8 Appendix

Model Name	Prompt

mE5	`Instruct: Classify the emotions expressed in the given text snippet by identifying whether each of the following emotions is present: joy, sadness, anger, surprise, and disgust.`
	
	`Query: {{INPUT}}`

BGEV1	`<instruct> Represent this text for identifying the presence of emotions: joy, sadness, anger, surprise, and disgust`
	
	`<query> {{INPUT}}`

BGEV2	`<instruct> Represent this text for identifying the presence of the emotion {{EMOTION}}`
	
	`<query> {{INPUT}}`

Table 2: Prompt formulations used for mE5 and BGE models

Model	Hyperparameter
mBERT, XLMR	Learning Rate: 3×10^{-5}
	Training Batch Size: 32
	Evaluation Batch Size: 8
	Seed: 42
	LR Scheduler Type: Linear
	LR Scheduler Warmup Steps: $0.1\times$ total train steps
	Number of Epochs: 4

Table 3: Hyperparameter settings for mBERT and XLM-R models.

Abstract

This paper presents our Multi-LLM Agentic System that helps solve the problem of tabular question answering as posed in the SemEval Task- 8:Question Answering over Tabular Data. Our system incorporates a Agentic Workflow where we assign each agent a role along with the context from other agent to better help resolve the ambiguity. As the user poses their question along with the dataframe, we firstly try to infer the types of the columns from the dataframe and also the expected answer type given the question and the column types, then the planner agent gives out a plan that tells us about the steps that we have to take to get the answer, each step is written such that it helps us write one line of python code. Then we call the cod- ing agent which attempts to write the code given the information from the previous agents. Then we do a debugging pass through a debugging agent which tries to resolve the issue given the previous context and finally deliver the answer if the code runs error free. Our system achieved 14th place on the overall open source models track.

1 Introduction

Question Answering (QA) over tabular data is a Natural Language Processing (NLP) task that involves extracting aanswers from structured tabular formats. This task is crucial as many financial reports, scientific data, and government records, exist in tabular form. Automating QA over tables enhances information retrieval and decision-making processes. The task covered in this work involves evaluating the performance of language models on tabular QA on *Databench (full tables)* benchmark, following the benchmark and methodologies outlined in the task overview paper (Grijalba et al., 2024).

The problem involves addressing challenges like diverse query intents, table structures, and complex answer types (Boolean, categorical, numerical, and lists). Key sub-problems include query intent disambiguation, efficient data retrieval, and reasoning over large tables and multi-turn interactions. The broader impact of this research lies in its potential to scale across diverse data sources. Our system utilizes *OpenAI's API*, accessed via *Python*, to interact with **Deepseek's R1** open-source model.

Through this competition, we gained valuable insights into the strengths and limitations of traditional Transformer-based models in *question answering over tabular data*. We ranked **fourteenth** among all submissions, highlighting both our achievements and areas for improvement. We explored various reasoning-based approaches and found that breaking the problem into smaller, more manageable subtasks significantly enhanced performance. By assigning each subtask—such as interpreting the question, extracting relevant information, searching and querying with code, and debugging errors—to specialized models, we distributed the workload effectively and provided each model with a focused area of operation. This multi-agent approach not only streamlined the process but also improved precision by reducing the cognitive burden on any single model. We observed that the model struggles with semantic meaning of some tricky questions, which requires additional reasoning before execution which suggests potential areas for improvement.

The implementation is publicly available at ***this Github repository***.

2 Background

2.1 Problem Definition

Tabular question answering (QA) involves generating accurate answers to natural language queries based on structured tabular data. Formally, given a table T and a natural language question Q, the goal is to produce an answer A:

$$(T, Q) \rightarrow A$$

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2165–2169

Example: Consider table T:

Name	Age
Alice	30
Bob	25

Given question Q: "What is Alice's age?", the expected answer A is "30".

2.1.1 Terminology and Definitions

- **Table** (T): A structured tabular dataset where each column C_i has a specific data type (e.g., numerical, categorical).
- **Question** (Q): A natural language query for extracting information from table T.
- **Answer** (A): The response derived from table T that satisfies question Q.

2.1.2 Our Approach

We propose a multi-agent, self-correcting framework for Question Answering over Tabular Data, addressing the limitations of direct table encoding seen in models such as TAPAS (Herzig et al., 2020), TaBERT (Yin et al., 2020), and StruBERT (Trabelsi et al., 2022). Our approach leverages modern Large Language Models (LLMs) (Fang et al., 2024) to iteratively refine understanding, code generation, and debugging.

Our methodology uses the *Deepseek's* latest **Deepseek R1** model in a multi-agent setting. We use *OpenAI*'s API to call the model at various substeps of the Query task, mainly plan generation, relevant column extraction, query code generation, and debugging. First, we extract dataframe metadata, including column names, types, statistical metrics, and expected answer types. This, along with the question and dataframe, is sent to the *Planner Agent*, which formulates a solution strategy. The plan is passed to the *Relevant Column Agent*, which identifies essential columns and refines the context for the *Coder Agent*. The *Coder Agent* then generates and executes Python query code, verifying success based on error-free execution and correct answer type.

If execution fails due to errors or incorrect output, the *Debugger Agent* modifies the code and retries execution. This process is repeated up to three times to enhance accuracy. If all attempts fail, the system outputs *NULL*. This structured approach balances efficiency and reliability in query resolution.

2.2 Related Works

The survey by Fang et al. (Fang et al., 2024) provides an in-depth review of tabular question answering (QA) using large language models (LLMs). This work not only summarizes existing methodologies but also categorizes the research into several key areas that address the multifaceted challenges of working with tabular data. It explains how different approaches tackle issues such as clarifying ambiguous user intents, retrieving relevant segments from tables, managing sequential interactions, and enabling autonomous query answering.

Specifically, the survey examines **Query Intent Disambiguation** techniques, which focus on clarifying the user's query (Zha et al., 2023; Deng et al., 2022). It further reviews **Search & Retrieval** methods aimed at extracting the most pertinent portions of a table (Zhao et al., 2024; Sundar and Heck, 2023) and discusses strategies for handling **Multi-Turn Settings** in sequential interactions (Sui et al., 2024; Ye et al., 2023; Liu et al., 2023). In addition, the survey explores **Autonomous Tabular Question Answering** through multi-agent approaches (Zhu et al., 2024; Ye et al., 2024, 2023) and highlights the role of **Few-shot and Zero-shot Learning** in efficiently adapting models with minimal labeled data (Ye et al., 2024). These distinct research directions collectively underscore the evolving landscape of tabular QA using LLMs.

2.3 Corpus/Data Description

This project utilizes *DataBench*, a benchmark dataset designed for evaluating question answering over tabular data in structured CSV-style files.

Dataset Overview: DataBench comprises 65 publicly available tabular datasets across five domains: Health, Business, Social Networks and Surveys, Sports and Entertainment, and Travel and Locations. The dataset includes a total of 3,269,975 rows and 1,615 columns.

- **Domain Taxonomy:** Table 1 shows a breakdown of DataBench by domain, including the number of datasets, rows, and columns.
- **Column Types:** Table 2 illustrates the range of column data types found in DataBench, from simple numeric fields to more complex list structures.

2.4 Questions and Answers Generation

DataBench includes 1,300 hand-crafted question-answer pairs (20 per dataset) spanning five types:

Table 1: DataBench Domain Taxonomy

Domain	Datasets	Rows	Columns
Business	26	1,156,538	534
Health	7	98,032	123
Social	16	1,189,476	508
Sports	6	398,778	177
Travel	10	427,151	273
Total	**65**	**3,269,975**	**1615**

Table 2: Column Types in DataBench

Type	Columns	Example
Number	788	55
Category	548	Apple
Date	50	1970-01-01
Text	46	A red fox ran...
URL	31	`google.com`
Boolean	18	True
List[Number]	14	[1, 2, 3]
List[Category]	112	[sam, dee, lia]
List[URL]	8	[`ggu.uk`, `abc.in`]

Boolean, **Category**, **Number**, **List[Category]**, and **List[Number]**.
Examples:

- *Question*: "What's the oldest passenger's class?" *Answer*: First
- *Question*: "Who are the passengers under 30?" *Answer*: [Lil Lama, Cody Lama]

3 System Overview

We explored various approaches to Question Answering over Tabular Data, including transformer-based models and LLM-based coding paradigms. While models such as TAPAS (Herzig et al., 2020), TaBERT (Yin et al., 2020), and StruBERT (Trabelsi et al., 2022) showed promise, their direct encoding of table context was insufficient for our analytical needs.

To overcome these limitations, we developed a multi-agent, self-correcting framework using modern LLMs (viz. DeepSeek-V3, DeepSeek-R1):

- **Understand the table and Plan**: We firstly extract some relevant information about the dataframe by writing functions that help infer the column types and also have an LLM call that determines the datatypes given the dataframe head and the query. This provides the LLM with a better understanding of both the data and the query via in-context learning. Then, we call the Planner Agent to devise an easy step-by-step plan that guides the coding agent to better interpret the query and dataframe for code generation.
- **Plan then Code**: Once the plan is obtained, another LLM call identifies the relevant columns required for answering the question, thereby clarifying the objective for the Coder Agent via in-context learning.
- **Output Analysis and Code Correction**: After receiving the code output from the Coder Agent, we execute the code and debug it using a Debugging Cycle involving the Debugging Agent. This cycle runs for a maximum of three attempts to optimize execution time. Figure 1 illustrates the workflow of our multi-agent code and output-based approach.

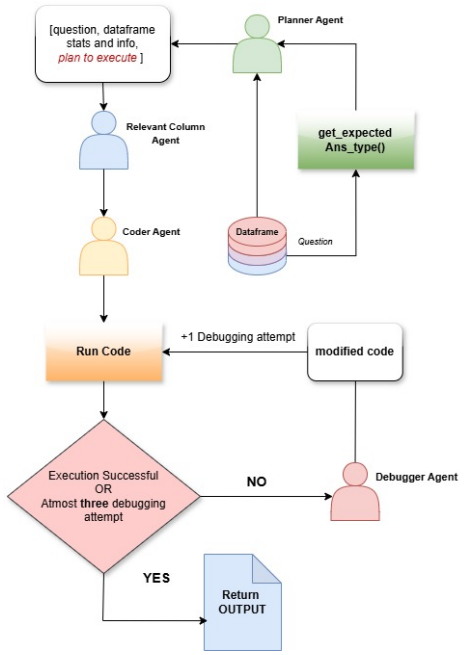

Figure 1: Workflow of the Multi-Turn Code and Output-Based Approach. The first agent generates code based on a plan, while the second agent evaluates and iteratively corrects the output.

Structured Outputs: We establish a defined structure for communication between the LLMs when certainty is required. For example, for inferring column types, determining the answer type, and generating code for extraction and execution, we employ intermediate LLM passes that produce outputs in a JSON structure.

4 Experimental Setup and Results

In our experiments, we evaluated our multi-agent, self-correcting framework for question answering over tabular data on the full DataBench dataset. The evaluation metric used was **accuracy**—the percentage of correctly answered queries based on the official evaluation script. All experiments were performed exclusively on the full dataset, in line with our design decisions, and the reported results are those obtained on the test set.

4.1 Baselines and Compared Systems

We compare our system against:

1. **Baseline Model:** The relevant baseline presented in the task paper (Grijalba et al., 2024) achieves an accuracy of 26% on the test set.
2. **Top Performer:** As reported in the official task ranking the best-performing system attained an accuracy of 95.02% on the full dataset.
3. **Our System:** Our multi-agent system, which leverages a sequence of specialized agents for planning, code generation, and debugging, achieves an accuracy of 79.69%. Despite this notable improvement over the baseline, our submission was ranked 14th in the overall task.

Table 3 summarizes the performance of these three systems.

Method	Accuracy (%)	Rank
Baseline (Task Paper)	26.00	33rd
Top Performer (Team TeleAI)	95.02	1st
Ours	79.69	14th

Table 3: Performance on the Full DataBench Dataset in the Open Source Models Track

4.2 Evaluation Metrics

We assess performance using:

- **Accuracy**: Percentage of correctly answered questions.
- **Leaderboard Ranking**: Our multi-turn framework is ranked on the SemEval leaderboard.

5 Results

The experimental results highlight several key points:

- **Improved Accuracy:** Our system outperforms the baseline by a substantial margin, demonstrating the benefits of decomposing the problem into distinct subtasks handled by specialized agents.
- **Iterative Refinement:** The multi-agent framework—with dedicated agents for planning, relevant column identification, code generation, and debugging—plays a crucial role in handling complex queries over tabular data. The iterative debugging cycle ensures that errors in code generation are corrected promptly, leading to a higher likelihood of accurate outputs.
- **Ranking Implications:** Although our system achieves a high accuracy of 79.69%, the overall task ranking (14th) indicates that there remains significant room for improvement. Future works in this direction related to question ambiguity removal and iterative refinement through better understanding the semantics of the table in relation to the query will help improve the results.

These findings not only validate the effectiveness of our multi-agent approach on the full dataset but also provide a roadmap for future enhancements in tabular question answering systems.

6 Conclusion

The proposed 2-LLM agent framework combines intent-driven code generation with output-based refinement. Our Multi-Agent Code and Output-Based Approach outperforms baseline methods and transformer-based models in handling complex queries. Ranked third on the SemEval leaderboard, our framework sets a strong foundation for further work on prompt engineering, improved retrieval mechanisms, and domain-specific extensions.

Acknowledgments

We conducted this research at the Exploration Lab, IIT Kanpur, and the Department of Computer Science and Engineering at IIT Kanpur. We extend our heartfelt gratitude to all members for their invaluable support and guidance. We also thank the organizers and all contributors to the DataBench dataset for their contributions to the research community.

Abstract

In this paper, we propose an approach to detecting hallucinations based on a Named Entity Recognition (NER) task. We train a model to identify spans of text likely to contain hallucinations, treating them as a form of named entity. We focus on efficiency, aiming to develop a model that can detect hallucinations without relying on external data sources or expensive computations that involve state-of-the-art large language models with upwards of tens of billions of parameters. We utilize the SQuAD question answering dataset to generate a synthetic version that contains both correct and hallucinated responses and train encoder language models of a moderate size (`RoBERTa` and `FLAN-T5`) to predict spans of text that are highly likely to contain a hallucination. We test our models on a separate dataset of expert-annotated question-answer pairs and find that our approach achieves a Jaccard similarity of up to 0.358 and 0.227 Spearman correlation, which suggests that our models can serve as moderately accurate hallucination detectors, ideally as part of a detection pipeline involving human supervision. We also observe that larger models seem to develop an emergent ability to leverage their background knowledge to make more informed decisions, while smaller models seem to take shortcuts that can lead to a higher number of false positives. We make our data and code publicly accessible, along with an online visualizer. We also release our trained models under an open license.

1 Introduction

Hallucinations in language models (LMs) are a well-known issue that has been studied in the context of text generation tasks (Ye et al., 2023; Huang et al., 2024; Zhang et al., 2023; Rawte et al., 2023), with some authors affirming they are inevitable (Xu et al., 2024; Banerjee et al., 2024). However, despite the open discussion on their avoidability, a community of authors have worked on methods to detect, prevent, or mitigate them (Tonmoy et al., 2024; Mündler et al., 2023; Harrington et al., 2024; Dhuliawala et al., 2023; Manakul et al., 2023, inter alia). Our work contributes to this effort by addressing hallucination detection in instruction-tuned LMs, a shared task proposed in the SemEval 2025 Task 3, Mu-SHROOM (Vázquez et al., 2025). We approach the chanllenge by framing hallucination detection as a Named Entity Recognition (NER) task, leveraging NER's ability to identify specific spans of text.

NER extracts structured information, such as names, dates, or locations, from unstructured text (Nadeau and Sekine, 2007). Traditionally, it has been applied to sequence labeling tasks using rule-based systems or machine learning models trained on annotated datasets (Yang et al., 2024). However, its versatility has led to applications beyond information extraction, including social media analysis, knowledge graph construction, reinforcement learning for entity augmentation, and more (Sufi et al., 2022; Bunescu and Paşca, 2006; Wan et al., 2020; Keraghel et al., 2024). In our approach, we adapt NER to detect hallucinated spans by treating them as a specialized type of named entity, allowing us to efficiently identify incorrect or fabricated text segments without relying on external data sources or computationally expensive large-scale LMs.

The rest of this article is organized as follows: in Section 2, we provide background information on the task setup; in Section 3, we describe our system's approach; in Section 4, we detail our experimental setup and present qualitative evaluations; in Section 5, we report on the quantitative results of our models and discuss their performance; and in Section 6, we conclude our work and suggest future directions. We also address ethical considerations in Section 7 and discuss the limitations of our approach in Section 8. We make our code, dataset and models publicly available at `https://github.com/ACMCMC/hallucinations-ner`.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2170–2176

2 Background

The shared task that our work is based on, MuSHROOM, involves detecting spans of text that correspond to hallucinations in the outputs of LMs, with the goal of predicting where hallucinations occur in a given text.

For example, given the following example from the validation dataset of the task:

> **Question.** What is the population of the Spanish region of Galicia?
>
> **Tagged answer.** As of 2021, the estimated population in the region is around 1.5 million people.[a]
>
> [a]The opacity of the underlines represents the probability of the character being a hallucination.

The task consists of predicting the spans of text that are more associated with hallucinations, which in this case would be "2021" and "1.5 million".

The authors of the task provide a dataset of expert-annotated question-answer pairs in 14 languages, but we choose to focus on English due to the complexity of generating a synthetic dataset of faithful and hallucinated responses, which we use to train our models (see Section 3).

Our approach is thus based on training a model to predict spans of text that are likely to contain hallucinations, which we model as a Named Entity Recognition (NER) task, under the assumption that hallucinations can be seen as a form of named entity that can be detected by a model trained to recognize them. This assumption may not cover all types of hallucinations, as we discuss in Section 8, but serves as a starting point that can be later expanded upon.

We implement our NER strategy using an IOB (Ramshaw and Marcus, 1995) tagging scheme, which is a common approach in NER tasks that assigns each token in a sequence a label indicating whether it is inside (I), outside (O), or at the beginning (B) of a named entity. In our case, however, instead of named entities, we turn the task into predicting if we are outside or inside a hallucination. Also, while IOB assigns an I label to single-token entities, we slightly alter this approach by assigning a B label to the first token of all entities, including single-token entities, and an I label to all subsequent tokens, often referred to as IOB2 (Sang and Veenstra, 1999).

It is important to note that NER is not limited to IOB tagging; it can be performed using other approaches that may leverage graphs (Muis and Lu, 2017; Wang et al., 2021), neural networks (Sohrab and Miwa, 2018; Wang and Lu, 2019), constituency discriminators (Finkel and Manning, 2009), or translation to an augmented natural language form that can be easily extracted (Paolini et al., 2021), among others. Likewise, the IOB tagging scheme is not exclusive to NER tasks, as it can be applied to any sequence labeling task.

3 System overview

Our goal is to train an encoder model to predict spans of text that are likely to contain hallucinations, so we choose to model the task as a NER problem. We do not employ any of the common NER-specific labels, such as dates or verbs, but rather focus on the general applicability of the IOB tagging scheme to our task.

We first need to have a collection of correct and hallucinated responses to train our model, for which we use the SQuAD dataset (Rajpurkar et al., 2016). SQuAD is primarily intended for question answering based on a given context, but we repurpose it by discarding the context and using exclusively the question and suggested answers to build a synthetic dataset of correct and hallucinated responses.

The first model is tasked with the transformation of the SQuAD answers, which are an extracted span of text from the context, into a full sentence that a human could understand. Then, we use the second model to generate variations of that correct response in a way that it becomes a hallucination.

We assemble a synthetic dataset of question-answer pairs, where the answers are either correct or hallucinated, and we use this dataset to train our models. Figure 1 shows our approach.

4 Experimental Setup

For our training process, we abstain from using the training set provided by the shared task authors, exclusively training on our synthetic dataset, which we split on a 80/10/10 ratio for training, validation, and testing, respectively. We use the validation set to decide when to stop training. We only use the test set to evaluate our models internally; the results shown in Section 5 are based on the test set provided by the shared task authors.

We choose a smaller model, `SmolLM2-360M-Instruct` (Allal et al., 2025)

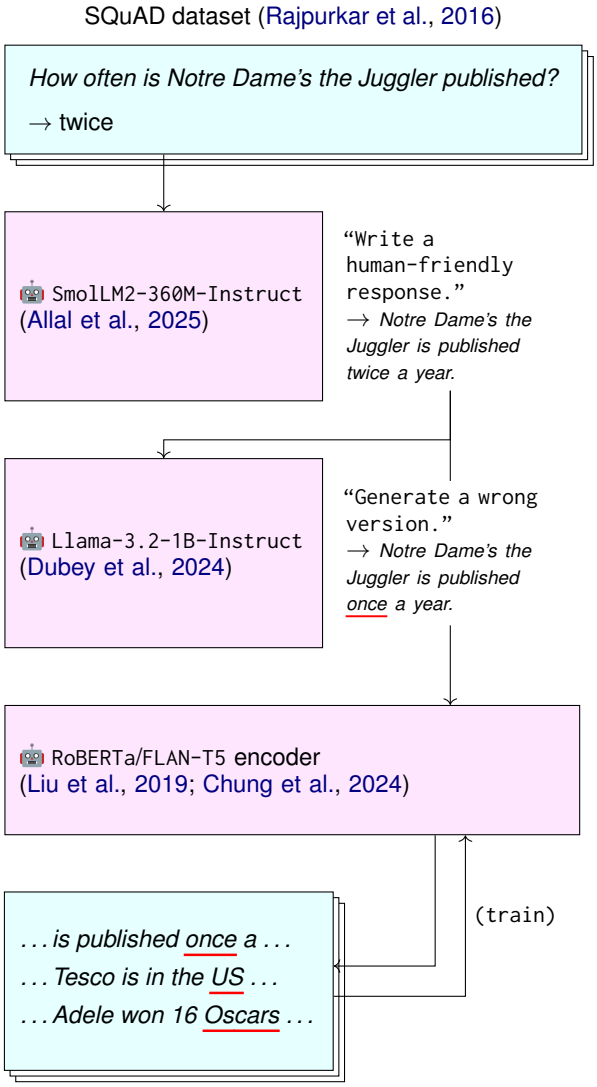

Figure 1: **Our approach.** We employ two instruction-tuned language models to generate synthetic question-answer pairs from the SQuAD dataset, including correct responses and hallucinated variants. These are used to train an encoder model, utilizing a Named Entity Recognition framework, to identify and tag spans of text likely to contain hallucinations.

to generate the correct answers since we anticipate that this is a simpler task — however, when it comes to generating hallucinated responses, we want a larger model to generate more diverse and creative hallucinations, so we select `Llama-3.2-1B-Instruct` (Dubey et al., 2024).

Since we wish for the hallucinated responses to be significantly different both from the correct response and among themselves, so we select a generation configuration to encourage this. Specifically, we set the number of beams and beam groups to 3, the diversity penalty to 0.5, the repetition penalty to 1.2, and the temperature to 1.3; all to force diversity in the generated hallucinations.

We take the generated result of the three beams from the hallucination model and add those as hallucinated responses to our dataset. To ensure we have a balance of correct and hallucinated responses, we include the same number of correct and hallucinated responses in our synthetic generation process by upsampling the correct responses to match the number of hallucinated responses.

For our choice of encoders, we selected models of the `BERT` and `T5` families, `RoBERTa-Base` and `RoBERTa-Large` (Liu et al., 2019) and `FLAN-T5-XL` (Chung et al., 2024), respectively. We opted for the `FLAN` variant of `T5` as we hypothesize that its more extensive training on a diverse set of tasks may help it generalize better to our task.

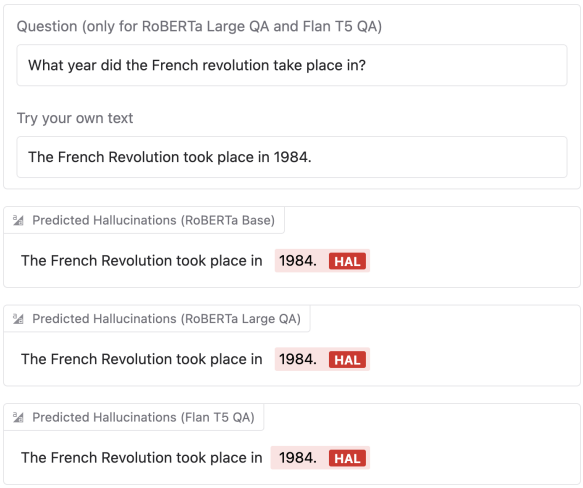
It is important to highlight that we only run the hallucination generation step once, which we acknowledge may lead to a decrease in the representativeness of our synthetic dataset. The test dataset, in fact, can contain more than one hallucination per question-answer pair. This could be addressed by running the hallucination generation step more than once, which we leave for future work.

We only generate hard labels for evaluation (0.0 or 1.0) and do not use the probabilities assigned by the models to each token, which could be a potential improvement to our approach.

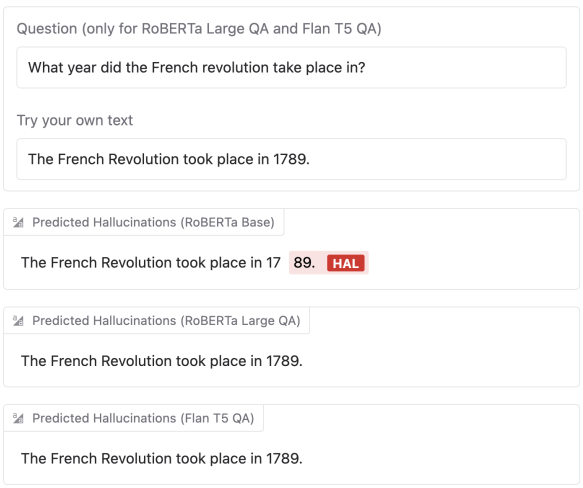
4.1 Qualitative evaluation

We conducted both quantitative (Section 5) and qualitative evaluations, which we describe next.

We developed a visualizer that allows to explore the test split of our synthetic dataset and the predictions we make for each data point, as well as writing any text to explore the predictions of our models. We utilized this tool to qualitatively interpret whether and how our models learned to identify hallucinations. We also make it publicly



(a) **Hallucination.** All models correctly tag "1984".



(b) **Correct answer.** The smaller model, `RoBERTa-Base`, incorrectly tags "89" (part of the year entity) as a hallucination. The two larger models are correct in not finding any.

Figure 2: **Emergent abilities.** Qualitative analysis seems to indicate that larger models go beyond tagging spans of text likely to contain hallucinations, a shortcut that the smaller model seems to take. These models may be learning to extract their background pretrained knowledge to make more informed decisions.

available at https://huggingface.co/spaces/shroom-semeval25/cogumelo-visualizer.

We observe that our models do not exclusively tag spans of text that present a higher possibility of having been hallucinated, such as figures and names of named entities. For instance, when given the question "What year did the French Revolution take place in?", the answer "The French Revolution took place in 1984" gets the correct hallucination tag "1984", while a correct answer (1789) is not tagged in the case of larger models (Figure 2).

This points to the intuition that smaller and larger models are learning in different ways. It appears that the smaller model learns to identify what spans of text usually contain hallucinations (*e.g.*, 1984 or 1789), which is a shortcut that serves to identify some hallucinations — but can also lead to a higher number of false positives. On the other hand, the larger models seem to avoid running into this shortcut and instead seem to be learning to leverage the knowledge that they acquired during their pretraining to identify when a specific figure or claim contradicts such background knowledge. Nevertheless, this observation cannot be generalized, and further investigation is needed to understand the underlying mechanisms that allow our models to make these decisions.

Architecture	**IoU**	**Sp. Corr.**
Neural baseline	0.031	0.119
`RoBERTa-Base`	0.191	0.129
`RoBERTa-Large` (QA)	0.219	0.153
`FLAN-T5-XL` (QA)	0.358	0.227

Table 1: **Scores** obtained on the Mu-SHROOM English test set for the three architectures considered. QA indicates that the model was trained with the question prepended to the answer. The neural baseline is based on `XLM-R` (Conneau et al., 2020).

5 Results

Table 1 shows the scores for our three models, along with a baseline based on `XLM-R` (Conneau et al., 2020). We report on the two metrics official to the Mu-SHROOM shared task: the Intersection over Union (IoU) of characters marked as hallucinations in the gold reference vs. predicted as such, and the Spearman correlation (Sp. Corr.) of the probability assigned by the system that a character is part of a hallucination with the empirical probabilities observed in the annotations.

The results show that larger model sizes seem to correlate with better performance. Model architecture also seems to play a role, with the `FLAN-T5-XL` model outperforming the `RoBERTa` models in both metrics.

In general, while above a baseline model, our results tend to be lower than some other participants in the shared task, which we attribute to the fact that the models we utilize may not have enough capacity to learn the task effectively; the synthetic data we generate, which is not fully aligned with the hallucinations found in the evaluation dataset; and the fact that other techniques such as RAG (Lewis et al., 2020) can retrieve ground truths that greatly improve the performance of the models, since the types of questions asked in the evaluation dataset are at times very specific and we do not expect that such niche knowledge is present in the background knowledge of our models.

It should also be noted that the Spearman correlation is generally lower than the IoU, which is very dependent on the threshold used to determine if a character is part of a hallucination or not. As seen in Figure 2b, the models may sometimes tag just subparts of a hallucination, which we expect will particularly lower the Spearman correlation. Additionally, since we make our models generate hard labels exclusively, we expect that the Spearman correlation would also be lower than if we had used soft labels.

6 Conclusion

In this article, we present an approach to detecting hallucinations in the output of language models based on a named entity recognition task. We train moderate-size encoding models on a synthetic dataset generated from the SQuAD question-answering dataset, which we use to predict text segments that are likely to contain hallucinations.

Our models achieve a Jaccard similarity of up to 0.358 and a Spearman correlation of up to 0.227, suggesting that our models can serve as moderately accurate hallucination detectors, although our scores are lower than some other participants in the shared task. We also observe an interesting pattern in the behavior of our models, where larger models seem to develop an emergent ability to use their background knowledge to make more informed decisions, while smaller models seem to take shortcuts that can lead to a higher number of false positives. We publicly release a synthetic dataset, open-source code and models, along with an interactive visualizer to facilitate further research. Future work could explore enhancing this NER-based approach by incorporating diverse hallucination types and multilingual data to improve detection accuracy.

7 Ethical considerations

Our work aims to contribute to the development of better systems to detect hallucinations, which has important implications for the development of more reliable and trustworthy language models. However, we acknowledge that our models are not perfect and that they may make mistakes. We hope that our approach can be used as part of a pipeline involving human supervision to ensure that the decisions made by the models are correct and that the models do not make decisions which could have negative consequences.

8 Limitations

English-centricness. Our models were trained on English data only, which may limit their performance on other languages. Further work is needed to investigate how our models generalize to other languages, and to develop localized versions of our synthetic datasets to train models that can detect hallucinations in other languages.

Alternative architectures. We only considered models from the `RoBERTa` and `T5` families, but it is up for debate whether other encoder architectures may be more suitable for the task. Further experimentation should be conducted to determine the best architecture for the task, which may involve architectures of different families and sizes, not necessarily transformer-based.

Hallucination types. In our approach, we primarily generate *factual* hallucinations, but the evaluation datasets may contain other types of hallucinations, such as logical, context or instruction inconsistencies (Huang et al., 2023). For instance, in the evaluation dataset, we may find question-answer pairs like "What is the capital of France?" with the answer "France is a country in Europe.", which is an instruction inconsistency. We expect this to limit the generalization capabilities of our models, since they have been trained on a narrower set of hallucinations than those found in the evaluation datasets.

Knowledge cutoff date. Our synthetic dataset is derived from the SQuAD dataset, which dates back to 2016 (Rajpurkar et al., 2016) and may not be representative of the current state of knowledge. This may deteriorate the performance of our models.

CDHF at SemEval-2025 Task 9: A Multi-Task Learning Approach for Food Hazard Classification

Chu Duong Huy Phuoc
University of Information Technology
Vietnam National University - Ho Chi Minh City, Vietnam
23521229@gm.uit.edu.vn

Abstract

We present our system in SemEval-2025 Task 9: Food Hazard Detection. Our approach focuses on multi-label classification of food recall titles into predefined hazard and product categories. We fine-tune pre-trained transformer models, comparing BERT and BART. Our results show that BART significantly outperforms BERT, achieving an F1-score of 0.8033 during development. However, in the final evaluation phase, our system obtained an F1-score of 0.7676, ranking 14th in Subtask 1. While our performance is not among the top, our findings highlight the importance of model choice in food hazard classification. Future work can explore additional improvements, such as ensemble methods and domain adaptation.

1 Introduction

SemEval 2025 Task 9: The Food Hazard Detection Challenge (Randl et al., 2025) focuses on classifying food incident reports to identify hazards and affected products. The task includes two sub-tasks: (ST1) food hazard prediction and (ST2) hazard and product vector detection.

We present a multi-task learning approach using the facebook/bart-large-mnli (Lewis et al., 2020) model to predict hazard and product categories. Our system fine-tunes a transformer-based model with a custom neural network featuring two classification heads for multi-label prediction. Experimental results highlight the effectiveness of this approach in food hazard detection. [1]

2 Task and Background

The Food Hazard Detection task focuses on developing explainable classification models to analyze the titles of food-incident reports collected from web sources. These models aim to assist automated systems, such as web crawlers, in identifying and extracting food safety issues from online platforms, including social media. Given the potential economic and public health impact of food hazards, ensuring transparency in these classification systems is essential.

2.1 Task Description

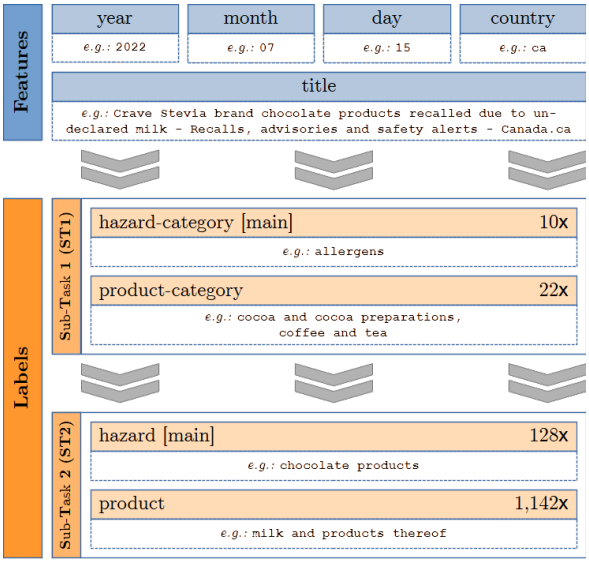

Figure 1: The blue boxes are model inputs; the orange boxes are ground truth labels per sub-task. The number on the right indicates unique values per label.

SemEval-2025 task 9: The Food Hazard Detection with two main subtask: **Subtask 1: category classification:** In this subtask, the goal is to classify a food-incident report into predefined categories. Specifically, models must predict both the product category (e.g., "meat, egg, and dairy products") and the hazard category (e.g., "biological contamination"). Since the dataset is highly imbalanced, handling rare categories effectively is a key challenge.**Subtask 2: vector classification:** This subtask requires a more detailed prediction by identifying the exact product (e.g., "ice cream") and hazard (e.g., "salmonella") mentioned in the report. Instead of selecting from broad categories, models

must extract precise labels, making this task more complex. Performance is evaluated based on macro F1, with a focus on hazard detection.

2.2 Related Work

Explainability in food hazard detection remains underexplored despite its importance for trust and decision-making. Existing research mainly focuses on two types of explainability methods: model-specific and model-agnostic approaches. Model-specific methods are designed for particular models, offering tailored explanations. For example, (Assael* et al., 2022) and (Pavlopoulos et al., 2022) explored techniques that integrate explainability within neural architectures. These methods enhance transparency but are limited to the models they are built for. Model-agnostic approaches, such as LIME (Ribeiro et al., 2016), provide explanations that work across different models. They approximate model behavior by generating local explanations, making them more flexible but sometimes less precise.

In this task, explainability is emphasized by requiring participants to submit vector labels (ST2) as justifications for their category classifications (ST1). This ensures that predictions are interpretable and supports better validation of food safety risks.
[2].

3 System Overview

Our system for the Food Hazard Detection task focuses exclusively on Subtask 1 (ST1), which involves classifying food-related hazard and product categories based on textual data. We employ a transformer-based multi-task learning approach to handle both classification tasks simultaneously. This section details the key components of our system, including data preprocessing, model architecture, training strategy, and evaluation.

3.1 Dataset

We use the dataset provided by the organizers, which consists of 6,644 short texts related to food recall incidents. Each text is a title extracted from official food agency websites (e.g., FDA) and has been manually labeled by two food science or food technology experts. The text length ranges from 5 to 277 characters, with an average of 88 characters. All texts are in English and are annotated with a hazard category and a product category. Upon task completion, the full dataset will be released under the Creative Commons BY-NC-SA 4.0 license on (Randl et al., 2024).

"Randsland brand Super Salad Kit recalled due to Listeria monocytogenes"	
hazard:	listeria monocytogenes
hazard-category:	biological
product:	salads
product-category:	fruits and vegetables
"Create Common Good Recalls Jambalaya Products Due To Misbranding and Undeclared Allergens"	
hazard:	milk and products thereof
hazard-category:	allergens
product:	meat preparations
product-category:	meat, egg and dairy products
"Nestlé Prepared Foods Recalls Lean Cuisine Baked Chicken Meal Products Due to Possible Foreign Matter Contamination"	
hazard:	plastic fragment
hazard-category:	foreign bodies
product:	cooked chicken
product-category:	prepared dishes and snacks

Figure 3: A sample of the dataset.

3.2 Model Architecture

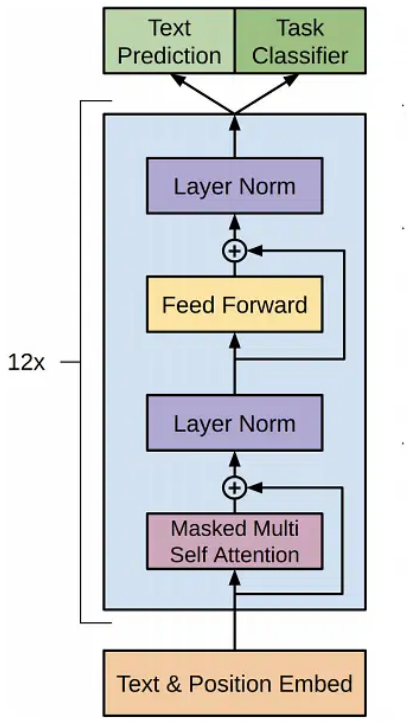

Figure 4: Simplified architecture based on BART.

We use BART (facebook/bart-large-mnli) (Lewis et al., 2020) as the backbone for food hazard classi-

[2] https://zenodo.org/records/10891602

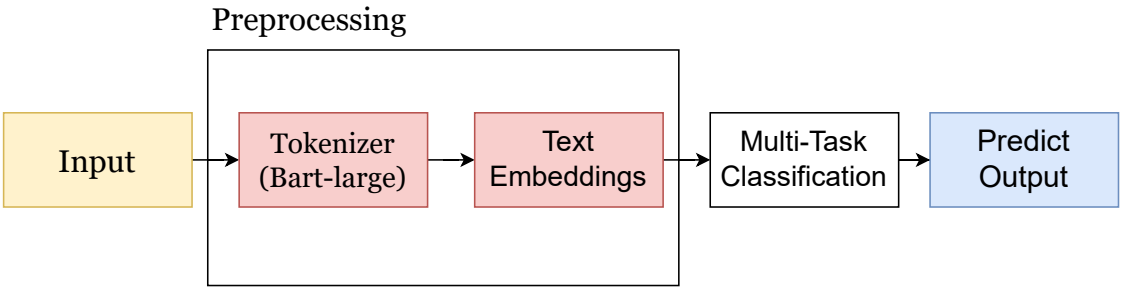

Figure 2: Our System Pipeline.

fication. BART is a transformer-based autoencoder pretrained for sequence-to-sequence tasks, making it well-suited for text classification. In our model, BART serves as an encoder to extract contextual representations from input text. The output from the [CLS] token is passed through two separate linear classifiers to predict the hazard category (10 classes) and product category (22 classes). BART enables the model to capture contextual information effectively, improving classification accuracy despite the imbalanced label distribution in the dataset.

3.3 Multi-Task Classification

Our model performs two parallel classification tasks:The hazard-category classifier predicts one of 10 possible hazard categories.The product-category classifier predicts one of 22 product categories. Both classifiers share the same base model but have separate fully connected (linear) layers for final classification. The CLS token representation is used as input to these classification layers. Formally, given an input text x, we obtain:

$$\hat{y}_{\text{hazard}} = \text{softmax}(W_h h + b_h)$$

$$\hat{y}_{\text{product}} = \text{softmax}(W_p h + b_p)$$

where W_h, W_p and b_h, b_p are learnable weight and bias parameters. The dataset is highly imbalanced, with certain classes appearing much more frequently than others. To address this, we use label encoding to convert categorical labels into numerical indices. Apply shuffling during training to improve generalization. Use early stopping to prevent overfitting.

4 Experimental Setup

We use the dataset provided by the organizers, which consists of 6,644 short texts. The data is split into training, validation, and test sets. The training set is used for model training, the validation set for hyperparameter tuning and early stopping, and the test set for final evaluation. Each text is tokenized using the BART-large-MNLI (Lewis et al., 2020) tokenizer with a maximum sequence length of 128. Labels are encoded using Scikit-learn's `LabelEncoder`, and missing labels in the validation and test sets are assigned default values. We fine-tune the BART-large-MNLI model for multi-label classification with a batch size of 16 and the AdamW optimizer (learning rate 2×10^{-5}). A learning rate scheduler (`ReduceLROnPlateau`) adjusts the learning rate based on validation loss. Early stopping is applied with a patience of 3 epochs, and training runs for up to 20 epochs. Our implementation uses Transformers (Wolf et al., 2020), Torch (Paszke et al., 2019), Scikit-learn (Pedregosa et al., 2011), and Pandas.

4.1 Evaluation Mectric

Task organizers compute the performance for ST1 and ST2 by calculating the macro-F1-score on the participants' predicted labels (`hazards_pred` & `products_pred`) using the annotated labels (`hazards_true` & `products_true`) as ground truth. The F1-score is calculated as follows:

$$F_1 = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}}$$

where Precision and Recall are defined as:

$$\text{Precision} = \frac{\text{TP}}{\text{TP} + \text{FP}}, \quad \text{Recall} = \frac{\text{TP}}{\text{TP} + \text{FN}}$$

where TP, FP, and FN represent true positives, false positives, and false negatives, respectively.

Phase	Team	Subtask 1 (F1)

	SRCB	0.8039

Table 1: Top 5 results of Subtask 1.

5 Results

Our system did not achieve a high ranking in the competition, placing 14th in Subtask 1. However, we observed notable improvements in performance through model selection. Initially, using BERT resulted in a macro-F1 score of 0.71. By switching to BART, performance increased significantly to 0.8033 on the validation set. Finally, in the evaluation phase, our system achieved a macro-F1 score of 0.7676. To further analyze the effectiveness of our approach, we compared different model architectures. The results confirm that leveraging a more powerful pretrained model such as BART provides a substantial boost over BERT, likely due to its stronger contextual representation and sequence-to-sequence training paradigm.

For error analysis, we examined some misclassified examples and found that many errors involved ambiguous or rare hazard categories, suggesting that our model struggles with underrepresented classes. A confusion matrix could provide more insight into these misclassifications, highlighting specific categories where performance can be improved. Future improvements could focus on handling class imbalance, exploring data augmentation techniques, or incorporating external knowledge sources to enhance classification accuracy.

6 Conclusion

In this paper, we presented our approach for Subtask 1 of the Food Hazard Detection shared task. Our system leveraged pre-trained transformer models fine-tuned for multi-label classification, focusing on identifying food hazard categories and affected product types. Through our experiments, we observed a significant performance improvement when switching from BERT to BART, with the F1-score increasing from 0.71 to 0.8033 on the development set. This result highlights the advantage of using more advanced transformer architectures for text classification tasks. However, in the final evaluation phase, our system's performance slightly declined to an F1-score of 0.7676, ranking 14th overall. While our model did not achieve top-tier rankings, our findings underscore the potential of transformer-based approaches for food hazard classification. The results suggest that further optimizations, such as better handling of class imbalances, domain adaptation, or ensemble methods, could further enhance performance in future iterations of this task.

7 Future Work

While our multi-task design with two classification heads achieved reasonable results, we plan to explore more advanced architectures, such as shared bottlenecks or task-specific modules, to better capture task differences. The model's difficulty with rare and similar classes suggests applying class-balanced losses, targeted augmentation, and domain adaptation to improve generalization.

8 Limitations

Despite the improvements gained from using BART, our system still faced several challenges. First, our performance remained significantly lower

than the top-ranked teams, suggesting that further enhancements are needed, such as better preprocessing, data augmentation, or more sophisticated model architectures. Second, our approach did not fully leverage domain-specific knowledge, which might have contributed to misclassifications. Finally, we did not explore ensemble methods, which could have further improved robustness and generalization. Future work could focus on addressing these limitations to develop a more effective food hazard detection system.

A Bart Model Architecture

BART (Bidirectional and Auto-Regressive Transformer) is a denoising autoencoder that combines a bidirectional encoder (like BERT) and an autoregressive decoder (like GPT). The encoder processes the full input context, while the decoder generates text sequentially from left to right. During training, BART applies text corruption techniques such as token masking, deletion, and sentence permutation, then learns to reconstruct the original text. It is widely used for text classification, summarization, and generation tasks. During training, BART applies text corruption techniques such as token masking, deletion, and sentence permutation, then learns to reconstruct the original text. It is widely used for text classification, summarization, and generation tasks.

UT-NLP at SemEval-2025 Task 11: Evaluating Zero-Shot Capability of GPT-4o Mini on Emotion Recognition via Role-Play and Contrastive Judging

AmirHossein Safdarian* University of Tehran a.safdarian@ut.ac.ir

Milad Mohammadi* University of Tehran miladmohammadi@ut.ac.ir

Hesham Faili University of Tehran hfaili@ut.ac.ir

Abstract

Emotion recognition in text is crucial in natural language processing but challenging in multilingual settings due to varying cultural and linguistic cues. In this study, we assess the zero-shot capability of GPT-4o Mini, a cost-efficient small-scale LLM, for multilingual emotion detection. Since small LLMs tend to perform better with task decomposition, we introduce a two-step approach: (1) Role-Play Rewriting, where the model minimally rewrites the input sentence to reflect different emotional tones, and (2) Contrastive Judging, where the original sentence is compared against these rewrites to determine the most suitable emotion label. Our approach requires no labeled data for fine-tuning or few-shot in-context learning, enabling a plug-and-play solution that can seamlessly integrate with any LLM. Results show promising performance, particularly in low-resource languages, though with a performance gap between high- and low-resource settings. These findings highlight how task decomposition techniques can enhance small LLMs' zero-shot capabilities for real-world, data-scarce scenarios.

1 Introduction

SemEval-2025 Task 11 (Muhammad et al., 2025b) addresses emotion recognition in text across multiple languages, ranging from high-resource to low-resource languages, which is a crucial area in NLP with far-reaching applications in social media analytics, customer service, and healthcare.

By providing a multilingual, multi-labeled dataset of 28 languages, the task highlights the challenges of building robust emotion detection systems under limited training data conditions.

In this paper, we describe our team's participation in SemEval-2025 Task 11, specifically in:

- **Track B (Emotion Intensity):** Predicting ordinal intensity (0–3) for emotions such as joy, sadness, fear, anger, surprise, and disgust.
- **Track C (Cross-lingual Emotion Detection):** Zero-shot emotion detection in a target language using only training data from a different language.

Our primary goal was to evaluate the zero-shot capability of a small-sized LLM, GPT-4o Mini, which is a more cost-efficient model in the GPT-4o family (OpenAI et al., 2024). As LLMs have demonstrated impressive zero-shot capabilities in recent years (Kojima et al., 2022), we did not fine-tune the model on any task-specific data but instead introduced a zero-shot approach: **role-play** and **contrastive judging**, illustrated in Figure 1.

1. **Role-Play Rewriting:** Prompt the model to rewrite a given sentence as if it inherently conveyed a target emotion—altering only minimal surface details while preserving meaning.
2. **Contrastive Judging:** Have the model compare the original and rewritten sentences for each of the emotions, reason through the differences (via chain-of-thought), and then produce a final emotion score or label.

We hypothesize that rewriting the text to inject various emotional tones helps the model disentangle subtle cues, while contrastive judging ensures a reasoned final decision. By relying solely on prompting and structured reasoning, we aimed to investigate whether a smaller-scale LLM could discern subtle emotional cues without specialized training.

* Equal contribution, ordered randomly.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2183–2189

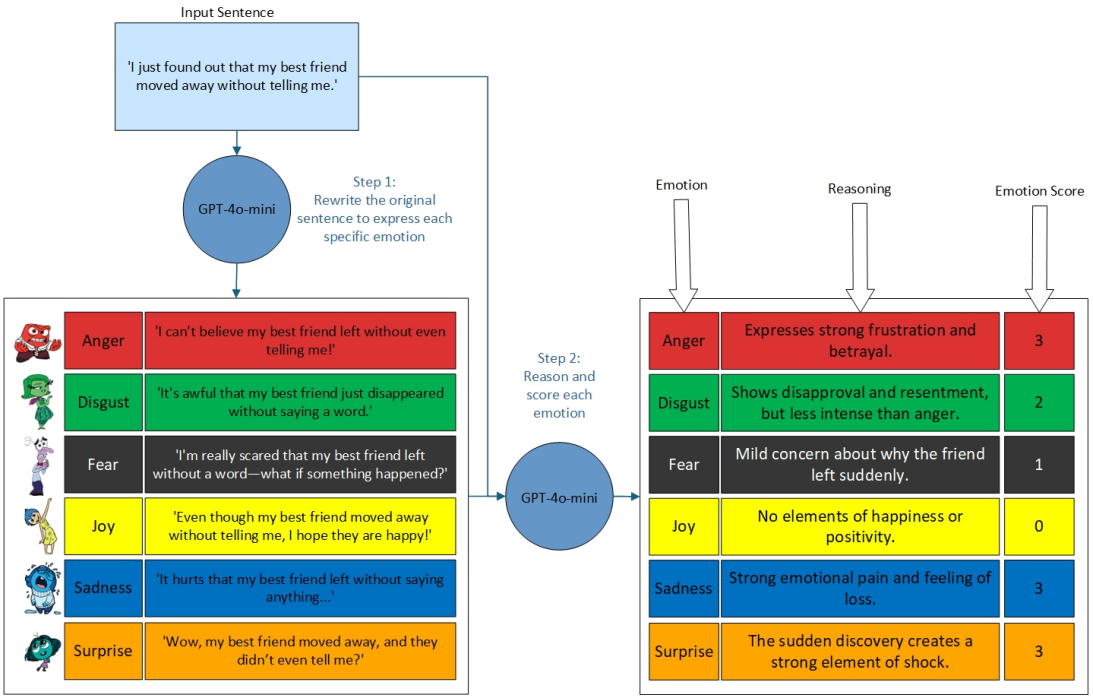

Figure 1: Brief overview of our system

Our zero-shot method, although not striving for state-of-the-art performance, yielded results around the baseline for both Track B and Track C. We observed that:

- The role-play mechanism helped the model clarify the emotional content in ambiguous texts.
- Contrastive judging offered explicit reasoning steps but was prone to occasional misclassifications, especially for nuances such as *fear* vs. *surprise*.
- Performance varied notably across languages, echoing the challenges of low-resource settings.

We have released our code, prompts, and intermediate outputs (rewritten sentences and model reasoning) on GitHub for reproducibility and further research GitHub Repository.

2 Background

2.1 Classic Approaches to Emotion Recognition

Early approaches to emotion recognition often relied on lexicons and feature-based machine learning. Lexicon-based methods drew on resources like WordNet-Affect and the NRC Word–Emotion Lexicon to match emotion words in a text (Nandwani and Verma, 2021). Although transparent and easy to use, such methods struggled with context and intensity (Nandwani and Verma, 2021). Feature-based supervised learning went further by encoding various cues (e.g., n-grams, emotion lexicon hits, negation) and training models like SVM or MaxEnt (Oberländer and Klinger, 2018; Nandwani and Verma, 2021).

2.2 Neural Networks and Transformers

Neural network approaches like LSTMs and CNNs automatically learn higher-level features. Studies showed bi-directional LSTMs outperformed linear models on emotion classification, while CNNs captured relevant n-grams (Oberländer and Klinger, 2018). Transformer-based architectures such as BERT advanced these gains by providing rich contextual representations. For instance, GoEmotions (58K Reddit comments with 27 emotion labels) showed a fine-tuned BERT achieving strong F1 scores, though still leaving room for improvement (Demszky et al., 2020). In dialogue scenarios, hierarchical models (e.g., DialogueRNN, HiGRU) incorporate utterance- and dialogue-level encoders to handle context across multiple turns (Zhu et al., 2021).

2.3 Large Language Models for Zero/Few-Shot Emotion Classification

LLMs like GPT-3.5 and GPT-4 can perform zero-shot classification via prompts without fine-tuning. However, prompt design is critical, as poorly phrased instructions can lead to suboptimal performance. (Kazakov et al., 2024). Cultural variance and domain mismatch pose further difficulties (Plaza-Del-Arco et al., 2024). While fine-tuned models often outperform LLM zero-shot prompts (Juan et al., 2024), some results show LLMs can close the gap on simpler tasks (Juan et al., 2024).

2.4 Our Work in Context

In this work, we explore a creative strategy for emotion detection leveraging the capabilities of GPT-4o Mini in a two-step process: a role-play rewriting step followed by a contrastive judging step.

In the first stage, the model is prompted to "role-play" – effectively rewriting or rephrasing the input text as if it were being expressed with a specific emotional stance. In the second stage, a contrastive evaluation is performed: the model (or a separate process) compares the original text to the emotion-specific paraphrases and judges which emotion's paraphrase best matches or explains the original.

This two-step approach is reminiscent of prompting techniques where the model is encouraged to reason or decompose the task before giving an answer (Bhaumik and Strzalkowski, 2024), that frames emotion detection as a generative question-answering problem – essentially asking the model to explain what might be happening or felt in the text before naming the emotion. This is analogous to our idea of role-play generation as a form of explanation. Moreover, the practice of using chain-of-thought (CoT) prompting for reasoning tasks has shown that LLMs can often improve accuracy by elaborating on the problem before answering (Wei et al., 2022).

By positioning our approach in this context, we aim to leverage both the generative flexibility and knowledge of an LLM and its ability to function as a classifier. There is little prior work that explicitly uses a role-play rewriting technique for emotion detection, so we believe this adds a fresh perspective to the toolkit of LLM-based emotion analysis. Our method aligns with the trend of using LLMs as reasoning engines that are more interpretable than classic methods.

3 System Overview

Our approach relies on a minimalistic two-step pipeline built using GPT-4o Mini (`gpt-4o-mini-2024-07-18`) as the processing core:

1. **Role-Play Rewriting**, where the model is prompted to rewrite the input sentence multiple times—once per candidate emotion—making minimal changes to reflect that emotion while preserving the original meaning.

2. **Contrastive Judging**, where a second call to GPT-4o Mini compares the original sentence to each of these rewrites and determines the best-matching emotion. (figure 1)

Both steps use OpenAI's structured output feature to parse the results, and no hyperparameter changes (e.g., temperature, max_tokens) were made. We leveraged the BRIGHTER dataset (Muhammad et al., 2025a) only for zero-shot inference—no training or fine-tuning was performed—and used the development set purely to refine our prompts.

Since our method is self-contained, switching LLM providers or models requires only updating the client and model name. The simplicity of the pipeline (two API calls, standardized prompt structure) and the absence of fine-tuning or other methods that require labeled data make our approach a plug-and-play solution.

4 Experimental Setup

We tested our pipeline on Track B and Track C of SemEval-2025 Task 11 using the official splits provided in BRIGHTER (Muhammad et al., 2025a) (train, dev, test). We crafted our prompts using the dev set (treating it only for evaluation and prompt iteration) and then ran the final prompts on the test data. This included languages of varying resource levels, from English and Chinese to Ukrainian and isiZulu.

We did not apply any explicit preprocessing or domain adaptation (e.g., removing special characters), relying on GPT-4o Mini's internal handling. For each test instance, we called the model twice: once per emotion candidate (for role-play rewriting) and once for the final contrastive judgment, both using the `Structured Output` built-in feature of the GPT-4o Mini model.

The prompts and schemas are provided in the appendix. We employed the OpenAI Python client library to run our prompts and used macro-averaged F1 (for emotion recognition) and mean absolute error (for intensity), aligned with the task's official evaluation metrics.

5 Results

Overall, our system provided near-baseline results on both tracks, reflecting the minimalist nature of our zero-shot approach. For Track B (figure 2), English performed best (0.5693 average Pearson r), followed by Ukrainian (0.3517), Hausa (0.3372), and Chinese (0.3068). We see that English data achieved higher scores for fear and joy, which aligns with the fact that GPT-4o Mini is primarily trained on extensive English corpora. Chinese exhibited the lowest consistency for surprise ($r = 0.133$), suggesting that the model struggled with subtle intensities in non-Latin scripts.

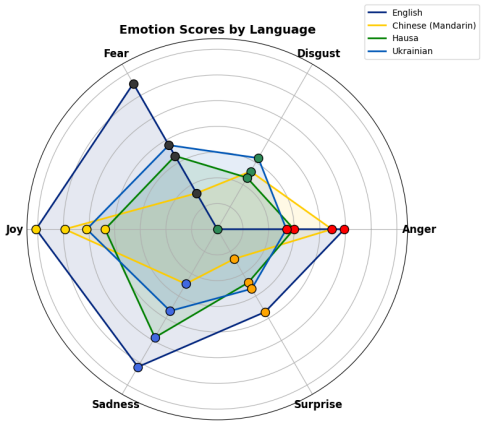

Figure 2: Track B Emotion Comparison Among Different Languages

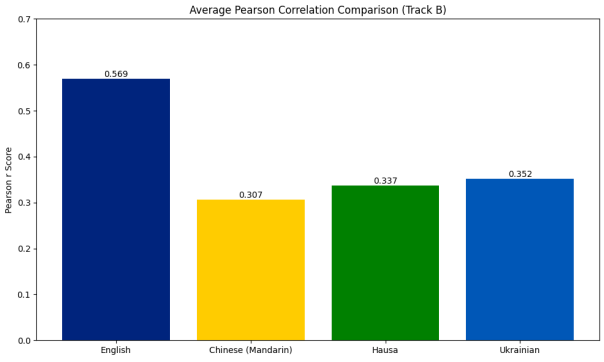

Figure 3: Track B Language Comparison

For Track C (figure 4), macro-F1 ranged from 0.5598 in English down to 0.1894 for isiZulu. Notably, languages with sparse resources—like isiZulu (0.1894) and Ukrainian (0.237)—lagged behind. Even within medium-resource languages (e.g., Indonesian at 0.5055 macro-F1), performance varied across emotions: fear and surprise were particularly challenging, possibly due to cross-lingual semantic gaps and fewer training signals in GPT-4o's domain knowledge. This discrepancy highlights how zero-shot performance can fluctuate significantly by language (figures 3, 5) and emotion category.

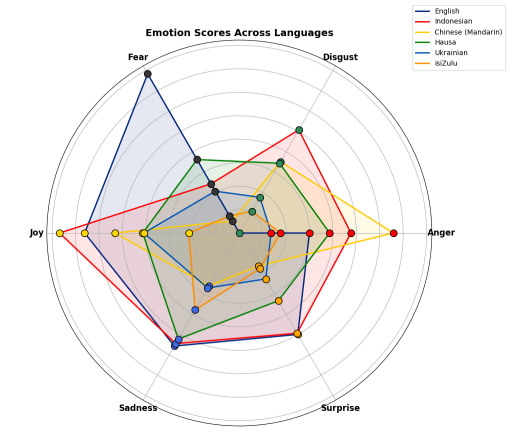

Figure 4: Track C Emotion Comparison Among Different Languages

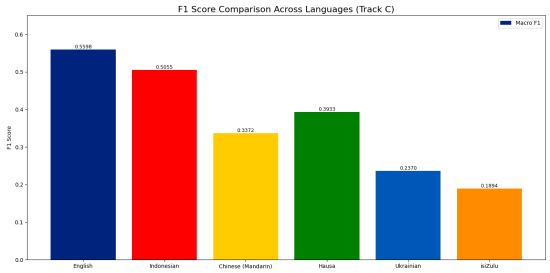

Figure 5: Track C Language Comparison

A closer look at error patterns revealed that many mistakes occurred when the Role-Play Rewriting step excessively modified or insufficiently modified the texts. When the rewrite did not accurately reflect the target emotion, the Contrastive Judging step struggled to pick a correct match. Conversely, when the rewrite was successful, the model often selected the correct emotion label. We suspect that isolating the contrastive judging mechanism (i.e., removing the rewriting stage) might help gauge how much rewriting errors degrade final predictions—an avenue for future systematic ablation.

