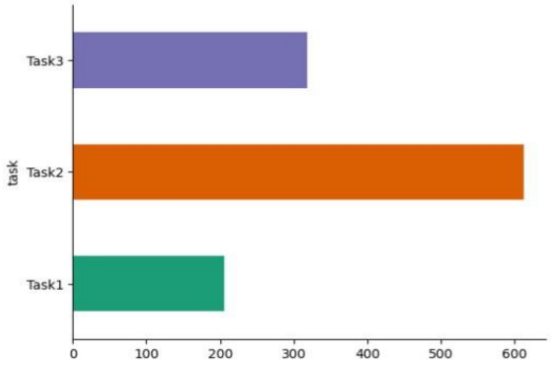

Figure 2: Number of rows of each subtask (Retain Dataset)

[1] https://huggingface.co/datasets/locuslab/TOFU
[2] https://openai.com/index/gpt-4/

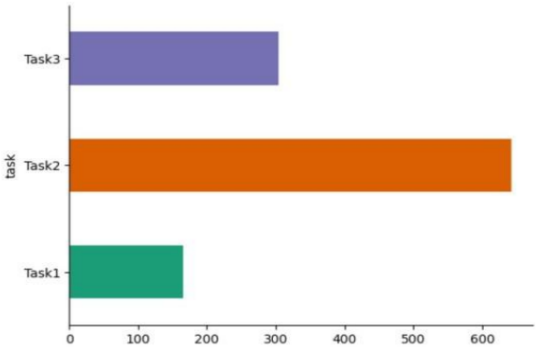

Figure 3: Number of rows of each subtask (Forget Dataset)

The main goal here is to remove selective information present in the forget set from the causal Learning model while preserving the information from the retain set, ensuring that the overall utility of the model is preserved. For this task, an approach called NGDiff Unlearning has been used. This approach is based on computing the gradients separately for the retain and forget sets and then using their difference (NGDiff) to guide the weight updates.

4.2 Custom Dataset Class

The dataset was given in the Pandas data frame format, as discussed above in the Data Set Section. We used a custom dataset class in our algorithm to work with the data. This class takes the pandas dataset given to us, tokenizes the text using the appropriate hugging face tokenizer, and returns the tensor representations of input and output sequences.

Input encodings are generated by tokenizing the input text using the provided tokenizer and converting the tokenized text into a PyTorch tensor using `return_tensors="pt"` during the tokenization process. A similar process has been adopted for the output text. A maximum length of sequence has been set and truncation has been set to true along with setting padding equal to the maximum length of sequence, ensuring uniform sequence length via truncation and padding.

This class returns this tokenized data in the form of PyTorch tensors. `input_ids`, `attention_mask`, `labels` are returned. Here `input_ids` are the tokenized representation of input text. `attention_mask` is a mask that indicates which tokens are real words(1) vs padded tokens(0). Labels are the tokenized representation of output text. While returning these the

`squeeze(0)` operation is applied to each of these to remove the unnecessary batch dimension that has been added because `return_tensors="pt"` adds an extra dimension. This class is used with PyTorch's `Dataloader` to efficiently batch and shuffle data during training.

4.3 Computing Loss and Gradients

An user-defined function named `compute_loss_and_gradients()` has been written that computes the loss and gradients for a given dataset using dataloader. Firstly, it computes the loss and gradients of all the batches in the dataset, and then returns the average loss over all the batches and average gradients accumulated over all the batches. The loss is computed using `outputs.loss` where the output is the output predicted for a given text by the model. `outputs.loss` typically computes the cross-entropy loss if it is not customized or overridden manually. For computing gradients `loss.backward()` is used which computes gradients of loss using model parameters. Gradient clipping is done by capping their norm to `max_norm=1.0`. Gradients are extracted and are accumulated. Normalize the gradients over total batches. The total loss is computed as:

$$L = \frac{1}{N} \sum_{i=1}^{N} L_i \tag{6}$$

where N is the number of batches and L_i is the loss for each batch. The gradient accumulation is given by:

$$g = \frac{1}{N} \sum_{i=1}^{N} \nabla_\theta L_i \tag{7}$$

where g is the averaged gradient over all batches.

4.4 Computing normalized Gradient Difference

We have computed not only the normalized gradients for retain and forget sets but also the difference by subtracting the normalized forget gradients from the normalized retain gradients. The normalized gradient difference is computed as:

$$g_{NGDiff} = \frac{g_R}{||g_R||} - \frac{g_F}{||g_F||} \tag{8}$$

where g_R and g_F are the gradients from the retain and forget datasets and g_{NGDiff} is the normalized gradient difference.[Ramakrishna et al., 2025a]

4.5 Adaptive Learning Rate

The best *learning rate* is dynamically selected to update the model parameters based on the Normalized Gradient Difference(NGDiff). The main idea behind this is to find the optimal learning rate that minimizes the impact of unlearning and preserving the useful knowledge, or in other words the utility of the model.

Quadratic fitting is used to determine the best optimal learning rate. The losses are calculated based on each learning rate. We fit a quadratic function to losses computed for different candidate learning rates and find the minimum:

$$\eta^* = \frac{-b}{2a}, \quad \text{if } a > 0 \tag{9}$$

Otherwise, the minimum learning rate is chosen from predefined candidates:

$$\eta^* = \min(\eta_1, \eta_2, ..., \eta_n) \tag{10}$$

where a and b are the coefficients from quadratic fitting of learning rates and losses. Losses are computed using:

$$L(\eta) = \sum_i |g_R - \eta . g_{NGDiff}|^2 \tag{11}$$

where g_R is the retain gradient, and g_{NGDiff} is the normalized gradient difference. The learning rate that minimizes this function is chosen dynamically.

4.6 LoRA

The ***Low-Rank Adaptation***(LoRA) reduces the number of trainable parameters by decomposing weight updates into low-rank matrices:

$$\Delta W = AB \tag{12}$$

where $A \in \mathbb{R}^{d \times r}$ and $B \in \mathbb{R}^{r \times k}$ with $r \ll d, k$. This reduces the computational cost while maintaining effective updates. Since the models that were given, in which unlearning had to be performed, were very large in terms of size. So, running them on low resources and then performing unlearning became a very difficult task. Hence we took advantage of LoRA.

LoRA modifies the fine-tuning process by freezing the original model weights and applying changes to a separate set of weights, which are then added to the original parameters. LoRA transforms the model parameters into a lower-rank dimension, reducing the number of parameters that need training(trainable parameters), thus speeding up the process and lowering costs. A detailed explanation of

how LoRA works and how it is used can be found here [Hu et al., 2021].

5 Evaluation And Results

5.1 Evaluation Metrics

The evaluation metrics that were officially provided by the task organizers are provided below. We have only mentioned the Results that are based on these evaluation metrics. Also, all the three scoring techniques described here were aggregated to form a final score.

1. Task-specific regurgitation rates (measured using ***rouge-L*** scores) on the sentence completion prompts and exact match rate for the question answers on both retain and forget sets. We have inverted the forget set metrics to $1 -$ their value. We have aggregated all 12 distinct scores described above to generate a single numeric score via harmonic mean.

2. A ***Membership Inference Attack*** (MIA) score using loss-based attack on a sample of member and non-member datasets, given by $1 - abs(mia\_normloss\_normauc\_normscore - 0.5) * 2$.

3. The model performance on the ***MMLU*** benchmark, measured as test accuracy on 57 STEM subjects.

5.2 Results

The following models were provided - **7B Model**[3] and **1B Model**[4]. The results were obtained on both of these models separately. Table 1 shows the results obtained by our algorithm by all the scoring techniques that were used by the task organizers.

	Model 7B	Model 1B
Final Score	0.165	0.397
Task Aggregate	0.0	0.0
MIA Score	0.0	0.929
MMLU Score	0.495	0.261
Rank Obtained	11	9

Table 1: Results and Rank obtained by the Unlearning Algorithm for the official Task Evaluation Metrics

[3]https://huggingface.co/allenai/OLMo-7B-0724-Instruct-hf

[4]https://huggingface.co/allenai/OLMo-1B-0724-hf

Analysis of LoRA's Size-Dependent Performance: With a fixed low-rank ratio, LoRA tunes about 48M parameters in the 1B model versus 314M in the 7B model [Hu et al., 2021, Houlsby et al., 2019], that is, roughly 4.8% of each network. However, the 7B version still freezes approximately 6.7B weights, so its updates cover a much smaller fraction of the overall parameter space. According to established scaling laws [Kaplan et al., 2020], fixed ratio adaptations yield diminishing returns at larger scales, which explains why the 1B model achieves stronger targeted forgetting under LoRA.

6 Conclusion

We formulate the machine learning problem and propose a novel NGDiff unlearning method based on the normalized gradient difference and the adaptive learning rate. By leveraging insights from multitask optimization, NGDiff improves forgetting quality while maintaining utility of the Retain set.

Due to limited compute and data, we relied on LoRA (Low-Rank Adaptation) to shrink the number of trainable parameters while preserving performance. We explored several adaptive learning-rate schedules to minimize loss, but extensive hyperparameter sweeps and larger-scale evaluations remain out of reach. In future work, we will investigate alternative parameter-reduction techniques—such as prompt tuning or sparsity-based pruning—and conduct more thorough ablation studies to further improve unlearning efficacy.

pingan-team at SemEval-2025 Task 2: LoRA-Augmented Qwen2.5 with Wikidata-Driven Entity Translation

DiYang Chen
Ping An Insurance Company of China, Ltd
Shenzhen, China
ytimespace@gmail.com

Abstract

This paper presents our solution for SemEval-2025 Task 2 on entity-aware machine translation. We propose a parameter-efficient adaptation framework using Low-Rank Adaptation (LoRA) to fine-tune the Qwen2.5-72B model, enabling effective knowledge transfer while preserving generalization capabilities. To address data scarcity and entity ambiguity, we design a Wiki-driven augmentation pipeline that leverages Wikidata's multilingual entity mappings to generate synthetic training pairs. Our system achieves state-of-the-art performance across 10 languages, securing first place in the competition. Experimental results demonstrate significant improvements in both translation quality (COMET) and entity accuracy (M-ETA).

1 Introduction

The accurate translation of named entities remains a critical challenge in modern machine translation systems, particularly when processing rare, ambiguous, or culture-specific references. This paper presents our approach to Task 2 of SemEval-2025 (Conia et al., 2025), a shared task aimed at developing robust machine translation systems for complex entity translation between English and 10 target languages: Arabic (Ar), French (Fr), German (De), Italian (It), Japanese (Ja), Korean (Ko), Spanish (Es), Thai (Th), Turkish (Tr), and Traditional Chinese (Zh-TW).

Named entities - including personal names, organizations, geographical locations, and culture-specific items (CSIs) such as movie titles, literary works, and commercial products - present unique translation difficulties. While neural machine translation (NMT) systems have achieved remarkable progress in general domain translation, their performance significantly degrades when encountering low-frequency or domain-specific entities. This limitation stems from multiple factors: the inherent ambiguity of proper nouns across linguistic contexts, the lack of transliteration conventions for emerging entities, and the cultural specificity embedded in certain references.

The SemEval-2025 Task 2 challenge specifically addresses these limitations by constructing a testbed containing carefully curated named entities across three complexity categories: 1) Rare entities with limited parallel corpus occurrences 2) Cross-lingual ambiguous terms 3) Novel entities absent from training data.

Our investigation makes two primary contributions: First, we implement a parameter-efficient adaptation framework for the Qwen2.5-72B (Qwen et al., 2025) model through Low-Rank Adaptation (LoRA) tuning, enabling effective knowledge transfer while preserving the base model's generalization capabilities. This approach addresses the computational challenges of fine-tuning ultra-large language models (LLMs) for domain-specific named entity translation tasks. Second, we design a Wikidata Data-driven augmentation pipeline that systematically injects cross-lingual entity knowledge into the training process (see figure 1). By leveraging Wikidata's multilingual entity mappings and property graphs, our method automatically generates synthetic training pairs.

2 Related Work

Prior work on entity-aware translation has focused on retrieval-augmented methods (Conia et al., 2024) and cross-lingual alignment techniques (Wang et al., 2023). Our approach is based on the task framework proposed by (Conia et al., 2025), which formalizes the challenges of translating rare, ambiguous and novel entities. Recent advances in parameter-efficient adaptation (Hu et al., 2021) and synthetic data generation (Li et al., 2022) inspired our LoRA-based fine-tuning strat-

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2065–2070

egy and Wikidata augmentation pipeline. While traditional NMT systems struggle with low-frequency entities (Vaswani et al., 2017), our work extends the capabilities of large language models through targeted adaptation, addressing limitations in cross-cultural transliteration and contextual disambiguation.

3 System Description

3.1 System Components

Pre-processing: Add information on Wiki data based on Wiki id to the prompt (see Appendix 1). To address the inconsistent language labeling of Traditional Chinese translations in Wikidata (e.g., *zh*, *zh-tw*, *zh-hant*, *zh-yue*), we implemented two preprocessing methods: 1) Prioritizing *zh-tw* translations extraction from Wikidata, with fallback to *zh* labels when unavailable; 2) Utilizing the *zhconv* toolkit to convert Simplified Chinese entities to their Traditional Chinese equivalents.

Model: The Qwen2.5-72B-DA model (see 3.3) utilized by our system builds upon the Qwen2.5-72B pre-trained language model, a 72 billion-parameter decoder-only transformer optimized for instruction-following tasks and released by Alibaba Cloud as an open-source large language model (LLM), enhanced through the synergistic integration of Low-Rank Adaptation (LoRA) and data augmentation techniques, enabling efficient domain-specific fine-tuning.

Post-processing: To ensure output consistency, we implement a regex-based filtering mechanism that removes non-final translation segments. When performing translation tasks, the Qwen2.5-72B model occasionally exhibits a tendency to generate hybrid-language preliminary explanations before producing the target translation. This phenomenon occurs in all languages. As illustrated in Appendix 3, the model initially outputs a Traditional Chinese sentence containing an English entity, followed by an explanation for retaining the English entity, and finally provides the correct Traditional Chinese translation. To address this issue, we employ a regular expression-based approach that segments paragraphs using newline characters and selects sentences containing the target entity at the paragraph end as the final output. Notably, while the final sentence typically contains the correct translation in most cases, we observe that in rare instances the valid translation appears in the penultimate sentence.

3.2 Hyperparameters

In our fine-tuning setup for the Qwen2.5-72B-Instruct model, we employ parameter-efficient LoRA (Low-Rank Adaptation) with rank 8 applied to all trainable layers, optimized through DeepSpeed ZeRO-3 for memory-efficient distributed training. The training configuration adopts a global batch size of 64 (8 per-device batch size with 8 gradient accumulation steps), cosine learning rate scheduling with an initial rate of 1e-4 and 0.1 warmup ratio, running for 3 epochs to balance convergence and computational cost. We set the sequence length cutoff at 2048 tokens to match the model's context window. This configuration leverages adaptive mixed-precision training (bfloat16) and LORA's low-rank reparameterization to maintain the base model's linguistic capabilities while efficiently adapting to downstream tasks.

3.3 Data Augmentation

Data augmented (DA) is a widely used strategy to mitigate data scarcity in low-resource environments. The insufficient training data issue for certain languages is addressed through the application of this technique.

We trained the initial model, Qwen2.5-72B-LoRA, using the training set provided in the task along with the Qwen2.5-72B model. We compared the translation capabilities of Qwen2.5-Max, Deepseek-R1 (DeepSeek-AI, 2025), qwen-mt, and qwen-mt-turbo in Chinese and Korean. After comparative evaluation revealed the superior cost-effectiveness of the baseline model over alternative approaches, we strategically repurposed the trained Qwen2.5-72B-LoRA model for synthetic data generation.

Then, for each target language, we first randomly sampled data from Wikidata and filtered out entities lacking translations in the specific target language, resulting in entity pairs (original entity and its translated counterpart). These entities were then formatted into prompts for generation using our Qwen2.5-72B-LoRA model(see Appendix 2). To ensure the richness of the generated data, the sampling parameters with a temperature value of 0.7 and a top-p value of 0.9 were used. We subsequently filtered out samples where 1) the English sentence didn't contain the original English entity, or 2) the target language sentence lacked the corresponding translated entity. The filtered data is incorporated into the training set through reference

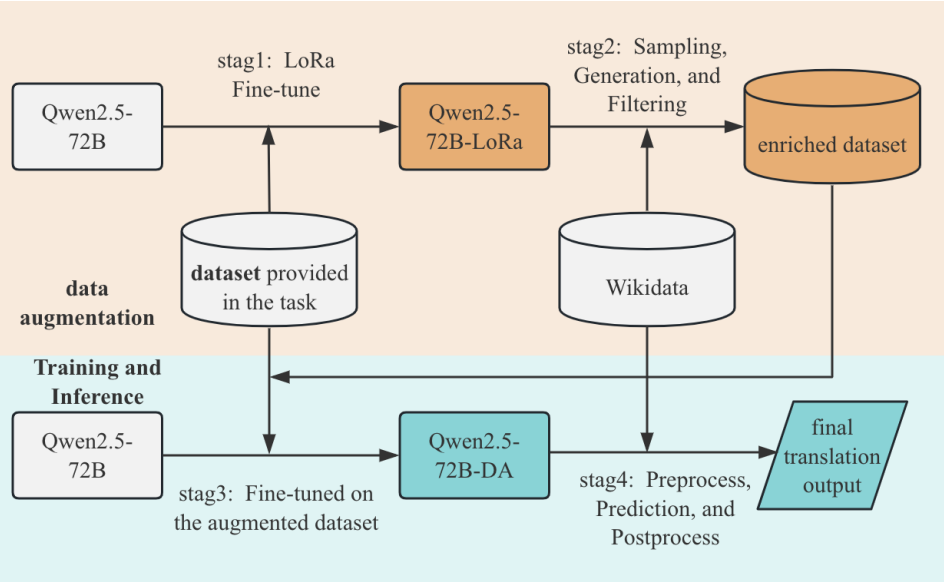

Figure 1: Data Augmentation and Training Pipeline

inference prompts(see Appendix 1). Finally, we combined this augmented dataset with the original training data to fine-tune Qwen2.5-72B, yielding our final translation model Qwen2.5-72B-DA.

4 Experimental Setup

The experiments were conducted on 8×NVIDIA A100 GPUs, which each contain 80GB HBM2 memory. The experiments is evaluated using the official metric of the competition: the harmonic mean of translation quality (COMET) and the precision of the translation of the entity (M-ETA). COMET is a metric for assessing machine translation quality by comparing system outputs to human reference translations. It utilizes a pre-trained model to generate translation quality scores, quantifying the semantic and linguistic fidelity of translations. M-ETA evaluates the accuracy of entity translations. Given a gold-standard set of entity translations and a system's predicted entities, M-ETA calculates the proportion of correctly translated entities. The final overall score will be the harmonic mean of the two scores:

$$\text{FinalScore} = \frac{2 \cdot \text{COMET} \cdot \text{M-ETA}}{\text{COMET} + \text{M-ETA}} \quad (1)$$

5 Results and Analysis

5.1 Determining Base Model

To identify an optimal open-source foundation model for fine-tuning and establish performance baselines for subsequent enhancement comparisons, we conducted a systematic comparative analysis of inference capabilities across multiple candidate models. All models were evaluated under identical experimental conditions, using a standardized prompt template. As shown in Table 1, the Qwen2.5-72B model demonstrated superior performance across benchmark evaluations, leading to its selection as our base architecture. Interestingly, our comparative analysis revealed that the DeepSeek-R1 distilled model underperformed the original model in translation tasks, a phenomenon potentially attributable to knowledge distillation effects that may enhance model capabilities for complex reasoning tasks at the expense of linguistic transfer proficiency.

	Average across all languages		
Model	**M-ETA**	**Comet**	**Overall**
DeepSeek-R1-Distill-Qwen-32B	87.51	91.56	89.44
Qwen2.5-32B	87.72	91.87	89.71
DeepSeek-R1-Distill-Llama-70B	87.31	93.10	90.06
Phi-4	87.81	93.33	90.45
Llama-3.3-70B	88.40	93.83	90.98
Qwen2.5-72B	**88.71**	**94.01**	**91.24**

qwen-mt-plus	-	-	**91.00**	95.10
Qwen2.5-72B-LoRA	**81.26**	**94.44**	90.24	**95.44**

Table 2: Comparative evaluation of Qwen2.5-72B-LoRA against commercial LLMs on traditional Chinese (ZH) and Korean (KO) machine translation, measured through M-ETA and COMET metrics.

5.2 Determining Data Augmentation Model

To address data imbalance issues, we adopted a closed source LLM-based data enhancement strategy to improve system capabilities. Our selection encompassed four state-of-the-art commercial models: Qwen2.5-Max (the most powerful LLM in Qwen series), Qwen-MT-Plus (Qwen's premium machine translation model), Qwen-MT-Turbo (Qwen's efficiency-optimized MT model), and DeepSeek-R1 (a high-performance reasoning LLM comparable to OpenAI's o1 model, accessed via API due to computational constraints precluding local deployment of its 671B variant).

Limited to two linguistically distinct languages, Traditional Chinese and Korean, our evaluation revealed critical performance boundaries. The Qwen-MT series exhibited subpar performance in Traditional Chinese translation tasks, whereas DeepSeek-R1 showed constrained multilingual proficiency beyond Chinese-English language pairs, as documented in their respective technical reports. For controlled comparison, we included Qwen2.5-72B-LoRA(our LoRA fine-tuned Qwen2.5-72B), the top-performing model on task leaderboards without data augmentation.

As detailed in Table 2, Qwen2.5-72B-LoRA achieved superior performance in traditional Chinese while maintaining competitive results in Korean. This performance-cost equilibrium led to the selection of Qwen2.5-72B-LoRA for the final implementation. Our analysis suggests that domain-adapted fine-tuning effectively compensates for data sparsity without requiring extensive augmentation pipelines.

5.3 Main Results

During the validation phase, the Qwen2.5-72B-LoRA (without data augmentation) achieved state-of-the-art performance with a score of 91.79, securing the top position on the task leaderboard (see Table 3). In the subsequent post-validation phase, we implemented a data augmentation strategy by automatically generating sentences and their corresponding translations based on the source and target entities of Wikidata using Qwen2.5-72B-LoRA. The augmented dataset, formed by merging these synthetic instances with the original training data, was utilized to re-fine-tune the Qwen2.5-72B model via LoRA, yielding the enhanced Qwen2.5-72B-DA variant. This optimized model demonstrated superior efficacy, attaining an improved score of 91.93.

5.4 Analysis

As shown in Table 3, languages including Arabic, German, Italian, Japanese, Korean, and Thai achieve the most significant performance gains in our system. As revealed in Table 4, these improvements stem primarily from the enhancements in COMET (C) scores. The M-ETA (M) metric is primarily influenced by the presence of entities in translated sentences. However, since we directly retrieve corresponding target-language entities via Wiki IDs, and given that many entities in the test set lack target-language entries in Wikidata, it becomes challenging to improve M-ETA scores substantially. In contrast, the COMET (C) scores are model-generated evaluations that can better capture grammatical and semantic improvements through training. This explains why experiments demonstrates consistent improvements in COMET (C) scores across nearly all languages, which consequently drives the overall performance gains. The distinct evaluation mechanisms of these two metrics account for the observed differential improvement patterns.

6 Conclusion

Our work demonstrates that combining parameter-efficient adaptation with structured knowledge injection significantly improves entity translation accuracy. The LoRA-tuned Qwen2.5-72B model outperforms both commercial MT systems and open-source LLMs. The Wikidata augmentation strategy proves particularly effective for handling culture-specific items and rare entities. should investigate neural entity linking frameworks to supplant structured knowledge base alignment, enabling dynamic adaptation to emerging entities beyond predefined Wikidata schemas.

Limitations

(1) **Cross-lingual entity alignment challenges**: Systematic misalignment between Wikidata reference translations and human-annotated entities in linguistically distant languages (e.g., Traditional Chinese) degrades M-ETA performance. Our mitigation strategy—optimizing for COMET score improvements—partially compensates but fails to resolve the underlying knowledge base inconsistencies.
(2) **Structured knowledge dependency**: Reliance on Wikidata ID matching creates deployment bottlenecks, as real-world applications rarely provide structured knowledge base identifiers.

Acknowledgments

This research was enabled by computational infrastructure support from Ping An Life Insurance (Group) Co., Ltd. of China. We additionally acknowledge the SemEval-2025 Task 2 organizers for establishing the multilingual evaluation framework that catalyzed this investigation.

A Appendix

Listing 1: Entity-aware Translation Prompt

```
Please translate the following English sentence
    into {target_lang}, requiring an accurate
    translation of the entity.
The sentence to be translated is:
'{sentence}'
You must translate sentences using the entities
    mentioned below:
'{source_entity}': '{target_entity}'
Please output the translated sentence directly.
```

Listing 2: Data Augmentation Prompt

```
### Role and Task Specification
Generate 3 natural English sentences containing
    '{source_entity}', then translate them into
    {target_language} using the exact
    translation '{target_entity}'.

### Requirements
1. Apply different tenses (past/present/future)
    and voices (active/passive)
2. Include these styles:
   - 1 conversational sentence (daily)
   - 1 formal sentence (news/tech)
   - 1 literary expression
3. Return JSON array format with fields:
   - "source": Original English sentence
   - "target": {target_language} translation
   - "style_tag": (daily/news/tech/literary)

### Example Input:
{{
  "source_entity": "Quantum Computing",
  "target_entity": "量子計算",
  "target_language": "Chinese"
}}

### Example Output:
[
    {{
        "source": "The breakthrough in quantum
            computing could revolutionize data
            encryption.",
        "target": "量子計算領域的突破可能徹底改變
            數據加密技術。",
        "style_tag": "tech"
    }},
    # ...other examples...
]
```

Listing 3: Examples with explanations of the process and mixed language output.

```
{
    "id": "0404e153f1dbd9d8",
    "source_language": "English",
    "target_language": "zh",
    "text": "What are some notable traits or
        characteristics of You Sanjie?",
    "prediction": "尤三姐有哪些 notable traits 或
        特性？\n\n(Note: \"notable traits 或特
        性\" can be more naturally phrased as \"
         notable 的特質或特
        點\" in Traditional Chinese, but I kept
        it closer to the original English
        structure for clarity.) \n\nFor a more

Abstract

Idiomatic expressions present significant challenges for natural language understanding systems as their meaning often diverge from the literal interpretation. While prior works have focused on textual idiom detection, the role of visual content in reasoning about idiomaticity remains underexplored. This study introduces a Chain-of-Thought reasoning framework that enhances idiomatic comprehension by ranking images based on their relevance to a compound expression used in a reference sentence, requiring the system to distinguish between idiomatic and literal meanings. We comprehensively evaluate our approach by quantitatively analyzing the performance improvements achieved integrating textual and visual information in the ranking process through different prompting settings. Our empirical findings provide insights into the capabilities of visual Large Language Models to establish meaningful correlations between idiomatic content and its visual counterpart, suggesting promising directions for multimodal language understanding.

1 Introduction

Idiomatic Expressions (IEs) are a unique and challenging natural language aspect. Their meaning often cannot be inferred directly from their individual words, making them particularly difficult for computational models to process (Mi et al., 2024). Unlike literal phrases, IEs require understanding linguistic conventions, context, and sometimes even cultural background (Hajiyeva, 2024). Given their widespread use, accurately interpreting idioms is crucial for many natural language processing (NLP) tasks, including fact-checking, hate speech detection, sentiment analysis, machine translation, and question-answering (Yosef et al., 2023; Tan and Jiang, 2021), Misunderstanding the idiomatic meaning can lead to significant errors in these applications, affecting accuracy and usability.

The recent success of Large Language Models (LLMs) has significantly advanced the field. They have demonstrated strong performance in several NLP tasks through zero-shot and few-shot prompting (Wei et al., 2022b,a), showcasing their ability to handle complex reasoning challenges with minimal supervision. However, their ability to effectively process IEs remains an open question (De Luca Fornaciari et al., 2024). Additionally, as visual LLMs become widespread, it is worth investigating whether these models can effectively associate visual information with the IEs' meaning.

In this work, we propose a novel Chain-of-Thought (CoT) framework to explore multimodal idiomaticity understanding. Specifically, we investigate how visual LLMs can integrate textual and visual information to establish meaningful connections between IEs and their corresponding visual representations. Our approach leverages structured reasoning to guide LLMs in ranking images based on their relevance to a given either literal or idiomatic compound, assessing whether visual-text content relations contribute to a more accurate interpretation of IEs' meaning.

Our contributions are twofold: (i) We introduce a novel multimodal idiomaticity understanding framework using Chain-of-Thought prompting, and (ii) We investigate how visual LLMs can leverage step-by-step reasoning to accurately rank images based on the meaning of a compound word as used in a given sentence, distinguishing between idiomatic and literal interpretations.

The code and some examples are available at PoliTo-AdMIRe repository[1].

2 Related Works

While previous research has explored idiom detection and interpretation from text, the role of mul-

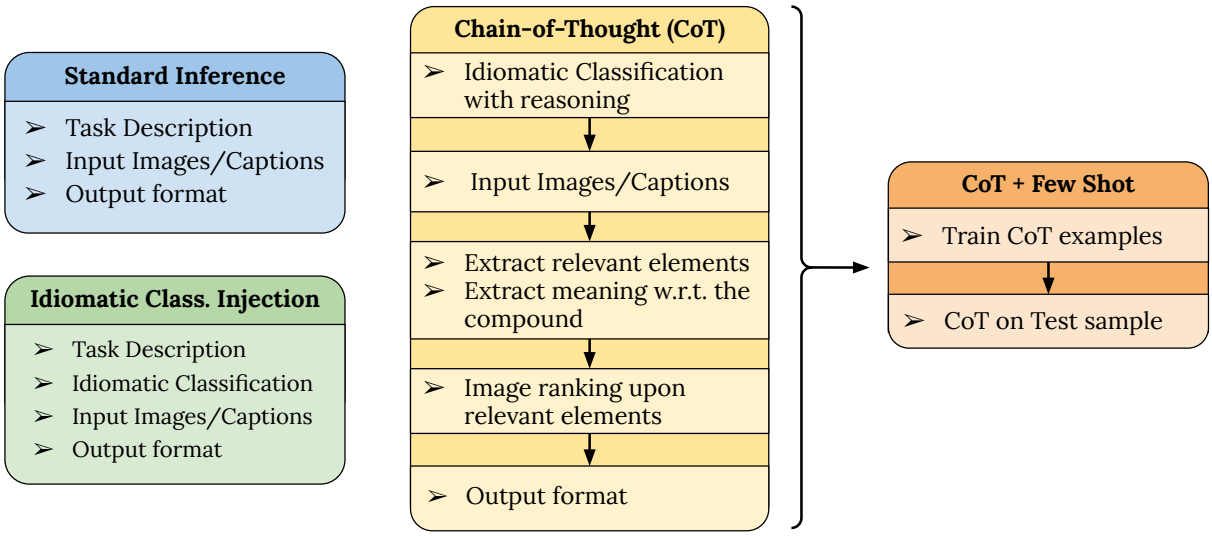

Figure 1: Different Prompt settings. Each titled block describes a different tested approach. Each inner block represents an interaction with the LLM. Consecutive inner blocks connected by an arrow represent consecutive interactions in the same LLM chat.

timodality in idiomaticity understanding remains largely unexplored. Most related studies have addressed figurative language understanding and disambiguation of a mix of visual and textual content. Specifically, visual figurative meaning understanding (Saakyan et al., 2024) aims to asses visual premise entails or contradicts a textual hypothesis. Instead, given a target word with limited textual context, visual-word sense disambiguation (Raganato et al., 2023) focuses on selecting, among a set of candidate images, those corresponding to its intended meaning. The AdMIRe challenge (Pickard et al., 2025) extends this idea to idiomatic expressions, considering idioms as textual descriptions and images that capture their intended meaning.

Transformer architectures, such as CLIP (Radford et al., 2021), and visual LLMs, such as LLaVA (Liu et al., 2023), have already shown promising performance on several multimodal tasks (Kulkarni et al., 2024; Vaiani et al., 2023; D'Amico et al., 2023; Napolitano et al., 2024) Furthermore, more advanced visual LLMs, such as Qwen2.5-VL (Bai et al., 2025) or Gemini (Team et al., 2023), have been trained to handle multiple images. Finally, combining visual models and LLMs with multimodal Chain-of-Thoughts (CoT) already demonstrated state-of-the-art performance in many vision-language tasks (Shao et al., 2024; Mondal et al., 2024; Zhang et al., 2024). Accordingly, our approach relies on CoT to improve visual LLMs' understanding of idiomatic expressions.

3 Methodology

Our approach investigates whether visual LLMs can accurately rank candidate images based on their relevance to a given textual compound used in a reference sentence. Since the compounds can assume either an idiomatic or a literal meaning, disambiguating their usage is crucial for meaningful image ranking. To address this, we propose a Chain-of-Thought (CoT) framework that integrates explicit reasoning steps to improve the ranking process. Figure 1) depicts the proposed solution.

As a starting point, we evaluate off-the-shelf visual LLMs by providing them with a sentence, the target compound expression, and five candidate images, prompting them to rank the images based on how well they reflect the compound's meaning in context. The *Standard Inference* block in Figure 1 refers to this approach. This setup allows us to assess whether these models can naturally align visual content with textual semantics.

We introduce a stepwise CoT framework incorporating structured reasoning into the ranking process to improve performance. The first step involves text-based idiomaticity classification, where a standard text-only LLM is used to determine whether the compound is being used literally or idiomatically in the given sentence. This binary classification provides crucial disambiguation before any visual reasoning takes place. Once the compound's usage is classified, this information is explicitly injected into the visual LLM's prompt,

helping the model contextualize the ranking task correctly. Equipped with this knowledge, the visual LLM is then asked to rank the images, now with a clearer understanding of whether the compound should be interpreted in a literal or idiomatic sense. The *Idiomatic Classification Injection* block in Figure 1 describes this strategy.

To increase the quality of this approach, we also propose an iterative CoT framework, where the visual LLM undergoes a multi-step reasoning process before producing a final ranking. This method retains the idiomaticity classification step, where the visual LLM explicitly informs whether the compound is used literally or idiomatically. Then, the model is prompted to extract key visual elements from each image that may be relevant to the compound's meaning. This step allows the model to focus on meaningful visual details that align with the expected interpretation. After identifying these elements, the model is instructed to rank the images based on the extracted features and the previously injected idiomaticity classification. Notably, the ranking prompt is adapted depending on whether the compound is used literally or idiomatically, ensuring that images are evaluated based on the correct semantic perspective. This technique is depicted in the *Chain-of-Thought* block of Figure 1. Each arrow represents a subsequent interaction in the visual LLM chat.

Finally, we incorporate a few-shot learning approach to improve idiomaticity-aware image ranking further. This approach provides the visual LLMs with in-context examples before performing the ranking task, where each example follows the entire Chain-of-Thought pipeline. The *Chain-of-Thought + Few Shot* block in Figure 1 visually describes this technique.

4 Experimental Results

4.1 Dataset

The AdMIRe challenge organizers released a dataset designed for understanding idiomatic expressions in a multimodal context. Each sample consists of a reference sentence, a compound expression used in the sentence, and five candidate images with their relative captions that could represent the compound's meaning within the given context.

The dataset is divided into three subsets:

- *Train Set*, it contains 70 samples, enriched with target annotations, including the compound's usage type (literal or idiomatic) and the image ranking based on its relevance to the compound's meaning.
- *Test Set*, contains 15 samples, released without target annotations at challenge time.
- *Extended Test Set*, it expands the previous Test Set with 100 additional samples, offering a more extensive evaluation benchmark.

Given the relatively small size of these sets, training a model could be challenging. However, the dataset still provides enough diverse examples to explore effective CoT prompting strategies and construct heterogeneous in-context learning demonstrations, allowing for a meaningful analysis of multimodal idiomaticity understanding.

4.2 Experimental Setup

To evaluate the effectiveness of our Chain-of-Thought (CoT) framework in multimodal idiomaticity understanding, we conduct experiments using several visual LLMs:

- **Qwen2.5-VL** (Bai et al., 2025), an open-source vision-language model that integrates visual perception with large-scale text generation. We employ the 7B instruction-tuned version of this model[2].
- **Gemini Flash (F)** (Team et al., 2023), both 1.5 and 2.0 versions, a Google proprietary multimodal model designed for fast inference while maintaining strong performance across vision-language tasks[3].
- **Gemini Flash Thinking (FT)** (Team et al., 2023), version 2.0 only, a variant of Gemini Flash designed to enhance complex reasoning, making it particularly relevant for structured multimodal reasoning tasks[4].

As a baseline, we frame the task as a text-to-image retrieval problem, using the large[5] version of CLIP (Radford et al., 2021) to measure the semantic similarity between the sentence containing the compound and the five candidate images, ranking them accordingly.

In our CoT approach, we first determine whether the compound in the sentence is used in a literal

Table 1: Model Performance Comparison for both Multimodal and Text-only approaches. Best results are reported in bold

or idiomatic sense. To ensure high-quality classification, we rely on the best-performing LLM to generate this classification label. In our case, Gemini 2.0 FT is identified as the candidate compound usage type classifier (i.e, if the compound usage in the sentence is idiomatic or literal), providing the best classification result on the AdMIRe *Train Set*, with an accuracy of 90%. The resulting idiomaticity class is then injected as prior knowledge into the prompts of all tested visual LLMs.

Regarding the few-shot approach, we randomly select three different train samples as in-context examples for both the literal and the idiomatic use case. These samples undergo the same CoT pipeline described in Section 3. For the Qwen model, we decrease the number of in-context examples to one, due to memory constraints.

We also apply the proposed framework to the text-only version of the AdMIRe challenge. In the absence of visual input, we maintain identical prompt formats as delineated in Section 3, substituting image inputs with their corresponding textual captions provided in the dataset.

All tested models have been evaluated using the official AdMIRe competition test sets, denominated as *Test Set* and *Extended Test Set*, and metrics, i.e., top 1 accuracy and Discounted Cumulative Gain (DCG) score. In detail, Top-1 accuracy measures the model's ability to select the most appropriate image from five candidates. On the other hand, the DCG score evaluates the quality of the entire ranking of these images, providing insight into the model's overall ordering capabilities.

4.3 Results

Table 1 shows the obtained results. All employed visual LLMs in their default inference setting were prompted to directly provide a rank of the images and overcome the CLIP baseline, with Gemini 2.0 FT achieving the highest performance.

The three techniques constituting our framework, i.e., idiomatic classification, CoT, and few-shot learning, are evaluated as incremental steps. Injecting the result of idiomatic classification (CLS: ✓) only into the prompting of visual LLMs does not produce relevant performance changes and the results reflect those of the standard approach, with a slightly improved performance on the *Extended Test Set*. However, Qwen and Gemini 2.0 FT performance only increases on the *Test Set*. Although this improvement affects only two out of four tested models, it can be attributed to the composition of this specific evaluation set. The *Test Set* presumably contains more ambiguous usages of the com-

pounds, making the idiomatic classification result a piece of valuable information to address the ranking task. Notably, Gemini 2.0 FT obtains the higher Top-1 accuracy value on the *Test Set* with this approach.

The introduction of Chain of Thought (CoT) without adopting few-shot learning produces model-dependent effects with notable differences between the test and extended test sets. We can notice a significant decrease in the Qwen performance on both evaluation sets. This is probably due to the model size, which is too small to handle the entire reasoning pipeline completely. On the other hand, this approach is beneficial for all the Gemini family models: Gemini 2.0 FT improves on the *Extended Test Set*, Gemini 2.0 F improves on the *Test Set*, and Gemini 1.5 F improves on both evaluation sets. Noteworthy that Gemini 2.0 F obtains the higher DCG value on the *Test Set* with this approach.

Moving forward, including a few-shot learning technique (Few Shot: ✓) in our CoT pipeline leads to the best results. For Gemini 1.5 F, this combination maintains the improvements obtained using CoT only on *Test Set*, while substantially improving *Extended Test Set* performance. Gemini 2.0 F performance slightly decreases from CoT-only to CoT plus Few Shot on the *Test Set* but achieves its peak performance on the *Extended Test Set*, representing the best performance among all models. This combination of CoT and in-context learning allows Gemini 2.0 FT to achieve the highest overall results on both metrics for the *Test Set*. Also, the results on the *Extended Test Set* improve significantly, settling slightly below those of the Gemini 2.0 F. Moreover, thanks to introducing few-shot learning, Qwen can better understand the previous CoT pipeline, partially restoring its performance.

Although the effect of the proposed steps seems to be model-dependent, the results demonstrate the effectiveness of employing both CoT and few-shot learning, which always lead to the best result.

Finally, we use the best-performing model overall, i.e., Gemini 2.0 FT, to evaluate the proposed approach in a text-only fashion and compare it with a baseline model, i.e, CLIP-Text. The results reported in the bottom section of Table 1 provide valuable comparative insights. The textual encoder of CLIP performs similarly to its multimodal counterpart. Accordingly to the multimodal case, Gemini 2.0 FT achieves substantial improvement. However, it achieves lower metric values than its multimodal implementation, indicating that the visual modality provides essential information to accurately associate idiomatic expressions with the corresponding meaning.

5 Conclusions

In this work, we investigated the role of multimodal reasoning in idiomaticity understanding, introducing a novel Chain-of-Thought (CoT) framework to enhance the ranking of images based on their association with idiomatic expressions.

We observed that standard prompting of Visual LLMs is insufficient for correctly ranking images according to idiomatic meanings. The joint introduction of idiomatic classification, CoT reasoning, and few-shot learning consistently led to the best results, proving the effectiveness of step-by-step reasoning and in-context learning for this task. Furthermore, we evaluated the extent to which visual components contribute supplementary information that enhances task resolution, assessing its relevance.

Future work could explore more advanced prompting strategies, model fine-tuning, and larger-scale idiomaticity datasets to enhance the robustness of multimodal idiomaticity understanding further.

Abstract

This study reports the YNU-HPCC team's participation in Subtask A of SemEval-2025 Task 1 on multimodal idiomatic representation. The task requires ranking candidate images based on their semantic relevance to a target idiom within a given sentence, challenging models to disambiguate idiomatic semantics, and aligning them with abstract visual concepts across English and Portuguese. Using AltCLIP-m18 as the base model, our approach enhances its zero-shot capabilities with LoRA fine-tuning and combines ListMLE ranking optimization with Focal Loss to handle hard samples. Experimental results on the primary test set show significant improvements over the base model, with Top-1 Accuracy/DCG scores of 0.53/2.94 for English and 0.77/3.31 for Portuguese. The code is publicly available at https://github.com/1579364808/Semeval_2025_task1.

1 Introduction

Idioms, as a class of multiword expressions (MWEs), pose significant challenges for natural language understanding due to their non-compositional nature—their meanings cannot be derived from the literal interpretation of their constituent words (Dankers et al., 2022; Villavicencio et al., 2005). For instance, *bad apple* metaphorically refers to a disruptive individual rather than a decayed fruit. Despite the remarkable progress of pre-trained language models (PLMs) in text comprehension tasks, their ability to model idiomatic expressions remains limited. Key issues include susceptibility to literal meaning interference (Phelps et al., 2024; Chakrabarty et al., 2022; Madabushi et al., 2022) and insufficient grounding in multimodal experiences, such as visual perception (Lakoff and Johnson, 1980; Lu et al., 2023).

SemEval-2025 Task 1 introduces a multimodal evaluation framework, i.e., Advancing Multimodal Idiomaticity Representation (Pickard et al., 2025). Subtask A ranks candidate images based on their semantic relevance to a target idiom within a given sentence. This task requires models to disambiguate idiomatic semantics from textual contexts and align them with abstract visual concepts, presenting a significant challenge for current approaches. For example, in the *kangaroo court* case, the model must distinguish between the literal depiction of a kangaroo and the metaphorical representation of an unjust judicial process.

Given the task's bilingual nature (English and Portuguese), we propose a multilingual approach based on AltCLIP-m18 (Chen et al., 2022), a multilingual variant of the CLIP (Contrastive Language-Image Pre-training) (Radford et al., 2021) model. We employ Low-Rank Adaptation (LoRA) (Hu et al., 2022), a parameter-efficient fine-tuning technique to efficiently adapt the model to the task. Additionally, we introduce a combined loss function integrating ListMLE Loss (Xia et al., 2008) and Focal Loss (Lin et al., 2017). ListMLE Loss optimizes the global ranking of candidate images, while Focal Loss addresses the challenge of distinguishing between literal and metaphorical meanings by focusing on hard-to-classify samples.

The main works in this paper are as follows:

- **AltCLIP-m18 for Idiomatic Expression Ranking**: We propose AltCLIP-m18 to rank images based on semantic relevance to potential idiomatic expressions in English and Portuguese.
- **LoRA for Efficient Adaptation**: We apply LoRA to AltCLIP-m18, reducing computational costs while maintaining performance.
- **Hybrid Loss for Improved Performance**: By combining ListMLE Loss and Focal Loss, our approach achieves Top-1 Accuracy/DCG scores of 0.53/2.94 for English and 0.77/3.31

for Portuguese on the primary test set, outperforming the base model.

2 Related Works

2.1 Multimodal Alignment Models

Recent advances in multimodal learning have been driven by models like CLIP (Radford et al., 2021), which maps images and text into a shared embedding space through contrastive learning. CLIP's architecture consists of a vision encoder (e.g., ResNet (He et al., 2016) or ViT (Dosovitskiy et al., 2021) and a text encoder (Transformer (Vaswani et al., 2017)), enabling effective semantic alignment between visual and textual representations. Extending CLIP to multilingual scenarios, AltCLIP-m18 introduces multilingual contrastive pre-training, supporting 18 languages and achieving state-of-the-art performance in cross-modal tasks. This capability is particularly relevant for SemEval-2025 Task 1 Subtask A, which involves both English and Portuguese, providing a strong baseline for further fine-tuning.

2.2 Parameter-Efficient Fine-Tuning

Fine-tuning large pre-trained models requires significant computational resources. LoRA has emerged as an efficient alternative to address this (Zhang et al., 2024b). LoRA reduces the number of trainable parameters by decomposing the weight update matrix into low-rank components (Hu et al., 2022). This approach allows for efficient adaptation while preserving the model's performance and has been successfully applied in various domains, including natural language processing (Zhang et al., 2024a) and multimodal learning (Shen et al., 2024; Lu et al., 2023).

2.3 Learning-to-Rank Methods

Learning-to-rank (LTR) methods have been extensively studied in information retrieval (Liu et al., 2009), with applications ranging from document ranking to recommendation systems. SemEval-2025 Task 1 Subtask A aims to rank candidate images based on their semantic relevance to a nominal compound (NC) in a given sentence.

Traditional classification or regression losses are ill-suited for this task because they do not directly optimize ranking metrics such as Discounted Cumulative Gain (DCG). Generally, LTR methods can be categorized into the following three paradigms (Liu et al., 2009) :

- **Pointwise Methods**: Treat ranking as a classification or regression problem, focusing on individual samples but ignoring relative order.
- **Pairwise Methods**: Model the relative preferences between pairs of items, capturing local ordering relationships but lacking a global perspective.
- **Listwise Methods**: Optimize the entire ranking list directly, aligning more closely with ranking metrics like DCG.

Among these, Listwise methods, such as ListMLE Loss (Xia et al., 2008), are particularly effective for tasks where global ranking consistency is critical, making them a natural choice for Subtask A.

3 Datasets and Evaluation Metrics

The dataset for SemEval-2025 Task 1 Subtask A includes 70 English and 32 Portuguese training items. Each item contains a context sentence containing a potentially idiomatic NC and five candidate images. The images are categorized into five types: a synonym for the idiomatic meaning, a synonym for the literal meaning, something related to the idiomatic meaning (but not synonymous), something related to the literal meaning (but not synonymous), and a distractor unrelated to both meanings.

For each data item, the primary fields used are **compound** (the idiomatic NC), **sentence_type** (indicating whether the sentence uses the idiomatic or literal sense), **sentence** (the context sentence), **expected_order** (the ground-truth ranking of images), and **image{n}_name** (the filenames of the five candidate images, where n ranges from 1 to 5). In the training data, **sentence_type** and **expected_order** are provided for supervised learning. In the development and test data, these fields are empty, and the model is required to predict **expected_order** based on the context sentence and compound.

The model is evaluated using two key metrics: **Top 1 Accuracy** and **Discounted Cumulative Gain (DCG)**. Top 1 Accuracy measures the model's ability to correctly identify the most representative image for the given context. DCG evaluates the overall ranking quality by assigning higher weights to images ranked closer to the ground-truth top positions. The DCG score is calculated as fol-

lows:

$$DCG = \sum_{i=1}^{k} \frac{rel_i}{\log_2(i+1)} \quad (1)$$

where rel_i represents the relevance score of the i-th result, and i is the rank position of the result, starting from 1. The term $\log_2(i+1)$ acts as a discount factor, reducing the influence of results that appear later in the ranking.

4 Methodology

Our approach for SemEval-2025 Task 1 Subtask A consists of four key components: (1) the base multimodal model (AltCLIP-m18), (2) parameter-efficient fine-tuning using LoRA, (3) a combined loss function integrating ListMLE Loss and Focal Loss, and (4) a data augmentation strategy to enhance the diversity and robustness of the training data.

4.1 Base Model: AltCLIP-m18

We adopt AltCLIP-m18, a multilingual extension of CLIP, as the base model. AltCLIP-m18 consists of a Transformer-based text encoder and a Vision Transformer (ViT) image encoder, which maps text and images into a shared embedding space. Given a sentence s and an image I , the model computes their similarity score as:

$$\text{sim}(s, I) = \cos(E_{\text{text}}(s), E_{\text{image}}(I)) \quad (2)$$

where E_{text} and E_{image} denote the text and image encoders, respectively, and cos is the cosine similarity function (see Figure 1).

4.2 Parameter-Efficient Fine-Tuning with LoRA

To adapt the pre-trained AltCLIP-m18 model to the task, we employ LoRA, which reduces the number of trainable parameters by decomposing the weight update matrix into low-rank components:

$$\Delta W = A \cdot B \quad (3)$$

where A and B are low-rank matrices with rank r , and ΔW is the weight update. The updated weight matrix is then:

$$W' = W + \alpha \cdot \Delta W \quad (4)$$

where α is a scaling factor that controls the strength of the update.

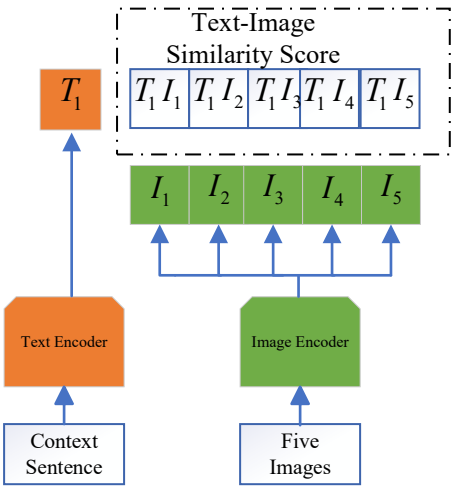

Figure 1: Architecture of AltCLIP-m18 for Text-Image Similarity Computation

In our implementation, LoRA is applied to the query and value projection matrices in the Transformer layers of the text and image encoders (see Figure 2). Research shows that adapting these two projection layers enables effective parameter-efficient tuning (Hu et al., 2022). Detailed hyperparameter configurations are discussed in the Experiments section.

4.3 Combined Loss Function

To optimize the ranking of candidate images, we propose a combined loss function integrating **ListMLE Loss** and **Focal Loss**.

ListMLE Loss maximizes the likelihood of the correct ranking by considering the entire list of candidate images. Given a ground-truth ranking y and a predicted ranking $f(x)$, the loss is defined as:

$$\begin{aligned} \mathcal{L}_{\text{ListMLE}} &= -\log P(y|x) \\ &= -\log \prod_{i=1}^{n} \frac{\exp(f(x_{y_i}))}{\sum_{k=i}^{n} \exp(f(x_{y_k}))} \end{aligned} \quad (5)$$

where y_i denotes the i-th item in the ground-truth ranking, $f(x_{y_i})$ is the predicted score for the i-th item, and x is the input to the model.

Focal Loss dynamically adjusts the weight of each sample to emphasize hard-to-classify cases (Lin et al., 2017), i.e., those for which the predicted probabilities are close to 0.5. In our approach, images of NCs with idiomatic and literal interpretations are regarded as hard-to-classify instances.

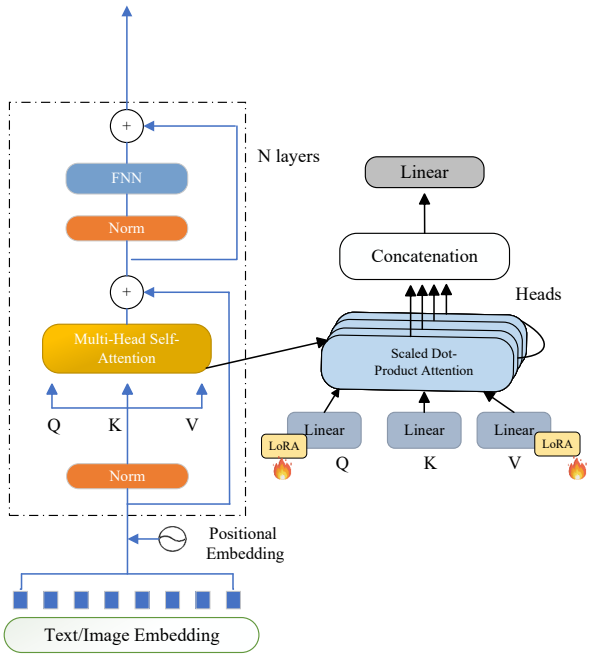

Figure 2: Application of LoRA to Query and Value Projection Matrices.

Misclassification of these cases can significantly impact the Top-1 Accuracy. The loss function is defined as:

$$\mathcal{L}_{\text{Focal}} = -\alpha_t (1 - p_t)^{\gamma} \log(p_t) \tag{6}$$

where $p_t = p$ for positive samples and $1-p$ for negative samples, with p being the model's confidence in the positive class. γ is the focusing parameter, and α_t is a weighting factor for class balancing. In the expected_order, the first image is treated as the positive sample, while the remaining images are considered negative. This setup allows the model to focus on distinguishing the most representative image from the candidates, thereby improving Top 1 Accuracy.

By combining Focal Loss with ListMLE Loss, our approach optimizes both the overall ranking distribution and the model's ability to handle ambiguous samples. The final loss function is a weighted combination of ListMLE Loss and Focal Loss:

$$\mathcal{L} = \lambda \cdot \mathcal{L}_{\text{Focal}} + (1 - \lambda) \cdot \mathcal{L}_{\text{ListMLE}} \tag{7}$$

where λ is a balancing factor.

4.4 Data Augmentation

To enhance the diversity and robustness of the training data, we employ a data augmentation strategy using the DeepSeek-V3 [1] model. For each data point, we generate two sentence variants using carefully designed prompts (see Figure 3): one preserving the original sentence_type and another inverting sentence_type. When sentence_type is inverted, we also invert the top four images in expected_order, ensuring the model learns to distinguish between idiomatic and literal meanings more effectively.

5 Experiments

5.1 Experimental Setup

We trained our model on the augmented dataset with a learning rate of 1×10^{-4}, batch size of 8, and 2 epochs. For Focal Loss, we set $\gamma = 2$ and $\alpha_t = [0.35, 0.1, 0.15, 0.3, 0.1]$ through empirical experiments. For LoRA, we used rank $r = 6$, scaling factor $\alpha = 48$, and dropout rate 0.5 to balance performance and computational efficiency. Table 2 compares the trainable parameters of AltCLIP-m18 between full fine-tuning and the LoRA setup used in our experiments.

5.2 Comparison with Baseline

We compared our approach to the baseline model (AltCLIP-m18) in zero-shot performance. Table 1 presents the baseline results alongside our model's performance with Focal Loss weight $\lambda = 0.15$, while Figure 4 illustrates the impact of different Focal Loss weights on the primary test set.

On the development set, with λ = 0.15, our method achieved identical **Top 1 Accuracy** (0.60) and comparable **DCG** scores to the baseline in both English and Portuguese.

On the primary test set, with λ = 0.15, our model achieved a **Top 1 Accuracy** of 0.53 and **DCG** of 2.94 for English, outperforming the baseline's **Top 1 Accuracy** (0.40) and **DCG** (2.98). For Portuguese, our model achieved a **Top 1 Accuracy** of 0.77 and **DCG** of 3.31, surpassing the baseline's **Top 1 Accuracy** (0.55) and **DCG** (2.98).

On the extended test set, with λ = 0.15, our model achieved a **Top 1 Accuracy** of 0.59 and **DCG** of 2.97 for extended English, outperforming the baseline's **Top 1 Accuracy** (0.57) and **DCG** (2.95), and for extended Portuguese, it matched the baseline's score of 0.53 while maintaining a **DCG** of 2.98.

The improvements over the baseline model stem from Focal Loss and LoRA Fine-Tuning. Focal

Table 2: Comparison of trainable parameters between full fine-tuning and LoRA for AltCLIP-m18

	Trainable Params	Percentage
Full Fine-tuning	1,194,000,897	100%
LoRA	983,040	0.0823%

Loss improves Top 1 Accuracy by focusing on hard-to-classify samples, while LoRA Fine-Tuning ensures efficient adaptation with minimal computational overhead. Together, they enhance multimodal idiomaticity representation.

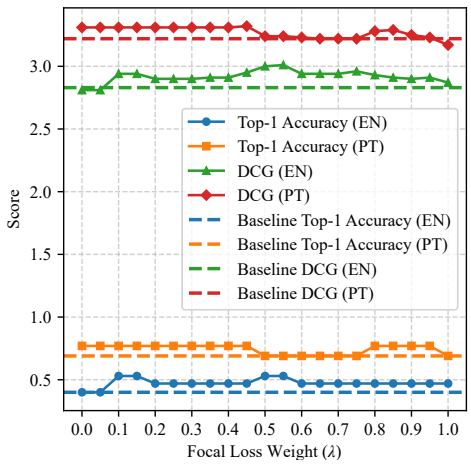

Figure 4: Comparison of Model Performance with Baseline on the Primary Test Set Across Different λ Values

5.3 Ablation Study: Focal Loss Weight λ

We conducted an ablation study to analyze the impact of different Focal Loss weights λ in the combined loss function across development, primary test, and extended test sets. The results are summarized in Table 3.