In terms of competition ranking, our system was not among the top-scoring submissions. However,

Languages	Emotions						Average Pearson r
	Anger	Disgust	Fear	Joy	Sadness	Surprise	
English	0.4951	-	0.6545	0.7062	0.6186	0.3719	0.5693

Table 2: Macro and Micro F1 scores for emotion classification in Track C.

it notably required no labeled data and relied on a lightweight LLM, making it cost-effective for low-resource use cases. The results indicate that while role-play rewriting and chain-of-thought reasoning can enhance emotion detection, further optimization—such as improved prompt engineering or partial fine-tuning—may significantly improve accuracy across languages.

6 Conclusion

We presented a novel zero-shot pipeline for multilingual emotion recognition using GPT-4o Mini, employing a role-play rewriting step followed by contrastive judging. Despite near-baseline official results, our method remains highly adaptable, requiring no labeled data and minimal computational cost.

Future work can explore replacing or refining the rewriting step, comparing this approach across different LLMs, and systematically evaluating each module (rewriting vs. judging) in isolation. We believe this line of research will open opportunities for more accessible, modular, and interpretable emotion detection solutions—especially valuable in low-resource and multilingual settings.

Appendix

Prompts and Schemas

Rewrite Prompt

```
PROMPT_REWRITE = """
You are a helpful language model tasked with rewriting a given text to
convey specific emotional tones. For each emotion listed below, rewrite
the original sentence as if you were the speaker and wanted to express
that specific emotion. Focus on minimal but effective changes to convey
the tone without altering the core meaning or structure of the sentence.
Ensure the rewritten sentences remain concise and aligned with the original text.

Emotions to rewrite for:
- Joy
- Sadness
- Fear
- Anger
- Surprise
- Disgust

Please rewrite the text for each emotion. Do not extend or shorten the text
unnecessarily.
"""
```

The corresponding schema for the rewritten text is structured as follows:

```
class EmotionRewrittenText(BaseModel):
original_text: str
joy: str
sadness: str
fear: str
anger: str
surprise: str
disgust: str
```

Scoring Prompt

```
PROMPT_SCORE = """
You are a helpful language model tasked with analyzing the emotional
intensity of an original sentence. Given a set of rewritten sentences
(one for each emotion), evaluate the original sentence to determine
how strongly it aligns with each emotion. The rewritten sentences
are clues to help guide your assessment, but your focus should
remain on the original sentence.

Instructions:
1. For each emotion (joy, sadness, fear, anger, surprise, disgust),
compare the original sentence to its corresponding rewritten version.
2. Assess how closely the original sentence aligns with the tone of
each rewritten sentence, considering subtle cues in language,
context, and implied sentiment.
3. Provide a brief reasoning for each emotion explaining the alignment.
4. Assign an intensity score for each emotion:
- 0: No emotion present
- 1: Low degree of emotion
- 2: Moderate degree of emotion
- 3: High degree of emotion

Provide your analysis and intensity scores for each emotion.
"""
```

The schema for the emotion analysis output is structured as follows:

```
class EmotionAnalysisNonNestedOutput(BaseModel):
    joy_reasoning: str
    joy_intensity: int
    sadness_reasoning: str
    sadness_intensity: int
    fear_reasoning: str
    fear_intensity: int
    anger_reasoning: str
    anger_intensity: int
    surprise_reasoning: str
    surprise_intensity: int
    disgust_reasoning: str
    disgust_intensity: int
```

These two prompts and their corresponding schemas illustrate our modular approach for role-play rewriting (`PROMPT_REWRITE`) and contrastive judging/scoring (`PROMPT_SCORE`). By calling the language model twice—once to obtain the rewritten text for each emotion, and once to assign intensities based on those rewrites—we maintain a clean separation between generation and evaluation steps, facilitating easy adjustments or substitutions of different large language models.

FactDebug at SemEval-2025 Task 7: Hybrid Retrieval Pipeline for Identifying Previously Fact-Checked Claims Across Multiple Languages

Abstract

The proliferation of multilingual misinformation demands robust systems for cross-lingual fact-checked claim retrieval. This paper addresses SemEval-2025 Shared Task 7, which challenges participants to retrieve fact-checks for social media posts across 14 languages, even when posts and fact-checks are in different languages. We propose a hybrid retrieval pipeline that integrates both sparse lexical matching techniques (utilizing BM25 and BGE-m3) and dense semantic retrieval methods (leveraging both pretrained and fine-tuned BGE-m3 embeddings). Our approach implements the dynamic fusion of these complementary retrieval strategies and employs curriculum-trained rerankers to optimize retrieval performance. Our system achieves 67.2% cross-lingual and 86.01% monolingual accuracy on the Shared Task MultiClaim dataset.

1 Introduction

Nowadays, fact-checking has become crucially important because it helps maintain accuracy and credibility, prevents the spread of misinformation, and ensures informed decision-making by verifying information before dissemination.

SemEval-2025 Task 7 is focused on *Previously Fact-Checked Claim Retrieval* (PFCR) (Shaar et al., 2020). The task involves ranking a set of fact-checked claims according to their relevance to an input claim such as a social media post, with the highest-ranking ones being most pertinent and beneficial for fact-checking.

So far only monolingual PFCR has been tackled, when the input claim and the fact-checked claims are in the same language. To address these shortcomings, the SemEval-2025 Task 7 (Peng et al., 2025) has been organized with the MultiClaim dataset (Pikuliak et al., 2023) to encourage the community to develop a multilingual fact-checking system. The task is divided into two main subtasks: (1) monolingual fact-checking – given a social post, participants must develop systems to identify and retrieve the most relevant fact-checked claim written in the same language as the post; (2) cross-lingual fact-checking – the task is essentially the same as the first one, but now posts and their relevant fact-checks can be written in a different language. This subtask requires participants to build a multilingual retrieval system.

This paper is structured as follows. Section 2 discusses existing work on fact-checking. Section 3 describes the modified version of the MultiClaim dataset that was used in the SemEval-2025 Task 7. Section 4 introduces the evaluation metrics. Section 5 describes the proposed hybrid retrieval pipeline. Section 6 reports the results of the applied approaches.

Our contribution can be summarized as follows. We introduce a lightweight yet effective fact-checking hybrid retrieval system that incorporates multistage fine-tuning components. This technique efficiently aligns multilingual social media posts with a multilingual fact-check corpus.

2 Related Work

The information retrieval component is an essential part of any QA system, not only because it improves QA performance, but also because it enhances fact-checking (Krayko et al., 2024). PFCR task is time-consuming for professional fact-checkers and information retrieval methods can speed up the process. Multilingual PFCR is an even more complicated version for humans because it requires a deep understanding of multiple languages. Multilingual information search can facilitate the fact-checking between different languages.

For PFCR, traditional methods of information retrieval can be utilized. Vo and Lee (2018) effectively employed the BM25 method to identify

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2190–2196

fake news. Various text embedding techniques have been used to improve the retrieval process, allowing more nuanced comparisons between claims, and also techniques such as reranking are used to combine multiple methods, enhancing the efficiency and accuracy of claim retrieval (Pikuliak et al., 2023; Konovalov and Tumunbayarova, 2018). Similar ideas are used to retrieve claims for comparative questions (Shallouf et al., 2024). In addition, some approaches enhance the results by incorporating visual data from images, using abstractive summarization, or identifying key sentences.

XLM-RoBERTA based BGE-M3 provides more contextually rich and semantically accurate representations of text, ultimately leading to more relevant and precise search results. It can simultaneously perform the three common retrieval functionalities of embedding model: dense retrieval, multi-vector retrieval, and sparse retrieval utilizing the Transformer ability to integrate several tasks (Karpov and Konovalov, 2023).

Research emphasizes the importance of context in detecting previously fact-checked claims, especially in political debates or documents (Shaar et al., 2022). Some studies focus on detecting claims within entire documents, aiming to rank sentences based on their verifiability using previously fact-checked claims (Shaar et al., 2020)

Zhang et al. (2023) presented a dataset for monolingual information search for 18 different languages and demonstrated the work of some baseline approaches for information retrieval.

Future research will likely focus on improving the efficiency and accuracy of these systems, particulary in low-resource languges and complex contextual scenarios.

3 Dataset

The competition organizers represented a modified version of the MultiClaim dataset. The original MultiClaim dataset consists of 28k posts in 27 languages on social media, 206k fact checks in 39 languages performed by professional fact checkers, and 31k connections between the two groups. Each connection consists of a post and a fact-check reviewing the claim made in the post. The main difference between the modified version presented in the competition and the original one is that the modified version contains fewer languages (14), but contains more fact checks (272k) and few more posts. In the competition a modified MultiClaim dataset was used. The entire dataset is split into three sections: training (comprising 153k fact-checks in 8 languages, 4,972 cross-lingual and 1,7016 monolingual posts), testing (featuring 272,447 fact-checks in 12 languages, 4,000 crosslingual and 4,276 monolingual posts) and development (consisting of the same fact-checks as training, 552 cross-lingual, and 1,891 monolingual posts). There are also 25,743 connections between posts and fact-checks for training and development parts.

4 Evaluation

To evaluate retrieval in Shared Task 7, we use **Success-at-10** (**S@10**) as a quality measure for both monolingual and cross-lingual subtasks. This is because we depend on the retrieval module to capture as much relevant information as possible.

5 Proposed Approach

Our rather classical retrieval pipeline combines sparse and dense retrieval paradigms with fusion and reranking to address cross-lingual and monolingual fact-checking tasks. The architecture consists of four stages: (1) sparse vector encoding for lexical matching, (2) dense vector encoding for semantic alignment, (3) fusion to merge multi-perspective results, and (4) reranking to refine relevance ordering. This pipeline was used successfully for the retrieval in the specific domain (Aushev et al., 2025).

5.1 Sparse Retrieval

Sparse vector representations are generated using the following methods:

(1) BM25: Traditional sparse retrieval using TF-IDF weighting. (2) BGE-m3 Lexical Weights (Chen et al., 2024): Enhanced sparse vectors from the sparse component of `BAAI/bge-m3`[1], which captures the importance of the term through learned token-level scores.

As for the preprocessing step, we only converted all emoji to their text aliases.

5.2 Dense Retrieval

Dense vector representations are generated using several transformer-based models: (1) BGE-m3 Dense Encoder: The `BAAI/bge-m3` model is also employed to produce dense vectors, taking advantage of its large-scale pretraining on diverse

[1] https://hf.co/BAAI/bge-m3

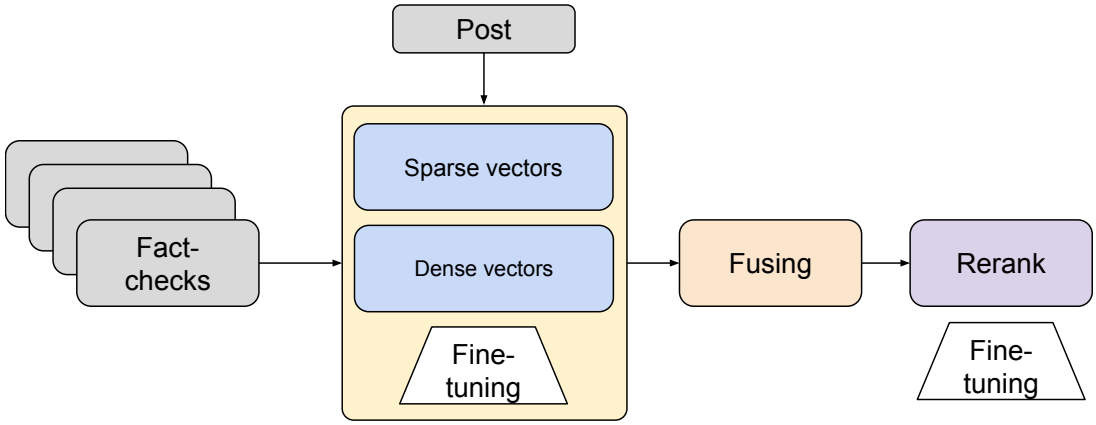

Figure 1: Hybrid Fact-Check Retrieval Pipeline. The pipeline combines sparse (BM25 or BGE-m3-lexical) and dense (BGE-m3-dense) retrieval, fuses their outputs via Reciprocal Rank Fusion, and reranks results using fine-tuned cross-encoders.

data sources; (2) Task-Specific Adaptation: A fine-tuning process using contrastive loss is applied to the `BAAI/bge-m3` model to optimize its ability to discriminate between relevant and irrelevant results.

5.3 Fusion

To unify sparse and dense signals, we employ Reciprocal Rank Fusion (RRF) (Cormack et al., 2009) with tunable weights, ensuring a balanced combination of both approaches:

$$\text{RRF}(d) = \sum_{i=1}^{n} \frac{w_i}{k + \text{rank}_i(d)} \quad (1)$$

where k is a smoothing constant, $rank_i(d)$ denotes the rank of document d in the i-th retrieval system, and w_i represents the retriever-specific weight coefficient.

5.4 Rerank

The reranking phase refines the top retrieved documents based on additional features, improving relevance and quality. We tried several rerankers: (1) BGE-m3 Reranker: `BAAI/bge-reranker-v2-m3` cross-encoder model, based on the `BAAI/bge-m3` architecture, it computes query-document relevance scores by jointly encoding pairs, resolving ambiguities in lexical matches; (2) Curriculum-Learned Reranker: `BAAI/bge-reranker-base` fine-tuned in two stages: First, adaptation to fact-checking using focal loss (with parameters `alpha=0.95` and `gamma=0.4`) to handle class imbalance; second, optimization on hard negations derived from sparse search errors to refine decision boundaries.

6 Results and Discussion

6.1 NLI Analysis

Fact-check retrieval requires identifying claims that entail (support) or contradict a social media post. To quantify this relationship, we analyze post-fact-check pairs using `FacebookAI/roberta-large-mnli` (Liu et al., 2019), pretrained on large web-text corpora (Appendix A).

Entailment Distribution. Entailment scores exhibit a bimodal distribution: 68% of pairs cluster near 0 (no entailment) and 24% near 1 (strong entailment), with only 8% in the ambiguous middle range (0.2–0.8). This polarization likely reflects the NLI model's overconfidence rather than true task-specific relationships, as social media claims often involve nuanced or implicit connections.

Contradiction Rarity. About 92% of pairs score below 0.1 for contradiction. The scarcity of high-contradiction pairs may stem from the NLI model's limited exposure to adversarial social media claims during pretraining, rather than genuine absence of contradictions.

Neutrality as Noise. Neutral scores follow a U-shaped distribution: 54% near 0 (non-neutral) and 32% near 1 (strongly neutral). The high-neutrality cluster may include false negatives where the NLI model fails to recognize subtle entailment/contradiction signals, particularly in code-switched or informally phrased text.

Despite the bias of the out-of-the-box NLI model, these results reveal that the task can be noise-aware retrieval: prioritize lexical overlap for high-recall candidate generation, mitigating re-

Sparse Retrieval	Dense Retrieval	Fusion	Rerank	Mono	Cross
BGE-m3-lexical	–	–	✗	79.18	57.87

Table 1: Performance of retrieval systems on cross-lingual (Cross) and monolingual (Mono) tasks. Measured in Success@10, %. Fusion $k : n$ indicates that the sparse weight is k and the dense weight is n in Reciprocal Rank Fusion.

liance on noisy semantic signals.

6.2 Retrieval Analysis

Table 1 compares the performance of sparse, dense, and hybrid retrieval systems on cross-lingual and monolingual fact-checking tasks.

Component Analysis. The standalone BGE-m3-lexical sparse retriever achieved strong monolingual performance (80.44%), outperforming the dense-only BGE-m3-dense-finetuned system (67.02%). This lexical advantage persisted in cross-lingual settings (61.17% vs. 65.4%), though dense retrieval showed greater cross-lingual robustness. The BM25 baseline (62.96% Mono, 56.15% Cross) underperformed modern neural methods, highlighting the need for learned lexical representations.

Fusion Strategies. Combining sparse and dense components via RRF yielded substantial gains. A 1:1 sparse-dense ratio with reranking produced the best cross-lingual performance (67.2% Cross), surpassing individual components. Monolingual performance peaked at 86.01% with an 8:2 sparse-dense ratio and reranking, demonstrating lexical dominance in single-language contexts. Notably, reranking consistently improved monolingual results (improvements of 0.58-1.27 points across metrics) but showed mixed cross-lingual effects, suggesting language-specific optimization potential (see Appendix B).

Crosslingual Performance. Optimal cross-lingual performance required balanced sparse-dense fusion – 1:1 ratio. In contrast to the monolingual results, there is a lexically heavy 8:2 ratio, which is consistent with our NLI analysis. This suggests that while lexical matching anchors retrieval quality, cross-language generalization benefits from controlled semantic integration, but this may be due to the nature of cross-lingual translation utilisation.

Ablation Study. In addition to the results in Table 1 we evaluated configurations for `stella_en_1.5B_v5`[2] (Zhang and FulongWang, 2024) and `multilingual-e5-large-instruct`[3] (Wang et al., 2024) with the prompt *"Given a post on a social network, retrieve the claims it contains"*, but it did not give any increase in quality. Replacing the dense retriever in hybrid pipeline with `stella_en_1.5B_v5` performs 84.45% Mono and 65.47% Cross, `multilingual-e5-large-instruct` performs 84.86% Mono and 66.37% Cross.

Conclusion

In this paper, we have described the system we submitted for the SemEval Task 7 challenge, specifically concentrating on developing a multilingual and crosslingual fact-checked claim retrieval. We proposed a simple yet effective hybrid retrieval pipeline with fine-tuned components. The proposed pipeline can be employed independently or integrated within a NLP framework such as DeepPavlov (Burtsev et al., 2018).

Future directions include dynamic fusion mechanisms that weight sparse and dense contributions per language pair, and joint training of sparse and dense components to enhance overall performance.

[2] https://hf.co/NovaSearch/stella_en_1.5B_v5
[3] https://hf.co/intfloat/multilingual-e5-large-instruct

Limitations

Our approach has two key constraints: (1) Partial fine-tuning – only dense and reranker components were optimized, leaving potential gains from end-to-end sparse-dense co-training unexplored due to optimization instability; (2) Translation and OCR inaccuracies propagate through the pipeline, particularly harming low-resource languages and slang-heavy social media text.

Abstract

Tabular Question Answering (QA) is crucial for enabling automated reasoning over structured data, facilitating efficient information retrieval and decision-making across domains like finance, healthcare, and scientific research. This paper describes our system for the SemEval 2025 Task 8 on Question Answering over Tabular Data, specifically focusing on the DataBench QA and DataBench Lite QA subtasks. Our approach involves generating Python code using Large Language Models (LLMs) to extract answers from tabular data in a zero-shot setting. We investigate both multi-step Chain-of-Thought (CoT) and unified LLM approaches, where the latter demonstrates superior performance by minimizing error propagation and enhancing system stability. Our system prioritizes computational efficiency and scalability by minimizing the input data provided to the LLM, optimizing its ability to contextualize information effectively. We achieve this by sampling a minimal set of rows from the dataset and utilizing external execution with Python and Pandas to maintain efficiency. Our system achieved the highest accuracy amongst all small open-source models, ranking 1st in both subtasks.

1 Introduction

Tabular Question Answering (QA) is a critical area in Natural Language Processing (NLP) that enhances data accessibility and facilitates automated information extraction from structured datasets. The SemEval 2025 task on "Question Answering over Tabular Data" (Osés Grijalba et al., 2025) advances this field by introducing DataBench (Grijalba et al., 2024b), a benchmark comprising diverse, large-scale tabular datasets spanning multiple domains. The task challenges participants to develop systems capable of answering questions over these datasets, with two subtasks: DataBench QA (full datasets) and DataBench Lite QA (sampled datasets with a maximum of 20 rows) to support models with limited context windows. Expected answer types include boolean, category, number, or lists of these values.

	Accuracy	General	Open Models	Small Models
Databench	73.18%	25^{th}	18^{th}	1^{st}
Databench Lite	73.75%	26^{th}	18^{th}	1^{st}

Table 1: Performance on the DataBench QA and DataBench Lite QA subtasks, showing accuracy and rank among all systems (General), open-sourced models, and small open-sourced models ($\leq 8B$ parameters).

Our system employs a code generation approach using Python[1] and Pandas[2] to extract answers from tabular data using open-source Large Language Models (LLMs). Given a table and a question, our system generates executable code that loads the table, performs the necessary computations, and returns the answer. This approach ensures interpretability, as the reasoning process is encoded explicitly in the generated code, and it remains agnostic to the table structure. We explore both a multi-step agentic Chain-of-Thought (CoT) approach, where one LLM generates structured reasoning steps and another translates them into executable code, and a unified LLM approach, where the model simultaneously reasons and writes code. We prioritize a zero-shot setting to minimize the amount of table data passed to the LLM, optimizing for low resource consumption and scalability.

Our system achieved the highest accuracy among small open-sourced LLMs, ranking 1^{st} in both subtasks (Table 1). Through our participation in this task, we discovered several key insights into optimizing LLM-driven code generation for tabular QA. First, prompt engineering plays a crucial role

[*]Equal contribution

[2]https://pandas.pydata.org

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2197–2204

in improving performance - highlighting the importance of structuring inputs effectively to guide model reasoning. Second, we demonstrate that it is possible to achieve strong results while minimizing the amount of table data passed to the LLM. Notably, our results indicated that a unified LLM approach outperformed the agentic CoT method. We hypothesize that discrepancies in reasoning styles between different models led to cascading errors from the reasoning step to the final answer. This motivated our shift towards a unified system. Our approach relied on code execution, hence a major challenge was to ensure the generation of syntactically and semantically correct parsable code. We implemented iterative retry mechanisms that provided the LLM with error codes to refine its output. Our work is publicly available[3] for reproducibility.

2 Background

Our work is based on the dataset collection originally presented in the paper (Grijalba et al., 2024a). The dataset comprises 65 tables designed to evaluate LLMs on the task of QA over structured real-world tabular data.

2.1 Dataset Details

The dataset collection consists of 3,269,975 rows and 1,615 columns in total, covering a diverse range of domains such as business, health, travel, social networks, sports, and more. Across all datasets, a total of 1,300 questions were designed to evaluate QA performance. The number of questions per dataset varies, with the *Forbes* dataset containing 25 questions, while all other datasets contain 20 questions each. Every question in the train data can be answered by using ~ 1.45 columns. Table 2 summarizes the distribution of answer types.

Answer Type	Sample	Number of Questions
Boolean	True/False	262
Number	4, 10	260
Category	Automotive, United States	263
List[category]	[apple, mango]	261
List[number]	[2, 4, 6, 8, 10]	262

Table 2: Distribution of Answer Types in train data

2.2 Dataset Composition

The dataset includes a variety of sources, covering different domains and real-world scenarios. Table 3 presents an overview of the datasets used.

2.3 Related Work

LLMs have significantly advanced automated code generation, particularly in the domain of zero-shot reasoning and structured prompting techniques. Traditional approaches to Verilog code generation, such as VRank (Zhao et al., 2025), emphasize self-consistency by clustering and ranking multiple generated candidates, thereby improving functional correctness. CoT prompting (Kojima et al., 2022) has demonstrated the effectiveness of reasoning through multi-step logical processes before generating outputs. However, CoT alone can struggle with syntax correctness, which CodeCoT (Huang et al., 2023) addresses by introducing a self-examination mechanism — iteratively refining outputs based on execution feedback.

AutoAgent (Tang et al., 2025) introduces a fully automated LLM-based framework that eliminates the need for manual intervention, enabling users to deploy intelligent agents through natural language alone. Similarly, SCoT prompting (Li et al., 2025) enhances CoT by explicitly incorporating program structures such as sequences, branches, and loops, achieving more structured and correct code outputs. Meanwhile, fine-tuning and prompting techniques such as those applied to Code Llama (Roziere et al., 2023) and GPT-based models (Haider et al., 2024) show that augmenting metadata, function call graphs, and iterative refinements can further optimize performance.

While LLMs excel in general-purpose code generation, their application to tabular data processing remains limited. TableGPT (Zha et al., 2023) proposes an approach for interacting with structured tables using natural language, offering functionalities like data manipulation, visualization, and analysis. However, its reliance on external functional commands and constrained dataset sizes limits its scalability for large-scale applications. This contrasts with the broader adaptability of agentic AI methods like AutoAgent, which can dynamically

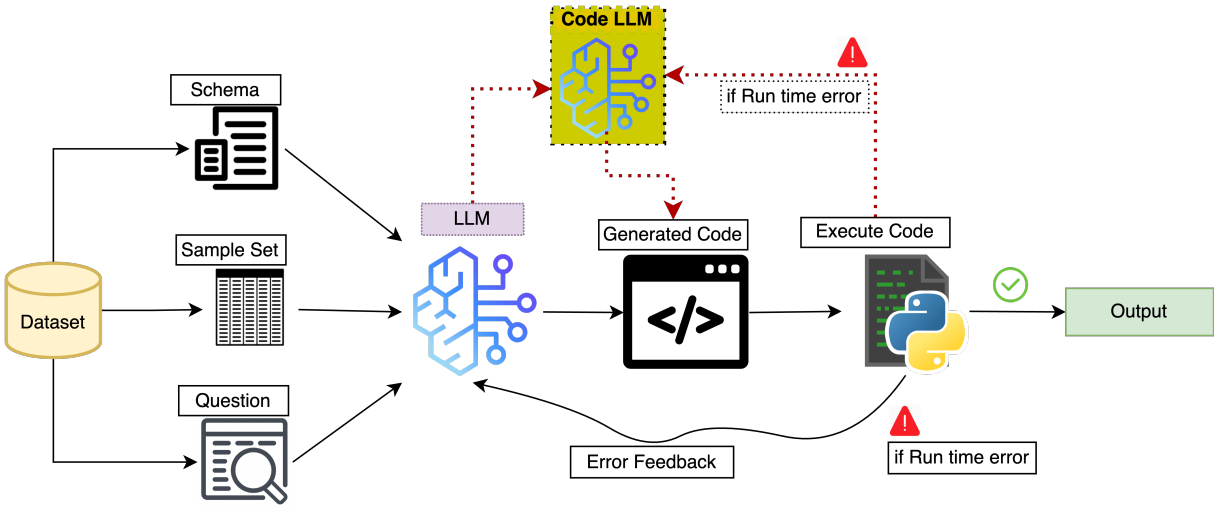

Figure 1: Flowchart illustrating the data preprocessing and model workflow for Subtasks 1 and 2 using a unified and an agentic approach. In the agentic setting the central 'LLM' turns into a 'reasoner LLM' which delineates steps for the 'Code LLM' to write code, which on execution feeds back the error codes to both the reasoner and code LLMs. This is illustrated by using red-dashed arrows in the figure.

generate and refine responses without predefined dataset limitations.

Recent works (Mullick et al., 2022b,a, 2023; Raghav et al., 2023) has also explored fine-grained task-specific adaptations of LLMs across various domains highlighting the importance of domain-aware prompting and structured reasoning. Similarly, generative techniques have been applied to structured tasks like sentiment analysis (Raghav et al., 2022).

In parallel, advancements in retrieval-augmented models and robustness enhancements through knowledge conflict augmentations (Carragher et al., 2025a,b) illustrate emerging techniques for improving generalization and resilience in large model architectures, many of which are transferable to structured tabular reasoning. Additionally, (Raghav et al., 2025) demonstrate the efficacy of large-scale instructive fine-tuning of LLMs – technique that bears promise for improving reasoning quality over structured data.

As LLMs continue to evolve, the integration of zero-shot reasoning, structured CoT prompting, agentic retries, and task-specific augmentations presents a promising direction for improving code generation and complex reasoning over diverse paradigms, including tabular QA.

3 System Overview

Our system Figure 1, reframes the tabular QA task as a code generation problem in zero-shot setting. Given an input dataset table D and a natural language question Q, the system follows a structured pipeline. First, the dataset schema is extracted, including column names, data types, and a sample of the first three rows. This information is then used to construct a structured prompt using the system-user-assistant format that provides essential context while reducing the amount of information provided to the LLM. The system proceeds to generate Python code designed to load the dataset and execute the necessary computations to extract the answer. Subsequently, the generated code is parsed for errors and executed to obtain the final output.

To enhance robustness, we incorporate an execution-aware retry mechanism. If the generated code encounters errors, the error message is fed back to the LLM, allowing it to iteratively refine its output (up to 3 retries). This significantly improves the accuracy of generated code and reduces failure.

By reducing the input size, we optimize both computational efficiency and scalability, while also improving the LLM's ability to effectively contextualize the given data. Additionally, because our system follows a code generation approach and provides only the essential information about the tables, it can be seamlessly applied to both subtasks without requiring any modifications. This design ensures adaptability across different task configurations, further enhancing the system's versatility.

3.1 Agentic CoT Approach

In this approach, we use two separate LLMs: one dedicated to reasoning and another responsible

for code generation. The first LLM decomposes the given question into structured reasoning steps, breaking it down into logical sub-components. These steps are then passed to the second LLM, which translates them into executable Python code.

We conduct experiments with combinations of LLMs for both reasoning and code generation. Specifically, we explore the following model pairs:

- LLaMA 3.1 (8B Instruct) (Touvron et al., 2023) + CodeLLaMA (7B) (Roziere et al., 2023)
- LLaMA 3.1 (8B Instruct) + Phi-4 (8.48B) (Abdin et al., 2024)
- Phi-4 8.48B + CodeLLaMA (7B)

where the first model in each pair was responsible for reasoning and the second for generating executable code. These configurations allowed us to evaluate the impact of model specialization on logical coherence and code correctness.

While the agentic CoT approach provides explicit reasoning traces, discrepancies between the reasoning and code generation LLMs led to cascading errors. CodeLLaMA often struggled with syntax errors or misinterpreted reasoning instructions, while LLaMA failed to generate accurate reasoning steps, resulting in flawed code. Although larger models might have improved performance, computational constraints forced us to use smaller versions. This motivated us to explore a unified approach using a single LLM.

3.2 Unified LLM Approach

To overcome the limitations of the CoT approach, we developed a streamlined pipeline using a single LLM to jointly perform reasoning and code generation. We hypothesized that this method should improve consistency and eliminate the error propagation observed in the multi-step approach.

We experimented with several LLMs, including LLaMA, CodeLLaMA, and Phi-4. Our initial hypothesis was that LLaMA's reasoning capabilities would enhance its code generation, whereas CodeLLaMA would exhibit the inverse relationship. However, Phi-4 demonstrated superior consistency by effectively handling both reasoning and code generation within a single inference pass. This proved more adaptable to diverse question types and table structures, resulting in more robust performance across different datasets.

3.3 Challenges and Solutions

We encountered several challenges in this task:

- **Generating Correct and Parsable Code:** Ensuring the syntactic and semantic correctness of generated code remains a significant challenge. To address this, we employ an error feedback loop, where execution-triggered error messages are used as signals for iterative refinement, guiding the LLM toward producing correct outputs. We allow up to **three retries** within this loop: most simple syntax or small logical errors are typically corrected within the first two attempts, while errors persisting beyond three retries are rarely resolved with additional attempts, as they often stem from fundamental limitations of the model (e.g., ambiguous prompts, missing dependencies, or deeper logical flaws). To validate this choice, we conducted a small experiment by sampling examples that failed even after three retries and allowing them up to ten retries; however, only $\sim 2\%$ of these cases succeeded, confirming that the gains diminish sharply beyond three retries.
- **Handling Large Tables:** It is hard for LLMs to reason on long and wide tables. Instead of providing full datasets, we sample the first three rows along with the schema information, ensuring that the system receives sufficient context with minimal tokens.
- **Ensuring Robust Answer Formatting:** As the task requires specific output data type, we enforce strict formatting constraints on the generated code's output through our prompts.
- **Prompt Engineering:** We adopted a System-User-Assistant chat template as it yielded the best results for our task. The *System* message included the task introduction and LLM conditioning to guide it through the expertise it would need, while the *User* message contained the dataframe schema, sample rows and generation instructions. A detailed illustration of the prompt can be found at subsection A.1 and in our code repository.

4 Experimental Setup

Our experimental setup is designed to evaluate the effectiveness of our approach across both Subtasks 1 and 2. We focus on zero-shot prompting using

quantized LLMs, leveraging prompt engineering techniques to optimize performance. Our methodology incorporates the system-user-assistant chat template, ensuring structured interactions with LLMs. To facilitate efficient inference, we employ Unsloth's (Daniel Han and team, 2023) dynamically quantized 4-bit versions of these models, allowing for computationally efficient execution while maintaining strong performance. We used dymamic 4-bit quantized LLaMA 3.1 (8B Instruct)[4], CodeLLaMA (7B)[5] and dymamic 4-bit quantized Phi-4 (8.48B)[6] models from Unsloth. Experiments were conducted on a single NVIDIA T4 GPU using Google Colab and Kaggle, emphasizing the feasibility of achieving high performance with limited compute resources. Predictions were generated on the validation and blind test set.

4.1 Evaluation Function

The evaluation function for this task measures accuracy while allowing for minor variations in formatting. This ensures that models are not overly penalized for trivial differences in output representation.

For boolean values, the function accepts different valid representations such as "true/false" or "yes/no." In the case of categorical outputs, string matching is applied, while date values undergo parsing to check equivalence. Numerical outputs are evaluated by extracting relevant digits and rounding to two decimal places. List-based outputs are assessed using a set comparison approach, allowing for minor differences in ordering. The evaluation function has been iteratively refined during the competition to be more lenient while maintaining robustness. A manual review of leading systems was conducted before final ranking to ensure fair assessment and identify discrepancies that automated evaluation may overlook.

5 Results

Our system demonstrated exceptional performance, ranking 1^{st} in the "Small Open-Source Models" category ($\leq 8B$ parameters) (refer to Table 1). The single LLM approach consistently outperformed the CoT method, highlighting the importance of maintaining logical consistency within a single model. Additionally, our optimizations in prompt engineering and execution-aware retry mechanisms significantly improved efficiency and accuracy, making our approach well-suited for real-world tabular QA tasks. Detailed results and ablation studies can be found in Table 4.

Model	η	DataBench	DataBench Lite
LLaMA + CodeLLaMa	**1**	**0.13**	0.17
	3	0.10	**0.18**
	5	0.10	0.15
	7	0.10	0.14
LLaMA + Phi-4	**1**	**0.21**	**0.26**
	3	0.20	0.26
	5	0.20	0.25
	7	0.19	0.25

	3	**0.55**	**0.57**
	5	0.54	0.57
	7	0.55	0.55
Phi-4	1	0.70	0.70
	3	**0.71**	**0.72**
	5	0.71	0.70
	7	0.69	0.70

Table 4: Ablation study on the validation dataset to decide on the ideal number of rows to be provided to the model. η is the number of rows chosen from the dataset which is sampled and provided to the model. We choose η based on the performance on both the datasets

5.1 Key Findings

Our key findings through our ablations (Table 4) include:

- The single LLM approach consistently outperformed the CoT method, highlighting the benefits of maintaining logical consistency within a unified model.
- Consolidating reasoning and code generation into a single inference step reduced error propagation and improved system stability.
- Minimizing the amount of table data passed to the LLM optimized computational efficiency, while maintaining performance.
- Optimizations in prompt engineering and execution-aware retry mechanism contributed to improvements in both speed and accuracy.

[4] https://huggingface.co/unsloth/Meta-Llama-3.1-8B-Instruct-unsloth-bnb-4bit

[5] https://huggingface.co/unsloth/codellama-7b-bnb-4bit

[6] https://huggingface.co/unsloth/phi-4-unsloth-bnb-4bit

- Our system is highly adaptable to diverse datasets, ensuring robust performance across a wide range of tabular QA tasks.
- Although there are five distinct types of possible answers, providing more than three examples does not yield any performance improvement. We hypothesize that this behavior arises from the limited context window available to large language models (LLMs) to handle long prompt templates.
- In particular, we observe that LLaMA-based models tend to perform slightly better with shorter prompts, and the Phi-4 model demonstrates a stronger ability to handle longer prompts.

5.2 Error Analysis

Error analysis revealed several recurring issues. CodeLLaMA, when used in isolation for code generation, often produced syntactically incorrect or semantically flawed code. This was particularly evident in cases with complex queries requiring intricate data manipulations. LLaMA struggled with reasoning tasks, which led to incomplete or inaccurate code generation. These findings reaffirmed our decision to use a single LLM approach, which alleviated many of these issues by ensuring consistency between reasoning and code generation.

Furthermore, retry mechanisms were essential for handling edge cases and failed executions. In future work, we plan to explore fine-tuning techniques to improve the handling of more complex queries and further reduce the occurrence of errors in generated code.

6 Conclusion

Our system demonstrates the effectiveness of LLM-driven code generation for zero-shot question answering on tabular data. We highlight the advantages of a unified LLM approach for maintaining logical consistency and the importance of prompt engineering for guiding model reasoning effectively. Additionally, we emphasize the benefits of minimizing LLM input for improved contextualization, computational efficiency, and scalability. Further exploration of fine-tuning techniques could improve the generation of complex aggregation queries and reduce errors in generated code.

Agentic systems have greater potential than what has been portrayed in this work. While our current system demonstrates the effectiveness of LLMs for tabular QA, we recognize that further engineering is needed to fully exploit the potential of agentic systems in this domain. Future research will focus on refining the agentic framework to enable more complex reasoning and data manipulation capabilities.

A Appendix

A.1 Prompt Template

We present the prompt template which follows the system-user-assistant chat paradigm. The same template was used for both Databench and Databench Lite datasets.

System

```
You are an expert Python data engineer.
Your task is to generate pandas code based on a structured reasoning process
You only generate code, no references or explanation - just code
You generate only 20 lines of code at max
```

User

```
Dataframe Schema:
<The schema of the dataset which would contain the column name and its data type>

Sample Rows:
<The first 3 rows of the dataset serialized into a list of dictionaries, where each dictionary
represents a row with column names as keys>

User Question:
<The question that is asked about the dataset>

Expected Output Format:
Generate runnable Python code that follows the given reasoning using pandas.
The code should assume that the dataframe is already loaded as `df`.
The final output should be stored in a variable named `result`.

The expected answer type is unknown, but it will always be one of the following:
    * Boolean: True/False, "Y"/"N", "Yes"/"No" (case insensitive).
    * Category: A value from a cell (or substring of a cell) in the dataset.
    * Number: A numerical value from a cell or a computed statistic.
    * List[category]: A list of categories (unique or repeated based on context). Format: ['cat',
    'dog'].
    * List[number]: A list of numbers.

Given the user question, you need to write code in pandas, assume that you already have df.
Generate only the code.
```

The assistant prompt was left blank during inference. The code obtained from the model would then be run on the dataset to evaluate the answer to the question.

TechSSN at SemEval-2025 Task 10: A Comparative Analysis of Transformer Models for Dominant Narrative-Based News Summarization

Abstract

This paper presents an approach to Subtask 3 of Task 10 of SemEval 2025, which focuses on summarizing English news articles using a given dominant narrative. The dataset comprises news articles on the Russia-Ukraine war and climate change, introducing challenges related to bias, information compression, and contextual coherence. Transformer-based models, specifically BART variants, are utilized to generate concise and coherent summaries. Our team TechSSN, achieved 4th place on the official test leaderboard with a BERTScore of 0.74203, employing the DistilBART-CNN-12-6 model.

1 Introduction

In recent years, automated narrative extraction has gained significant attention in natural language processing (NLP), particularly in understanding complex socio-political events. A central challenge in this area is ensuring that the extracted summary faithfully captures the key information from the original narrative without losing context or meaning. This study focuses on Task 10 in SemEval 2025, which aims to extract, justify and summarize dominant narratives from news articles (Piskorski et al., 2025). The task is based upon shared tasks focusing on persuasion techniques and subjectivity, like the labs organized as part of SemEval 2023 (Piskorski et al., 2023), SemEval 2020 (Da San Martino et al., 2020), and the CheckThat! (Barrón-Cedeño et al., 2024) Labs that are part of the CLEF tasks. Specifically, we work on Subtask 3, with English data, which involves generating a concise, free-text explanation that supports the selection of a given dominant narrative. The dataset comprises articles related to the Russia-Ukraine war and climate change. Framed as a text-to-text generation problem, this subtask requires models to produce well-structured, contextually relevant explanations.

Our work primarily investigates the effectiveness of transformer-based models for summarization, with a particular focus on BART. We evaluate the variants of BART, with the subtasks' official metric- BERTScore (Zhang* et al., 2020). TechSSN achieved the 4th place on the official test leaderboard, achieving a BERTScore of **0.74203** using **distilbart-cnn-12-6**. Table 4 shows the leaderboard for this subtask. We notice that nearly all of the BART models, show fairly similar results. The system demonstrates superior performance with a BART-based architecture compared to a T5 model, highlighting a clear distinction in effectiveness. This can be attributed to BART's bidirectional encoder-decoder architecture, which enables more comprehensive contextual understanding, whereas T5 follows a standard encoder-decoder paradigm with a unidirectional decoder. However, within the BART variants, no single model consistently outperforms others across different types of BART models. The code for our work can be found in this repository.

2 Related Work

Text summarization research has evolved through distinct methodological paradigms, primarily categorized into extractive approaches, which select and concatenate salient text segments, and abstractive methods, which generate novel paraphrases to synthesize coherent summaries, with the latter gaining prominence due to their capacity to distill complex information into fluent narratives. Early efforts in abstractive summarization focused on sequence-to-sequence (seq2seq) architectures enhanced with attention mechanisms, as exemplified by (Sheik and Nirmala, 2021), who leveraged pretrained language models like BERT and GPT to address the intricate syntax and domain-specific terminology of legal texts, demonstrating the superiority of abstractive methods over extractive ones

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2205–2212
July 31 - August 1, 2025

while proposing a hybrid framework that combined extractive preprocessing (to identify key sentences) with abstractive generation (to refine coherence); however, this approach lacked rigorous empirical validation against standardized benchmarks, leaving its scalability and generalizability uncertain. Subsequent innovations sought to enhance semantic fidelity and structural coherence: (Song et al., 2019) introduced the ATSDL framework, integrating LSTM networks for sequential context modeling with CNNs for local feature extraction, guided by a Multiple Order Semantic Parsing (MOSP) method—a phrase extraction technique that hierarchically identifies multi-level semantic units (e.g., clauses, propositions) to steer abstractive generation—though its reliance on phrase-level processing limited scalability for long documents, as recursive segmentation introduced redundancy. To address length constraints, (Wilman et al., 2024) adapted the BART model with a chunking strategy, splitting inputs into segments shorter than 1,024 tokens, summarizing each incrementally and aggregating results, achieving competitive ROUGE-1 and ROUGE-2 scores (43.02% and 20.57%, respectively) on the CNN/DailyMail benchmark; however, their dependency on pretraining data from news articles hindered generalization to highly abstractive domains like XSum, where brevity and conceptual synthesis are paramount. Parallel efforts explored summarization's utility for downstream tasks: (Tran and Kruschwitz, 2022) combined extractive summarization (via DistilBART) with abstractive generation (using T5-3B) for cross-lingual fake news detection, translating German articles to English summaries to train classifiers, achieving a modest F1 score of 28.99% on German subsets—highlighting the challenges of language-specific biases and information loss during cross-lingual transfer. Despite these advancements, critical gaps persist: hybrid frameworks remain under-validated, long-document methods prioritize technical scalability (e.g., token limits) over conceptual nuance (e.g., preserving socio-political context), and existing models inadequately address bias propagation, particularly in contested domains like geopolitics or climate science, where dominant narratives can skew summary tone and factual balance. Our work bridges these gaps by adapting BART to generate concise (80-word), domain-aware summaries for topics such as the Russia-Ukraine war and climate change, explicitly incorporating narrative context (e.g., dominant perspectives, subnarratives) during generation to study bias modulation. Unlike prior studies fixated on metrics like ROUGE, we prioritize correctness (factual alignment with source content) and unbiasedness (neutral framing of contentious claims), tackling the unique challenge of compressing complex, ideologically charged narratives into balanced summaries—a task demanding both architectural innovation and ethical rigor, as models must disentangle factual reporting from rhetorical framing without amplifying systemic biases inherent in pretraining data.

3 Dataset

The objective of this subtask is to generate a concise, free-text explanation (up to 80 words) that elaborates on a dominant narrative within an article. Table 1 shows the data distribution. The dataset for this subtask is divided into training, development, and test sets. The training set comprises 203 instances, each containing four key fields: article_id, dominant_narrative, dominant_subnarrative, and explanation. Similarly, the development set consists of 30 instances with the same structure. The test set includes 68 instances, providing all fields except the explanation, which serves as the target output. Here, article_id represents the filename of the input article, dominant_narrative denotes the main narrative conveyed in the article, and dominant_subnarrative corresponds to its specific subnarrative. The explanation is a free-text justification that supports the identified dominant narrative (Stefanovitch et al., 2025).

Subtask 3 requires models to generate explanations that align closely with established ground truth. The official evaluation metric for this subtask is the BERTScore, which measures the average similarity between the predicted explanations and the gold-standard references. This ensures that the generated explanations are not only semantically accurate but also contextually aligned with human annotations.

4 System Overview

Summarization methods in general, can be grouped into Abstractive Summarization (Shi et al., 2020), Extreme Summarization (Cachola et al.), and Dialogue Summarization (Feng et al.). Each of these serve a different purpose in terms of the nature of the summarized text. Abstractive summarization generates summaries that may contain words and

Dataset	Total Entries	CC Count	URW Count
Train	203	93	110
Dev	30	17	13
Test	68	34	34

Table 1: Distribution of CC and URW in Train, Dev, and Test datasets.

phrases that are not present in the original text. This allows for greater flexibility in language as well as coherence. On the contrary, extreme summarization produces highly compressed summaries, often consisting of a single sentence that captures the core idea of the input text. Dialogue summarization summarizes conversational text while maintaining contextual coherence. Models for dialogue summarization are usually trained on corpora like DialogSum or Samsum (Gliwa et al., 2019).

For this study, we employed a range of transformer-based summarization models with varying architectures, depths, and training objectives. Our selection includes models based on BART (Bidirectional and Auto-Regressive Transformer), DistilBART (a distilled version of BART), T5 (Text-to-Text Transfer Transformer), and FalconAI's summarization model. Below, we provide an architectural overview of these models.

4.1 BART and its Variants

BART is a denoising autoencoder that combines a bidirectional encoder, similar to BERT, with an autoregressive decoder (Lewis et al., 2019). The bidirectional encoder enables full contextual understanding of the input text by processing tokens in both directions, while the autoregressive decoder generates outputs sequentially, ensuring fluency—a critical feature for abstractive summarization. This architecture makes BART highly effective for sequence-to-sequence tasks such as text summarization. Pretraining involves corrupting input text (e.g., through masking, sentence shuffling, or token deletion) and training the model to reconstruct the original text. This denoising objective aligns closely with summarization, as both tasks require condensing and rephrasing content while preserving meaning. In this study, we use bart-large-cnn, trained on the CNN corpus (Lins et al., 2019) for abstractive summarization, bart-large-xsum, trained on the XSum corpus (Narayan et al., 2018) for extreme summarization, and bart-large-cnn-samsum for dialogue summarization.

4.2 DistilBART

DistilBART is a distilled version of BART that retains much of its summarization capability while significantly reducing computational overhead. By using knowledge distillation, DistilBART achieves efficiency gains without a substantial drop in performance (Adhik et al., 2024). The models employed in this study include distilbart-cnn-12-6, distilbart-6-6-cnn, distilbart-xsum-12-1, distilbart-xsum-6-6, distilbart-xsum-12-3, distilbart-xsum-9-6, and distilbart-xsum-12-6. The numerical notation in DistilBART model names corresponds to the number of encoder and decoder layers, with the first number representing the encoder layers and the second indicating the decoder layers. For example, distilbart-cnn-12-6 contains 12 encoder layers and 6 decoder layers, striking a balance between computational efficiency and summarization performance (Yadav et al., 2023). In contrast, distilbart-6-6-cnn features 6 encoder layers and 6 decoder layers, making it a lighter model suited for constrained environments. Meanwhile, distilbart-xsum-12-1 retains 12 encoder layers but reduces the decoder to a single layer, optimizing it for short-text summarization.

4.3 T5

T5 reframes NLP tasks into a text-to-text format, making it highly adaptable for summarization. Unlike BART, which reconstructs text through a denoising objective, T5 is trained using a span corruption task, in which continuous chunks of text are randomly selected and replaced with special mask tokens such as $< extra_i d_0 >$ and $< extra_i d_1 >$. The model then learns to reconstruct the missing spans. While this approach enables T5 to handle diverse tasks, the span prediction objective prioritizes local coherence over global contextual synthesis, potentially limiting its effectiveness for abstractive summarization compared to BART. In this study, we use T5-small and mT5-small (Xue et al., 2020), the latter being a multilingual extension of T5 trained on the mC4 corpus (Dodge et al.,

2021). Additionally, we include FalconAI/Text-Summarization, a model derived from T5-small but trained on a proprietary corpus. Notably, T5's text-to-text framework requires task-specific prefixes (e.g., "summarize:") during inference, adding minor overhead compared to BART's more direct sequence-to-sequence mapping.

4.4 Architectural Trade-offs

BART's pretraining aligns closely with summarization tasks due to its focus on reconstruction and fluency, whereas T5's span corruption objective emphasizes versatility across NLP tasks. While both models use encoder-decoder architectures, BART's bidirectional encoder captures richer contextual relationships, making it particularly suited for abstractive summarization where rephrasing and coherence are critical. In contrast, T5's strength lies in its unified text-to-text approach, which simplifies adaptation to multiple tasks but may sacrifice summarization-specific optimization. Additionally, BART's larger default size (e.g., 12 encoder/decoder layers in bart-large) contributes to higher computational costs but enables deeper contextual processing, while T5-small trades capacity for efficiency with fewer parameters.

Among these models, the bart-large variants are the most computationally intensive, requiring significant resources for training and inference. Models such as distilbart-12-6 and distilbart-xsum-12-6 offer a balance between computational efficiency and summarization performance. Lighter models, including distilbart-6-6, distilbart-xsum-6-6, T5-small, and mT5-small, are more suitable for environments with constrained computational resources. These differences in model architecture and computational requirements enable the selection of an appropriate model based on document length, and the nature of the generated summary. The structural differences in the models allow for varying trade-offs between processing speed, memory consumption, and summary quality.

5 Experimental Setup

This section details the steps taken in the implementation of the summarization models, including preprocessing, model training and hyperparameters.

5.1 Data Preprocessing

The first step in data preprocessing involved handling the tab-separated text file containing annotations. Since the news article texts and their corresponding annotations were stored separately, processing them efficiently required unifying them into a single JSON structure. This unified JSON file included the filename, article text, dominant narrative, and dominant sub-narrative. The annotations file was parsed, and for each entry, the corresponding news article text file was identified and combined.

The next step involved refining the text by removing specific prefixes that indicated the article type - `"URW:"` for Ukraine-Russia war articles and `"CC:"` for climate change articles. This ensured a cleaner input for subsequent processing. Following this, tokenization was performed using the Hugging Face tokenizer to prepare the text for model training. The tokenizer was applied to the input text with a maximum length of 1,024 tokens, truncating longer sequences. Similarly, the target summaries were tokenized with a maximum length of 512 tokens. The processed tokens were then structured into model inputs, with the tokenized summaries assigned as labels. The processed data looks as follows:

```
{
    "file": "EN_CC_100013.txt",
    "text": "Bill Gates Says He
       Is  The  Solution
       ...",
    "dominant_narrative": "CC:
       Criticism of climate
       movement",
    "dominant_subnarrative":
       "CC: Criticism of climate
       movement: Ad hominem
       attacks on key activists",
    "summary": "The text accuses
       climate activist Bill
       Gates for his alleged
       hypocritical behavior as
       he flies in private jets
       that pollute the
       environment while
       advocating for the
       climate cause."
}
```

The dominant_narrative, dominant_subnarrative, and the summary are concatenated together.

5.2 Model Training

The training process fine-tunes pre-trained summarization models using the Seq2SeqTrainer from the Hugging Face transformers library. The corpora that each model is trained on is listed in Table A1 in the Appendix.

The tokenized training data is fed into the model with a learning rate of 2e-5, a batch size of 16, and four training epochs. Weight decay is applied for regularization, and mixed-precision training (fp16) is enabled for efficiency. The training was conducted on an NVIDIA A100 GPU with 40GB of VRAM. The training loop includes evaluation at each epoch using the BERTScore metric, which assesses the generated summaries' precision, recall, and F1 score against reference texts. Table 2 summarizes the hyperparameters.

Hyperparameter	Value
Learning Rate	2e-5
Train Batch Size	16
Eval Batch Size	16
Weight Decay	0.01
Number of Epochs	4
FP16	True

Table 2: Hyperparameter Configuration for Training

6 Results

This section presents the results of the models on both the development and test sets. Table A2 in the Appendix illustrates the performance of various models on the development set. The best-performing model is distilbart-cnn-12-6, achieving a BERTScore of **0.74459**. This is the model that we submitted to the official test leaderboard.

Similarly, Table 3 summarizes the performance of different models on the test set, where the best-performing model is facebook/bart-large-xsum, with a BERTScore of **0.74707**. Both tables highlight the performance of BART-based models in comparison to other transformer models. In contrast, models such as T5, mT5, and FalconAI perform only marginally better than the baseline and exhibit significantly lower performance.

7 Conclusion

This work primarily explores the use of transformer-based models for news article summarization, demonstrating their effectiveness in generating concise and coherent summaries. The findings highlight the strong performance of BART-based models compared to other transformer models.

For future work, integrating large language models (LLMs) into the summarization process offers a promising direction, given their advanced capabilities and adaptability across diverse domains. Leveraging LLMs can enhance the quality and coherence of generated summaries, particularly in domain-specific and real-world applications. This integration opens up new possibilities for building more effective and context-aware summarization systems.

MINDS at SemEval-2025 Task 9: Multi-Task Transformers for Food Hazard Coarse-Fine Classification

Flavio Giobergia
Politecnico di Torino
Turin, Italy
flavio.giobergia@polito.it

Abstract

Food safety is a critical concern: hazardous incident reports need to be classified to be able to take appropriate measures in a timely manner. The SemEval-2025 Task 9 on Food Hazard Detection aims to classify food-related incident reports by identifying both the type of hazard and the product involved, at both coarse and fine levels of granularity. In this paper, we present our solution that approaches the problem by leveraging two independent encoder-only transformer models, each fine-tuned separately to classify hazards and food products, at the two levels of granularity of interest. Experimental results show that our approach effectively addresses the classification task, achieving high-quality performance on both subtasks. We additionally include a discussion on potential improvements for future iterations, and a brief description of failed attempts. We make the code available at https://github.com/fgiobergia/SemEval2025-Task9.

1 Introduction

The success of Language Models has made it possible to annotate datasets with very limited human intervention. This is the case for a wide variety of tasks, including some with peculiar domains that make it difficult to obtain high-quality labels manually (e.g., classification of legal documents (Shaheen et al., 2020), or dialect detection (Koudounas et al., 2023)). This trend has enabled a thorough analysis of documents that could not be reasonably processed in acceptable times. Among these documents, there are life-critical ones such as the analysis of food-related incident reports (Randl et al., 2024). The Food Hazard Detection task (Randl et al., 2025) from SemEval 2025 focuses specifically on this challenge, with the goal of helping classify food incident reports collected from the web.

The proper classification of these incidents is a vital task, as it provides potentially life-saving insights. These insights are typically in the form of structured labels that indicate the type and severity of the hazard, such as contamination, mislabeling, or adulteration; as well as the specific, or category of food involved. Accurate classification enables regulatory bodies, food safety organizations, and the public to respond effectively by issuing warnings, recalling products, or implementing stricter safety measures.

The large quantities of incidents available online makes manual processing generally infeasible. As such, automated crawlers can be used to find food issues from web sources; whereas Natural Language Processing techniques can be adopted to correctly classify these documents based on (1) the type of food involved, and (2) the type of hazard described.

The task is focused on classifying incidents based on these two targets, at two different levels of granularity (coarse and fine). As a part of this paper, we note that there is limited correlation between the hazard and the type of food – as such, we address the task by proposing a solution based on the fine-tuning of two pretrained, encoder-only transformer-based models, that focus on different aspects of the problem. We show that the proposed solution achieves competitive performance, with a final ranking of 9^{th} place for subtask 1, 5^{th} place for subtask 2.

The rest of the paper is organized as follows. Section 2 describes the dataset and the task under study. We present the proposed approach, and the rationale for it, as a part of Section 3. The main results obtained are shown in Section 4, with some additional considerations on the choices made. We cover some of the failed attempted in Section 5 and the main limitations of the proposed approach in Section 6. Finally, Section 7 wraps up the paper with considerations on the task and solution.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2213–2218
July 31 - August 1, 2025

2 Problem description

The goal of the task is to correctly classify incidents available on the web. The dataset is provided in three splits: training data (5,082 samples), validation data (565 samples) and test data (997 samples). Each sample corresponds to the description of an incident. These incidents are taken from official food agency websites (e.g., FDA). For each incident, a set of attributes is known: some are structured (date and country); whereas others are textual (title and text). For training and validation data, the correct classification is also available. This classification consists of two attributes: the *hazard category* (10 classes) and the *product category* (22 classes). Each of these categories is further refined into a specific *hazard* (128 classes) and *product* (1,142 classes). Each text is labeled by two food science or food technology experts. The first subtask (ST1) of the challenge consists in predicting the hazard and product categories, whereas the second one (ST2) aims to predict the specific hazard and product. For convenience, we report in Table 1 an instance of an incident, with all available information.

For ST2, the main metric of interest is $F_1^{(ST2)} = (F_1^{(h)} + F_1^{(p|h)})/2$. Here, $F_1^{(h)}$ is the macro F_1 score for the hazard classification problem; whereas $F_1^{(p|h)}$ is the macro F_1 score, computed *only* on samples whose hazard has been correctly predicted. For ST1, we adopt a metric computed in a similar way, $F_1^{(ST1)} = (F_1^{(hc)} + F_1^{(pc|hc)})/2$, using the F_1 scores for the hazard and product categories. This choice of metrics places additional importance on the identification of the correct hazard: failure to do so results in a 0 score being achieved, regardless of the performance on the product identification problem.

3 Proposed methodology

The proposed solution consists of two separate encoder-only, pretrained transformers fine-tuned on the fine-coarse dual prediction problem.

We first discuss the rationale behind using two models, each working on a dual granularity. Next, we present the main details of the adopted solution.

3.1 Targets correlations

Multi-task learning allows to exploit useful information from related learning tasks (Zhang and Yang, 2018). Based on this knowledge, a promising approach to improve a classic transformer-based classifier is to introduce a single backbone, with multiple tasks being aggregated into a single loss function. However, this approach only works if the four target categories are somewhat related. To quantify the relationships between the four targets, we compute the pair-wise Adjusted Mutual Information (AMI) between the targets. The AMI is a version of Mutual Information, which quantifies how mutually dependent (correlated) two variables are (i.e., how informative knowing one variable is in predicting the other one). We remark that some of the targets have a large number of possible classes (up to hundreds, or thousands). As a consequence, we make use of the Adjusted verison of MI, which accounts for random chance and the fact that a large number of clusters tends to produce a higher MI score. We report the pair-wise AMI as a part of Figure 1.

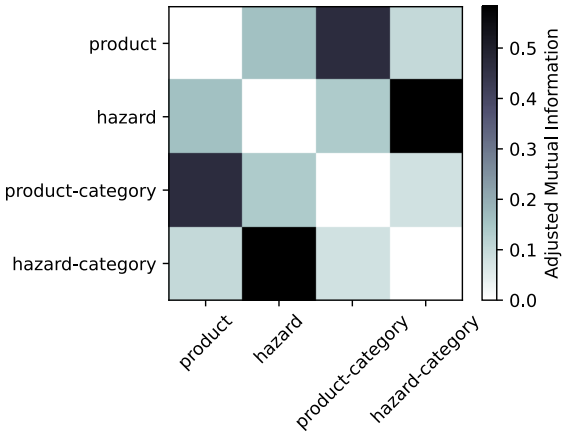

Figure 1: Adjusted Mutual Information between pairs of targets. Fine-coarse categories have high AMI, whereas different categories show lower correlation.

It is clear from this result that the strongest correlation exists between the fine and coarse versions of each target. This is to be expected, because of the hierarchical nature of the relationship. However, the figure also highlights a low correlation between the two targets (product, hazard). This is true for both fine-grained and coarse results. From a domain-agnostic perspective, this may be considered, in many cases, reasonable: a hazard (e.g., the presence of a foreign piece of plastic) is not necessarily related to the type of food affected. Based on these insights, we adopt two separate models: one addressing the coarse-fine prediction of products, the other addressing the coarse-fine prediction of hazards.

Table 1: Example for an incident report. In blue are the time/location metadata, in orange are the text information, in green are the four target classes. Underlined is the information useful to identify the product and product category, in *italic* is the information useful to identify the hazard and hazard category.

year	2014	**hazard-category**	allergens
month	5	**product-category**	ices and desserts
day	4	**hazard**	eggs and products thereof
country	us	**product**	ice cream
title	2013 - Blue Bunny Premium Bordeaux Cherry Chocolate Ice Cream Recalled for *Undeclared Allergen*		
text	Wells Enterprises, Inc., maker of Blue Bunny ice cream said today it has recalled Blue Bunny Premium Bordeaux Cherry Chocolate Ice Cream sold at retail grocery stores in Kansas, Indiana and Iowa because the product may contain *egg* not declared on the label.		

3.2 Adopted architecture

We adopt the same architecture for both models. We rely on a pretrained encoder-only transformer model (e.g., BERT (Devlin et al., 2019), RoBERTa (Liu et al., 2019)). We use, as the representation of each incident, the $title$ and the $text$. We tokenize the two as two distinct [SEP]-separated sentences (i.e., making use of Sentence A and B in BERT-like models). We define d as the encoder's hidden size, and n_f and n_c as the fine-grained and the coarse number of classes, respectively. We adopt the output for the [CLS] token as a summary vector $v \in \mathbb{R}^d$ of the entire incident,

$$v = encoder([CLS] \;||\; title \;||\; [SEP] \;||\; text) \;,$$

where $\cdot||\cdot$ represents a concatenation operation. We use v as the input to two classifications heads: one for the fine-grained task, the other for the coarse task. Both classification heads are characterized by an initial $d \times d$ layer, followed by a non-linearity (ReLU) and a linear layer that projects the results into n_f- and n_c-dimensional outputs, thus producing the logits $\hat{y}_f \in \mathbb{R}^{n_f}$ and $\hat{y}_c \in \mathbb{R}^{n_c}$ for the two tasks. Assuming a ground truth y_c and y_f for the two problems, we define the multi-task loss function as the cross-entropies for the two granularities, with a scaling factor λ to regulate the weight between the two targets:

$$\mathcal{L} = \sum_i y_{n_c,i} log(\hat{y}_{n_c,i}) + \lambda \sum_j y_{n_f,j} log(\hat{y}_{n_f,j}) \;.$$

We separately build one model to predict hazards, and the other to predict products involved.

4 Experimental results

We report, as a part of this section, the main results obtained. First, we present an initial overview of the metrics reported. Then, we study the performance of the proposed pipeline, using different backbone models. We further study the results that would be obtained by framing the problem in different ways. Finally, we mention the main hyperparameters adopted for the solution.

4.1 Metrics

We use, as the main metric of interest, the average macro F_1 score – as reported in Section 2, i.e., $F_1^{(ST1)}$ and $F_1^{(ST2)}$. Although these metrics summarize the quality of the solution on the entire task, we additionally report the performance for each task, separately. Based on the large number of classes, and the heavy class imbalance, we choose the macro F_1 score, for each subtask, as the most suitable metric. For ST1, we report the F_1 score for the product and the hazard categories ($F_1^{(pc)}$ and $F_1^{(hc)}$, respectively); whereas for ST2, we report the F_1 score for the specific product and the hazard ($F_1^{(p)}$ and $F_1^{(c)}$, respectively).

4.2 Backbone selection

The proposed approach heavily relies on a valid selection of the backbone model used for the encoding of the incident text and title. A wide variety of encoder-only transformers exist in literature. Based on their popularity, we adopted three possible encoders: BERT (base, large) (Devlin et al., 2019) and RoBERTa (large) (Liu et al., 2019). We report the results obtained in Table 2.

	Subtask 1 (coarse)			Subtask 2 (fine)		
	$\mathbf{F_1^{(hc)}}$	$\mathbf{F_1^{(pc)}}$	$\mathbf{F_1^{(ST1)}}$	$\mathbf{F_1^{(h)}}$	$\mathbf{F_1^{(p)}}$	$\mathbf{F_1^{(ST2)}}$
BERT base	**0.789 ± 0.004**	0.653 ± 0.004	0.721 ± 0.001	0.569 ± 0.013	0.241 ± 0.005	0.405 ± 0.007
BERT large	0.777 ± 0.009	0.708 ± 0.002	0.743 ± 0.005	**0.626 ± 0.006**	0.305 ± 0.003	0.461 ± 0.006
RoBERTa large	0.783 ± 0.007	**0.723 ± 0.005**	**0.754 ± 0.005**	0.625 ± 0.010	**0.337 ± 0.009**	**0.479 ± 0.003**

Table 2: Performance on the various classification problems, for the main solution proposed. Best results for each metric highlighted in **bold**, second best is underlined.

The results clearly show that RoBERTa achieves the best performance in terms of task-related metrics of interest; as well as the best performance for the product-related metrics. Interestingly, RoBERTa is the second-best performer for the hazard categories; with BERT obtaining better results.

4.3 Alternative tasks & baselines

In Section 3, we argue that the most promising multi-task approach appears to be the one with two separate models on fine-coarse targets. Producing a single 4-task solution did not appear to be promising, given the low Mutual Information between products and hazards. We empirically verify this claim, showing that building a single model, trained on 4 tasks, does provide any particular benefit.

For fairness of comparisons, all solutions are trained with the same computing budget, evenly distributed across models. The proposed solution uses 7 + 7 training epochs (7 for each model). As such, we train the single 4-task model for 14 epochs. We adopt the same 1:5 ratio of scaling factors between coarse and fine tasks, as it has provided the best results for the proposed solution.

The results are reported in Table 3. The results obtained are mostly comparable with those achieved by the RoBERTa-based proposed solution. Interestingly, RoBERTa achieves better performance on the fine-grained versions of the problem. The four-task version generally achieves slightly better performance on the coarse problems. Although the "best" result is obtained by using the dual-task to solve Subtask 2, and the four-task version to solve Subtask 1, we propose, for consistency, a single solution based on two dual-task models.

We also report results obtained for a baseline method, namely a Random Forest, trained on (1) the TF-IDF representation (Sparck Jones, 1972) of each document, or (2) the average word embeddings for each word contained in the title and text, using FastText (Bojanowski et al., 2017). Computing the average word vector (i.e., using distributed bags of words) is a commonly adopted approach with traditional word embeddings, as done in several works (Le and Mikolov, 2014; Giobergia et al., 2020; Reimers and Gurevych, 2019), despite losing the order among words. These baselines provide better context for the difficulty of the problem. The proposed approach significantly outperforms both. Interestingly, the TF-IDF version shows better performance than FT. We expect this to be the case due to the technical nature of the problem: without proper fine-tuning, the word embeddings cannot capture the domain-specific nuances of the problem.

4.4 Hyperparameters

We conducted a tuning phase to identify the best configuration of hyperparameters, by making use of the development set available. The best set of hyperparameters is reported in Table 4. In the interest of limiting the computing cost of this operation, we only tuned a subset of all reported hyperparameters; using well-established values for the others.

5 Failed attempts

In this section, we present some of the attempts that have been considered, but that did not yield promising results.

Hierarchical knowledge injection The fine-coarse labels follow a well-defined hierarchy. In literature, several approaches have been proposed to address hierarchical multi-label classification problems coherently (Giunchiglia and Lukasiewicz, 2020). Based on intuition and experimental results, we additionally acknowledge that predicting the coarse label is an easier task, w.r.t. the prediction of the fine-grained version of the same label. It stands to reason, therefore, that the fine label should be conditioned by the predicted coarse label. Conditioning the fine label choice provides an advantage in early training stages (when the model has not yet learned the relationship between fine

	Subtask 1 (coarse)			Subtask 2 (fine)

RoBERTa large (4-task)	0.777 ± 0.012	0.729 ± 0.010	0.755 ± 0.003	0.617 ± 0.004	0.289 ± 0.022	0.456 ± 0.010
RF (250 est.) + TF-IDF	0.566 ± 0.010	0.458 ± 0.007	0.528 ± 0.010	0.294 ± 0.008	0.186 ± 0.004	0.256 ± 0.007
RF (250 est.) + FT	0.389 ± 0.042	0.348 ± 0.011	0.367 ± 0.036	0.197 ± 0.015	0.112 ± 0.008	0.185 ± 0.011
Proposed (RoBERTa)	0.783 ± 0.007	0.723 ± 0.005	0.754 ± 0.005	**0.625 ± 0.010**	**0.337 ± 0.009**	**0.479 ± 0.003**

Table 3: Performance on the various classification problems, for other baselines models. Best results for each metric highlighted in **bold**. Second best is underlined.

Hyperparameter	Value
number of epochs	7
batch size	8
warmup	500 steps
learning rate	$5 \cdot 10^{-5}$
weight decay	0.01
λ	5

Table 4: Main hyperparameters used for the proposed solution.

and coarse labels), but the improvement wanes as the training continues, resulting in no substantial advantage over the base solution.

In-Context Learning (ICL) Large Language Models can easily be used for the labelling of documents (e.g., social media posts (Tan et al., 2024), scientific papers (Giobergia et al., 2024), or news articles(Li et al., 2024)). It stands to reason, thus, that these models should be able to perform competitively in this classification task as well. We attempted various few-shot prompt engineering approaches, using LLMs on the small end of the scale (e.g., Llama 3.1 8B (Dubey et al., 2024)). However, as is well-known in literature, ICL can be outperformed by task-specific, fine-tuned SOTA models (Brown et al., 2020). This was the case for this challenge, where the available training data was sufficient to produce an adequately fine-tuned classifier.

6 Limitations

We acknowledge several limitations in the proposed approach, as indicated by the average results obtained in the public leaderboard (9^{th} place for subtask 1, 5^{th} place for subtask 2). Among them, there is the usage of only the textual information, without considering temporal and spatial information available. In addition, we make a rather strong assumption of independence between products and hazards. While initial results pointed in that direction, we may assume that further explorations could potentially reveal that a single multi-task solution, if properly defined, may yield even better performance. Finally, we note that the problem is characterized by a heavy class imbalance: simple attempts to mitigate this problem (e.g., introducing different weighting schemes for different classes) did not produce promising results. However, more sophisticated approaches (e.g., with data augmentation to increase dataset size and variety (Bayer et al., 2022), or contrastive learning to reduce model biases (Koudounas et al., 2024)) may still be explored to provide additional benefits.

7 Discussion and conclusions

In this paper we discussed a solution to the Food Hazard Detection task of SemEval 2025. The task, framed as a multi-task learning problem, highlighted how hierarchical labels can benefit from being predicted together. We show that we observed no clear benefit in simultaneously predicting results across the two targets (product, hazard). This can be explained given the low Mutual Information observed between the two labels, at all levels of granularity. We presented experimental results that corroborate the claims made and that allow to identify a candidate solution. We finally covered some of the attempts that appeared to be promising, but that did not yield any meaningful improvement.

MINDS at SemEval-2025 Task 8: Question Answering Over Tabular Data via Large Language Model-generated SQL Queries

Flavio Giobergia
Politecnico di Torino
Turin, Italy
flavio.giobergia@polito.it

Abstract

The growing capabilities of Large Language Models (LLMs) have opened up new opportunities for answering questions based on structured data. However, LLMs often struggle to directly handle tabular data and provide accurate, grounded answers. This paper addresses the challenge of Question Answering (QA) over tabular data, specifically in the context of SemEval-2025 Task 8. We propose an LLM-based pipeline that generates SQL queries to extract answers from tabular datasets. Our system leverages In-Context Learning to produce queries, which are then executed on structured tables, to produce the final answers. We demonstrate that our solution performs effectively in a few-shot setup and scales well across tables of different sizes. Additionally, we conduct a data-driven error analysis to highlight scenarios where the model encounters difficulties. We make the code available at https://github.com/fgiobergia/SemEval2025-Task8.

1 Introduction

The introduction of general purpose Large Language Models has made it possible to address a wide variety of tasks, with no need to fine-tune a specific model every time. This capability has enabled a widespread adoption of LLMs to address a wide variety of tasks (e.g., machine translation (Xu et al., 2024), document classification (Giobergia et al., 2024) and summarization (Pu et al., 2023)). However, these models often provide answers that are either based on the data available in the training data (i.e., they cannot leverage external data), or that are not grounded in factual data – a phenomenon referred to as hallucinations. This can lead to issues like generating inaccurate facts, fabricating citations, or incorrect summarizations despite the model seeming confident in its output.

Although attempts have been made to detect and mitigate hallucinations (Ji et al., 2023; Borra et al., 2024), off-the-shelf models used for In-Context Learning still cannot provide meaningful answers to questions related to a specific data source, unless access to the data source itself is provided. One such example is the answering of questions that can only be addressed based on the contents of a separate data source. The SemEval 2025 Task 8 – Question Answering Over Tabular Data (Osés Grijalba et al., 2025) addresses exactly this kind of scenario, by framing a Question Answering (QA) problem, with answers that can be extracted from tabular data. In this paper we address the challenge by building a LLM-based pipeline that receives information on the structure of the target table, produces a SQL query to answer the question, and provides a final answer by executing the query on the tabular data. We show that the proposed solution achieves remarkable results in few-shot mode, and that it provides satisfactory performance regardless of table size. We additionally perform a data-driven error analysis to identify corner cases that the LLM cannot easily address; and improve model performance by manually labelling useful cases to be used as shots within the prompt.

The rest of the paper is organized as follows: Section 2 introduces the task, dataset and metrics. Section 3 presents the main methodology adopted, with an overview of the pipeline, as well as the error analysis that has been conducted to identify promising shots to be used. Section 4 presents the main results obtained. Finally, Section 5 wraps up the paper, with considerations and possible future extensions of the work.

2 Problem description

SemEval Task 8 consists in addressing QA problems based on tabular data. To this end, the Task makes use of DataBench (Grijalba et al., 2024). DataBench is the first benchmark that makes use of real-world tables, with a wide variety of distinct questions related to various data types. Answers to the questions are in the form of either a number, a

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2219–2224

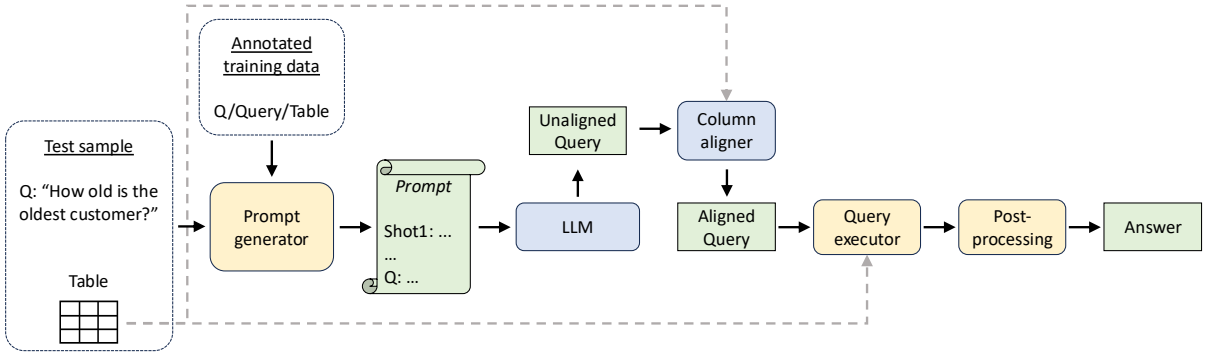

Figure 1: Overview of the architecture for the proposed solution. In green are the results produced (intermediate, e.g. queries, and final, i.e. the answer). In blue are the LM-based components of the solution. In yellow are the pre- and post-processing steps.

categorical value, a boolean value or lists of several types. DataBench includes a training set (49 tables, 988 questions), a validation set (16 tables, 320 questions) and a test set, specifically released for SemEval (15 tables, 522 questions).

The challenge consists of two subtasks: a *full* one, where the entire table (all rows, all columns) are used, and a *lite* one, where only a subset of all rows and columns are used.

The quality of the provided answers is quantified in terms of the fraction of correctly answered questions (i.e., accuracy).

3 Proposed methodology

We present the architecture of the overall solution in Figure 1. The architecture takes any one question (and related table) and produces the prompt with the *prompt generator*. Next, this prompt is used to generate an answer query from an LLM. This *unaligned query* may contain some errors that are adjusted by a *column aligner* module. The correct query is then automatically executed on the target SQLite table. The answer returned by the query is post-processed to produce the final answer. The rest of this section presents, in more details, the various blocks.

3.1 Prompt generator

The prompt generator is used to produce the prompt for the LLM. The prompt is comprised of three parts: (1) the general description of the task to be addressed (i.e., producing the query that answers a question), (2) some examples (shots) of questions, summaries of tables, and queries that are expected as the answer, and (3) the actual question and table summary to be addressed by the LLM.

```
The following are examples of
question/table/answer.
Provide the answer to the last
question. Only include the query.
Use exactly the specified column names,
as reported between backticks ``.
If the answer is boolean, use CASE WHEN
... THEN ... ELSE ... END.

Question: [Question for shot 1]
Table (`column name`: list of values):
`column1`: value1, value2, value3, ...
`column2`: value4, value5, value6, ...
`column3`: value7, value8, value9, ...
...
Answer: [Query for shot 1]

[shot 2]
...
Question: [Test question]
Table (`column name`: list of values):
[Test table]
Answer:
```

Listing 1: Example of a prompt used in our experiments. In blue is the problem description, in orange the shots, in green the actual question.

We report in Listing 1 a summarized prompt. As shown, each shot is represented as a triplet (Question, Table, Answer). The *Question* is the natural language question that needs to be addressed. The *Table* is a list of columns found in the table of interest. For each column, in addition to the column name, a few (5, in our case) sample values are reported. The *Answer* is the query that can be executed on the specified table to extract the correct answer. We note that the training set does not contain queries associated to the actual answers. We discuss the annotation process of a limited number of queries as a part of Section 3.5. The final question is appended at the end of the list of shots. Because of memory limitations, we limit the number of shots used in the prompt to 7.

Finally, we note that the usage of the `CASE ... WHEN ... THEN ... ELSE ... END` allows the model to directly return true/false answers, instead of 0/1. This is convenient to simplify the post-processing step. We empirically verified that the models adopt the pattern correctly if explicitly asked to do so in the prompt, and if the shots contain such examples.

3.2 Large Language Model

The key component for the proposed solution is an LLM, that produces the query to address the answer. We considered small and medium LLMs that have been specifically fine-tuned on code generation tasks, and that have been instruction-tuned. More specifically, we identified the two most promising candidates in Code Llama 7b and 34b (Roziere et al., 2023), Codestral 22b (MistralAI, 2024) and Qwen2.5-Coder 32b (Hui et al., 2024). The experimental section contains a comparison between the two models.

The output of the model is, in general, a valid query that can be executed. However, a further alignment step is required, in some cases, to guarantee that the columns adopted in the query actually exist.

3.3 Column aligner

We note that, when generating the query, the LLM sometimes struggles to correctly specify some of the column names; despite receiving the correct names as a part of the prompt. To fix this problem, we introduce a step of semantic alignment, to replace invalid generated columns with correct ones.

This problem likely stems from the fact that the model struggles to use the correct names, if they contain non-SQL-standard characters. For instance, in dataset `054_Joe`, one of the attribute names is `author_name<gx:category>`. This attribute is always used as `author_name` in the LLM-generated queries, resulting in the execution of invalid queries.

Since the model wraps all column names with backticks ``, we can easily extract the set C_Q of columns used in the generated queries. The set C_V of valid column names is also known from the table schema. If $C_Q \setminus C_V \neq \emptyset$, some columns adopted in the query are not part of the available columns. Only for those columns, we apply an alignment step based on semantic similarity.

We adopt a pre-trained encoder-only transformer model (e.g., BERT (Devlin et al., 2019)) to produce vector encodings for the columns in $C_Q \setminus C_V$ (the columns to be replaced), and for columns in C_V (the columns to be used for the replacements). We replace each invalid column with the most similar valid column (based on cosine similarity). We acknowledge that using BERT for the encoding of column names (i.e., short strings of text, without adequate context) goes against the rationale of the model. Alternative approaches (e.g., fastText (Mikolov et al., 2018)) also allow generating vector representations for words, without requiring a context. This is also true for representations across multiple languages (Grave et al., 2018) and tasks (e.g., sentiment analysis (Giobergia et al., 2020)), even for out-of-vocabulary words (Savelli and Giobergia, 2024): both properties could be useful, when handling column names. However, we empirically observe satisfactory results even for BERT, and use it despite the lack of a context.

3.4 Query executor and post-processing

The Parquet datasets are converted into SQLite tables, which are then used to run the SQL queries generated by the LLM. This step can produce an error, if a query is not valid. In this work, we do not include iterative steps to improve the quality of the results. However, it is reasonable to assume that the results could benefit from it. If the query executes correctly, the result is adjusted during a final, very simple post-processing step, to produce the final answer (for instance, length-1 lists of values are returned as a single value).

Medoid question	Closest Train question
What are the bottom 2 languages in terms of tweet count?	Which are the top 4 events with the highest average number of comments?
Has the author with the highest number of followers ever been verified?	What is the maximum number of reviews a property has received?
Identify the top 3 foods with the least amount of sugar.	Identify the 3 departments with the lowest average satisfaction levels.
How many respondents are from the region adjacent to the South Atlantic Ocean?	How many participants are from the United Kingdom?

Table 1: Questions for the 4 clusters (as defined by their medoids), with corresponding most similar questions (via cosine similarity) in the training set. The questions in the training set (and corresponding manually annotated queries) have been included as a part of the prompt.

3.5 Error analysis

We initially annotated a small number of questions with the corresponding SQL query. This pool of annotations provides the intial shots used in the definition of the prompts. We then run the proposed pipeline, on the validation set. We isolate the cases that produce incorrect answers, and try to identify the most recurring types of questions that cannot be addressed by the LLM. To identify common patterns in incorrectly answered questions, we use clustering. We first build a vector representation for each incorrectly answered question, using an encoder-only model (e.g., RoBERTa large (Liu et al., 2019)). Then, we apply K-medoids (Park and Jun, 2009) to identify 4 clusters[1] of questions, with the corresponding medoids (i.e., the most representative question, for each cluster). Finally, we identify, among the training questions, the most semantically similar ones[2] to each of the medoids. We manually annotate those 4 questions with the corresponding queries, which are then included as a part of the prompt. We show, in Table 1, the medoids (from the validation set), paired with the corresponding most similar training question.

[1]The number of clusters has been selected based the total number of shots that could be included in the prompt.

[2]Based on the cosine similarity computed on the latent vectors.

Model	Accuracy (full)	Accuracy (lite)
Code Llama 7b	49.81	52.87
Code Llama 34b*	6.70	60.34
Codestral v0.1 22b*	**72.41**	**74.14**
Qwen2.5-Coder 32b*	<u>72.03</u>	<u>69.92</u>

Table 2: Performance, in terms of accuracy, on the full and lite tasks, using three different LLMs. (*) represents models that have been quantized with PTQ, on 4 bits. Best result in **bold**, second best <u>underlined</u>.

4 Experimental results

We present the main results obtained using the proposed pipeline. First, we evaluate the performance for different LLMs. Next, we highlight some of the limitations in the responses generated by the different models.

4.1 Main results

We test four separate instruction-tuned LLMs, trained on code generation tasks: Code Llama 7b, Code Llama 34b (Roziere et al., 2023), Codestral v0.1. 22b (MistralAI, 2024) and Qwen2.5-Coder 32b (Hui et al., 2024).

We quantized CodeLlama 34b, Codestral 22b and Qwen2.5-Coder 32b with Post-Training Quantization (PTQ) on 4 bits, to execute them on the available hardware.

Table 2 presents the main results obtained on the full and lite tasks, in terms of accuracy, using the proposed solution.

Interstingly, Codestral emerges as the clear winner, on both tasks, closely followed by Qwen2.5-Coder. Interestingly, in the Code Llama family, the 7b version obtains more consistent performance across the tasks, whereas the 34b version obtains abysmally low performance on one task, and reasonable results on the other – despite the minor differences between the tasks.

4.2 Common mistakes

We note that the proposed approach sometimes produces SQL queries that cannot be executed. For such cases, the answer to the question is left blank. Table 3 reports the number of blank answers given by the four models under study.

This result helps explain the poor performance obtained by Code Llama 34b, especially for the full task: a large number of answers is in the form of queries that do not execute correctly. Upon manual inspection, we note that Code Llama 34b often

Model	% missing (full)	% missing (lite)
Code Llama 7b	**7.47**	**7.85**
Code Llama 34b*	18.42	10.34
Codestral v0.1 22b*	<u>7.85</u>	<u>8.05</u>
Qwen2.5-Coder 32b*	12.26	15.71

Table 3: Fraction of missed queries, for each model (i.e., queries that did not correctly execute). (*) represents models that have been quantized with PTQ, on 4 bits. Best result in **bold**, second best <u>underlined</u>.

returns answers in natural language that do not include the requested query (e.g., by attempting to answer the question directly, or providing irrelevant comments). Other models do not behave as poorly, with consistent behaviors between the two tasks. Qwen2.5-Coder, interestingly, produces a large number of empty results[3]. Despite this high percentage of blank answers, it is impressive that Qwen2.5-Coder achieved the second-best performance: we argue that, if this behavior was to be limited (e.g., with sufficient prompt engineering, which has not been carried out in this work), Qwen could prove to be an even more competitive solution.

We highlight an additional problem often found in incorrect answer for some of the models. This common error consists in returning a list of values when a single, aggregate one was expected. This is the case, for example, with questions that require an answer on the overall behavior across the dataset. For instance, the question *are all employees older than 20?* has a single true/false outcome. The question should be addressed using a query such as `SELECT COUNT(*) = (CASE WHEN age > 20 THEN 1 END) FROM data`. Instead, models often incorrectly produce a query that returns an outcome for each entry in the table, such as `SELECT age > 20 FROM data`.

Answers obtained from these queries are generally much longer than valid answers. Based on this consideration, Figure 2 presents the distribution in answer lengths for the models considered, on the *full* task. Longer answers (300+ characters) are generally linked with incorrect results. Interestingly, all models but Qwen2.5-Coder present several of these failure cases. In particular, Code Llama 7b is affected by this problem the most.

We attempted to mitigate this problem by introducing specific shots that provide correct queries. However, those shots only marginally helped: as soon as a slightly different request was encountered, the LLM reverted to the undesired behavior.

[3]We additionally note that we failed to test the 7b version, as it consistently produced invalid responses.

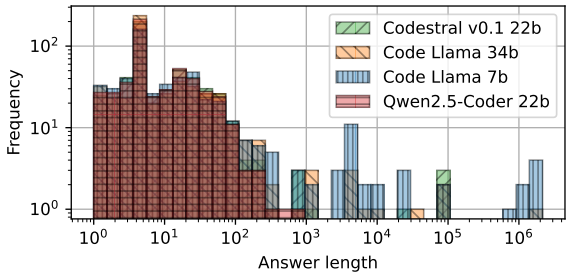

Figure 2: Distribution of the length of the answers obtained by executing the queries generated by different models. Lengths above 2-300 characters can generally be considered as the result of faulty queries.

5 Discussion and conclusions

In this paper we presented a solution to the QA problem on tabular data from SemEval 2025 Task 8. The solution is based on generating SQL queries that are executed to produce answers to the proposed questions. We make use of an instruction-tuned LLM trained for code generation. We show that the pipeline allows to achieve acceptable performance. We tested several models and find Codestral v0.1 22b to be the one providing the most accurate results. Interestingly, almost all considered models show no gap in performance between the full and the lite versions of the task, indicating robustness to noisy information (e.g., the presence of unused columns). We acknowledge that one of the main limitations of the proposed approach is the conversion of the datasets into SQLite tables: the original Parquet datasets contain potentially complex data types (e.g., lists of values), which cannot be easily cast into SQLite columns. As such, we expect that a transposition of the proposed solution to other querying approaches (e.g., Python-based) may yield even more promising results.

Abstract

Emotion detection in text is particularly challenging for low-resource languages due to linguistic diversity and cultural nuances. To promote inclusivity, SemEval introduces a multilingual, multi-label emotion dataset spanning several low-resource languages. We analyze this dataset to examine cross-lingual emotion distribution and address the performance limitations of existing models, which often overfit to high-resource language patterns. We propose AfroEmo, a multilingual emotion classification model built on Afro-XLM-R. Our approach involves adaptive pre-training on domain-specific corpora, followed by fine-tuning on the shared task dataset. We evaluate our model using Macro-F1, Micro-F1, and other official metrics. AfroEmo achieves a Macro-F1 of 0.71 on Amharic and shows strong generalization to Hausa and Yoruba. We further conduct an ablation study and error analysis to assess the contributions of each model component.

1 Introduction

Emotion detection refers to the process of identifying and interpreting human emotions by analyzing indicators such as body language, tone of voice, facial expressions, and physiological signals. It has broad applications across multiple domains, such as in mental health for detecting depression and emotional distress (Calvo et al., 2015; Baziotis et al., 2018; Almutairi et al., 2024), enhancing customer service engagement (Cambria et al., 2017; Poria et al., 2019), improving cross-cultural communication (Colombo et al., 2020) and in conversational agents to create more emotionally intelligent interactions (Kusal et al., 2024). Traditionally, emotion detection is performed in a monolingual setting. However, researchers have attempted to shift the paradigm toward multilingual emotion detection. Shifting from monolingual to multilingual emotion detection poses challenges, including data scarcity, linguistic diversity, reduced model interpretability across languages (Wang et al., 2024; De Bruyne, 2023; Zhang et al., 2024) and the complexities of code-switching (Wang et al., 2024; De Bruyne, 2023; Zhang et al., 2024). For example, detecting sentiment in an Urdu-English code-mixed sentence like '*I am feeling so udaas today*" ("*udaas*" meaning "*sad*" in Urdu) requires nuanced interpretation that many models lack. Low-resource languages exacerbate these issues (Muhammad et al., 2023), as existing pre-trained models often focus on resource-rich languages (Devlin et al., 2019; Liu et al., 2019; Raffel et al., 2020), thus, failing to capture emotional subtleties in underrepresented languages (Tatariya et al., 2023). To address key challenges, SemEval-2025 Task 11 (Muhammad et al., 2025b) introduces a large-scale, low-resource multilingual emotion dataset. This dataset includes 32 languages from seven language families, featuring many underrepresented languages from Africa, Asia, and Latin America. It contains over 100,000 instances, manually annotated by native speakers across six emotion classes: Joy, Sadness, Fear, Anger, Surprise, and Disgust, with emotion intensity on a 4-point Likert scale (0 to 3). Consequently, in this work, we present the following contributions:

- An exploratory data analysis is performed to examine the distribution of emotional indices across multiple low-resource languages.
- We develop a robust multilingual emotion detection model for low-resource languages based on Afro-XLM-R. Our model consists of a two-stage process: adaptive pre-training to improve low-resource language understanding, followed by fine-tuning with the multilingual emotion dataset. The source code is publicly available on GitHub.
- Our empirical evaluation shows strong performance on the test set, ranking among the top

*Corresponding author: raja-khurram.shahzad@miun.se

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2225–2232

systems on the benchmark.

- We also conduct error analysis and an ablation study assessing model's performance and two-stage process.

2 Related Work

2.1 Monolingual

Monolingual emotion detection focuses on identifying emotions within a single language. Supervised and lexicon-based methods perform well on labeled datasets, especially when paired with techniques like TF-IDF and word embeddings (Malagi et al., 2023). Deep learning plays a central role, with convolutional neural networks (CNNs) capturing emotion-bearing phrases and Bidirectional LSTMs (BiLSTMs) enhancing contextual understanding (Trimukhe et al., 2024; V and K J, 2024). Integrating BERT with BiLSTM or parallel CNN blocks further improves performance by leveraging contextual and bidirectional representations. Psycholinguistic features also contribute to higher accuracy in monolingual settings (Juyal and Kundalya, 2023).

2.2 Multilingual

Recent work increasingly targets multilingual emotion detection in low-resource languages. Muhammad et al. (2023) introduce AfriSenti-SemEval, while Raihan et al. (2024) present EmoMix-3L, highlighting the value of pre-trained models like MuRIL. Ameer et al. (2023) propose a multi-attention RoBERTa model for multi-label emotion classification. Despite progress, transformer models such as Afro-XLM-R and XLM-RoBERTa still struggle with emotional subtleties. To address this, researchers improve transfer learning using models like BERT and GoEmotions, and explore cultural context to enhance accuracy (Barnes et al., 2022). Other efforts focus on automatic feature selection (Haider et al., 2021) and evaluating large language models for multilingual, multi-label emotion tasks (Belay et al., 2025).

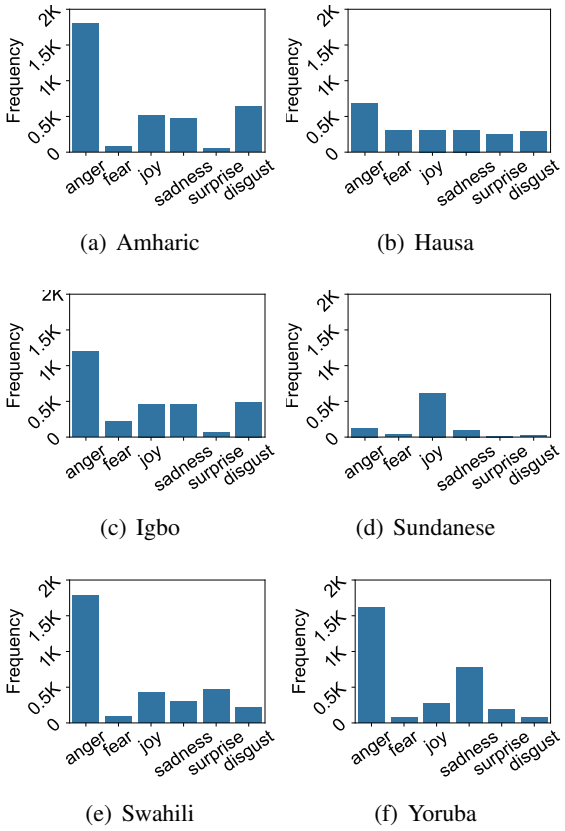
In summary, while traditional methods offer interpretability, deep learning—especially transformer-based models dominates monolingual emotion detection. In multilingual contexts, transfer learning and curated datasets continue to advance the field, though challenges with nuanced emotions and domain variability remain.

Language	Train	Dev	Test	Total
Hausa (hau)	2,145	356	1,080	3,581
Igbo (ibo)	2,880	479	1,444	4,803
Sundanese (sun)	924	199	926	2,049
Swahili (swa)	3,307	551	1,656	5,514
Yoruba (yor)	2,992	497	1,500	4,989

Table 1: Overview of the multilingual emotion dataset.

3 Dataset Analysis

We perform an exploratory data analysis to gain insights of distribution of emotional indices across languages. Table 1 summarizes the dataset properties Hausa, Igbo, Swahili, Sundanese, and Yoruba (Muhammad et al., 2025a). The number of annotators per sample varies slightly, with social media and news articles serving as the primary data sources.



(a) Amharic (b) Hausa

(c) Igbo (d) Sundanese

(e) Swahili (f) Yoruba

Figure 1: Emotion distribution in all six languages

Figure 1 illustrates the distribution of six emotion categories—*anger, joy, sadness, fear, disgust, and surprise*—across six low-resource languages. A strong class imbalance is evident, with *anger* and *joy* dominating most languages, particularly Amharic, Igbo, and Yoruba. In contrast, Hausa exhibits a relatively more balanced distribution. Sundanese stands out with *joy* as the most prevalent

emotion. The limited representation of *surprise*, *disgust* and *fear* across most languages highlights the challenge of developing robust multilingual emotion classifiers, especially under low-resource and imbalanced conditions.

4 Proposed Model

We propose AfroEmo, a multilingual emotion detection model built upon the Afro-XLM-R Large architecture (Alabi et al., 2022), which comprises 24 transformer layers, each with 16 self-attention heads and a 4096-dimensional feedforward network. As shown in Figure 2, our training process consists of two stages: adaptive pre-training on domain-specific corpora and fine-tuning on a labeled multilingual emotion dataset. The implementation and data are publicly available on GitHub.[1]. Hereafter, we call our proposed model as AfroEmo.

4.1 Domain Corpus

We use a diverse set of corpora sourced from Hugging Face, focusing on low-resource African languages across a variety of domains including folklore, conversational text, and web-scraped content. We consider the following datasets: KerVerse (2023) for Amharic, Gurgurov (2023c) for Swahili, Gurgurov (2023b) for Sundanese, Gurgurov (2023a) for Igbo, and Babs (2023) for Hausa. Due to hardware limitations, we randomly sample approximately 30% of each corpus per epoch for adaptive pre-training. This sampling strategy enables efficient training while preserving linguistic diversity across domains. By resampling every epoch, we ensure sufficient exposure to the broader language distribution without overwhelming compute resources.

4.2 Adaptive Pre-training

In the first stage, we pretrain Afro-XLM-R using the masked language modeling (MLM) objective to adapt it to the domain-specific corpora. We apply a 15% token masking strategy, enabling the model to better capture contextual semantics in low-resource language settings. Inputs are tokenized and embedded before passing through the model's 24 transformer layers. The architecture includes a pooling layer, a feedforward layer with ReLU activation, a dense output layer matching vocabulary size, and a softmax layer to produce token probabilities.
We train the model for three epochs and evaluate it on domain-representative validation samples to ensure effective adaptation. This Pre-training phase aims to bridge the domain gap between the original training data and our target emotion detection task.

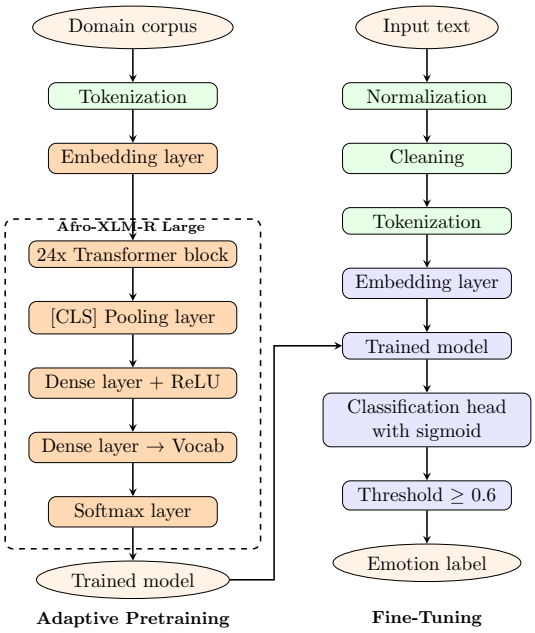


Figure 2: The base model for AfroEmo is Afro-XML-R. The first stage involves adaptive pre-training on domain-specific corpora. The second stage fine-tunes the model for multi-label multilingual emotion classification.

4.3 Preprocessing

Prior to fine-tuning, we preprocess the labeled emotion dataset. We perform the following preprocessing: (1) convert text to lowercase, (2) normalize non-ASCII characters to their ASCII equivalents, (3) remove emojis, special characters, and stopwords, and (4) apply subword tokenization to handle rare or out-of-vocabulary words. This preprocessing pipeline ensures clean, standardized input that emphasizes semantically meaningful content.

4.4 Fine-tuning

We fine-tune the adaptively pretrained model for multilingual, multi-label emotion classification. Emotion labels are converted to binary vectors to support multi-label learning. The classification head consists of two feedforward layers ($1024 \rightarrow 512$ with ReLU, followed by $512 \rightarrow 5$), a sigmoid activation function, and a final thresholding step (≥ 0.6) to produce binary emotion predictions. The model classifies each input into one or more of the five target emotion categories: *joy*, *anger*, *surprise*, *disgust*, and *sadness*.

[1] https://github.com/mhm930/NustTitans

5 Experimental Setup

5.1 Dataset

We adopt the official dataset splits provided by the SemEval-2025 Task 11 organizers. For each language (except Sundanese), the data is partitioned into 60% training, 10% development, and 30% test samples for each language except Sundanese. As Sundanese contains fewer samples (2049), it is split into 45% training, 10% development, and 45% test samples. We use the train and development sets for evaluating and tuning our model, while the final evaluation is conducted on the unseen test set.

5.2 Models

We compare our model with the following baselines: (1) LaBSE (Feng et al., 2022), (2) RemBERT (Chung et al., 2020), (3) XLM-R (Conneau et al., 2020), (4) mBERT (Devlin et al., 2019), and (5) mDeBERTa (He et al., 2020).

5.3 Evaluation

We evaluate the perfomance with given metrics by SemEval shared task: Macro F1-score, Micro F1-score, precision, recall, and accuracy. Macro F1 accounts for per-class performance, while Micro F1 is sensitive to class imbalance—making both essential for evaluating multi-label classification in low-resource settings.

5.4 Training Details

We conduct systematic experiments to identify optimal hyperparameters for both adaptive pre-training and fine-tuning phases. For adaptive pre-training, we use a learning rate of 2×10^{-5}, a training batch size of 8, an evaluation batch size of 16, and a maximum sequence length of 128 tokens for 3 epochs. We use a 15% token masking rate for the masked language modeling (MLM) objective and monitor validation loss to ensure effective domain adaptation.

The configuration settings for fine-tuning are as follows: a learning rate of 5×10^{-6}, a batch size of 8, and a sequence length of 128 tokens over the course of 20 epochs. We use binary cross-entropy loss as our training objective with a sigmoid activation function to enable the prediction of multiple emotion labels for each instance.

5.5 Libraries and Hardware

All experiments are conducted on Kaggle's cloud-based infrastructure, utilizing NVIDIA Tesla P100/T4 GPUs with 16GB RAM. The experiments are implemented in Python by using the following libraries. For preprocessing the input text, we use re, nltk, unidecode, sentencepiece, and nltk stopwords libraries. To transform the output, we use sklearn multi label binarizer. For adaptive pre-training and fine-tuning, we use Hugging Face's Trainer API.

Lang	Mic-F1	Mac-F1	Acc	P	R	Rank
Amh	0.90	**0.71**	0.53	0.70	0.73	**2**
Hau	0.88	**0.69**	0.51	0.68	0.71	**4**
Ibo	0.69	0.18	0.13	0.13	0.14	31
Yor	0.91	0.31	0.58	0.38	0.29	10
Swa	0.85	0.29	0.38	0.29	0.31	15

Table 2: Emotion classification results with Mac(ro)-F1, Mic(ro)-F1, Acc(uracy), P(recision), R(ecall) and Rank on the test dataset.

6 Results

We evaluate the performance of AfroEmo against multilingual baselines using standard metrics given by organizers.

6.1 Overall Performance

Table 2 summarizes AfroEmo's performance on the multilingual test set across a diverse set of languages, including both African and non-African. Among African languages, Amharic achieves the strongest results, attaining a Macro-F1 score of 0.71 and ranking second overall across all languages. Hausa follows with balanced metrics and ranks fourth, while Yoruba demonstrates moderate performance, particularly in precision (0.58) and joy detection (0.38), placing 13th. In contrast, Igbo and Sundanese show significantly lower recall and F1 scores, highlighting difficulties in generalization. Swahili falls in the mid-range, ranked 19th, suggesting partial adaptation.

The disparity between Macro-F1 and Micro-F1 scores reveals AfroEmo's sensitivity to class imbalance. While high Micro-F1 scores suggest the model captures dominant emotional expressions well, lower Macro-F1 scores across languages reflect its difficulty in detecting minority classes consistently—an ongoing challenge in multilingual, multi-label emotion classification.

6.2 Comparison with Baselines

Table 3 presents a comparison of the Macro-F1 scores achieved by AfroEmo and five baseline mod-

Model	Hau	Ibo	Yor	Swa	Sun	Avg.
LaBSE	0.38	0.18	0.11	0.21	**0.35**	0.25
RemBERT	0.31	0.74	0.53	0.19	0.19	**0.39**
XLM-R	0.16	0.10	0.66	0.17	0.26	0.27
mBERT	0.15	**0.99**	**0.96**	0.18	0.25	0.5
mDeBERTa	0.32	0.95	0.10	0.15	0.27	0.36
AfroEmo	**0.69**	0.18	0.31	**0.29**	**0.35**	0.36

Table 3: Macro-F1 comparison of AfroEmo with LaBSE, RemBERT, XLM-R, mBERT, mDeBERTa on five languages.

Emotion	Amh	Hau	Ibo	Yor	Swa	Sun
Anger	**0.67**	0.62	0.16	0.39	0.30	0.17
Disgust	0.77	**0.79**	0.23	0.13	0.21	0.19
Fear	0.64	**0.75**	0.04	0.00	0.17	0.00
Joy	**0.77**	0.71	0.40	0.38	0.41	0.83
Sadness	**0.75**	0.72	0.23	0.68	0.32	0.57
Surprise	**0.68**	0.57	0.02	0.30	0.35	0.32

Table 4: Emotion-wise Macro-F1 on the test dataset for all languages.

els: LaBSE, RemBERT, XLM-R, mBERT, and mDeBERTa. The proposed AfroEmo model outperforms the baselines in three languages—Hausa, Swahili, and Sundanese. While the average Macro-F1 score of AfroEmo is comparable to that of mDeBERTa, RemBERT achieves the highest overall performance. It is noteworthy that several of these baseline models are not evaluated on Amharic due to Vocabulary Limitation, as it is an underrepresented language, the best-performing low-resource language for AFroEmo. To improve the Macro-F1 score, class imbalance is addressed using techniques such as resampling, class weighting, and focal loss. However, these methods did not yield significant performance gains.

7 Discussion

Table 4 presents the Macro-F1 scores across six target languages for each emotion class, and Figure 1 shows the training distribution of those emotions. Together, they reveal several important insights about model performance and class imbalance.

7.1 Emotion Analysis

A clear pattern of class imbalance emerges across the training data, with *anger* being the most dominant emotion in nearly all languages—accounting for over 50% of the samples in languages such as Amharic, Igbo, and Swahili.

This skewness partially explains the relatively strong F1 scores for anger in some cases (e.g., 0.67 in Amharic, 0.62 in Hausa). However, frequency alone does not guarantee high performance: for instance, Igbo shows high anger frequency but yields a very low F1 score (0.16), likely due to a combination of limited training samples and linguistic complexity.

Conversely, *disgust*, *surprise*, and *fear* are consistently underrepresented—virtually absent in Sundanese—and correspondingly result in very low F1 scores (e.g., Fear is 0.00 in Sundanese and Yoruba; Surprise is 0.02 in Igbo). This highlights the vulnerability of emotion classification models to sparse training data, particularly for nuanced emotions.

Despite only moderate representation in most languages, *joy* demonstrates relatively strong performance, especially in Sundanese (F1 = 0.83) and Amharic (F1 = 0.77). This suggests that the model is better able to generalize joy-related patterns, potentially due to more consistent lexical cues or semantic clarity across languages.

Among the studied languages, Amharic and Hausa exhibit the most balanced class distributions and, correspondingly, perform best on several emotion categories. Amharic achieves the highest F1 scores for emotions such as *disgust*, *joy*, and *sadness*, with Hausa closely following. These results reaffirm the value of balanced training data in enhancing model robustness.

In contrast, languages with extreme class imbalance exhibit generally poor generalization, with uniformly low F1 scores across emotions—underscoring the limitations of even transfer learning in such settings.

Overall, this analysis reveals a strong link between class balance in training data and downstream performance, while also exposing persistent language-specific challenges. Addressing these issues may require more nuanced interventions, such as targeted data augmentation, synthetic oversampling of minority classes, or techniques like label smoothing to mitigate imbalance-induced bias in low-resource emotion detection.

7.2 Error Analysis

Despite AfroEmo's strong overall performance, several limitations persist in AfroEmo and require further investigation.

Emotion Confusion: The model frequently misclassifies *fear* as *sadness*, highlighting limitations in capturing fine-grained emotional distinctions. This suggests the need for more nuanced emotional representations, particularly for culturally sensitive emotions (see Table 4).

Sparse Classes: Emotions such as *disgust* and

surprise consistently yield low F1 scores, which correlates with their sparse presence in the training data. This imbalance constrains the model's learning capacity. Future work may benefit from class-balancing strategies such as data augmentation, oversampling, or curriculum learning.

Generalization: AfroEmo performs well on in-domain text, however, its performance deteriorates on unseen distributions. This underscores the need for more robust domain adaptation techniques to improve generalizability in real-world multilingual contexts.

7.3 Ablation Study

To quantify the contribution of each stage of the AfroEmo architecture, we conduct a series of ablation experiments focusing on adaptive pre-training, and fine-tuning for perceived emotions.

Removing the masked language modeling (MLM) step and directly fine-tuning Afro-XLM-R on the emotion dataset results in an average Macro-F1 drop of approximately 10% for low-resource languages like Hausa and Swahili. This demonstrates the critical role of domain-adaptive pre-training in enhancing contextual understanding of emotionally rich, morphologically complex languages.

Substituting Afro-XLM-R with a general-purpose multilingual model (XLM-RoBERTa) leads to consistent performance degradation across all metrics. This highlights the importance of Afro-XLM-R's linguistic specialization for African languages, which better captures regional nuances and syntactic patterns.

Excluding perceived emotion annotations and relying solely on explicit emotion labels causes a 4% decline in Macro-F1, particularly affecting culturally variable emotions like *fear* and *surprise*. This confirms the utility of incorporating perceived emotional signals to improve emotion disambiguation across culturally diverse language data.

To conclude, each component—adaptive pre-training, use of Afro-XLM-R, and perceived emotion integration—plays a vital role in enabling state-of-the-art performance in multilingual, low-resource emotion detection.

Conclusions

We present a novel approach to emotion detection in low-resource languages using an AfroXLM-R-based architecture-AfroEmo. It demonstrates strong performance, particularly on Amharic, setting a new benchmark for multilingual emotion classification. However, variation in performance across languages highlights the persistent challenges posed by limited training data and cultural variability in emotional expression. To mitigate class imbalance and further enhance accuracy, future work will explore integration of ensemble learning and data augmentation. We also plan to implement zero-shot learning for extremely low-resource settings. These directions aim to strengthen multilingual emotion detection and contribute to broader advancements in low-resource natural language understanding.

Acknowledgments

We sincerely thank the SemEval-2025 Task 11 organizers for designing an engaging shared task and for releasing a valuable multilingual, multi-label emotion classification dataset that spans diverse low-resource languages. We also extend our gratitude to the reviewers for their insightful comments, constructive feedback, and generous support, all of which significantly contributed to the improvement of this work.

Limitations

Despite the promising outcomes, our model has the following limitations.

Emotion Ambiguity: Certain emotions, particularly *Surprise* and *Fear*, are highly dependent on cultural context, making consistent classification challenging.

Generalization Challenges: The model's effectiveness diminishes on out-of-domain test sets, emphasizing the necessity of domain adaptation techniques.

Abstract

Understanding covert narratives and implicit messaging is essential for analyzing bias and sentiment. Traditional NLP methods struggle with detecting subtle phrasing and hidden agendas. This study tackles two key challenges: (1) multi-label classification of narratives and sub-narratives in news articles, and (2) generating concise, evidence-based explanations for dominant narratives. We fine-tune a BERT model with a recall-oriented approach for comprehensive narrative detection, refining predictions using a GPT-4o pipeline for consistency. For narrative explanation, we propose a ReACT (Reasoning + Acting) framework with semantic retrieval-based few-shot prompting, ensuring grounded and relevant justifications. To enhance factual accuracy and reduce hallucinations, we incorporate a structured taxonomy table as an auxiliary knowledge base. Our results show that integrating auxiliary knowledge in prompts improves classification accuracy and justification reliability, with applications in media analysis, education, and intelligence gathering.

1 Introduction

The rise of digital media has dramatically reshaped the way information is produced and consumed, enabling direct communication between content creators and audiences. Although this has democratized information access, it has also made it easier for manipulative narratives and disinformation to spread, especially during crises and politically sensitive events. News articles often employ implicit messaging, strategic framing, and loaded language to subtly shape public perception (Mokhberian et al., 2020). These covert techniques are not always explicitly deceptive, but instead rely on suggestive phrasing, selective omissions, and emotionally charged language, making them difficult to detect through traditional Natural Language Processing (NLP) methods.

This phenomenon is especially common in geopolitical conflicts and environmental discourse, where language is often used to shape ideological perspectives, downplay motivations, or influence opinions. For example, narratives surrounding climate change policies or the Ukraine-Russia conflict frequently employ carefully constructed rhetoric to promote certain viewpoints without making direct claims. Identifying these hidden patterns is essential to analyze the influence of the media and counter disinformation. Beyond news media, the ability to detect implicit meaning is valuable in various domains such as education, legal analysis, cross-cultural studies and security.

This study builds upon the foundation laid by prior research in implicit narrative detection and develops a system designed to address the objectives and evaluation framework introduced in (Piskorski et al., 2025). Specifically, we focus on two key tasks in the analysis of implicit narratives in news articles. First, we fine-tune bert-base-uncased (Devlin et al., 2019) for the multi-label classification task to identify and categorize dominant narratives present in a given text. This is then passed through a prompt engineered Large Language Model (LLM) to identify the final classification from the shortened classification list returned by BERT. Second, we introduce a methodology for generating structured justifications that explain why a particular narrative has been assigned to a text. This explanation process relies on retrieving semantically relevant evidence from the article itself and structuring the justification using a ReACT (Reasoning + Acting) framework (Yao et al., 2023b). To enhance the factual reliability of these justifications, we incorporate a taxonomy-based knowledge lookup, which provides formal definitions and examples of narratives and sub-narratives.

By refining methods for extracting implied mean-

*These authors contributed equally to this work.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2233–2239

ing, this research contributes to media analysis, automated content understanding, and intelligence gathering. Ultimately, advancing NLP-driven narrative detection will provide deeper insight into how narratives influence perception in diverse languages, cultures, and discourse contexts.

2 Related Work

The task of extracting dominant and sub-narratives from text and also generating free-text explanations that justify a dominant narrative within a text article falls under the broader domain of computational narrative extraction and discourse analysis. These are fundamental tasks in NLP and we have explored research on multilabel text classification, Explainable AI (XAI) for text generation, Retrieval-Augmented Generation (RAG), and ReACT prompting techniques.

2.1 Narrative Extraction

Narrative extraction tasks have their roots in the extraction of 'topic' and 'event'. (Feng et al., 2018) has worked on language-independent neural networks to capture sequence and semantic information for event detection. This approach though multilingual is not effective in extraction of narratives where content is implicit with subtle language dependent paraphrasing causing complex dependencies amongst narratives and sub-narratives.
With advancements in encoder-decoder architectures and the semantic capabilities of large language models (LLMs), significant progress has been made in natural language understanding. However, key challenges remain: (1) designing annotation schemes that are both comprehensive enough to capture narrative features while remaining concise to prevent input dilution and hallucinations (Huang et al., 2025); (2) ensuring robustness across diverse writing styles (formal/informal) and multilingual inputs (Qin et al., 2024); and (3) improving explainability in intermediate steps to enhance the interpretability of results (Zhao et al., 2024). Another critical issue in fine-tuning LLMs is data scarcity and class imbalance, which can negatively impact model performance. To address this, ensemble methods have been explored as a way to leverage complementary strengths across models. (Randl et al., 2024) employs such an ensemble-based classification approach, which proves effective for extracting labels when explicit class mentions are present in the text. However, this method has limitations, particularly in handling implicit features and lacks intermediate explanatory steps, which are crucial for improving transparency and interpretability.

2.2 Narrative Explanation

Research in narrative explanation is rooted in Explainable AI (XAI) frameworks designed to ensure factual consistency. While limited work exists on multi-label narrative justification, traditional approaches often employ Named Entity Recognition (NER) to model sentence structures (Santana et al., 2023), integrating these with text generation models to produce coherent outputs. Although computationally efficient, these methods struggle with hierarchical labels, where dominant narratives encompass multiple sub-narratives, leading to subtle modifications in the overall explanation. Recent advancements in large language models (LLMs), particularly with reasoning-enhancing prompting techniques such as "ReACT" (Yao et al., 2023b), "Chain-of-Thought" (Wei et al., 2022), and "Tree-of-Thought" (Yao et al., 2023a), have demonstrated promising results in structured reasoning. However, these approaches often fail to capture the full complexity of hierarchical relationships, especially when critical information is embedded in short sentences or within the dataset's taxonomy.

3 Task Description

Understanding implicit narratives in news articles is essential for detecting bias, framing, and potential manipulation. This task focuses on two key challenges: multi-label classification of narratives and sub-narratives (Subtask 2) and generating concise, evidence-based explanations for dominant narratives (Subtask 3).
In Subtask 2 (Narrative Classification), given a news article and a predefined two-level taxonomy of narratives and sub-narratives, the goal is to accurately assign all relevant sub-narrative labels to the article. This is a multi-class, multi-label classification problem where both the primary narrative and its sub-narratives must be correctly identified.
In Subtask 3 (Narrative Extraction), given a news article and a dominant narrative, the goal is to generate a brief, text-based explanation (maximum 80 words) supporting the dominant narrative. The generated justification must be grounded in the article by referencing textual evidence that aligns with the claims of the dominant narrative. Both

subtasks are crucial for enhancing media analysis, fact-checking, and disinformation detection by providing structured narrative classification and transparent, text-grounded justifications.

4 Methodology

This section describes our approach to solving the two subtasks: (1) Narrative Classification, where we assigned narratives and sub-narratives to news articles in a multi-label classification setup, and (2) Narrative Explanation, where we generated grounded justifications for dominant narratives using a retrieval-augmented LLM-based approach.

4.1 Narrative Classification (Subtask 2)

4.1.1 Data Preparation

The dataset consisted of news and web articles in five languages (Bulgarian, English, Hindi, Portuguese, and Russian), focusing on the Ukraine-Russia war and climate change. Each article was labeled with a dominant narrative and one or more sub-narratives. We structured the dataset for training by one-hot encoding the dominant narrative labels, enabling a multi-label classification setup. The data was split into an 80-20 train-validation split for training.

4.1.2 Fine-Tuned BERT Model

For classification, we fine-tuned a BERT-base-uncased model with focal loss (Cao et al., 2021) to address label imbalance implicitly. The model was fine-tuned with a primary focus on maximizing recall to ensure the inclusion of all relevant labels (Sun et al., 2019). In multi-label classification tasks, precision and recall present a trade-off (Zhang et al., 2019a): prioritizing recall increases the likelihood of retrieving all relevant labels, albeit at the cost of increased false positives (Type I errors). Given the hierarchical nature of our approach, where we have a second highly specific classification step, missing a correct label is more detrimental than including an incorrect one (Type II errors). Hence we ensure that relevant labels are not missed by prioritising high recall.

The model was trained for eight epochs with a batch size of 8, a learning rate of 2e-5, and the AdamW optimizer ($\epsilon = 1e - 8$, weight decay = 0.05). A lower weight decay was used to prevent excessive regularization, which could suppress recall. Additionally, a linear learning rate scheduler with a 10% warm-up was applied to improve convergence stability. To further minimise false negatives, we applied adaptive threshold tuning, ensuring that relevant labels were retained without excessively increasing false positives. Increasing the decision threshold reduces the risk of Type II errors but raises the likelihood of Type I errors. Given our priority on recall, we adjusted the threshold adaptively to minimize false negatives while maintaining an acceptable false positive rate.

Finally, we trained two separate models: one for Climate Change narratives and another for Ukraine-Russia War narratives, ensuring task-specific adaptation.

4.1.3 GPT-4o Post-Processing

To refine the BERT predictions, we implemented a two-stage `GPT-4o` pipeline leveraging taxonomy-based reasoning. We employed Tree-of Thought prompting techniques (Yao et al., 2023a) to encourage the Large Language Model to evaluate intermediate steps and solve the problem with a structured reasoning process. The process involved:

1. **Narrative Label Refinement:** The article and initial BERT-predicted labels were passed to `GPT-4o` along with a taxonomy defining the meaning of each narrative. The model was instructed to filter incorrect labels while ensuring true positives were retained.

2. **Sub-Narrative Classification:** Given the refined narrative labels, `GPT-4o` was prompted again with a taxonomy for sub-narratives corresponding to each narrative, generating the final set of sub-narrative labels.

This approach helped enforce hierarchical label consistency and align predictions with predefined taxonomies.

4.2 Narrative Explanation (Subtask 3)

4.2.1 Semantic Sentence Retrieval

For generating evidence-based justifications, we combined semantic sentence retrieval (Jingling et al., 2014) with GPT-4o based ReACT prompting to ensure explanations were grounded in the article text. Our retrieval approach involved:

1. Sentence Segmentation: Articles were split into sentences using period-based segmentation.

2. Semantic Indexing: Each sentence is embedded using OpenAI's text-embedding-ada-002

model (Rodriguez and Spirling, 2022) and stored in a vector database. Cosine similarity is used as the distance metric for retrieval. After retrieval, the article is deleted from the database to optimize memory usage.

3. Dual-Pass Cosine Similarity Retrieval: Top 5 sentences were retrieved based on cosine similarity with the dominant narrative. A second retrieval was then performed for sub-narratives, adding any sentence that exceeded the similarity threshold set by the 5th-ranked sentence from the first retrieval.

This dynamic thresholding ensured that only semantically relevant sentences were used while preventing arbitrary cutoff points.

Column	Description
Main Narrative	Unique identifier for the dominant narrative.
Main Narrative Definition	Ground-truth definition of the dominant narrative.
Main Narrative Example	Example cases supporting the dominant narrative.
Metadata (Main Narrative)	Additional distinguishing attributes.
Sub-Narrative	Unique identifier for the sub-narrative.
Sub-Narrative Definition	Ground-truth definition of the sub-narrative.
Sub-Narrative Example	Example cases supporting the sub-narrative.
Metadata (Sub-Narrative)	Additional distinguishing attributes.