On the development set, English (EN) showed consistent **Top 1 Accuracy** (0.60) across all λ values, while Portuguese (PT) exhibited more variation, peaking at $\lambda = 0.65$ with **Top 1 Accuracy** **Top 1** (0.77) and **DCG** of 3.13. This stability in development suggests our model's robustness during initial parameter tuning. For the English (EN) primary test set, the best **Top 1 Accuracy** (0.53) was achieved in the vicinity of $\lambda = 0.1$ and $\lambda = 0.5$, while the highest **DCG** (3.01) was observed at $\lambda = 0.55$. In the Portuguese (PT) primary test set, the **Top 1 Accuracy** remained stable at 0.77 for most values of λ, with the **DCG** peaking at 3.32 when $\lambda = 0.45$. For the extended test set, the best **Top 1 Accuracy** (0.59) in the extended English

Table 3: Performance comparison across different λ values. Red highlights indicate the maximum values, while green highlights indicate the minimum values for each metric.

test set was achieved around $\lambda = 0.1$ and $\lambda = 0.2$. Notably, in the extended Portuguese test set, the highest **Top 1 Accuracy** (0.62) and **DCG** (3.04) were observed at $\lambda = 1$. These results indicate that the optimal value of λ varies across languages and test sets, with a moderate range (e.g., $\lambda = 0.1$ to 0.5) generally balancing ranking performance and classification accuracy.

6 Conclusion

This study proposes a multilingual and parameter-efficient approach for SemEval-2025 Task 1 Subtask A, leveraging AltCLIP-m18, LoRA fine-tuning, and a combined loss function of ListMLE Loss and Focal Loss. The experiments demonstrate significant improvements over the baseline model. However, it is important to acknowledge the limitations of our study. One key limitation is the relatively small size of the training dataset, especially for Portuguese, which may affect the generalizability of our results. Future work could address this by expanding the dataset or exploring transfer learning techniques to leverage larger, related datasets.

Abstract

Fact-checkers are often hampered by the sheer amount of online content that needs to be fact-checked. NLP can help them by retrieving already existing fact-checks relevant to the content being investigated. This paper presents a systematic approach for the retrieval of top-k relevant fact-checks for a given post in a monolingual and cross-lingual setup using transformer-based pre-trained models fine-tuned with a dual encoder architecture. By training and evaluating the shared task test dataset, our proposed best-performing framework achieved an average success@10 score of 0.79 and 0.62 for the retrieval of 10 fact-checks from the fact-check corpus against a post in monolingual and crosslingual track respectively.

1 Introduction

The rapid proliferation of misinformation across social media platforms has made manual fact-checking an increasingly daunting task. Automated retrieval systems, powered by Natural Language Processing (NLP) techniques, offer a scalable solution by identifying and presenting previously verified fact-checks relevant to new claims. In this work, we present a robust fact-check retrieval framework that leverages transformer-based dual encoder architectures, fine-tuned separately for monolingual and cross-lingual settings.

Our framework involves three state-of-the-art pre-trained models: GTR-T5 (Ni et al., 2021a) for both monolingual and coss-lingual fact-check retrieval, E5-Large-v2 (Wang et al., 2022) and MiniLM (Wang et al., 2020) for cross-lingual retrieval. Evaluated on the *SemEval 2025 Shared Task 7: Multilingual and Crosslingual Fact-Checked Claim Retrieval* dataset, our proposed system achieves a Success@10 score of 0.79 on the test set with GTR-T5 in the monolingual track. For the cross-lingual track, GTR-T5 and E5-Large-v2 achieved Success@10 scores of 0.62 and 0.58 on the test set, respectively. In addition, a MiniLM-based framework was also developed as a lightweight alternative that converts posts and fact-checks into normalized vector embeddings using MiniLM-L12-v2, which are then indexed with FAISS for rapid retrieval.

The proposed retrieval system not only addresses the challenge of the vast online misinformation but also provides a scalable solution that can be adapted to diverse multilingual environments.

2 Related Work

Early fact-checking retrieval systems relied on keyword-based and traditional IR methods, which lacked semantic understanding and multilingual support. Neural IR models like DRMM (Guo et al., 2016) and MatchPyramid (Pang et al., 2016) improved performance but struggled with scalability and cross-lingual generalization.

Transformer-based models such as BERT (Devlin et al., 2019) and Sentence-BERT (Reimers and Gurevych, 2019) enabled dense vector representations and improved semantic retrieval. Dual encoder models like GTR-T5 (Ni et al., 2021b) and E5 (Wang et al., 2022) further enhanced efficiency by allowing independent query-document encoding, making them suitable for large-scale applications.

Earlier approaches such as DSSM (Huang et al., 2013) and KNRM (Xiong et al., 2017) demonstrated the potential of deep learning for retrieval tasks but were often limited by shallow interaction architectures and difficulties in handling long input sequences. These models, while offering initial improvements over traditional IR, did not fully capture the complex semantic relationships necessary for effective claim retrieval, especially in multilingual contexts.

Multilingual models like **LaBSE** further pushed the boundaries of multilingual semantic retrieval.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2084–2089

3 Data

All textual analysis and experiments were performed using data from the *SemEval 2025 Shared Task 7: Multilingual and Crosslingual Fact-Checked Claim Retrieval* (Peng et al., 2025). During the training and development phase, the dataset consisted of approximately 24,431 social media posts in multiple languages, 153,743 fact-checked claims, and 25,743 post-to-fact-check pairs where each post was linked to at least one fact-check claim. The 24,431 posts were further divided into cross-lingual and monolingual tracks where 18,907 posts were used for monolingual evaluation and 5,524 posts were used for cross-lingual evaluation.

Furthermore, in the monolingual track, the 18,907 posts and 153,743 fact checks were distributed into eight different languages: French (fra), Spanish (spa), English (eng), Portuguese (por), Thai (that), Deutsch (due), Modern Standard Arabic (msa) and Arabic (ara). The distribution of monolingual and crosslingual data are provided in Figure 1 for both training and development sets.

For the testing dataset, there was a total of 272,447 fact checks distributed over 10 languages (8 languages were the same as training and development sets, 2 extra languages were added: Polish or pol and Turkish or tur) and 8,276 posts. Among 8,276 posts, 4000 posts were for cross-lingual tracks and the remaining posts were for monolingual tracks. The overall data distribution for test data is provided in Figure 2

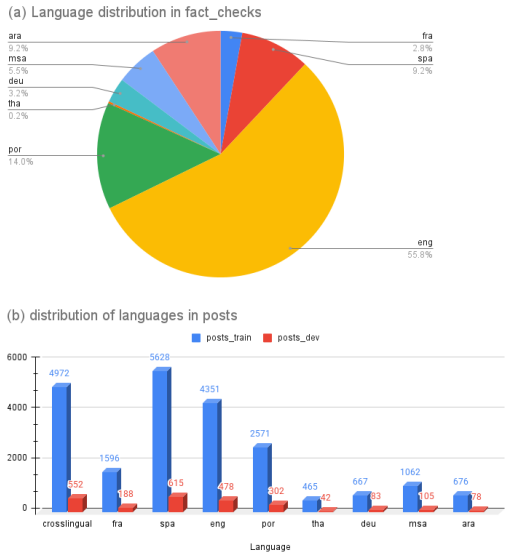

Figure 1: Distribution of training and development data

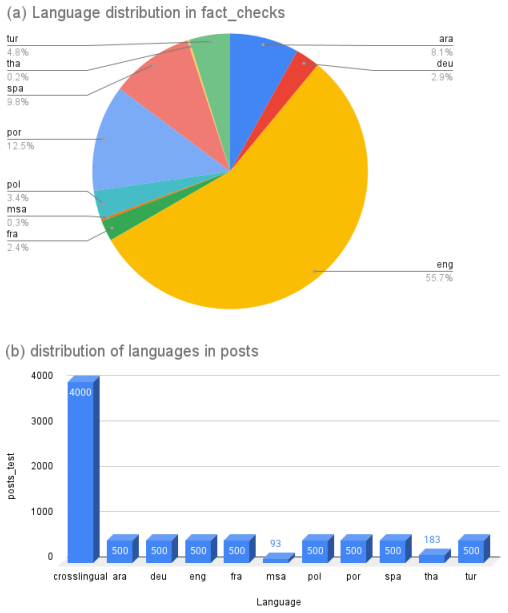

Figure 2: Distribution of test data

4 Methodology

This section briefly discusses the methodologies used to develop our proposed frameworks.

4.1 Text Preprocessing

Before diving into the actual system development and training, a few post-processing steps were applied such as 1) Removal of escape characters (e.g., `\n`, `\t`), 2) Decoding of Unicode characters, 3) OCR and post text were concatenated, 4) Tokenization of texts into tokens etc.

4.2 Framework Development

This section outlines the development of the proposed framework for the cross-lingual and monolingual relevant fact-check retrieval system.

We selected GTR-T5, E5-Large-v2, and MiniLM based on extensive evaluation across multilingual retrieval benchmarks. GTR-T5 is pretrained on large-scale multilingual corpora and fine-tuned for dense retrieval using contrastive learning, resulting in strong performance in zero-shot and multilingual retrieval tasks. E5-Large-v2, on the other hand, is optimized for retrieval-specific objectives such as passage ranking, supports multiple languages with task-specific embeddings, and remains efficient and scalable for large datasets. MiniLM was chosen for its lightweight and fast architecture, making it ideal for real-time applications while providing a good trade-off between

speed and retrieval performance.

The benchmark dataset allowed us to evaluate all models under controlled and consistent conditions, ensuring fair comparison across multilingual pairs. GTR-T5, E5-Large-v2, and MiniLM emerged as top performers based on retrieval accuracy, latency, and generalization to low-resource settings. These models demonstrated robustness across diverse language directions, including low-resource to high-resource queries and vice versa. In contrast, models that were not selected showed inferior performance on key metrics such as MRR, Recall@k, and precision, further justifying their exclusion from final deployment.

4.2.1 Dual Encoder with E5-Large-v2 and GTR-T5

The framework leverages a dual-encoder architecture used for independent fine-tuning of two transformer-based pre-trained models: E5-Large-v2 and GTR-T5. E5-Large-v2 was pre-trained on large-scale retrieval tasks and fine-tuned on datasets such as MS MARCO (Craswell et al., 2021) and various multilingual benchmarks, rendering them highly suitable for cross-lingual retrieval. In contrast, GTR-T5 is specifically designed for dense retrieval tasks and has been pre-trained on extensive monolingual datasets, making it highly effective for monolingual fact-check retrieval. Accordingly, E5-Large-v2 was employed for the cross-lingual track while GTR-T5 was employed for both the monolingual and cross-lingual tracks.

In this dual-encoder framework, separate encoders process both the query (i.e. posts) and passage (i.e. fact-check) and then yield dense vector representations. The dot product similarity scores matrix between these representations quantifies the relevance of the passage to the query. The overall model flow diagram is provided in Figure 3

Framework Description: The dual encoder architecture for the mentioned two models consists of two independent encoders—one for the query (i.e., post) and one for the passage (i.e., fact-check). For the E5-Large-v2, the encoders are implemented using `TFBertModel` to tokenize input queries and passages. GTR-T5 uses `TFT5EncoderModel` for both encoders, enabling it to process input sequences efficiently.

Let the input query/post be Q (e.g., "Is climate change real?") and passage/fact-check be P (e.g., "Scientific consensus states climate change is happening."), which are tokenized into input IDs using

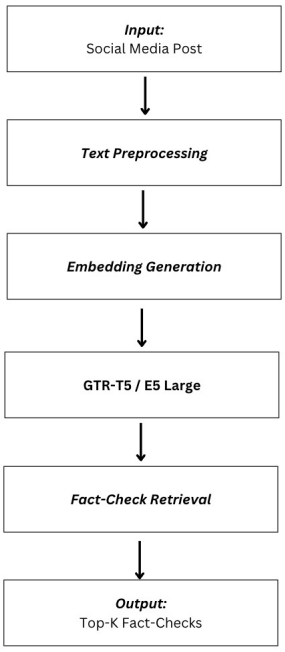

Figure 3: Flow diagram of E5-Large and GTR-T5 based frameworks

the common tokenizer. Input IDs of each input Q and P are passed through the query encoder and passage encoder to generate Query Embedding (E_Q) and Passage Embedding (E_P), which are dense vector representations. The embeddings are then normalized:

$$E_Q = \frac{E_Q}{\|E_Q\|}, \quad E_P = \frac{E_P}{\|E_P\|} \tag{1}$$

The model computes the cosine similarity to find similarity scores between all query and passage embeddings in the batch:

$$S_{ij} = E_{Q_i} \cdot E_{P_j} \tag{2}$$

where S_{ij} is the similarity score between the i^{th} query and the j^{th} passage. This results in a similarity score matrix $S \in \mathbb{R}^{n \times n}$ for a batch of size n.

4.2.2 A lightweight framework using MiniLM

This approach was built around three key components: how we represent the data, how we retrieve relevant fact-checks, and how we fine-tune our model to improve accuracy. The overall flow-diagram for the MiniLM-based framework is provided in Figure 4.

Data Representation: To compare social media posts with fact-checked claims, we first converted them into vector embeddings using the all-

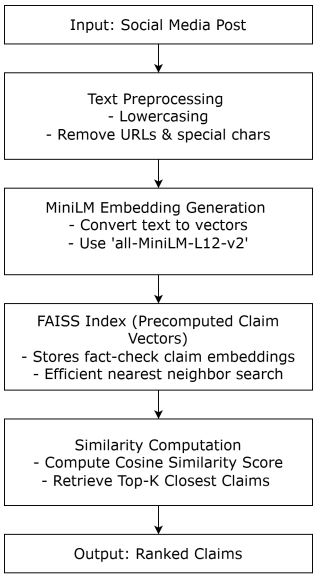

Figure 4: Flow diagram MiniLM-based framework.

MiniLM-L12-v2 (Wang et al., 2020) model. This helped us to capture similarities in meaning, even across different languages, so that we can match posts with the most relevant fact-checks.

Framework Description: To find the right fact-check efficiently, we used FAISS (Facebook AI Similarity Search) (Douze et al., 2024) a fast and scalable tool for searching through large datasets. The retrieval process works as follows: We generated MiniLM embeddings for both social media posts and fact-check claims. To improve accuracy, we normalized these embeddings, ensuring that they have the same scale before comparison. We then used the FAISS indexing system to quickly find and retrieve the most relevant fact checks based on similarity.

4.3 Training

During training, the contrastive loss ensured that the model maximized the similarity for positive pairs and minimized it for negative pairs. For each query-passage pair in the batch:

$$y_i = \begin{cases} 1, & \text{if positive pair} \\ 0, & \text{if negative pair} \end{cases} \tag{3}$$

A margin m is used to separate positive and negative pairs (e.g., $m = 0.2$):

$$L = y_i(1 - S_i)^2 + (1 - y_i)\max(0, S_i - m)^2 \tag{4}$$

The contrastive accuracy measured how well the model classified positive and negative pairs using a threshold τ (e.g., $\tau = 0.5$):

$$\hat{y}_i = \begin{cases} 1, & \text{if } S_i \geq \tau \\ 0, & \text{otherwise} \end{cases} \tag{5}$$

4.4 Retrieval of Top-K Relevant Fact-Checks

For a given query or post Q, the similarity scores were computed for all passages (or fact-checks) in the corpus:

$$Scores_P = [S_1, S_2, \ldots, S_n] \tag{6}$$

The passages were then ranked by their similarity scores, and the top-K fact-checks with the highest scores were retrieved for the given post:

$$Top\text{-}K = \text{argsort}(-Scores_P)[:K] \tag{7}$$

In our experiments, we chose $K = 10$. This means we retrieved the top 10 fact-checks with the highest scores.

4.5 Fine Tuning

The proposed GTR-T5 framework was fine-tuned with a batch size of 16 and a learning rate of 3e-5 with PyTorch as the deep learning framework. The model was trained for 5 epochs, and early stopping was applied to prevent overfitting. The contrastive loss function with a margin of 0.2 was used to optimize the model and the Adam (Kingma and Ba, 2017) optimizer was used for gradient updates.

The proposed E5-Large-v2 framework was trained with TensorFlow as the deep learning framework and fine-tuned for 1 epoch with a learning rate of 1e-5. No layer of the model was frozen during training. The optimizer was chosen as Adam and the batch size was taken as 2. The loss function used was contrastive loss with a margin of 0.2 and the optimizer was chosen as Adam. The accuracy was calculated during fine-tuning of the model with the help of the contrastive accuracy function.

E5-Large-v2 showed early saturation in validation metrics, and training beyond one epoch led to performance degradation due to overfitting; hence, it was fine-tuned for only one epoch. In contrast, GTR-T5-Large, with its larger architecture and slower learning dynamics, required fine-tuning for five epochs to achieve convergence.

The miniLM model was trained with a batch size of 32 and a learning rate of 2e-5 with PyTorch as the deep learning framework and the 'MultipleNegativesRankingLoss' loss function was used. To

test the impact of extended fine-tuning, we experimented with varying training times, using runs that lasted 3 and 10 epochs. However, the best result was produced at epoch 10 and reported in Table 1 in Section 5. To prevent overfitting, we applied dropout layers and weight decay in the respective model.

All the above models were trained and evaluated on the Kaggle platform using the NVIDIA Tesla T4 GPU.

5 Result

All the proposed frameworks were evaluated on the development and testing datasets using the Success@10 metric by retrieving the top 10 fact-checks from the corpus. The success@10 metric can be defined as:

$$\text{Success@10} = \begin{cases} 1, & \text{at least one fact-chek in top 10,} \\ 0, & \text{otherwise.} \end{cases}$$

The overall results are provided in Table 1 where we can see the GTR-T5-based framework provides the best performance in both monolingual and cross-lingual tracks for both development and test datasets. The E5-Large-v2 and MiniLM models didn't perform well and we can see a performance downgrade of 6.45% and 22.58% in the test data for the mentioned models respectively compared to the GTR-T5 model.

Track	Model	Dev	Test
Monolingual	GTR-T5	0.77	0.79
Crosslingual	GTR-T5	0.59	0.62
	E5-Large-v2	0.58	0.58
	MiniLM	0.51	0.48

Table 1: Success@10 results for monolingual and crosslingual retrieval in development and test phases

6 Conclusion

In this article, we proposed GTR-T5-based monolingual and cross-lingual frameworks and E5-Large-v2 and MiniLM-based cross-lingual frameworks only for fact-checked claim retrieval from social media posts. Our experiments show that the GTR-T5 model works well for both monolingual and cross-lingual settings with success@10 scores of 0.79 and 0.62 respectively in the test dataset. These results underscore the robustness of the proposed models in their respective tasks. However, further optimization is needed to improve recall for lower-ranked fact-checks and enhance cross-lingual retrieval performance. Future work will explore incorporating language mapping using multilingual transformer-based embeddings (TEMs) and employing advanced fine-tuning techniques to further improve performance. Also, we will experiment with the E5-large-v2 and MiniLM models for monolingual settings in our future work.

7 Limitations

Although the models perform well in retrieving relevant fact-checks, several limitations remain for monolingual and cross-lingual frameworks.

In the monolingual setting, while the proposed framework achieved a Success@10 of 0.79 in the test phase, there is still room for improvement in retrieving lower-ranked fact-checks. Additionally, the model's performance on low-resource languages within the same language family remains suboptimal.

In the case of the cross-lingual framework, a Success@10 of 0.62 was achieved in the test phase using GTR-T5, but the result was not impressive in the E5-Large-v2 and MiniLM-based models. One possible reason behind the batch size being restricted to 2 in the E5-Large-v2 model is that it may downgrade performance. In our future work, we will use higher batch sizes to determine whether the performance improves. Also, there is some scope for more hyperparameter tuning in the MiniLM model to improve performance, which we'll try in our future work.

Abstract

This paper presents our system developed for track A of the SemEval-2025 Task 11: Multi-label Emotion Detection. The primary goal of this task is to identify the emotions that most people would associate with a given sentence from a speaker, allowing multiple labels per instance. Our system focuses on detecting emotions in Russian-language sentences. To enhance model performance, we perform data pre-processing on special characters, punctuation, and expressions to better understand the relationship between textual features and emotion labels. We fine-tune a pre-trained language model specifically designed for Russian. To identify the best-performing model architecture, we employ a K-Fold Cross-Validation strategy during the model selection phase. Our final system achieved fourth place on the official leaderboard for the Russian sub-task.

1 Introduction

Emotion detection is a subfield of natural language processing (NLP) that involves identifying and classifying emotions expressed in text according to what most people are likely to perceive the speaker to be feeling. Importantly, the task does not aim to determine the actual emotional state of the speaker or the emotions of other entities mentioned in the text. For example, a sentence like "I am really happy now" would commonly be interpreted as expressing happiness due to the presence of emotional cues. This task has broad applications in various domains, making it an essential component in modern AI systems. In customer service, emotion detection enables companies to analyze user feedback, detect dissatisfaction, and improve overall user experience (Guo et al., 2024). In the mental health domain, it can help identify signs of emotional distress such as depression or anxiety from user input, supporting early intervention and automated screening processes (Francese and Attanasio, 2022). Given these applications, SemEval-2025 Task 11 focuses on the detection of multi-label emotion from sentences in several languages, including Russian, to model how the general public would interpret the emotional content of a speaker's statement (Muhammad et al., 2025b). In this paper, we describe our approach for Track A of the task, which includes comprehensive data preprocessing techniques, the use of a pre-trained Russian language model, and a K-Fold Cross-Validation strategy to identify potential model weaknesses and reduce overfitting. We also perform model selection to find the best-fitting architecture for our dataset. Our final system achieved fourth place on the official leaderboard for the Russian sub-task. The implementation of our system is available on Github[1].

2 Related Work

2.1 Models

The main goal of the multi-label classification problem is to find the relevance between classes and corresponding samples. Additionally, in the emotion detection problem, each emotion will correspond to special expressions or characters. There are many methods for this task, such as Decision Tree (Rokach and Maimon, 2005) or Support Vector Machine (SVM) (Evgeniou and Pontil, 2001). But today's language models outperform traditional machine learning algorithms (Liu et al., 2023). We tested many different language models that have been trained in Russian.

Since we want to fine-tune only Russian, we will focus on Encoder-only Models. Because of the support of HuggingFace, we can make predictions directly from the pre-trained model. We tested many different language models and compared them. These models are XLM-RoBERTa

(Conneau et al., 2019), DistilBERT (Sanh et al., 2019), TwHIN-BERT (Zhang et al., 2022), ruBert and ruRoberta (Zmitrovich et al., 2023). These models were trained on a large dataset including Russian.

2.2 Dataset

The provided Russian data are divided into 3 parts for training, validation, and testing (train/val/test, 2679/200/1000). The final ranking will be decided on the test set based on the last submission. Each sample in the datasets will have a sentence with 6 labels corresponding to 6 emotions: *Anger, Disgust, Fear, Joy, Sadness, Surprise* with value **1** for that emotion existing in the sentence and **0** otherwise. In addition, a distinct id is assigned to each sentence. For instance, the saying: *Hooray, I got an iron man* has the corresponding label **Joy**, so the value of Joy is 1 and the remaining emotions are 0 (Muhammad et al., 2025a).

3 System Overview

In this section, we describe the system in detail. We first clean the data and generate correlations between text and sentiments through data pre-processing. Then we use K-FOLD Cross-Validation to evaluate the model and analyze the mispredicted patterns. Furthermore, we use the sigmoid function (Han and Kaliraj, 1995) to make predictions with a single threshold for all labels. Finally, we experiment with different models to select the best models.

3.1 Pre-Processing

Each emotion type is associated with expressions in text or special punctuation and characters to express that emotion type. We encoded these expressions into Russian words that correspond to each emotion type. The Anger label is associated with red-faced expressions of anger, and we encoded these expressions as the word **anger**. In addition, anger emotion often appears in sentences with exclamation marks, and we encode exclamation marks (which are often grouped together and with the number 1) as a single exclamation mark. Next, the label Fear is associated with sentences with panic expressions (expressions with blue heads), we encoded it as **fear**. The emotion Sad is associated with sad facial expressions, crying faces, and a series of consecutive closing parentheses, which we encoded as **sadness**. The emotion of surprise is associated with a flushed face and two "O"s together (usually with a dot or underscore in the middle), which we encoded as the word **surprise**. The embarrassed expression (an underscore between two dots or two dashes) is associated with the three emotions Anger, Disgust, and Surprise, which we encode as the word **embarrassed**. Finally, the label Joy is associated with a smiling face, a heart, and a series of parentheses, which we encode as the word **joy**.

The data also contains swear words and asterisks, which are often associated with the anger label, we replace the asterisks to get the full word. In addition, we remove all remaining special characters such as periods, pound signs, or semicolons and replace them with spaces. Moreover, the dataset still contained spam words in which characters were excessively repeated, such as "xxXxxxx" or "OooOoo". To address this issue, we initially normalized these patterns by merging repeated characters into a single one. However, this approach unintentionally distorted some valid words, such as "running" being transformed into "runing". Therefore, we applied a reverse normalization step to restore such words to their correct forms, based on a predefined vocabulary or context-aware correc-

tion. Finally, there are some Russian letters that look similar to letters in the alphabet but are unique to Russian. For example, the characters "o" and "3" have different writings in Russian. All steps were implemented using the **regex** library.

3.2 K-FOLD Cross Validation

To evaluate the model and the data pre-processing methods, we used all labeled samples (including the validation set) and divided them into k folds. Due to the limited amount of data, we divided them into 30 folds, with 29 folds for the training set and only 1 fold for the validation set. We tested each model 10 times on 10 different validation folds to get an overview of the model. The standard binary cross-entropy loss (BCE) is used to optimize the model.

3.3 Model selection

We evaluated the model on the validation set using K-FOLD Cross-Validation, we computed the average F1-score (Doe and Smith, 2020) over the validation set. The best model is the one with the highest average value. Finally, we fine-tune the best model on the entire labeled dataset (training set and validation set) and use this model to make our final submission. According to Table 1, we choose **ruRoberta-large** as the best model.

4 Experimental Setup

Model	Pre-processing	Batch size	F1-score
ruRoberta-large	Yes	32	**0.841**
ruRoberta-large	No	32	0.831

Table 2: Performance of different models on the validation set based on pre-processing

We use the AdamW optimizer (Loshchilov and Hutter, 2017) with a learning rate of 10^{-5}, a weight decay of 0.01, and an epsilon of 0.09. Due to GPU limitations, each model has a different batch size, as detailed in Table 2. Furthermore, we conducted a small search to find the optimal threshold, using **ruRoberta-large** as the model and the F1-score to evaluate it in the validation set. The complete search results are shown in Table 5.

Model	F1-score	Language	Size (GB)

5 Results

5.1 Main Result

Based on Table 3, we see that the fine-tuned model only on Russian gives better results. Additionally, within the same model type, the larger version will give better results. The ruRoberta-large is the best model when it outperforms all other models with the best F1-score. Data pre-processing plays a crucial role in helping the model establish the relationship between words and their corresponding emotions. As shown in Table 2, all models performed better when pre-processing was applied. We also found that the optimal threshold for all labels lies between 0.4 and 0.5. In our final submission, we set **0.43** as the threshold and fine-tuned **ruRoberta-large** throughout the training and development sets. There were a total of 53 final submissions on Track A for Russian (rus), our system ranked fourth with a score of **0.889** on the test set, as shown in Table 4.

5.2 Error Analysis

In this section, we will analyze in detail the cases where our model went wrong. First, the relationship between words and their corresponding emo-

tions is so tight that any sentence containing that word always predicts the corresponding emotion. For example, in the sentence "Yeah, damn it! Yes baby, you gotta be awesome", the phrase "damn it" is associated with the emotion Anger, but this sentence has the emotion Joy. Secondly, our model cannot distinguish between the speaker's and referred person's emotions. For instance, in the text "Turtles are afraid of small spaces", the word "afraid" describes the turtle's sad emotion, not the speaker's, but our model predicts the turtle's feelings. Moreover, happy expressions often appear on the Joy and Surprise labels, confusing our model when predicting these two emotions. The text "Oh my gosh, what's going on tonight? :3 I think it's normal" has the emotion ":3" which usually appears in sentences labeled Joy but appears in sentences labeled Surprise. Finally, in a text, there are two sentences with two different emotions like "I love you. I'm so sad now", our model can only predict the label Joy or the label Sadness but cannot predict both.

6 Conclusion

In this paper, we introduced a good system to classify the speaker's emotions for the SemEval Challenge 2025 Task 11 track A. The key point of our system is to find the relationship between data and labels by pre-processing and testing different models to choose the model that fits the dataset. Our system achieved a top five ranking for Russian in the rankings.

Abstract

This paper presents a system description for the SemEval Mu-SHROOM task, focusing on detecting hallucination spans in the outputs of instruction-tuned Large Language Models (LLMs) across 14 languages. We compare two distinct approaches: Prompt-Based Approach (PBA), which leverages the capability of LLMs to detect hallucination spans using different prompting strategies, and the Fine-Tuning-Based Approach (FBA), which fine-tunes pre-trained Language Models (LMs) to extract hallucination spans in a supervised manner. Our experiments reveal that PBA, especially when incorporating explicit references or external knowledge, outperforms FBA. However, the effectiveness of PBA varies across languages, likely due to differences in language representation within LLMs.

1 Introduction

Large Language Models (LLMs) have brought advancements to many areas of NLP, including natural language understanding, natural language generation, and reasoning tasks (Naveed et al., 2024; Zhao et al., 2024; Minaee et al., 2024). Broadly speaking, LLMs such as GPT-4 (OpenAI et al., 2024) and LLaMA (Touvron et al., 2023) are based on transformer models and are trained on vast amounts of internet text to understand and generate human language in a coherent and contextually relevant manner (Brown et al., 2020; Chowdhery et al., 2022). The increasing scale of training data and model capacity has enabled LLMs to exhibit emergent capabilities such as chain-of-thought reasoning, instruction following, and in-context learning (Wei et al., 2023; Brown et al., 2020; Peng et al., 2023).

Currently, Natural Language Generation (NLG) faces a major challenge: Large Language Models (LLMs) can produce text that is fluent and coherent but contains factual inaccuracies or statements ungrounded in reality—a phenomenon known as hallucination (Rawte et al., 2023; Huang et al., 2025). These hallucinations are difficult to detect automatically because existing evaluation methods primarily measure fluency rather than accuracy. Detecting hallucinations is often the first step in ensuring that a model's output is consistent with known facts and in preventing the generation of misleading or false information (Chang et al., 2023). In many NLG applications, such as question-answering and translation tasks, the correctness of the model's output is crucial for its utility.

The SemEval Mu-SHROOM task focuses on detecting hallucination spans in the outputs of instruction-tuned LLMs across 14 languages (Vázquez et al., 2025). The main goal of the task is to determine which spans of a given text produced by an LLM are part of a hallucination. The organizers provide the LLM output as a string of characters, a list of tokens, and a list of logits. Participants are required to compute the probability of hallucination for each character in the LLM-generated text. Submissions are evaluated using two approaches: (1) the intersection-over-union of characters marked as hallucinations in the gold reference and the predicted output, and (2) the correlation between the probability assigned by the participants' system that a character is part of a hallucination and the empirical probabilities observed from annotators.

We explore two distinct approaches to address the Mu-SHROOM task: the Prompt-Based Approach (PBA) and the Fine-Tuning-Based Approach (FBA). In the Prompt-Based Approach, we experiment with different strategies. First, we explore prompting an instruction-tuned model without a reference by providing only the question and the model's answer. For this, we use GPT-4 (OpenAI et al., 2024) to identify hallucination spans by providing the input text and the model's output