Table 1: Narrative Taxonomy Specifications

4.2.2 ReACT-Based Prompting

To generate structured and interpretable justifications, we implemented a ReACT (Reasoning + Acting) framework that follows a chain-of-thought reasoning process. This approach ensures that explanations are logically structured and grounded in the retrieved text. The process involves three key steps: (1) identifying central claims, (2) justifying the dominant narrative, and (3) justifying the sub-narrative. First, the model identifies central claims by analyzing the retrieved sentences and detecting references to key themes and implicit messaging. For example, if a text discusses globalists and environmentalists orchestrating events in secret, the model searches for evidence of powerful groups exerting hidden influence, such as mentions of "globalists," "communists," and "environmentalists" manipulating public opinion.

Next, the model justifies the dominant narrative by identifying claims that reinforce the overarching theme. If the dominant narrative suggests that climate policies are part of a coordinated, deceptive effort by powerful entities, the model locates supporting statements, such as assertions that globalists "deliberately start fires" or "use climate change as an excuse for depopulation." Based on this evidence, the model concludes that the dominant narrative aligns with "Hidden plots by secret schemes of powerful groups."

Finally, the model applies the same process to justify the sub-narrative, focusing on more specific underlying themes. If the sub-narrative suggests that climate policies have an ulterior motive beyond environmental concerns, the model extracts relevant claims, such as statements equating sustainability efforts with abortion and depopulation agendas. This leads to the conclusion that the text supports the sub-narrative of "The climate agenda has hidden motives."

To optimize this reasoning process, we experimented with few-shot prompting but found that ReACT prompting yielded more structured and interpretable justifications. By breaking down the process into Thought, Action, Observation, and Conclusion, the model systematically evaluates retrieved evidence, minimizing inconsistencies and improving transparency.

4.2.3 Taxonomy Table Integration

While prompting and retrieval alone improve justification generation, we introduce a structured taxonomy table as an auxiliary knowledge base to further enhance interpretability and factual alignment. We tested two approaches for integrating this information: Explicitly inserting the taxonomy table as instructions (Sarmah et al., 2024) in the prompt. Embedding it within the "Action" section of the ReACT prompt. Our experiments found that the second approach gave better results, as defining the taxonomy as a part of the Action section led to more reliable and factually consistent justifications.

5 Results

We evaluated our two tasks—multilabel classification and the generation of evidence-based explanations for narratives—using F1 scores. The approach with the highest F1 score was chosen as the objective, as we aimed to balance precision and

Task	GPT 4o-mini	GPT 4o	BERT + GPT 4o-mini	BERT + GPT 4o
Narrative CC	0.227	0.227	0.6	0.6
Narrative URW	0.301	0.301	0.342	0.326
Narrative Overall	0.251	0.251	0.458	**0.467**
Sub Narrative CC	0.156	0.158	0.239	0.244
Sub Narrative URW	0.187	0.187	0.188	0.2
Sub Narrative Overall	0.164	0.166	0.208	**0.217**

Table 3: BERT Score F1 Results

recall while minimizing False Positives and False Negatives.

For the text generation task, we utilized BERTScore (Zhang et al., 2019b) to compare results, as it measures semantic similarity between strings using contextual embeddings. Unlike n-gram-based metrics (e.g., BLEU, ROUGE) (Culy and Riehemann, 2003), which struggle with paraphrased or implicit reasoning, BERTScore effectively captures meaning equivalence by leveraging deep contextual representations.

Table 2 presents results for Narrative Classification (Subtask 2) across experiments, while Table 3 showcases results for Narrative Justification (Subtask 3).

5.1 Narrative Classification

Our framework for predicting dominant and sub-narratives achieved an overall F1 score of 0.467 and 0.217, respectively, when using `GPT-4o`. The results with `GPT-4o-mini` were comparable, yielding 0.458 and 0.208 for dominant and sub-narratives, respectively. These findings were compiled after the task was complete, and highlight how refining our approach with a weaker classifier before the final classification step provides better results while keeping the context for the LLM as concise as possible.

5.2 Narrative Justification

The text generation resulting from our novel approach—integrating Semantic Similarity Search to retrieve sentences from the article text and pairing them with an auxiliary knowledge base in a ReACT prompt—consistently outperformed both the simple prompt and the prompt paired solely with the knowledge base across all five languages (Bulgarian, English, Hindi, Portuguese, and Russian). Moreover, our text justification framework demonstrated superior performance across all three evaluation metrics—BERT F1, Precision, and Recall—consistently surpassing alternative approaches. These results emphasize the effectiveness of leveraging semantic similarity and external knowledge augmentation to enhance justification quality across multilingual settings. The results prove that the efficiency of the designed framework allows us to utilize smaller LLMs in future work, enhancing scalability.

6 Conclusion

This study advances NLP-driven narrative analysis by introducing a framework for classifying and justifying implicit narratives in news articles. Our multilabel classification approach, fine-tuning `bert-base-uncased` with a prompt-engineered LLM, effectively identified dominant and sub-narratives. The framework maintained strong performance even with `GPT-4o-mini`, demonstrating the scalability and adaptability of the system without significant performance compromises. This lightweight configuration reduces computational overhead and enables deployment in resource-constrained environments, making the framework practical for real-world, large-scale applications. Future implementations can further optimize resource usage by incorporating retrieval caching mechanisms and distributed modular processing across subtasks.

Furthermore, our narrative justification approach, which combines Semantic Similarity Search with a ReACT-based reasoning structure and auxiliary knowledge retrieval, significantly improved text generation quality across multiple languages. The model consistently outperformed the baseline methods in BERT F1, underscoring the effectiveness of integrating contextual retrieval mechanisms with generative reasoning to generate coherent and factually aligned justifications.

These findings improve media analysis, automated content understanding, and intelligence gathering by improving the detection of implicit ideological framing. As NLP advances, our approach lays the groundwork for more transparent, explainable AI-driven media analysis, supporting efforts to combat misinformation and strengthen media literacy across diverse linguistic and cultural contexts. Looking ahead, future work will investigate the use of dynamic crowd-sourced knowledge bases and adversarial testing to identify and minimize potential biases introduced via semantic retrieval or taxonomy-driven prompting. This will further ensure the fairness, robustness and generalizability of the system across sociopolitical domains and multilingual settings.

Abstract

In SemEval 2025 Task 10, which addresses the multilingual characterisation and extraction of narratives from online news, our team *Narrlangen* focused on Subtask 2 (narrative classification), and we tried several conceptually straightforward approaches: (1) prompt engineering of LLMs, (2) a zero-shot approach based on sentence similarities, (3) direct classification of fine-grained labels using SetFit, (4) fine-tuning encoder models on fine-grained labels, and (5) hierarchical classification using encoder models with two different classification heads. We list results for all systems on the development set, which show that the best approach was to fine-tune a pre-trained multilingual model, XLM-RoBERTa, with two additional linear layers and a softmax as classification head.

1 Introduction & background

Narratives shape how information is conveyed and understood, influencing public discourse and decision-making processes. Since both corporate and state actors are actively seeking to influence public discourse on topics such as climate change, vaccinations, migration, or the war in Ukraine by pushing their own narratives, one of the greatest challenges of contemporary democracies is to identify and counteract such campaigns while upholding the ideal of freedom of expression. Identifying narratives in texts, e.g. online news or social media, is a key part of this. More generally, robust methods for identifying and classifying narratives would also provide important support for large-scale analysis of textual data, allowing researchers to track the evolution of discourses across time.

Despite significant advancements in NLP, predicting narratives remains a complex challenge due to their abstract, multi-layered nature. Traditional classification methods struggle with the implicit and evolving structures of narratives, which often span multiple sentences or paragraphs. Recent approaches, including zero-shot learning and fine-tuning of transformer models, have demonstrated promise in capturing nuanced narrative patterns without requiring extensive labelled datasets (see e.g. Heinrich et al., 2024).

The task is additionally complicated by terminological uncertainty. Over the years, scholars have proposed various interpretations for the very term *narrative* itself, reflecting the difficulty in reaching a consensus (see e.g. Santana et al., 2023). Chatman (1980) e.g. offers a structuralist perspective, defining narratives as comprising a story (a chain of events and characters) and discourse (how the content is communicated).[1] Riedl and Young (2010) see narratives and storytelling as cognitive tools for making sense of the world. Broader definitions highlight that narratives are sequences of events that form a cohesive whole, with significance derived from the relationship between events. Consequently, detailed *annotation* of narratives usually comprises key features such as participants, events, and time (Silvano et al., 2021).

In Subtask 2 of SemEval-2025 Task 10 (Piskorski et al., 2025) narrative annotation is provided as coarse- and fine-grained labels given to whole news articles. The provided data covers news in five different languages, namely English, Portuguese, Bulgarian, Russian, and Hindi, and the task is to automatically annotate texts with all (sub-)narratives in a multi-label fashion. The narratives belong to two macro topics: climate change and the War in Ukraine, both prime domains for fake news and disinformation intended to mislead the public. In our contribution, we compare a variety of state-of-the-art approaches; all our code is publicly available.[2]

[1]However, it is needless to say that also the term *discourse* is highly problematic, since "it is used in social and linguistic research in a number of inter-related yet different ways." (Baker, 2006, 3)

2 Data & labels

2.1 Data sets

The task organisers provided training, development, and test data for English, Bulgarian, Portuguese, Russian, and Hindi, respectively. Table 2 in the Appendix shows how many news texts there are in each set and gives an impression of their typical lengths.

Training and development data sets are annotated with ten coarse-grained labels for narratives related to climate change, eleven for the Russo-Ukrainian War, as well as the label "Other". Fine-grained labels further subdivide these narratives (for example, the coarse-grained label "Downplaying climate change" allows for subnarratives like "Humans and nature will adapt to the changes" or "Climate cycles are natural"). In total, there are 96 possible fine-grained levels, including "Other" subnarratives for each coarse-grained label which are not explicitly included in the taxonomy (Stefanovitch et al., 2025). Frequencies of fine-grained labels vary wildly between languages and, in some cases, even between training and development data.[3] Each data set only contains a subset of coarse- and fine-grained labels, the most extreme case being Russian, where no narratives relating to climate change are to be found.

2.2 Narrative descriptions

We manually created paragraph-length descriptions of subnarratives to be used in the sentence-similarity based zero-shot approach outlined below.[4] By using the provided taxonomy (Stefanovitch et al., 2025), we matched each subnarrative with narrative descriptions in the form of English example sentences. The sentences are intended to concisely describe the subnarratives and should contain all discourse-relevant terms. The provided examples within the taxonomy were used as a basis; further aspects were added based on domain knowledge, academic publications, online searches, and fact-checking websites[5].

Existing research on climate change skepticism and conspiracy theories (as outlined e.g. in Tam and Chan, 2023) as well as a vast array of material available online provided the necessary information for the creation of descriptive sentences for all subnarratives related to climate change. For instance, for the subnarrative "Climate policies are ineffective", our narrative description reads as follows: "Ineffective climate policies have done more harm than CO2 emissions. Even if we reduce our CO2 emissions, it won't save the planet."

Pro-Russian narratives related to the Russo-Ukrainian war are very frequent and well outlined in the academic literature (Aleksejeva, 2023; Amanatullah et al., 2023; Kalashnikova and Schäfer, 2024; Pekar and Rashkovan, 2024), making the creation of descriptive sentences straightforward. On the other hand, pro-Western narratives are less studied and less common. Descriptive sentences here are thus derived from discussions on social media platforms (e.g. "The West belongs in the right side of history"). Note that many subnarratives are interconnected, which makes it difficult to assign description sentences to one particular subnarrative; the subnarratives "Ukraine is the aggressor" and "Ukraine is a puppet of the West" e.g. both assume "the West" as an intermediate, and both "Ukraine is associated with nazism" and "Russia actions in Ukraine are only self-defence" involve Russia's allegations of "genocide" committed by Ukraine as the justification for the invasion.

3 System overview

Machine learning (ML) baseline We initially ran simple multi-label classification experiments with classical machine learning algorithms for all languages in order to get stronger baselines than the ones based on random guessing provided by the organisers. We use logistic regression (LR) and support vector machines (SVM) on bags of words for this purpose. The baselines are computed separately for each language.

Prompt engineering LLMs (PromptEng) We also implemented a structured approach of prompt engineering large language models (LLMs), namely GPT-4o (OpenAI, 2024) and Deepseek R1-32B (Guo et al., 2025) in a step-by-step fashion. The LLMs were tasked to proceed level by level and output the response in json format.

Similarity-based zero-shot (SentSim) A simple approach to scoring texts can be constructed by looking at similarities between sentences in texts and subnarrative descriptions. If there is at least one

[3] For example, the label "Other" appears in 98 of 366 texts in the Hindi training set (26.8%), but only twice in the development set of 35 texts (5.7%).

[4] Our description sentences can be found alongside our code in the repository linked above.

[5] See http://euvsdisinfo.eu/ and https://www.weareukraine.info/.

sentence in a text which is very similar to a sentence of a subnarrative description, the text will likely contain this subnarrative. This approach can have decent zero-shot performance as we have shown in the context of detecting COVID-19 related conspiracy narratives in German Telegram posts (Heinrich et al., 2024).

Let S_d denote the sentences of text d and S_n the sentences (or paragraphs) of subnarrative n. Following Heinrich et al. (2024), we use cosine similarity between sentence embeddings $\mathbf{e}_{s_i}$ and $\mathbf{e}_{s_j}$ for scoring each pair of sentences

$$s(s_i, s_j) = \cos\left(\mathbf{e}_{s_i}, \mathbf{e}_{s_j}\right) \quad \forall s_i \in S_d, s_j \in S_n.$$

Note that individual sentences of subnarrative descriptions capture different ways of expressing the subnarrative, and since we are chiefly interested in the overall presence of subnarratives, we aggregate via taking the maximum

$$\text{score}\,(d, n) = \max_{s_i \in S_d, s_j \in S_n} \left(s(s_i, s_j)\right)$$

for getting a single value for each pair of subnarrative and text. This score is then translated into an actual prediction by determining a language- and subnarrative-specific cut-off value that maximises F_1 on all available labelled data.[6] Note that this last step of maximising the desired evaluation metric technically changes the approach to a supervised algorithm.

SetFit SetFit (Tunstall et al., 2022), a framework for few-shot fine-tuning Sentence Transformers (Reimers and Gurevych, 2019), is another approach that achieved good results in detecting COVID-19-related conspiracy narratives (cf. Heinrich et al., 2024). Coupled with the fact that it does not require prompting and is relatively fast to train, this makes it a sensible choice to use it for the task at hand. SetFit works by (1) fine-tuning a pre-trained Sentence Transformers model on contrastive pairs of labelled texts, (2) using the resulting model to encode the training data, (3) using the encoded data to train a text classification head.

Fine-tuning on fine-grained labels (FGM) In this approach, we fine-tune a multilingual masked language model and introduce two linear layers with a ReLU activation in between, followed by a final softmax function to predict fine-grained labels. This model prioritises subnarrative classification accuracy, which is considered most crucial for competitive performance. Coarse narrative labels are then inferred from the subnarratives. We trained the model on the combined data from all five languages in order to obtain a unified model that is applicable across all languages involved in the competition.

Hierarchical models We further conduct experiments with a model architecture that takes the nature of the labels into account, i.e. the relationship between narratives and subnarratives. In the course of these experiments, we fine-tune a multilingual masked LLM with two additional classification heads. The models are trained in two different manners, namely multi-label and multi-class with narratives attention. The hierarchy in the model is constructed by using the embeddings generated by the masked LLM to predict the coarse-grained labels, i.e. the narratives, and subsequently use the outputs to extract additional features to classify subnarratives.

The **multi-label model (MLHM)** takes the raw logits from the narrative level and feeds it to a sigmoid function in order to derive label probabilities, which are then utilised as additional features for the subnarratives level head. This method aims to establish a dependency between different hierarchical levels, thereby strengthening the interrelationship during training. We therefore assume that the subnarratives head is capable of optimising the probabilities for particular labels, leveraging the predictions from the narratives head.

The **narratives attention based model (NAHM)** employs separate attention mechanisms, one for each classification level. Each attention mechanism independently attends to the hidden states of the masked LLM to extract level-specific features from the text. As in MLHM, hierarchical relationships are established by feeding the output probabilities from higher levels as input features to lower levels. This architecture allows information to flow from broader categories to more specific ones. The model maintains a dictionary of label mappings which is crucial for both training consistency and interpreting predictions during inference.

In order to maintain consistent predictions throughout all hierarchical levels, a batch consistency loss function $\mathcal{L}_c$ is implemented as the learning objective. Let ℓ_m denote a loss function accord-

[6] This corresponds to the training data for predictions on the development set and to the combined training and development set for predictions on the test set.

ing to the model architecture[7] and let $i \in [1, N]$ be the current level (where N is the total number of all hierarchical levels). The consistency loss $\mathcal{L}_c$ is then defined as

$$\mathcal{L}_c = \sum_{i}^{N} \ell_m(p_\theta(\hat{y}_i|x_i), y_i)$$

where the x_i populate the feature matrix, y_i are the true labels of i-th hierarchical level, $p_\theta(\hat{y}_i|x_i)$ are the predicted probabilities, and θ are the trainable parameters of the model. For the attention based model, the mean of $\mathcal{L}_c$ is computed for each batch using

$$\bar{\mathcal{L}}_c = \mathcal{L}_c \frac{1}{|\text{batch}|}$$

as final loss that needs to be minimised during training.

4 Experimental setup

All our models make use of the combined training data during training and are evaluated on the development data. Note that since most of our models were trained to predict fine-grained narratives, we inferred the corresponding coarse-grained narratives from the fine-grained labels using regular expressions. Where applicable, we used multilingual models, which enables us to combine the full training data for all five languages to train a single model, thereby addressing the problem of data scarcity in fine-grained labels.[8]

ML We implement logistic-regression and support vector machine with a tf.idf-weighted feature matrix based on uni- and bigrams using `scikit-learn` (Pedregosa et al., 2011).

PromptEng For prompt engineering, the LLMs are provided with the multi-level labels and prompted to choose a narrative first and only choose the subnarrative within that particular narrative second. We used a few-shot learning framework within this methodological sequence by providing some examples in English.

SentSim For the zero-shot experiments, we split texts by double new lines into paragraphs and treat each paragraph as a sentence; for subnarrative description, we experiment with two approaches: using subnarrative descriptions as a whole, and splitting them into smaller segments (which mostly correspond to single sentences, but can also comprise two or three sentences). We then calculate sentence embeddings using four different multilingual SBERT (Reimers and Gurevych, 2019) models available off-the-shelf[9] from Hugging Face, namely

- paraphrase-multilingual-MiniLM-L12-v2
- paraphrase-xlm-r-multilingual-v1
- distiluse-base-multilingual-cased-v1
- paraphrase-multilingual-mpnet-base-v2[10]

We refer to these models as mini, XLM, distiluse, and mpnet, respectively.

SetFit For SetFit, we seek to find the most suitable parameters to fine-tune the model on the training dataset by using a batch size of 16, setting the learning rate $lr \in \{1\text{e-}4, 1\text{e-}6\}$ and the number of epochs $e \in \{1, 3\}$. The best model after hyperparameter tuning is subsequently evaluated using the development set. We use the mpnet model as above.

FGM The model is trained on a combined dataset of all the languages, while taking only the subnarrative labels into account. The subnarrative labels are one-hot encoded, thus enabling easier training and prediction, as well as maintaining the multi-label status. The narratives are subsequently extracted from the subnarratives. We use the base versions of both English-specific BERT[11] (Devlin et al., 2019), and multilingual XLM-RoBERTa[12], and fine-tune them for 100 epochs[13]. We apply the AdamW optimiser (Loshchilov and Hutter, 2017) configured at a learning rate of 2e-5. The learning objective is to minimise the binary Cross Entropy Loss.

Hierarchical models As the results of XLM-RoBERTa and English-specific BERT were similar

[7] This corresponds to binary cross entropy for MLHM and negative log-likelihood for NAHM

[8] Although this introduced another, albeit smaller problem, in that some labels from the taxonomy do not appear in the training and/or development sets of individual languages at all.

[9] We use the Python module `SentenceTransformers` here, see https://www.sbert.net/.

[10] https://huggingface.co/sentence-transformers/paraphrase-multilingual-mpnet-base-v2

[11] https://huggingface.co/google-bert/bert-base-uncased

[12] https://huggingface.co/FacebookAI/xlm-roberta-base

[13] During our initial experiments, we set the epoch sizes to 10 and 20 for fine-tuning FGM but did not acquire any sensible insights. The model was just able to predict the category "Other" and failed to learn the other ones. A possible reason for this issue is the scarcity of training examples for all categories.

in FGM, we decided to utilise XLM-RoBERTa as encoder model for these experiments. We adopt the AdamW optimiser with a learning rate of 3e-5, a batch size of 16 for both hierarchical models and train them for 120 (MLHM) as well as 100 (NAHM) epochs. Both models are subsequently evaluated on the provided development set.[14]

5 Results

We list results on the development set for all our systems in Table 4 in the Appendix, and visualise them in Figure 1 in comparison to other results published on the official task leaderboard[15]. Results for out submitted system (FGM) on the test set can be found in Table 1. We ranked between 3^{rd} and 6^{th} place across the five languages of the shared task, achieving 3^{rd} place in Hindi (out of 13 participating teams), 4^{th} in Russian (14 teams), 5^{th} in Bulgarian (11 teams), and 6^{th} in both English (28 teams) and Portuguese (13 teams).

ML baseline As can be seen in Figure 1, the ML baselines fail to adequately predict subnarratives, with F_1 ranging from 0.01 to 0.07 on the development set, thus barely beating random guessing.

PromptEng The strategy of prompt-engineering GPT-4o was considerably worse than our other approaches when we evaluated it on the English development set, especially looking at F_1 scores on fine-grained labels. The results from Deepseek-R1:32B were even worse, and thus this approach was not considered any further.

SentSim For the approach based on sentence similarities, we compare a total of eight architectures (segmenting subnarratives in sentences or paragraphs, and four different language models). We assess their performance for each language on the development set in Table 3 in the Appendix. We quickly summarise the table as follows, focussing on the prediction of subnarratives: (1) We easily beat the baselines across all languages; (2) comparing paragraph embeddings with paragraph embeddings yields almost exclusively better results than comparing sentence embeddings with paragraph embeddings (except for XLM on Portuguese); and (3) the mpnet model performs best across all languages (except for English, where it performs remarkably poorly).[16] We include the architecture with the mpnet model and comparing paragraphs with paragraphs in Figure 1. We do not reach median performance of participating systems with this approach (except for Russian) but note that this approach does not need any labelled data (except for maximising F_1).

SetFit We report performance after training and hyperparameter optimisation[17] in Table 4 and Figure 1. Given that SetFit was used with whole labelled news texts instead of much shorter units of text, it still achieves decent results. In principle, SetFit should also work well in a zero-shot setting, using only narrative descriptions as its initial input. In our case, however, the resulting model was essentially useless. Contrary to Heinrich et al. (2024), using narrative descriptions as additional training data did not improve the model.

FGM Fine-tuning XLM-RoBERTa only on the finegrained labels has been shown to be an effective approach and the best model among all our experiments. This architecture is only outperformed by the MLHM approach for Portuguese. To be consistent, we submitted FGM predictions for all languages on the test set for final evaluation. Table 1 and Figure 1 show performance on the test set; results are overall competitive, especially for Hindi, enabling a top 3 placement. To check whether a single-language model would perform better, we also tested an English-only BERT model as the base model. The results, however, did not show an improvement over XLM-RoBERTa.

Error analysis on the development sets across task languages reveals several things.[18] First, good performance is mostly based on accurately predicting the absence of subnarratives. Second, performance would have slightly increased if predictions of labels not included in the respective language trainings sets had been removed in a post-processing step (for English, for example, the model predicts one instance of "Amplifying Climate Fears: Earth will be uninhabitable soon" while this subnarrative features neither in the English training nor in the development set). Third,

[14] We ran all our experiments with encoder models on an NVIDIA RTX 4090 with 24 GB of VRAM, with an average run time of approx. 40 minutes to complete each training.

[15] https://propaganda.math.unipd.it/semeval2025task10/leaderboard.php

[16] Note that distiluse was trained neither on Bulgarian nor on Hindi, which explains its poor performance on these languages.

[17] Hyperparameter optimisation was, however, largely inconsequential compared to out-of-the-box performance.

[18] Confusion matrices for all labels are available at https://github.com/fau-klue/narrlangen-semeval2025.

	coarse		fine	
	F_1	σ	F_1	σ
EN	0.44	0.41	0.34	0.39
BG	0.50	0.40	0.36	0.38
PT	0.48	0.34	0.29	0.26
RU	0.57	0.37	0.41	0.32
HI	0.40	0.46	0.39	0.47

Table 1: Results on test set using XLM-RoBERTa on fine-grained labels (FGM).

prediction quality for some of the underspecified "Other" subnarratives for coarse-grained labels varies wildly between languages: for "Discrediting the West, Diplomacy: Other", the model accurately predicts 4 out of 5 instances in the Bulgarian dev set whereas it only gets 1 out of 6 right for English. This likely results from large differences between instances in the training data (in this case, 61 vs. 26). The same holds true for the even more general label "Other": there are more training examples for English (169) than for all other languages combined (159), so that the model only achieves a somewhat decent performance in this language (precision .62, recall .73). Finally, results for Russian and Hindi are only better than those for other languages since they only (or mostly, in the case of Hindi) include subnarratives related to the Russo-Ukrainian War. m

Hierarchical models The results of our multi-label hierarchical model (MLHM) outperforms the attention-based approach (NAHM) across all languages for both coarse- and fine-grained labels. Especially for Portuguese, we can observe a gain of 0.21 in F_1, where MLHM also surpasses the otherwise best-performing system FGM by 0.03 in F_1. This might be due to the complexity of the attention layer and the fact that it is trained to predict one single label compared to the multi-label approach, which is not constrained to a certain narrative or subnarrative.

6 Discussion & perspectives

The results of our experiments suggest that traditional machine learning approaches provide little utility in the given task, as their performance remains significantly below that of more advanced methods. In contrast, our sentence-similarity based zero-shot approach proves to be a viable alternative, delivering competitive results without the need for domain-specific training. Nonetheless, while the zero-shot method offers a cheap alternative, fine-tuning masked LLMs remains the most effective approach, given a large amount of labelled data as in the task here. We also note that incorporating multiple languages into a single training set is a reasonable strategy, likely due to shared linguistic patterns across languages.

For future work, several directions could enhance classification performance. Firstly, since many annotated texts contain lengthy narratives including irrelevant sections, preprocessing techniques that extract relevant portions before model training could reduce noise and improve classification accuracy for all models. Similarly, SetFit could benefit from individually labelled paragraphs; it might also perform better as an ensemble of several models to predict fine-grained labels for each previously predicted coarse-grained label. For SentSim, an iterative refinement process for narrative descriptions could enhance model interpretability and predictive accuracy by incrementally improving label definitions and annotations.

While prompt engineering LLMs was not a successful strategy here, chain-of-thought prompting could improve the results (Wei et al., 2023). Findings from previous work (Jiang et al., 2024; Qi et al., 2024; He et al., 2024) suggest that LLMs have difficulty following complex instructions. Given that our task requires multi-label classification at various levels and a strict json output, this approach might not be sufficient to address the task's complexity.

Applying the narrative attention layer to the multi-label hierarchical model might strengthen the relationship between coarse- and fine-grained hierarchies. This enhancement can improve the model's ability to predict subnarratives which correspond to the classified narratives. Another possibility would be to experiment with the hierarchical loss by minimising the subnarrative loss only. We assume that focusing on subnarratives might improve the performance of our approaches.

Finally, after a thorough error analysis of the individual models presented here, it would be straightforward to use an ensemble model which could potentially improve overall performance.

Abstract

Question Answering over Tabular Data (Table QA) presents unique challenges due to the diverse structure, size, and data types of real-world tables. The SemEval 2025 Task 8 (DataBench) introduced a benchmark composed of large-scale, domain-diverse datasets to evaluate the ability of models to accurately answer structured queries. We propose a Natural Language to SQL (NL-to-SQL) approach leveraging large language models (LLMs) such as GPT-4o, GPT-4o-mini, and DeepSeek v2:16b to generate SQL queries dynamically. Our system follows a multi-stage pipeline involving example selection, SQL query generation, answer extraction, verification, and iterative refinement. Experiments demonstrate the effectiveness of our approach, achieving 70.5% accuracy on DataBench QA and 71.6% on DataBench Lite QA, significantly surpassing baseline scores of 26% and 27% respectively. This paper details our methodology, experimental results, and alternative approaches, providing insights into the strengths and limitations of LLM-driven Table QA. The code is available at this GitHub Repository.

1 Introduction

Question Answering over Tabular Data (Table QA) is a fundamental problem in natural language processing (NLP) that aims to retrieve structured information from tables given natural language queries. This task is crucial for making structured data more accessible, enabling users to interact with databases, spreadsheets, and structured documents without requiring expertise in SQL or database querying. However, Table QA presents unique challenges compared to traditional open-domain QA, as it requires models to understand schema structures, perform logical reasoning over tabular relationships, and generate precise queries that extract relevant data (Soliman and Gurevych).

Early approaches to Table QA relied on rule-based systems (Khalid et al., 2007), manually designed templates, and retrieval-augmented generation (RAG) (Pan et al., 2022). While effective for constrained domains, these methods struggle with scalability, particularly when handling large and diverse tables with complex relationships. More recent advances employ neural models for end-to-end Table QA, including methods that directly generate SQL queries from natural language inputs. Large language models (LLMs) have demonstrated impressive capabilities in this space, enabling the dynamic generation of SQL queries without requiring predefined schemas or manually curated rules (Baig et al., 2022).

Despite these advancements, several challenges remain. LLM-generated SQL queries often suffer from structural errors, incorrect column selections, and ambiguous reasoning over tabular data. Additionally, extracting precise answers from retrieved SQL results requires careful post-processing, as LLMs may misinterpret numerical values, categories, or required formats. To address these issues, verification and refinement steps are necessary to ensure query correctness and answer reliability.

In this work, we present an LLM-driven Natural Language to SQL (NL-to-SQL) pipeline that dynamically translates user questions into SQL queries, retrieves structured data, and refines the final output to maximize answer accuracy. Our approach integrates multiple stages, including example selection, query generation, answer extraction, and verification. By leveraging LLMs for both SQL generation and answer refinement, we aim to improve robustness across diverse table structures and query types. We apply our system to the SemEval 2025 Task 8 (DataBench), a benchmark designed to evaluate Table QA over real-world datasets. By refining query formulation and integrating a verification mechanism, our system significantly outperforms baselines. In this paper, we detail our

system architecture, performance evaluation, and key insights derived from our experiments.

2 Related Work

The task of Question-Answering on Tabular Data (Table QA) involves extracting precise, grounded answers from structured data based on natural language queries. Various methods have been explored to tackle this problem, yet challenges such as data sparsity, feature heterogeneity, context-based interconnections, and order invariance remain significant (Fang et al., 2024). Previous research in Table QA has introduced generative, extractive, and retriever-reader-based methods, each addressing different aspects of reasoning and information retrieval (Jin et al., 2022).

Generative models, such as those introduced in (Pasupat and Liang, 2015) generate answers directly instead of producing logical forms. Extractive methods, in contrast, select spans of text from tables rather than generating them, relying on effective table cell representations to capture only relevant information. Structure-aware approaches like TAPAS (Herzig et al., 2020) incorporate row/-column embeddings to encode positional information, while models like TableFormer (Gupta et al., 2022) introduce attention bias techniques to enhance table reasoning. While both generative and extractive models excel at handling simple queries, their performance deteriorates on reasoning-based queries that require logical inference and multi-hop reasoning. (Jin et al., 2022)

Among these, NL-to-SQL has emerged as a powerful approach (Mohammadjafari et al., 2025), translating natural language queries into structured SQL statements for efficient information retrieval. Traditional NL-to-SQL models followed encoder-decoder-based architectures suited for structured databases, but real-world applications often involve semi-structured and free-form tables, necessitating alternative techniques (Hong et al., 2025). The advent of large language models (LLMs) has brought a paradigm shift to NL-to-SQL. Unlike traditional chat-based completion models, reasoning-driven LLMs excel at understanding complex question intent, handling multi-step logical reasoning, and adapting to diverse database schemas with minimal training. Researchers have also experimented with prompt engineering and fine-tuning to improve SQL query generation efficiency. Chain-of-Thought (CoT) prompting enables LLMs to break down complex queries step by step, further enhancing reasoning capabilities.

LLM-based approaches have demonstrated superior evaluation metrics on benchmark datasets such as SPIDER (Yu et al., 2019), surpassing traditional models. As research progresses, improvements in model size, reasoning capabilities, and dataset quality are expected to drive further performance gains, solidifying LLMs as the dominant paradigm for Table QA.

3 Task Description

The SemEval 2025 Task 8 (Grijalba et al., 2025), known as DataBench, is designed to evaluate systems that answer questions using real-world tabular datasets. The challenge comprises two subtasks:

1. **DataBench QA**: Participants are provided with entire datasets and corresponding questions, requiring systems to extract answers from potentially large and complex tables.

2. **DataBench Lite QA**: This subtask involves answering questions using a sampled version of each dataset, limited to a maximum of 20 rows, focusing on models' ability to handle smaller data contexts.

The DataBench benchmark encompasses 65 diverse real-world datasets, each accompanied by multiple questions. These datasets span various domains and exhibit a wide range of data types and table sizes, challenging systems to adapt to different structures and content. The questions associated with these datasets are designed to elicit various response types, including numerical values, categorical data, boolean judgments, and lists. This diversity necessitates that participating systems possess robust capabilities in understanding and processing heterogeneous tabular data to generate accurate and contextually appropriate answers.

4 Methodology

Our approach leverages a Natural Language to SQL (NL-to-SQL) agent to generate structured queries that retrieve relevant information from tabular data. The system follows a multi-stage pipeline consisting of example selection, SQL query generation, answer extraction, verification, and iterative refinement. This framework ensures high accuracy and adaptability across datasets with varying structures and question complexities. Alternative methods

such as rule-based retrieval and RAG were tested but proved less effective, especially when handling large-scale tabular reasoning tasks.

Additionally, we experimented with multiple models on the same pipeline to optimize performance, including GPT-4o, GPT-4o-mini, and DeepSeek v2:16b. Our system follows the following five-stage pipeline.

4.1 Example Selection

To improve SQL query generation, we curated a set of 25 example question-query pairs, where each question is a natural language input and each query is the corresponding SQL output, covering diverse question patterns such as filtering, aggregation, grouping, sorting, joins, subqueries, and conditional retrievals (Nan et al., 2023). These examples were designed to represent various structural and semantic variations commonly found in tabular data questions. Given an input question, we computed cosine similarity with these pre-defined examples and selected the two most relevant question-query pairs to provide as context.

To determine the most relevant examples for a given input question, we utilized an embedding-based similarity approach. First, we generated vector representations (embeddings) for all example questions using text-embedding-ada-002 and stored it in a ChromaDB vector database collection. When a new question was received, we computed its embedding using the same model and calculated the cosine similarity between the embedding of the input question and those of the pre-defined examples in the collection. The two most similar examples were selected as context for SQL generation, ensuring that the model received relevant references closely matching the structure and intent of the input question. This approach helped guide the model in producing more precise and contextually appropriate queries, improving the accuracy of our system.

4.2 SQL Query Generation

To generate accurate SQL queries, we provided the LLM with a structured prompt that included the table schema, specifying column names and data types, along with a few sample rows to offer contextual grounding (Wu et al., 2024). Additionally, we incorporated the two most relevant example natural language question-sql query pairs, selected based on cosine similarity, to guide the model in producing syntactically and semantically appropriate SQL statements. To enforce query validity, explicit SQL syntax constraints were included in the prompt, ensuring that the generated queries adhered to the expected format. The primary objective of the initial retrieval step was to extract relevant table rows rather than compute direct answers, allowing for a structured query execution process. These generated SQL queries were then executed on the SQLite database containing the DataBench datasets, retrieving the necessary rows, which were subsequently processed in later stages to derive the final answers.

4.3 Answer Extraction and Formatting

Once rows were retrieved via SQL, a secondary prompt analyzed and extracted the data to derive the final answer, ensuring compliance with expected data types (e.g., ordered lists, numerical outputs). This step was crucial for refining the raw SQL outputs into the structured response format required by the task. To enhance the reasoning capability of the model, we employed Chain-of-Thought (CoT) prompting (Liu and Tan, 2023), which allowed the LLM to break down the answer derivation process into logical steps. The model was instructed to analyze the retrieved rows, extract only the necessary values, and format them correctly based on the expected answer type.

The prompt provided structured guidelines for different expected output types, including boolean values, categorical selections, numerical computations, and list-based answers. By leveraging structured CoT reasoning, the LLM could systematically evaluate the retrieved data, determine the most relevant cell or computed value, and return a precise answer aligned with the question intent.

4.4 Answer Verification

A verification step using an additional GPT-4o prompt classified responses based on two key criteria: format validity and relevance to the given question (Wang et al., 2024). The system was designed to assess whether an answer adhered to expected formats—such as Boolean values, numerical values, dates, or categorical lists—without performing fact-checking. If an answer deviated from these predefined formats or was entirely unrelated to the question, it was flagged for reprocessing. To ensure robustness, borderline cases were defaulted to acceptance unless a clear and significant violation of format or relevance was detected. This step minimized incorrect responses by identifying cases

where the initial SQL query retrieved extraneous or irrelevant information, ensuring that only properly structured and contextually appropriate answers progressed to the final stage.

4.5 Answer Reprocessing

If a response was flagged for reprocessing, the system adapted its approach to improve answer precision. The examples used in SQL generation were updated to prioritize queries that retrieved specific values rather than entire rows, ensuring a more targeted extraction of relevant information. Additionally, the SQL generation prompt was refined to directly extract the exact answer values from the dataset, minimizing unnecessary retrieval of irrelevant data. A final formatting step enforced consistency with the expected output type, whether numerical, categorical, or list-based, aligning responses with the required structure. The entire query generation and execution pipeline was re-executed after these refinements were made on queries that were flagged for reprocessing. This iterative refinement process enhanced overall answer correctness and significantly reduced extraneous outputs.

After reprocessing, the outputs from the newly refined queries were combined with the outputs from the original successful (approved) queries. If a query was flagged and reprocessed, its new result replaced the earlier one. If a query was not flagged, its original output was retained. This way, the final set of results included the best available answer for each query—either from the initial run (if it was already correct) or from the reprocessed run (if it had been improved). The system ensured there were no duplicates and that each query had exactly one final, verified result in the merged output.

5 Results

To evaluate the effectiveness of our Natural Language to SQL (NL-to-SQL) query agent, we conducted experiments on two benchmark datasets - Databench and Databench-Lite, using three Large Language Models (LLMs): GPT-4o, GPT-4o-mini, and deepseek-v2:16b (DeepSeek-AI et al., 2024). Additionally, we compared our results to the provided baseline model to establish a reference point for performance (Sinha et al., 2024).

GPT-4o consistently demonstrated superior performance compared to other models. Its ability to accurately interpret and break down user queries played a crucial role in generating results in the expected format. This allowed for more precise and contextually relevant outputs, particularly in complex scenarios. GPT-4o-mini also exhibited many of the advantages of GPT-4o, particularly in question understanding and structured output generation, though to a lesser extent due to its smaller model size and optimization for cost-effective applications. DeepSeek v2:16b showed some capability in processing structured queries but lacked the same level of precision, adaptability, and ability to follow prompt instructions.

For evaluation, the organizers rank the system based on accuracy of the answers on the question answering task. Our approach ranked 10th on the Databench task proprietary model leaderboard and 9th on the Databench-Lite task proprietary model leaderboard, demonstrating the capabilities of our system. Table 1 presents the accuracy of our models compared to the baseline.

Our NL-to-SQL pipeline, combined with LLM capabilities, resulted in substantial improvements over the baseline across all models. The enhancements introduced in our approach directly contributed to these improvements:

1. Embedding-based example selection improved query contextualization and standardization, leading to more accurate SQL generation and a higher success rate for complex queries.

2. Chain-of-Thought (CoT) reasoning significantly reduced errors in answer extraction, particularly in handling numerical computations, categorical selections, and ordered lists.

3. Answer verification and iterative reprocessing helped eliminate hallucinated SQL queries and irrelevant outputs, ensuring greater response reliability.

These methodological improvements enabled GPT-4o to achieve the highest accuracy (70.50% on Databench and 71.65% on Databench-Lite), clearly outperforming the baseline performance. Even deepseek-v2:16b, despite its lower overall accuracy, showed a significant improvement over the baseline, demonstrating the effectiveness of our multi-stage NL-to-SQL framework.

6 Conclusion

This study advances NL-to-SQL translation by developing a multi-stage LLM-driven agentic

Model	Databench	Databench-lite
Baseline	26.00	27.00
GPT-4o-mini	60.34	61.49
GPT-4o	**70.50**	**71.65**
deepseek-v2:16b	39.68	45.78

Table 1: Accuracy Score Comparison across models

pipeline that significantly improves query accuracy, explanability and query consistency compared to previous models. Our approach integrates example selection, Chain-of-Thought (CoT) reasoning, and answer verification, which collectively enhance SQL generation by improving query structure consistency, reducing ambiguity, and refining output accuracy. GPT-4o achieved the highest accuracy across both benchmark datasets, demonstrating the effectiveness of this structured approach over baseline methods.

By leveraging context-aware question selection and structured reasoning, the system effectively mitigates common NL-to-SQL challenges, such as misinterpretation of input question intent and incorrect SQL syntax. The incorporation of an iterative refinement process further ensures robust query generation, reducing errors, and enhancing the overall accuracy.

The results on smaller datasets like Databench-Lite illustrate the effectiveness of our pipeline in generating accurate and well-structured SQL queries for constrained datasets. Furthermore, the consistent performance observed on larger datasets demonstrates the scalability of our framework, making it well-suited for enterprise applications that require high reliability and adaptability across diverse corporate databases. This robustness ensures that organizations can leverage our approach for complex query generation at scale, improving efficiency and decision-making processes.

These findings reinforce the potential of LLM-driven NL-to-SQL systems as a scalable and efficient solution for automating database interactions. The integration of structured reasoning and verification mechanisms represents a significant step toward improving the accuracy and interpretability of automated question answwering over tbaular data.

7 Future Work

While the proposed NL-to-SQL pipeline demonstrated significant improvements over baseline methods, an analysis of system outputs revealed several challenges affecting query accuracy and reliability. These errors primarily fall into two categories:

1. Complex Numerical Reasoning Errors: The system exhibited difficulties in handling queries that required multi-step numerical reasoning, particularly those involving ranking, aggregation, and filtering operations.

2. Categorical Misclassification: The system occasionally misclassified categorical values, selecting responses that were semantically related but incorrect.

Advances in LLM architectures with better contextual understanding, improved token representations for tabular data, and stronger reasoning capabilities could enhance the accuracy of query generation. Additionally, developing more structured NL-to-SQL frameworks that incorporate explicit schema understanding, enhanced query verification, and iterative refinement processes may further improve performance. Combining these advancements with more effective post-processing techniques and adaptive learning strategies could lead to a more reliable NL-to-SQL system.

Acknowledgments

We would like to thank the organisers of *SemEval 2025 Task 8: Question Answering over Tabular Data* for providing the dataset as well as being extremely helpful for the entire duration of the task. We would also like to thank Shaz Furniturewala for his support and guidance throughout the process of conducting this research.

A Appendix

A.1 Prompt Templates

SQL Query Prompt Template

You are a PostgreSQL expert. Given an input question, create a syntactically correct PostgreSQL query to run. Unless otherwise specified.
Here is the relevant table info: {table_info}
Most columns have intuitive names. Return the entire row(s) that contain the final answer in context of the original question based strictly on the SQL table you are given (always use SELECT (*)). Every question will be answered only from the table provided, no other source of data.
Below are a number of examples of questions and their corresponding PostgreSQL queries.

Final Response Prompt Template

Given the following user question and row(s) containing the answer, infer and answer the user question in exactly the format expected. You are also given columns headers for the table from which the row is extracted for context. Answer only the user question directly with the information from the SQL rows given to you. Answers should strictly contain only the value expected, NOTHING ELSE. Ensure you respond only with values directly from the rows, do not write full sentences. The following answer formats are expected based on the question asked: Boolean: Valid answers include True/False. If a question expects a yes/no answer, respond strictly only with True or False. Category: A value from a cell (or a substring of a cell) in the dataset. Number: A numerical value from a cell in the dataset, which may represent a computed statistic (e.g., average, maximum, minimum). List: A list containing a fixed number of categories or numbers. The expected format is: "['cat', 'dog']". Columns available in the dataset: {column_headers} Question: {inputs['question']} SQL Result: {inputs['result']} Answer:

HiTZ-Ixa at SemEval-2025 Task 1: Multimodal Idiomatic Language Understanding

Anar Yeginbergen, Elisa Sanchez-Bayona, Andrea Jaunarena and Ander Salaberria
HiTZ Center, University of the Basque Country
{anar.yeginbergen, elisa.sanchez, andrea.jaunarena, ander.salaberria}@ehu.eus

Abstract

In this paper, we present our approach to the AdMIRe (Advancing Multimodal Idiomaticity Representation) shared task, outlining the methodologies and strategies employed to tackle the challenges of idiomatic expressions in multimodal contexts. We discuss both successful and unsuccessful approaches, including the use of models of varying sizes and experiments involving zero- and few-shot learning. Our final submission, based on a zero-shot instruction-following vision-and-language model (VLM), achieved 9th place for the English test set and 1st place for the Portuguese test set on the final leaderboard.

We investigate the performance of open VLMs in this task, demonstrating that both large language models (LLMs) and VLMs exhibit strong capabilities in identifying idiomatic expressions. However, we also identify significant limitations in both model types, including instability and a tendency to generate hallucinated content, which raises concerns about their reliability in interpreting figurative language. Our findings emphasize the need for further advancements in multimodal models to improve their robustness and mitigate these issues.

1 Introduction

While substantial progress has been made in the abilities of large language models (LLMs) to process literal meanings, their capacity to handle non-literal language remains an open research topic. The challenge is further amplified in multimodal settings, where figurative expressions may not have straightforward visual correspondences. Idioms, specifically, are typically defined as multi-word and non-compositional expressions. Non-compositionality implies that the meaning of the overall expression does not match the sum of meanings of its parts (words). Thus, they pose an inherent challenge for their understanding. For instance, an idiomatic expression like *"kick the bucket"* may not have a direct visual counterpart that aligns with its intended meaning in a sentence. Its use can be literal or idiomatic/figurative, requiring models to incorporate contextual and world knowledge for accurate interpretation.

In order to evaluate how current vision-and-language models (VLMs) align idiomatic and literal meanings to visual representations, Pickard et al. (2025) have built the AdMIRe (Advancing Multimodal Idiomaticity Representation) dataset and proposed a shared task with it. This shared task is composed of two subtasks where the ability to distinguish figurative and literal uses of idioms is needed to rank images by semantic similarity.

In our proposed approach, we investigate how well contemporary models handle figurative language in this multimodal context. By evaluating their performance on the first subtask of the AdMIRe dataset provided by the task organizers, we aim to assess whether these models can recognize and interpret idiomatic expressions effectively, moving beyond simple text-image correlations to capture deeper, non-literal meanings. Addressing this challenge is essential for advancing the interpretability and robustness of multimodal AI systems in real-world applications.

In this paper, we share our experiments and findings from our submission for the SemEval-2025 Task 1: Multimodal Idiomatic Language Understanding. We sum up our observations in our proposed solution to the shared task as follows:

- A state-of-the-art open-source vision-and-language model, *Qwen2-VL* (Wang et al., 2024), is capable of performing well using a zero-shot approach, achieving 73.3% and 100.0% accuracy on the small English and Portuguese test sets, respectively.
- *Qwen2-VL* struggles to do anything when we use a few-shot approach. We hypothesize that

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2256–2261

the model has not learned to process several sequences of images at the same time during pretraining, and that more sophisticated approaches are needed to solve the task in this manner.

- We show that, for this task, a smaller version of *Qwen2-VL* outperforms the biggest one, that is, the model with 7B parameters performs better than the 72B one.

2 Background

A key challenge in multimodal learning is ensuring that models can effectively capture both explicit and implicit relationships between visual and linguistic elements. While VLMs have shown remarkable progress in literal image-text alignment, their ability to understand figurative language, such as idioms and metaphors, remains an open research question. Idiomatic expressions often convey meanings that cannot be directly inferred from their constituent words, requiring models to move beyond surface-level associations and incorporate contextual understanding (Shwartz and Dagan, 2019).

Vision-Language Models (VLMs) have emerged as a powerful class of multimodal models that integrate visual and textual information, enabling machines to process and generate language in relation to images. These models build upon the success of large-scale pre-trained language models and vision encoders, leveraging architectures such as transformers (Vaswani et al., 2017) to bridge the gap between vision and language. By aligning textual and visual representations in a shared embedding space (Radford et al., 2021), VLMs have demonstrated impressive performance across various multimodal tasks, including image captioning (Anderson et al., 2018), visual question answering (Antol et al., 2015), and text-to-image generation (Ramesh et al., 2022).

Understanding figurative language requires models to go beyond literal word meanings and incorporate contextual, common sense, and world knowledge. Prior research has explored various approaches to tackling idioms, metaphors, and other forms of non-literal expressions, using both symbolic and neural methods.

Inside the figurative language we can find metaphors. The word **metaphor** was defined as a novel or poetic linguistic expression where one or more words for a concept are used outside of their normal conventional meaning to express a *similar* concept (Lakoff, 1993). So that, a linguistic metaphor takes a concept from a source domain and applies it to a target domain. Metaphors follow this schema: *TARGET* IS/ARE *SOURCE*. For example, behind the metaphor *She used some sharp words*, the source is *weapons* and the target is *words*, leading to *Words are weapons* relation. We can see another example with this metaphor: *I am the richest man in the world: I have the love of my family*, where the relation is *Well-being Is Wealth*, being *Wealth* the source and *Well-being* the target. As understanding metaphors with Large Language Models (LLMs) is something challenging, some previous works (Chakrabarty et al., 2023; Saakyan et al., 2024) have proposed working both hand in hand with linguistic metaphors and visual metaphors, in order to improve results in figurative language understanding. A visual metaphor is an image that wants to express a metaphorical message. Like in linguistic metaphors, visual metaphors also take a concept from a source domain and apply it to a target domain. Now, the main difference is that these domains need to be visually representable. Many experts have worked with linguistic metaphors; however, very few go deep into the multimodal field (Xu et al., 2024; Zhang et al., 2021).

Recent text-only approaches combine various types of figurative language, namely idioms, metaphor, sarcasm, or hyperbole, to improve models' understanding capabilities (Stowe et al., 2022; Lai et al., 2023; Kabra et al., 2023). Chakrabarty et al. (2021) introduced metaphor generation techniques using neural models, highlighting the potential of deep learning in handling figurative language. (Madabushi et al., 2021; Chakrabarty et al., 2022; Phelps et al., 2024; Liu et al., 2022) further analyzed the capabilities of current LLMs to understand idiomatic language.

3 Data

We are provided with the dataset for idiomatic expression understanding comprised from Madabushi et al. (2022), Pickard et al. (2025). Each idiomatic expression contains an idiomatic nominal compound (NC), a phrase where the NC is used in a literal or idiomatic way, and a set of 5 images.

The images for each sentence cover the following range of idiomaticity:

- A synonym for the idiomatic meaning of the NC.
- A synonym for the literal meaning of the NC.

Set	Language	#Examples	#Idiomatic	#Literal	#Avg. Words
Train	EN	70	39	31	124
Validation	EN	15	7	8	125
Test	EN	15	8	7	134
Test	EN_x	100	46	54	121
Train	PT	32	13	19	109
Validation	PT	10	5	5	112
Test	PT	13	6	7	114
Test	PT_x	55	31	24	108

Table 1: The distribution of the data. *EN* and *PT* are English and Portuguese data respectively. *EN_x* and *PT_x* pertain to the extended evaluation set.

- Something related to the idiomatic meaning, but not synonymous with it.
- Something related to the literal meaning, but not synonymous with it.
- A "distractor", which belongs to the same category as the compound (e.g. an object or activity) but is unrelated to both the literal and idiomatic meanings.

The goal of the tackled task was to rank the images according to the given sentence. Depending on the literal or idiomatic use of the NC in the sentence, the expected rank changes. Therefore, only a system that is capable of distinguishing such uses will be able to generalize well in this task. The overall distribution of the data is shown in Table 1.

4 System Description

In this section, we provide a description of our approach to *subtask A* of the shared task. Our primary objective is to investigate the capability of vision-and-language models (VLMs) to establish a meaningful connection between idiomatic expressions and their corresponding visual representations. Specifically, we aim to assess how effectively these models can associate idiomatic phrases with relevant visual cues and comprehend their intended meanings within a multimodal and multilingual context. By doing so, we seek to gain insights into the extent to which VLMs can interpret idiomatic language beyond literal meanings, leveraging both textual and visual information.

During the preliminary experiments, we discovered that the majority of the text-only LLMs are capable of recognizing idiomatic expressions from the context in which they occur no matter if it is idiomatic or literal. This finding motivated us to extend our investigation to VLMs under similar conditions. In our proposed solution, we employed *Qwen2-VL-7B-Instruct*[1] and *Qwen2-VL-72B-Instruct*[2] (Bai et al., 2023; Wang et al., 2024), by designing the instruction with the description of the task. This choice was taken due to two main reasons: i) its strong performance across different vision-and-language tasks and the capability of processing multiple images at the same time, which not many contemporary open-source VLMs can do.

Our approach is simple. We provided the details of the task in the prompt, explicitly indicating that one of the images is a distractor and that it should be placed in the last position of the output ranked images. The prompt we used in the experiments is illustrated in Figure 1.

5 Results

In this section, we will describe the results we obtained from different sets of experiments. We start with our main results obtained with the model described in Section 4, following with ablation studies carried out during our experimentation.

5.1 Main Results

In table 2, we show the performance and positions obtained in the test and extended test sets of *subtask A*. Top-1 accuracy measures the proportion in which the most similar images are ranked first in the output, whereas DCG measures the correct order of the entire ranking. For English, we ended up tied with 5 other participants in the 9th position of the leaderboard out of 33 contestants. For Portuguese, we achieved a perfect score and the 1st position in the test set due to a stroke of luck

[1]https://huggingface.co/Qwen/Qwen2-VL-7B-Instruct
[2]https://huggingface.co/Qwen/Qwen2-VL-72B-Instruct

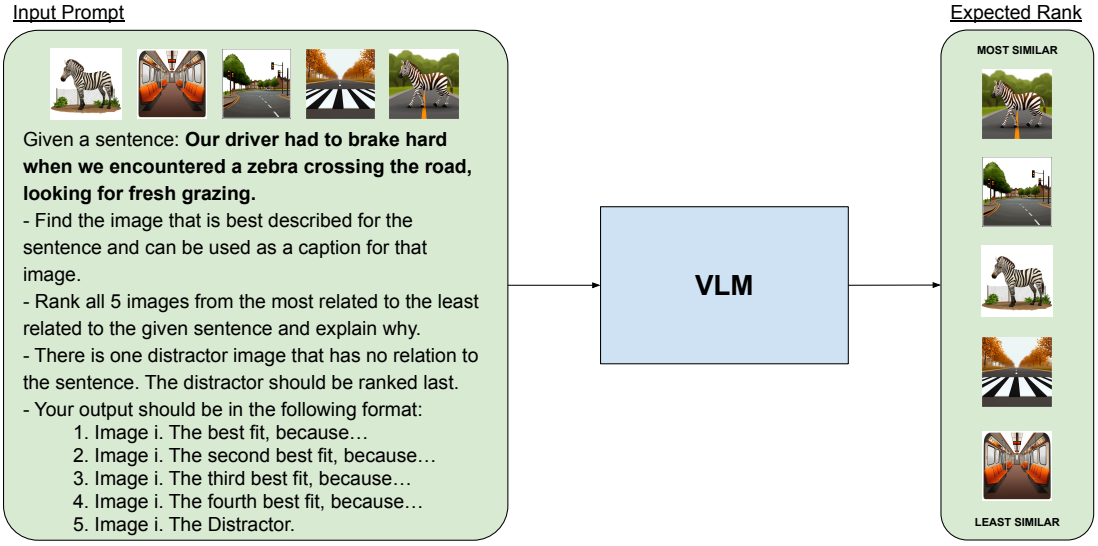

Figure 1: Our system requires a VLM that can process multiple images at a time to output the rank of each input image with textual tokens, that is, following the format described in the input.

with the small number of test instances (see Table 1). The drop in the extended test set is a better representation of the performance that our naive approach has, which would leave us in the middle positions of the leaderboard.

If we combine the results obtained in both test and extended test sets, we get a top-1 accuracy of 60.0% and 58.9% for English and Portuguese, respectively. These combined sets contain 115 and 68 instances, which depict better the performance of our system. It is worth mentioning that the difference in performance across both languages is minimal. When comparing DCG metrics in these combined test sets, we end up with the same conclusion, as we get a DCG of 3.0 and 2.95 for English and Portuguese, respectively.

5.2 Ablation Studies

Model size. We have compared our system containing 7B parameters with the biggest *Qwen2-VL* model available, that is, *Qwen2-VL-72B-Instruct*. Even though models with a higher capacity usually show better performance across different tasks, this model fails to properly follow the provided instructions, being keen to hallucination.

On the contrary, we note that in our preliminary experiments, when we tried the text-only version to assess the quality of the LLMs for figurative language identification, *Llama-3.1-70B-Instruct* [3] performed better than *Llama-3.1-8B-Instruct*. [4]

Few-shot setting. We also investigated in-context few-shot learning by incorporating examples into the input prompt. However, due to limitations in context length and hardware, we were only able to include up to three examples from the training set. Despite this, the inclusion of these examples caused the Vision-Language Models (VLMs) to hallucinate, preventing the acquisition of reliable results. The issue was consistent across both 7B and 72B models.

In the technical report of *Qwen2-VL* family (Wang et al., 2024), the training and evaluation on vision-and-language tasks was done in a zero-shot manner. The model learned during training to intake several frames of a video at the same time, but it has never been trained with multiple sequences of images in a few-shot approach. Thus, we hypothesize that *Qwen2-VL* models are not capable of managing multiple sequences of multiple images in the same input prompt due to the lack of these examples during their multimodal training stage.

Object detection. In another approach, we wanted to analyze the effectiveness of object detectors in detecting figurative or literal usages of nominal compounds (NCs) in images. If the object detector were capable of detecting NCs only in

[3] https://huggingface.co/meta-llama/Llama-3.1-70B-Instruct

[4] https://huggingface.co/meta-llama/Llama-3.1-8B-Instruct

Position	Lang.	Team	Top-1 Acc.	DCG	Top-1 Acc. (Extended)	DCG (Extended)
9	EN	hitz_ixa	73.33	3.13	58.0	3.00
1	PT	hitz_ixa	100.00	3.51	45.45	2.82

Table 2: Position and performance in the preliminary leaderboard for both the English and Portuguese test sets and their respective extended test sets.

images where their use was literal, we would feed this information to the input prompt of *Qwen2-VL* models to ease their task.

By feeding the NC to an open-vocabulary object detector OwL-VIT with the template "A photo of a NC." (Minderer et al., 2022), we computed the proportions in which the NC is detected in different types of images.[5] On the one hand, the detection rate is 35% in images containing something related to the literal meaning of the NC. On the other hand, the ones relating a figurative meaning achieve a detection rate of 26%.[6] We conclude that this signal is too noisy to be useful and did not elaborate on further experimentation with object detectors. This noisiness can be easily understood when looking at Figure 1, where the figurative use of *zebra-crossing* (e.g. a crossing for pedestrians) has quite prominent visual features and can be easily detected by contemporary object detectors.

6 Conclusions

In this paper, we present our approach to the AdMIRe - Advancing Multimodal Idiomaticity Representation shared task, detailing the methodologies and strategies we employed to address the challenges posed by idiomatic expressions in multimodal contexts. We describe different successful and unsuccessful approaches, such as models of different size, zero- and few-shot experiments. With the final submission based on zero-shot instruction-following VLM, we were able to obtain 9th and 1st places in the preliminary leaderboard for English and Portuguese test sets respectively.

We explore the effectiveness of open vision-language models (VLMs) in achieving comparable performance in this task. While our findings indicate that LLMs demonstrate a strong ability to identify idiomatic expressions, and VLMs can achieve similar results, we also observe significant limitations in both model types. Specifically, these models often exhibit instability and are prone to generating hallucinated content, which raises concerns about their reliability in correctly interpreting figurative language. Our analysis highlights the need for future work for further improvements in multimodal models to enhance their robustness to mitigate these issues.

[5]We use a threshold of 0.2 to discard low probability predictions.

[6]The detection rate for distractor images is 23%.

Abstract

Task 10 of SemEval 2025 was proposed to develop supporting information for analyzing the risks of misinformation and propaganda in news articles. In this study, we selected Subtask 3—which involves generating evidence explaining why a particular dominant narrative is labeled in an article—and fine-tuned PEGASUS for this purpose, achieving the best performance in the competition.

1 Introduction

Task 10 of Semeval 2025 (Piskorski et al., 2025; Stefanovitch et al., 2025) was proposed to support the research and development of new analytical functions aimed at analyzing the news ecosystem and characterizing manipulation attempts, in recognition that internet consumers are at risk of exposure to deceptive content and manipulation attempts, and that major crisis situations are also susceptible to the spread of harmful misinformation and propaganda.

The task focused on climate change and the Ukraine–Russia conflict as its main topics and provided three subtasks related to news articles. Subtask 1 involves assigning roles to each named entity mention in a news article using a predefined fine-grained role classification scheme. Subtask 2 requires assigning all appropriate subordinate narrative labels to a given article based on a two-stage narrative labeling system specific to a domain. Subtask 3 entails generating a free-text explanation, limited to 80 words, that provides evidence supporting the selection of the dominant narrative in an article.

In this study, we chose Subtask 3 and selected PEGASUS large (Zhang et al., 2020a) as the model best suited for this task. We fine-tuned PEGASUS large using the provided training dataset for this challenge. Section 2 explains the dataset and task for sub-task 3, Section 3 describes the model used and fine-tuning process, Section 4 details the hyperparameter settings and evaluation methods, Section 5 compares the results from Pegasus large with the baseline, and Section 6 concludes.

2 Background

2.1 Dataset

The training dataset provided for SemEval Task 11 Subtask 3 comprises news article text file titles, dominant narratives, subdominant narratives, and the target text to be generated. As our team employed the sequence-to-sequence model PEGASUS, we configured the input and output formats to align with the model's architecture. The input is constructed by listing the dominant narrative and the subdominant narrative separated by a space, followed by the news article prefixed with "Context:" at the end. The output is the target text to be generated. The input format is as follows:

$$Input = \{D; S; Prefix; Article\} \quad (1)$$

where D denotes the dominant narrative, S denotes the subdominant narrative, $Prefix$ is "Context:", and $Article$ represents the news article.

2.2 Task

Subtask 3 is a task that, given a news article along with its dominant and subdominant narratives, requires generating an explanation that provides evidence for why these narratives were selected. This task was designed with reference to the following studies: (Da San Martino et al., 2020; Piskorski et al., 2023, 2024). Since generating an explanation within 80 words based on the article and its narratives essentially amounts to a summarization task, our team selected PEGASUS large—a model well-suited for summarization—for this challenge.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2262–2264

3 System Overview

3.1 Model

PEGASUS is a model that employs the full transformer architecture and has been pre-trained specifically for the downstream task of summarization. Under the assumption that performing pre-training on tasks similar to the downstream task leads to better performance on that task, it was pre-trained using the Gap Sentence Generation (GSG) method, which is analogous to summarization. In this study, only PEGASUS large was used; unlike the base model, PEGASUS large was trained solely with GSG based on experimental results indicating that MLM is ineffective.

3.2 fine tuning

No special methods were used for fine tuning the model. The training followed the procedure described in Section 2.1, where the inputs from the training set were fed into the encoder and outputs were generated via the decoder. The model was saved only when the highest BERTScore F1 score (Zhang et al., 2020b) was achieved during training over several epochs.

4 Experimental Setup

4.1 hyper parameter setting

The model 'google/pegasus-large' was downloaded from Hugging Face, with the maximum input length set to 1024 and the maximum output length set to 128. The maximum number of epochs was set to 5, the batch size to 8, the learning rate to 3e-4, and the warmup rate to 0.00. AdamW was used as the optimizer, and the warm-up scheduler was implemented using the transformers' "get linear schedule with warmup" function. During validation, the BERTScore was used for evaluation, with roberta-large serving as the BERTScore model.

4.2 BERTScore

Subtask 3 of Task 11 is evaluated using the BERTScore. In this task, Precision is calculated to measure the similarity between the tokens of the generated sentence and those of the gold sentence, while Recall is computed to measure the similarity between the tokens of the gold sentence and those of the generated sentence. The performance of Subtask 3 of Task 11 is assessed using the F1 score, which is the harmonic mean of Precision and Recall. Let x represent the tokens of the generated sentence and y represent the tokens of the gold sentence. The similarity between the tokens of the generated sentence and those of the gold sentence is calculated as shown in Equation (2), with Precision computed as in Equation (3) and Recall as in Equation (4). Here, $\frac{1}{|C|}$ represents the total number of tokens in the generated sentence, and $\frac{1}{|R|}$ represents the total number of tokens in the gold sentence. The harmonic mean is calculated as shown in Equation (5).

model	Precision	Recall	F1 macro
ours	0.7669	0.7352	0.7504
baseline	0.6514	0.6834	0.6669

Table 1: Results of BERTScore.

$$S_{i,j} = \frac{\mathbf{x}_i \cdot \mathbf{y}_j}{\|\mathbf{x}_i\| \|\mathbf{y}_j\|} \tag{2}$$

$$P = \frac{1}{|C|} \sum_{x_i \in C} \max_{y_j \in R} S_{i,j} \tag{3}$$

$$R = \frac{1}{|R|} \sum_{y_j \in R} \max_{x_i \in C} S_{i,j} \tag{4}$$

$$F1 = 2 \times \frac{P \times R}{P + R} \tag{5}$$

5 Results

Our team conducted only Subtask 3 in English. With just a single training run, we secured first place, and the scores are as shown in the table 1. Compared to the baseline, our model achieved an increase of 0.11 points in precision, 0.05 points in recall, and 0.09 points in F1 macro score. It is evident that the improvement in precision was significant, and the F1 macro score benefited considerably from this enhancement. Instead of employing the latest decoder-only large language models, our team utilized PEGASUS-large—an encoder–decoder model pre-trained for summarization that was introduced in 2019—and even after five years since its release, it still demonstrates the best performance in this task.

6 Conclusion

Although it has been five years since the introduction of PEGASUS, our experiments have confirmed that it continues to exhibit robust performance, and the results of this study may offer valuable insights

to the organizers of SemEval Task 11. While the three subtasks of Task 11 have distinct characteristics, the third subtask can be effectively addressed by employing a summarization-specialized model such as PEGASUS.

Shouth NLP at SemEval-2025 Task 7: Multilingual Fact-Checking Retrieval Using Contrastive Learning

Santiago Lares Harbin and Juan Manuel Pérez
Universidad de San Andrés
slaresharbin@udesa.edu.ar

Abstract

We present a multilingual fact-checking retrieval system for the SemEval-2025 task of matching social media posts with relevant fact checks. Our approach utilizes a contrastive learning framework built on the multilingual E5 model architecture, fine-tuned on the provided dataset. The system achieves a Success@10 score of 0.867 on the official test set, with performance variations between languages. We demonstrate that input prefixes and language-specific corpus filtering significantly improve retrieval performance. Our analysis reveals interesting patterns in cross-lingual transfer, with specifically strong results on Malaysian and Thai languages. We make our code public for further research and development.

1 Introduction

The proliferation of misinformation on social media is referred by social scientists as a threat to the integrity of democracy and the public sphere (Chambers, 2021; Lewandowsky et al., 2023) This scenario has increasingly created an urgent need for automated fact-checking systems that can retrieve relevant fact-checks for dubious claims. The SemEval-2025 Task (Shahi et al., 2025) addresses this challenge by requiring participants to develop systems that can retrieve the most relevant fact checks for social media posts from a large corpus of 272,447 fact checks among multiple languages.

In this paper, we present our approach to this task, which utilizes a fine-tuned multilingual embedding model based on the E5 architecture (Wang et al., 2024). Our system employs a contrastive learning framework to optimize the semantic matching between posts and fact checks on fine-tuning. We focus in particular on multilingual representation learning and cross-lingual retrieval functions. The code for our system is publicly available on GitHub[1].

[1] https://github.com/sanlares/semeval_2025

Our main contributions include: (1) an analysis of various model architectures and their performance among different languages, (2) an examination of how input prefixes affect retrieval accuracy, and (3) a demonstration of the importance of language-specific corpus filtering for improving retrieval performance. Our system achieved an average Success@10 score of 0.867 on the official test set, ranking 20th out of 28 published participants.

2 Background

Automated fact-checking has emerged as a critical tool in combating the spread of misinformation online. (Zhou and Zafarani, 2020) speak about the immense volume of in- formation shared online, and suggest and evaluate different methods to detect fake news. The SemEval-2025 Task (Peng et al., 2025) focuses especially on multilingual fact-check retrieval, where the goal is to match social media posts with relevant fact-checks from a large multilingual corpus. Most automated fact-checking system consist of three steps (Guo et al., 2022): first, the claim de- tection (is this check-worthy?); then, the evidence retrieval (given a claim, retrieve relevant informa- tion to verify it); and lastly and claim verification (given a claim and evidence, define if the claim is true or false).

The task (Peng et al., 2025) has two subtasks: monolingual retrieval and cross-lingual retrieval. We focus only on the monolingual subtask.

Recent advances in multilingual embedding models have shown promising results for multilingual retrieval tasks (Feng et al., 2022; Litschko et al., 2022). These models learn a shared semantic space between languages, allowing for effective comparison of text regardless of the source language. In particular, contrastive learning approaches have proven effective for training such models (Chen et al., 2020), as they explicitly op-

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2265–2269

timize for similarity between related texts while pushing unrelated texts apart in the embedding space. In this paper, we present our retrieval approach to this task, which uses a fine-tuned multilingual embedding model based on the E5 architecture (Wang et al., 2024). This model has demonstrated strong performance on multilingual retrieval benchmarks (Zhang et al., 2021) by combining transformer-based encoders with contrastive pre-training. We additionally fine-tune this model on the task-specific data to improve its performance for fact-check retrieval.

3 System Overview

Our system addresses the challenge of retrieving relevant fact checks from a large corpus of 272,447 documents by implementing a fine-tuned contrastive learning approach based on the multilingual E5 model architecture. The system consists of three main components: (1) a text embedding model, (2) a contrastive learning framework, and (3) a retrieval pipeline.

The core of our system is built upon the `Multilingual E5 Model` (Wang et al., 2024), which we improve with a custom architecture. The model architecture is illustrated in Figure 1, consisting of a transformer encoder, mean pooling layer, dense projection layer with GELU activation, and L2 normalization for cosine similarity calculation.

The model processes both posts and fact checks using language-specific prefixes (`query:` and `passage:` respectively) to optimize the semantic matching between them.

We trained our model using the Multiple Negatives Ranking Loss (MNRL) (Jadwin and Huang, 2023), which can be formulated as:

$$L = -\log \frac{\exp(sim(x_i, x_i^+)/\tau)}{\sum_{j=1}^{N} \exp(sim(x_i, x_j)/\tau)} \quad (1)$$

where:

- x_i represents the anchor text embedding (post)
- x_i^+ represents the positive pair embedding (matching fact-check)
- x_j represents all other samples in the batch (negative pairs)
- τ is a temperature parameter that controls the sharpness of the distribution
- $sim(\cdot, \cdot)$ is the cosine similarity function

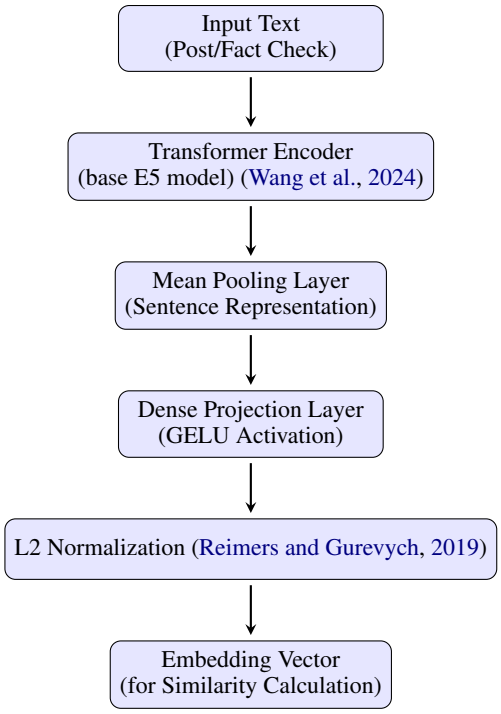

Figure 1: Architecture of the embedding model used in our system. The model processes both posts and fact checks using language-specific prefixes to optimize semantic matching.

We used in-batch negatives for computational efficiency while maintaining effective contrastive learning. The temperature parameter τ is dynamically adjusted during training to optimize the learning process.

The retrieval process follows these steps:

1. **Language Detection**: The system first identifies the language of the input post.
2. **Corpus Filtering**: The fact-check corpus is filtered to prioritize documents in the same language as the input post.
3. **Embedding Generation**: The model generates embeddings for both the input post and the filtered fact checks.
4. **Similarity Ranking**: The system computes Pearson cosine similarity between the post and fact check embeddings.
5. **Top-K Selection**: The 10 most similar fact checks are retrieved and ranked.

This pipeline is set for both monolingual and cross-lingual retrieval, with special consideration

for language-specific distinctions in the embedding space.

4 Experimental Setup

4.1 Dataset

The dataset used for this study was derived from the official SemEval-2025 competition data. We divided the training set into training (80%) and validation (20%) subsets while maintaining the language distribution for both sets.

For preprocessing, we utilized the `load.py` file recommended by the competition organizers. Our approach involved creating semantic representations for both posts and fact checks. For posts, we concatenated the OCR-extracted text (`ocr` column) with the manual transcription (`text` column) from the `posts.csv` file. Similarly, for fact checks, we combined the `claim` and `title` columns from the `fact_checks.csv` file. For model input, relevant prefixes (e.g., `query:`, `passage:`) were prepended to these concatenated texts prior to tokenization to guide the model's contextual understanding.

In addition to fine-tuning our primary model, we conducted experiments with various base models available in the SentenceTransformers framework, testing different prefix combinations that yielded varying performance results.

4.2 Implementation Details

The system was implemented using the following configuration:

- **Base Model**: multilingual-e5-large-instruct
- **Framework**: SentenceTransformers (v3.4.1)
- **Deep Learning Backend**: PyTorch (v2.5.1)
- **Python Version**: 3.12.7
- **Computing Environment**: macOS 15.1 (24B83)

The model was trained with the following hyperparameters:

The primary evaluation metric for our system was Success@10 (S@10), which measures the proportion of posts for which the correct fact check appears in the top 10 retrieved results. We evaluated the model's performance in both monolingual and cross-lingual settings:

Parameter	Value
Maximum Sequence Length	512 tokens
Pooling Mode	Mean
Embedding Dimension	384
Batch Size	4
Evaluation Batch Size	16
Gradient Accumulation Steps	2
Learning Rate	2e-5
Temperature	0.05
Mixed Precision Training	Enabled

Table 1: Model training hyperparameters

5 Results

We evaluate our system's performance on both the validation and test sets, analyzing the impact of different model configurations and language-specific performance. Our system achieved an average Success@10 score of **0.867** on the official test set, ranking 20th out of 28 published participants.

The results demonstrate considerable variability in model performance across languages, with Malaysian (msa) showing the strongest performance at 0.978 and English (eng) and Portuguese (por) showing the lowest at 0.796. This disparity suggests that linguistic factors may play a significant role in retrieval performance.

Table 3 shows the performance comparison of different base models and input prefix configurations on the validation set. The results demonstrate that the multilingual-e5-large-instruct model with appropriate prefixes consistently outperforms other configurations. The base model $intfloat/multilingual-e5-large-instruct$ (Wang et al., 2024) improved from an average Success@10 of 0.834 to 0.867 when fine- tuned with the training dataset, along with the rec- ommended query and passage prefixes. This im- provement was consistent for all languages tested in the competition.

5.1 Impact of Input Prefixes

Our experiments revealed that the choice of input prefixes significantly impacts model performance. Using the recommended prefixes on multilingual-e5-large-instruct base model ('passage:' and 'query:') improved the average Success@10 score by 0.013 points (from 0.821 to 0.834) compared to using no prefixes. This improvement was consistent across all languages, with the largest gains observed in:

- English: +0.022 (from 0.766 to 0.788)
- Spanish: +0.012 (from 0.857 to 0.869)

Language	Success@10	Relative Performance
Malaysian (msa)	**0.978**	+12.8%
Thai (tha)	0.940	+8.4%
Arabic (ara)	0.912	+5.2%
French (fra)	0.894	+3.1%
Spanish (spa)	0.866	-0.1%
German (deu)	0.858	-1.0%
Turkish (tur)	0.828	-4.5%
Polish (pol)	0.806	-7.0%
English (eng)	0.796	-8.2%
Portuguese (por)	0.796	-8.2%
Average	0.867	–

Table 2: Official test set results of the fine-tuned multilingual-e5-large-instruct model by language. Languages are ordered by Success@10 score. Best performance is shown in **bold**. The model shows strong performance on Malaysian and Thai languages.

Base Model	Posts Prefix	Facts Prefix	Success@10
`multilingual-e5-large-instruct` (Wang et al., 2024)	passage:	query:	**0.834**
`multilingual-e5-large-instruct` (Wang et al., 2024)	–	–	0.821
`multilingual-e5-small` (Wang et al., 2024)	–	–	0.795
`e5-large-v2` (Wang et al., 2022)	–	–	0.758
`modernbert-embed-base` (Nussbaum et al., 2024)	`search_query:`	`search_document:`	0.779
`paraphrase-multilingual-mpnet-base=v2` (Reimers and Gurevych, 2019)		–	0.736

Table 3: Performance comparison of base models on the validation set. Models are ordered by Success@10 score. Best result is shown in **bold**.

- Portuguese: +0.018 (from 0.781 to 0.799)

These results suggest that appropriate input formatting plays a vital role in improving the model's cross-lingual understanding and retrieval functions.

5.2 Corpus Reduction Analysis

Our experiments showed that performance improves significantly when the fact-check corpus is reduced in size. Specifically, when using only the subset of approximately 16,000 fact checks corresponding to the validation set (versus the full corpus of 272,447), Success@10 scores improved by an average of 10.2%. This improvement demonstrates the impact of corpus size on retrieval accuracy. For more detailed experiments on corpus reduction with the fine-tuned model, see Table 4 in Appendix A.

Our analysis revealed several key outcomes:

- The base model multilingual-e5-large-instruct consistently outperforms other options.
- The implemented model training architecture is well-suited for the provided dataset training, allowing to obtain a fine-tuned model that outperforms the best base model tested in experiments.
- Appropriate input prefixes can provide substantial performance gains, improving Success@10 by 0.013 points on average.
- There is considerable variability in model performance between languages, suggesting that language-specific tuning could yield extended improvements.
- Corpus reduction by language dramatically improves retrieval accuracy, highlighting the importance of effective pre-filtering strategies.

Subsequent work could focus on addressing the performance discrepancy among languages, perhaps through language-specific fine-tuning or more sophisticated cross-lingual transfer techniques. Moreover, exploring ensemble methods that combine multiple embedding models might improve retrieval accuracy for challenging languages.

6 Acknowledgments

We would like to thank the SemEval-2025 task organizers for creating this challenging and impactful

task, and for providing thorough evaluation metrics and datasets.

A Corpus Reduction Analysis

Table 4 shows the impact of corpus reduction on the fine-tuned model's performance. The results demonstrate that using language-specific subsets of the fact-check corpus significantly improves retrieval performance.

Model	Posts Prefix	Facts Prefix	S@10
multi-e5	query:	passage:	**0.934**
multi-e5	–	–	0.933
multi-e5	post:	fact check:	0.934
multi-e5	This is a post...	This is a fact...	0.936
multi-e5	<[language]>	–	0.933
multi-e5	The following...	The following...	0.934

Table 4: Fine-tuned model performance with different configurations when using a reduced corpus. All experiments were conducted on the validation set with a corpus containing only fact checks in the same language as the query posts, resulting in higher overall scores compared to the full corpus evaluation.

Our experiments showed that performance improves significantly when the fact-check corpus is reduced to include only documents in the same language as the query post. For example, when retrieving from a language-specific subset of approximately 16,000 fact checks (versus the full corpus of 272,447), Success@10 scores improved by an average of 10.2%.

Abstract

Idioms are integral components of language, playing a crucial role in understanding and processing linguistic expressions. Although extensive research has been conducted on the comprehension of idioms in the text domain, their interpretation in multi-modal spaces remains largely unexplored. In this work, we propose a multi-expert framework to investigate the transfer of idiomatic knowledge from the language to the vision modality. Through a series of experiments, we demonstrate that leveraging text-based representations of idioms can significantly enhance understanding of the visual space, bridging the gap between linguistic and visual semantics.

1 Introduction

Idioms, such as "kick the bucket" or "spill the beans," are a common subset of multi-word expressions (MWEs) that play a crucial role in natural language understanding. MWEs are sequences of words that exhibit idiosyncratic properties, meaning their overall meaning cannot always be inferred from the meanings of their components (Sag et al., 2002). Studying idioms and MWEs is essential in natural language processing (NLP), machine translation, and sentiment analysis. Traditional NLP models often struggle with idioms since their literal interpretation differs from their intended meaning.

In recent years, the rapid advancement of deep learning and large language models has sparked significant interest in the study of idioms. Most research in this area has primarily focused on machine translation (Dankers et al., 2022; Baziotis et al., 2023; Donthi et al., 2025) and semantic analysis (Tahayna et al., 2022), yielding promising results. While significant progress has been made in understanding idioms within the textual domain, their representation in a multi-modal context remains largely unexplored.

In Task 1 of SemEval-2025 (Pickard et al., 2025), we must receive some images, a sentence, and a phrase used in it as input. Whether the phrase is literal or idiomatic, we must identify which image is closest to that meaning and rank the images accordingly. So, in this work, we aim to bridge this gap by analyzing how images convey idiomatic knowledge and investigating the relationship between visual and linguistic representations of idioms. To address this task, we propose an architecture composed of two expert models for the English language: one dedicated to processing idiomatic sentences and the other to handling sentences in their literal sense. We first classify the phrase in the sentence, and then the corresponding expert ranks images based on their specialized training. Further details about the architecture are provided in Section 4.

2 Related Work

BERT is a deep learning model introduced by (Devlin et al., 2019) that has revolutionized natural language processing (NLP) by leveraging a bidirectional Transformer architecture (Vaswani et al., 2017). Unlike traditional language models that process text sequentially, BERT captures context from both left and right directions, allowing it to understand the meaning of words in relation to their surroundings. Pre-trained on vast amounts of text using masked language modeling and next-sentence prediction tasks, BERT has demonstrated state-of-the-art performance on various NLP benchmarks.

CLIP is a multi-modal model developed by OpenAI (Radford et al., 2021) that learns to associate images with textual descriptions using contrastive learning. It consists of two separate encoders: a Transformer architecture (Vaswani et al., 2017) for processing text and a Vision Transformer (ViT) (Dosovitskiy et al., 2021) for encoding images. These encoders project their respective modalities

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2270–2275

into a shared embedding space, where contrastive learning aligns visual and linguistic representations. Trained on diverse image-text pairs, CLIP enables zero-shot classification and retrieval even without task-specific fine-tuning, showcasing broad generalization across domains.

SemEval-2022 Task 2 (Tayyar Madabushi et al., 2022) focuses on multilingual idioms in three languages: English, Portuguese, and Galician. This task is divided into two subtasks: Subtask A evaluates a language model's ability to identify idiomatic expressions, while Subtask B assesses how effectively a model generates sentence representations containing idioms. Subtask A includes two evaluation settings: Zero-Shot and One-Shot, whereas Subtask B includes Pre-Training and Fine-Tuning settings. The dataset used in SemEval-2022 Task 2 is an extension of the one introduced by (Tayyar Madabushi et al., 2021). It comprises 8,683 entries across the three languages (English: 5,352, Portuguese: 2,555, Galician: 776). For Subtask A, multilingual BERT served as the baseline model, and for Subtask B, the approach involved introducing single tokens for each multiword expression (MWE) in the dataset.

(Phelps et al., 2024) investigates the capacity of LLMs to comprehend idioms. The study suggests that LLMs perform worse than fine-tuned encoder-only models on these tasks. However, it also observes that performance in idiomaticity detection improves as the model size increases.

3 Dataset

The AdMIRe dataset (Pickard et al., 2025) contains 200 data points, divided into four subsets: train, validation, test, and extended test, which accordingly have 70, 15, 15, and 100 data points. Each data point consists of a phrase, a sentence containing the phrase, five images, and corresponding captions. Additionally, each data point is annotated with a label indicating whether the phrase is used idiomatically in the sentence. The dataset also provides the expected ranking order of the images, representing the ground truth for their relevance to the phrase in the sentence.

Figure 1 shows a sample data point. The phrase for this data point is "open book," used idiomatically in the sentence, which means a person whose thoughts and feelings are easy to know. As you see, two of the images are close to literal meaning, two of them are close to idiomatic meaning, and there is an image that is completely different from the phrase and sentence, so the ranking must be "B E C A D". The labeled dataset is publicly available at this link.

For our idiom detection and representation models, we use the English subset of the AStitchInLanguageModels dataset (Tayyar Madabushi et al., 2021), which contains 4,645 examples from 223 different phrases. Each instance represents either the idiomatic or literal meaning of the phrase. Additionally, the dataset provides a literal meaning for each phrase, while phrases with idiomatic examples include 1 to 3 non-literal (idiomatic) meanings. The dataset is available at this link.

4 System Overview

Our system consists of three experts and works as follows. First, the BERT-based classifier receives the sentence and phrase as input to determine whether the phrase is used in its idiomatic or literal sense. If the phrase is used idiomatically, the idiomatic expert takes the sentence, phrase, image, and its caption to calculate a relevance score for each image and ranks them accordingly. If the phrase is used literally, the literal expert follows the same process to compute relevance scores and rank the images based on their alignment with the literal meaning of the phrase. The overview of our system is shown in Figure 2. We will see the details of each expert in the following.

4.1 Classifier Expert

We fine-tuned a BERT model for idiom classification on the AStitchInLanguageModels and AdMIRe datasets to serve as our classifier expert. The model takes a phrase and a sentence as input, separated by the [SEP] token (i.e., "phrase [SEP] sentence"). The [CLS] token embedding is extracted and passed through a projection layer that maps it to a logit for classification. During the training phase of the entire system, this classifier is not used since the true labels are available. Instead, the classifier is only employed at inference time when the labels are unknown.

4.2 Idiomatic Expert

Once a data unit is identified as a term, we use our term specifier to score its images. This expert consists of 4 components. The first component is a BERT model fine-tuned to take a sentence and the phrase and translate it into an embedding space that

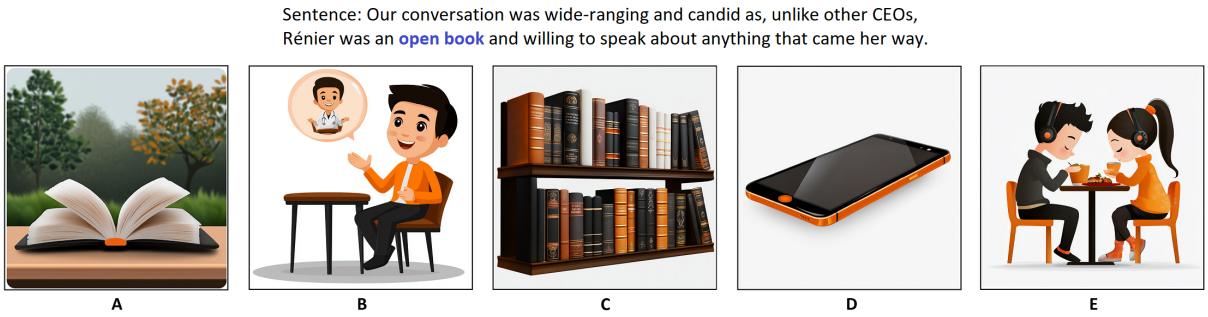

Figure 1: The images of a sample data point in the AdMIRe dataset, where the related phrase is "open book" and the sentence is "Our conversation was wide-ranging and candid, as, unlike other CEOs, Rénier was an open book and willing to speak about anything that came her way."

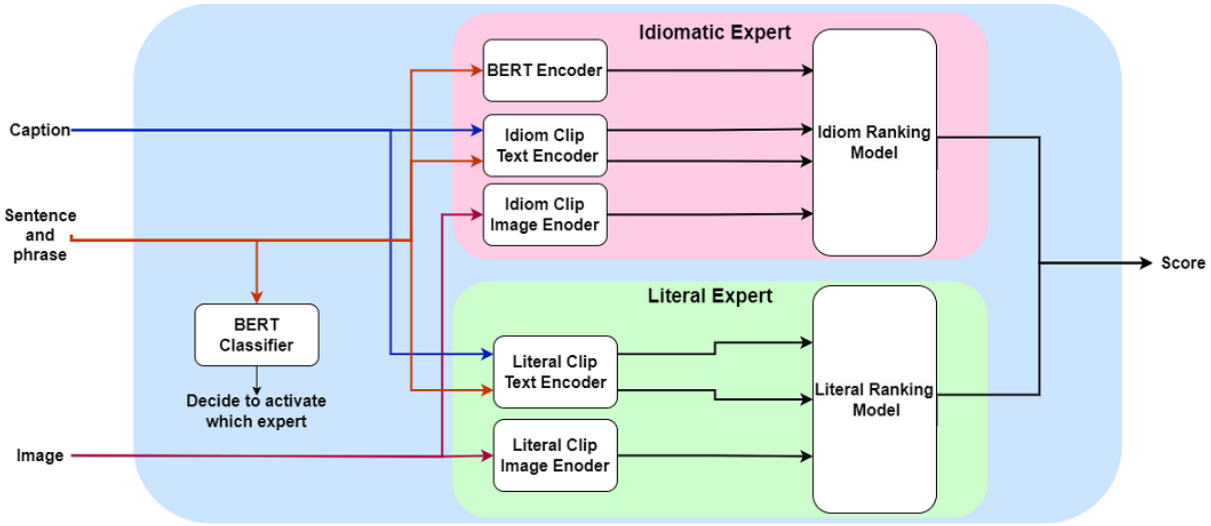

Figure 2: The first expert (BERT classifier) activates the idiomatic expert or literal expert, respectively, based on whether the phrase in the sentence has an idiomatic meaning or a literal meaning, so that the selected expert can assign a score by taking the sentence, image, and caption

has a good representation of the idiomatic meaning of that phrase. The details are discussed in Section 4.2.1.

The second and third components are the text encoder and image encoder of a pre-trained CLIP model. The text encoder maps sentences and captions into the embedding space, while the image encoder performs the same transformation for images, aligning both modalities in a shared space. Due to the limited size of our training data, one of the primary challenges is overfitting. To mitigate this, we simplified the model during training by freezing the image encoder and fine-tuning only the last two layers of the text encoder. Additionally, since many image captions exceeded the input length of the text encoder, we summarized them using the (Lewis et al., 2019) model, reducing their length to a maximum of 60 words.

The final component is a ranking model, implemented as a simple feed-forward neural network with one hidden layer. This network receives four 768-dimensional embeddings from the previous components and projects each embedding into a 128-dimensional hidden state using a fully connected layer followed by a ReLU activation function. The four hidden vectors are then concatenated and projected onto a single scalar value, representing the final similarity score for the input embeddings. The ranking model is trained simultaneously with the last two layers of the CLIP text encoder.

4.2.1 Bert Encoder

To improve the representation of phrase meanings in the BERT encoder, we incorporated additional loss components alongside the classification loss in the final objective function. Specifically, we provided the literal and idiomatic meaning of the phrase to a CLIP text encoder and extracted em-

Table 1: The rank-1 accuracy, rank difference, and classification accuracy for the entire system and each expert module independently

	Data	Rank-1 Acc.	Rank Diff.	Class Acc.
Entire System	Train	0.757	3.543	0.986
	Dev	0.667	4.933	0.800
	Test	0.650	5.807	0.933
	Ex-test	0.500	5.260	0.740
Idiom Expert	Train	0.744	3.641	0.974
	Dev	0.714	5.143	0.857
	Test	0.750	6.250	0.875
	Ex-test	0.510	4.939	0.826
Literal Expert	Train	0.774	3.419	1.000
	Dev	0.625	4.750	0.750
	Test	0.571	5.143	1.000
	Ex-test	0.480	5.548	0.667

beddings for each. Using cosine similarity, we introduced a contrastive loss that encourages the BERT encoder's output embedding to be closer to the embedding corresponding to the correct meaning (based on the ground truth label) and farther from the other.

4.3 Literal Expert

The literal expert architecture is very similar to the idiomatic expert architecture, with the main difference being that the BERT encoder is not used. This is because the task is simpler. The CLIP model has seen most expressions in their literal sense during its pre-training and does not require additional semantic information. As a result, the ranking model receives three inputs instead of four.

5 Experimental Setup

The dataset was split into training, validation, and test sets. We applied basic pre-processing like tokenization and encoding using the Hugging Face Transformers library. The model was trained with the AdamW optimizer, using a learning rate of 3×10^{-6} and a weight decay of 1×10^{-4}, over 30 epochs with a batch size of 4. To keep the results consistent, we set a fixed random seed. The training was done using PyTorch on a P100 GPU.

6 Results and Analysis

To evaluate the system during inference, we employ our BERT classifier for classification, where its errors directly impact the final output. The evaluation consists of two types of tests: one on the entire system and another on each expert module independently. For example, to measure the performance of the idiom expert, we input only data labeled with the idiom attribute into the system. The evaluation metrics include Rank-1 Accuracy and Rank Difference, defined as the absolute difference between the predicted and ground truth rankings. The results of both the overall system and individual expert modules are presented in Table 1. Further analyses are provided in the following sections.

6.1 Remove captions and use cosine for literal expert

In one of our experiments, we excluded the image captions and modified the literal expert module to compute the image score by measuring the cosine similarity between the image encoder's and text encoder's output embeddings of CLIP. This system was submitted to Task 1 of SemEval-2025, achieving 87% rank-1 accuracy on the test set and 48% on the extended test set.

As shown in Table 2, the baseline system (using cosine similarity without captions) achieves higher rank-1 accuracy on the test set compared to our proposed system. However, our system performs better on the extended test set, which contains a larger and more diverse set of samples. This suggests that our final system generalizes better to broader, unseen data compared to the baseline.

Table 2: Rank-1 accuracy for the baseline (without captions and cosine similarity for literals) and the proposed system on test and extended test sets.

	Data	Rank-1 Acc.
Baseline	Test	87%
	Ex-test	48%
Proposed System	Test	65%
	Ex-test	50%

6.2 Different Losses

One of the key factors for achieving better learning and generalization is selecting an appropriate loss function. Therefore, we train the models using different loss functions, including Pairwise Hinge, Listwise Softmax, and Top-1 Hinge. The details of these loss functions are provided in Appendix A, and the results of these experiments are presented

in Figure 3. As you can see, the pairwise loss function achieves higher accuracy compared to other loss functions.

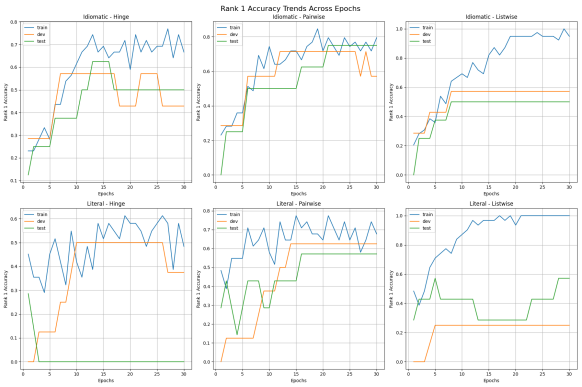

Figure 3: Rank 1 accuracy trends over epochs for different ranking loss functions on idiomatic and literal data. The results show that the pairwise loss function achieves higher accuracy compared to other loss functions, indicating better ranking performance.

6.3 Analyze impact of BERT encoder

One of the key components of the Idiom Expert model is its BERT encoder, which plays a crucial role in generating high-quality representations of idioms. In this experiment, we evaluated its contribution by removing the encoder and analyzing its impact on the model's performance. As you can see in Figure 4, using BERT embeddings helps our model achieve better performance and generalization.

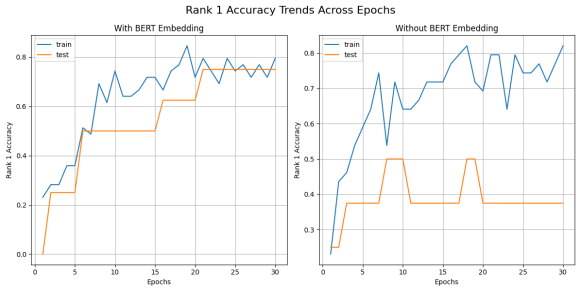

Figure 4: Rank 1 accuracy trends over epochs for idiomatic data. The left graph shows results using BERT embeddings as a feature of the ranking model, and the right one without using these embeddings. The BERT model helps the model generalize better and improves performance.

7 Conclusion

In this paper, we propose a multi-expert architecture to rank images based on whether a given phrase is used as an idiom or a literal expression in the accompanying sentence. By leveraging datasets from idiom detection tasks in the text domain, we successfully transfer their knowledge to the image space. Additionally, we explore various loss functions to identify the most effective one for the ranking task, demonstrating the impact of each component through ablation studies that remove different parts of the architecture.

For future work, these datasets open up exciting possibilities, such as generating images for idiomatic expressions, converting idiom-related images into textual descriptions, and other multimodal tasks. Moreover, new image-based datasets can be constructed from existing text datasets, facilitating the development of more robust models and addressing increasingly complex challenges in the intersection of language and vision.

A Loss Functions

A.1 Pairwise Hinge Loss

This loss ensures that a higher-ranked item has a greater predicted score than a lower-ranked one by a margin m, penalizing violations:

$$\mathcal{L}_{\text{pairwise}} = \frac{1}{N} \sum_{i,j} \max(0, m - (s_i - s_j)) \cdot \text{sign}(r_j - r_i)$$

where s are predicted scores, r are ground truth ranks, and N is the number of item pairs.

A.2 Listwise Softmax Loss

This loss applies softmax normalization on ranking scores and minimizes cross-entropy to align predicted and true rankings:

$$\mathcal{L}_{\text{listwise}} = -\sum_{j} p_j \log \hat{p}_j$$

where $p_j = \frac{e^{-r_j}}{\sum_k e^{-r_k}}$ is the true rank distribution and $\hat{p}_j$ is the softmax-normalized prediction.

A.3 Top-1 Hinge Loss

This loss maximizes the margin between the top-ranked item and others while suppressing overall scores:

$$\mathcal{L}_{\text{top1}} = \sum_{j \neq \text{top1}} \max(0, m + s_j - s_{\text{top1}}) - s_{\text{top1}} + \alpha \sum_{j} s_j$$

where s_{top1} is the score of the most relevant item, and α controls non-top-1 suppression.

YNU-HPCC at SemEval-2025 Task 8: Enhancing Question-Answering over Tabular Data with TableGPT2

Kaiwen Hu, Jin Wang and Xuejie Zhang
School of Information Science and Engineering
Yunnan University
Kunming, China

Abstract

This paper describes our systems for SemEval 2025 Task8, Question Answering over Tabular Data. This task encourages us to develop a system that answers questions of the kind present in DataBench over day-to-day datasets, where the answer is either a number, a categorical value, a boolean value, or lists of several types. Participating in Task 8, we engage in all subtasks. The challenge lies in the multi-step reasoning process of converting natural language queries into executable code. This challenge is exacerbated by the limitations of current methods, such as chaining reasoning, which have difficulty handling complex multi-step reasoning paths due to difficulty evaluating intermediate steps. On the final competition test set, our DataBench accuracy is 65.64%, and DataBench Lite accuracy is 66.22%. Both exceed the baseline. The competitive results in two subtasks demonstrate the effectiveness of our system.[1]

1 Introduction

The rise of large language models (LLMs) has transformed research in natural language processing (NLP). Their ability to learn from little data has made them useful for tasks like summarization (Zhang et al., 2024a) , machine translation, and text sentiment analysis (Zhang et al., 2024b). This progress has been driven by the development of general-purpose LLMs and the discovery of their unexpected abilities. However, the rapid growth of these models hasn't been matched by high-quality benchmarks for comparing their performance.

Question answering (QA) has been a key NLP task focused on finding the best answer from unstructured text. The issue of structured knowledge grounding has been widely researched for years. Furthermore, tables, a common form of (semi)-structured data that stores world knowledge, have garnered considerable attention from the natural language processing (NLP) community. Traditionally, accessing the information inside the structured data (like tables) has depended on synthesizing executable languages like SQL or SPARQL. Still, these methods don't understand the meaning of text in the fields or allow natural language questions. Such challenges have led to interest in using LLMs to answer questions from structured or tabular data. Recently, the ability of LLMs to perform table question answering (Chen, 2023; Chen et al., 2020; Nan et al., 2021; Zhu et al., 2021) has emerged as a valuable skill. This highlights the need for a reliable benchmark to evaluate LLM performance.

Our contributions can be summarized as follows: We propose an approach exploring using the TableGPT2-7B (Su et al., 2024) model to solve the corresponding subtasks. The model develops a tabular encoder that processes the entire table, generating compact embeddings for each column.

The rest of this paper is structured as follows: Section 2 covers related work, Section 3 presents an overview of the model and our system, and Sections 4, 5, and 6 detail the experiments, key results, and conclusions, respectively.

2 Related Work

2.1 Semantic Parsing

In table question answering (QA) context, semantic parsing refers to converting a natural language question into a formal, structured representation that can be understood and processed by a machine. This structured representation often takes the form of a query (like SQL) that can be executed to retrieve the relevant data from the table like WikiTableQuestions (Pasupat and Liang, 2015), WikiSQL (Zhong et al., 2017), and Spider (Yu et al., 2018). For example, for the question *What is the total sales for Product X in January?*, the semantic parser would convert it into a query: *SELECT*

[1]The code of the paper is available at https://github.com/ywh5/semeval2025-task8

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2276–2282

SUM(sales) FROM table WHERE product = 'Product X' AND month = 'January';. Semantic parsing in table QA aims to accurately interpret the intent behind the natural language question and maps it to the appropriate data manipulation or retrieval query that can be executed on the structured table. In short, it's about bridging the gap between the natural language used by the user and the structured data format needed for querying.

2.2 Table question answering

Table question answering or question answering on tabular data aims to provide answers to natural language questions from data in tables (Jin et al., 2022), which is a spin-off task of QA. The user's question involves table-based question answering, which focuses on delivering accurate responses by comprehending and reasoning through tables.

Table QA tasks generally originate from querying relational databases using natural language, where the tables are well-structured. This approach addresses the table QA task by employing a semantic parser to convert natural language into a structured query (such as SQL), which is then executed to retrieve the answers (Zhong et al., 2017).

3 System Overview

Our system is designed to generate Python code using the Pandas library to extract information from these datasets.

3.1 Prompt Generator

The prompt generator creates prompts for the LLM, which include three components: (1) a general task description (creating a query to answer a question), (2) examples of questions, table summaries, and expected answers, and (3) the actual question and table summary for the LLM to process. We show a summarized prompt in the follow Listing.

Listing 1: Example of a prompt used in our experiments.

```
Your task is to generate pandas code to
    answer a specific question based on
    a provided table of data.
You will receive a list of column names,
     a DataFrame in JSON format, and the
     question itself.
Select the relevant columns and complete
     the 'answer' function accordingly.
Ensure proper type compatibility in
    aggregate operations, and always
    close expressions before applying
    further operations.
Use 'empty' to check if any columns are
    missing data.
Provide the answer to the last question.
Keep the output straightforward and
    focused on solving the problem.

TODO: complete the following function in
     one line.
Question: How many rows are there in
    this dataframe?
Function:
def example(df: pd.DataFrame) -> int:
    df.columns=["A"]
    return df.shape[0]

TODO: complete the following function in
     one line.
Question: {question}
Function:
def answer(df: pd.DataFrame) -> {row["
    type"]}:
    df.columns = {list(df.columns)}
    return
```

3.2 Model Selection

We conducted empirical experiments to find the best model for code generation. TableGPT2's language framework is built on the Qwen2.5 (Yang et al., 2024) architecture. It undergoes continual pretraining (CPT), supervised fine-tuning (SFT), and an agent framework for production-level ability. These steps set it apart from traditional LLMs, as the pretraining and fine-tuning focus more on coding, multi-turn reasoning, and tool utilization. This approach ensures the model excels in natural language processing and addressing the complex demands of table-related tasks.

TableGPT2 introduces a unique modality module designed specifically for reading and interpreting tabular data. Similar to vision-language models (VLMs), it features a tabular data reading module that generates specialized embeddings, which are then combined with token embeddings from textual input. This module enhances TableGPT2's ability to understand the structure and semantics of tabular data, improving its performance in complex business intelligence scenarios.

The conceptual diagram of the TableGPT2 model revolves around continuous pretraining

(CPT) and supervised fine tuning (SFT).

Continual Pretraining (CPT). CPT focuses on enhancing coding and reasoning abilities. 80% of the CPT (Ke et al., 2023) data was well-commented code, aligned with DeepSeek-v2 (DeepSeek-AI et al., 2024), ensuring strong coding capabilities. The remaining data included domain-specific knowledge to improve reasoning. A two-level filtering strategy was used: categorizing documents with 54 labels for diverse coverage and fine-tuning token selection with the RHO-1 (Lin et al., 2024) technique. Additionally, strategies for code length and context windows were introduced (Kim and Lee, 2024), optimizing model performance for handling different code segments. After filtering, the CPT data comprised 86 billion tokens, boosting the model's coding and reasoning for complex BI tasks.

Supervised Fine-Tuning (SFT). This stage focuses on adapting the model for BI-specific tasks and addressing its prior limitations. The dataset coveres multi-turn conversations, complex reasoning, tool usage, and business-specific queries. It includes 2.36 million samples and billions of tokens. Key areas of specialization includes table-based tasks such as code generation (Wang et al., 2021; Ahmad et al., 2021) (Python, SQL), table querying, data visualization, and predictive modeling. The dataset ensures variety by incorporating different input formats and table metadata combinations. A multi-step filtering pipeline is employed, with rule-based checks for code correctness, anomaly detection, and scoring using models like GPT-4o. Only high-quality samples pass, with manual calibration and validation against a fixed validation set of 94.9K cases.

The overall system framework is shown in Figure 1, which also demonstrates how QA works over tables from a particular industry and how the LLM encodes the tabular data. As shown in the figure, the table encoder takes the entire table as input and generates compact embeddings for each column. This architecture is optimized for the unique properties of tabular data, which differs significantly from text, images, or other data types. The semantics of the table are represented in four key dimensions: cells, rows, columns, and the entire table structure, all of which exhibit permutation invariance. To address this, a bi-dimensional attention mechanism is used without positional embeddings, along with a hierarchical feature extraction process to capture both row-wise and column-wise relationships effectively. Additionally, a column-wise contrastive learning approach is employed to encourage the model to learn meaningful, structure-aware semantic representations of the table.

3.3 Automatic code execution

Our system automatically extracts the Python function from the LLM's response and runs it on the validation and test dataset. The output from the function serves as the system's answer to the query. If an error occurs during execution, the system captures it and sends an updated prompt to the model, including the erroneous code and details about the error.

The overall workflow of the system is as follows:

- **Input:** Our system retrieves the question and loads the relevant DataFrame.
- **Prompt:** The prompt is produced through the utilization of the question and the dataset header.
- **LLM:** Utilize the generated prompt to make a call to the LLM and extract the corresponding answer out of the response.
- **Execution:** The answer function is operated on the DataFrame so as to acquire the answer.
- **Error Handling:** In case the execution fails, the error is caught, and the LLM is prompted once more with the inclusion of the error details.
- **Output:** The final output is to answer the initial question.

The above approach enhances our system's ability to reduce errors and improve entire accuracy.

4 Experimental Settings

4.1 Dataset

There are 65 publicly available datasets summarized in Table 1 and Table 2. Each dataset for this task includes natural language questions, relevant column information, and corresponding answers. Moreover, it has 20 hand-made questions per dataset, with a total number of 1300 questions. Questions are further split in different types depending on the type of answer (i.e., true/false, categories from the dataset, numbers or lists), and their corresponding gold standard answer accompanies each question.

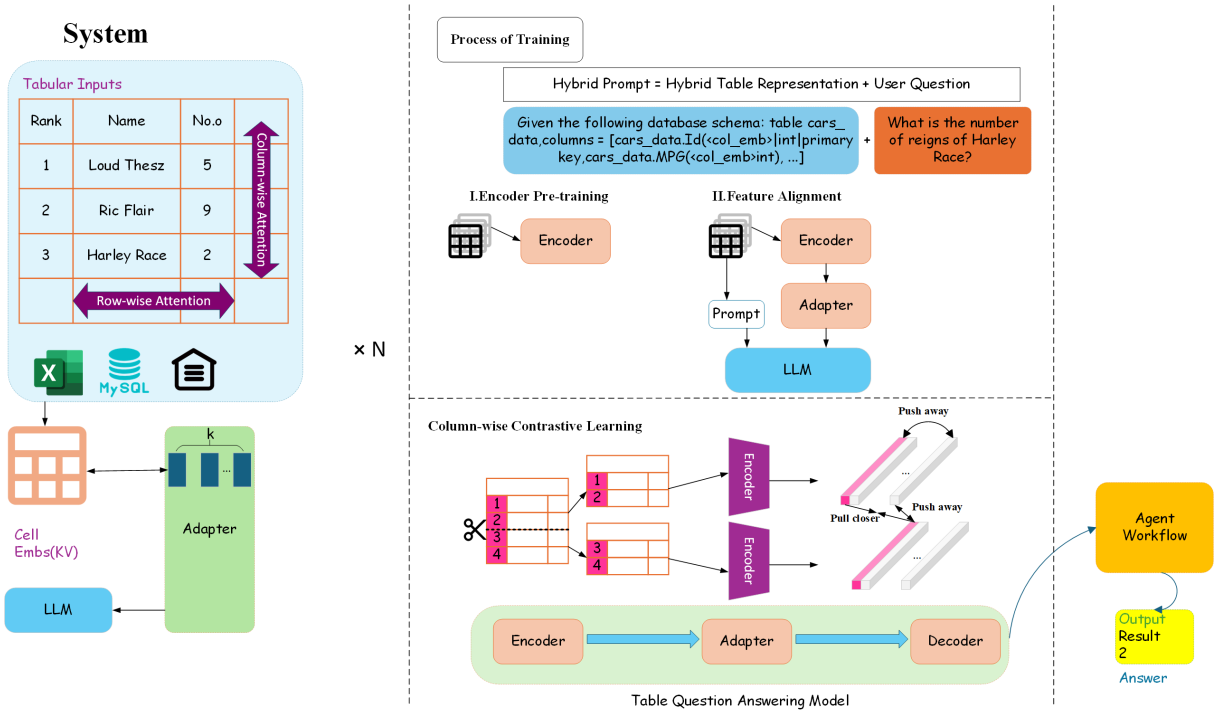

Figure 1: An illustration example of table QA system. The number (2) is the target answer.

Domain	Datasets	Rows	Columns
Business	26	1,156,538	534
Health	7	98,032	123
Social	16	1,189,476	508
Sports	6	389778	177
Travel	10	427,151	273
Total	65	3,269,975	1615

Table 1: DataBench domain taxonomy.

Type	Columns	Example
number	788	583600
category	548	Flat
date	50	1934-02-09
text	46	Such a ...
url	31	apple.com
boolean	18	False
list[number]	14	[21, 14, 13, 11]
list[category]	112	[sales, technical]
list[url]	8	[apple.com, ...]

Table 2: Column types present in DataBench.

4.2 Baselines

In these experiments, we mainly consider the following baseline models.

Stable-Code. Stable-Code-3B (Pinnaparaju et al.) is a 2.7B billion parameter decoder-only language model pre-trained on 1.3 trillion tokens of diverse textual and code datasets. It is trained on 18 programming languages (selected based on the 2023 StackOverflow Developer Survey) and demonstrates state-of-the-art performance (compared to models of similar size) on the MultiPL-E metrics across multiple programming languages tested using BigCode's Evaluation Harness.

CodeLlama. CodeLlama, a specialized version of Llama2 designed for coding tasks (Rozière et al., 2023), excels in coding benchmarks and benefits from a 16K token window. We utilized its instruction models with 7B parameter sizes, emphasizing its ability to generate and understand code.

Deepseek-Coder. Deepseek Coder comprises a series of code language models, each trained from scratch on 2T tokens, with a composition of 87% code and 13% natural language in both English and Chinese. It provides various sizes of the code model, ranging from 1B to 33B versions. Each model is pre-trained on project-level code corpus by employing a window size of 16K and an extra fill-in-the-blank task to support project-level code completion and infilling. For coding capabilities, Deepseek Coder achieves state-of-the-art performance among open-source code models on multiple programming languages and various benchmarks.

4.3 Implementation Details

The deployment of Stable-Code, CodeLlama, Deepseek-Coder, and TableGPT2 used the official checkpoints provided by HuggingFace. The experiments were run on a machine equipped with a single NVIDIA Tesla P100 GPU with 16GB VRAM, only suitable to run these models.

4.4 Evaluation Metrics

The evaluation focuses on accuracy and is further split by question types and other factors. The accuracy is obtained by comparing predicted answers with the correct answers across various domains (such as booleans, categories, numbers, etc.). However, one issue with LLMs is that their responses often lack a consistent formatting pattern. Relaxing the criteria for a correct answer to allow small format variations is an effective solution to address this. For example, answers like "true," "True," or "Yes" will all be considered correct for a boolean question that is meant to be true. This flexibility has a minimal impact on code-based models. Furthermore, for lists, the order of elements is not considered in contrast to the ground truth, which may be important in some cases.

5 Experimental Results

Results on Dev Set. When processing input prompts in batches and generating text, we adjust some parameters to change the diversity and length of the generated text. For example, the parameter *temperature* controls the randomness or creativity of the generated text. When the *temperature* is low, the text generated by the model is more deterministic and tends to choose words with higher probability; when the *temperature* is high, the generated text is more diverse and random. We use two *temperatures* of 0.1 and 0.2. As shown in Table 3, the model performs better when the *temperature* is lower, especially on DataBench Lite. If *do_sample* is set to True, the sampling strategy is enabled. The model will generate the next token based on probability distribution sampling. This method will increase the diversity of generated text. If set to False, the model will use a greedy strategy to select the next token with the highest probability.

Competition Results. Our experimental results on the test set for the task competition are summarized in Figure 2. It can be observed that the TableGPT2-7B model achieves the highest performance scores in all subtasks. Also, we observe a large performance gap between these models, although their number of parameters is similar.

Analysis. As indicated in Figure 2, TableGPT2-7B achieves 0.65% accuracy on the DataBench benchmark and 0.66% accuracy on the DataBench Lite benchmark. The consistency across both benchmarks (DataBench and DataBench Lite) further validates its robustness and generalizability.

When comparing it with other models like the Deepspeek-Coder-6.7B-Base, which shows an accuracy of 0.51% on DataBench and 0.50% on DataBench Lite, the TableGPT2-7B outperforms them by a notable margin, indicating that it benefits from more refined training or a more effective architecture for this type of task. In contrast, the Stable-Code-3B and CodeLlama-7B-hf models exhibit comparatively lower accuracy rates, highlighting the potential advantages of using larger or more specialized models like TableGPT2-7B for similar tasks. The result suggests that further fine-tuning or enhancement of such models could lead to even more significant improvements in performance.

Meanwhile, the results of Deepseek-Coder's three different parameter models (Deepspeek-Coder-1.3B-Base, Deepseek-Coder-5.7Bmqa-Base and Deepspeek-Coder-6.7B-Base) show that the accuracy improves as the model size increases.

The accuracy of Deepspeek-Coder-1.3B-Base on DataBench is 0.40%, and slightly lower on DataBench Lite, 0.39%. The accuracy of Deepspeek-Coder-6.7B-Base is 0.51% and 0.50%, respectively, which is more than 27% higher than the 1.3B-version. Increasing the number of model parameters (from 1.3B to 6.7B) impacts model performance. Generally speaking, larger models can capture more data features and subtle patterns and thus perform better in complex tasks. This suggests that the 6.7B version of Deepseek-Coder may have obtained more contextual information during training and can better cope with the challenges in the task.

However, an important point can also be drawn from this, that is, simply increasing the parameters of the model does not always guarantee unlimited improvement. Taking the Deepspeek-Coder model as an example, when the number of parameters increased from 5.7B to 6.7B, the results do not improve much. After a certain scale, the performance improvement of the model gradually stabilizes; in other words, other factors such as data quality and training strategy are equally important in affecting the model's performance.

Model	Temperature	Do_sample	Accuracy	
			DataBench	DataBench Lite
Stable-Code-3B	0.1	True	0.48	0.47
	0.2	True	0.47	0.44
	0.1	False	0.48	0.48
TableGPT-7B	0.2	True	**0.72**	**0.68**

Table 3: Comparison on different parameters.Evaluation is based on accuracy(%).

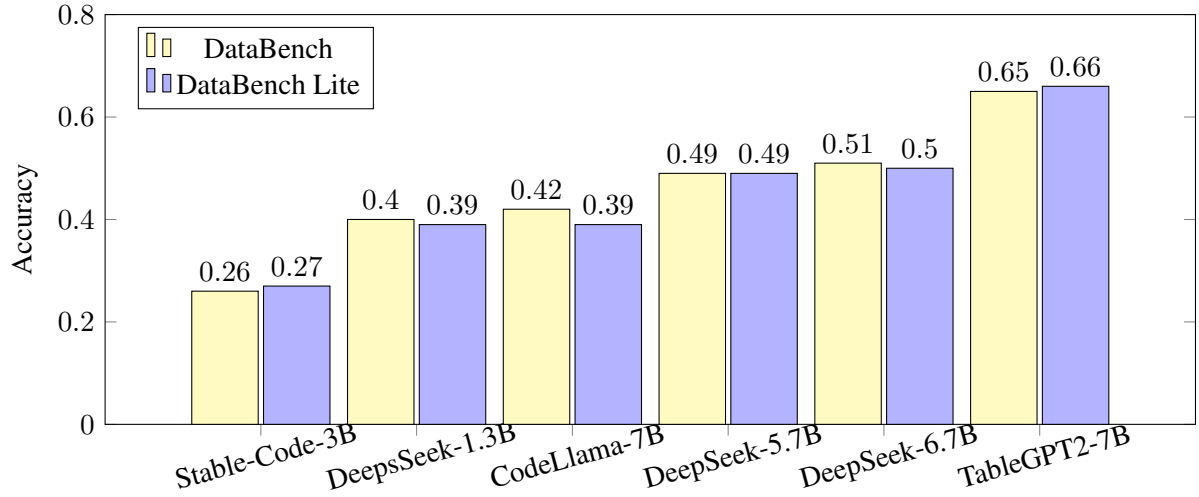

Figure 2: Comparison of model accuracy on DataBench and DataBench Lite.

In general, the increase in parameter scale brings about performance improvement, but this improvement is not endless, so optimizing other factors is also the key to improving model performance.

6 Conclusions

During Task 8 in SemEval 2025, we made prediction for each question provided by final competition. Conducting preliminary exploration on the training set and validation set, we finally decided to use the TableGPT2 model to complete the competition. Due to the powerful table understanding ability of this model, it has an inherent advantage in handling Task 8. Our approach proved to be highly effective by outstanding performance in this task. In future work, we may adjust some basic parameters or explore models with larger parameters to optimize the experimental results (which have been proven to be effective in above work). Thus, our goal is to continue progressing in this area.

Abstract

As human-machine interactions become increasingly natural through text, accurate emotion recognition is essential. Detecting emotions provides valuable insights across various applications. In this paper, we present our approach for SemEval-2025 Task 11, Track A, which focuses on multi-label text-based detection of perceived emotions. Our system was designed for and tested on English language text. To classify emotions present in text snippets, we initially experimented with traditional techniques such as Logistic Regression, Gradient Boosting, and SVM. We then explored state-of-the-art LLMs (OpenAI o1 and DeepSeek V3) before developing our final system, utilizing a fine-tuned Transformer-based model. Our best-performing approach employs an ensemble of fine-tuned DeBERTa-large instances with multiple seeds, optimized using Optuna and StratifiedKFold cross-validation. This approach achieves an F1-score of 0.75, demonstrating promising results with room for further improvement. Additionally, this paper provides benchmark for 30 emotion classification methods on the BRIGHTER-English dataset.

1 Introduction

SemEval-2025 Task 11 (Muhammad et al., 2025b) focuses on detecting perceived emotion in short text snippets. Emotion detection has valuable applications in fields such as healthcare, education, finance (Hajek and Munk, 2023), customer service, and other applied domains (Kusal et al.; Liu et al.). Our participation in this task was centered on the English language, where we explored various approaches before ultimately adopting DeBERTa-large (He et al., 2021).

This task provides insights into how both humans and machines perceive emotions in written text, particularly in context-free scenarios. Our focus is on Track A, which involves identifying the presence of emotions in sentences without their intensity.