text. In this approach, since no reference context is provided, the model is expected to rely implicitly on its pre-trained knowledge to determine which parts of the output constitute hallucinations. The details of this approach are described in Section 3.1.

In the second strategy, which we refer to as the dual-prompt approach, we break down the prompt into two phases. In the first phase, we prompt the model to answer the question explicitly. In the second phase, we use the output from the first phase as a reference answer and prompt the model to identify hallucinations by comparing this reference with the model's original output.

In the third approach, we incorporate external knowledge to create a reference context and prompt the model to answer the question based on this reference.

For the Fine-Tuning-Based Approach, we experiment with an encoder model by framing the task as a token classification task. We describe the details in Section 3.1.

In summary, our experiment shows that:

- Prompting LLMs to identify hallucinations without providing a reference or context results in more hallucinations. We hypothesize that this may be caused by the limitations of LLMs in implicitly recalling knowledge correctly without explicit prompting, which is crucial since no additional context is provided.
- We test this hypothesis by using dual prompts to make implicit knowledge recall explicit. We observe that providing an explicit reference from the target LLM significantly improves detection performance in most of our target languages.
- We further experiment by providing a RAG context in our prompt instead of prompting the model for a reference. We observe that providing a RAG-like context with the prompt further improves model performance in identifying hallucination spans.

2 Background

Hallucination is one of the main limitations of NLG models, where the generated text sounds fluent and coherent but contains factual inaccuracies or statements ungrounded in reality (Rawte et al., 2023; Huang et al., 2025). Hallucinations in NLG models can take two forms: intrinsic hallucinations and extrinsic hallucinations (Ji et al., 2023; Dziri et al., 2021).

In the case of intrinsic hallucinations, there is a contradiction between the source text and the generated text. Since this contradiction appears in one or more spans, it is possible to verify where the hallucination occurred. In contrast, extrinsic hallucinations do not exhibit an observable contradiction between the source and the generated text, making it impossible to pinpoint the hallucination. In the extrinsic case, there is no available evidence in the input text to determine the correctness or incorrectness of the generated text.

2.1 Hallucination Detection

Various approaches have been introduced to address hallucination in NLG, with knowledge-based methods being the most commonly used (Ji et al., 2023).

In knowledge-based approaches, a domain-specific knowledge base is used to fact-check the model-generated text. This approach is effective but is only applicable to domains where a relevant knowledge base is available. In cases where the LLM's hidden state is accessible, white-box and grey-box analyses can be employed by training an MLP classifier on the hidden state to predict truthfulness (Azaria and Mitchell, 2023).

In grey-box methods, the probability of the tokens generated by LLMs is used to detect hallucinations based on the assumption that correct text consists of high-probability tokens. In the self-evaluation approach, the LLM itself is prompted to score the likelihood of the text it generated (Kadavath et al., 2022). Similarly, any public model can be used as a proxy to assess the factuality of the

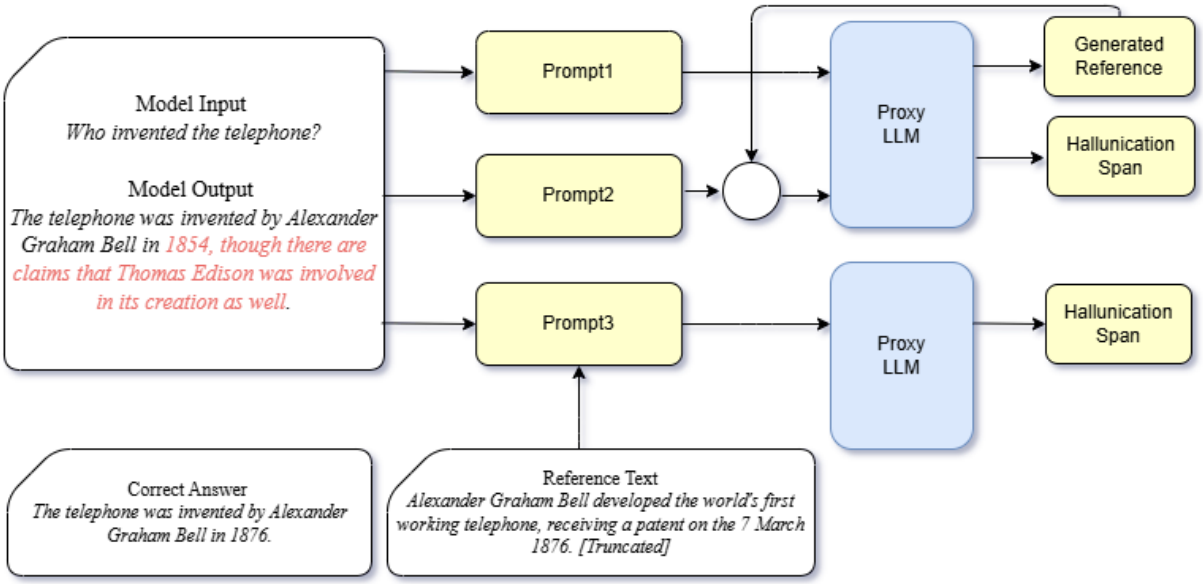

Figure 1: Overview of the prompt-based approach. In the first approach (Prompt-1), we directly prompt the proxy model to identify hallucination spans by providing the model input and output. In the second approach (Prompt-2), we first prompt the model to generate an answer based on the model input, and then use this generated reference to prompt the proxy model to identify hallucinations. In the third approach (Prompt-3), we use an external reference text along with the model input and output to prompt the proxy model to identify hallucinations.

generated text by estimating the token probability of a black-box model.

SelfCheckGPT (Manakul et al., 2023) is another black-box, sampling-based approach. It relies on the hypothesis that if an LLM has correct knowledge of a particular topic, sampled responses on that topic will have high similarity, whereas hallucinated text will diverge significantly.

2.2 Task Description

The SemEval Mu-SHROOM task focuses on the detection of hallucination spans in the outputs of instruction-tuned LLMs across 14 languages: Arabic, Basque, Catalan, Chinese (Mandarin), Czech, English, Farsi, Finnish, French, German, Hindi, Italian, Spanish, and Swedish (Vázquez et al., 2025). The data distribution across the splits is provided in Table 1.

The following data points are provided as part of the challenge:

- **Model Input**: A prompt provided to the model to generate text.
- **Model Id**: The name of the models used to produce each output. Two models are used: TheBloke/Mistral-7B-Instruct-v0.2-GGUF and TheBloke/SauerkrautLM-7B-v1-GGUF.
- **Model Output**: A string of characters, a list of tokens, and a list of logits.
- **Hard Labels**: A label of 1 is assigned when the corresponding span contains a hallucination. We determine hard labels using majority voting among the annotators.
- **Soft Labels**: The confidence-based judgments of the annotators. Calculated as the proportion of annotators who marked the span as part of a hallucination out of the total number of annotators.
- **Evaluation**: Submissions are evaluated using intersection-over-union (IOU) of characters marked as hallucinations in the gold reference and predicted, and the probability assigned by the participants' system that a character is part of a hallucination correlates with the empirical probabilities observed in the annotation. For hard labels, intersection-over-union (IoU) is used and the Spearman correlation between predicted and reference soft labels is used for soft labels.

2.3 Models

We employ GPT-4o-mini from OpenAI as a proxy model for all prompt-based experiments. For fine-tuning, we use XLM-R (Conneau et al., 2019) as

the base model and fine-tune it by framing the task as a token classification task. Additionally, we utilize Perplexity AI with search capability to generate more accurate reference text.

3 System Description

In this section, we describe our proposed system. We employ two distinct approaches: the Prompt-Based Approach (PBA) and the Fine-Tuning-Based Approach (FBA). In the prompt-based method, we use an LLM as a proxy model and apply a standard prompt to identify hallucination spans by providing pairs of input text and model output. In the fine-tuning approach, we fine-tune an encoder model by framing the task as a token classification problem.

3.1 Prompt-Based Approach

Figure 1 shows an overview of our PBA approach. We experiment with three prompt strategies: prompting without a reference, dual prompting, and prompting with an external reference.

Prompt without Reference (PWR) In this approach, we design a simple prompt and request a proxy model to identify hallucination spans by providing the model input and output. Since no reference text is provided, the proxy model implicitly relies on its pre-trained knowledge to answer the question correctly and compare this answer with the provided output to determine which parts of the text contain hallucinations. We test the hypothesis that a proxy model can reliably identify hallucinations in text generated by another LLM.

Dual Prompting (DP) In this approach, we modify the first method by splitting the prompt into two parts. In the first part, we prompt the proxy model to generate an answer by providing the original model input. In the second part, we prompt the model to identify hallucinations by comparing the generated answer with the model output. By explicitly prompting for the answer, we can assess whether the proxy model relies on correct knowledge or introduces errors when comparing the reference with the model output.

Prompting with External Reference (PEXT) In this approach, we use external knowledge to create a reference text. We utilize an API from Perplexity, which has search capabilities, to generate the reference text. We then use this reference to prompt the proxy model to identify hallucination spans.

Perplexity AI integrates an LLM with internet search capabilities to retrieve reference text from external sources.

Fine-Tuning-Based Approach (FBA) For the fine-tuning-based approach, we fine-tune a multilingual encoder model by framing the task as a token classification problem. Specifically, we use XLM-R as the base model. We combine the training sets for four languages—English, Spanish, French, and German—and fine-tune the model on this multilingual dataset. The input consists of tokenized model outputs, and the objective is to predict, for each token, whether it is part of a hallucination span.

4 Analysis and Conclusion

In this section, we compare the strengths and limitations of the four proposed approaches. Table 2 presents the performance of these approaches in detecting hallucinations across 14 languages, evaluated using two metrics: Intersection over Union (IoU) and Correlation (Cor). We analyze the performance differences between the approaches and examine variations across languages, providing possible explanations for these differences.

4.1 Prompting Approaches

PWR The PWR approach exhibits variable performance across languages. In terms of IoU, it achieves the highest scores in languages such as French and Hindi but performs notably worse in languages like Chinese. Similarly, the correlation scores align with the IoU results, showing strong performance in French and Hindi but weaker performance in Chinese. Overall, while PWR demonstrates strong performance with high correlation in certain languages, its effectiveness remains inconsistent across languages.

Dual Prompting The DP method consistently outperforms PWR across both metrics, achieving high IoU scores in languages such as Hindi and French. These improvements can be attributed to explicitly prompting the model for a reference text, which reduces ambiguity and minimizes potential hallucinations. The correlation scores follow a similar trend, demonstrating relatively stable performance across languages.

PEXT The PEXT approach further improves upon the DP approach. One possible explanation for this improvement is that when the proxy model lacks the correct answer, incorporating reliable external knowledge helps bridge the gap. This pre-

Method	Metric	AR	CA	CS	DE	EN	ES	EU	FA	FI	FR	HI	IT	SV	ZH

Table 2: Performance of the four approaches for hallucination span detection on the test set across 14 languages. PWR refers to prompting without a reference text, DP denotes dual prompting, PEXT indicates prompting with external context, and FBA corresponds to the fine-tuning-based approach.

vents the model from relying on incorrect or hallucinated information when identifying hallucinations. PEXT performs similarly to DP in most target languages, with IoU and correlation scores often comparable to those of DP. However, like DP, it struggles with Chinese (41.41 IoU, 28.27 Cor).

FBA The FBA approach shows the lowest scores across all languages in both IoU and correlation metrics. IoU values are particularly low, especially for English (4.06) and French (20.73). Similarly, correlation scores are weak, with negative values in languages such as English (-0.08), further indicating that FBA is not well-suited for hallucination detection. Despite being fine-tuned specifically for this task, the poor performance suggests that fine-tuning encoder models may not be the most effective strategy for hallucination detection, at least within the current setup.

4.2 Cross-lingual Analysis

The performance variation of prompt-based methods across languages reflects differences in the proxy LLM's ability to analyze text in different languages. We hypothesize two possible explanations for this variation. First, the type of questions used in the prompt may vary across languages, leading to discrepancies in generating accurate reference texts. For instance, the distribution of simpler or easier questions might favor certain languages. Second, LLMs do not perform equally well across all languages, favoring high-resource languages that are better represented in the model's training data. For example, the PWR approach relies solely on the prompt without additional context or external references. The variation in hallucination detection performance suggests that languages with higher representation in the training data tend to achieve better results, as the proxy LLM is more effective at understanding the task even with a simplified prompt.

5 Conclusion

In this work, we investigate the efficacy of prompt-based and fine-tuning-based approaches for detecting hallucinations in instruction-tuned LLMs, using the SemEval Mu-SHROOM task across 14 languages as a benchmark. Our findings indicate that prompt-based approaches (PBAs), particularly those leveraging explicit references or external knowledge, outperform the fine-tuning-based approach (FBA). Providing explicit references enhances a model's ability to pinpoint hallucination spans, while prompting without references leads to a higher incidence of hallucinations. Furthermore, incorporating external knowledge improves the identification of hallucination spans.

As future work, exploring hybrid approaches could be highly beneficial. Combining the strengths of both prompt-based and fine-tuning-based methods might lead to improved performance. For instance, a fine-tuned model could be integrated with a knowledge base system, where the knowledge base generates reference answers and the fine-tuned model uses both the LLM-generated output and the reference to identify hallucinations.

Limitations

Our study has several limitations. First, the prompt-based approaches heavily rely on a single proxy model (GPT-4o-mini), making the system's effectiveness dependent on the proxy's multilingual capabilities and potential biases. Second, the fine-tuning-based approach was implemented with a relatively simple setup using XLM-R, without explor-

ing more advanced strategies. Third, while external references in the PEXT approach were retrieved via Perplexity AI, no rigorous filtering was applied, introducing the possibility of noisy or irrelevant knowledge negatively affecting performance. Additionally, our system exhibited variability across languages, particularly for lower-resource or typologically distinct languages like Chinese, highlighting challenges in cross-lingual generalization. Finally, our evaluation was limited to the Mu-SHROOM dataset, and further validation on broader hallucination detection benchmarks or real-world outputs remains an important direction for future work.

Acknowledgments

This work was conducted as part of an internship by Wondimagegnhue Tufa at Huawei Technologies Finland Research Center. We thank the Huawei Research team for providing computational resources and technical support throughout the project. We also express our gratitude to the SemEval-2025 Task 3 organizers for creating the multilingual hallucination detection benchmark and offering valuable guidelines. Finally, we appreciate the feedback from anonymous reviewers, which helped improve the quality of this paper.

UCSC NLP T6 at SemEval-2025 Task 1: Leveraging LLMs and VLMs for Idiomatic Understanding

Judith Clymo, Adam Zernik, Shubham Gaur
University of California, Santa Cruz
{jclymo, azernik, sgaur2}@ucsc.edu

Abstract

Idiomatic expressions pose a significant challenge for natural language models due to their non-compositional nature. In this work, we address Subtask 1 of the SemEval-2025 Task 1 (AdMIRe) (Pickard et al., 2025), which requires distinguishing between idiomatic and literal usages of phrases and identifying images that align with the relevant meaning. Our approach integrates large language models and vision-language models, and we show how different prompting techniques improve those models' ability to identify and explain the meaning of idiomatic language.

1 Introduction

Idiomatic expressions challenge natural language models as their meanings often defy the compositional rules of literal language. For example, *"a piece of cake"* (Figure 1) may literally refer to dessert but idiomatically means an easy task. Neural models struggle to differentiate these uses, as idiomaticity often requires contextual and cultural understanding. Linguistic theories suggest that idioms derive their meaning from real-world interactions, motivating multi-modal approaches that integrate text and images.

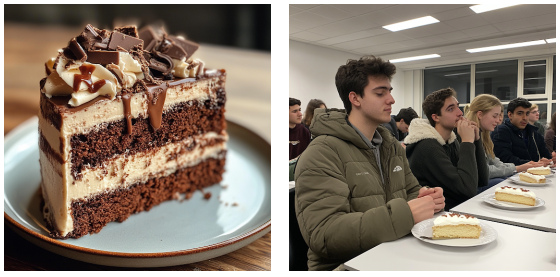

Figure 1: The result of prompting Midjourney with *"the dessert was a piece of cake"* and *"the exam was a piece of cake"*.

Understanding idiomaticity is vital for improving machine translation, sentiment analysis, and dialogue systems. SemEval AdMIRe task (Pickard et al., 2025) assesses idiomatic comprehension by ranking images based on how well they match the meaning of idiomatic or literal phrases

1.1 Task Details

Figure 2 illustrates the task setup (Pickard et al., 2025). We are given a **context sentence** containing a potentially idiomatic or literal **target phrase** along with five images. The task challenges us to rank these five images according to their semantic similarity to the meaning of the phrase in the context sentence.

Figure 2: Image ranking based on semantic similarity to the target phrase *"old flame"* in the context sentence *"She ran into an old flame at the high school reunion"*. The correct order is *[4,2,1,5,3]*

The following metrics are used for evaluation:

- **Top-1 Accuracy:** Accuracy in selecting the correct highest-ranked image.
- **Discounted Cumulative Gain (DCG):** Weighted measure of ranking quality that discounts the impact of lower positions.

The task is available in both English and Portugese, however we focus only on the English version. We present a system that combines a large language model (LLM) for reasoning about idiomatic language with a vision-language model (VLM) for image ranking[1].

2 System description

2.1 Sentence Type Classification

A natural starting point is to identify whether the compound phrase in each context sentence was used in a literal or idiomatic sense. We use GPT-4 as our classifier, asking it to consider both potential meanings of the phrase while analyzing its usage in the given sentence.

2.2 Semantic Enhancement of Text Inputs

The use of carefully designed prompts to elicit targeted responses from large, pre-trained language models has shown promise in multiple domains (Liu et al., 2023). GPT-3 was among the first models to perform well with task-specific prompting in few-shot scenarios without requiring fine-tuning (Brown et al., 2020). More recently, query reformulation techniques have been shown to optimize inputs for pre-trained language models, with paraphrased inputs improving performance on downstream tasks (Haviv et al., 2021). Based on these insights, we designed an approach leveraging GPT-4 to produce context-aware definitions of the target phrase, testing a series of prompts that progressively layer prompting strategies, such as:

Manual Template Engineering Crafting a task-specific template using human introspection and domain knowledge has been shown to elicit contextually appropriate responses (Brown et al., 2020).

Prompt Augmentation Augmenting the prompt with few-shot examples improves performance by demonstrating the expected task behavior directly in the prompt (Liu et al., 2023).

Output Formatting Specifying a structured output format ensures consistency in responses and allows straightforward extraction of the final answer (Liu et al., 2023).

Chain-of-Thought This prompting technique (Wei et al., 2023) has been shown to improve performance on tasks requiring complex reasoning and contextual understanding, making this strategy particularly suited to idiomatic language.

Prompt Composition Complex tasks are decomposed in to smaller sub-tasks within a unified prompt (Liu et al., 2023).

The aim of our prompts is to obtain context-aware definitions of the compounds as they're used in the context sentences. The definitions are then used as the text inputs to the VLMs.

We present results below from two prompts used for generating definitions. Both prompts anchor GPT-4 in the role of a linguistics expert, include multiple examples and both require responses to follow a formal JSON schema specified in the prompt. Both prompts employ chain-of-thought reasoning but differ in their strategic approaches. Prompt 1 aims to find the ideal generalized definition of the idiom. GPT is asked to consider both literal and idiomatic definitions of the phrase before settling on a definition for the idiom that does not overlap with the literal meaning. Prompt 2 recognizes that even an ideal definition is not necessarily a useful image description, primarily because it might overgeneralize. Instead, it prompts the model to imagine five distinct scenes that depict the idiom then generate a single caption that is general enough to describe all five scenes.

Prompt 2 resulted in some interesting and descriptive outputs. For example, the Prompt 1 generated definition of *"graveyard shift"* is *"A late-night work schedule, often going until sunrise"*. While the definition is accurate, the inclusion of the word "often" points to generalization rather than specificity. In contrast, the result from Prompt 2 captures the idiom's meaning while describing a specific scene: *"Toiling through the night while the world sleeps"*. However sometimes the core meaning of the definition was diluted by this approach, for example, *"fancy dress"* received the definition *"Let your costume do the talking"*.

Both prompts are reproduced in the Appendix.

2.3 Image Alignment

To compare multi-modal inputs and find common themes we make use of models that are trained to match pairs of related text and images. Two encoders create embeddings for their inputs that are compared in batches using cosine similarity. Given n text and image inputs, we have a matrix of n^2 cosine similarities. In training, the categorical cross entropy loss is applied across both text and image dimensions. The image and text embedding spaces are therefore forced to have similar structure and the models are encouraged to extract similar information from the different modalities. Our experiments focus on the models CLIP (Radford et al., 2021), ALIGN (Jia et al., 2021) and OpenCLIP (Ilharco et al., 2021).

CLIP has variants that use a ResNet or a vision

transformer (ViT) for the image model. We experiment with both options, and with two different sized ViT encoders. ALIGN instead uses EfficientNet (Tan and Le, 2019) for the image encoder. Both have a transformer for the text encoder, however ALIGN uses the BERT architecture (bi-directional attention) and CLIP uses causally masked attention. The bigger difference between CLIP and ALIGN is in the data used to train them. CLIP is trained on about 400 million text-image pairs, and considerable effort was spent cleaning the data to ensure high quality. ALIGN used over 1 billion training examples but with less effort spent on data cleaning. Experiments on standard benchmarks suggest that the two models perform similarly well. The differences between CLIP and OpenCLIP are minimal, the latter being an open-source implementation of the former.

3 Results

The scores for our best performing model are shown in Table 1 and Table 2. We use GPT first to classify the usage type, then with Prompt 1 to define the meaning of the compounds that are used idiomatically. In the case of samples that are found to use their phrase literally, the compound is used directly without the context sentence or any definition. We used ALIGN to determine the final ranking of the five images from the provided text input.

	Top-1 Accuracy		
	Literal	**Idiomatic**	**All**
Test	0.86	0.88	0.87
Extended	0.74	0.61	0.68

Table 1: Performance results for Top-1 accuracy.

	DCG		
	Literal	**Idiomatic**	**All**
Test	3.34	3.47	3.41
Extended	3.29	3.11	3.20

Table 2: Performance results for DCG.

We show a comparison of different VLMs given this text input in Figures 3 and 4. ALIGN and OpenCLIP show stronger performance and greater consistency across the different metrics and data sets than the CLIP models tested, however none of the models was the clear winner across all settings.

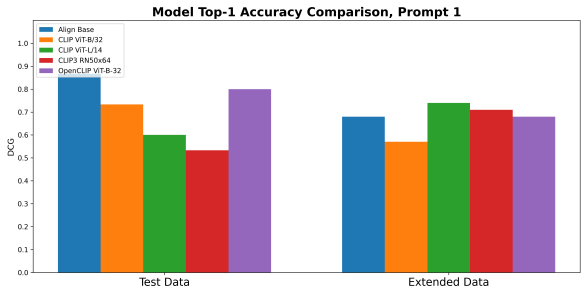

Figure 3: Top-1 accuracy for all models using GPT generated inputs with prompt 1.

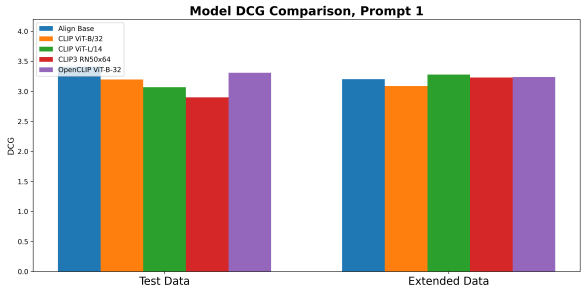

Figure 4: DCG for all models using GPT generated inputs with prompt 1.

3.1 Classification

The classification step using GPT is highly reliable. We benefited from an explicit classification step since this allowed us to use the compound phrase as input for the literal use samples, which consistently performed at least as well as using any generated definition. Further, we avoided the need to invoke the longer reasoning chain required to generate definitions for the literal samples.

		Predicted	
		Literal	**Idiomatic**
True	**Literal**	**52/7**	2/1
	Idiomatic	0/0	**46/8**

Table 3: Confusion matrix of classification results for literal and idiomatic expressions in extended/test sets.

3.2 Definition

Manually reviewing the definitions returned for the test set, we find that all of the definitions from

Prompt 1 correctly capture the meaning of the idiom. The weakest definition was for *"cold feet"*, *"Feeling scared or nervous before an important event"*. This is correct but misses the implication that a person with cold feet is thinking of not going ahead with the intended action or event.

A closer inspection of consistently low-scoring examples sheds light on where and why our system struggles. For instance, consider the phrase *"best man"*, used literally in the sentence, *"The best man means the quickest and most intelligent drive"*. Both the literal and idiomatic meanings of the phrase describe a man in a standout role, making it hard to visually separate one from the other. As a result, the model likely defaulted to the more familiar wedding-related meaning.

We see a similar failure case with *"eye candy"*. In the sentence, *"They gave me the impression that the development team has been focusing too much on eye candy rather than actual gameplay or level design,"* the idiomatic phrase criticizes style over substance. But our text input - *"something visually attractive but lacking depth"* - left too much room for literal interpretations. The literal images, including one showing colorful candies shaped like eyeballs, fit the figurative definition well enough to confuse the model.

4 Ablations

To demonstrate the value of the additional information provided by GPT, we test several other inputs to our VLMs.

4.1 Compound Only

In this experiment, only the compound phrase itself is given as the text input. This is insufficient information to complete the task, since the model cannot know whether the compound is meant to be understood literally or idiomatically. However, this serves to show the strength of the models' bias towards literal language. The performance in image ranking is already quite strong when the usage is literal, which demonstrates why in our final system we decided to use the compound as input when the usage has been classified as literal.

4.2 Sentence and Compound (Baseline)

The baseline experiment used the text input "{compound} in the context of {sentence}". All models continue to show much stronger performance on literal usage, which may also be because the images for literal use often incorporated other details from the sentence. Performance in the baseline experiments is summarized in Figure 5.

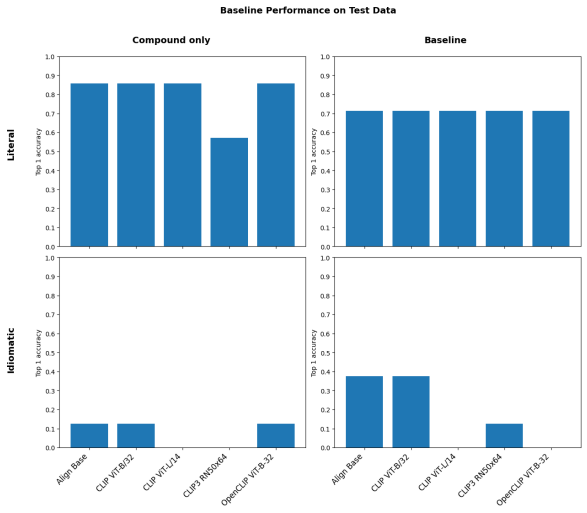

Figure 5: Top-1 accuracy for baseline experiments, test data.

4.3 Classification Only (Ablation 1)

We use GPT to classify the type of usage but do not generate any definition of the phrase. The text input for the VLMs is "{compound} in its {classification} sense". Although this input appears to remove some of the reasoning burden, it does not result in better ranking of the images compared to the baseline.

4.4 Zero Shot Prompt (Ablation 2)

We ask GPT for a definition of the compound in the simplest possible way, using the result as input for the VLMs. The prompt was "define {compound} as it's used in {sentence}". We see better performance on sentences with idiomatic use at the expense of reduced performance on literal use sentences.

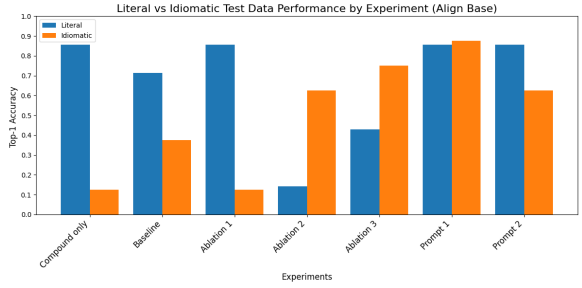

Figure 6: Top-1 accuracy for test data across all ablations, using ALIGN for text-image comparisons.

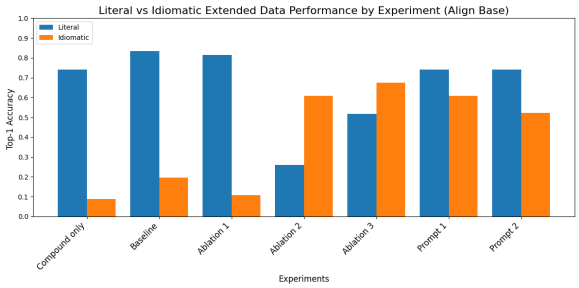

Figure 7: Top-1 accuracy for extended data across all ablations, using ALIGN for text-image comparisons.

4.5 Zero Shot Prompt with Classification (Ablation 3)

We ask GPT for a definition of the compound using a prior classification (also from GPT): "define {compound} in its {classification} sense". Overall performance is improved, however it remains lower than the baseline for literal samples.

4.6 Ablation Results

Figure 6 and Figure 7 show the performance of ALIGN on the test and extended data sets respectively across the different ablation experiments described above and using the definitions generated by the two prompts described in Section 2.2. We noted similar trends in performance across all five VLMs tested.

We see that the definitions generated by Prompt 1 and Prompt 2 result in differing performance on the image ranking task, with Prompt 1 giving the better results, although this was not consistent across all models tested. For the idiomatic use samples it is unclear whether the definitions from these more complex prompts offer significant improvement compared to those from Ablation 3.

Full results of all ablation experiments are presented in the Appendix.

5 Discussion

We initially expected that a separate, fine-tuned model would be needed to classify the type of language, with queries to GPT only used to generate definitions for the idiomatic phrases. However, it turned out that GPT was highly effective for the classification task.

Despite impressive zero-shot performance on the literal inputs, none of the VLMs we tested was able to perform well for the idiomatic context sentences. It was surprising that given only the target phrase the models strongly preferred the literal use. Most of the phrases are very commonly used idiomatically and several seem unnatural in attempted literal usage. This is likely due to the specific purpose and training of the VLMs we used. Datasets built from tasks such as image captioning, for example, will tend to have a bias towards literal, descriptive language rather than poetic or abstract language. GPT instead preferred the idiomatic definition when prompted with only the phrase and was more likely to mistake literal usage for idiomatic, which better reflects the most common uses of such phrases.

Across our different experiments we saw that some samples were consistently easier for the VLMs to work with, regardless of the exact form of the text input. Figure 8 shows the combined top-1 accuracy for each sample across all experiments. The data points are colored according to the compound's usage, showing again that the literal use samples were in general easier than the idiomatic use samples.

A major limitation of our approach is that GPT does not respond in exactly the same way each time, even when given an identical prompt. It is difficult to fully understand the relationship between prompt and output, and this is further complicated in the present task by the output being then passed through another language model in the image ranking task. For the classification task, simple voting helps to mitigate this. A more complex voting algorithm could be used to combine multiple attempts at image ranking, for example finding a ranking whose total deviation from each of several individual ranks is minimized.

In addition, model updates will alter the behavior with respect to a prompt, sometimes in unexpected ways. To manage these changes over time, behavior on a training data set can be monitored and the prompts updated if average performance drops below some threshold. Language models can propose prompt modifications, so there is potential for these prompt updates to be applied automatically.

Many of the techniques we explored are applicable to a wide variety of tasks. Using language models to rephrase an input into a simple, direct and possibly structured form prior to further processing aids tool use. Chaining language model calls is also common in agentic frameworks.

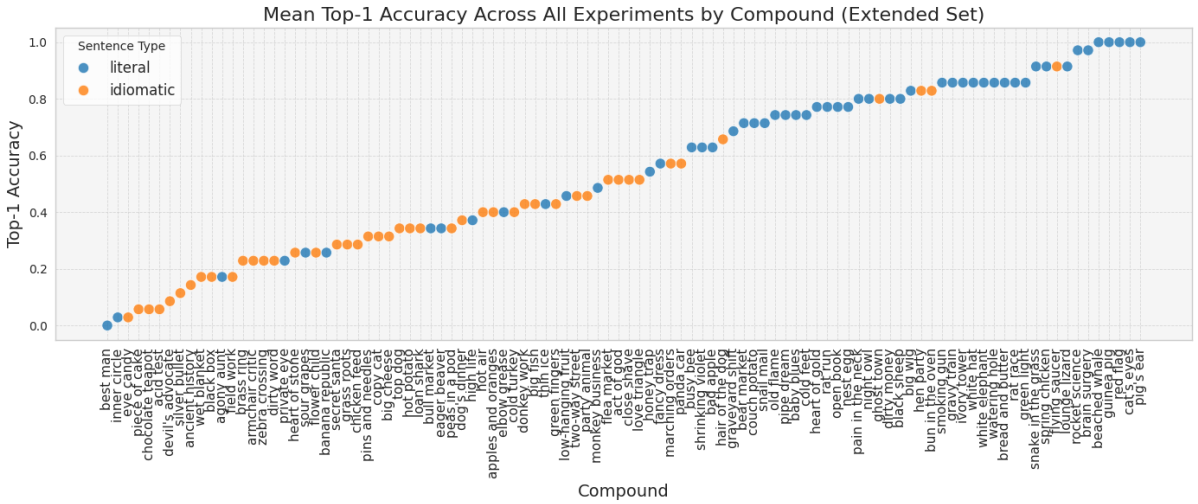

Figure 8: Average top-1 accuracy for every compound across all examples.

A Prompt 1

Listing 1: The Python string template for Prompt 1.

```
prompt = """
You are a linguistics expert
    specializing in idioms. You will be
    given a set of idioms to process.
    For each one, do the following steps
     aloud (in writing):
1. Give a verbose explanation of the
    idiom, including what connotations
    it carries or undertones it evokes.
2. Give a definition of the *literal*
    meaning of the phrase. For noun
    phrases representing physical
    objects, focus on unambiguous visual
     descriptors.
```

```
3. Taking into consideration your
    response for #1 and #2, list three
    potential definitions, no longer
    than 20 words each, that capture the
     **core emotional or situational
    essence** conveyed by the idiom. Use
     **simple language that an average
    high-schooler would understand** and
     avoid figurative or overly abstract
     language. Focus on clear, visually
    interpretable descriptions that are
    distinct from the literal definition
    .
4. Choose the best definition.

B Prompt 2

Listing 2: The Python string template for Prompt 2.

```
prompt = """You are a linguistics and
    visual storytelling expert, with an
    expertise on differentiating
    idiomatic from literal language. For
     each sample idiom below, your task
    is to create visual and textual
    representations that align well with
     the idioms figurative meaning
    for use in matching with images.
    Follow these steps:

1. Identify the phrase: Give a concise
    definition of the phrase in its
    idiomatic sense.
2. Note the literal usage (briefly):
    Mention the plain or surface meaning
    , but clarify that you are focusing
    on the figurative interpretation for
     your examples.
3. Generate 5 distinct image ideas: For
    the given idiom, imagine 5 different
     scenes or situations that visually
    depict its figurative meaning.
    Describe each scene in 1-2 sentences
    , focusing on visual details.
4. Generalize the captions: Write a
    single caption that could apply to
    all 5 scenes. It should capture the
    essence of the idiom in a way that
    is broad enough to fit any of the
    scenes.
5. Refine: Reflect on how well your
    caption generalizes to all five
    scenes, then attempt to improve on
    it.
6. Consider which caption is best: Weigh
     the captions against each other,
    then pick the one that best fits all
     5 scenes.
7. Select the best caption: Repeat the
    caption you selected.

---

Example outputs:
{
  "data": [
    {
      "target_phrase": "glass ceiling",

C Experimental Results

In this section, we present the results across all 6 sets of experiments with different approaches. We evaluate the performance of various models using three key metrics: **Top-1 Accuracy**, **Spearman Correlation**, and **Discounted Cumulative Gain (DCG)**. For each metric, we provide results for both **idiomatic** and **literal** subsets of the data. The models evaluated include:

- **Align**: Align Base
- **CLIP1**: CLIP ViT-B/32
- **CLIP2**: CLIP ViT-L/14
- **CLIP3**: CLIP3 RN50x64
- **OpenClip**: OpenCLIP ViT-B-32

The results are divided into two sets: **Test** and **Extended**. Each set contains three tables, one for each metric. Below, we present the results in detail.

C.1 Test Set Results

Top-1 Accuracy (Table 4)

Spearman Correlation (Table 5)

Discounted Cumulative Gain (Table 6)

C.2 Extended Dataset Results

JUNLP_Sarika at SemEval-2025 Task 11: Bridging Contextual Gaps in Text-Based Emotion Detection using Transformer Models

Sarika Khatun, Dipanjan Saha, Dipankar Das
Jadavpur University, Kolkata, India
{sarikakhatun088, sahadipanjan6, dipankar.dipnil2005}@gmail.com

Abstract

Because language is subjective, it can be difficult to infer human emotions from textual data. This work investigates the categorization of emotions using BERT, classifying five emotions—angry, fearful, joyful, sad, and surprised—by utilizing its contextual embeddings. Preprocessing techniques like tokenization and stop-word removal are used on the dataset, which comes from social media and personal tales. With a weighted F1-score of 0.75, our model was trained using a multi-label classification strategy. BERT has the lowest F1-score when it comes to anger, but it does well when it comes to identifying fear and surprise. The findings demonstrate the difficulties presented by unbalanced datasets while also highlighting the promise of transformer-based models for text-based emotion identification. Future research will use data augmentation methods, domain-adapted BERT models, and other methods to improve classification performance.

1 Introduction

Natural language processing (NLP) has made emotion identification from textual data a crucial problem because of its many uses, which include social media trend prediction, consumer sentiment analysis, mental health monitoring, and human-computer interaction. However, because language is inherently subjective, figurative phrases like sarcasm and metaphors are present, and people express emotions differently, it is still difficult to accurately identify emotions in writing. Text-based emotions, in contrast to structured data, are frequently implicit and need a thorough contextual knowledge in order to correctly categorize various emotional states.

Using hand-crafted features and word embeddings, traditional machine learning techniques like Support Vector Machines (SVM) (Cristianini and Ricci, 2008) and Random Forests have been used to emotion identification. Nevertheless, these techniques frequently have trouble capturing contextual relationships and deeper semantic meaning, which results in less than ideal classification performance. Transformer-based models, such as BERT (Bidirectional Encoder Representations from Transformers) (Devlin et al., 2019a), have transformed natural language processing (NLP) by offering strong contextual representations that allow more accurate emotion detection thanks to developments in deep learning. BERT is well-suited to handling the complexity of emotional expressions in text due to its bidirectional text processing capability, which allows it to understand both local and global relationships..

In order to enable the model to identify several emotions in a single text instance, we use BERT for multi-label emotion categorization in this work. We test the model's performance using a benchmark dataset drawn from internet forums, social media postings, and personal narratives.This work is submitted under SemEval 2025 Task 11, Track A: English-only multi-label emotion classification. We concentrate on five main emotions: anger, fear, joy, sadness, and surprise. To enhance the quality of textual inputs, the dataset is subjected to preparation procedures such as Named Entity Recognition (NER), tokenization, and stop-word removal.Our method addresses issues with ambiguity and overlapping emotional states by improving classification performance through the use of BERT's contextual embeddings.

2 Problem Statement

Understanding human emotions from textual data is a complex challenge due to the inherent ambiguity and subjectivity of language. The primary objective of this project is to develop a robust model capable of accurately classifying multiple emotions present in a given text snippet. Specifically, we aim to predict the following emotions:

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2116–2120

joy, sadness, fear, anger, surprise. Each emotion will be represented as a binary label, indicating its presence (1) or absence (0) in the text.

3 Dataset Description

We used the dataset provided in SemEval-2025 Task 11 (Muhammad et al., 2025b), (Muhammad et al., 2025a) used for this challenge consists of annotated textual data sourced from personal narratives, social media posts, and various online forums. The Track A English dataset contains only 2769 samples across diverse sources. The dataset comprises five primary features, with preprocessing steps such as tokenization, stop-word removal, and Named Entity Recognition (NER) to effectively extract emotional expressions.

The training and validation datasets contain 5 columns, supporting two tasks: Multi-label emotion classification, where the model predicts the presence of multiple emotions (anger, fear, joy, sadness, surprise) within the text, and Emotion intensity detection, where the model assesses the strength of each identified emotion. In contrast, the test data set includes only the *ID*, *text* and corresponding emotion labels, which require models to infer emotional information without predefined labels. These datasets enable structured prediction of emotional states based on textual expressions.

4 Related Work

Earlier approaches to emotion detection from text used machine learning models like SVMs and Naive Bayes with hand-crafted features. These lacked contextual understanding. With the rise of deep learning, models like RNNs and CNNs improved emotion classification but still had limitations in capturing long-range dependencies.

Transformer-based models, especially BERT(Devlin et al., 2019b), brought significant improvements by capturing deep contextual relationships. Recent studies (Muhammad et al., 2025b), have shown that fine-tuning BERT on emotion datasets improves multi-label classification performance. This motivates our use of BERT for the current task.

5 Methodology

In this study, we propose a methodology for emotion classification from English text using a neural network architecture built upon the BERT (Bidirectional Encoder Representations from Transformers) model. Our approach leverages the contextual embeddings of BERT to effectively understand the semantics of textual data and classify them into five emotion categories: *anger*, *fear*, *joy*, *sadness*, and *surprise*. This methodology integrates state-of-the-art natural language processing techniques with a deep learning model optimized for multi-label emotion classification.

5.1 Data Preparation and Preprocessing

The dataset used in this study comprises English textual inputs labeled with multiple emotions. Each sample can express more than one emotion, necessitating a multi-label classification approach. Columns = ID, text, and 5 emotion columns = 7 columns total. A value of *1* indicates the presence of a particular emotion, while *0* indicates its absence. To ensure the quality of the input data, we first remove any incomplete or noisy records using the **`dropna()`** function in pandas. This step eliminates missing values and ensures consistency in model input. The textual inputs are then extracted as a NumPy array, and the corresponding emotion labels are stored as a separate array of shape $N \times 5$, where N is the number of samples.

The dataset is divided into training and validation sets using an $80 - 20$ split. We employ the **`train_test_split()`** function from scikit-learn, ensuring a randomized distribution while maintaining the relative proportion of each class. This is critical for preventing overfitting and ensuring that the model generalizes well to unseen data.

5.2 Text Tokenization and Encoding

To convert the textual inputs into numerical form suitable for BERT, we utilize the `BertTokenizer` from the Hugging Face Transformers library. The tokenizer encodes each text by breaking it down into subword tokens and mapping them to unique input IDs from the BERT vocabulary. Additionally, it generates attention masks to distinguish real tokens from padded elements. Each text is padded or truncated to a maximum sequence length of 200 tokens to maintain consistency across inputs. The tokenization process employs the encode_plus method, which adds special tokens `[CLS]` at the beginning and `[SEP]` at the end of each sequence. These tokens help BERT understand the start and end of the input. The encoded input consists of:

- **input_ids :**Tokenized numerical representation of the text.

- **attention_mask:**Binary mask indicating real tokens and padded elements.

The inputs are then wrapped in a custom `EmotionDataset` class, which inherits from PyTorch's Dataset module. This class facilitates efficient data loading and batching using the `DataLoader`, which iterates through the dataset in mini-batches of size 8. We use **`shuffle=True`** for the training set to introduce randomness and prevent model overfitting.

5.3 Model Architecture

We employ a neural network architecture built on the pre-trained BERT model (**`bert-base-uncased`**). BERT's bidirectional attention mechanism enables it to learn complex contextual relationships in text. Specifically, we use the `[CLS]` token's hidden representation as the aggregate sequence embedding for classification purposes. The model architecture consists of two primary components:

- **BERT Feature Extractor:**The base BERT model is used to obtain contextualized embeddings for each input sequence. The hidden state corresponding to the `[CLS]` token is extracted as it captures the overall meaning of the sentence.

- **Fully Connected Layer:** A linear layer projects the hidden state to five neurons, corresponding to the five emotion categories. This layer computes the emotion logits as follows:

$$Logits = W \cdot H_{CLS} + b \tag{1}$$

  where W and b are the weights and biases of the fully connected layer.

5.4 Loss Function and Optimization

Given the multi-label nature of the problem, we use the Binary Cross Entropy with Logits Loss (`BCEWithLogitsLoss`) as the loss function. This function applies a sigmoid activation to the logits and computes the binary cross-entropy for each emotion category independently.

To optimize the model, we use the AdamW (Loshchilov and Hutter, 2019) optimizer with a learning rate of 1×10^{-5} and weight decay of 0.01. `AdamW` is known for its adaptive learning rates and weight decay regularization, which enhances generalization.

5.5 Training and Evaluation

The model is trained for 5 epochs, iterating through mini-batches from the `DataLoader`. During each epoch, the model's parameters are updated using *backpropagation* and *gradient descent*. The training loss is accumulated and averaged across batches to monitor learning progress. This is represented as:

$$Loss_{train} = \frac{1}{B} \sum_{k=1}^{B} L_k \tag{2}$$

where B is the total number of batches. After each epoch, the model is evaluated on the validation set in inference mode using **`torch.no_grad()`** to reduce memory usage. The validation loss is calculated similarly to the training loss. To generate predictions, the model's logits are passed through a sigmoid activation, and a threshold of 0.5 is applied to determine the presence of each emotion:

$$\hat{y} = I(\sigma(z) > 0.5) \tag{3}$$

where I is the indicator function. Performance is measured using precision, recall, and F1score, computed using scikitlearn's classification_report. This comprehensive evaluation ensures that the model accurately identifies multiple emotions per text.

5.6 Implementation and Deployment

The model is implemented using PyTorch and Hugging Face's `Transformers` library. The training is accelerated using GPU support for faster computation. After training, the model's state dictionary is saved in the **`.pth`** format for future inference and fine-tuning.

The proposed methodology demonstrates the effectiveness of leveraging BERT's contextual embeddings for multi-label emotion classification. This approach can be extended to other emotion recognition tasks and adapted for different languages or text domains.

6 Results and Discussions

Our model's classification performance on the validation dataset is shown in Table 1, which is assessed using precision, recall, and F1-score for each of the five emotion classes. With the greatest F1-score of 0.84, and recall of 0.90, the model shows excellent performance in identifying fear. Similarly, with F1-scores of 0.74 and 0.71, respectively, surprise and sadness show respectably strong

categorization results. With the lowest F1-score of 0.55, rage is the emotion that the model finds most difficult to differentiate from other emotions. The F1-score of 0.67 indicates that the joy class performs somewhat as well.

	precision	recall	f1-score	support
anger	0.61	0.50	0.55	34
fear	0.78	0.90	0.84	168
joy	0.66	0.69	0.67	48
sadness	0.76	0.67	0.71	84
surprise	0.73	0.75	0.74	83
micro avg	0.74	0.77	0.75	417
macro avg	0.71	0.70	0.70	417
weighted avg	0.74	0.77	0.75	417
samples avg	0.70	0.73	0.68	417

Table 1: Classification Report on Validation Dataset

Overall, the weighted and micro-averaged F1-scores are 0.75, indicating that the model does well when label distribution is taken into account. However, the macro-averaged F1-score is somewhat lower at 0.70, suggesting that overall performance is impacted by some class imbalance. Inconsistencies across occurrences are further reflected in the sample-average F1-score of 0.68. According to these findings, the model needs more refinement, especially for underrepresented emotions like anger, even while it successfully categorizes dominating emotions like surprise and fear. To increase model resilience, future developments may use sophisticated feature extraction and data augmentation strategies.

7 Limitations

Notwithstanding the encouraging outcomes of text-based emotion categorization using BERT, our work has certain drawbacks. One significant issue is the dataset's class imbalance, which has an impact on the model's capacity to fairly identify all emotions. The model has the lowest F1-score when it comes to anger, but it does well when it comes to fear and astonishment. Due to this imbalance, the model could perform poorly on less common emotion classes while favoring dominating ones. Furthermore, BERT is less suited for real-time or low-resource applications, as it is a transformer-based model that requires substantial computing resources for both training and inference.

The categorization of emotions based only on textual input is another drawback. A solely text-based method lacks multimodal signals like tone, pitch, and facial expressions, which are frequently more effective in eliciting emotions. The model's capacity to distinguish between emotions that exhibit comparable textual patterns—like sarcasm or neutral statements with emotional undertones—is hence limited. Additionally, even while BERT does a good job of capturing contextual meanings, it may still misread emotions in texts that include casual language, slang, or cultural differences. To increase classification robustness, future studies should investigate domain-specific fine-tuning and the use of multimodal data.

8 Conclusion and Future Work

In this work, we used text data to classify emotions using BERT, and we assessed how well it performed across five different emotion classes : anger,fear,joy,sadness and surprise. According to the results, anger performed the worst, whereas BERT successfully categorizes emotions like fear and surprise, obtaining high F1-scores. Although the somewhat lower macro-average F1-score of 0.70 indicates that there is potential for improvement in addressing class imbalances, the overall weighted F1-score of 0.75 emphasizes the model's strong generalization capabilities.

In order to improve classification performance, especially for underrepresented emotions, our future research will investigate domain-adapted BERT models and data augmentation strategies. In order to enhance emotion recognition, we also intend to look into multimodal techniques by combining text with audio and visual data. It may also be possible to obtain more balanced categorization across all emotion categories by experimenting with ensemble models and further optimizing BERT through emotion-specific pretraining.

Abstract

This paper presents our approaches for three subtasks in SemEval-2025 Task 10, which focus on entity framing, narrative classification, and narrative extraction in news analysis, respectively. We propose a two-stage news analytical framework for both Subtask 1 and 2. In Subtask 1 (Entity Framing), we design an entity-oriented data processing pipeline to address the issue of redundant information in a news article, and explore ways to use multilingual datasets effectively through sufficient experiments. The system achieves the first place in Bulgarian and the second place in English and Portuguese. In Subtask 2 (Narrative Classification), a similar narrative-oriented data processing pipeline is adopted to obtain condensed news chunks for each narrative. We conduct in-depth discussion regarding approaches to enhancing both data quality and volume, and explore one-vs-rest classification models and sequence prediction models for multi-label classification tasks. The system ranks first in Bulgarian and second in Russian and Portuguese. In Subtask 3 (Narrative Extraction), we build our system with data augmentation, supervised fine-tuning, and preference-based reinforcement learning. This system achieves the first place in Bulgarian, Russian and Hindi and the second place in Portuguese.

1 Introduction

The rise of the Internet and artificial intelligence has revolutionized how we access information, but also leaves us vulnerable to manipulative content and disinformation. Various tasks on media analysis have studied entity roles in memes (Barrón-Cedeño et al., 2024) and persuasion techniques in textual and multimodal datasets (Piskorski et al., 2023; Dimitrov et al., 2021). SemEval-2025 Task 10 (Piskorski et al., 2025; Stefanovitch et al., 2025), building on top of these tasks, proposes the challenge of developing cutting-edge NLP systems for multilingual characterization and extraction of narratives from online news. The task aims to automatically identify narratives and the roles of the relevant entities involved. These news analytics capabilities are essential for studying disinformation phenomena on specific targets.

The task focuses on three core news analytics challenges in five languages (Bulgarian, English, Hindi, Portuguese, and Russian).

- Entity Framing: Determine how entities are portrayed.
- Narrative Classification: Identify all the storylines of a news article.
- Narrative Extraction: Generate short explanations for dominant narratives.

The original dataset poses two main challenges. Firstly, Training classification models with entire articles leads to poor performance. We observe that new articles usually contain multiple entities and narratives and, therefore, redundant or interfering information for identifying a specific target.

The small number of articles compared to the number of different labels and label power sets is another challenge. In cases where there is not enough supervised data to train a BERT-like model, the advantages of leveraging the pre-trained knowledge of LLMs to solve downstream tasks with a small amount of data become apparent.

In summary, this paper presents the following contributions:

- Target-oriented semantic segmentation with multiple prompts is adopted to alleviate redundant information within news articles and leads to significant performance gain.
- Sufficient experiments with multilingual and monolingual approaches are conducted to identify effective ways to utilize cross-lingual datasets.
- The correlation between coarse-grained and fine-grained roles or narratives is captured by multi-turn dialogues training set for LLMs, which further improves model performance.
- Finally, our systems achieve five first places, five second places, and several top-10 rankings on SemEval 2025 task 10 Test Leaderboards.

We present specific approaches and observations for each subtask separately in Sections 4 to 6.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2121–2132

2 Related Work

(Zhou et al., 2024) addresses the problem of noisy information by employing language models to automatically generate data cleaning programs and developing manual rules to enhance the quality of pre-training data. This method improves corpus usability with semantic segmentation techniques, such as filtering redundant paragraphs and removing low-quality texts. Similarly, (Gehman et al., 2020) utilizes semantic segmentation to identify toxic content in generated texts, combining rule-based and model-based predictions to filter harmful segments. Building upon these approaches, we leverage the ability of open-source LLMs and propose a target-oriented semantic segmentation technique during the data preparation phase and achieve significant improvements.

To address the challenge of low-resource scenarios in NLP tasks, Wei and Zou propose data augmentation methods including Synonym Replacement, Random Insertion, Random Swap, and Random Deletion (Wei and Zou, 2019). Advanced strategies namely metadata-aware data augmentation, which exchange similar products within a food category (Zhang et al., 2021), and prototypical networks, (Snell et al., 2017) show promise for data augmentation in professional domains. To take full advantage of the world knowledge within open-source LLMs, including LLaMa3.3-70B (AI@Meta, 2024) and Qwen2.5-72B(Yang et al., 2024), we design various prompt to generate multiple sets of training data to mitigate the problem of unbalanced data and overfitting in low-resource scenarios. (Wang et al., 2023) discusses multilingual training as another solution to low-resource scenarios of African languages. We perform sufficient experiments on combinations of monolingual datasets in the context this task and identify effective ways to conduct multilingual training.

Multi-dimensional Type-slot Label Interaction Network (MTLN) proposed by (Wan et al., 2023) is a neural network designed to address multiple NLP tasks using a unified architecture. Compared with single-task learning, multi-task learning (MTL) shows enhanced generalization abilities by learning task correlations and complementary features, and mitigates the issue of underfitting (Guo et al., 2018). Built upon this idea, we transform the correlation between coarse-grained and fine-grained roles or narratives into a multi-turn dialogue to build multi-task training sets for LLMs and observe a steady increase.

3 System Overview

3.1 Model Training Approaches

3.1.1 Supervised Fine-Tuning (SFT)

Supervised Fine-Tuning (SFT) is the primary method used in three subtasks. During the SFT stage, model weights are updated by minimizing a supervised loss function to encourage better predictions of labeled data. The loss function during SFT is generally defined as:

$$\mathcal{L}_{SFT} = \frac{1}{N}\sum_{i=1}^{N}\mathcal{L}_{\text{cross-entropy}}(y_i, \hat{y}_i) \tag{1}$$

where $\mathcal{L}_{\text{cross-entropy}}$ is the cross-entropy loss of the predicted label sequence $\hat{y}_i$ given the true label sequence y_i, and N is the number of training samples.

3.1.2 Reinforcement Learning (RL)

Reinforcement Learning (RL) is a common approach to improve model performance in hard cases where supervised fine-tuning fails. While the PPO (Proximal Policy Optimization) algorithm (Schulman et al., 2017) is widely used to align the behavior of pre-trained LLMs with complex human preferences, DPO (Direct Preference Optimization) (Rafailov et al., 2024) shows decent performance in downstream tasks with simple goals or evaluation metrics such as classification and summarization. The DPO algorithm also requires much less computational resources by transforming an RL problem into an SFT problem. The objective of DPO is to maximize the probability ratio of selecting a referred output over a rejected output. The objective function is written as:

$$\begin{aligned}\mathcal{L}_{DPO}(\pi_\theta; \pi_{\text{ref}}) = \\ - E_{(x,y_w,y_l)\sim\mathcal{D}}\Big[\log\sigma\Big(\beta\log\frac{\pi_\theta(y_w|x)}{\pi_{\text{ref}}(y_w|x)} \\ - \beta\log\frac{\pi_\theta(y_l|x)}{\pi_{\text{ref}}(y_l|x)}\Big)\Big]\end{aligned} \tag{2}$$

where π_θ is the policy model to be trained, π_{ref} the reference model that is kept frozen, y_w the chosen sequence, and y_l the rejected sequence.

3.1.3 LoRA (Low-Rank Adaptation)

To implement SFT and RL in low-resource scenarios, LoRA (Low-Rank Adaptation)(Hu et al., 2022) is adopted for parameter-efficient tuning. The idea of LoRA is to approximate model weight updates ΔW by the product of two low-rank matrices A and B, reducing the number of parameters to be trained while maintaining model performance. The process can be written as:

$$W_{\text{new}} = W + \Delta W = W + AB^T \tag{3}$$

where A and B are two trainable matrices and ΔW is kept frozen to improve computational efficiency. The loss function for LoRA is typically the standard SFT loss.

3.2 Data Processing Techniques

3.2.1 Data Preprocessing

Both the experimental results and the text analysis show that it is not an effective approach to use entire news articles as input to train classification models. An excessively long input contains redundant or noise information. In Subtask 1, a news article may contain multiple

entities and one entity (such as Russia) may also appear multiple times, each with a different fine-grained role. The mixture of different targets in an article makes it difficult for the model to accurately identify the characteristics of each one. The case is similar in Subtask 2. The latest advances in generative LLMs provide a convenient solution. We build prompts to describe each entity and narrative and use LLMs for semantic segmentation to obtain the most relevant contextual information for each target.

3.2.2 Data Augmentation

(Mahmoud et al., 2025) presents a corpus of 1,378 recent news articles in five languages (Bulgarian, English, Hindi, Portuguese and Russian). However, it is difficult to train a monolingual model with robust representations with only hundreds of examples in each language. To address data sparsity, we perform data augmentation by rewriting, summarizing, and semantic segmentation with multiple prompts, and resampling to improve data quality and alleviate unbalanced distribution across languages. We also investigate using multilingual training data as a technique for data augmentation as well.

3.3 Multi-label Classification

Multi-label classification is a machine learning task that addresses problems where instances are associated with multiple interdependent labels. Traditional approaches often transform the problem into binary subtasks (e.g., one-vs-rest, one-vs-one). These methods may struggle with label correlations and scalability when the label space is large. We adopt the method of label sequence generation to model interdependent relationships among labels and expand this idea by leveraging the ability of multiturn conversations of LLMs to model hierarchical relationships. The performance of these systems are further improved by constructing high-quality training data.