As multimodal research continues to advance, integrating text, visual, and audio modalities, text remains a critical component of emotion-recognition systems (Cheng et al.). Improving emotion detection in text-based snippets not only enhances classification accuracy but also better informs the selection of key triggers for emotional shifts.

Furthermore, text-based communication remains the dominant form of online interaction.

We approach this problem with a plethora of natural language processing techniques, from traditional methods to modern Large Language Models (LLMs) such as DeepSeek V3 (DeepSeek-AI et al., 2025) and OpenAI o1 (Jaech et al., 2024). The dataset for English language for this task is heavily imbalanced, making classification challenging. Performance is evaluated using the F1-score, which allows for a balanced identification of emotion's presence and absence.

We define *traditional* methods as those relying on rule-based, feature-based, lexicon-based, or static-embedding classifiers, such as models using TF-IDF, bag-of-words, or pre-trained word embeddings like GloVe, combined with algorithms such as SVM, Logistic Regression, MLP, or Gradient Boosting. *Beyond traditional* refers to transformer-based, pre-trained, or prompt-based models-such as BERT, DeBERTa, OpenAI o1, and DeepSeek V3, which leverage deep contextual representations, large-scale transfer learning, and, in the case of models like OpenAI o1 and DeepSeek V3, zero-shot inference capabilities. (Garrido-Merchan et al., 2023; Zhao et al., 2022)

To streamline experimentation, we initially used BERT-base (Devlin et al., 2018) before applying our optimizations to our best-performing model, DeBERTa-large. This allowed us to iterate efficiently while ensuring improvements translated effectively to our final model.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2283–2296
July 31 - August 1, 2025

Text	Anger	Fear	Joy	Sadness	Surprise
But not very happy.	0	0	1	1	0
Well she's not gon na last the whole song like that, so since I'm behind her and the audience can't see below my torso pretty much, I use my hand to push down on the lid and support her weight.	0	0	1	0	0
She sat at her Papa's recliner sofa only to move next to me and start clinging to my arms.	0	0	0	0	0
Yes, the Oklahoma city bombing.	1	1	0	1	1
They were dancing to Bolero.	0	0	1	0	0

Table 1: Emotion annotations for text samples, 0 is for absence of emotion and 1 is for its presence

Throughout this task, we encountered several counterintuitive challenges. These challenges are discussed in Section 3, along with our hypotheses regarding their causes.

Our final system achieved an F1-score of 0.7537, placing us 27th out of 96 participating teams in the English track.

An analysis of our model's performance reveals notable class detection disparities. Anger, the least common emotion in our dataset, suffers from under-detection with the lowest recall (61.04%), meaning 38.96% of anger instances were missed. Conversely, fear, the most prevalent emotion, exhibits over-prediction tendencies, achieving excellent recall (91.20%) but the lowest specificity (64.77%). Despite these challenges, our model demonstrates strong overall performance, achieving multi-label subset accuracy of 47.04%, meaning the exact combination of emotions was correctly predicted in nearly half of all cases.

2 Background

2.1 Task 11 Bridging the Gap in Text-Based Emotion Detection (Track A Multi-label Emotion Detection)

In Task 11, Track A, we focused on detecting whether the emotion is present in a given sentence in English. This task revolves around perceived emotions, the emotions that most people are likely to infer from a short snippet of text provided without any context.

2.2 Related Research

In recent years, there has been significant research in this area of NLP, with various approaches proposed. These range from traditional Machine Learning techniques, such as Logistic Regression, Neural Networks, and XGBoost to Transformer-based models (Vaswani et al., 2023) like BERT, RoBERTa, DeBERTa. More recently, LLMs such as GPT-3.5, LLama 3, Mistral 7B, and Zephyr have been explored for emotion detection.

Initially, we were curious to see how more traditional and lightweight approaches would perform on this dataset. We experimented with different preprocessing and tokenization techniques, including tf-idf, word2vec (Mikolov et al., 2013), GloVe (Pennington et al., 2014). Additionally, we used the NRC Emotion Lexicon (Mohammad and Turney, 2013) and the Sentiment Intensity Analyzer from NLTK. As shown in Subsection 3.1, even when incorporating Transformer-based tokenizers, the results were underwhelming.

Further research indicated that Transformer-based models consistently delivered the best performance. This led us to experiment with BERT, RoBERTa, DeBERTa, and other Transformer-based models. For the final system, we used a homogenous ensemble, leveraging initialization variance rather than architectural diversity.

2.3 Task Setup

Track A focuses solely on the presence (or absence) of emotions in a sentence, without considering their intensity. The dataset for the English language track covers five emotions: anger, fear, joy, sadness, and surprise. Since this is a multi-label classification task, any given sentence can express multiple emotions simultaneously.

Our final system was trained on both the train-

ing and development datasets, totaling 2,884 sentences. As noted in the competition paper, the English language data was sourced from social media, primarily from Subreddits such as *r/IAmA*. The sentences were annotated by multiple annotators using *Mechanical Turk* (Muhammad et al., 2025a). No additional datasets were utilized for model training.

3 System Overview

3.1 Experiments

See Appendix E, Table 3 for a ranking of F1 scores and correlating precision and recall scores across all our experiments, including our final model.

Preparation. Our initial investigation focused on data exploration and visualization to understand the dataset's characteristics. We conducted various analyses, including examining emotion distribution, computing the correlation matrix between emotions, and analyzing text length distribution. These insights allowed us to observe the class imbalances and potential biases within the dataset. We found that **anger** was significantly underrepresented, whereas **fear** was the dominant emotion (see Appendix A, Figure 2).

Traditional ML. We first explored traditional machine learning methods for emotion classification. Using Word2Vec, tf-idf, and GloVe embeddings, we converted text into numerical representations and fed them into various classifiers, including Support Vector Machines (SVM), Neural Networks (MLP), Logistic Regression, and Gradient Boosting. Despite their computational efficiency, these models struggled to capture complex contextual relationships. While the Neural Network classifier showed moderate performance, this approach could not model complex contextual dependencies, underperforming compared to transformer-based models. This reinforced the necessity of using more advanced approaches.

Preprocessing. We experimented with different preprocessing techniques to assess their impact on classification performance: grammar recognition and correction through tagging and lemmatization, removal of stop words (e.g., *the*, *is*, *but*), and removal of non-alphabetic characters (punctuation, numbers, and special symbols). However, these modifications resulted in only negligible improvements in model performance.

Lexicon-based Approaches. Lexicon-based methods are widely used in sentiment analysis. We tested two approaches: NRC Emotion Lexicon, which has predefined mappings of words to specific emotions, and NLTK Sentiment Analyzer, a polarity-based sentiment classifier. Neither approach yielded significant improvements, likely due to the inability of predefined word mappings to capture nuanced emotional contexts in text.

Transformer-based Models. Given that transformer-based models have consistently outperformed traditional approaches in sentiment analysis, we evaluated pre-trained models such as BERT, DistilBERT (Sanh et al., 2019), DeBERTa, and RoBERTa, followed by fine-tuned versions of these models to assess the impact of domain adaptation. As expected, fine-tuned transformers outperformed their pre-trained counterparts. BERT became our baseline for further experimentation as a lightweight model with comparable results.

BERT-Tokenizer + Traditional Classifier. We also experimented with using a BERT tokenizer for text representation, followed by classification using various traditional techniques: Neural Networks (MLP), Logistic Regression, SVM, GradientBoosting (LightGBM), and k-Nearest Neighbours (KNN). The best-performing combinations involved a neural network or logistic regression classifier, but their macro F1-scores still lagged behind fine-tuned transformer models.

Addressing the Class Imbalance. Since our dataset exhibited significant class imbalance, we explored two mitigation strategies:

1. Data Augmentation. We applied synonym replacement and back-translation (Edunov et al., 2018) (via French) using OPUS-MT models (Tiedemann et al., 2023; Tiedemann and Thottingal, 2020) to generate additional samples while preserving the linguistic patterns provided. However, this had minimal or even negative effects on performance. These methods often introduced semantic drift or unnatural phrasing, adding noise rather than reinforcing emotional cues. Emotional nuances, critical for multi-label classification, were easily distorted during augmentation.

For future work, more advanced techniques like conditional text generation, semi-supervised learning, or cost-sensitive training could offer better solutions by preserving emotion-specific contexts while addressing imbalance more effectively.

2. Loss function Adjustments. We experimented with Class-Weighted Binary Cross-Entropy (to penalize misclassification of underrepresented emotions) and Focal Loss. Neither approach outperformed our baseline models.

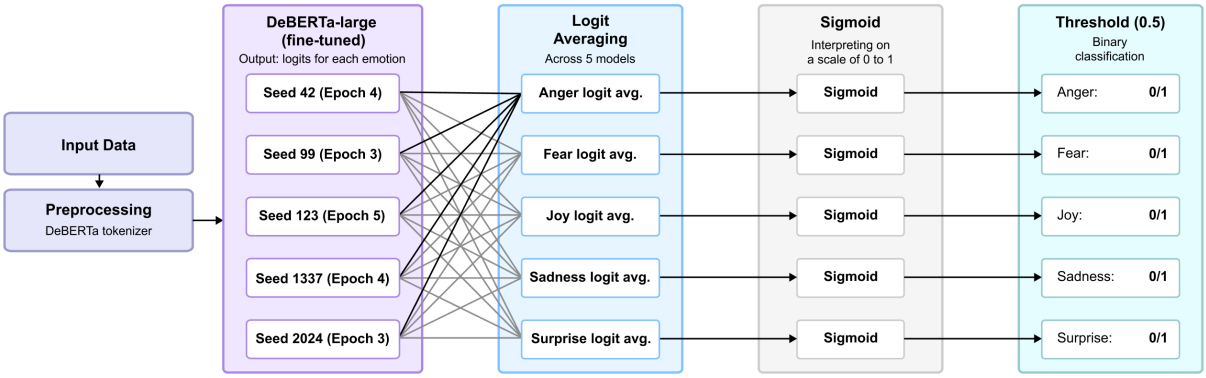

Figure 1: Runtime prediction pipeline for the final model

GPT-based LLMs. We chose to evaluate OpenAI o1 and DeepSeek V3 in a zero-shot setting, as it has been shown that few-shot prompting tends to perform even worse than zero-shot and fine-tuning (Kazakov et al.). These models performed worse than simpler methods like a BERT tokenizer with logistic regression. This is likely because zero-shot models rely on general pretraining rather than adopting the dataset's specific distribution and nuances. See Appendix D, Figure 14 for prompt details.

Ensembling. We explored ensembling by combining fine-tuned transformer models using various voting methods: SoftVoting, HardVoting, WeightedVoting, and Stacking (meta-learning). Ensembling had the most significant positive impact on predictive abilities, consistently outperforming individual transformer models.

Hyperparameter Optimization. Since ensembling yielded the best results, we further refined our approach using Optuna (Akiba et al., 2019), an open-source hyperparameter optimization framework. Optuna enabled an automated search for optimal configuration, tuning parameters such as learning rate, batch size, and dropout rate.

3.2 Final Model.

After extensive experimentation, DeBERTa-large consistently achieved the highest overall F1-scores, outperforming other transformer-based models like BERT, DistilBERT and RoBERTa.

To enhance robustness and reduce overfitting, we trained DeBERTa-large using five different seeds (42, 99, 123, 1337, and 2024). To maintain the class distribution of the original dataset, we applied stratified cross-validation with three folds.

Hyperparameter Selection. We used Optuna to optimize hyperparameters, resulting in the following configuration applied to all five seeds: *learning_rate* of 7.130877023256217e-06, *batch_size* of 8, *max_length* of 128, and *number_of_epochs* of 5.

Training and Prediction Process. Each model was trained for five epochs per seed. For the final ensemble prediction, we first computed the logits from each model (corresponding to different seeds), then averaged these logits across all models. Next, we applied the sigmoid function to obtain probability scores for each emotion. Finally, we assigned labels based on a threshold of 0.5: if the probability was ≥ 0.5, the emotion was considered present; otherwise, it was considered absent. Prediction pipeline can be seen in Figure 1.

Performance and Computational Cost. Fine-tuning DeBERTa-large improved generalization across underrepresented emotions, making it the most effective model for our final predictions. However, this approach was computationally expensive, requiring 435 million parameters. Due to our resource constraints, we were unable to test larger models.

We discuss performance-cost trade-off in-depth in Subsection 5.5.

4 Experimental Setup

4.1 Training Data

The dataset provided by the competition was split into train, dev, and test, consisting of 2,768, 116, and 2,767 sentences, respectively. For fine-tuning our model, we utilized both the train and dev datasets. The distribution of emotions across the combined dataset can be found in Appendix A, Figure 2.

4.2 Training Details

We fine-tuned the pre-trained DeBERTa-large model from HuggingFace. We trained five instances using different seeds (42, 99, 123, 1337, 2024) and trained them each for five epochs. The best epoch for each seed was 4, 3, 5, 4, and 3, respectively. Hyperparameters such as learning rate, batch size, and max length were optimized using Optuna. The stochastic optimization method used was AdamW.

4.3 Hardware and Hyperparameters

Our experiments were implemented using PyTorch 2.5.0, HuggingFace transformers 4.46.3 (for DeBERTa-large), and scikit-learn 1.5.1 (for evaluation and preprocessing). Model training was conducted using the free version of Google Colab, while the final model was trained fully on an Apple M2 Pro chip.

4.4 Evaluation Metrics

As specified by the shared task, we evaluated model performance using the macro-F1 score. All formulas mentioned throughout the paper can be found in Appendix D, Figure 13.

5 Results

5.1 Key Findings

Our final model demonstrated strong performance in multi-label emotion detection, particularly in identifying fear (91.20% recall) and joy (84.18% recall), however, it struggled with anger (61.04% recall), likely due to its underrepresentation in the dataset.

5.2 Main Quantitative Findings

Summary of recall (sensitivity) and specificity for each emotion can be found in table 5.2 summarizes.

Emotion	Recall (Sensitivity)	Specificity
Anger	0.6104	0.9704
Fear	0.9120	0.6477
Joy	0.8418	0.8759
Sadness	0.8079	0.8571
Surprise	0.7983	0.8540

Table 2: Performance of the model on the test set.

The class imbalance issue negatively impacted anger detection, as the low number of training samples made it harder for the model to learn meaningful patterns, resulting in lower recall.

To complement our macro F1 evaluation, further reports can be found in Appendix B, such as ROC-AUC (receiver operating characteristic, area under the curve) curves per emotion and Matthews Correlation Coefficient (MCC) per emotion, as well as precision-recall graphic. Our MCC scores range from 0.59 (fear) to 0.67 (joy), indicating strong and balanced performance across labels.

5.3 Error Data

Our confusion matrices and error analysis revealed several key insights:

- Fear was frequently over-predicted, leading to a high false positive rate (434 FP).
- Anger had the lowest recall (61.04%), likely due to its low representation in the dataset.
- False Positives: The model often overpredicted emotions, particularly in ambiguous snippets where multiple interpretations were possible.
- False Negatives: Implicit emotions (e.g., subtle anger) were often missed, suggesting that the model struggled with nuanced emotional expressions.

5.4 Error Analysis

An in-depth analysis of the misclassified sentences uncovered several patterns.

Ambiguous Phrasing. Many sentences had multiple valid emotional interpretations, making classification difficult. The model often assigned incorrect labels in these cases.

Sentence Length Variability. The dataset contained short, medium, and long sentences, adding complexity. Short sentences lacked emotional cues, while longer sentences often contained mixed emotions, both cases made classification harder.

Labeling Inconsistencies. Some annotations appeared counterintuitive, potentially introducing noise into the training process and reducing model accuracy.

Overprediction of Multiple Emotions. For single-label sentences, the model frequently predicted two emotions instead of one, indicating overlapping textual patterns. For multi-label sentences (three or more emotions), accuracy declined, with inconsistent predictions regarding the number of emotions present.

These findings suggest potential future improvements, including enhancing neutral sentence classification, refining multi-label prediction strategies,

and improving robustness to ambiguous text. Despite these challenges, our model demonstrated strong generalization and competitive performance, underscoring its effectiveness in detecting emotions in text.

5.5 Considerations for Balancing Accuracy and Efficiency

While our final system, based on an ensemble of fine-tuned DeBERTa-large models, achieved the best empirical performance, it introduced substantial computational costs. DeBERTa-large, with approximately 435 million parameters per model, combined with training multiple seeds, resulted in high memory and processing requirements.

Although we considered lighter alternatives such as DistilBERT during our model selection phase, we prioritized DeBERTa-large for its superior performance. Nevertheless, it is well-known that smaller models generally offer faster inference at the cost of reduced accuracy, presenting a trade-off between efficiency and performance.

Balancing performance and computational demands remains a critical challenge. Future work could explore approaches such as:

Model Compression Techniques. Add pruning or quantization in order to reduce model size without significant loss of accuracy.

Optimized Ensembling Strategies. Reducing the number of models combined or adopting techniques like snapshot ensembling to maintain robustness with lower resource usage.

Adopting these strategies could help retain strong predictive power while making the system more practical and scalable for real-world applications.

6 Conclusion

Our proposed approach, leveraging DeBERTa-large with multiple seeds, ensemble methods, Optuna hyperparameter optimization, and StratifiedKFold cross-validation, achieved an F1-score of 0.7537, surpassing the baseline provided by the task organizers. While our model demonstrated strong performance, our final ranking suggests room for improvement. This study explored traditional emotion recognition techniques, LLMs, and Transformer-based approaches, highlighting the successful application of advanced ensemble methods to Task 11 at SemEval-2025.

Future improvements may focus on exploring computationally efficient alternatives to DeBERTa-large for better scalability, expanding and balancing training data to reduce class imbalance issues, and implementing more robust labeling strategies, accounting for shortcomings of the current model discussed in Section 5.

While our research explored several widely used approaches, we recognize that other promising techniques could achieve comparable or better results, potentially with lower computational costs. These include lexicon-based approaches (NRC VAD (Garcia et al., 2024), SenticNet (Butt et al., 2021)), alternative transformer models (SiEBERT (Rozado et al., 2022)), LLM approaches (Zephyr (Shaik et al.), LLama 2, InstructERC (Cheng et al.; Lei et al., 2024)), more traditional machine learning methods (LSTM (Geethanjali and Valarmathi, 2024; Kumar et al.)), and explainability techniques like SHAP (Hajek and Munk, 2023; Butt et al., 2021).

Although our initial attempts at re-weighting and naïve augmentation did not yield significant results, future work could explore multi-label aware oversampling (e.g., MLSMOTE (Charte et al., 2015) or similarity-based oversampling (Karaman et al., 2024)), adaptive batch-level strategies, such as loss-driven batch selection (Loshchilov and Hutter, 2016; Zhou et al., 2024), and deferred re-weighting schedules (Cao et al., 2019), that apply stronger class weights only after an initial warm-up phase, to mitigate the severe class imbalance.

Moreover, addressing dataset biases remains crucial. Generalization is particularly challenging in English, where linguistic and cultural diversity influences both text production and emotional perception. Future work should extend beyond English to encompass multilingual and cross-cultural perspectives, incorporating sociolinguistic and anthropological insights. Additionally, integrating non-verbal elements like emojis into text-based emotion recognition may improve model robustness and real-world applicability.

7 Ethical Considerations

This study addresses perceived emotions rather than the true internal emotional states of users. Perception of emotion is inherently subjective, shaped by individual factors such as gender, culture, language, and personal experience. As such, we do not claim that our model's outputs reflect any universal or objective emotional truth.

Importantly, the data used in this task was sourced from online and social media contexts, which may introduce cultural, linguistic, and demographic biases. Such biases can affect both the generalization ability and fairness of the model, leading to underrepresentation or misinterpretation of emotions from diverse user groups. Additionally, the dataset was annotated by crowdsourced workers whose backgrounds are unknown, potentially reinforcing subjective or culturally specific patterns.

To promote more equitable development in emotion detection, we recommend to strive to capture a broader diversity of emotional expressions across different populations in the future, in order to mitigate risks of marginalization or misrepresentation.

Given these limitations, we strongly discourage the deployment of this system in high-stakes applications requiring precise emotional interpretation, such as clinical diagnostics, automated decision-making, or areas involving sensitive personal data. Potential misuses could include emotional manipulation, targeted social engineering, or exploitation of vulnerable groups, and developers should exercise caution in adapting the model to real-world settings.

8 Acknowledgment

This research was conducted as part of the Bachelor Lab Course on Natural Language Processing at TUM, under the guidance of Prof. Dr. Alexander Fraser's Data Analytics & Statistics Group at TUM School of Computation, Information and Technology. We extend our gratitude to the research group for providing us with the opportunity to participate in this competition and apply hands-on NLP techniques.

We are deeply grateful to the anonymous reviewers for their constructive feedback, which helped us improve the quality of this paper.

We also thank the SemEval-2025 Task 11 organizers for curating this challenge and advancing research in text-based emotion recognition. Additionally, we acknowledge the academic teams behind the BRIGHTER dataset, which bridges the gap in human-annotated emotion recognition resources by providing multi-label emotion data across 28 languages, thereby fostering innovation in multilingual emotion analysis.

$$\text{Recall} = \frac{\text{True Positives}}{\text{True Positives} + \text{False Negatives}} \qquad F1\text{-Score} = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}}$$

$$\text{Specificity} = \frac{\text{True Negatives}}{\text{True Negatives} + \text{False Positives}} \qquad \text{Macro } F1\text{-Score} = \frac{\sum_{i=1}^{n} F1\text{-Score}_i}{n}$$

Figure 13: Formula definitions for metrics used in our evaluation. High precision indicates a low rate of false positives. High recall means the model identified most positive samples correctly. Specificity measures the model's ability to correctly identify negative samples. F1 is useful when balancing precision and recall, especially with imbalanced classes. Accuracy represents the overall correctness across all predictions. The macro F1 Score is the average of F1 scores for each class.

prompt: Now you are an expert on sentiment and emotional analysis. Please infer, considering the content and the way the sentence is written, what emotions from a list of [anger, fear, joy, sadness, surprise], if any, are perceived from this sentence by the majority of people
format: Return your answer in .csv format "sentence, 0/1, 0/1, 0/1, 0/1, 0/1", where 0 represents absence of emotion and 1 its presence
warning: Don't hallucinate and find the emotions the majority of people would agree with
target: [sentence S_i].

Abstract

We address the challenge of retrieving previously fact-checked claims in monolingual and crosslingual settings - a critical task given the global prevalence of disinformation. Our approach follows a two-stage strategy: a reliable baseline retrieval system using a fine-tuned embedding model and an LLM-based reranker. Our key contribution is demonstrating how LLM-based translation can overcome the hurdles of multilingual information retrieval. Additionally, we focus on ensuring that the bulk of the pipeline can be replicated on a consumer GPU. Our final integrated system achieved a success@10 score of 0.938 (∼0.94) and 0.81025 on the monolingual and crosslingual test sets respectively. The implementation code and trained models are publicly available at our repository[1].

1 Introduction

Misinformation poses serious risks to society worldwide, with the World Economic Forum ranking it among the most pressing global threats. Social media acts as a key channel for false content, breaking down trust in institutions and dividing communities, an effect seen most clearly during political events. Our work addresses this problem through SemEval-2025 Shared Task 7, which focuses on developing multilingual retrieval systems that can identify previously fact-checked claims, from the curated MultiClaim dataset, when given social media posts in various languages. Success is measured simply: the system is considered effective if a relevant fact-checked claim appears among the top 10 retrieved results.

1.1 Task Overview

SemEval-2025 Shared Task 7 (Peng et al., 2025) introduces the problem of finding previously fact-checked claims across multiple languages - a task difficult to perform manually, especially when claims and fact-checks appear in different languages. The task is split into monolingual and crosslingual tracks, allowing participants to build systems that help fact-checkers identify relevant fact-checks for social media posts. The task uses a subset of the MultiClaim dataset (Pikuliak et al., 2023) comprising posts and fact-checks in various language pairs. The dataset provides rich information, including the original post text, text extracted from images via OCR, and translations. Systems are evaluated using the success@10 metric, which measures whether a correct match appears in the top 10 results. This research addresses a real-world challenge faced by fact-checkers who struggle to keep up with misinformation that spreads globally across language boundaries, often requiring knowledge of many languages to identify existing fact-checks effectively.

2 Related Work

Research in fake news detection has evolved significantly over the past decade. Early works (Castillo et al., 2011; Shu et al., 2017) introduced methods to assess information credibility on social media, and also explored multi-modal approaches combining textual, user, and network features. Recent works (Kumar and Shah, 2018; Pérez-Rosas et al., 2018) focused on linguistic characteristics along with external taxonomies to devise novel detection mechanisms.

Fact verification systems represent a critical approach to combating misinformation. The pioneering work of Thorne et al. (Thorne et al., 2018) introduced FEVER (Fact Extraction and VERification), dataset and evaluation framework that has become a benchmark in the field. Building on this foundation, Augenstein et al. (Augenstein et al., 2019) developed multi-domain fact-checking models that can transfer knowledge across differ-

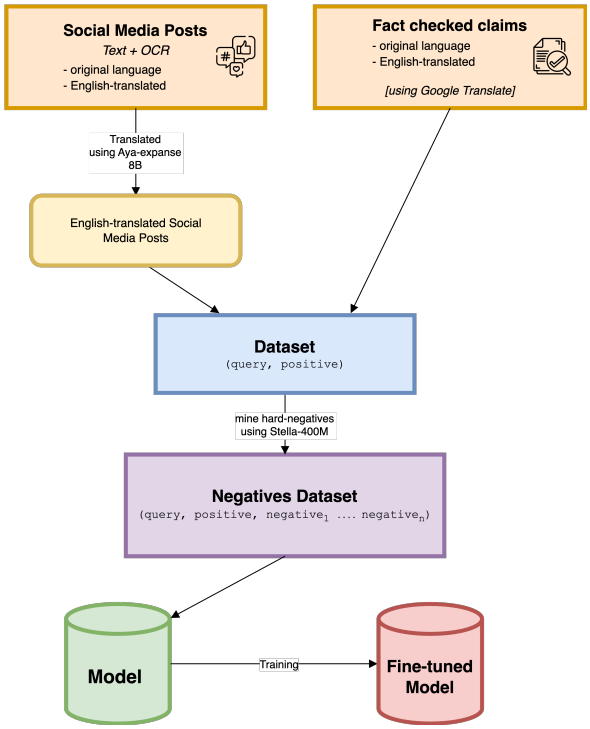

Figure 1: Data Preparation and Model Fine-tuning Pipeline.

ent topics and domains. Neural fact verification approaches have gained prominence, with Nie et al. (Nie et al., 2018) proposing the Neural Evidence Retriever-Aggregator (NERA) framework, which integrates evidence retrieval with claim verification. Transformer-based architectures have further enhanced verification capabilities, as demonstrated by Wadden et al. (Wadden et al., 2020) with their KGAT (Knowledge Graph Attention Network) model that leverages structured knowledge for improved reasoning.

Recent work by (Lewis et al., 2020) introduced retrieval-augmented generation (RAG) models that combine neural retrievers with language models to generate verifiable explanations.

3 Methodology

3.1 Baseline Embedding-Based Retrieval with Data Augmentation

Finding relevant fact checks for social media posts in multiple languages is an information retrieval (IR) problem. As a starting point, we opted for an embedding-based retrieval system due to its straightforward implementation and scalability. While the dataset includes social media posts and fact checks in their original languages, it also provides English translations via Google Translate. These translations proved particularly useful, allowing us to begin with a purely English retrieval setup while deferring the complexities of multilingual IR—challenges we explore in detail in a later section.

To establish a strong reference model, we selected the top 10 performing models from the MTEB English v2 benchmark from MTEB English v2 (Muennighoff et al., 2022a) considering only those with fewer than 1B parameters to ensure compatibility with consumer GPUs. This choice was motivated by our decision to initially focus on English translations, ensuring a more controlled evaluation before tackling cross-lingual retrieval challenges. To complement these selections, we included MPNet v2 (built on top of MPNet) (Song et al., 2020) and the GTR-T5 (Ni et al., 2021) family, as they were among the top contenders in the MultiClaim dataset paper. We also include MiniLM (Wang et al., 2020), a 90M parameter model, to better quantify performance trade-offs across model sizes

Ultimately, we chose Stella 400M (Zhang et al., 2024) due to its strong baseline performance as described in this table for our embedding purposes.

3.2 Data Augmentation

Multilingual IR presents significant challenges due to diverse writing systems, grammatical structures, and computational constraints for low-resource languages. The MultiClaim dataset, with social media posts in 27 languages and fact-checking articles in 39 languages, exemplifies these complexities. Our solution was to translate all social media posts into English, simplifying system design by eliminating the need for language-specific models while reducing computational demands. This approach solves memory and processing constraints of multilingual systems. While translation may cause loss of meaning, it leverages advanced English models to improve accuracy, enabling cross-lingual pattern learning that particularly benefits low-resource languages.

For translation, we selected the Aya Expanse 8B model (Prompt) (Dang et al., 2024) over Google Translate based on compelling empirical evidence. Recent studies demonstrate that large language models produce translations that are 4-18% more accurate than traditional systems according to BLEU scores, with superior capability in preserving contextual nuances and idiomatic expressions.

[2] Aya's coverage of 23 languages outperforms comparable models like mT0 and Bloomz (Muennighoff et al., 2022b) in benchmarks, making it ideal for our diverse dataset. This selection is further supported by research showing that newer LLM-based translation systems require fewer post-translation corrections and achieve better performance compared to conventional approaches, including Google's PaLM 2 model, (Anil et al., 2023) outperforms Google Translate.

The single-model translation approach offers considerable benefits beyond computational efficiency. It simplifies development, deployment, and maintenance relative to managing multiple specialized models while enabling transfer learning where cross-lingual patterns benefit all languages, especially those with limited training data. This design choice to use translation was further inspired by Sarvam's IndicSuite (Khan et al., 2024) system, which achieved state-of-the-art results for Indian languages through (Gala et al., 2023) machine translation of large datasets. Our approach balances quality and efficiency by converting languages into English while preserving semantic meaning, addressing challenges of different writing systems and grammar structures, while utilizing English-focused embedding models for better retrieval results.

3.3 Re-ranking strategies

In our exploration of re-ranking methodologies to further improve upon the initial retrieval performance achieved through the Stella 400M embedding model (which attained 0.86 average success@10 on the development set), we investigated several approaches including cross encoders, Colbert v2 (Khattab and Zaharia, 2020; Santhanam et al., 2022), T5/Seq2Seq (Raffel et al., 2020) architectures, and a Cohere reranker. Although initial experiments with the Cohere reranker [3] showed promising improvements, further analysis revealed that similar performance gains could be achieved by fine-tuning the embedding model with hard negatives as described in Section 3.4, effectively neutralizing its advantages. Based on these findings, we transitioned to an LLM-based re-ranking strategy that directly processes the top 50 candidates, evaluating several large language models including Gemini 1.5 Pro (Team et al., 2024), Meta Llama 3.1 70B, Llama 3.3 70B Instruct (Dubey et al., 2024), and Qwen 2.5 72B Instruct (Yang et al., 2024). Qwen 2.5 72B Instruct demonstrated superior performance and was ultimately selected for our final system (Prompt). This approach leverages the model's world knowledge and semantic understanding to establish the final ranking order, yielding additional performance improvements in our system's overall effectiveness.

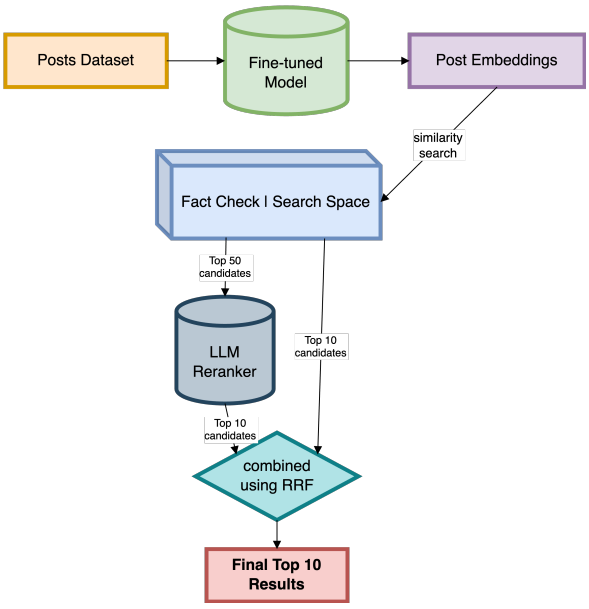

Figure 2: Two-Stage Retrieval and Ranking Architecture

3.4 Hard-Negative Mining and Finetuning of the Embedding Models

The effectiveness of re-ranking is inherently tied to the quality of the initial candidate set, necessitating improvements to the underlying embedding model. To this end, we investigated fine-tuning strategies through extensive experimentation, comparing two approaches. The first approach relied solely on positive query-document pairs, but this provided only marginal improvements in retrieval performance, suggesting that learning from relevant matches alone was insufficient. In contrast, incorporating hard negatives into the training process led to substantial gains. We leveraged Sentence Transformers' [4] native negative mining capabilities, systematically varying the number of negative examples per query from 5 to 80. Our analysis revealed that performance gains plateaued at approximately 40 negatives per query. To optimize computational efficiency while maintaining perfor-

[3] https://cohere.com/blog/rerank

[4] https://www.sbert.net/index.html

mance benefits, we ultimately selected 20 negatives per query, which successfully elevated our system's success@10 metric beyond 0.90.

3.5 Hybrid Search

Integrating a sparse embedding model along with a dense embedding model represents a common configuration employed within RAG systems for enhanced reliability. Performance typically improves because sparse models excel at capturing exact lexical matches and relevant keywords, while dense models focus on semantic features and contextual understanding. However, in our experiments, we observed that the use of BM25 alongside base embedding models improved performance only for smaller models, such as MiniLM, but appeared to reduce the effectiveness of top-performing embedding models, such as Stella. This performance degradation likely occurs because sophisticated embedding models already effectively encode both lexical and semantic information within their high-dimensional representations, making the additional signal from sparse retrieval redundant or potentially introducing noise that dilutes the precision of the embedding model. An additional observation from the MultiClaim dataset study demonstrated that BM25 exhibits a higher false positive rate as the fact-check pool size increases, particularly affecting languages with larger collections (Pikuliak et al., 2023). Consequently, rather than combining sparse and dense approaches, we evaluated using multiple dense models within a hybrid search and established final rankings using Reciprocal Rank Fusion (RRF) (Cormack et al., 2009). The simplest configuration that yielded performance improvements was combining the model's base retrieval results with its reranked outputs using RRF.

3.6 Final Pipeline

Our final system implements a two-step pipeline, with the first stage employing a fine-tuned Stella 400M trained on our augmented dataset to perform baseline retrieval. This is followed by a Qwen-based reranker that processes the top 50 candidates. The pipeline culminates in a hybrid search mechanism using RRF to combine results from the fine-tuned model and reranked outputs. This integrated approach delivers robust retrieval performance while maintaining practical computational requirements for real-world applications.

3.7 Compute Requirements

We ran timing experiments to estimate our approach's compute requirements. As shown in Table 3, translating the test-set posts (monolingual and cross-lingual) took 61 minutes, and fine-tuning the Stella embedding model took 35 minutes—both on an NVIDIA RTX 4090. These numbers show that the core system can run on consumer hardware without requiring large-scale infrastructure.

4 Results

Our experimental evaluation revealed several key findings about the effectiveness of different retrieval approaches.

As shown in Table 1, the Stella 400M model demonstrated strong performance across multiple languages, achieving a baseline success@10 score of 0.8159. While most models performed well for Malay (msa) and Thai (tha), performance varied considerably for others, particularly German (deu) and Portuguese (por).

Notably, Stella's built-in s2p prompt provided a meaningful boost, improving performance from 0.8159 to 0.8305 (+1.8%), demonstrating its effectiveness in enhancing query formulation. Further, incorporating translated posts yielded a much larger improvement, increasing success@10 to 0.8837 (+6.8% relative to baseline), highlighting the value of cross-lingual augmentation.

Fine-tuning on translated posts further enhanced retrieval effectiveness, reaching a success@10 score of 0.9217. This represents an 11% relative improvement over the base Stella model and an additional 4.3% gain over using translated posts alone.

As shown in Table 4, conventional rerankers generally degraded performance, with deltas ranging from -0.127 to -0.032. However, the Qwen2.5-72B-Instruct reranker provided a modest but positive impact (+0.025).

Our final configuration (Table 5), which combined fine-tuning with translation, reranking, and reciprocal rank fusion (RRF), achieved the best overall performance at 0.938. However, the improvement from reranking and RRF was relatively modest (+1.7%) compared to the gains from fine-tuning and translation, suggesting that most of the effectiveness stemmed from improving the retrieval model rather than post-processing.

[5]Due to computational budget constraints, Qwen reranking was not evaluated with the MiniLM retriever.

Limitations

Our research operated with defined hardware limitations, using an NVIDIA RTX 4090 GPU with 24GB VRAM and 64GB system memory while leveraging TogetherAI's [6] cloud services for a serverless LLM endpoint. These resource limitations significantly influenced our evaluation scope, restricting our ability to comprehensively assess models exceeding 1 billion parameters, despite evidence suggesting such larger models have established state-of-the-art performance benchmarks. These practical constraints represent important context for interpreting our experimental results and methodology.

5 Conclusion and Future Work

We developed a novel approach for retrieving fact-checked claims across multiple languages using a multi-stage system that combines LLM-based translation, embedding models improved through hard-negative mining, and an advanced reranking approach incorporating reciprocal rank fusion. Our results on the task data set show that this integrated approach works well to find relevant information across language boundaries, achieving competitive performance. Additionally , we show that LLM-based re-ranking is not required from a performance standpoint as it offers minimal gains. Our recommendation is to simply use translation along with a finetuned embedding model, as this combination captures most of the performance gains. Future work includes testing generalizability on other datasets, applying these techniques to broader information retrieval problems, evaluating quantized embedding vectors for improved efficiency, and exploring LLM-based translation approaches for low-resource languages.

A Appendix

Table 6: Prompt used for LLM-based translation

You are given text (possibly noisy social media data) that may be partially or entirely in a non-English language. It could contain repeated emojis, excessive punctuation, or minor errors. Your task is to produce a "cleaned but faithful" English version. Specifically: 1) If the text is not in English, translate it to English as literally as possible. 2) Preserve important meaning, tone, and references (e.g., named entities, hashtags, or domain-specific terms). 3) Remove or reduce meaningless filler (like repeated punctuation or stray symbols) without losing factual content. 4) Avoid adding your own commentary, opinions, or extra interpretation. Keep the style and intent aligned with the original.

Table 7: Prompt used for LLM-based re-ranking

You are an expert fact-checker and information retrieval specialist. Your task is to analyze a query and a set of articles to identify the most relevant ones for fact-checking purposes.

Task:
1. Review the query that needs fact-checking
2. Analyze the candidate articles provided
3. Select the 10 most relevant articles that would be most useful for fact-checking the query
4. Return ONLY the article IDs of these 10 articles in a tab-separated format

Important Instructions:
- Focus on selecting articles that:
Directly address the claim in the query
Provide factual evidence or counter-evidence
Come from reliable sources
Contain specific details relevant to the query
Cover different aspects of the claim for comprehensive fact-checking
- Output format must be EXACTLY:
Only article IDs
Tab-separated
One line only
Top 10 articles in order of relevance
No explanations or additional text

Query for fact-checking: ***QUERY***
Data Augmentations: ***AUGMENTATION***
Candidate Articles:
ARTICLE 1*
ARTICLE 2*
-
-
-
ARTICLE N*
ONLY RETURN tab-seperated IDs....NOTHING ELSE

AKCIT at SemEval-2025 Task 11: Investigating Data Quality in Portuguese Emotion Recognition

Abstract

This paper investigates the impact of data quality and processing strategies on emotion recognition in Brazilian Portuguese (PTBR) texts. We focus on data distribution, linguistic context, and augmentation techniques such as translation and synthetic data generation. To evaluate these aspects, we conduct experiments on the PTBR portion of the BRIGHTER dataset, a manually curated multilingual dataset containing nearly 100,000 samples, of which 4,552 are in PTBR. Our study encompasses both multi-label emotion detection (presence/absence classification) and emotion intensity prediction (0 to 3 scale), following the SemEval 2025 Track 11 setup. Results demonstrate that emotion intensity labels enhance model performance after discretization, and that smaller multilingual models can outperform larger ones in low-resource settings. Our official submission ranked 6th, but further refinements improved our ranking to 3rd, trailing the top submission by only 0.047, reinforcing the significance of a data-centric approach in emotion recognition.

1 Introduction

Data quality plays a critical role in enabling machine learning models to generalize effectively and generate meaningful predictions (Budach et al., 2022). On the other hand, poor data quality (e.g., a high level of noise, inconsistencies, imbalanced distributions, or annotation errors) can lead to biased models and unreliable outcomes (Sambasivan et al., 2021). Several studies have shown that well-constructed datasets significantly enhance model performance in NLP tasks (Mishra et al., 2020; Longpre et al., 2024). In the context of emotion recognition, high-quality data is essential for capturing subtle emotional nuances and reflecting variations across different contexts and linguistic structures.

In this paper, we investigate the impact of data quality on emotion recognition in Brazilian Portuguese (PTBR) texts, focusing on data distribution, linguistic context (e.g., word-sentiment lexicons), and augmentation strategies such as translation and synthetic data generation. To evaluate these aspects, we conduct experiments on the PTBR portion of BRIGHTER dataset (Muhammad et al., 2025a), a multilingual large-scale dataset manually curated comprissing nearly 100,000 samples, which 4,552 are in PTBR. The dataset originates from SemEval 2025 Track 11 (Muhammad et al., 2025b), and we participate in both sub-track A (Multi-label Emotion Detection; classifying either if the emotion is or is not present in the sentence) and sub-track B (Emotion Intensity; classifying the intensity from 0 to 3 of the emotion in the sentence) sub-tracks. Our findings highlight the importance of a data-centric approach, measuring the impact of different data processes alternatives, as the official submission achieved 6th in Portuguese emotion recognition. However, further analysis and post-competition refinements established a new 3rd place ranking, trailing the top-ranked submission by only 0.047.

Our main contributions can be summarized as follows:

- **Data-Centric Analysis:** We demonstrate the impact of data-centric techniques on model performance, highlighting the role of data distribution, augmentation, and linguistic context.
- **Style-Domain Translation:** We introduce a translation approach that preserves the emotional content of the original text while adapting it to the target style and domain using few-shot learning, achieving 3% improvement in Macro F1 compared to traditional literal translation, underscoring its effectiveness in enhancing emotion recognition performance.
- **Label Granularity Effect:** We show that models trained with Emotion Intensity labels

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2305–2310

outperform those trained with binary labels in multi-label emotion classification. This result suggests that modeling emotion intensity improves generalization.

The rest of this paper is organized as follows: Section 2, reviews the related work. Section 3 describes the methods and Section 4 the Experimental Setup, while experiments results are discussed in Section 5. Section 6 brings the conclusions.

2 Related Work

Sentiment analysis has been widely studied across various domains, including movie (Bodapati et al., 2019) and product reviews (Reddy et al., 2024), with social media platforms also receiving significant attention (Singh et al., 2021) due to the vast amount of user-generated content. Baziotis et al. (2017) propose a bidirectional LSTMs with attention mechanisms to predict sentiment polarity, categorizing tweets as positive, negative, or neutral. Their model achieved first place in SemEval-2017 Task 4. However, since it follows a single-label classification approach, it cannot effectively capture the overlapping and co-occurring emotions often present in social media text.

da Silva et al. (2018) introduced a corpus of tweets from Brazilian investors, annotated with emotional labels. The dataset was constructed by collecting tweets that referenced stocks from the Brazilian stock exchange (IBOVESPA) and manually labeling them according to Plutchik's model, which categorizes emotions into eight distinct types. Their work underscores the importance of high-quality annotated datasets for training machine learning models in Portuguese, a task that remains challenging due to the limited availability of labeled data.

To address the challenges of multilabel emotion classification, (Kim et al., 2018) proposed an attention-based convolutional neural network (CNN) model capable of handling multiple emotion labels per instance. Their system integrates self-attention mechanisms to enhance sentence representation, allowing emotions to be classified independently within a single sentence. Evaluated on SemEval-2018 Task 1, their approach ranked first in Spanish and fifth in English, demonstrating its effectiveness across languages.

3 Methods

3.1 Data

The Brazilian Portuguese subset of the BRIGHTER dataset (Muhammad et al., 2025a) comprises 4,652 social media posts annotated with six fundamental emotions: anger, disgust, fear, joy, sadness, and surprise. The dataset follows a multi-label classification setup, where each instance can express zero, one, or multiple emotions. The data is split into 2,226 training instances, 200 validation instances, and 2,226 test instances. Each post was annotated by five independent raters, generating probabilistic emotion distributions rather than discrete labels. Table 1 provides an overview of the label distribution within the training set.

Emotion	Number of samples	Percentage
Anger	718	32.26%
Disgust	75	3.37%
Fear	109	4.90%
Joy	581	26.10%
Sadness	322	14.47%
Surprise	153	6.87%
No emotion	632	28.39%

Table 1: Number of samples per emotion in the PTBR portion of the dataset.

3.2 Style-Domain Text Translation

To enhance model robustness and generalization, we expanded the dataset through cross-lingual translations. However, these translations introduce domain and stylistic discrepancies. For instance, Brazilian Portuguese data primarily originates from social media, while Algerian Arabic and Mozambican Portuguese include content from literature and news, leading to factual information in Mozambican Portuguese that is absent in Brazilian Portuguese. Even within social media, stylistic variations exist: Brazilian Portuguese posts rarely use emoticons, whereas Latin American Spanish contains emoticons in nearly 22% of samples.

To mitigate these inconsistencies, we introduce Style-Domain Text Translation, a methodology designed to simulate Brazilian Portuguese social media discourse. We guide the LLM-based translation process to preserve both the literal meaning and original emotional content, while incorporating colloquial expressions, abbreviations, and informal linguistic patterns typical of Brazilian social media. The translation model is additionally regularized to avoid excessive formality. Although this approach

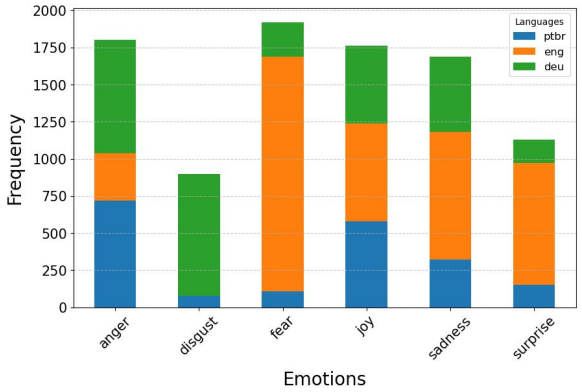

Figure 1: Proportion of each emotion in the dataset by adding English and Deutsch translation

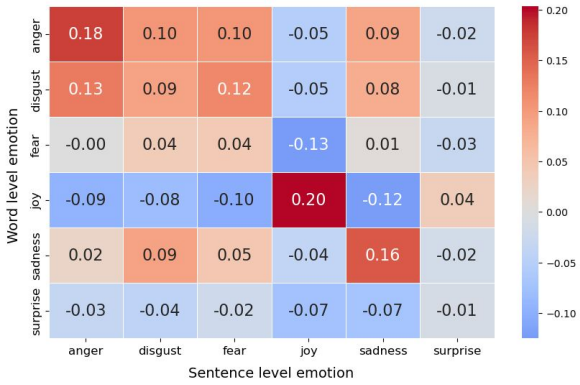

Figure 2: Pearson correlation between the emotion scores of individual words and the overall sentence emotion.

was applied across all languages in the dataset, our experiments primarily focus on English and German, allowing us to perform extensive evaluations with low-cost computational resources.

3.3 Synthetic data generation

LLM-based synthetic data augmentation has been widely explored across multiple domains, including social media text generation (Hosseini et al., 2024). However, existing studies predominantly focus on English, which dominates the pre-training and fine-tuning corpora of large-scale models. Our approach addresses this linguistic gap by generating synthetic informal social media posts in Brazilian Portuguese, incorporating realistic variability in emotion, text length, and sentiment intensity.

To ensure diversity in the synthetic samples, we adopt a few-shot prompting strategy that conditions the generation process on multiple aspects of the data. Emotions are dynamically sampled based on the original dataset, allowing for upsampling of underrepresented emotions while preserving the dataset's multi-label structure. Additionally, the generated texts mirror the natural length distribution of real social media posts, ensuring structural authenticity. By varying sentiment intensity levels within prompts, we enable the model to produce content with fine-grained emotional variation, improving alignment with real-world language use.

For text generation, we employ the GPT-4o mini model (Achiam et al., 2023), chosen for its cost efficiency and strong performance in instruction-following tasks (Kim et al., 2024). This approach allows us to conduct extensive experiments while maintaining a computationally efficient training pipeline.

3.4 Data Balance

Our analysis of the dataset revealed a class imbalance in the Portuguese training set, where disgust and fear were underrepresented. To address this issue, we improved emotion category distribution by augmenting the dataset through cross-lingual translation from English and German into Portuguese. This approach equalized class proportions across the six emotion categories, as shown in Figure 1, while preserving linguistic diversity in the samples.

While alternative strategies such as data duplication and LLM-based synthetic data generation were considered, translation provided the most effective solution for expanding low-frequency classes while maintaining natural language variability. As a result, our approach led to a more uniform label distribution and improved model performance across all emotion categories.

3.5 Word-based Emotion Lexicon

We also utilized the Portuguese version of the NRC Emotion Lexicon (Mohammad and Turney, 2010, 2013), which comprises a comprehensive set of words annotated with their associated emotions. Although the sentiment of an individual word does not necessarily imply that the entire sentence conveys that emotion, we examined the correlation between the sentiment of each word and the overall sentence emotion, which is shown in Figure 2. Furthermore, we incorporated this lexicon information into the model input and measured the impact of this information when training an LLM to identify emotions.

4 Experimental Setup

Implementation. All experiments were conducted using a single RTX 4090 GPU with a batch size of 8, a linear learning rate schedule of 2e-5, and a weight decay of 0.01. After identifying the best-performing strategy, we scaled up the approach and applied it to a larger model running on a single NVIDIA A100 GPU. All experiments were performed with 4-bit quantization and LoRA (Hu et al., 2022).

Model. We initially evaluated the Qwen 2.5 7B (Yang et al., 2024), LLaMA 3.1 8B (Dubey et al., 2024), and Phi-4 14B (Abdin et al., 2024) instruct models under few-shot and fine-tuning scenarios. Based on its superior performance in Brazilian Portuguese, we selected Qwen 2.5 7B as the base model for further experiments. The final tests were conducted using the Qwen 2.5 70B Instruct model (Yang et al., 2024), which shares pre-training and fine-tuning procedures similar to those of the selected base model.

5 Results

5.1 Model Selection

To identify the most suitable model for Brazilian Portuguese emotion recognition, we evaluated multiple architectures under few-shot and fine-tuning settings. Table 2 presents the performance results, highlighting the potential of the Qwen 2.5 architecture. Although its performance is slightly lower than that of the Phi model, Qwen 2.5 is half the size, offers scalable larger versions, and achieves better results than LLaMA 3.1 8B, making it a compelling choice for our study.

	Model	Macro F1	Micro F1
Few-shot	LLaMA 3.1 8B	0.35	0.44
	Phi 4 14B	**0.51**	**0.57**
	Qwen 2.5 7B	0.44	0.52
Fine-tuning	LLaMA 3.1 8B	0.46	0.66
	Phi 4 14B	**0.54**	**0.72**
	Qwen 2.5 7B	0.53	0.71

Table 2: Comparing base models in few-shot (4 shots) and fine-tuning on Brazilian Portuguese dataset portion.

5.2 Data processing

We examined both style-domain text translation and synthetic data generation. Table 3 shows that style-domain translation improved the macro-F1 score from 0.53 to 0.56, whereas traditional translation had no measurable impact. Although synthetic data generation increased the number of samples across all six emotions, it did not improve classification performance. This result suggests that while LLMs effectively translate existing samples into the target style and domain, they struggle to generate sufficiently diverse new samples from few-shot prompts, ultimately leading to a decline in overall performance.

Additionally, we investigated the correlation between NRC word-level emotions and sentence-level emotions. Our analysis revealed a low overall correlation, indicating that word-level sentiment features are not strong predictors of sentence-level emotion. For instance, the correlation between word-level and sentence-level "disgust" is lower than the correlation between "disgust" and "anger" (ranging from 0.09 to 0.13), as shown in Figure 2. The highest observed correlation was 0.20 for "joy", reinforcing that word-level sentiment signals provide limited value for sentence-level emotion prediction.

Data	Macro F1	Micro F1
Original baseline	0.53	0.71
NRC Lexicon	0.53	**0.73**
Traditional translation	0.53	0.64
Style-Domain Translation	**0.56**	0.67
Synthetic	0.49	0.68

Table 3: Performance impact of various data processing approaches on the original dataset. All methods were applied in combination with the original data, and results are reported in terms of Macro and Micro F1 scores.

5.3 Final Results

Following an extensive data analysis, we fine-tuned the Qwen 2.5 70B model (Yang et al., 2024) using the optimal hyperparameter configuration and data augmentation strategy on sub-tracks A and B. The final training dataset combined the original training set with English and German style-domain translations.

In our official submission, we ranked 6th place in sub-track A. However, further analysis revealed that using the model trained on sub-track B, which incorporated emotion intensity labels, and binariz-

ing the outputs (considering an emotion present if any intensity was detected), improved results by 3 percentage points, increasing the macro-F1 score from 0.61 to 0.64. When evaluated in the emotion intensity prediction task (sub-track B), the model achieved an average Pearson correlation (r) of 0.65.

6 Conclusion

Our study investigates how data quality and processing techniques influence emotion recognition in Brazilian Portuguese texts. We explored Style-Domain Text Translation, synthetic data generation, and the integration of a word-based emotion lexicon. Our findings show that cross-lingual translation improves the balance of low-frequency emotion classes while preserving linguistic diversity, leading to better model generalization.

Additionally, our experiments demonstrate that training with emotion intensity labels, rather than binary labels, enhances performance when the outputs are binarized. Model selection results suggest that smaller models can sometimes outperform larger ones in this task, emphasizing the importance of architecture choice in low-resource settings. Finally, our post-competition refinements led to significant performance gains, reinforcing the role of fine-grained data processing strategies in improving emotion recognition models.

Limitations

Despite the promising results, our work has several limitations. First, our experiments are constrained by the size and diversity of the available Brazilian Portuguese data, which may not capture all linguistic nuances. Second, while the style-domain translation methodology shows potential, it relies on few-shot learning and may require further validation across different domains and larger datasets. Third, the observed performance improvements when using intensity labels indicate potential sensitivity to label binarization methods, suggesting that additional samples with higher emotions intensities could beneficiate the model. Finally, our analysis primarily focused only in PTBR portion of BRIGHTER dataset, and results might vary when applied to other domains or languages. Future work should address these limitations by incorporating more extensive and diverse datasets and refining our data processing techniques.

{petersew, laeul100, anpih100, jujul100, pic28faw}@hhu.de

Abstract

Accurately representing non-compositional language, such as idiomatic expressions, is crucial to prevent misinterpretations that may affect subsequent tasks. This paper presents our submission to the SemEval 2025 task on advancing the representation of multimodal idiomaticity. The challenge involves matching idiomatic expressions with corresponding image descriptions that depict their meanings. We participate in the text-only tracks of both subtasks. Our system adopts a similarity-based approach and utilizes embeddings from pre-trained BERT-based large language models alongside ChatGPT-generated textual content. The primary goal is to explore the extent to which semantic similarity of embeddings from pre-trained models can effectively represent idiomaticity. For subtask A, our final submission ranked 5th on the test data and 3rd on the extended evaluation data (both out of 6).

1 Introduction

Idiomaticity of multiword expressions (MWEs) – the gap between the literal meaning of individual parts and the figurative meaning of the whole – is a major source of the lexical, syntactic and semantic quirks that make MWEs notoriously challenging for NLP systems (Baldwin and Kim, 2010). It is no surprise, that (Sag et al., 2002) dubbed MWEs 'a pain in the neck.'

Expressions like 'black sheep' have a literal and an idiomatic meaning. Identifying the intended meaning in context is crucial for tasks such as machine translation and question answering. While humans can easily distinguish between idiomatic and literal usage, language models often struggle. Addressing this challenge is the focus of the SemEval 2025 task *AdMIRe: Advancing Multimodal Idiomaticity Representation* (Pickard et al., 2025), an extension of the 2022 task *Multilingual Idiomaticity Detection and Sentence Embedding* (Tayyar Madabushi et al., 2022). Both tasks focus on nominal compounds. While the earlier task focused on classifying idiomatic versus literal uses of nominal compounds in context, the new task introduces a multimodal component, requiring models to select appropriate images (or image captions) based on the intended meaning. Two subtasks are defined: In Subtask A, images have to be ranked based on how closely they relate to a noun compound used idiomatically or literally in a given sentence. In Subtask B, the task is to decide which image best completes a given 2-element image sequence and to decide whether the image sequence illustrates the idiomatic or the literal meaning of the compound in question.

In this paper we address Subtasks A and B in their monolingual, English, text-only version – using image captions rather than images themselves. Our approach relies on comparing the similarity of contextualized compound and sentence embeddings. The central question we explore is whether these tasks can be effectively tackled without specialized training or fine-tuning, using only contextualized embeddings from pre-trained large language models. In line with the famous essay title by Vaswani et al. (2017), we ask, "Is similarity all you need?"[1]

2 Background

For **Subtask A**, the given data consists of a nominal compound, a sentence in which it is used either literally or idiomatically, and five images accompanied by detailed textual descriptions (referred to as captions). These images vary in how closely they relate to the possible meanings of the compound: one represents the idiomatic and one the literal meaning, two are semantically related (one to the idiomatic and one to the literal meaning), and one functions as a distractor. The distractor image is not directly related to the compound but

[1]The code of our approach can be found at https://github.com/WiebkePetersen/Transformer25.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2311–2317

may come from a similar semantic domain. For instance, in the case of the compound 'rotten apple,' a distractor might be a sugar-coated peach.

The task is to rank the images as follows: (i) If the compound is used literally in the sentence, the desired order is literal, related-to-literal, related-to-idiomatic, idiomatic, distractor. (ii) If the compound is used idiomatically, this order is reversed, except that the distractor remains in the final position: idiomatic, related-to-idiomatic, related-to-literal, literal, distractor. For evaluation the system's predicted rankings are compared to the expected ones using two metrics. The first is Top Image Accuracy (or top-1 accuracy), which checks whether the system correctly identifies the most representative image (literal or idiomatic, depending on usage) by ranking it first. The second is Rank Correlation, which assesses the overall alignment of the predicted ranking with the gold standard using Spearman's rank correlation coefficient.

For **Subtask B** only the nominal compound is provided but no sentence containing it. Instead, a sequence of two images with captions and four additional candidate images with captions are given. The task is twofold: (i) determine whether the initial image sequence represents an idiomatic or literal use of the compound; (ii) out of the four additional images choose the one that best completes the sequence. The four images are composed such that one is the optimal continuation for the idiomatic interpretation and one for the literal interpretation of the compound. The remaining two images are semantically related to the first two but are not ideal completions, analogous to the related images in Subtask A. Evaluation of the subtask is based on the accuracy of both predictions: (i) identifying the correct type (literal vs. idiomatic) and (ii) selecting the appropriate image to continue the sequence.

The English datasets used in the tasks are based on the data from the 2022 task and comprise 250 nominal compounds. The images for both subtasks were generated using Midjourney v6.0, based on prompts created with Gemini Pro 1.5 to capture the relevant meaning nuances. Context sentences for the compounds were either sourced from the web or written specifically for this task. The data is divided into training, development, test, and extended evaluation sets. Table 1 provides an overview of the dataset sizes and the distribution of idiomatic and literal instances across these splits.

Subtask A data set	**# sentences**	**idiomatic / literal**
Training	70	39 / 31
Development	15	7 / 8
Test	15	8 / 7
Extended Evaluation/Test	100	46 / 54

Subtask B data set	**# compounds**	**idiomatic / literal**
Training	20	13 / 7
Development	5	2 / 3
Test	5	3 / 2
Extended Evaluation/Test	30	12 / 18

Table 1: Summary of datasets for Subtask A and B.

3 System overview

For both subtasks, we participate in the monolingual, English, text-only track, which means that we rely solely on image captions and do not use the images themselves. Our approach is based on computing similarity scores between embeddings of the provided textual material (sentences and captions) as well as additional texts that we generate automatically. Subsection 3.1 outlines the process of generating this additional material and computing embeddings. The following subsections, 3.2 and 3.3, describe how predictions for Subtasks A and B are derived from the computed similarity scores.