3.4 Ensemble Learning for Performance Boosting

Voting with multiple models is an effective approach to correct obvious errors that occur with a single model, and therefore, reduces model variance and improves generalization of a system (Ruta and Gabrys, 2005; Zhang et al., 2014). We sample multiple subsets of training data and fine-tune LLMs with LoRA on each subset. The checkpoint with the best validation result is chosen for each fine-tuning process. Finally, we run inference with each chosen checkpoint and vote for a final output.

4 System Description for Subtask 1

4.1 Model Design

Subtask 1 is a hierarchical multi-label classification task of entity roles in news articles. As discussed in the previous sections, the challenge is redundant information in long articles and limited data for each language. To address the first challenge, we propose a two-stage news analytical framework to enhance the accuracy of entity role classification. The first stage is semantic segmentation. Only paragraphs or sentences that are closely related to the target entity are extracted to form a coherent context for classification. This step facilitates data cleaning and dynamically restructure the context according to the target entity. The second stage is hierarchical multi-label classification. Phi-4(Abdin et al., 2024) and Qwen2.5-32B(Yang et al., 2024) models are fine-tuned using LoRA to specialize in multi-turn conversational reasoning, enabling nuanced understanding of role-specific patterns at both coarse and fine through sequential interaction analysis.

For the second challenge, we build multiple prompts to rewrite, summarize, and extract context from the news text for data augmentation. We also conduct sufficient experiments to explore the use of multilingual training set in depth.

As we design four prompt-based data augmentation methods, five sets of training data are obtained in total. Consequently, we create a five-fold validation of LoRA fine-tuning of LLMs. The best checkpoint in each validation is selected, and the final best results are given by a majority voting mechanism. This ensemble method leverages the collective wisdom of multiple models, reducing the potential biases and errors of a single model, and enhancing the overall model performance and generalization ability.

4.2 Experimental Setup

We utilize LLama-Factory (Zheng et al., 2024) to implement training setups. LoRA is adopted to fine-tune Phi-4 and Qwen2.5-32B, with rank=4, alpha=8, and low-rank adapters applied to all layers. Adam optimization (Kingma and Ba, 2014) with a warm-up step of 10% and a learning rate of 1e-4. Distributed training is implemented with Deepspeed Zero-3 on two NVIDIA A100 GPUs (80GB) , with a batch size of 2 per device and a gradient accumulation of 32, training for a total of 3 epochs.

4.3 Best Results

The best results on the validation datasets are obtained by fine-tuned Qwen2.5-32B-Instruct for English and Portuguese and by Phi-4 for Russian, Bulgarian and Hindi. The target-oriented semantic segmentation technique leads to significant boost in model performance. The use of multilingual datasets and a voting mechanism bring additional benefits. The results are shown in Table 1.

Dataset	Language	Phi-4 EMR%	Qwen2.5 EMR%
EN+PT	English	53.65	**54.95**
EN+PT	Portuguese	76.99	**77.59**
EN+RU+BG	Russian	**65.12**	61.63
RU+BG	Bulgarian	**61.29**	54.48
HI	Hindi	**48.93**	44.64

Table 1: Best results on the validation set for Subtask 1

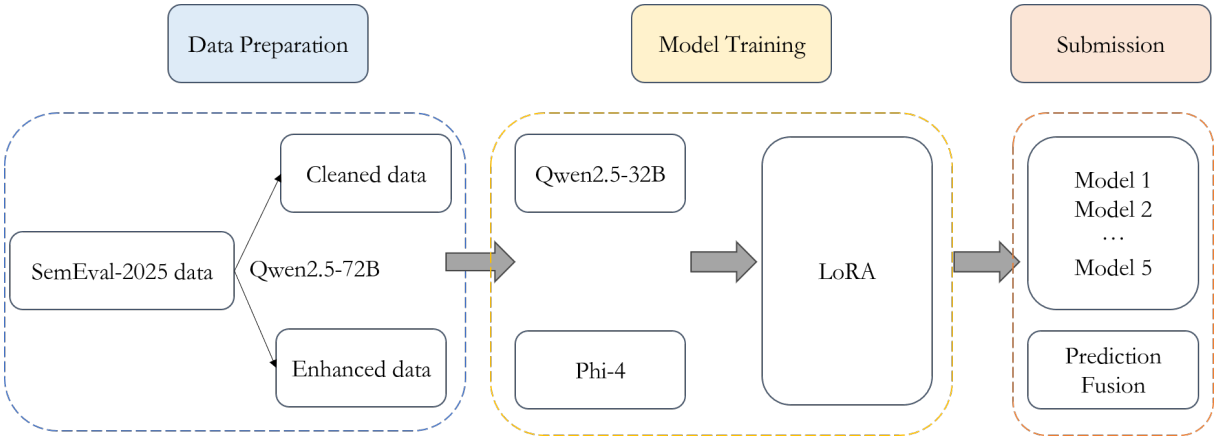

Figure 1: Task experimental progress

we select the best-performing model settings for each language and conduct inference on the test set. As presented in Table 2, the system achieves the first place in Bulgarian, and the second place in English and Portuguese.

Language	EMR	micro P	micro R	micro F1	Accurracy	Rank
English	0.38300	0.46150	0.43020	0.44530	0.88940	2
Portuguese	0.49160	0.55370	0.52630	0.53970	0.90570	2
Russian	0.44390	0.49780	0.48900	0.49330	0.78040	6
Bulgarian	0.51610	0.53970	0.53120	0.53540	0.92740	1
Hindi	0.26900	0.35330	0.29320	0.32050	0.69620	11

Table 2: Official SemEval results on the test set for Subtask 1

4.4 Ablation Experiment

4.4.1 Trial 1: Selecting a model for each language

A multi-turn dialogue training set as shown in A.2 is constructed to train Qwen2.5-32B and Phi-4 with the news articles in each language. In the first round, LLMs are instructed to infer the primary roles of entities based on the original news text. In the second round, models are guided to select fine-grained roles that are consistent with the predicted primary roles. Finally, the results are evaluated using EMR.

The purpose of this experiment is to select the most suitable model for each language. The experimental results are shown in Table 3.

Dataset	Language	Phi-4 EMR%	Qwen2.5 EMR%
EN	English	37.68	**38.06**
PT	Portuguese	42.60	**42.98**
RU	Russian	**40.86**	40.80
BG	Bulgarian	**30.90**	20.36
HI	Hindi	**24.22**	16.76

Table 3: Validation results for Phi-4 and Qwen2.5-32B in five languages

Results and analysis: Phi-4 and Qwen2.5-32B show similar performance in English and Portuguese, with Qwen2.5-32B being slightly better. Phi-4 is significantly more effective in Hindi and Bulgarian, which can be attributed to its extensive support for low-resource languages. Therefore, Qwen2.5-32B is used for English and Portuguese tasks and Phi-4 for Hindi, Bulgarian, and Russian tasks subsequently.

However, neither model shows competitive performance on the training set built from the full texts of the news articles, which shows the necessity of the data processing step in our two-stage news analytical system.

4.4.2 Trial 2: Training with Semantic Segmented Data

As shown in Figure 2, we observe that the same entity can appear multiple times at different positions in an article, each time having a different role. Models struggle to determine which specific entity and location to analyze given the entire news text. To address this issue, we design a target-oriented semantic segmentation method to extract relevant context from news texts according to a specific entity and its specific position. The method is described in Appendix A.1 in detail.

Figure 2: An example of redundant and noisy information for role classification in one article: red represents the *antagonist*, blue represents *protagonist*, green represents *innocent*, and orange represents entities that do not need to be classified. The fine-grained roles of the entities are indicated within the boxes.

The training set is constructed with the same prompt

in trial 1 but replacing full texts for coherent context obtained from semantic segmentation. The results in Table 4 demonstrates the effectiveness of this data processing technique in reducing redundant information and enhancing model accuracy.

Dataset	Language	Phi-4 EMR%	Qwen2.5 EMR%
EN	English	50.46	**50.86**
PT	Portuguese	71.90	**72.80**
RU	Russian	**57.42**	57.06
BG	Bulgarian	**50.73**	43.00
HI	Hindi	**43.57**	39.62

Table 4: Validation results for training with semantic segmented context in five languages

Results and analysis: Both models achieve significant improvements in five languages. The improvement can be attributed to gathering contextual information for entities at specified positions in the original news text, which effectively eliminates redundant information and noise.

4.4.3 Trial 3: Training with Multilingual Data

We observed that data is limited for each language, and a lack of data diversity can lead to suboptimal model performance. Aside from various prompts for rewriting, summarizing, and semantic segmentation, we investigate the use of multilingual datasets as a data augmentation technique to improve model performance and generalization capabilities.

Dataset	Language	EMR%
EN	English	53.35
EN+PT	English	**53.65**
EN+RU	English	52.75
EN+RU+BG	English	45.05
All	English	49.52
PT	Portuguese	75.72
EN+PT	Portuguese	**76.99**
All	Portuguese	74.50
RU	Russian	58.64
EN+RU	Russian	62.79
RU+BG	Russian	58.14
EN+RU+BG	Russian	**65.12**
All	Russian	61.63
BG	Bulgarian	56.86
RU+BG	Bulgarian	**61.29**
EN+RU+BG	Bulgarian	58.14
All	Bulgarian	51.61
HI	Hindi	**48.93**
All	Hindi	48.57

Table 5: Phi-4 on monolingual and multilingual data based on LoRA fine-tuning after 5 models voted after inference on the validation set.

Results and analysis: As shown in Table 5, a combination of the Portuguese and English training sets outperforms both single-language and other multilingual training sets on the validation sets for English and Portuguese. We deduce that both English and Portuguese belong to the Indo-European language family, sharing significant similarities that help the model better capture key information.

For the Bulgarian validation set, a combination of Russian and Bulgarian training sets outperforms other combinations. This might also be attributed to the linguistic similarity between Bulgarian and Russian, which enables knowledge transfer and improves model performance in Bulgarian. However, for the Russian validation set, the combination of English, Russian, and Bulgarian datasets achieves the best performance. The addition of the English dataset enhances the performance in Russian significantly. The reason might require further analysis on data distributions.

For the Hindi validation set, training with Hindi data alone yields better results compared to other multilingual combinations. This is probably because Hindi has a grammatical structure that is significantly different from other languages, and mixing data from other languages does little help in model performance.

This analysis provides some insights into how language similarity influences model performance in multilingual tasks. Despite a minor inconsistency, the takeaway is an actionable guideline for future experiments.

5 System Description for Subtask 2

5.1 Model Design

In Subtask 2, we adopt a similar pipeline for narrative-based semantic segmentation as in Subtask 1. For each news article, we obtain a list of relevant paragraphs for each subnarrative in its golden label set.

Two types of models for multilabel classification are trained, one-vs-rest classification models (referred to as OVR) and label sequence generation models (referred to as SGM). Therefore, two data aggregation approaches are employed to convert the above data into proper training data for different types of models, respectively.

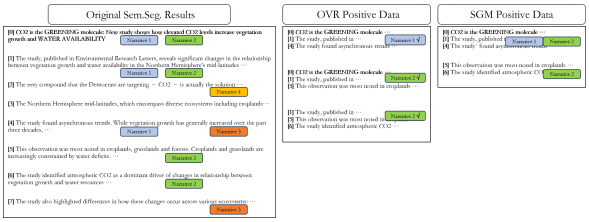

Figure 3: Construct positive training samples for OVR models and SGMs

As demonstrated in the Figure 3, to train classification models, we concatenate several (two to three) relevant paragraphs for each subnarrative to form a large paragraph. Positive data points are made up of these large

paragraphs and their corresponding subnarratives, and negative data points are sampled from combinations of large paragraphs and subnarratives that are not relevant to the entire news article. LLM-based OVR models for multilevel label predictions are trained on multitask datasets that contain training data for coarse and fine labels.

For generation models, a label powerset for each paragraph is first obtained from the original processed data. Then we concatenate several (two to three) paragraphs sharing the same label powerset to form a large paragraph. The volume of data decreases rapidly after concatenation. Therefore, we use various prompts for rewriting, summarizing, and semantic segmentation to expand the training set to contain 10k data points per language (5k for Russian). We train LLM-based sequence generation models for multilevel label predictions using multiturn dialogues that predict coarse and fine labels in turn.

The considerations and effectiveness of the underlined data processing decisions, along with semantic segmentation and OVR and SGM models, will be discussed in the ablation analysis.

5.2 Experimental Setup

We fine-tune the Phi-4 and Qwen2.5 models with LoRA applied to all modules, setting rank = 8, alpha = 16 and dropout of 0.1. We implement distributed training with Deepspeed Zero-2 or Zero-3 on two NVIDIA A100 GPUs with 2 or 4 samples per device and various gradient accumulation parameters to achieve a total batch size of 64. We train the models for 3 epochs and evaluate their performances on the Subtask 2 validation set to select the best checkpoints.

During the prediction phrase, we first perform semantic segmentation without instruction of narratives to divide the entire article into chuncks. Then OVR models are applied to decide whether a chunk is relevant to each narrative and the corresponding subnarratives. SGMs are used to generate a subset of narratives and subnarratives for each chunk. To get the final result for the entire article, we take the union set of the results for all chunks. Finally, we evaluate the results on the validation set using F1 metrics (Piskorski et al., 2025).

5.3 Best Results

The best results on the validation datasets for different languages are obtained by fine-tuned Phi-4 and Qwen2.5-32B-Instruct respectively. Combining English and Portuguese datasets, English, Russian, and Bulgarian datasets leads to further performance gain, which is consistent with the result of Subtask 1. Both multitask OVR models and multiturn SGM models are effective in multilabel classification tasks.

We use the best-performing models for test set inference and the final leaderboard results are presented in Table.

Language	Dataset	Base	Method	F1 samples
English	EN+PT	Qwen2.5-32B	SGM	0.520
Portuguese	EN+PT	Qwen2.5-32B	SGM	0.512
Russian	BG+RU	Phi-4	SGM	0.496
Bulgarian	EN+BG+RU	Phi-4	OVR	0.543
Hindi	HI	Phi-4	OVR	0.457

Table 6: Best results on the validation set for Subtask 2

Language	F1 coarse	F1.st.dev coarse	F1 samples	F1.st.dev samples	Rank
English	0.52100	0.35600	0.33900	0.29100	7
Portuguese	0.54100	0.29000	0.40900	0.26900	2
Russian	0.56600	0.26800	0.43400	0.24700	2
Bulgarian	0.63100	0.33800	0.46000	0.33300	1
Hindi	0.39200	0.39000	0.21800	0.35000	8

Table 7: Official SemEval results on the test set for Subtask 2

5.4 Ablation Experiments

5.4.1 Trial 1: Benefits of Semantic Segmentation

The narrative-oriented semantic segmentation pipeline is critical to enhancing model performance. The necessity of isolating coherent narrative units from an news article is to reduce noisy text spans that are related to other narratives, enabling the model to learn accurate features for each narrative. As shown in Table 8, the models trained on semantically segmented data significantly outperform those trained on full texts by +10pt.

Language	Dataset	Full Text F1 samples	Sem.Seg. F1 samples
English	EN+PT	0.314	**0.432**
Portuguese	EN+PT	0.303	**0.435**
Russian	RU+BG	0.332	**0.419**
Bulgarian	RU+BG	0.354	**0.463**
Hindi	HI	0.279	**0.394**

Table 8: Validation results for training with full texts and semantically segmented data

5.4.2 Trial 2: Data Quality Improvement and Augmentation

We observe that model performance may depend heavily on the quality of the subnarrative labels generated at the paragraph level. Concatenating paragraphs linked to a specific subnarrative or a specific set of subnarratives offers various advantages.

- Balance the specificity and richness of text spans: contain unique utterance that align with a narrative label and their contextual information as well
- Improve the accuracy of positive data points: the accuracy of original paragraph-level labels is around 80% according to manual inspection. By connecting two paragraphs sharing the same label, the accuracy of narrative labels for large paragraphs is around 96% in theory, and over 99% when connecting three. This is of critical importance for sequence generation models because they

do not leverage negative samples during the SFT stage.

For classification models, particular attention should also be paid to the construction of negative samples. It is risky to use narratives that appear in a new article but are not assigned to a paragraph as 'hard negatives', because there is a chance of 10-20% that the sentiment segmentation pipeline failed to recall the paragraph as relevant. Therefore, we construct negative samples with 'easy negatives' and achieve competitive results.

Original news articles are expanded via prompting LLMs for rewriting, summarization, and translation to generate diverse paraphrases while preserving label semantics. We perform semantic segmentation on the generated articles as well to address the rapid decline in training volume after data quality improvement and mitigate overfitting in low-resource scenarios. Data quality improvement and data augmentation yield consistent gains of 5-7pt in F1 samples, as shown in Table 9.

Language	Dataset	Sem.Seg. F1 samples	Sem.Seg.Aug. F1 samples
English	EN+PT	0.432	**0.501**
Portuguese	EN+PT	0.435	**0.483**
Russian	BG+RU	0.419	**0.481**
Bulgarian	BG+RU	0.463	**0.521**
Hindi	HI	0.394	**0.457**

Table 9: Validation results for training with Data Augmentation and Quality Improvement

5.4.3 Trial 3: Comparing OVR and SGM Models

Fine-tuning sequence generation models (SGMs) with multiturn dialogue data further improves task performance. This modeling choice aligns with the hierarchical and interdependent nature of narratives, where coarse labels inform fine-grained labels, and one narrative often co-occurs with a handful of others. The ablation of OVR models and SGMs architectures highlights the efficacy of modeling label dependencies. As shown in Table 10, SGMs outperform OVR models in English, Portuguese, and Russian by 2-3 pt and give comparative results in Bulgarian and Hindi. One limitation is that SGMs only learn from positive labels during SFT. We will explore incorporating negative samples to further improve the performance of SGMs with preference-based reinforcement learning in future experiments.

6 System Description for Subtask 3

6.1 Model Design

Subtask 3 is a task of generating explanations for a given dominant narrative. Despite the outstanding ability of open-source base LLMs for synthetic data generation, there are cases where the models performed poorly in professional areas. Therefore, we employ supervised fine-tuning and reinforcement learning methods to train LLMs and enhance their performance in news analysis.

Language	Dataset	OVR F1 samples	SGM F1 samples
English	EN+PT	0.501	**0.520**
Portuguese	EN+PT	0.483	**0.512**
Russian	BG+RU	0.481	**0.496**
Bulgarian	BG+RU	**0.521**	0.519
Hindi	HI	**0.457**	0.443

Table 10: Validation results for OVR models and SGMs on multilabel classification

To overcome the challenge of limited data, we applied data augmentation through large pre-trained models (Qwen2.5-72B and LLaMa3.3-70B) for text rewriting. We also used resampling techniques to balance the dataset across different languages, ensuring that the model was trained on a representative distribution of data.

For data augmentation, each text sample x_i in the training set was augmented by rewriting it at varying lengths $L \in \{300, 500, 800\}$. The augmented dataset D_{aug} was then formed by mixing the original data and rewritten samples, denoted as:

$$D_{\text{aug}} = \{(x_1, \hat{x}_1^{300}, \hat{x}_1^{500}, \hat{x}_1^{800}), \dots\} \quad (4)$$

where $\hat{x}_i$ represents the augmented version of the original sample x_i.

Reinforcement learning is another technique to improve model performance. The preference data for RL is constructed by leveraging LLMs fine-tuned with SFT datasets. We use fine-tuned models to generate narrative explanations for all data multiple times. The generated explanations for each data point are ranked by their BertScore (Zhang et al., 2019) similarity to the golden label. The top 1 output with a BertScore less than 0.7 is selected as the rejected sequence and the preferred sequence remains the golden label.

Using above methods, we expand the training datasets and empower base LLMs with the ability of generating high-quality outputs in a professional area. Finally, the system achieves outstanding performance in five languages.

6.2 Experiment Setup

we present the design and implementation of the system used for training and fine-tuning multilingual models. The main objective of this work was to explore effective strategies for improving model performance in cases where training data is scarce, leveraging a combination of Supervised Fine-Tuning (SFT), Data Augmentation, and Reinforcement Learning (RL)techniques. The base model we utilized is phi4 (small), with Qwen2.5-72B and LLaMa3.3-70B(AI@Meta, 2024) as the large models for synthetic data generation. Throughout the experiments, we used BertScore as the evaluation metric.

The training process was designed to handle the challenge of limited data for each individual language. To

mitigate this, a multilingual dataset was created by combining five different languages, making the model more adaptable and better at handling diverse linguistic inputs.

6.3 Best Results

6.3.1 Quantitative Analysis

The combination of data augmentation, SFT, and RL produces the best performance on the validation set as shown in Table 11.

Data Augmentation increased the diversity of the training set, enhancing the model's generalization capability and allowing it to perform well across a broader range of inputs. By providing additional data, the model was exposed to various contexts and language patterns, which mitigated the risks of overfitting to a small, homogeneous dataset.

Supervised Fine-Tuning ensured that the models were tailored to the specific task at hand. By fine-tuning the model on a mixed dataset, we enabled it to specialize in producing task-relevant text while still benefiting from a broad linguistic context. This balancing act between generalization and task-specific adaptation is critical for achieving optimal performance.

Preference-Based Reinforcement Learning provided a mechanism for continuous improvement. By incorporating a feedback loop that ranked outputs based on quality metrics like BertScore, the model learned to prioritize high-quality responses. This reinforcement learning step allowed the model to focus not just on producing text, but on generating outputs that were aligned with human preferences and task-specific criteria.

Language	Method	F1 macro
English	DPO	0.75109
Portuguese	DPO	0.75471
Russian	DPO	0.72848
Bulgarian	DPO	0.72466
Hindi	DPO	0.75159

Table 11: Best results on the validation set for Subtask 3

Finally, we achieve first place in Russian, Hindi and Bulgarian, and remarkable results in Portuguese and English on the official SemEval test set leaderboard, as shown in Table 12.

Language	Precision	Recall	F1 macro	Rank
English	0.72371	0.72589	0.72433	8
Portuguese	0.75365	0.73984	0.74637	2
Russian	0.69984	0.71423	0.70639	1
Bulgarian	0.71405	0.69478	0.70396	1
Hindi	0.75097	0.76045	0.75540	1

Table 12: Official SemEval results on the test set for Subtask 3

6.4 Ablation Experiment

This section describes the various experiments conducted to train and fine-tune the models, exploring the impact of different approaches on the model's performance.

6.4.1 Trial 1: Direct Inference with Base Models

Objective: The first experiment aimed to establish a baseline by directly using the base models (phi4) for inference on the validation set without any fine-tuning. The prompt is lited in the appendix B.1.

Methodology: No training was performed, and the raw outputs of the models were evaluated using BertScore to measure the quality of the generated text.

Language	Precision	Recall	F1 macro
English	0.67740	0.72317	0.69948
Portuguese	0.68768	0.74247	0.71378
Russian	0.65268	0.71828	0.68379
Bulgarian	0.65624	0.73164	0.69156
Hindi	0.72861	0.71984	0.72390

Table 13: Results of phi-4 in Direct Inference.

6.4.2 Trial 2: Multilingual SFT Training with Mixed Dataset

Objective: Given the insufficient amount of data for each language, the next experiment involved mixing the five languages into a single training set. This mixed-language dataset was used to train the models.

Methodology: The five languages were combined into one dataset, ensuring that the models had a broader context to learn from. This trial aimed to assess how well the models could handle multiple languages simultaneously.

Language	Precision	Recall	F1 macro
English	0.75589	0.73780	0.74648
Portuguese	0.74036	0.74964	0.74464
Russian	0.73371	0.71030	0.72084
Bulgarian	0.70630	0.71394	0.70963
Hindi	0.75723	0.71460	0.73488

Table 14: Results of phi-4 in Multilingual SFT Training with Mixed Dataset.

Results and analysis: By comparing Table 13 and Table 14, it was found that multilingual mixed SFT fine - tuning is effective, and the model is able to maintain competitive performance across all languages. This experiment highlights the feasibility of training multilingual models with a mixed - language dataset of five languages, indicating that the model can successfully learn from data in different languages.

6.4.3 Trial 3: Data Augmentation through Prompting

Objective: To combat the limited size of the training data, we used Qwen2.5-72B and LLaMa3.3-70B to augment the data. The goal was to generate additional samples that could enhance the model's generalization ability.

Methodology: We prompted the large models to rewrite the data at varying lengths (300, 500, 800 tokens). These augmented data points were mixed with the original training data to create a richer, more diverse training set.

- **Augmented Training Set:** Mixing original and augmented data led to improvements in model performance, especially in cases with a low number of original data points.
- **Balanced Dataset:** To address discrepancies in the amount of data for each language, we employed a resampling technique to balance the data, ensuring that each language had an equal representation in the training set.

Language	Precision	Recall	F1 macro
English	0.76814	0.76814	0.74961
Portuguese	0.73819	0.75801	0.74752

Hindi	0.74930	0.74930	0.74368

Table 15: Results of phi-4 in Multilingual SFT Training with Data Augmentation and Random Replication.

Results and analysis: A comparison of Table 14 and Table 15 reveals that model performance can be further enhanced through data augmentation. This is attributed to the use of large models such as Qwen2.5 - 72B and LLaMa3.3 - 70B to generate additional data samples of varying lengths, as well as the resampling method employed to balance the representation of each language. By enriching the training set in this way, we have strengthened the model's generalization ability, thus demonstrating the effectiveness of data augmentation techniques in improving model performance.

6.4.4 Trial 4: Preference-Based Reinforcement Learning

Objective: In this trial, we aimed to improve the quality of the generated data by constructing preference data, and then fine-tuning the models using Reinforcement Learning based on these preferences.

Methodology: We first generated outputs for both the original and augmented datasets using the model weights from the previous experiment. These outputs were scored using BertScore, and the highest-scoring samples (top 2-3) were selected as negative samples for the RL training.

Results and analysis: As shown in Table 16, the model has achieved good performance across various languages, with precision, recall, and F1-score consistently remaining above 0.7, which is a further improvement compared to SFT fine-tuning. This is attributed to our use of BertScore to rank the outputs of the original dataset and the augmented dataset. We selected the top - scoring samples as negative samples for RL training. This preference-based RL fine-tuning can assist the model in generating more relevant and higher-quality responses, indicating that our approach is effective.

7 Conclusion

For Subtask 1 and 2 in SemEval-2025 Task 10, we perform semantic segmentation through narrative- or entity-based prompt engineering, obtaining the most relevant contextual information for each narrative or entity to reduce redundant and interfering information in classification. We also analyze the effectiveness of monolingual and multilingual training approaches in Subtask 1 and 2, and observe that multilingual datasets composed of adjacent languages achieve better results than monolingual datasets. In Subtask 3, we applied data augmentation and achieved strong results using SFT fine-tuning combined with preference-optimized reinforcement learning.

Our systems incorporate various state-of-the-art techniques, including prompt-engineering, LoRA fine-tuning, reinforcement learning, and LLM for data augmentation, and achieve a total of five first places and five second places in five languages. The results demonstrate the effectiveness of the proposed methods in entity framing, narrative classification, and narrative extraction from news articles.

To improve our work in the future, we plan to look deeper into the lexical or label distribution differences between the training set and the test set to help build more robust systems.

8 Limitation

In order to understand the errors made by the LLMs, we conduct a manual review of the generated content. While the system performed well in generating responses, some common error types were observed:

- Syntax Errors: LLMs sometimes struggle with complex sentence structures, particularly in lan-

guages with more intricate syntactical rules such as Hindi and Russian.

- Lexical Errors: LLMs occasionally selected words that were contextually inappropriate due to lack of domain knowledge. This was more apparent in languages with less raining corpora (e.g., Hindi).
- Translation Errors: In translation for data augmentation, LLMs sometimes failed to translate words or sentence structures accurately, especially between languages with significant morphological differences (e.g., Hindi and Russian).
- Overfitting to Augmented Data: After finetuning with augmented data, LLMs sometimes generate repetitive and verbose responses, which may be signs of overfitting to augmented data.

This analysis helps understand the limitations of LLMs in news analysis and areas that reuqire future refinement for complex sentence understanding and generation tasks.

A Subtask 1

A.1 Article Preprocessing

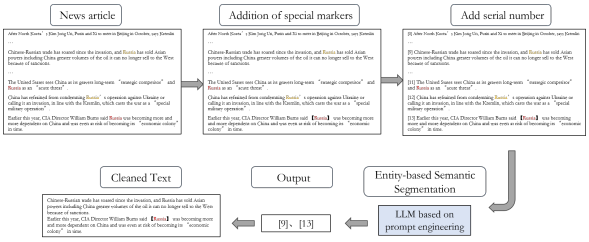

Figure 4: An example of a data preprocessing workflow for context aggregation based on entity positions in news text.