3.1 Data Extension and Embeddings

We augment the training data using the prompt-based strategy proposed by Dai et al. (2025), who demonstrate that synthetic samples generated with ChatGPT can improve performance in low-resource settings. For each compound we generate additional textual data using ChatGPT-4.[2] The model is prompted to generate for each compound (i) one definition each for its literal and idiomatic meanings, ensuring that the compound occurs in the definition; (ii) two example sentences using the compound, again one with its literal and one with its idiomatic meaning; (iii) for each meaning (literal and idiomatic) a caption for an image illustrating the compound. Definitions are included as Tsukagoshi et al. (2021) show that definition sentences may improve semantic textual similarity tasks. The prompts used, together with an example of generated definitions, sentences, and image captions are shown in Table 2.

Embeddings for both the GPT-generated and the provided textual data are extracted using two pre-trained language models: the standard BERT-model `bert-base-uncased` (Devlin et al., 2019,

[2] https://chatgpt.com/ (accessed in November 2024)

prompt: definitions and sentences (literal and idiomatic)	*I will give you expressions that have both a literal and an idiomatic meaning. Define each meaning, starting with "... is." Additionally, provide an example sentence using the expression.*
prompt: image captions	*I will give you expressions (mainly compounds) with both literal and idiomatic meanings. Provide descriptions of images illustrating both meanings. Start with "The image depicts ...".*

Output for 'piece of cake'

idiomatic definition	'Piece of cake' is a metaphor for something very easy to accomplish.
idiomatic sentence	The math test was a piece of cake; she finished in ten minutes.
idiomatic image caption	The image depicts a student effortlessly solving a problem or task, symbolizing something very easy to accomplish.
literal definition	'Piece of cake' is a literal term referring to a portion of a cake.
literal sentence	He cut a small piece of cake to enjoy with his coffee.
literal image caption	The image depicts a literal slice of cake on a plate, emphasizing the literal meaning of a 'piece of cake.'

Table 2: ChatGPT-4 prompts used for data extension, with output exemplified for the nominal compound 'piece of cake.'

in this paper referred to as BERT)[3] and a BERT-based sentence transformer `all-MiniLM-L6-v2` (Reimers and Gurevych, 2019, referred to as SBERT).[4]. The sentence embeddings from pre-trained BERT models are known to capture semantic meaning of sentences poorly (Li et al., 2020), which is why we include a specific sentence transformer that is pre-trained to perform well in semantic sentence comparison tasks.

For the BERT-embeddings, we experiment with three (pooling) methods: (a) the standard CLS-token embedding from the last hidden layer, as used for next sentence prediction during pre-training; (b) sequence mean pooling, where the element-wise arithmetic mean of the token-level embeddings from the last n hidden layers is computed; and (c) contextualized compound embeddings for texts that consistently contain the target compound (i.e., original and GPT-generated sentences and definitions). These contextualized compound embeddings are obtained by averaging the token embeddings corresponding to the compound itself across the last n hidden layers. With methods (b) and (c), we aim to better preserve the semantic information specific to the compound compared to the standard CLS embedding (a).

3.2 Subtask A

A series of experiments are conducted in order to develop the final system.

3.2.1 Experiment 1 (using only given data)

In the first experiment, our aim is to investigate how far similarity-based approaches can take us when using only the provided data. For each compound, we compute embeddings of the given context sentence and the five image captions using the models and pooling strategies described in Section 3.1. The images are ranked according to the cosine similarity of their embeddings to the sentence embedding.

Additionally, we explore whether preprocessing the data to reduce noise can improve modeling effectiveness. Our preprocessing pipeline includes text normalization by removing capitalization, special characters, extra whitespace, and punctuation. Moreover, we lemmatize all words and retain only nouns, adjectives and verbs.

For the image captions, we also experiment with shortening them to remove information that is not relevant to the content, such as the style or background of the image. However, since this does not lead to consistent improvements, we do not pursue this further.

Discussion of results: Results of Experiment 1 on the training data are presented in Table 3 for both unaltered and preprocessed data. A major observation is the overall weak rank correlations and the strong imbalance between literal and idiomatic expressions when analyzed separately.

Overall, the results for idiomatic compounds are consistently poor across all settings. The highest top-1 accuracy for idiomatic compounds without preprocessing (0.28) is achieved using the BERT model with the `meanLast` pooling strategy, which computes the mean of all token embeddings from the last hidden layer. This model configuration shares the best overall top-1 accuracy across all data with the `SBERT` model. SBERT, however, performs best on literal compound uses, showing a

without preprocessing:			
method	**all data**	**idiomatic**	**literal**
SBERT	**0.40** (0.20)	0.18 (0.12)	**0.68** (0.31)
BERT CLS	0.21 (-0.01)	0.15 (-0.12)	0.29 (0.12)
BERT sequence mean pooling			
mean2ndToLast	0.37 (0.07)	0.18 (-0.03)	0.61 (0.20)
meanLast4	0.36 (0.10)	0.21 (0.02)	0.55 (0.19)
meanLast	**0.40** (0.01)	**0.28** (-0.10)	0.55 (0.15)
BERT contextualized compound			
mean2ndToLast	0.26 (0.09)	0.05 (0.02)	0.52 (0.18)
meanLast4	0.23 (0.07)	0.03 (-0.06)	0.48 (0.24)
meanLast	0.26 (0.03)	0.08 (-0.11)	0.48 (0.21)
with preprocessing:			
method	**all data**	**idiomatic**	**literal**
SBERT	**0.46** (0.21)	0.21 (0.13)	**0.77** (0.30)
BERT CLS	0.27 (0.05)	0.18 (0.02)	0.39 (0.10)
BERT sequence mean pooling			
mean2ndToLast	0.33 (0.08)	0.21 (0.10)	0.48 (0.05)
meanLast4	0.31 (0.09)	0.21 (0.11)	0.45 (0.08)
meanLast	0.36 (0.10)	**0.26** (0.05)	0.48 (0.15)
BERT contextualized compound			
mean2ndToLast	0.31 (0.17)	0.10 (0.09)	0.58 (0.27)
meanLast4	0.31 (0.11)	0.10 (0.04)	0.58 (0.21)
meanLast	0.29 (0.09)	0.13 (-0.05)	0.48 (0.25)

Table 3: (Experiment 1) Top-1 accuracy (rank correlation) for ranking images by cosine similarity to the original sentence, using different models and various pooling methods (mean2ndToLast: average over token embeddings of the 2nd last hidden layer, meanLast4: average over token embeddings of the 4 last hidden layers, meanLast: average over token embeddings of the last hidden layer; see Section 3.1 for details).

clear advantage for more compositional meanings.

Another interesting finding is that the sentence transformer SBERT clearly outperforms the standard CLS embeddings from BERT (0.40 vs. 0.21 top-1 accuracy), highlighting that using a model specialized in capturing sentence-level semantics is beneficial for the task.

Preprocessing negatively affects the BERT mean sequence pooling results but improves performance for both SBERT and BERT CLS embeddings, which is surprising since our radical preprocessing method removes much of the sentence structure. In addition, the contextualized compound models also benefit from preprocessing.

Overall, the best results are achieved using the SBERT model with preprocessing, which reaches a top-1 accuracy of 0.46. This configuration also yields the highest rank correlation (0.21).

3.2.2 Experiment 2 (using GPT-data)

The core idea of the second experiment is to use the GPT-generated data described in Section 3.1 alongside the gold label information about idiomaticity provided in the training data. In this setting, the image captions are ranked based on their cosine similarity to the GPT-generated comparators (definition, sentence, caption), which are selected according to the given idiomatic or literal label. For this experiment, we focus on the two best-performing model configurations from Experiment 1: SBERT and BERT with meanLast pooling.

It is important to note that the prompts used for generating definitions enforce similar phrasing at the beginning of each definition. To evaluate whether this phrasing bias affects the results, we also include a *cut* version of the definitions, where standardized introductory phrases are removed before obtaining the embeddings. Specifically, for idiomatic uses, we remove the phrase "[...] is a metaphor for", and for literal uses, we remove "[...] literal".

without preprocessing		
comparator	**SBERT**	**BERT meanLast**
GPT-caption	**0.61** (0.13)	0.49 (0.14)
GPT-definition	0.37 (0.19)	0.37 (0.05)
GPT-definition cut	**0.61** (0.16)	0.47 (0.15)
GPT-sentence	0.36 (0.06)	0.29 (0.09)
with preprocessing		
comparator	**SBERT**	**BERT meanLast**
GPT-caption	**0.61** (0.16)	0.49 (0.14)
GPT-definition	0.44 (0.29)	0.47 (0.17)
GPT-definition cut	0.53 (0.19)	0.51 (0.13)
GPT-sentence	0.39 (0.15)	0.36 (0.14)

Table 4: (Experiment 2) Top-1 accuracy (rank correlation) for ranking image captions based on similarity to GPT-generated texts: captions, (cut) definitions, sentences.

Discussion of results: Results of Experiment 2 on the training data can be found in Table 4. Compared to Experiment 1, no stronger correlations can be observed. However, the top-1 accuracy has improved significantly, which is expected as the idiomatic/literal information is now taken into account. Accordingly, experiment 3 aims to automatically assign the idiomatic/literal label. Preprocessing does not provide a clear picture, showing both improvements and degradations in performance.

As expected, the GPT-caption is most suitable as a comparator, as it is compared against image captions. Notably, for SBERT, the cut GPT-definition performs just as well. This suggests that SBERT benefits particularly strongly when repetitive ele-

ments are removed from the sentences.

3.2.3 Experiment 3 (idiomaticity classifier)

In order to make use of the GPT-generated additional texts, it is necessary to classify the sentence as idiomatic or literal. Our classifier relies solely on cosine similarity of the sentence to a comparator: the sentence is either compared to the two GPT-sentences (literal and idiomatic), to the two GPT-definitions, or to the two GPT-captions. In each case, the higher similarity determines the class label. For the embeddings, we compare the methods described in Section 3.1.

As prior work (e.g. Taslimipoor et al., 2020) shows that even a modest amount of task-specific fine-tuning can noticeably improve MWE performance on unseen data, for comparison we additionally fine-tune the BERT-model on idiomatic/literal classification using HuggingFace's trainer[5] and training for 7 epochs and use the same similarity-based classification strategy as before.[6]

comparator	pooling method	accuracy
Sentence embeddings		
GPT-sentence	SBERT	0.79
GPT-sentence	BERT CLS	0.83
GPT-sentence	BERT meanLast	0.86
GPT-definition	SBERT	0.81
GPT-definition	BERT CLS	0.66
GPT-definition	BERT meanLast	0.76
GPT-definition cut	SBERT	0.57
GPT-definition cut	BERT CLS	0.59
GPT-definition cut	BERT meanLast	0.76
GPT-caption	SBERT	0.60
GPT-caption	BERT CLS	0.61
GPT-caption	BERT meanLast	0.79
pre-trained BERT compound embedding		
GPT-sentence	BERT meanLast	0.857
GPT-sentence	BERT meanLast4	**0.9**
GPT-definition	BERT meanLast	0.671
GPT-definition	BERT meanLast4	0.743
fine-tuned BERT compound embedding		
GPT-sentence	BERT meanLast4	**0.97**

Table 5: (Experiment 3) Accuracy of idiomaticity classifier: sentence embedding is compared to comparator embedding using the specified pooling method (see Section 3.1).

Discussion of results: Table 5 shows the accuracy scores. We report results for the best mean sequence pooling method (BERT meanLast), the two best compound pooling strategies (meanLast and meanLast4), and the sentence embedding models SBERT and BERT CLS. The results show that the generated sentences perform better as comparators than the generated definitions. The cut definitions that performed very well in experiment 2 perform worse than the intact ones in experiment 3. Furthermore, compound-based embeddings outperform sentence-based ones. Pooling over the last four hidden layers also improves accuracy compared to pooling over the last layer only.

It turns out, that comparing compound embeddings obtained from the fine-tuned model using the meanLast4 pooling strategy of the GPT generated sentences and the given sentences results in the most accurate idiomaticity classifier (0.97).

3.2.4 Experiment 4 (ranking improvement)

The final experiment builds on the classifier from Experiment 3 to improve the ranking. In Experiments 1 and 2, all five captions were ranked by their similarity to a single comparator, resulting in poor correlation scores. This setup serves as our *baseline* ranker. For classification, we use the best-performing setting from Experiment 3 (see Table 5): comparing meanLast4 compound embeddings of the given and GPT-generated sentences using the pre-trained BERT model, as we aim at investigating how far we can get without fine-tunig. For ranking, we use the GPT-captions as the comparator and SBERT as the embedding model, which together performed best in Experiment 2 (see Table 4). We propose two improved ranking algorithms:

The *pair ranker* first selects the caption most similar to the literal GPT-caption ('literal1') and the one most similar to the idiomatic GPT-caption ('idiomatic1'). Next, it identifies 'literal2' and 'idiomatic2' as the captions most similar to 'literal1' and 'idiomatic1', respectively, among the remaining captions. The leftover caption is marked as 'unrelated'. If the classifier labels the sentence as literal, the predicted order is: literal1-literal2-idiomatic2-idiomatic1-unrelated; otherwise, it is: idiomatic1-idiomatic2-literal2-literal1-unrelated.

The *extreme ranker* differs from the pair ranker only in how 'literal2' and 'idiomatic2' are chosen. They are the captions (out of the remaining captions) with the second highest similarity to the according (literal/idiomatic) GPT-caption.

Results (see Table 6) show that both improved rankers outperform the baseline clearly, with little difference between the two new methods.

[6] Fine-tuned model: https://huggingface.co/jlsalim/bert-uncased-idiomatic-literal-recognizer

method	train	test	xe
baseline (experiment 1)	0.201	0.053	0.169
with GPT-data and classifier			
baseline (experiment 2)	0.086	0.027	0.14
pair ranker	**0.324**	**0.18**	0.298
extreme ranker	0.246	0.087	**0.334**
top-1 accuracy	0.56	0.47	0.48

Table 6: Experiment 4: Rank correlations for various ranking methods on different datasets (xe: extended evaluation) and top-1 accuracy (computed with cosine similarity).

3.3 Subtask B

The same embedding strategies are used for Subtask B as for Subtask A. For classifying the image sequence as idiomatic or literal, the captions are compared to the GPT-generated data (see Section 3.1. The best results are achieved by comparing both image captions of the series to all GPT-generated data (GPT-sentence, GPT-definition, GPT-caption, each in idiomatic and in literal version). The pairing of GPT-generated data and image caption with the highest similarity predicts the label for the sequence. This method outperforms alternative methods such as averaging over similarities per class or per GPT-text-type.

Our basic approach to the second part, selecting the matching final image caption to continue a sequence of two image captions, is to determine the best fit based on similarities between SBERT embeddings in line with the approach for Subtask A. For this, the embeddings for each of the four potential final captions are compared to the average of the two previous captions of the sequence by calculating the cosine similarity. The caption scoring the highest similarity is chosen as the matching one to complete the sequence.

4 Results

Our best performing system for Subtask A uses the fine-tuned BERT-model and a compound-based mean pooling over the last four hidden states to predict whether the compound is used literally or idiomatically in the sentence. Based on this classification the pair-based ranking method predicts the ranking of the five image captions. No preprocessing is applied.

On the final test data the system reaches a top-1 accuracy of 0.47 and on the extended evaluation dataset an accuracy of 0.54. The correlation score for the test set is 2.82 and for the extended evaluation dataset 3.04. With these results the system ranks 5 out of 6 participating teams on the test set and 3 out of 6 on the extended evaluation set.

For Subtask B only two teams competed and our system described in Section 3.3 came out second on the test set (image selection accuracy: 0.8, sentence type prediction: 0.6) and first on the extended evaluation set (image selection accuracy: 0.6, sentence type prediction: 0.9).

5 Limitations and conclusion

Our approach relies heavily on GPT-generated data. While effective, better prompt design or more careful postprocessing – such as trimming irrelevant parts of captions (e.g. describing image backgrounds) – could further improve results. We have experimented with automatically cutting off caption endings but without consistent gains.

Throughout all experiments, we consistently have used cosine similarity to compare embeddings. Exploring alternative distance metrics could be a promising direction for future work (thanks to our reviewer for the suggestion). In an initial test, we apply negative Manhattan distance and observe a significant improvement for the pair ranker from Experiment 4, while other rankers show no consistent gains (see Table 7).

method	train	test	xe
baseline (experiment 1)	0.166	0.107	0.079
with GPT-data and classifier			
baseline (experiment 2)	0.111	0.133	0.119
pair ranker	**0.376**	**0.313**	**0.367**
extreme ranker	0.284	0.2	0.331
top-1 accuracy	0.54	0.47	0.51

Table 7: Same data as in Table 6 but computed with negative Manhattan distance

The experiments demonstrate that even without fine-tuning, the raw embeddings from BERT and SBERT models contain enough semantic information to solve the task via similarity comparisons. Moreover, using GPT-generated examples for idiomatic and literal uses significantly boosts performance, highlighting the value of synthetic data in semantic modeling. Overall, our findings suggest that simple similarity-based methods, supported by carefully generated auxiliary data, offer a strong baseline for idiomaticity detection and related ranking tasks.

6 Acknowledgement

The work discussed in this paper is a collaborative effort by a seminar group. We would like to thank

the students of the bachelor seminar 'Transformers in CL' at the Heinrich Heine University Düsseldorf in the winter term 2024/2025 for helpful hints and questions.

Furthermore, we thank the anonymous reviewers for their valuable comments and suggestions, and the organizers of the shared task for their tremendous effort and dedication in setting up and running the competition.

HITSZ-HLT at SemEval-2025 Task 8: Multi-turn Interactive Code Generation for Question Answering on Tabular Data

Jun Wang[1]* **Feng Xiong**[1]* **Hongling Xu**[1] **Geng Tu**[1] **Ruifeng Xu**[1]†
[1]Harbin Institute of Technology, Shenzhen, China

Abstract

This paper introduces the system developed by the HITSZ-HLT team for SemEval-2025 Task 8: DataBench, Question-Answering over Tabular Data. The primary objective of Table Question Answering (TableQA) is to provide accurate answers to user queries by interpreting and understanding tabular data. To address this, we propose the **M**ulti-turn **I**nteractive **C**ode Generati**O**n (MICO) framework. Specifically, MICO employs code generation as proxy task for TableQA and integrates feedback from the execution of the generated code via multi-turn dialogue process, thereby guiding the model towards self-correction. Experimental results demonstrate the effectiveness of our framework, achieving notable performance with a rank of 4/38 on the DataBench and 5/38 on the DataBench lite.

1 Introduction

Table Question Answering (TableQA) (Pal et al., 2023; Hu et al., 2024; Zhao et al., 2024; Osés-Grijalba et al., 2025) has gained significant attention due to the extensive use of tabular data in various domains (Jin et al., 2022; Nan et al., 2022). The primary objective of TableQA is to accurately interpret and process tabular data, enabling autonomous generation of answers to user queries. As shown in Fig. 1, the goal of the model to leverage the information provided within the table to identify the author of the shortest post. By empowering machines to reason over structured data in tables, TableQA systems seek to offer a more effective and efficient approach to interacting with large datasets (Giang et al., 2024). While this task holds great potential, it is also accompanied by several challenges (Wu et al., 2024). The inherent complexity of tabular data, which includes large datasets (Su et al., 2024), unordered structures, and high-precision numerical values, presents significant obstacles in generating accurate and efficient responses to queries.

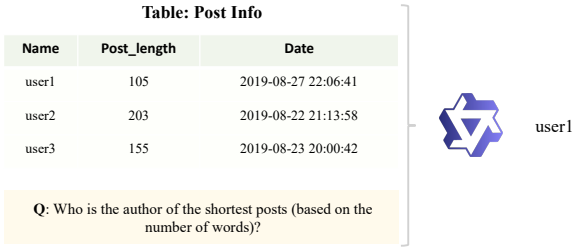

Figure 1: An example of TableQA system.

In this paper, we propose **M**ulti-turn **I**nteractive **C**ode Generati**O**n (MICO). Specifically, we leverage code generation tasks as a surrogate for TableQA to reduce the model's complexity in processing long-context inputs and performing precise numerical computations. Initially, we integrate the table's metadata along with a few sample instances into the prompt, thereby directing the model to generate code. The generated code is then executed within a sandboxed environment[1] to acquire feedback. In subsequent rounds of interaction, if the model determines the code has been successfully executed, it will regenerate the structured output and deliver the final result. Conversely, if the execution is deemed unsuccessful, the model will engage in self-correction and restart the process.

Additionally, we conducted a thorough evaluation of our approach using the DataBench and DataBench Lite datasets, which provided strong evidence of its effectiveness. This extensive validation process resulted in impressive performance, securing a ranking of 4th out of 38 participants on the DataBench leaderboard and 5th out of 38 on the DataBench Lite leaderboard, as reported on the official rankings. Moreover, additional experiments further confirm the effectiveness of each component.

* Equal contribution.

2 Related Work

Existing TableQA research primarily focuses on two main directions: semantic parsing and query generation. Research in the semantic parsing direction involves joint training of natural language questions and tabular text data, followed by fine-tuning for specific tabular tasks, enabling the model to understand the semantic information in the table and provide accurate answers (Mueller et al., 2019; Eisenschlos et al., 2020; Zhou et al., 2022; Hu et al., 2024). Another approach is query generation, where natural language questions are transformed into formal query languages to retrieve relevant data from the table for answering (Zhong et al., 2017; Jin et al., 2022; Wang et al., 2020; Min et al., 2019). These approaches assumes that the table has a known, well-structured format suitable for query translation, but its effectiveness may be challenged when dealing with complex or unstructured tables. However, current researches still lack exploration of multi-turn dialogue. Our work is the first to explore the use of multi-turn dialogue for self-correction in the code generation process for TableQA.

3 Method

In this section, we introduce the system used, which addresses the Question Answering on Tabular Data task through an multi-turn interactive code generation approach, as shown in Fig. 2.

3.1 Information Retrieval and Prompt Construction

In this step, we construct suitable prompts based on the column names and example values of the table. Specifically, we retrieve the set of values for each column from the table and randomly select three values from this set as examples. The column names partially reflect the meaning of the columns, while the example values assist the model in better understanding the data types and content. For a given question, the model is required to first give the steps to solve the problem, then read the table data and perform calculations and analysis by writing Python code, and finally give the answer to the question in the form of a JSON dictionary. The prompt template is shown in Fig 3.

3.2 Data Augmentation

The original dataset provides only the final answers to the questions, lacking the reasoning process and code. To address this, we use GPT-4o to generate multi-turn dialogue data with chain-of-thought reasoning and code based on the constructed prompts, which is then used for subsequent model training.

Notably, the generated code may contain errors, such as accessing non-existent columns in the table or producing outputs that do not conform to the required format. To obtain as many correct code samples as possible while also equipping the model with error correction capabilities, we introduce a code executor and adopt a multi-turn interaction strategy. Specifically, upon receiving a model response, we check whether it contains Python code. If code is present, it is extracted and executed using the code executor. The execution results or traceback messages are then fed back to the model as dialogue messages, prompting it to modify the code accordingly or summarize the final answer. If no Python code is detected, the response is considered the final answer, and the dialogue terminates. The pseudo-code for this process is shown in Algorithm 1.

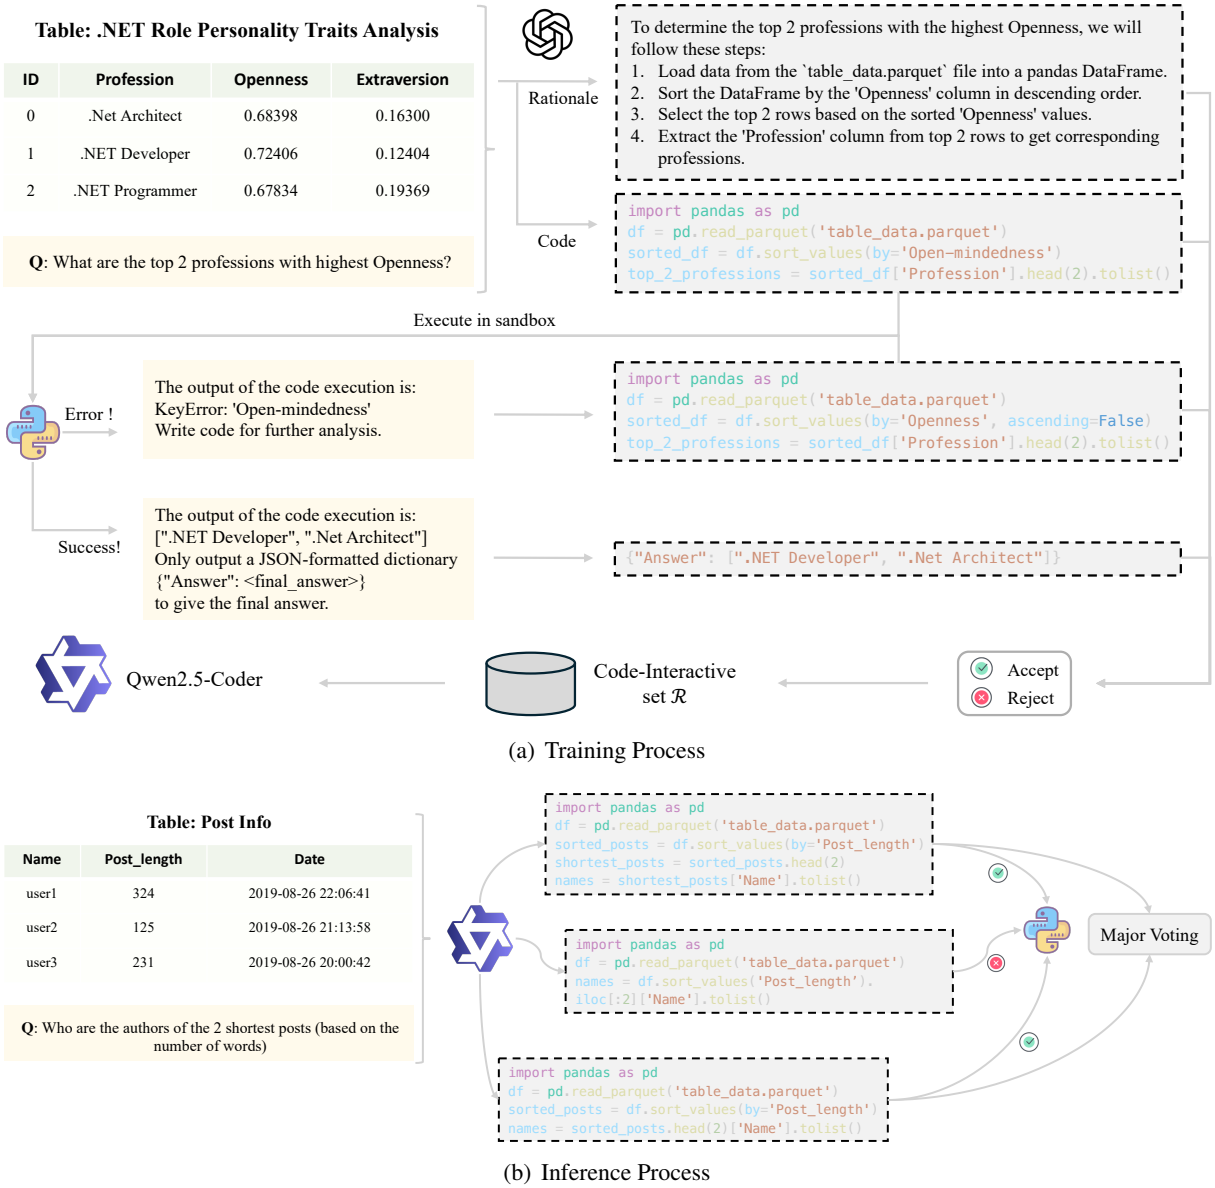
After obtaining the multi-turn interactive dialogue data, the model's answers are compared with the ground truth, and only the data with correct answers are retained for subsequent model training to avoid interference from low-quality data.

Algorithm 1: Multi-turn Interaction Strategy

Input: Question $\mathcal{Q}$; Maximum Number of Interactions $\mathcal{N}$.
Output: Dialogue Messages List $\mathcal{M}$.
$\mathcal{M} \leftarrow [(\text{User}, \mathcal{Q})]$;
for $n \in \{1, \cdots, \mathcal{N}\}$ **do**
  ▷ Obtain the response $\mathcal{R}$ from LLM.;
  $\mathcal{R} \leftarrow LLM(M)$;
  $\mathcal{M}.append((\text{Assistant}, \mathcal{R}))$;
  ▷ Extract the code from $\mathcal{R}$;
  $\mathcal{C} \leftarrow GetCode(R)$;
  if $\mathcal{C}$ *is not None* **then**
    ▷ Execute $\mathcal{C}$ and obtains output $\mathcal{O}$
    $\mathcal{O} \leftarrow Executor(\mathcal{C})$;
    $\mathcal{M}.append((\text{User}, \mathcal{O}))$;
  else
    break;
  end
end

3.3 Model Training

In this step, we fine-tune Qwen2.5-Coder-7B-Instruct (Qwen et al., 2025) using the augmented multi-turn dialogue data. Unlike single-turn dialogue data, multi-turn dialogue data contains multiple messages from the user or code executor. We use language modeling loss as the training loss



(a) Training Process

(b) Inference Process

Figure 2: Illustration of our proposed MICO.

function, calculating the loss only for the tokens generated by the model.

3.4 Model Inference

Similar to the data augmentation phase, during inference, the model interacts continuously with the code executor until the code analysis is complete and an answer is provided, or the maximum number of interactions is reached. If the maximum number of interactions is reached, the answer for the corresponding question will be set to null. For the decoding strategy, we first use greedy decoding for inference. For samples where the maximum interaction count is reached or the answer format is incorrect, we employ self-consistency (Wang et al., 2023) strategy. This involves sampling k responses and performing majority vote on the results to obtain final answer.

4 Experiments

4.1 Experimental Settings

We follow the exact dataset split as the competition organizers. The training set consists of 988 samples from 49 datasets, the validation set includes 320 samples from 16 datasets, and the test set contains 522 samples from 15 datasets. We use the databench_eval toolkit[2] to compute answer accuracy for evaluating different methods. For training, we fine-tune the model using LoRA (Hu et al.,

[2]https://github.com/jorses/databench_eval

````
Task Description
Answer the question based on the data in the table.
When you need to obtain the table data or perform
operations such as filtering and calculations, please
write Python code and wrap it with ```python and ```.
numpy and pandas are already installed and can be used.
You can use pandas to read table_data.parquet to obtain
table data. It is important to note that the code
should use print to return the result. Return value
must be a string and must be returned by print at the
end of the code. An example of the code is as follows.
```python
import numpy as np
import pandas as pd
import json
df = pd.read_parquet('table_data.parquet')
tgt_df = df.head(3)
result = tgt_df.to_json(orient="records",
force_ascii=False)
print(result)
```
Please think step by step, give your thought process
and then write the code to ensure correctness.

Table Description
The table data is stored in table_data.parquet. The
column names and example values are as follows.
{table_info}

Answer Format Requirements
You may write Python code or perform analysis multiple
times. When you get the code execution results and are
sure that you can get the final answer from the results
without writing code to perform analysis again, only
output a JSON-formatted dictionary
```json
{"Answer": <final_answer>}
```
to provide the final answer <final_answer>. The type of
<final_answer> must be one of the following: boolean,
category, number, list[category], or list[number].

Question
{question}
````

Figure 3: The prompt template.

2022). For LoRA parameters, we set the rank to 8, alpha to 16, and dropout to 0.1. The learning rate is set to 1e-4, with a batch size of 8. The model checkpoint with the lowest validation loss is selected for testing. During testing, the sampling temperature is set to 0.8, with a total of 10 sampled outputs per query.

4.2 Comparison Methods

For evaluating the effectiveness of our proposed system, we compare several methods: **Qwen-Single** utilizes Qwen2.5-Coder-7B-Instruct (Qwen et al., 2025) with greedy decoding, requiring the model to generate code that directly answers the question in a single response. **Qwen-Multi** follows a similar approach but uses the multi-turn interaction strategy to refine the response. **FullFT** builds on Qwen-Multi by fine-tuning the model with all generated multi-turn dialogue data. **FilterFT** further improves this by filtering the training data based on answer correctness, using only the filtered dataset for fine-tuning.

Method	# Score Databench
baseline	26.00
Qwen-Single	30.65
Qwen-Multi	52.30
FullFT	77.20
FilterFT	<u>81.03</u>
MICO	**82.18**

Table 1: The accuracy (%) of different methods. The results are presented such that the highest performance is denoted in bold, and the second highest performance is underlined.

5 Results

5.1 Comparison Results

Table 1 presents the comparison results of different models. Compared to Qwen-Multi, Qwen-Single shows a significant performance drop, indicating that providing both correctly formatted and accurate answers in a single-turn interaction is challenging. Introducing a multi-turn interaction strategy enables the system to refine code or organize answers based on execution feedback, significantly improving overall performance. After fine-tuning with enhanced multi-turn dialogue data, FullFT achieved a 24.9% accuracy improvement. This demonstrates the crucial role of multi-turn interaction data in enhancing the model's capabilities. Furthermore, by filtering data based on answer correctness, FilterFT achieved better training results with fewer data, increasing accuracy from 77.20% to 81.03%, demonstrating the crucial role of high-quality data in model training. By ensuring that only accurate responses contribute to learning, the model avoids the negative impact of low-quality samples, leading to more efficient training and improved overall performance. Building upon FilterFT, MICO optimized the decoding strategy by exploring the answer in a larger space through self-consistency for samples that reached the interaction limit or had formatting errors during greedy decoding, correcting these cases and achieving an additional 1.15% performance improvement.

5.2 Leaderboard Results

Table 2 and Table 3 present the performance of the top 10 teams in Databench dataset and Databench Lite dataset, respectively.

Rank	Team	# Score
1	TeleAI	95.02
2	SRPOL AIS	89.66
3	AILS-NTUA	87.16
4	HITSZ-HLT	86.97
5	null33	86.02
6	SBU-NLP	85.63
7	Oseibrefo-Liang	84.67
8	ITU-NLP	84.10
9	grazh	83.72
10	Howard University-AI4PC	81.42

Table 2: Top-10 score on Databench for Open Leaderboard.

Rank	Team	# Score
1	TeleAI	92.91

6 Conclusion

In this paper, we introduced the MICO framework for TableQA, aiming to enhance the accuracy and efficiency of answering queries over tabular data. By utilizing code generation as a proxy task for TableQA and incorporating multi-turn dialogue for feedback and self-correction, MICO effectively addresses the challenges of processing large, complex datasets and performing precise numerical computations. Our experimental results, conducted on the DataBench and DataBench Lite datasets, demonstrated the effectiveness of the MICO framework, with our system achieving a commendable rank of 4th out of 38 participants on the DataBench leaderboard and 5th out of 38 on the DataBench Lite leaderboard.

Limitations

Despite the promising results, our MICO framework has some limitations. The multi-turn interactive process, while enhancing self-correction, increases computational complexity and inference time, especially for more complex queries or larger datasets. Additionally, the model's performance is sensitive to the quality of training data, and noisy or incorrect data can impact its ability to generate accurate responses. Lastly, the framework relies on the structure and format of tabular data, which may limit its generalization across different domains or datasets. Further evaluation on diverse datasets is needed to assess its scalability.

A Case Study

````
## Task Description
Answer the question based on the data in the table. When you need to
obtain the table data or perform operations such as filtering and
calculations, please write Python code and wrap it with ```python and ```.
numpy and pandas are already installed and can be used. You can use pandas
to read table_data.parquet to obtain table data. It is important to note
that the code should use print to return the result. Return value must be
a string and must be returned by print at the end of the code. Please
think step by step, give your thought process and then write the code to
ensure correctness.
## Table Description
The table data is stored in table_data.parquet. The column names and
example values are as follows.
age: 19, 18, 28
sex: 'female', 'male'
bmi: 27.9, 33.77, 33.0
children: 0, 1, 3
smoker: 'yes', 'no'
region: 'southwest', 'southeast', 'northwest'
charges: 16884.924, 1725.5523, 4449.462
## Answer Format Requirements
You may write Python code or perform analysis multiple times. When you get
the code execution results and are sure that you can get the final answer
from the results without writing code to perform analysis again, only
output a JSON-formatted dictionary
```json
{"Answer": <final_answer>}
```
to provide the final answer <final_answer>. The type of <final_answer>
must be one of the following: boolean, category, number, list[category],
or list[number].

## Question
What is the gender of the person with the highest body mass index?
````

````
To determine the gender of the person with the highest body mass index (BMI),
we will follow these steps:

1. Load the data from the `table_data.parquet` file into a pandas DataFrame.
2. Identify the row with the maximum BMI value.
3. Extract the gender of the person associated with this maximum BMI value.

Let's proceed with the implementation:

```python
import pandas as pd

# Load the data from the parquet file
df = pd.read_parquet('table_data.parquet')

# Find the row with the maximum BMI
max_bmi_row = df.loc[df['bmi'].idxmax()]

# Extract the gender of the person with the maximum BMI
gender_of_max_bmi = max_bmi_row['sex']

# Print the result
print(gender_of_max_bmi)
```
This code will load the data, find the row with the highest BMI, and then
extract and print the gender of that individual. Let's execute this code to
get the answer.
````

````
The output of the code execution is:
Traceback (most recent call last):
File "/tmp/code.py", line 7, in <module>
max_bmi_row = df.loc[df['bmi'].idxmax()]
File "/usr/local/lib/python3.10/site-packages/pandas/core/indexing.py",
line 1191, in __getitem__
 return self._getitem_axis(maybe_callable, axis=axis)
 File "/usr/local/lib/python3.10/site-packages/pandas/core/indexing.py",
line 1431, in _getitem_axis
 return self._get_label(key, axis=axis)
 File "/usr/local/lib/python3.10/site-packages/pandas/core/indexing.py",
line 1381, in _get_label
 return self.obj.xs(label, axis=axis)
 File "/usr/local/lib/python3.10/site-packages/pandas/core/generic.py",
line 4321, in xs
 new_mgr = self._mgr.fast_xs(loc)
 File "/usr/local/lib/python3.10/site-
packages/pandas/core/internals/managers.py", line 1002, in fast_xs
 result[rl] = blk.iget((i, loc))
ValueError: could not convert string to float: 'male'

Only output a JSON-formatted dictionary
```json
{"Answer": <final_answer>}
```
to give the final answer, or write code for further analysis if necessary.
````

````
The error indicates that there might be non-numeric values in the 'bmi'
column, which could cause issues when trying to find the maximum value. To
resolve this, we need to ensure that all entries in the 'bmi' column are
numeric before attempting to find the maximum value.
Let's modify the code to handle this situation:
```python
import pandas as pd

# Load the data from the parquet file
df = pd.read_parquet('table_data.parquet')

# Ensure 'bmi' column is numeric, replacing any non-numeric values with NaN
df['bmi'] = pd.to_numeric(df['bmi'], errors='coerce')

# Drop rows where 'bmi' is NaN
df = df.dropna(subset=['bmi'])

# Find the row with the maximum BMI
max_bmi_row = df.loc[df['bmi'].idxmax()]

# Extract the gender of the person with the maximum BMI
gender_of_max_bmi = max_bmi_row['sex']

# Print the result
print({"Answer": gender_of_max_bmi})
```
This code ensures that any non-numeric values in the 'bmi' column are
treated as NaN and removed before finding the maximum BMI. Then, it extracts
and prints the gender of the person with the highest BMI. Let's execute this
updated code to get the final answer.
````

````
The output of the code execution is:
{"Answer": "male"}

Only output a JSON-formatted dictionary
```json
{"Answer": <final_answer>}
```
to give the final answer, or write code for further analysis if necessary.
````

````
```json
{"Answer": "male"}
```
````

MultiMind at SemEval-2025 Task 7: Crosslingual Fact-Checked Claim Retrieval via Multi-Source Alignment

Mohammad Mahdi Abootorabi* **Alireza Ghahramani Kure***

Mohammadali Mohammadkhani **Sina Elahimanesh** **Mohammad ali Ali panah**

{mahdi.abootorabi2, alireza.g.qre, mohammadali1379, sinaaelahimanesh, mohammadali.ap.2000}@gmail.com

Abstract

This paper presents our system for SemEval-2025 Task 7: Multilingual and Crosslingual Fact-Checked Claim Retrieval. In an era where misinformation spreads rapidly, effective fact-checking is increasingly critical. We introduce **TriAligner**, a novel approach that leverages a dual-encoder architecture with contrastive learning and incorporates both native and English translations across different modalities. Our method effectively retrieves claims across multiple languages by learning the relative importance of different sources in alignment. To enhance robustness, we employ efficient data preprocessing and augmentation using large language models while incorporating hard negative sampling to improve representation learning. We evaluate our approach on monolingual and crosslingual benchmarks, demonstrating significant improvements in retrieval accuracy and fact-checking performance over baselines.

1 Introduction

The rapid spread of misinformation on online platforms has become a major global challenge (Shaar et al., 2020; Aïmeur et al., 2023). False claims can now easily cross linguistic and regional boundaries, magnifying their potential impact (Leung et al., 2021; Fernández and Alani, 2018; Hakak et al., 2021). The multilingual nature of the Internet amplifies this issue, as misinformation quickly spreads across different language communities, making it harder to track and counteract (Bak et al., 2023). While professional fact-checkers work tirelessly to verify misleading information, the sheer volume of online content, often published in multiple languages (Kazemi et al., 2021), makes manual verification increasingly impractical (Warren et al., 2025). The growing speed and scale of misinformation make these efforts more urgent, yet even the most diligent fact-checkers cannot keep pace.

Automating the retrieval of fact-checked claims across different languages and cultures is crucial to enhancing the efficiency of fact-checking operations (Khurana et al., 2023). The challenge is retrieving relevant fact-checks for social media posts written in languages unfamiliar to fact-checkers (Thakur et al., 2021). To accurately match claims across linguistic boundaries, systems must recognize claims in different languages and contexts (Srba et al., 2022; Dementieva and Panchenko, 2020) while accounting for subtle language and cultural differences. Given the global nature of misinformation, there is a growing need for multilingual and crosslingual systems that can effectively bridge these gaps (Maity et al., 2023; Bontcheva et al., 2024). By addressing this challenge, we can significantly expedite the process of matching claims to fact-checks, enabling faster and more accurate verification (Quelle et al., 2023). This challenge motivated our participation in ***SemEval-2025 Shared Task 7: Multilingual and Crosslingual Fact-Checked Claim Retrieval*** (Peng et al., 2025).

In this study, we propose **TriAligner**, a retrieval pipeline designed to identify relevant fact-checked claims for social media posts across languages. Our system operates in both monolingual and crosslingual settings, reducing the manual effort required for fact-checking. By enhancing multilingual retrieval capabilities, our approach supports fact-checkers, researchers, and media organizations in combating the global spread of misinformation. Our pipeline builds upon the ***MultiClaim dataset*** (Pikuliak et al., 2023a), incorporating data augmentation techniques and a dual-encoder architecture designed for the challenges of multilingual claim retrieval. To enhance semantic understanding, we use GPT-4o (Hurst et al., 2024) to refine post representations, ensuring that fact-checking models can better capture claim-related nuances. Our retrieval system encodes both posts and fact-checks in their native language and English translation, leveraging multilingual embed-

*Equal contribution.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2325–2335

dings to bridge linguistic gaps. To refine retrieval quality, we introduce a contrastive learning framework that aligns matching claim-post pairs while distinguishing non-matching ones. GPT-4o is further employed as a reranker to refine the relevance of retrieved fact-checks. Our work advances multilingual information retrieval techniques as part of the effort to combat misinformation. We explore how integrating neural retrieval models with contrastive learning and data augmentation can enhance crosslingual fact-checking. Insights from this work are expected to shape the direction of future research in this field. Our team secured the 21st rank in the monolingual setting (Subtask 1) and the 24th rank in the crosslingual setting (Subtask 2) in the test competition.

2 Background and Related Work

The SemEval task features two tracks: monolingual and cross-lingual. In the monolingual track, the post and claim are written in the same language, whereas the cross-lingual track pairs a post with a claim in a different language.

Earlier datasets for previously fact-checked claim retrieval (PFCR), such as CheckThat! (Barrón-Cedeño et al., 2020), primarily focused on English and Arabic, and included manually filtered social media posts to ensure reliability. In contrast, we use the MultiClaim dataset (Pikuliak et al., 2023a), a large and linguistically diverse resource designed to support multilingual and cross-lingual PFCR. MultiClaim comprises approximately 206k fact-checks in 39 languages and over 28k social media posts in 27 languages. It also includes machine-translated posts and OCR-processed images, further facilitating experimentation across languages and modalities.

Regarding methodologies, BM25 and neural text embedding models (TEMs) are commonly used in PFCR tasks. (Shaar et al., 2020) relied on BM25 for its efficiency and robustness in monolingual retrieval. Additionally, (Sundriyal et al., 2023) applied the integration of neural and traditional approaches to the fact-checking problem on Twitter. However, multilingual and cross-lingual retrieval often requires more sophisticated embedding-based solutions. (Pikuliak et al., 2023b) shows that embedding models, especially when enhanced with machine translation and supervised fine-tuning, can outperform traditional retrieval methods like BM25 in multilingual contexts.

Recent studies have explored using large language models (LLMs) for multilingual PFCR. (Vykopal et al., 2025) evaluated seven LLMs across 20 languages, finding that while LLMs perform well for high-resource languages, they struggle with low-resource ones. Translating texts into English notably improved performance for low-resource languages. Similarly, (Singhal et al., 2024) assessed the multilingual fact-checking abilities of five LLMs across five languages using various prompting techniques. They found that zero-shot prompting with self-consistency decoding was most effective, and interestingly, LLMs showed better fact-checking performance in low-resource languages, suggesting potential for mitigating language disparities in PFCR tasks. Additional research has extended PFCR by incorporating modalities such as visual data (Mansour et al., 2022), abstractive summarization (Bhatnagar et al., 2022), and key sentence identification (Sheng et al., 2021) to improve retrieval accuracy and contextual understanding.

3 System Overview

Figure 1 provides an overview of our method. We employ various techniques to enhance model performance, which we detail in the following sections:

3.1 Preprocessing Data

Data Augmentation Using a Large Language Model We leverage GPT-4o (Hurst et al., 2024) large language model (LLM) to augment and rewrite posts by integrating text and OCR data into a cohesive version. Using a predefined prompt (Appendix (§A)), we enhance each post to improve the model's ability to comprehend content. After augmentation, each post contains at least 10 words, with all sources merged into a unified text while preserving the original meaning. The augmented and cleaned dataset is publicly available on Hugging Face [1].

Data Cleaning and Preprocessing We apply multiple preprocessing steps that are usually used in NLP approaches to improve the model's ability to interpret data effectively. One key step involves concatenating the title and OCR fields for posts and the title and claim fields for facts, creating unified text representations.

Hard Negative Sampling To enhance model robustness, we introduce hard negative samples. Using the BGE-M3 (Chen et al., 2024), we encode

[1] https://huggingface.co/datasets/MultiMind-SemEval2025/Augmented_MultiClaim_FactCheck_Retrieval

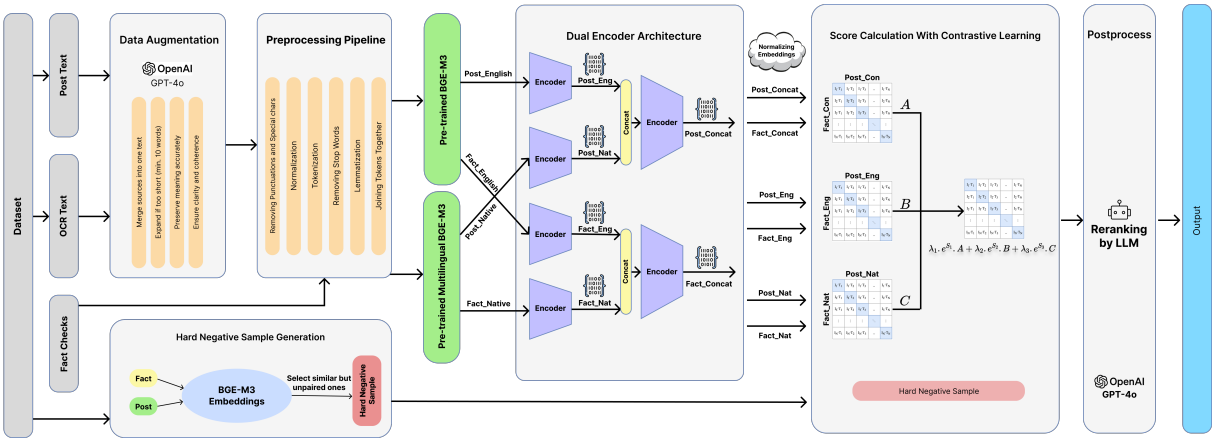

Figure 1: Our proposed system's pipeline includes data augmentation, preprocessing, hard negative sampling, the model's core network, score calculation, and re-ranking using a large language model to generate the final ranking for each social media post.

all facts and posts and identify unrelated pairs with similar representations. These hard negatives help the model better distinguish between semantically similar but unrelated claims and posts.

Generating Embeddings for Facts and Posts Since posts and facts exist in both English and their native languages, we encode them using both English-specific and multilingual pretrained encoders. This process produces four types of embeddings: **(i)** fact_native (fact-checked claim in its original language), **(ii)** fact_english (fact-checked claim translated to English), **(iii)** post_native (post in its original language), **(iv)** post_english (post translated to English).

3.2 Core Network of TriAligner

We employ a dual-encoder architecture to independently encode posts and fact-checked claims, drawing inspiration from CLIP (Radford et al., 2021) to align representations across different modalities and spaces.

We first utilize pretrained embeddings and map them into a shared semantic space using a neural network encoder in a lower-dimensional space. Next, we concatenate representations from both English and native sources separately, forming unified representations for each post and fact-checked claim. These concatenated encoded vectors then pass through an additional neural encoder to generate compact representations suitable for similarity computation. For final scoring, after normalization, we compute cosine similarity between embeddings to construct three similarity matrices: **(i)** Native post and fact-checked claim embeddings, **(ii)** English post and fact-checked claim embeddings, and **(iii)** Concatenated embeddings processed through an additional encoder. These correspond to three similarity matrices: **(A)** Concatenated posts and fact-checked claims, **(B)** English posts and fact-checked claims, and **(C)** Native posts and fact-checked claims.

To compute the final similarity matrix, we apply Formula 1, where $x_{i,j}$ represents the element in the ith row and jth column of the final matrix. Here, $\lambda_1, \lambda_2, \lambda_3$ are trainable coefficients that adjust the weights between different sources, and S_1, S_2, S_3 are scaling coefficients for each matrix. The value $x_{i,j}$ corresponds to the similarity score between the ith fact-checked claim and the jth post. In this way, we use three sources to compute the final similarity score between fact-checked claims and posts.

$$x_{i,j} = \lambda_1.e^{S_1}.(A_{i,j}) + \lambda_2.e^{S_2}.(B_{i,j}) + \lambda_3.e^{S_3}.(C_{i,j}) \quad (1)$$

We train the model using a symmetric contrastive loss applied to the final similarity matrix $X \in \mathbb{R}^{N \times N}$, where N is the batch size. This loss encourages true post–claim pairs (diagonal elements x_{ii}) to have higher similarity scores while discouraging mismatched pairs (off-diagonal elements $x_{ij}, i \neq j$). Given the element x_{ij} derived from Equation 1, we compute row-wise and column-wise softmax probabilities:

$$P_{ij} = \frac{\exp(x_{ij})}{\sum_{k=1}^{N} \exp(x_{ik})}, \quad Q_{ij} = \frac{\exp(x_{ij})}{\sum_{k=1}^{N} \exp(x_{kj})} \quad (2)$$

The loss is then formulated as the average negative log probability of the true pairs across both perspectives:

$$\mathcal{L} = -\frac{1}{2N} \sum_{i=1}^{N} (\log P_{ii} + \log Q_{ii}) \quad (3)$$

This training process and objective preserve residual information, enhance robustness, and enable the model to learn optimal weightings across embedding sources while effectively distinguishing between relevant and irrelevant pairings based on multi-source similarity signals.

Candidate Re-ranking In the final stage of our pipeline, we employ the GPT-4o model (Hurst et al., 2024) as a reranker to refine the ordering of candidate fact-checks. We created and utilized a tailored prompt (Appendix (§B)), guiding GPT-4o to rank these candidates strictly based on their relevance to the content of the associated post, producing an output list sorted in descending order of relevance. For each post, we provide the model with the post content and 15 pre-selected candidate fact-checks, instructing it to return the 10 most relevant ones. Since the reranker operates on a fixed pool of 15 candidates, metrics such as Success@20 and Recall@20 remain unchanged with or without the reranking step.

4 Experimental Evaluation and Results

For evaluation, we perform the retrieval task based on the alignment scores between query social media posts and fact-checked claims. The system returns the top-K most relevant fact-checked claims for each social media post in both monolingual and crosslingual configurations. In the monolingual setting, the model retrieves relevant fact-checked claims from the same language as the query post, while in the crosslingual setting, the model searches across fact-checked claims in all available languages.

For the architecture of our core TriAligner system, the first layer consists of four encoders with similar structures, each processing different language sources for posts and facts. Each encoder includes a linear layer that reduces the input dimension from 1024 to 256, followed by batch normalization, a ReLU activation function, dropout with a probability of 0.2, and a final linear layer that preserves the 256-dimensional representation. In the second stage, after concatenating the outputs from the previous layer's native and English translation sources, the processed embeddings are fed into additional encoders. Each of these encoders contains a linear layer that reduces dimensions from 512 to 256, followed by a ReLU activation function and another linear layer that maintains the 256-dimensional representation. Finally, the outputs of the post encoders and initial encoders are normalized, and all are used in the matrix construction phase, where the relevance scores between facts and posts are computed. Due to the dataset size, we did not make the encoders too complex to avoid overfitting. Computational constraints required us to construct the final similarity matrix incrementally by processing the data in batches. For more details of our experiment setup and hyperparameters, see Appendix (§D).

We evaluated our model with K values of 1, 10, and 20, reporting two metrics: Success@K (S@K) and Recall@K (R@K). Success@K equals 1 when at least one associated fact-check for a post is retrieved in the top K results, and 0 otherwise. Recall@K is more stringent, measuring the proportion of relevant fact-checks retrieved in the top K. For example, if a social media post has two associated fact-checks and only one appears in the top K results, the Recall@K score for that post is 0.5. The formal definitions of these metrics are as follows:

$$\text{S@K} = \frac{\text{\# queries with at least one relevant item in top K}}{\text{\# queries}} \tag{4}$$

$$\text{R@K} = \frac{1}{\text{\# queries}} \sum_{q=1}^{\text{\# queries}} \frac{\text{\# items in top K that are relevant to query q}}{\text{\# relevant items for query q}} \tag{5}$$

Table 1 shows the average performance of different model variants in both monolingual and crosslingual settings, without language-specific breakdowns. Tables 2 and 3 in Appendix (§E) provide detailed language-specific results for monolingual and crosslingual evaluations, respectively, across different stages of our approach. Table 4 in Appendix (§E) also compares our model's performance against the top-performing team in the test competition. The evaluation stages are as follows:

4.1 Baselines Evaluation

For the baselines, we use two powerful pretrained encoders capable of producing informative semantic embeddings at the sentence level:

BGE-M3 (Chen et al., 2024) A versatile embedding model trained through self-knowledge distillation. This method integrates relevance scores from different retrieval functionalities as teacher signals to enhance training quality. The model was trained on multiple datasets covering over 100 languages, making it highly effective for multilingual tasks. The English version also demonstrates excellent performance. BGE-M3 supports dense retrieval, multi-vector retrieval, and sparse retrieval within a unified framework. It can process inputs of varying granularities, from short sentences to long documents of up to 8192 tokens, making it appropriate

for our social media posts and fact-checks. It has demonstrated state-of-the-art performance on various benchmarks and tasks.

LaBSE (Feng et al., 2022) A multilingual BERT-based sentence embedding model trained on 17 billion monolingual sentences and 6 billion bilingual sentence pairs. The model combines masked language modeling (MLM) and translation language modeling (TLM) pre-training on a 12-layer transformer with a 500K token vocabulary, followed by fine-tuning on a translation ranking task. LaBSE covers over 109 languages within a shared embedding space, enabling crosslingual tasks like semantic search. It shows strong performance even for low-resource languages with limited training data.

We leverage these models without additional training by simply passing all posts and fact-checks through them to obtain embeddings. We then perform similarity ranking using cosine similarity to identify the most relevant fact-checks for posts. As demonstrated in Table 1, BGE-M3 outperforms LaBSE, providing superior representations for our task. Our results show that using content in its native language is somewhat more effective in monolingual settings, while in crosslingual settings, English translations perform slightly better. This suggests that multilingual encoders still have room for improvement in cross-language alignment, and translation-to-English pipelines remain more effective despite potential information loss. As Table 3 suggests, the performance gap between English and native language processing is substantial for low-resource languages like Thai, while for well-represented languages, this gap is negligible or even favors native processing. Finally, our evaluation of the refined dataset using BGE-M3 outperformed other baselines, demonstrating the effectiveness of our LLM-assisted refinement method.

4.2 Ablation Study

To assess the impact of different components in our system, we conducted ablation experiments focusing on two key approaches:

Concatenation-Based Encoding (ConcatEnc) This experiment evaluates the effectiveness of using only the similarity matrix derived from the concatenated embeddings. Instead of using all three similarity matrices as in our full system, we rely solely on the matrix generated from the concatenated native and English representations after they pass through the additional encoder. This allows us to isolate the contribution of the concatenation component to the overall performance without the influence of the individual language-specific matrices.

Multiple Similarity Scoring (MultiSim) This approach assesses the effectiveness of our scoring mechanism in aligning native and English dimensions without using concatenation. MultiSim focuses solely on combining similarity matrices from different language sources. The model produces two separate similarity matrices: one for native-language embeddings and another for English translations. The final similarity matrix is then computed as a linear combination of these matrices using trainable coefficients.

Both approaches demonstrate performance improvements over the baselines. The Concatenation-Based Encoding (ConcatEnc) approach yields superior results, as it introduces additional parameters that enable the model to learn more complex dependencies between posts and fact-checks. The fusion of different language representations through concatenation proves to be an effective mechanism for improving retrieval. More importantly, both methods significantly enhance performance in crosslingual settings by leveraging both native and translated sources. This suggests that aligning multilingual representations contributes to better retrieval capabilities. Given the observed improvements, we incorporate both techniques into our final model.

4.3 Final System Evaluation

In this stage, we integrate both proposed ideas to develop our final model, TriAligner. As described in Section 3, the final similarity matrix is a weighted combination of 3 sources: English, native, and fused shared space representations. We train the model with our augmented dataset and subsequently apply an LLM-based re-ranker to enhance performance. Moreover, we employ hard negative sampling to enhance training and incorporate marginal loss and contrastive loss. However, due to the large batch size, hard negative sampling did not yield significant performance improvements.

As shown in Table 1, combining both techniques results in the best performance across all metrics in both monolingual and crosslingual settings, demonstrating the impact of our alignment strategies. Furthermore, LLM-assisted data augmentation provides an additional performance boost, particularly in S@10 and S@20, indicating more effective handling of outlier posts with limited descriptive information. The LLM-based re-ranker also improves performance in both multilingual and crosslingual

Table 1: Evaluation results across stages for monolingual and crosslingual settings on the development dataset.

Stage 1: Baseline Evaluation Results

	Monolingual						Crosslingual					
Model/Source of Data	R@1	R@10	R@20	S@1	S@10	S@20	R@1	R@10	R@20	S@1	S@10	S@20

settings by approximately 5 to 10 percent across different metrics. We anticipate that employing LLMs specifically tailored for advanced reasoning, such as Claude 3.7 Sonnet Thinking (Anthropic, 2025) or Gemini 2.5 Pro (Google, 2025), could lead to even greater performance gains. However, due to the limitations of our available computational resources, we employed GPT4-o (Hurst et al., 2024) for this purpose.

Tables 2 and 3 provide detailed language-specific results that offer deeper insights into our system's performance. Languages such as Arabic, Malay, and French benefited significantly from data augmentation. Conversely, augmentation appeared detrimental for the German language, leading to decreased performance across most metrics. This suggests that while the augmentation technique often helps by enhancing sparse or unclear posts, its effectiveness can be language-dependent, potentially due to the LLM's handling of specific linguistic nuances or the nature of the original data for that language. Beyond data augmentation, the addition of the LLM-based re-ranker further improved retrieval performance across most languages in both monolingual and crosslingual settings. Notably, the re-ranker yields substantial gains in Recall@1 and Score@1, underscoring its ability to surface the single most relevant fact-check by leveraging deeper semantic understanding. However, the Malay language exhibited a notable decrease in performance with re-ranking. This divergence may stem from frequent code-mixing between Malay and English in social media posts, creating translation inconsistencies during cross-lingual re-ranking, or from the re-ranker's struggle with Malay's narrative-style debunking patterns that differ from Western fact-check templates. Both tables' baseline results (Stage 1) also highlight that while native embeddings offer slight advantages in some settings, English translations are crucial, particularly for low-resource languages. For instance, the large crosslingual performance gap for the Thai language highlights persistent challenges in multilingual encoder alignment and the continued utility of translation pipelines.