First, we annotate the entities to be classified in the news text using a special marker. Then, we slice the news text by newline characters and sequentially add a number at the beginning of each segment (e.g., [1] Text.), followed by concatenating the segments in order using newline characters. Next, the processed news text is input into the Qwen2.5-72B model, based on prompt engineering, to output the corresponding context segment numbers for each entity. Finally, based on the sequence of output numbers, we concatenate the cleaned segments using newline characters to obtain the text with redundant information and noise removed.

A.2 Fine-tuning Prompt

In Figure 5, the numbers highlighted in red indicate the corresponding input information: Number ① represents the input belonging to the Ukraine-Russia War or Climate Change domain; Number ② represents the entity to be predicted; Number ③ represents the input news text; Number ④ represents the output of the first-round dialogue (prediction or label) for the primary role; Number ⑤ represents the input for the entity to be predicted. By constructing the two-round dialogue fine-tuning prompt in this way, the model can focus on the relationship between the primary role and the fine-grained roles, thereby improving its performance.

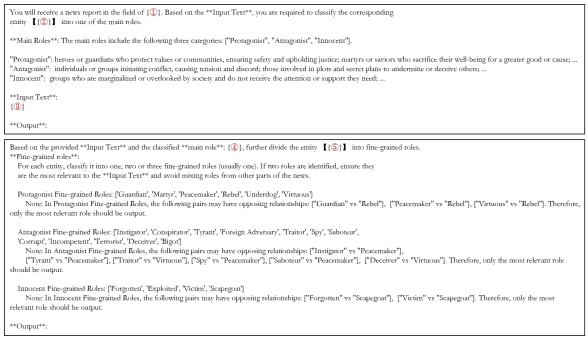

Figure 5: An example of prompt engineering fine-tuning based on a multi-turn dialogue. In the first round (shown above), the prompt engineering is used to guide the model in predicting the main role of the corresponding entity. In the second round (shown below), the prompt engineering utilizes the main role predicted in the first round to predict the fine-grained roles.

B Subtask 3

B.1 Fine-tuning Prompt

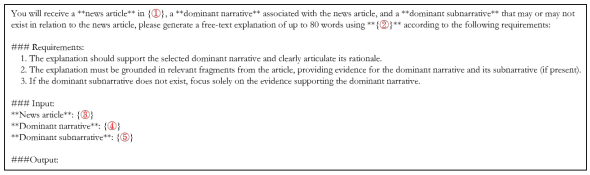

Figure 6: A example of a prompt for fine-tuning LLM based on LoRA.

In Figure 6, the numbers highlighted in red indicate the required input information: Number ① represents the domain of the input, either Ukraine-Russia War or Climate Change; Number ② represents the language in which the output is provided; Number ③ represents the input news text; Number ④ represents the main narrative; and Number⑤ represents the secondary narrative.

Abstract

This paper introduces a hierarchical classification framework, termed the **Tree-guided Stagewise Classifier (TGSC)**, which adopts a Chain-of-Thought (CoT) reasoning paradigm to address multi-label and multi-class classification challenges in multilingual news article analysis, as part of SemEval-2025 Task 10. Our approach leverages the zero-shot capabilities of Large Language Models (LLMs) through a structured hierarchical reasoning process. The classification proceeds step-by-step through the hierarchy: beginning at the root node, the model iteratively traverses category branches, making decisions at each level, and ultimately identifying the appropriate leaf-level category. To enhance classification accuracy, we design a prompt engineering strategy that embeds hierarchical structural constraints to better guide the reasoning process. Experimental results demonstrate the effectiveness of TGSC, showing competitive performance across multiple languages in both Subtask 1 and Subtask 2. The code for our system is publicly available at: https://github.com/startuniverse/SemEval_2025_task10.

1 Introduction

SemEval-2025 Task 10[1] (Piskorski et al., 2025) focuses on the multilingual characterization and extraction of narratives from online news. This task is of strategic significance for both computational social science and multilingual natural language processing (NLP), as it addresses key aspects of contemporary information ecosystems—such as cross-cultural narrative modeling and resilience to disinformation. The task comprises three subtasks. Our team participated in Subtask 1 (Entity Framing) and Subtask 2 (Narrative Classification), evaluating our approach across three languages: English, Portuguese, and Russian.

To address both subtasks, we propose the Tree-guided Stagewise Classifier (TGSC), a hierarchical reasoning framework that systematically harnesses the zero-shot capabilities of LLMs through parent-child knowledge propagation.

The architecture of TGSC adopts a stagewise classification protocol in which parent-level predictions dynamically condition subsequent child-level decisions by restructuring the reasoning context provided to the LLM. At each level of the hierarchy, validated parent class labels are explicitly integrated into CoT prompts using constrained text generation templates. This design guides the LLM's zero-shot inference toward taxonomically valid subclasses. The top-down classification process improves accuracy: parent-level decisions eliminate irrelevant categories, while child-level classification leverages contextual cues to resolve ambiguities among finer-grained classes. Importantly, TGSC achieves hierarchical constraint propagation purely through prompt engineering, without relying on parametric gating mechanisms. This preserves full zero-shot flexibility while structurally preventing category violations. By recursively anchoring coarse-grained classifications to guide more specific decisions, TGSC enables efficient knowledge transfer across classification tiers, effectively balancing broad conceptual coverage with fine-grained precision.

Our participation in this task demonstrates that a zero-shot hierarchical reasoning framework can achieve competitive performance across languages. Our contributions include the following:

- **Cognitive Scaffolding Framework**: Our approach embodies the pedagogical "scaffolding theory" through hierarchical chain-of-thought reasoning. This architecture progressively reduces decision entropy by initially resolving parent-level categorical ambiguities, then recursively refining predictions through child-node analysis using dynamically updated con-

[1] https://propaganda.math.unipd.it/semeval2025task10

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2133–2139

textual constraints. The multi-phase deliberation process intrinsically prevents semantic subspace contamination through early elimination of taxonomically incompatible candidates, mirroring human hierarchical reasoning patterns while maintaining computational tractability.

- **Parameter-Efficient Taxonomic Decomposition**:Our framework strategically decomposes hierarchical taxonomies into LLM-interpretable reasoning chains through structured prompts that cascade parent-level decisions into child inference contexts. This zero-shot approach leverages pre-trained models' inherent knowledge while preventing error propagation through contextual anchoring, achieving flexible yet precise classification. The taxonomy-aware mechanism balances conceptual breadth with granular differentiation without task-specific adaptations or labeled data.

2 Background

2.1 Problem Formulation

We participated in two subtasks of SemEval-2025 Task 10: Entity Framing and Narrative Classification.

In the Entity Framing task, the objective is to assign one or more roles to named entities mentioned in a news article, based on a predefined taxonomy. This task can be formulated as a multi-label, multi-class classification problem over text spans.

The Narrative Classification task involves assigning subnarrative labels to a news article according to a two-level taxonomy. Similar to Entity Framing, this is a multi-label, multi-class task, in which each article may be associated with multiple relevant subnarratives.

The annotation guidelines, including taxonomy definitions and operational instructions, are thoroughly documented in the official SemEval-2025 Task 10 technical report (Stefanovitch et al., 2025).

2.2 Related Work

Prior research in hierarchical classification has generally followed two main directions: hierarchical modeling approaches and reasoning-enhanced approaches.

Hierarchical Modeling Approaches. Dumais and Chen proposed hierarchical decomposition frameworks for efficient top-down categorization, though these methods typically require fully annotated datasets (Dumais and Chen, 2000). Wehrmann et al. introduced HMCN, a hybrid neural architecture that encodes hierarchical structures via specialized loss functions (Wehrmann et al., 2018). Zhu et al. developed HiTIN, a model that transforms label hierarchies into coding trees and incorporates structural encoders to encode hierarchical dependencies (Zhu et al., 2023). Pizarro et al. presented BA-CNN, an attention-based hierarchical model that enables dynamic feature flow between branches to enhance classification performance (Pizarro et al., 2023).

Reasoning-Enhanced Approaches. Cheng et al. proposed an end-to-end neural architecture search framework for hierarchical tasks, integrating domain-specific priors to guide model design (Cheng et al., 2020). In the realm of LLMs, Wei et al. introduced CoT prompting to support complex reasoning tasks (Wei et al., 2023), while Yao et al. explored tree-structured reasoning for more flexible and compositional inference (Yao et al., 2023). Zhang et al. proposed hierarchical knowledge integration to enrich LLM reasoning capabilities (Zhang et al., 2023). The AoR framework by Yin et al. uses dynamic sampling to select high-quality inference chains (Yin et al., 2024), and Goren et al. introduced Hierarchical Selective Classification (HSC), which refines inference by optimizing rule-based thresholds (Goren et al., 2025).

Unlike prior hierarchical models that rely heavily on annotated data or model modifications, our TGSC achieves hierarchical constraint propagation entirely through prompt engineering. TGSC harnesses the zero-shot reasoning ability of LLMs via structured Chain-of-Thought prompts, enabling taxonomically grounded multi-label classification without task-specific fine-tuning.

3 System Overview

3.1 Hierarchical Reasoning Algorithm

We introduce a Hierarchical Reasoning Algorithm (Algorithm 1) designed to overcome the limitations of traditional zero-shot classifiers by incorporating hierarchical constraints that reduce the prediction space and eliminate logical inconsistencies. This method directly addresses the challenges posed by flat label representations in complex taxonomies, where conventional approaches often fail to cap-

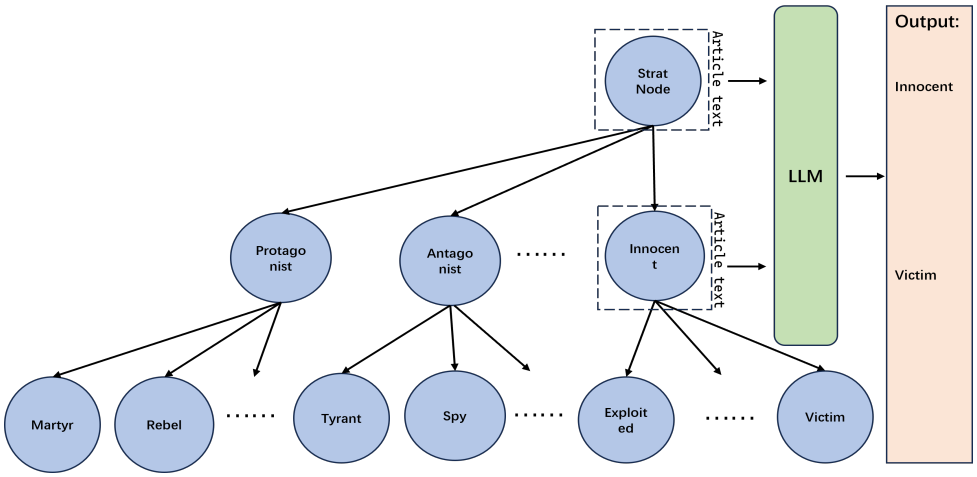

Figure 1: Overview of TGSC

ture the underlying hierarchical semantics. Inspired by the pedagogical theory of scaffolding, our algorithm mimics a staged, progressive learning process using a tree-structured reasoning framework.

During classification, the root node acts as the initial scaffold, offering a broad conceptual foundation to guide the model's reasoning. Internal nodes introduce intermediate constraints that systematically narrow the prediction space, steering the model through increasingly specific decision stages. This hierarchical guidance culminates at the leaf nodes, where the model makes fine-grained, context-aware predictions. The hierarchical structure of root and internal nodes serves not only as a constraint mechanism but also as a semantic guide that progressively structures the model's understanding from general to specific categories.

This top-down traversal—from root to internal nodes, and ultimately to leaf nodes—mirrors human decision-making patterns, where an initial high-level comprehension is incrementally refined into detailed, nuanced judgments. At each level, predictions are informed by the contextual signals propagated from higher tiers in the taxonomy. This staged reasoning process enhances prediction accuracy and coherence, aligning closely with cognitive strategies observed in human learning and decision-making.

3.2 Context-Aware Hierarchical Prompt Routing

We introduce a dynamic prompt engineering framework that leverages a novel context propagation mechanism through hierarchical prompt routing within a tree-structured classification process. In this framework, each node in the classification tree corresponds to a predefined prompt template, specifically designed for its respective classification level. As the model traverses the tree, each node integrates its prompt template with the article text to construct a level-specific input. This input serves as the final prompt for the LLM, guiding it to generate an informed and context-aware prediction.

The hierarchical nature of the tree ensures that context is progressively refined and propagated at each stage of reasoning. As the model moves from root to leaf nodes, the accumulated context from earlier stages constrains and informs subsequent predictions, enabling the LLM to perform increasingly fine-grained classification in alignment with the underlying taxonomy. This structured approach ensures semantic coherence across classification tiers and enhances the model's ability to distinguish

among closely related subcategories.

An example of the prompt generation process for Subtask 2 is illustrated in Figure 2. Since the task structures of Subtask 1 and Subtask 2 are largely similar, we only provide the prompt template for Subtask 2. Additional implementation details and the full code are available in our GitHub repository.

4 Experimental Setup

4.1 Datasets and Evaluation Metrics

The experimental datasets span three languages: English, Portuguese, and Russian. We utilized the official test sets provided for evaluation. For Subtask 1, the dataset includes 63 English samples, 57 Russian samples, and 71 Portuguese samples, totaling 191 instances. For Subtask 2, there are 101 English samples, 60 Russian samples, and 100 Portuguese samples, resulting in 261 instances overall.

The official metrics used in both subtasks include exact match ratio (EMR) and Sample F1. EMR evaluates the prediction accuracy at the level of leaf nodes. Sample F1 is the average of F1 scores across all test samples.

4.2 Implementation Details

For our experiments, we utilized the OpenAI API for token-based inference. Additionally, we integrated the Phi-3.5 model (Abdin et al., 2024) into our framework. Inference with the Phi-3.5 4B model was conducted on a single NVIDIA RTX 4090 GPU.

5 Results

5.1 Main Result

In Subtask 1, our method achieved rankings of 15th, 13th, and 12th for English, Portuguese, and Russian, respectively. In Subtask 2, we attained rankings of 8th, 8th, and 5th, demonstrating competitive performance across all three languages. Tables 1 and 2 compare our results with those of leading competitors and baseline models for Subtasks 1 and 2, respectively.

Both subtasks are framed as multi-label, multi-class classification problems. However, a key distinction lies in their focus: Subtask 1 emphasizes local information—particularly the semantic attributes of named entities—whereas Subtask 2 centers on capturing broader, global narrative structures. The performance differences observed between the subtasks suggest that LLMs are particularly effective at modeling global semantic patterns but may struggle with fine-grained, localized reasoning due to noise or complexity in the input.

Table 2: Official Evaluation on Subtask 2

This observation highlights an important direction for future work: enhancing the ability of LLMs to accurately extract and reason over local information, while preserving their strength in understanding global context. Developing methods to mitigate local noise and better isolate entity-level semantics could further improve classification performance in tasks requiring detailed linguistic precision.

5.2 Ablation Study

To evaluate the contribution of the hierarchical stagewise classification mechanism, we conduct an ablation study comparing our full model with a simplified variant that performs classification in a single stage, without hierarchical reasoning. The results are summarized in Table 3.

The hierarchical stagewise approach consistently outperforms the single-stage variant across both subtasks, highlighting its effectiveness in enhancing classification performance. These findings demonstrate that decomposing the task into multiple reasoning stages not only improves accuracy but also promotes consistency in multi-label, multi-class classification.

By first identifying a coarse-grained parent category, the stagewise process effectively constrains the subsequent prediction space, allowing downstream stages to focus on finer-grained distinctions within narrower semantic scopes. In contrast, the

Figure 2: Template of subtask 2

single-stage approach lacks this structured guidance, making it more susceptible to ambiguity and reduced precision. The observed performance gap reinforces the value of integrating hierarchical reasoning into the classification pipeline.

While the hierarchical structure is the key innovation of TGSC, we also investigated whether specific prompt template designs contributed significantly to the performance gains. To this end, we experimented with alternative prompt templates by varying the instruction styles, contextual phrasing, and information ordering across hierarchical levels.

The experimental results revealed that the overall performance remained largely stable across different prompt variants. This suggests that the hierarchical stagewise reasoning framework, rather than prompt template alone, plays the primary role in enhancing classification accuracy.

5.3 Experiments on Open-Source Models

We further evaluate TGSC on open-source LLMs to assess its generalizability beyond proprietary APIs. As shown in Table 4, introducing stagewise classification leads to a substantial performance improvement. Notably, the baseline model without stagewise classification performs at or near zero, underscoring the critical role of hierarchical, staged reasoning in achieving meaningful results on multi-label, multi-class classification tasks.

The stagewise approach enables the model to incrementally refine its predictions by traversing from coarse-grained parent categories to fine-grained child categories. This structured progression significantly narrows the decision space at each stage, reducing ambiguity and promoting more accurate, contextually grounded classifications. In contrast, single-stage inference lacks this hierarchical guidance, often resulting in vague or incorrect outputs.

These findings reaffirm the effectiveness of stagewise classification in enhancing model precision and consistency, particularly in complex classification scenarios where both global context and

local semantic distinctions must be captured.

6 Conclusion

This paper introduces the Tree-guided Stagewise Classifier (TGSC), a hierarchical framework that leverages Chain-of-Thought reasoning for multi-label news categorization. TGSC progressively narrows the classification space through stagewise refinement, transitioning from coarse-grained parent-category hypotheses to fine-grained child-category predictions via structured reasoning paths. Experimental results validate the effectiveness of TGSC in zero-shot multilingual settings, demonstrating consistent accuracy improvements over baseline models across English, Portuguese, and Russian—without requiring model retraining.

Nevertheless, TGSC also has limitations. Specifically, the stagewise hierarchical structure introduces a potential risk of error propagation: misclassifications at parent nodes may constrain or mislead subsequent child-level predictions. In future work, we plan to explore mechanisms such as confidence-based node re-evaluation, multi-path traversal, or uncertainty-aware prompting strategies to further enhance robustness against hierarchical prediction errors.

Abstract

This paper presents our system for SemEval 2025 Task 11: Bridging the Gap in Text-Based Emotion Detection (Track A) (Muhammad et al., 2025b), which focuses on multi-label emotion detection in short texts. We propose a feature-centric framework that dynamically adapts document representations and learning algorithms to optimize language-specific performance. Our study evaluates three key components: document representation, dimensionality reduction, and model training in 28 languages, highlighting five for detailed analysis. The results show that TF-IDF remains highly effective for low-resource languages, while contextual embeddings like FastText and transformer-based document representations, such as those produced by Sentence-BERT, exhibit language-specific strengths. Principal Component Analysis (PCA) reduces training time without compromising performance, particularly benefiting FastText and neural models such as Multi-Layer Perceptrons (MLP). Computational efficiency analysis underscores the trade-off between model complexity and processing cost. Our framework provides a scalable solution for multilingual emotion detection, addressing the challenges of linguistic diversity and resource constraints.

1 Introduction

Emotion labeling in Natural Language Processing (NLP) is critical for enabling machines to better interpret human emotional expressions, fostering empathetic and context-aware AI systems. Traditional single-label emotion detection oversimplifies human affect by assigning a single dominant emotion to text, ignoring the complex spectrum of overlapping emotions often present in real-world scenarios (Plutchik, 2001). In contrast, multi-label emotion detection aligns more closely with authentic human experiences, where texts may simultaneously express multiple emotions (e.g., joy and surprise, or sadness and anger). It provides ecologically valid representations of emotional complexity, better reflecting nuanced psychological states. However, multi-label emotion detection can be challenging, such as models must account for emotion co-occurrence, resolve subtle semantic ambiguities, and avoid overfitting to sparse or imbalanced label distributions (Ekman, 1992; Wang et al., 2016; Zhang et al., 2018).

Traditional approaches to multi-label emotion detection have predominantly relied on *feature-centric frameworks* that leverage handcrafted linguistic and statistical features. While effective in monolingual settings, such frameworks often required language-specific resources (e.g., lexicons for each target language (Baccianella et al., 2010)), limiting cross-lingual scalability. These features (e.g., lexicons, syntactic patterns) often fail to model the complex interdependencies and contextual nuances required for multi-label emotion detection, as they struggle to capture dynamic label correlations and contextualized affective semantics (Baccianella et al., 2010; Mohammad et al., 2018; Bostan and Klinger, 2018).

In this paper, we conduct a comprehensive study on the development of a feature-centric framework to address the challenges of cross-lingual adaptability and multi-label emotion detection through a three-stage methodological pipeline: (1) feature extraction/document representation, (2) dimensionality reduction and (3) model training. For (1), we unify diverse feature representations ranging from interpretable shallow features (e.g., TF-IDF, Bag-of-Words) to contextually rich embeddings (e.g., FastText, BPE) and Transformer-based semantic encodings (e.g., Sentence-BERT). For (2), we reduce the dimensionality of document representations to prevent model overfitting and accelerate the subsequent step. For (3), we systematically evaluate traditional machine learning classifiers (e.g., SVM, RF) and deep learning architectures (e.g.,

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2140–2148

MLP) to optimize label dependency modeling. The modular design allows interchangeable classifier integration, balancing interpretability (via traditional models) and performance (via neural approaches) for diverse multilingual use cases.

The source code for this paper is publicly available on GitHub[1].

2 Background and System Overview

The development pipeline within the system comprised three distinct stages: (1) feature representation utilizing a diverse set of techniques such as TF-IDF, FastText and Sentence-Transformers, (2) dimensionality reduction of feature vectors via Principal Component Analysis (PCA), and (3) model training and prediction employing a suite of algorithms such as Decision Trees (DT) and Multi-Layer Perceptrons (MLP).

2.1 Document Representation

Raw text data in human languages are sequences of variable-length symbolic representations, which challenge machine learning algorithms that require fixed-size numeric vectors (Mikolov et al., 2013). An effective document representation is essential for optimal NLP performance. To address the complexities of multi-language data, various feature representation techniques have been explored.

2.1.1 Traditional Features

The traditional approaches represent a document d by creating a list of unique words and assigning each word w a numeric value, such as Bag of words (BoW) and Term Frequency-Inverse Document Frequency (TF-IDF).

We use scikit-learn's `CountVectorizer` to extract BoW features, which represent word occurrence in a document without considering word frequency or significance. This approach considers all words equally, including common terms like "*the*" or "*a*", which carry minimal meaningful information. In contrast, TF-IDF adjusts for the importance of words by considering both their frequency in a document (TF) and their rarity across the corpus (IDF), reducing the impact of common words. We use scikit-learn's `TfidfVectorizer`, where IDF is computed as:

$$\mathrm{IDF}(w, d) = \log \frac{1 + N}{1 + \mathrm{DF}(w)} + 1 \qquad (1)$$

where N is the total number of documents and $\mathrm{DF}(w)$ is the document frequency of w.

Preprocessing is critical in traditional feature representations, since it directly influences feature quality and model training. To adapt our model to multilingual scenarios and capture nuanced emotional expressions, we employ GemmaTokenizer (Shelpuk, 2024) in the tokenization step, instantiated with the preset "*gemma_2b_en*". Trained on a diverse multilingual corpus, GemmaTokenizer excels in handling linguistic diversity and demonstrates robust performance in multilingual tokenization tasks.

2.1.2 Pretrained Word Embeddings

Traditional methods like TF-IDF and BoW treat words as discrete, independent units, thereby completely discarding word order and local contextual information during the encoding process, leading to high-dimensional, sparse representations that limit computational efficiency and NLP task performance (Mikolov et al., 2013; Pennington et al., 2014). In addition, their heavy reliance on training corpus results in their inability to handle out-of-vocabulary (OOV) words, as they lack a mechanism to infer the representation or meaning of terms that are not present in the training corpus.

Pre-trained word embeddings offer substantial advantages in capturing semantic meaning, contextual dependencies, and generalization capabilities. Unlike traditional sparse representations, these dense vector embeddings encode rich linguistic features by leveraging large-scale corpora during pretraining, enabling them to model nuanced semantic relationships and syntactic patterns. FastText (Bojanowski et al., 2017) can capture both syntactic and semantic relationships by effectively modeling morphological structures. Byte Pair Embeddings (BPEs)(Heinzerling and Strube, 2018) decompose words into subwords, while Contextual String Embeddings (CSEs)(Akbik et al., 2018) provide context-sensitive representations, dynamically adapting to word meanings. We use the Flair NLP Toolkit[2] to extract these embeddings and `DocumentPoolEmbeddings` for aggregating word-level embeddings into document-level representations via mean pooling.

Given that the cross-lingual representation ability of most mainstream pre-trained language models remains constrained by the limited coverage of training corpora, these models often manifest

[1] https://github.com/YhzyY/SemEval2025-Task11

[2] https://github.com/flairNLP/flair

systematic representational failures when processing low-resource languages excluded from training data. This closed-corpus modeling paradigm inherently imposes significant capabilities limitations in multilingual scenarios. To address this, we leverage Large Language Models (LLMs) to assist with unseen languages by leveraging language family classification. Considering a low-resource language such as the Oromo language, it is not included in the pre-trained FastText embeddings, as outlined in the FastText documentation (Bojanowski et al., 2017). we use Baidu `Qianfan`[3] model to identify the most linguistically similar supported language in FastText. The text in unseen languages, such as Oromo, is then represented using the embeddings of the identified language. The full query is presented in Appendix A. This end-to-end self-adaptive multilingual emotion detection framework significantly enhances the system's ability to process unseen languages while fundamentally eliminating the dependencies on manually annotated language family labels and expert-curated linguistic representation rules, thus circumventing the prohibitive costs of human annotation and resolving the acute scarcity of training data and domain experts in endangered languages.

2.1.3 Transformers

Transformer-based document representations, such as those produced by Sentence-BERT (Reimers and Gurevych, 2019, 2020), leverage the Transformer architecture to selectively focus on semantically relevant segments of text, thereby enhancing feature extraction and improving representational accuracy. Our system embedded the SentenceTransformers [4] with the pretrained "*paraphrase-multilingual-mpnet-base-v2*" model, which supports over 50 languages. Document embeddings are generated using the library's encode function.

2.2 Dimensionality Reduction

The inherent high cardinality of lexical features within textual data frequently results in high-dimensional embedding, which can lead to computational challenges and model overfitting. To reduce the dimensionality of document representations, we first normalize the text to unit norm using scikit-learn's `Normalizer`. Subsequently, Principal component analysis (PCA) (Pearson, 1901) is applied to project the features into a lower-dimensional space. Both the `Normalizer` and PCA utilize default parameter settings.

2.3 Model Training

In this section, we present the methods employed for model training, encompassing traditional machine learning approaches as well as simple deep learning architectures such as MLP.

2.3.1 Traditional Machine Learning

As candidate models for training, we employ a variety of traditional machine learning algorithms, including Decision Trees (DT), k-Nearest Neighbors (KNN), Random Forest (RF) and Support Vector Machines (SVM). However, relying solely on these traditional methods often results in suboptimal accuracy (Le and Mikolov, 2014). To overcome this limitation, we adopt ensemble learning techniques, specifically constructing a majority voting classifier that aggregates predictions from a collection of base classifiers to improve overall performance.

2.3.2 Deep Learning

Multi-Layer Perceptrons (MLPs), with their multi-layered neuron architecture, can learn complex patterns in data, making them well-suited for emotion detection tasks where sentiment often depends on intricate word combinations (Goodfellow et al., 2016). To account for linguistic variations across languages, we use Grid Search to evaluate multiple parameter combinations and select the one that maximizes the *F1-macro* score, ensuring robust and accurate emotion predictions across diverse linguistic contexts.

3 Experimental Data

We use the BRIGHTER dataset (Muhammad et al., 2025a; Belay et al., 2025) provided by SemEval 2025 Task 11 Track A to conduct our experiments., It consists of human-annotated short texts in 28 languages, such as English, German and Russian. The training dataset comprises 65,098 multi-label samples, each annotated with emotion labels — anger, fear, joy, sadness, surprise, and disgust — representing the emotions most likely experienced by the speaker, as inferred from the text. We used only the provided datasets during the development and evaluation phases, no additional training data was introduced to boost the performance. Table 1 shows the statistics in selected languages, with a full list available in the Appendix B.

4 Results

We perform experiments in 28 languages and evaluate model performance using the *F1-macro* score. Additionally, we record time consumption and generate confusion matrices to further analyze the models' performance.

4.1 Representation Selection

To investigate the impact of document representation methods on prediction outcomes, we conducted a controlled experiment with varying representations and a fixed learning algorithm.

We experimented with various representation methods, and Table 2 presents the *F1-macro* scores for the best-performing candidates from three representation approaches (i.e. traditional features, pre-trained word embeddings and transformers) across five languages[5]. To reduce the variance introduced by individual classifiers, we employ a majority voting classifier, thereby providing a more stable basis for evaluating the performance differences across various representation methods. The results of all 28 languages can be found in Appendix Section C. TF-IDF consistently outperforms other document representations across 3 out of 5 selected languages, achieving the highest F1-macro score, particularly in Marathi (0.7438). This highlights TF-IDF's effectiveness, especially in low-resource languages, as it relies on word frequency rather than pre-trained embeddings. Sentence-BERT (SBERT) shows mixed performance across languages. While it achieves the best result for Romanian (0.5630) and Hindi (0.5682), it performs worse than TF-IDF in the majority of other languages. This suggests that semantically rich contextual embeddings, such as those produced by SBERT, can offer advantages in certain linguistic contexts, but may not consistently outperform simpler lexical representations across all languages. FastText performs moderately well in some cases, such as Romanian (0.4486), but struggles in others, indicating its sensitivity to language-specific characteristics. These results emphasize that while pre-trained embeddings offer advantages in certain contexts, traditional frequency-based representations like TF-IDF remain highly competitive for emotion detection in multilingual settings.

4.2 Learning Algorithms

Using a consistent document representation, we evaluate the impact of different learning algorithms on prediction outcomes. Table 3 shows the performance of various algorithms with SBERT embeddings. The performance hierarchy is consistent across languages: MLP > Voting > DT, with MLP demonstrating the best ability to capture complex emotional patterns. The Voting classifier, combining KNN, DT and RF performs moderately, outperforming DT but lagging behind MLP. DT show weaker performance, indicating their limited capacity to model emotional nuances. These results highlight the importance of algorithm choice, with MLP being particularly effective for multilingual emotion detection.

4.3 Ablation Study

To access the contribution of individual components, we conducted an ablation study by removing specific modules and analyzing their impact on performance. The only removable component in

[5]Due to the page limit, we randomly selected five languages as examples.

Table 4: Training time in seconds with (w/) and without (w/o) PCA. The best results are bolded.

		DT	Voting	MLP
w/o PCA	TF-IDF	**1.4894**	**59.7822**	200.7861
	FastText	**0.8623**	**17.2231**	**34.3866**
	SBERT	**2.6267**	**36.9725**	**41.6211**
w/ PCA	TF-IDF	10.7575	201.4630	**114.9862**
	FastText	0.9941	23.4849	41.7187
	SBERT	2.7614	49.2546	47.1017

Table 5: F1-macro scores w/ and w/o PCA.

		DT	Voting	MLP
w/o PCA	TF-IDF	**0.5516**	**0.6561**	**0.6284**
	FastText	**0.3825**	0.4046	0.6479
	SBERT	**0.5022**	**0.5867**	0.7076
w/ PCA	TF-IDF	0.3710	0.3931	0.6100
	FastText	0.3805	**0.4407**	**0.6558**
	SBERT	0.4237	0.5038	**0.7093**

our system is the dimensionality reduction step. Using the Spanish language dataset as an example, we remove PCA to evaluate its impact on predictive performance. PCA impacts multilingual emotion detection frameworks differently based on representation-classifier pairings: for TF-IDF, it reduces MLP training time by lowering dimensionality but increases overhead for DT and the Voting classifier without accuracy gains. FastText benefits from PCA-driven noise reduction (i.e. improving accuracy) but incurs higher computational costs to retain variance, whereas SBERT's performance slightly declines as PCA strips contextual nuances critical for emotion differentiation, despite longer training times. Tree-based models such as DT remain unaffected, prioritizing raw feature hierarchies over reduced embeddings. These results emphasize that PCA's value depends on representation type (i.e. contextual vs. static) and classifier architecture, advocating for selective use to optimize multilingual systems.

4.4 Data Imbalance

Data imbalance in the training dataset can significantly impact model performance, causing bias towards the majority class and resulting in poor predictions for the minority class.

For the Hindi dataset trained with FastText and MLP, over 78% of 2,556 samples are labeled as not "*anger*" leading to a high specificity score (0.9405) but a low recall score (0.5625) for the "*anger*" label,

Table 6: Confusion matrix on Hindi language subset.

	anger	disgust	fear	joy	sadness	surprise
TP	0.5625	0.5000	0.6429	0.6364	0.2941	0.6667
TN	0.9405	1.0000	0.9651	0.9438	0.9277	0.9780
FP	0.0595	0.0000	0.0348	0.0562	0.0723	0.0220
FN	0.4375	0.5000	0.3571	0.3636	0.7059	0.3333

as shown in Table 6. A similar pattern is observed for other emotion labels, highlighting that imbalance between positive and negative samples can undermine prediction accuracy. These results emphasize the significant impact of label distribution on system performance.

4.5 Model Efficiency

The choice of document representation and learning algorithm significantly affects the computational efficiency of emotion detection systems, as demonstrated by comparing the efficiency of time over five languages using FastText embeddings in Table 7. Simpler models, such as DT, exhibit rapid training speeds (0.50–1.14s), making them computationally efficient but often at the expense of accuracy. In contrast, MLP achieves superior predictive performance but requires significantly longer training times (24.84–53.01s), representing a substantial increase in computational cost over DT. The Voting classifier, which integrates multiple models, falls between these extremes, with training times ranging from 9.67s to 23.51s. Despite these differences in training efficiency, all models achieve sub-millisecond inference speeds, with prediction times between 0.3 ms and 0.7 ms, except for Voting in Marathi (0.95 µs) and Russian (1.92 µs). This suggests that inference latency is primarily influenced by model architecture rather than language complexity. These results highlight key efficiency-accuracy trade-offs. While high-dimensional embeddings like TF-IDF achieve strong F1 scores (e.g., Marathi: TF-IDF 0.68), their computational costs (140.24s) may be prohibitive for real-time applications. FastText with MLP provides a balanced alternative, offering competitive accuracy (Marathi: 0.67) with moderate computational cost (embedding: 1.00s, training: 43.56s), underscoring the need for multi-objective optimization in multilingual emotion detection.

5 Conclusions

This study presents a feature-centric framework for cross-lingual multi-emotion detection in short

Table 7: Train and test time in seconds using FastText embeddings.

Language	DT		Voting		MLP	
	Train	Test	Train	Test	Train	Test
Marathi	1.06	6e-4	23.51	9.54e-7	43.56	6e-4

Hindi	1.14	3e-4	22.26	0.0000	49.78	7e-4
Romanian	0.50	3e-4	9.67	0.0000	24.84	6e-4
Russian	1.14	4e-4	22.69	1.92e-6	53.01	7e-4

texts, designed to dynamically adapt of document representations and learning algorithms for optimal language-specific performance. Through a comprehensive comparative study across 28 languages—highlighting five for demonstration—we evaluate three key components: document representation, dimensionality reduction, and model training. Our findings show that the proposed pipeline is adaptable across languages with minimal adjustments, effectively balancing computational efficiency and detection accuracy. Experimental results validate its robustness in multi-label emotion prediction, particularly for low-resource languages.

In future work, we plan to refine the framework by optimizing feature-classifier selection for each language, leveraging advanced LLMs for enhanced feature extraction, and training FastText word vectors to improve representation quality, particularly for low-resource languages. We will also focus on determining optimal PCA configurations and evaluating its impact on the performance across different languages and emotion categories to ensure the robustness and reliability of our framework.

Ethical Statements

This paper presents a feature-centric framework for cross-lingual multi-emotion detection, utilizing the publicly available BRIGHTER dataset (Muhammad et al., 2025a). While leveraging its multilingual resources, we explicitly acknowledge that emotional expression is culturally and linguistically dependent, which may introduce biases in annotation and model predictions, particularly in capturing nuanced emotional expressions across low-resource languages and dialects. To address these challenges, we advocate for responsible development and deployment of the framework, emphasizing ongoing research into bias detection, fairness in cross-lingual emotion analysis, and mitigation of potential data-driven biases. These efforts aim to ensure equitable and ethical applications of the technology while transparently addressing its cultural and linguistic limitations.

Acknowledgments

We would like to thank the organizers of SemEval 2025 Task 11 for hosting the shared task and providing valuable resources that enabled this research. Their efforts in promoting multilingual emotion analysis are greatly appreciated. We are also grateful to the anonymous reviewers for their insightful feedback and constructive suggestions, which have helped us improve the quality and clarity of this work.

C Model Performance

Table 9 shows the F1-macro scores across all 28 languages using three representation methods (TF-IDF, FastText and SBERT) combined with three classifiers (DT, Voting and MLP). The languages are listed in descending order based on the number of training samples, aligning with the organizational schema of Appendix B.

Overall, the transformer-based document representations, such as Sentence-BERT, generally outperform TF-IDF and FastText across 18 out of 28 languages, demonstrating their effectiveness in capturing semantic nuances. In contrast, the pretrained word embeddings such as FastText tend to yields lower scores in most cases, likely due to the limited representation of several low-resource or less commonly used languages in its pretraining corpus, resulting in suboptimal embedding quality for these languages. On the classifier side, the deep learning model MLP consistently delivers the best performance, particularly when combined with SBERT representation, highlighting the advantage of deep learning models in leveraging dense contextual representations. Traditional machine learning approaches, such as Decision Tree, performs better with sparse features like TF-IDF but struggles with dense representations. These findings collectively underscore the importance of combining semantically rich representations with expressive classifiers for robust multilingual emotion detection.

Table 9: F1-macro scores for all 28 languages.

Abstract

This paper presents our approach for SemEval 2025 Task 11 Track A, focusing on multilabel emotion classification across 28 languages. We explore two main strategies: fully fine-tuning transformer models and classifier-only training, evaluating different settings such as fine-tuning strategies, model architectures, loss functions, encoders, and classifiers. Our findings suggest that training a classifier on top of prompt-based encoders such as mE5 and BGE yields significantly better results than fully fine-tuning XLMR and mBERT. Our best-performing model on the final leaderboard is an ensemble combining multiple BGE models, where CatBoost serves as the classifier, with different configurations. This ensemble achieves an average F1-macro score of 56.58 across all languages.

1 Introduction

This paper presents the University of Indonesia's multi-label emotion classification system for all 28 languages included in SemEval 2025 Task 11 Track A (Muhammad et al., 2025b). The task focuses on recognizing multiple emotions expressed in text across diverse linguistic and cultural contexts.

Language is a rich and complex medium for conveying emotions (Wiebe et al., 2005; Mohammad and Kiritchenko, 2018). However, emotional expression and interpretation vary widely across individuals, even within the same cultural or social background. This variability introduces inherent uncertainty in accurately inferring emotions from textual cues.

Emotion recognition is a challenging task that involves multiple subproblems, such as identifying the speaker's emotional state, detecting emotions embedded in text, and analyzing the emotional impact on readers (Mohammad, 2022, 2023). Addressing these challenges requires models that can handle multiple emotional labels accurately.

To address this problem, we explore both classifier-only training and end-to-end fine-tuning strategies. Our approach leverages state-of-the-art encoder-based architectures, including Jina, BGE, and multilingual-E5 (mE5) (Sturua et al., 2024; Chen et al., 2024; Wang et al., 2024). These models are pretrained to generate high-quality embeddings, improving classification performance. We experiment with both pre-trained embeddings combined with machine learning classifiers and fine-tuning transformer-based models with specialized loss functions such as Focal Loss and Asymmetric Loss to mitigate class imbalance (Ridnik et al., 2021; Lin et al., 2017).

Our key findings indicate that embedding-based methods with tree-based classifiers, where we freeze the classifier, particularly BGE combined with CatBoost, outperform fine-tuning approaches for multi-label emotion classification. Specifically, employing separate prompts for each emotion in BGE leads to a improvement in F1-Macro scores. Finally, ensembling enhances the model's robustness, as reflected in our final submission, which shows an improvement compared to using a single model.

2 Related Works

This task focuses on multilingual multilabel emotion classification using the BRIGHTER dataset (Muhammad et al., 2025a), which includes predominantly low-resource languages from Africa, Asia, Eastern Europe, and Latin America. These instances, annotated by fluent speakers, span multiple domains, presenting unique challenges due to both multilinguality and the complexity of multilabel classification.

Recent advancements in decoder-based models such as LLaMA, GPT, DeepSeek, and Qwen (Brown et al., 2020; OpenAI et al., 2024; DeepSeek-AI et al., 2025; Yang et al., 2024;

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2149–2164

Grattafiori et al., 2024), alongside the widespread use of the BERT family of models (Devlin et al., 2019; Zhuang et al., 2021; Conneau et al., 2020), have demonstrated strong performance in multilingual natural language processing (NLP) tasks. Prior research (Belay et al., 2025; Muhammad et al., 2025a) has leveraged these architectures for emotion classification, yet the exploration of advanced encoder-based models like Jina, BGE, and mE5 (Sturua et al., 2024; Chen et al., 2024; Wang et al., 2024) remains limited. These models have performed exceptionally well in embedding benchmarks such as MTEB (Muennighoff et al., 2023), suggesting their potential for our task.

Multilabel classification poses distinct methodological challenges. A traditional approach is Binary Relevance (BR), where separate models are trained for each label (Luaces et al., 2012). More recent strategies leverage BERT-based architectures to enable multi-output classification, predicting multiple labels simultaneously (Kementchedjhieva and Chalkidis, 2023). Another technique incorporates the [SEP] token to convert multilabel classification into a sequence-labeling task, effectively treating it as a single-label problem (Zhang et al., 2021).

A persistent challenge in multilabel classification is class imbalance (Tarekegn et al., 2021). Unlike standard classification tasks, conventional stratification techniques do not naturally extend to multilabel settings. Iterative stratification methods (Sechidis et al., 2011) offer a partial solution, while alternative techniques such as weighted loss functions (Xia et al., 2021), focal loss, and asymmetric loss (Lin et al., 2017; Ridnik et al., 2021) help mitigate imbalance in deep learning models.

Linguistic diversity further complicates multilingual emotion classification. Given the authors' limited language proficiency, exhaustive linguistic analysis across all dataset languages is infeasible. To address this, we explore two approaches, training models separately for each language or collectively across all languages, following prior work (Jørgensen, 2024).

Our work builds on these foundations by investigating the underexplored potential of advanced encoder-based models in multilingual multilabel emotion classification. By combining these models with effective imbalance-handling techniques and leveraging external linguistic resources, we aim to advance the state of multilingual emotion classification beyond existing methodologies.

3 System Overview

3.1 Classifier-Only Training

In this approach, we leverage and freeze pre-trained encoders to extract feature representations from text and train classifiers separately for emotion prediction.

Utilized Encoder Architectures. The encoders used in our experiments include `Jinav3 (JINA)`, `bge-multilingual-gemma2 (BGE)`, `multilingual-e5 (mE5)`, and `XLM-RoBERTa (XLMR)` (Sturua et al., 2024; Chen et al., 2024; Wang et al., 2024; Conneau et al., 2020).

Classifier Models. We explore multiple machine learning models, including `Support Vector Classifier (SVC)`, `Logistic Regression(LR)`, `CatBoost(CB)`, and `XGBoost(XGB)` as classification models (**?**Hearst et al., 1998; Prokhorenkova et al., 2018). To mitigate the imbalance in emotion categories, we employ class weighting to improve the representation of minority classes during training, as defined by the following formula.

$$w_i = \frac{N}{|C_i| \times k} \tag{1}$$

Where: w_i is the weight for class i, N is the total number of samples, $|C_i|$ is the number of samples in class i, k is the total number of classes.

3.2 End-to-End Fine-Tuning

Fine-tuning Strategy. The first type of model involves fine-tuning independently for each emotion category (BR). For the cross-encoder model, we explore two strategies:

1. **Multiple Head Approach.** A single output layer predicts all emotion categories simultaneously. The model outputs independent probabilities for each emotion using a sigmoid activation function:

$$p(y_i|x) = \sigma(W_i x + b_i) \tag{2}$$

where W_i and b_i are the weights and biases for emotion i, and σ is the sigmoid activation function. This configuration is referred to as MultipleOutput `(MO)`.

2. **[SEP] Token Separation.** Each input is formatted as `<sentence> [SEP] <emotion>`, treating the problem as a binary classification for each emotion. This forces the model to consider the relationship between the sentence

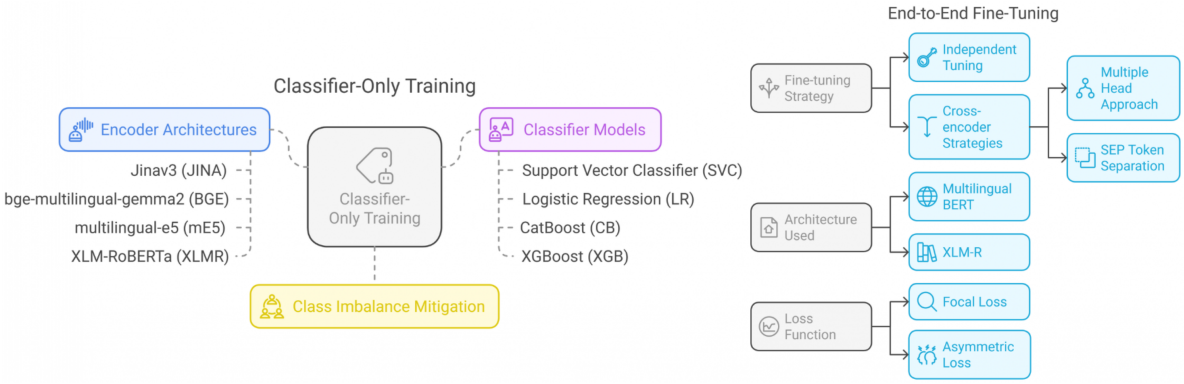

Figure 1: Our system overview

and a specific emotion. This configuration is referred to as SEP.

Architecture Used. In this experiment, we employ multilingual BERT (mBERT) and XLMR as the underlying architectures for fine-tuning. These models serve as the backbone for our emotion classification framework, leveraging their multilingual pretraining to enhance contextual understanding across diverse languages.

Loss Function. Due to the imbalance of the data set, we employ Focal Loss and Asymmetric Loss:

1. **Focal Loss (FL).** Focal Loss is designed to focus on difficult examples by down-weighting well-classified ones (Lin et al., 2017). The formula is:

$$FL(p_t) = -\alpha(1-p_t)^{\gamma}\log p_t \tag{3}$$

where p_t is the predicted probability for the correct class, and α and γ are parameters controlling class imbalance and focusing strength. Here, we set α based on the class weight (as in Formula 1), and $\gamma = 2$.

2. **Asymmetric Loss (AL).** Asymmetric Loss by applying different focusing strengths for positive and negative samples (Ridnik et al., 2021). The formula is:

$$\begin{cases} L^{+} = (1-p)^{\gamma^{+}}\log(p) \\ L^{-} = p^{\gamma^{-}}\log(1-p) \end{cases} \tag{4}$$

where γ^{+} and γ^{-} control the focusing for positive and negative examples, respectively. For this task, we set $\gamma^{+} = 0$ and $\gamma^{-} = 4$ as per the original paper. Additionally, to account for shifted probabilities, we use a margin m such that the probability p_m is:

$$p_m = \max(p - m, 0) \tag{5}$$

where $m = 0.05$. The negative loss term is then adjusted as:

$$L^{-} = (p_m)^{\gamma^{-}}\log(1-p_m) \tag{6}$$

4 Experiment Setting

Language & Data Splits. We utilize both multilingual and monolingual settings. In the multilingual setting, all available languages are incorporated during training All, while in the monolingual setting, only the target language is used LANG. We split the data into training and validation sets in an 80:20 ratio using iterative stratification (Tarekegn et al., 2021) to ensure an equal distribution of labels.

Computational Power Used. We use different machines for different experiments. Lightweight experiments, such as running tree-based models, are conducted using Kaggle's free GPU, while heavier tasks, such as inferencing with BGE, mE5, JINA, are performed on an RTX 4090 rented from the Vast.ai platform.

Hyperparameter Settings. In both approaches, no additional hyperparameter tuning is performed, ensuring that all models share a consistent set of parameters across experiments. The details are provided in Appendix Table 3.

Encoder Settings. XLMR is direct use require no additional settings. JINA required to set task and prompt_name parameter which both are set to 'classification'. mE5 and BGE require prompt which we adapt from the original papers. Specifically, mE5 and BGE (V1), we used general prompts asking to detect multiple emotions at once. Based on ablation studies, we hypothesized that specifying a single emotion per prompt could improve performance.

This led to BGE (V2), where each query focuses on one emotion. Results suggest that targeted instructions better guide the model's representation. Prompt can be seen in Appendix section.

5 Result

5.1 Development

In this section, we analyze the average F1 Macro scores across all languages to guide our model selection and evaluation based on our results on the development set. Evaluation table for classifier-only and others are on the Appendix section.

Quantitative Evaluation using Hypothesis Testing. We employ non-parametric tests to assess whether significant differences exist between model configurations. For paired scenarios, such as FL vs. AL and ALL vs. LANG, we use the Wilcoxon signed-rank test, while for unpaired scenarios, we apply the Mann-Whitney U test (Mann and Whitney, 1947; Wilcoxon, 1992). In paired comparisons, we ensure that only the relevant factor varies while keeping the architecture consistent.

FL vs AL. The Wilcoxon signed-rank test yielded no significant difference ($W = 4, p = 0.875$), suggesting that both loss functions perform similarly in addressing class imbalance within multi-label emotion detection. Despite their theoretical differences, our results show that neither approach provides a clear advantage. This finding underscores the importance of considering other factors, such as model architecture, in performance optimization.

ALL language vs LANG. The Wilcoxon signed-rank test showed no significant difference ($W = 48, p = 0.06$) between training on all languages (ALL) and training on a specific language (LANG). This suggests that multilingual training does not necessarily improve performance compared to language-specific models for this task. Moreover, training on LANG is computationally more efficient, as it operates on a smaller, more targeted dataset, making it a practical choice in resource-constrained settings. Additionally, the results suggest that the model's ability to leverage cross-language associations, a key advantage of multilingual architectures, does not play a significant role in this task.

LLM Prompt Based Encoder with Classifier Outperform Fully Finetuned Transformer. The Mann–Whitney U test indicates a significant difference ($U = 456, p < 0.001$), with prompt-based encoder models (BGE and mE5) outperforming all others. Their average F1 Macro scores, 47.3% for BGE and 37.7% for fully fine-tuned models, reveal a clear gap. This stems from BGE and mE5's demonstrated superiority on the MMTEB (Enevoldsen et al., 2025) multilingual embedding benchmark, which attests to their stronger multilingual representations; fine-tuning on low-resource task data cannot match this pre-validated embedding quality.

BGE as the Overall Best Result. The statistical test yielded a significant result ($W = 205, p = 0.009$), confirming that BGE-based models significantly outperform non-BGE models, particularly XLMR and mBERT, despite requiring less computational power. These findings reinforce the effectiveness of BGE's architecture in capturing emotion-related semantics, making it a strong candidate for future research in multilingual emotion classification.

Different prompt lead to different results. We observe that modifying the prompt from general to slightly more specific consistently improves performance. Although this experiment was conducted only on CB models with two samples, the observed differences are notable, with F1 Macro scores increasing from 5.3% to 5.5% and from 54.0% to 55.0%. These results suggest that refining prompts can enhance model effectiveness.

5.2 Submission

For this shared task, we have two types of submissions:

- **Model V1**: The highest score model, BGEV2-CB-ALL.
- **Model V2**: An ensemble of four models: BGEV2-CB-ALL, BGE-CB-LANG, BGE-CB-LANG, BGE-CB-ALL.

Table 1: Test set comparison of our models with the Qwen2.5-72B decoder model, which has the highest average F1 Macro score in the BRIGHTER paper (Muhammad et al., 2025a).

$$v_i = \begin{cases} 1, & \text{if } y_i = 1 \\ -1, & \text{if } y_i = 0 \end{cases} \tag{7}$$

The final predicted label is then given by:

$$\hat{y} = \begin{cases} 1, & \text{if } s > 0 \\ 0, & \text{otherwise} \end{cases} \tag{8}$$

We use weighted voting for ensemble predictions, assigning weights based on development set performance and handling zero weights, with the final prediction determined as follows.

$$s = \sum_{i=1}^{N} w_i \cdot v_i \tag{9}$$

where s is the aggregated weighted score, N is the number of models, w_i is the weight of the i-th model based on its development set score, and v_i is the adjusted prediction:

This ensures that zero predictions contribute negatively instead of being ignored, and the final decision is based on the sign of the weighted sum.

Based on Table 13, Model V2, an ensemble, outperforms Model V1 in 25 out of 28 languages. Using the Wilcoxon signed-rank test, we obtain $W = 285.0$ and $p < 0.001$, indicating a statistically significant improvement over Qwen2.5-72B (Muhammad et al., 2025a).

6 Limitations

The limitation of our study is the lack of extensive qualitative analysis due to limited language proficiency. Since we do not fully understand many of the languages in the dataset, our analysis primarily relies on quantitative methods.

7 Conclusion

Our study demonstrates that classifier-based approaches with prompt-based encoders, particularly BGE and multilingual-E5 (mE5), outperform fully fine-tuned transformer models for multilingual multi-label emotion classification. Our best-performing model, BGE with CatBoost and emotion-specific prompting, achieved the highest average F1-Macro scores across languages in our experiment. Additionally, an ensemble of multiple BGE-based models further improved performance, significantly surpassing the best decoder-based model from prior work. These results highlight the strength of high-quality embeddings combined with tree-based classifiers for emotion detection tasks.

Our findings also show that multilingual training does not provide a clear advantage over monolingual models. Furthermore, minor prompt modifications led to measurable gains, emphasizing the importance of prompt engineering. Overall, our study suggests that leveraging strong embedding models with efficient classifiers is a more effective strategy than full transformer fine-tuning for multi-label emotion classification across diverse languages.