5 Conclusion

In this work, we introduce TriAligner, a contrastive learning-based approach for multilingual and crosslingual fact-checking, leveraging a dual encoder setup and hard negative samples to improve fact-checked claim retrieval. Through data preprocessing and augmentation, our method improves robustness across diverse languages and social media contexts. Experimental results demonstrate the effectiveness of our approach in retrieving relevant evidence and mitigating misinformation. Future work can explore integrating additional modalities, refining negative sampling strategies, and adapting the model to evolving misinformation patterns. Our findings highlight the value of contrastive learning for fast and accurate fact-checking in a globally connected digital landscape. A detailed discussion of limitations and further potential future directions can be found in Appendix (§C).

A Prompt for Data Augmentation

In this section, we provide the prompt we used for data augmentation:

You are provided with 10 pairs of texts, each originating from the same social media post. For each pair, your task is to integrate the two sources into a single cohesive and enhanced text that best represents the content of the post. Combine the information from both the image and the text, rewrite the content to be meaningful, and preserve the post's original context and intent.
Rules:

- You should process pairs individually, ensuring each is handled independently of the others.
- The output should be in the language of the post and in the same narrative style.
- Do not use phrases like 'The post indicates...'.
- Convert abbreviations to their complete form.
- Remove hashtags and their tags.
- There should not be anything enclosed in brackets, such as [USER] or [URL].
- If the combined content is less than ten words, expand it to at least 15 words while staying relevant.

B Prompt for Reranking

In this section, we present the prompt we used to rerank the retrieved results with GPT-4o:

You are assisting with a fact-check retrieval system that uses neural networks to retrieve relevant fact-checks for social media posts. The current retrieval system returns 20 candidate fact-checks for each post, but its ranking is not perfect. Your task is to re-rank these candidate fact-checks for a single social media post so that the most relevant ones appear at the top.
Task: - Re-rank the candidate fact-checks based on their relevance to the post's content. - Select the top 10 fact-checks from the 15 provided. - Order the fact-check IDs in descending order of relevance (i.e., the most relevant fact-check appears first). - Output only the fact-check IDs.
Input Format: You will receive a dictionary representing a single social media post along with its candidate fact-checks. The structure is as follows:

```
sample_input = {
  "post": {
      "post_id": post_id,
      "post_content": post_content
  },

  "factChecks": [
    {"fact_id": fact_id_1,
    "fact_content": fact_content_1},
    {"fact_id": fact_id_2,
    "fact_content": fact_content_2},
    {"fact_id": fact_id_3,
    "fact_content": fact_content_3},
    ...
  ]
}
```

Output Format: Return a JSON object with a single key (the post_id) and its value as a list of the top-10 re-ranked fact-check IDs. For example:

```
sample_output = {
  "post_id": [
    fact_id_5,
    fact_id_2,
    fact_id_9,
    ... (total 10 items)
  ]
}
```

Important: - The output must include only fact-check IDs, with no additional scoring information. - The list must contain exactly 10 fact-check IDs, sorted in descending order of relevance. - Follow this format strictly.

C Limitations and Future Direction

In this work, we aimed to address the challenge of fact-check retrieval for social media posts. While our model demonstrates strong performance, certain limitations persist.

First, our crosslingual pipeline can be further improved. Future research should explore more advanced and effective architectures to bridge the

gap between different languages, ensuring better crosslingual alignment in a shared representation space.

Second, our approach relies on only two backbone models (BGE-M3 and LaBSE). This limitation can be addressed in future studies by experimenting with a wider range of backbone models to enhance robustness and generalizability.

Lastly, due to resource constraints, we were only able to apply data augmentation to English posts. Future work can extend this augmentation process to other sources (facts) and other languages, further improving the model's performance across diverse linguistic contexts.

D Experiment Setup and Hyperparameters

All experiments were conducted on a single NVIDIA P100 GPU with a batch size of 10000. Our implementation leverages the PyTorch Lightning and Transformers libraries. We trained all model variants using the AdamW optimizer (Loshchilov and Hutter, 2019) with a learning rate of $6e-4$ and a cosine annealing learning rate scheduler (Loshchilov and Hutter, 2017). The initial scaling factor is set to $log(1/0.07)$. The training was terminated using early stopping with patience of 5 epochs, monitoring the Recall@10 on the validation set.

E Supplementary Evaluation Results

In this section, we present evaluation results at different stages for both crosslingual (Table 3) and monolingual (Table 2) settings for the development dataset. We focus on the eight most frequently used languages in the dataset, as the data for other languages was insufficient for meaningful analysis. Table 4 presents a performance comparison between our model and the first-place team in the competition's monolingual setting. It is important to note that our model was evaluated without the re-ranker module during the competition's test phase due to computational resource limitations. We observe that in the separate crosslingual subtask of the test phase of the competition, our system achieved an S@10 score of 0.489, whereas the winning team attained a score of 0.859.

Table 2: Evaluation results across different stages for monolingual setting, covering the eight most frequently used languages in the dataset.

Abstract

Unlearning is a critical capability for ensuring privacy, security, and compliance in AI systems, enabling models to forget specific data while retaining overall performance. In this work, we participated in Task 4 of SemEval 2025, which focused on unlearning across three sub-tasks: (1) long-form synthetic creative documents, (2) short-form synthetic biographies containing personally identifiable information, and (3) real documents sampled from the target model's training dataset. We conducted four experiments, employing Supervised Fine-Tuning (SFT) and Direct Preference Optimization (DPO). Despite achieving good performance on the retain set—data that the model was supposed to remember—our findings demonstrate that these techniques did not perform well on the forget set, where unlearning was required.

1 Introduction

As machine learning (ML) continues to be integrated into critical domains, concerns over data privacy, security, and user autonomy have become more pressing than ever. From healthcare to finance, data-driven models play a crucial role, but their ability to retain and utilize information raises significant challenges. This issue has been further emphasized by legal regulations such as the General Data Protection Regulation (GDPR), which grants individuals the "right to be forgotten" (Voigt and von dem Bussche, 2017).

Machine unlearning has emerged as a key approach to tackling these concerns. It enables the selective removal of specific data points from a trained model without necessitating a full retraining process (Cao and Yang, 2015a). Unlike fine-tuning or knowledge editing, which focus on adjusting or adding new information, machine unlearning is designed to eliminate the influence of certain inputs, ensuring they no longer contribute to the model's predictions or behavior. The overall workflow of machine unlearning is illustrated in Figure 1.

The importance of machine unlearning is magnified by the intricate nature of deep learning models. These models often exhibit *data entanglement*, where information from different training instances becomes deeply intertwined within the model's parameters, making selective removal a challenging task (Tramèr et al., 2022). Additionally, unlearning must be carefully implemented to prevent unnecessary degradation of the model's performance on retained data, striking a balance between utility and privacy (Guo et al., 2019). Another significant hurdle is efficiency—particularly in large-scale architectures like LLMs—since retraining a model from scratch is often impractical due to the immense computational cost.

As large language models gain increasing prominence, it becomes essential to examine the relationship between machine unlearning and *knowledge editing*. Knowledge editing is typically used to update or correct specific facts or behaviors in LLMs without requiring a full model retrain (Yao et al., 2023; Wang et al., 2025; Mitchell et al., 2022). While both techniques modify a model's internal representations, they serve distinct purposes: knowledge editing injects or refines information, whereas unlearning aims to remove specific influences entirely. This distinction highlights both the challenges and the potential areas of overlap between these two approaches.

Beyond its technical implications, machine unlearning also plays a crucial role in ensuring ethical AI practices and regulatory compliance. By enabling models to forget specific information when required, unlearning enhances both user privacy and model transparency, making it an essential tool in the evolving landscape of responsible AI.

In this study, we explore machine unlearning in large language models by participating in SemEval-2025 Task 4. We focus on selectively remov-

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2336–2341

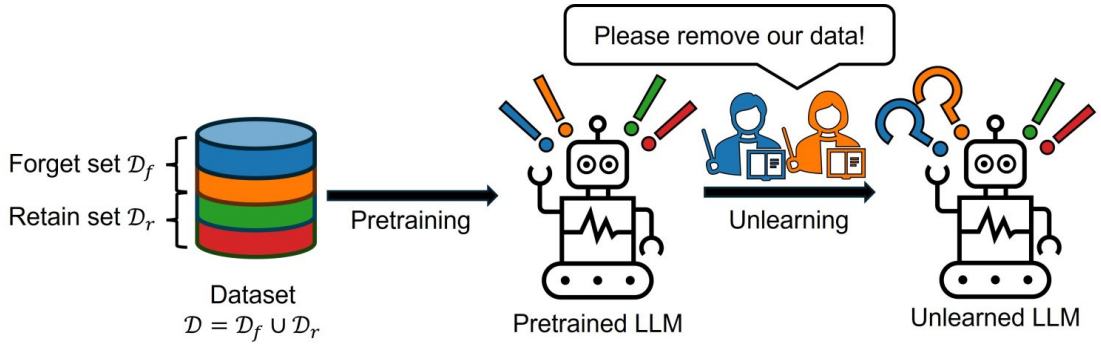

Figure 1: Workflow of machine unlearning.

ing memorized information across three document types: synthetic creative documents, synthetic biographies containing personally identifiable information (PII), and real-world documents, without compromising the model's general performance. For this, we conduct four experiments using Supervised Fine-Tuning (SFT) and Direct Preference Optimization (DPO) techniques. Our findings reveal the challenges of achieving effective unlearning, emphasizing that current approaches, while promising for retention, still fall short in forgetting sensitive data. Through this work, we aim to contribute insights into the limitations and future directions for improving machine unlearning in large-scale AI systems. [1]

2 Background

In recent years, machine unlearning has attracted significant attention as concerns about data privacy, regulatory compliance, and ethical AI practices have grown. The fundamental concept of machine unlearning is to allow trained models to remove specific data points without the need for complete retraining, thereby achieving a balance between efficiency and privacy demands. This section examines the leading approaches and methodologies presented in the literature.

2.1 The Rationale for Machine Unlearning

Users may want to delete their data for various reasons, mainly for security and privacy concerns. Each reason is discussed further below.

Privacy, Several approaches have been proposed to mitigate privacy risks in LLMs. Differential privacy (Dwork, 2006) introduces noise to training data to prevent individual data points from being memorized. Federated learning (McMahan et al., 2017) minimizes direct data exposure by training models on decentralized data. However, these techniques do not fully address the problem of post-hoc data removal, which is where unlearning methods become crucial (Bourtoule et al., 2021). **Security**, Adversarial attacks generate data nearly identical to real data, tricking deep learning models into incorrect predictions. In critical fields like healthcare, this can lead to misdiagnoses or harmful treatments. Detecting and removing such data is crucial for security, and machine unlearning must eliminate detected attacks (Cao and Yang, 2015b).

2.2 Unlearning Methods

Several unlearning methods have been developed to address the challenges of removing specific knowledge influences from trained models while maintaining overall performance. These methods include:

- **Gradient Ascent:**This approach builds upon the concept of gradient ascent by aiming to maximize the loss on the forget set (Trippa et al., 2024).
- **Gradient Difference:** This method, expands on the idea of gradient ascent. It seeks to increase the loss on the forget set, while simultaneously preserving performance on the retain set (Liu et al., 2022).
- **KL Minimization** In the KL Minimization approach, the goal is to balance two objectives during the unlearning process of a model: (1) Minimize the Kullback-Leibler (KL) divergence: This ensures that the predictions of the unlearned model on the sensitive data (SR) remain close to those of the original model fine-tuned on the original data. (2) Maximize

[1] Additional details and code are available on our GitHub repository.

the conventional loss on the safe data (SF): This encourages the model to perform well on non-sensitive data (Maini et al., 2024).

- **Negative Preference Optimization** It addresses the limitations of existing gradient ascent-based methods and demonstrates that NPO-based methods outperform other approaches, providing a superior balance between unlearning effectiveness and model utility. The evaluation is conducted on the Task of Fictitious Unlearning (TOFU) dataset, and the paper concludes with a discussion of model utility and forget quality (Zhang et al., 2024).
- **Preference Optimization** Inspired by the concept of Negative Preference Optimization (NPO) (Rafailov et al., 2023). The goal is to ensure that while the model aligns with the newly generated answers for forget set, its natural language capabilities and predictions for retain set remain unchanged.
- **Direct Preference Optimization:** a training methodology in which a language model is fine-tuned directly on human preference data. Instead of relying on complex reward modeling or reinforcement learning frameworks such as RLHF (Reinforcement Learning with Human Feedback), the model learns by imitating human-identified preferred outputs. (Rafailov et al., 2024)

2.3 Task Setup

The task focuses on three document types with escalating complexity and evaluates both information retention and forgetting efficacy through multiple metrics. For a given fine-tuned 7B parameter OLMo model (OLMo-7B-0724-Instruct-hf) that has been pre-trained and has memorized task-specific documents, our goal is to efficiently remove information from a forget subset (F) while retaining information from a retain set (R) without a performance decrement. A sample of the dataset can be seen in Figure 2. The original benchmark (Ramakrishna et al., 2025) consists of three separate tasks designed to thoroughly assess LLM unlearning algorithms across creative documents, PII, and biographies.

3 System Overview

This study explores unlearning in large language models (LLMs) through four experiments using

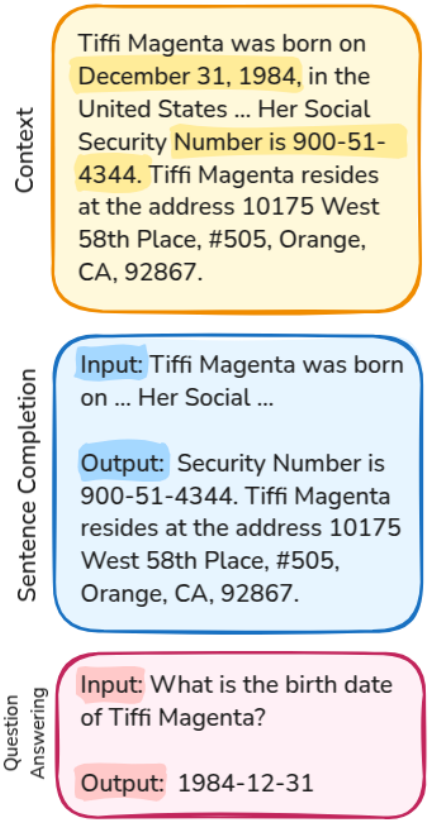

Figure 2: An example of a dataset sample for two tasks: "sentence completion" and "question answering."

two training methods: Direct Preference Optimization (DPO) and Supervised Fine-Tuning (SFT). The approach for data collection and training is outlined below.

3.1 Data Collection

For the DPO-based experiments, training data was structured into accepted and rejected pairs. In the first experiment, the forget set from the training data was used as the rejected part. The accepted responses were generated using the Phi-4 model, ensuring minimal lexical overlap with the forget set. ROUGE was used to verify low lexical similarity. For the retain set, the training data was used as accepted responses, and the rejected counterparts were created in the same way as in the forget set.

In the second experiment, the same approach was followed, except that different synonyms of "I do not know" were used as the accepted responses for the forget set instead of Phi-4 generations.

For the SFT-based experiments, the same data structure was used, but without rejection-based training. Instead, only accepted responses were used for training. In experiment three, the ac-

Algorithm/Dataset	Task Aggregate	MIA Score	MMLU Avg.	Aggregate
DPO-Phi4	0.0	0.0	0.495	0.165
DPO-Idk	0.0	0.0	0.423	0.141
SFT-Phi4	0.0	0.0	0.423	0.141
SFT-Idk	0.0	0.0	0.426	0.142

Table 1: The results of applying DPO and SFT methods for unlearning.

cepted responses from experiment one were used as training data. In experiment four, the accepted responses from experiment two were used.

3.2 Training Methods

For the first two experiments, DPO was applied to train the model by optimizing it to prefer accepted responses over rejected ones. This preference learning process guided the model to align with the desired unlearning behavior by distinguishing between retained and forgotten knowledge.

For the last two experiments, SFT was used, where the model was fine-tuned solely on the accepted responses. Unlike DPO, which explicitly learns to prefer one response over another, SFT updates the model's parameters directly based on the provided training data without contrastive comparisons.

Through these four experiments, different strategies for unlearning were explored, and their effectiveness in reducing retention of the forget set while maintaining performance on the retain set was evaluated.

4 Experimental Setup

4.1 Preprocessing

For each sample in the forget set (F), we use the Phi-4 model to generate multiple candidate answers. From these candidates, we select the one with the lowest ROUGE-L score as the final accepted response. This approach ensures that the chosen answer is distinct, minimally redundant, and still relevant to the input.

For the retain set (R), we also use the Phi-4 model to generate candidate responses. Rejected samples are created by selecting responses that are lowest ROUGE-L scores to the original answer. These rejected samples are carefully curated to ensure they do not align with the desired output, thereby strengthening the model's ability to distinguish high-quality responses.

Due to the need for additional experiments, we introduce variations of the phrase *"I do not know"* as accepted responses in the forget set (F) and as rejected responses in the retain set (R). This helps train the model to recognize uncertainty and respond appropriately.

The SFT dataset is constructed separately from the DPO dataset and consists solely of high-quality accepted answers from both the forget set (F) and the retain set (R). These carefully selected responses are used to fine-tune the model in a supervised manner.

4.2 Evaluation Metrics

4.2.1 Primary Task Metrics

- *Forget Efficacy*: Measures the model's ability to forget specific information. It is computed as:

$$1 - \text{ROUGE-L}(\text{completions}) \quad (1)$$

and

$$1 - \text{EM}(\text{answers}) \quad (2)$$

where:

  - ROUGE-L: Measures the longest common subsequence overlap between generated and reference text.
  - EM (Exact Match): Computes the fraction of predictions that exactly match the reference answers.

- *Retention Quality*: Evaluates how well the model retains general knowledge and is given by:

$$\text{Original ROUGE-L/EM scores} \quad (3)$$

ensuring that forgetting one piece of knowledge does not degrade overall text generation quality.

- *Aggregation*: The final score is computed using the harmonic mean over 12 different scores, corresponding to:

$$3\,(\text{subtasks}) \times 2\,(\text{metrics: ROUGE-L, EM}) \times 2\,(\text{document sets}) \quad (4)$$

4.2.2 Privacy Guarantees

- *Membership Inference Attack (MIA) Score*: Measures resistance to privacy attacks by computing:

$$1 - 2 \times |\text{AUC}(\text{loss-based MIA}) - 0.5| \quad (5)$$

where:

  - AUC (Area Under the Curve): Measures the attack's ability to distinguish between memorized and non-memorized data.
  - Loss-based MIA: Uses model loss to infer whether a given sample was part of the training set.

Higher scores indicate stronger privacy protection.

4.2.3 Utility Preservation

- *MMLU Benchmark Accuracy Threshold*: Ensures the model maintains general capabilities by requiring:

$$\text{Acc}_{\text{MMLU}} \geq 0.371 \quad (6)$$

where:

  - Acc_{MMLU}: Model accuracy on the Massive Multitask Language Understanding (MMLU) benchmark.
  - The threshold (0.371) represents 75% of the baseline accuracy of a 7B parameter model.

The evaluation spans 57 subjects, primarily in STEM fields.

4.2.4 Final Scoring

Submissions are ranked using the final score formula:

$$\text{Final Score} = \frac{1}{3}(\text{Task Score} + \text{MIA Score} + \text{MMLU Score}) \quad (7)$$

where each component represents a weighted contribution to the overall evaluation.

4.3 Configuration

Our model is trained using the AdamW optimizer with a learning rate of 5×10^{-5} for 3 epochs and a batch size of 1. We employ a linear decay scheduler with warm-up to adjust the learning rate dynamically. To address task scheduling constraints, we enforce a strict 1-hour training limit, utilizing a single A100 GPU. Additionally, we apply a weight decay of 0.1 and freeze the first 4 layers of the model to improve generalization. We also set the β preference parameter to 0.5 to regulate preference optimization. This configuration effectively balances performance and computational efficiency.

5 Results

The results show that these methods had little effect on the model's performance since key performance measures barely changed after using them. This means that while DPO and SFT may help in some parts of the unlearning process, they are not enough on their own to make the model forget significantly. The results are presented in Table 1. Our team has achieved 11th place out of 26 teams in the competition.

Additionally, our analysis suggests that the model still remembers much of its previous knowledge, even after the unlearning process. These findings highlight the need for additional and diverse approaches to enhance the effectiveness of unlearning. Future studies should look into other techniques or a combination of methods to improve the unlearning process.

6 Conclusion

In this study, we applied Direct Preference Optimization (DPO) and Supervised Fine-Tuning (SFT) methods to achieve unlearning in the target model. Our results show that these methods had only a limited effect on the model's performance, indicating that they are not sufficient by themselves for effective unlearning. This highlights the challenges involved in making a model truly forget specific information. To improve the unlearning process, it is important to explore additional strategies and combine different methods. Future work should focus on developing new techniques and investigating how multiple approaches can work together to achieve better unlearning outcomes.

Abstract

This paper presents a system for SemEval 2025 Task 2 on entity-aware machine translation, integrating GPT-4o with Wikidata-based translations, retrieval augmented generation (RAG), and function calling. Implemented in RAGthoven, a lightweight yet powerful toolkit, our approach enriches source sentences with real-time external knowledge to address challenging or culturally specific named entities. Experiments on English-to-ten target languages show notable gains in translation quality, illustrating how LLM-based translation pipelines can leverage knowledge sources with minimal overhead. Its simplicity makes it a strong baseline for future research in entity-focused machine translation.

Lang	Sentence
EN	I watched the movie "*The Shawshank Redemption*" last night.
FR	J'ai regardé le film "*Les Évadés*" hier soir.
EN	I bought a new book called "*The Catcher in the Rye*".
IT	Ho comprato un nuovo libro chiamato "*Il Giovane Holden*".

Table 1: EA-MT Task Examples. Note that in both cases the entities (emphasized in *italic*) are completely different in the source (English) and target (French and Italian) languages.

1 Introduction and Background

The aim of the EA-MT task, also referred to as SemEval 2025 – Task 2 (Conia et al., 2025), is to develop systems capable of accurately translating English sentences containing challenging named entities into one of the target languages: Arabic, German, Spanish, French, Italian, Japanese, Korean, Thai, Turkish, or Chinese. Named entities, which often denote proper names—such as those of people, organizations, landmarks, locations, events, or even titles of books, movies, TV series, and products—pose significant translation challenges that require deep domain and cultural expertise. Examples of input sentences a system solving this task might receive, as well as the desired French and Italian translations, are provided in Table 1.

Our methodology is designed to replicate the practical challenges encountered by data scientists, including the constraints under which solutions are typically developed. To this end, we intentionally limit our approach to in-context learning without fine-tuning, while augmenting the standard Retrieval Augmented Generation (RAG) pipeline with additional tools, taking inspiration from prior work (Conia et al., 2024). Moreover, our approach leverages off-the-shelf tools such as RAGthoven (discussed in Section 2) and integrates multiple publicly available data sources (e.g., Wikipedia and Wikidata, as detailed in Section 2.3.1), systematically evaluating various combinations of these data sources and configuration options.

Our empirical results outlined in Section 3 demonstrate that, even under these constraints, a well-optimized RAG system can serve as a robust baseline, achieving state-of-the-art performance in certain contexts. To aid future development in this area, we release all our code and configuration under the terms of an opensource license[1].

2 System Overview

2.1 The RAGthoven Toolkit

The system used by our team in this task is based on RAGthoven (Karetka et al., 2025), a configurable toolkit for RAG-based experiments. To reflect the experiments executed in this shared task, the toolkit was substantially enhanced to incorporate parallel

[1] https://github.com/ragthoven-dev/semeval-2025-task-2

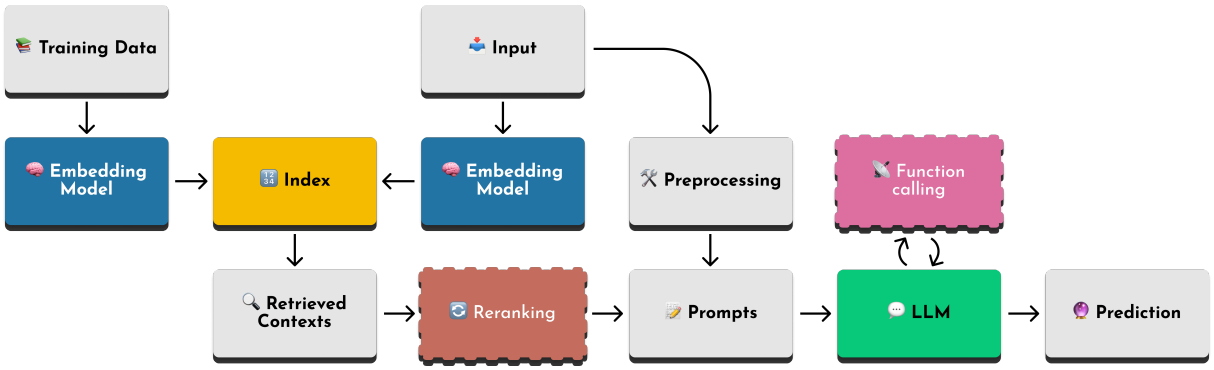

Figure 1: A diagram depicting the respective components of RAGthoven. The Index, Reranking, Preprocessing, and Function calling steps are optional.

execution of jobs, a *Preprocessor* (described in Section 2.1.2), and the ability of LLMs to use various tools via *Function Calling* (Section 2.1.3).

In line with our self-imposed constraints, all of our experiments make use of the GPT-4o model (OpenAI et al., 2024) accessed via the Azure OpenAI Service[2] using API version `2024-10-21` with the `temperature` parameter being set to 0 to aid reproducibility. We use the term Large Language Model (LLM) to refer to this model throughout the paper.

2.1.1 Understanding RAGthoven

RAGthoven is a configurable toolkit that enables researchers to quickly establish a baseline for an NLP task using (almost) any LLM. The tool provides simple functionality for fast development with easy setup (such as zero-shot evaluation) while being extensible with more sophisticated tools such as Retrieval Augmented Generation (RAG), preprocessing of the input datasets, and function calling for the LLMs that support it. The minimal setup for a RAGthoven experiment is defined in a single `yaml` configuration file, specifying dataset, prompt, and LLM hyper-parameters. The preprocessing and function calling allow custom Python code to be executed. An overview of RAGthoven and its components can be seen in Figure 1.

2.1.2 Data Preprocessor Module

In the RAGthoven context, the preprocessor module enables a custom Python code to take the original data and transform them in any way desired. Multiple preprocessing functions can be executed sequentially together. As part of the shared task, we implemented a *Wikidata preprocessor*, a sample abbreviated implementation of which can be seen in Figure 4, and its specification in the RAGthoven configuration in Figure 7. This particular preprocessor takes a whole data point (Wikidata Id of an entity, source language, target language, text) and returns a new data point, enriched with a new entry which contains the translation of the named entity in the source and target languages. These entity entries can be later used in some of the prompts passed to the LLM.

2.1.3 Enabling Function Calling in LLMs

Certain LLM API providers enable models to interact with a variety of external tools, such as APIs for retrieving real-time data or executing custom functions. This capability allows the LLM to autonomously determine when to invoke these functions and which arguments to pass.

RAGthoven's function calling module leverages this feature by equipping the LLM with user-defined tools, which are specified in its `yaml` configuration file. In this context, a tool is any arbitrary piece of Python code. When the LLM decides to execute one of these functions, RAGthoven runs the code and seamlessly integrates its output into subsequent LLM API requests.

2.2 Baseline Configuration

As a baseline, we utilized an LLM, which was instructed by the prompts to perform machine translation from the source to the target language. The model was instructed to use the target language and to translate the named entities as a *native speaker*. An example of such configuration can be seen in Figure 2.

2.3 Key System Components

2.3.1 Integrating the Wikidata API

The Shared Task sentences featured obscure named entities that were likely underrepresented in the datasets used to pre-train and post-train our LLM—a fact underscored by the model's low M-ETA score in translating these entities. Our preliminary analysis revealed that many of these entities are available in public knowledge bases such as Wikidata. Consequently, we leveraged the Wikidata API to retrieve target language translations for these named entities, incorporating the results into the LLM prompt to enhance the overall translation of the remaining sentence.

Since the input data already included Wikidata entity IDs, we explored two experimental configurations:

Query Using Gold Data Each test data point comes with gold-standard annotations, including the Wikidata ID for the named entity. By employing the RAGthoven Preprocessor (see Section 2.1.2), we queried the Wikidata API with the provided Wikidata ID to fetch the corresponding translation in the target language.

Query Without Using Gold Data Building on the previous approach, we developed a method to eliminate the reliance on gold data (i.e., the Wikidata ID). Utilizing RAGthoven's Function Calling feature (introduced in Section 2.1.3), we prompted the LLM to first identify the named entity in the test sentence. The LLM then passed the entity name as an argument to a function that queried the Wikidata API for matching entities. For simplicity, we assumed that the first entity returned was the best match (though this selection method could be refined in future iterations). With the Wikidata ID obtained, we proceeded to retrieve the named entity's translation in the target language in the same manner as described above.

2.3.2 Retrieval Augmented Generation (RAG)

Some of our machine translation system variants leveraged Retrieval Augmented Generation (RAG) to enhance performance by incorporating relevant example translations of similar sentences (from English to the target language) directly into the prompt provided to the LLM.

In this approach, a small number of examples (typically three) is selected via a RAG pipeline. The process begins with an initial set of training examples, which are embedded using the `all-MiniLM-L6-v2` SentenceTransformer model and stored in a vector database. The cosine similarity between source language sentences is used to retrieve the most appropriate examples. To ensure the highest quality examples are included, we initially retrieve the top 10 responses from the vector database and subsequently re-rank them using the `ms-marco-MiniLM-L-12-v2` model, resulting in the final selection for the prompt, a full example of which can be found in Figure 3.

For each target language, the initial set of training examples is derived from the provided train set—or, when unavailable, the validation set—of the Shared Task. For Arabic, German, Spanish, French, Italian, and Japanese, we utilized the available training sets. For the remaining languages (Chinese, Korean, Thai, and Turkish), the validation set examples were employed.

2.3.3 Addressing Chinese Translation Challenges

In our experiments, the language model consistently produced Simplified Chinese when asked to translate into "Chinese," likely reflecting inherent biases in its training data. Upon further examination of the validation dataset, we observed that the expected output was Traditional Chinese. By

explicitly instructing the model to generate Traditional Chinese, we achieved improved results. This strategy was uniformly applied across all experiments and may have contributed to our submissions ranking first and third in the Chinese (`zh_TW`) category during the final evaluation.

2.4 End-to-End System Variants

2.4.1 Gold Data System: Best Performing Configuration

Our best performing system utilizing gold data (Wikidata Id) employed querying the Wikidata API with the Wikidata Id, as well as RAG as described in Section 2.3.1 and Section 2.3.2 respectively. The resulting approach utilizes the most similar translation pairs from the training dataset as examples. It provides the model with the named entity translations fetched from the Wikidata API, and instructions on using them in the target translation. This approach scored fourth in the overall score and first in Chinese. This system variant is referenced as `GPT-4o + Wikidata + RAG` in Table 2 and Table 3.

2.4.2 Non-Gold Data System: Best Performing Configuration

Our best-performing system, which operates entirely without gold data, leverages a multi-stage process that combines Wikidata API queries with Retrieval-Augmented Generation (RAG) (see Section 2.3.1 and Section 2.3.2). The novelty of our approach lies in its sequential workflow:

1. **Entity Extraction:** The LLM first extracts the named entity from the source sentence.
2. **Entity Identification:** Using the extracted name, we query the Wikidata API to search for matching entities. We assume that the first result represents the best match, thereby providing the Wikidata ID for the entity without relying on gold data.
3. **Translation Retrieval:** With the obtained Wikidata ID, we make a second API call to fetch the target language translation of the named entity.
4. **Sentence Translation:** Finally, we prompt the LLM to translate the source sentence, incorporating the translated named entity from the previous step.

This experiment not only integrates RAG, as previously described, but also utilizes RAGthoven's function calling capabilities. By providing the LLM with available tools, it can autonomously request function executions using parameters of its choice—specifically, the entity name extracted from the source sentence and the target language. An example configuration is presented in Figure 5, with the corresponding Python implementation detailed in Figure 6.

This approach was not submitted to the final leaderboard, but it would have scored first among the systems that did not use gold labels. It is referenced as `GPT-4o + Thinking (w/ NER + API call) + RAG` in Table 2 and Table 4.

2.5 Ablation Studies

2.5.1 Zero-Shot with Gold Data (Wikidata Ids)

This approach (referenced as `GPT-4o + Wikidata` in Table 2 and Table 3) builds on the zero-shot approach by utilizing a single prompt enriched by a named entity translation sourced from the Wikidata API. The named entity is looked up by the provided `wikidata_id`, and the corresponding source-language <-> target-language translation pair is provided in the prompt for the model alongside the instructions to use the correct name for the entity in the final translation. If Wikidata does not contain a translation for the searched `wikidata_id` the model is informed in the prompt.

2.5.2 RAG with Named Entity Parametric Knowledge Elicitation

The main idea behind this approach (referenced as `GPT-4o + Thinking (param. knowledge) + RAG` in Table 2 and Table 4) is to split the translation process into several simple steps. This way, the model is given the space to *reason* about the input, which is hypothesized to help it perform better than just a single zero-shot approach. The translation process is split into three steps: *Find & Summarize*, where the model is instructed to find named entities in the text and to provide the summary of everything it knows about them; *Entity translation*, where the model is tasked to translate the named entities to the target language; and *Translate*, where the model is tasked to translate the source sentence by utilizing all the information it gained in previous steps.

2.5.3 Zero-Shot with Wikidata Aliases

Wikidata provides alternative names for entities, known as aliases, which appear in the "Also known

Systems	Rank	AR	DE	ES	FR	IT	JA	KO	TH	TR	ZH	Avg

Table 2: Overall results and ranking of submitted and non-submitted (denoted with * in the Rank column) systems across Arabic (AR), German (DE), Spanish (ES), French (FR), Italian (IT), Japanese (JA), Korean (KO), Thai (TH), Turkish (TR), and Chinese (ZH). The provided score is the combined score of M-ETA and COMET, the official aggregated metric used by the Shared Task. The performing system for a specific language or on average (Avg) is bolded.

as" section on each item's page. In this experiment, we used the Wikidata Id (considered gold standard) to query the Wikidata API, retrieving both the target-language name of the entity and its associated aliases. We then incorporated these identifiers into our prompt, instructing the language model to translate the sentence and select the most appropriate identifier from the list—one that closely mirrors the entity's mention in the source text. This approach is referenced as `GPT-4o + Wikidata + Wikidata aliases` in Table 2 and Table 3.

3 Results and Analysis

Our main results are summarized in Table 2, which details the combined M-ETA and COMET scores for each language, the average score across all systems, and the final ranking of our system.

First, our baseline—a zero-shot prompt described in Section 2.2—achieved a modest score of 54.72, largely due to its low performance on Thai (34.74) and Chinese (16.85). Incorporating a single example resulted in notable improvements, with absolute increases of over 8 points in Thai (42.82) and nearly 40 points in Chinese (56.67). To further examine the impact of the number of examples retrieved via the RAG pipeline, we experimented with different values of the `k` variable. While increasing the number of examples generally improved the average performance, the gain from one (`k = 1`) to ten (`k = 10`) was relatively minor (from 59.72 to 60.90) but took significantly longer to evaluate. Consequently, we used three examples in the prompts of subsequent experiments. Additionally, we evaluated a configuration without reranking (`k = 3, no reranking`), which showed a slight regression of 0.05 absolute points; thus, re-ranking was retained in all further experiments involving the RAG pipeline.

Our findings indicate that incorporating Wikidata IDs leads to a significant performance boost—improving absolute scores by at least 20 points. This suggests that leveraging this external data source effectively addresses the challenge. Furthermore, the fact that the top 10 models on the final leaderboard[3] all utilized the gold data reinforces this conclusion. Notably, although our model ranked second among the non-finetuned approaches, the performance gap was minimal (91.72 vs. 91.62). In contrast, experiments that combined Wikidata with Wikipedia data and employed Wikidata aliases resulted in inferior performance, as detailed in Table 3.

To isolate the impact of gold data, we conducted additional experiments without its use. As evidenced in Table 2 and Table 4, our multi-step prompting strategy described in Section 2.4.2—where the LLM first identifies the entity to be translated, then retrieves its translation via a function call, and finally incorporates that translation into the final prompt—delivered the best results. This configuration would have ranked first among the systems that did not use gold labels in the final leaderboard (with overall score of 86.82), suggesting that it might be a potent alternative when entity data is not available.

Table 4: Ranking of systems which **do not** use gold labels. The ranking takes into consideration only systems that did not use gold labels during evaluation. The number of examples in RAG is three unless stated otherwise.

Table 5: Overall score ranking of submitted and non-submitted (*) systems using gold labels and those that **do not** use gold labels. The provided score is a combined score of M-ETA and COMET, the official aggregated metric used by the Shared Task.

4 Conclusion

In this work we introduce a family of modular, LLM-centric translation pipelines that combine GPT-4o with Wikidata-driven entity linkage, automatic function calling, and retrieval-augmented generation to tackle the Entity-Aware Machine Translation task. Controlled experiments with and without gold entity identifiers show that symbolic priors can be exploited to close the entity gap: the gold-aware configuration reaches an average M-ETA + COMET score of 91.62, ranking **4th** overall, **2nd** among non-finetuned approaches and best overall for Chinese, while the non-gold variant attains **1st** place among all submissions that forgo labeled data. Achieved without task-specific fine-tuning, these results suggest that lightweight retrieval–reasoning hybrids may serve as strong baselines for future research in multilingual, entity-aware machine translation and motivate their adoption as reference systems in forthcoming studies and shared tasks.

Limitations

In our work we make use of an LLM which is only available via an API, and despite our best efforts to make our results reproducible, it might be difficult to do so, as they depend on a third party we do not have control over.

A Appendix

Prompt Example

System prompt: You are the best translator. You are given sentences and are expected to translated them on native spearker level. These are some example translations:

Original sentence: Who is the president of North Macedonia?
Translation: Chi è il presidente della Macedonia del Nord?

Original sentence: What is a very famous temple in Greece in honor of the Greek Goddess of wisdom?
Translation: Qual è un templio greco molto famoso costruito in onore della dea greca della saggezza?

Original sentence: What is the population of the country where the Acropolis is located?
Translation: Qual è la popolazione del Paese dove si trova l'Acropoli?

User prompt: Please translate this sentence from en to it. The entity in the original sentence Šarena Mosque is called as Moschea Šarena in the target language.

The sentence to translate: What is the significance of Šarena Mosque in Tetovo, North Macedonia?

Model response: Qual è il significato della Moschea Šarena a Tetovo, Macedonia del Nord?

Figure 3: An example of a prompt generated by the RAGthoven system with preprocessing configuration, the first part of which is then provided to the LLM for inference. The model response can be seen in the second part, underneath the horizontal line.

```python
def get_entity_in_language(args: dict[str, any]):
    # Create WikibaseIntegrator instance
    wbi = WikibaseIntegrator()

    # Extract identifiers and locales
    entity_id = args["wikidata_id"]
    target_loc = args["target_locale"]
    source_loc = args["source_locale"]

    # Retrieve entity from wikibase
    entity = wbi.item.get(entity_id=entity_id)

    # Get label for target locale
    tgt_label = entity.labels.get(target_loc)

    # Get label for source locale
    src_label = entity.labels.get(source_loc)

    # Save results in args dictionary
    args["tgt_l_entity_name"] = (
        str(tgt_label.value) if tgt_label
        else 'Not found in data!'
    )
    args["src_l_entity_name"] = (
        str(src_label.value) if src_label
        else 'Not found in data!'
    )

    return args
```

Figure 4: A sample RAGthoven preprocessing function implementation. Note that the input to the function (`args`) is the whole data row, and the returned value is the same data row modified by the function.

fact check AI at SemEval-2025 Task 7: Multilingual and Crosslingual Fact-checked Claim Retrieval

Pranshu Rastogi
Independent Researcher
rastogipranshu29@gmail.com

Abstract

SemEval-2025 Task 7: Multilingual and Crosslingual Fact-Checked Claim Retrieval is approached as a Learning-to-Rank task using a bi-encoder model fine-tuned from a pre-trained transformer optimized for sentence similarity. Training used both the source languages and their English translations for multilingual retrieval and only English translations for cross-lingual retrieval. Using lightweight models with fewer than 500M parameters and training on Kaggle T4 GPUs, the method achieved **92% Success@10** in multilingual and **80%** Success@10 in **5th** in **crosslingual** and **10th** in **multilingual** tracks.
Github-SemEval-2025-ACL-Multi-and-Crosslingual-Retrieval-using-Bi-encoders

1 Introduction

The rapid spread and multilingual nature of online disinformation pose a significant challenge to traditional fact-checking workflows. *SemEval-2025 Task 7: Multilingual and Crosslingual Fact-Checked Claim Retrieval* (Peng et al., 2025) addresses this issue by aiming to automate the retrieval of previously verified claims across languages. The corpus for this task consists of fact-checked claims and social media posts in eight languages: French, Spanish, English, Portuguese, Thai, German, Malay, and Arabic. To further evaluate the generalization of the model, the evaluation step introduced two new unseen languages, Pol and Tur, underlining the demand for strong multilingual and cross-lingual retrieval approaches. Our approach tries to tackle these challenges by improving performance both in multilingual and crosslingual scenarios. We utilize lightweight, scalable transformer models that can be trained efficiently even on modest hardware. Our approach produces rich semantic representations and utilizes methods such as layer freezing and gradient checkpointing to tune the trade-off between efficiency and effectiveness. The outcome is a practical, adaptable tool for global misinformation detection that addresses both retrieval accuracy and computational scalability. We trained independent models for each language and utilized English translations of the source language inputs to boost the retrieval. For cross-lingual tasks, we predominantly used English translations to achieve consistency. In multilingual environments, we retrieved the top 10 fact verify claims from several models and ranked them according to their scores. For crosslanguage retrievals, we repeated the same process using outputs from a five-fold ensemble. This allowed us to combine diversity, accuracy, and speed very well. Our approach finally ended up being 5th in crosslanguage retrieval and 10th in multilingual retrieval. All models were less than 500M parameters, and training was done using only two Kaggle T4 GPUs showing that high performance is attainable even with constrained computational resources.

2 Background

The SemEval-2025 Task 7 is all about creating systems that can find reliable fact-checked claims for social media posts. This helps fact-checkers who deal with different languages. It's tough to look for fact-checks in many languages by hand. So, we need to automate this to save time and effort.

There are two main parts to the task:

Multilingual Retrieval: Here, both the social media post and the fact-check are in the same language.

Crosslingual Retrieval: In this case, the post and the fact-check are in different languages. This needs strong techniques for matching across languages.

2.1 Input and Output Format

The input includes social media posts and fact-checks. Each has text, metadata, and English translations. The system gives a ranked list of up to 10 fact-checks for each post.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2352–2357

Example Output: `{ "Post-12345": [987, 654, 321, 789, 456, 222, 111, 333, 555, 777] }`
This means that Post-12345 is best matched with Fact-check IDs 987, 654, etc., sorted by relevance.

2.2 Dataset Details

The training dataset includes Fact-checks and Posts in 8 languages: Arabic (ara), German (deu), English (eng), French (fra), Malay (msa), Portuguese (por), Spanish (spa), Thai (tha) However, in the final test set, two surprise languages—**Tur (tur) and Pol (pol)**—were introduced, making the task more challenging as models needed to generalize to unseen languages without direct training data. As shown in Table 1

2.3 Dataset Files

The dataset has three key files: (Pikuliak et al., 2023)
1. **Fact-checks.csv** - This file has fact-check claims, titles, and URLs. It's available in both the original language and in English.
2. **Posts.csv** - Here, you'll find social media posts. It includes text from those posts, fact-checks taken from images, Meta's verdicts like False Information, and their English translations.
3. **Fact-check-Post-mapping.csv** - This file connects social media posts to their fact-checks. It also shows the language pairs, like spa-eng, which means a Spanish post was fact-checked in English.

2.4 Evaluation Metrics

To assess system performance, we use: **Success@10 (S@10)** – Measures whether at least one correct Fact-check appears in the top 10 retrieved results.

3 System Overview

Our system uses a Bi-encoder setup (Reimers and Gurevych, 2019). This helps match Posts and Fact-checks quickly. We also use smart pooling methods to improve pre-trained Sentence similarity models. The model has a few important parts:

3.1 Bi-Encoder Retrieval Model

We use a Bi-encoder design. This means we have a **Post Encoder** and a **Fact-check Encoder**. They take inputs and turn them into dense vector representations. We use a pretrained transformer backbone for this. In each batch, we have posts and fact-checked claims. We then find the similarity between their embeddings with a simple math function. For training, we apply MNR Loss (Henderson et al., 2017) and Vanilla Cross-Entropy Loss.

3.2 Pretrained Transformer Encoder

The encoders are initialized with publicly available transformer weights. Given an input sequence $X = (x_1, x_2, ..., x_n)$, the model outputs contextualized token embeddings:

$$H = \mathcal{M}(X) \in R^{n \times d} \tag{1}$$

where H represents the hidden states, n is the sequence length, and d is the hidden dimension.

3.3 Pooling Mechanisms

To obtain a fixed-size sentence representation, we explore multiple pooling strategies:

Mean Pooling: Computes the mean of token embeddings weighted by attention masks:

$$\text{MeanPooling}(H, A) = \frac{\sum_{i=1}^{n} H_i \cdot A_i}{\sum_{i=1}^{n} A_i + \epsilon} \tag{2}$$

Attention Pooling with BiLSTM: A bidirectional LSTM (Hochreiter and Schmidhuber, 1997) enhances contextual aggregation:

$$L = \text{BiLSTM}(H) \in R^{n \times 2h} \tag{3}$$

An attention mechanism assigns dynamic weights to tokens:

$$\alpha = \text{softmax}(W_a L), \quad S = \sum_{i=1}^{n} \alpha_i L_i \tag{4}$$

where W_a is a learnable dense layer.

3.4 Similarity Function

Relevance between a Post embedding q and a Fact-check embedding c is computed using **temperature-scaled cosine similarity**:

$$S(q, c) = \frac{\cos(q, c)}{T} \tag{5}$$

where T is a temperature parameter kept at 0.05.

3.5 Contrastive Learning with MNR Loss (Henderson et al., 2017) and Cross Entropy Loss

To optimize retrieval, we employ a **MNR Loss** (Henderson et al., 2017) function that maximizes similarity for positive pairs:

Table 1: Number of Post and Fact-check IDs in Train and Test Sets for Each Language

Multi-Lingual	Train		Test	
	Post IDs	Fact-check IDs	Post IDs	Fact-check IDs
Arabic (ara)	14,201	676	500	21,153
German (deu)	4,996	667	500	7,485
English (eng)	85,734	4,351	500	145,287
French (fra)	4,355	1,596	500	6,316
Malay (msa)	8,424	1,062	93	686
Portuguese (por)	21,569	2,571	500	32,598
Spanish (spa)	14,082	5,628	500	25,440
Thai (tha)	382	465	183	583
Pol (pol)	-	-	500	8,796
Tur (tur)	-	-	500	12,536
Cross-Lingual	153,743	4,972	8,276	272,256

$$\mathcal{L} = -\sum_{i} \log \frac{\exp(S_{ii})}{\sum_j \exp(S_{ij})} \tag{6}$$

To improve efficiency, we use a symmetric formulation:

$$\mathcal{L} = \frac{1}{2}\left(\text{CrossEntropy}(S, y) + \text{CrossEntropy}(S^T, y)\right) \tag{7}$$

3.6 End-to-End Flow

Posts and Fact-checked claims are processed through separate encoders that shares weights. Get embeddings using LSTM (Hochreiter and Schmidhuber, 1997) or by Mean Pooling. Similarities are computed via temperature-scaled cosine similarity, The model is optimized using Loss functions defiend above to rank relevant claims higher.

In this architecture defined above I have initialised Encoder models with these Pre-trained Models

1. The NovaSearch/stella-en-400M-v5 model (Zhang et al., 2025), This model is ranked 41st on the MTEB leaderboard, has 435M parameters and balances scalability with retrieval accuracy.

2. The intfloat/multilingual-e5-large-instruct model (Wang et al., 2024), with 24 layers and 1024 embedding size, ranks 22nd on the MTEB leaderboard with 560M parameters. Built on xlm-roberta-large (Conneau et al., 2020), it supports 100 languages. This model was the primary choice for direct training on source languages.

3. The mixedbread-ai/mxbai-embed-large-v1 model (Lee et al., 2024) is a state-of-the-art English embedding model that balances efficiency and performance with 335M parameters, currently ranking 49th on the MTEB leaderboard.

All the models we selected have fewer than 500M parameters, making them suitable for training on free online GPUs. This allows for extended training, which helps produce richer deep text representations. Our training architecture is designed to balance computational efficiency and retrieval accuracy. We achieve this by using lightweight transformer models with techniques like gradient checkpointing and selective layer freezing, ensuring scalability without compromising performance.

During evaluation, we generate embeddings for both social media posts and fact-checked claims. To retrieve matches, we employ semantic search, which compares the embeddings to identify the most similar pairs. Our system uses an optimized retrieval pipeline that indexes the data efficiently, enabling fast similarity matching. We then select the top 10 most relevant claims for each query post.

We also experimented with other models like `jina-embeddings-v3` and `KaLM-embedding-multilingual-mini-v1`, which are currently ranked 20th and 19th on the MTEB leaderboard. While both models performed reasonably well with average scores of 58.37 (Jina) and 57.05 (KaLM)—they fell short of the performance achieved by **multilingual-e5-large-instruct**, which scored 63.23 on average. These comparisons informed our decision to prioritize higher-performing models for downstream tasks.

Before training and evaluation, we applied pre-

processing steps to improve data quality. This included filtering out short or symbol-heavy text, removing URLs, emojis, and excessive whitespace, and standardizing punctuation. For OCR-extracted data, we excluded noisy text segments. Twitter-specific cleaning involved replacing image references and shortened URLs with placeholders to maintain consistency across samples.

4 Experimental Setup

4.1 Multi-Lingual Training

For Multilingual bi-encoder (Reimers and Gurevych, 2019) training, the full dataset was utilized for each language, benefiting low-resource languages like German, French, Malay, and Thai Table 1. Without synthetic or external data, multiple training epochs allowed the model to capture both semantic and syntactic patterns more effectively.

4.1.1 Evaluation Measures

The model is trained with contrastive loss(MNR loss (Henderson et al., 2017) and cross-entropy over similarity scores) to optimise retrieval performance. At training time, similarity scores between posts and fact-checked embeddings are calculated, which ensures correct matches rank higher. The performance of the model is measured on Success@10 metrics

4.1.2 Training Strategy

For training, we used the Full dataset for all source languages. We did multiple epochs of training to improve learning. When training with English translations, we picked a random **30%** sample of negative cases for testing. We used a random seed of **42**.

4.1.3 Backbone Model

`multilingual-e5-large-instruct` (Wang et al., 2024) and `stella-en-400M-v5` (Zhang et al., 2025) is fine-tuned with gradient checkpointing disabled

4.1.4 Pooling Mechanisms

- **Mean Pooling**: Mean of hidden states unless "cls" token-based pooling is specified.
- **Attention Pooling**: Uses a bidirectional LSTM followed by an attention mechanism to weight token embeddings dynamically.

4.1.5 Optimizer

AdamW optimizer is configured with Learning Rate: 5×10^{-6} for transformer, 1×10^{-4} for custom layers. Weight Decay: 0.005. Gradient Clipping: Clip Value = 1.0

4.2 Cross-Lingual Training

For cross-lingual training, we re-used the same bi-encoder models but trained them on English-translated text by default. Rather than training on the entire dataset, we split the training data into 5 folds. This enabled us to train several models on varying data distributions, which promoted robustness. The text diversity mitigated overfitting and improved generalization, especially in low-resource language situations.

4.2.1 Training Strategy

We used English-translated training data to enhance training data and limit overfitting. This method also improved performance in low-resource environments. Instead of synthetic data, we observed that ensembling English-trained models was a more efficient method for cross-lingual generalisation. This process was further amplified using 5-fold ensembling, which showed consistent improvement in retrieval performance. As indicated by Table 2, ensembling resulted in significant improvements in all models. For instance, **multilingual-e5-large-instruct** went from **0.7685** to **0.7975** in cross-lingual retrieval, and from **0.9091** to **0.9232** in multilingual retrieval.

4.2.2 Backbone Model

`multilingual-e5-large-instruct` (Wang et al., 2024) and `stella-en-400M-v5` (Zhang et al., 2025) and `mxbai-embed-large-v1` (Lee et al., 2024) were fine-tuned with gradient checkpointing disabled.

4.2.3 Pooling Mechanisms

The Pooling Mechanisms was similar to that in Multi-Lingual retraining

Optimizer configuration was similar to that in Multilingual settings

5 Results

Multi-Lingual Rank 10th (S@10 avg = 0.9232)

Performances

Insights on `fact check AI` Rankings and Scores

Overall Performance:
Ranked **10th overall** with an average S@10 score of **0.923178**.While the model performs decently across languages, it falls behind top teams in consistency.

Strongest Languages:
Thai (S@10 = 0.994536, Rank = 4th) and French (S@10 = 0.944, Rank = 5th) are its best-performing languages. The model competes well in these languages, staying in the upper half of rankings.

Weakest Languages:
Pol (S@10 = 0.864, Rank = 10th) and Tur (S@10 = 0.884, Rank = 10th) have the lowest rankings.

English Performance (Rank = 7th):
Middle of the pack, meaning the model isn't optimized exclusively for English but is balanced across multiple languages.

Generalization Strength vs. Overfitting Risks: The model's strong performance in underrepresented languages like Thai and Malay suggests good generalization capabilities. In contrast, lower scores in languages such as English and Pol may point to potential domain overfitting or dataset imbalance. The wide performance range (S@10 from 0.864 to 0.9945) underscores the need for better multilingual adaptation, particularly for morphologically rich languages like Pol and Tur.

6 Cross-Lingual Performance Analysis of `fact check AI`

6.1 Comparison with Top Teams

Rank	Team Name	S@10 (avg)
1	PINGAN AI	0.85875
2	PALI	0.82675
3	Sherlock	0.8245
4	TIFIN India	0.81025
5	**fact check AI**	**0.7975**

Table 6: Cross-lingual ranking of `fact check AI` in comparison to other teams.

6.2 Overall Performance

Our Cross lingual model ranks **5th**, achieving an average S@10 score of **0.7975**. It performs competitively in the upper half but remains behind the top-performing teams.

6.3 Risks and Performance Insights

A key challenge is the potential for fact-check retrieval error, especially for low-resource or morphologically complex languages where semantic representations are less stable. The variation in performance across languages (S@10 from 0.864 to 0.9945) indicates probable training biases or domain overfitting. Examination showed solid performance where claims and posts had evident semantic overlap, even for under-represented languages like Thai and Malay. Performance dropped in morphologically dense languages like Pol and Tur, where inflectional complexity concealed semantic similarity. Cross-lingual retrieval was particularly prone to mistakes with regard to idiomatic expressions or culturally specific references, revealing the difficulty in modeling deeper semantic subtleties between languages. Also, incorrect fact-checks were sometimes strongly ranked because of surface similarities e.g., common named entities—despite factual variations. These issues identify the risk of false positives where language-specific context is not correctly addressed. To mitigate these threats, improved multilingual adaptation by means of methods like language-aware fine-tuning, balanced sampling, and dynamic ensembling can help close performance disparity. Performance Risks and Insights,

7 Acknowledgments

We would like to thank the SemEval-2025 Task 7 organizers for providing the cross-lingual and multilingual fact-check retrieval corpus and evaluation setup.We thank the anonymous reviewers very much for their thoughtful and constructive comments, which helped significantly in improving the quality of our manuscript. Relevant answers of your reviews can be found in the sections (Training Strategy) 4.2.1, (End-to-End Flow) 3.6 and (Risks and Performance Insights) 6.3 in our paper.

8 Conclusion

We evaluated how effectively different multilingual em-embedding models perform for Multi and cross-language retrieval. We established that their effectiveness differs with the language, especially in low-resource environments like Pol and Tur Table 2. Combining methods helped in improving retrieval performance, but variances still existed. Multilingual-e5-large-instruct worked best in single-language settings and cross-language situations. On the other hand, stella-en400M-v5 and mxbai-embed-large-v1 did not improve single-language performance. Going forward, we need to improve cross-language re-trievals more stable. We can achieve this by incorporating more data for less resource-full languages, tuning to specialized domains, and conbining various modeling strategies. This will enable real-world fact-check retrieval systems to become more robust.

AlphaPro at SemEval-2025 Task 8: A Code Generation Approach for Question-Answering over Tabular Data

Anshuman Aryan and Laukik Wadhwa and Kalki Eshwar D and Aakarsh Sinha and Durgesh Kumar
School of Computer Science and Engineering (SCOPE)
Vellore Institute Of Technology, Vellore, Tamil Nadu, India - 632014

Abstract

This work outlines the AlphaPro team's solution to SemEval-2025 Task 8: Question Answering on Tabular Data. The task evaluates the question-answering capabilities of LLMs over tabular data. The proposed system introduces a three-stage pipeline: question transformation, intermediate Python code generation, and code execution. Utilizing the deepseek-v3 model produces overall 77.43% accuracy on the task dataset, demonstrating the feasibility of code generation for tabular question answering. A comparative analysis of deepseek-v3 with five current state-of-the-art LLMs tested has been presented. The strengths of the system are outlined and directions for further research are provided. The code and generated results for each tested model have been made available in a public code repository [1] to promote reproducibility and research in this area.

1 Introduction

Large Language Models (LLMs) have demontrated impressive abilities to understand, reason and interact with structured tabular data (Sui et al., 2024; Wu et al., 2025). By integrating Natural Language (NL) processing with advanced reasoning, LLMs offer a powerful and flexible way to extract valuable insights from tabular datasets (Liu et al., 2023).

Tabular data are prevalent in various fields, from financial reports to scientific findings and statistical analyses. SemEval-2025 Task 8 (Osés Grijalba et al., 2025) focuses on the importance and challenge of developing systems capable of answering questions (QA) over tabular data. The ability to query tables using natural language, instead of specialized languages like SQL, significantly reduces the barrier to accessing and interpreting data.

Earlier research on tabular datasets used a translation-based system to translate from natural language to SQL using semantic parsing techniques (Zhong et al., 2017; Li and Jagadish, 2014) and deep learning-based techniques (Xu et al., 2017). These methods lack schema awareness of the table and suffer from the ambiguity of natural languages. Recent advancements, such as RAT-SQL (Wang et al., 2021) and NL2SQL (Liu et al., 2024), address schema integration but still encounter limitations related to semantic context representation and query diversity (Liu et al., 2024; Zhang et al., 2024). Traditional query languages such as SQL are limited in this regard, as they primarily understand only the structural aspects of tables but struggle to capture their underlying semantics (Zhang et al., 2024).

To address the above limitations, this work proposes a schema-infused LLM prompting approach leveraging few-shot learning and intermediate Python code generation effectively handling the semantics. Unlike traditional SQL-based methods, this approach capitalizes on schema-aware question paraphrasing and dynamically generated Python code, substantially improving semantic expressiveness and flexibility in handling NL queries. Figure 1 illustrates the three-stage pipeline of the proposed system to answer questions posed in natural language, employing schema-aware question paraphrasing and generating Python code as intermediaries. In the first stage, the answer type is predicted and the user's question is transformed into a schema-aware format, optimizing it for the subsequent stage. In the second stage, the model generates Python code utilizing the pandas framework [2]. The final stage involves extracting and executing this generated Python function, subsequently retrieving the results. Python was selected due to its powerful libraries for manipulating tabular datasets, such as pandas, and its minimalistic and dynamically typed nature, which facilitates

[2] pandas

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2358–2367

effective analysis of the generated code.

The key contributions of this work are summarized as follows:

- A novel three-stage LLM prompting framework leveraging few-shot learning is proposed for question answering over tabular data. This framework integrates schema-aware paraphrasing and intermediate Python code generation, explicitly utilizing table schema information such as column names and data types to enhance the reasoning capabilities of the system.
- A systematic comparison and detailed performance analysis are conducted across six state-of-the-art open-source LLMs, ranging from 7B to 671B parameters, evaluating their effectiveness across questions of varying complexity.
- A comprehensive error analysis is provided, highlighting significant challenges in code-based tabular reasoning, particularly in the processing of categorical data and special characters.
- An end-to-end implementation with outputs generated by all evaluated models has been publicly released, promoting reproducibility and supporting future research endeavours in tabular reasoning.

The proposed system using the DeepSeek-v3 model (DeepSeek-AI, 2024), evaluated on the DataBench dataset (Grijalba et al., 2024), outperforms five contemporary state-of-the-art open-source LLMs, achieving an average accuracy of 77.43%.

2 Related Work

Recent advances in question answering (QA) over structured data have spurred research into neural architectures, semantic parsing, and program generation for tabular reasoning.

2.1 QA over Structured Data

Early work on structured data QA often employed semantic parsers to translate natural language questions into SQL or other formal query languages (Zhong et al., 2017). These approaches typically relied on handcrafted grammar rules and domain-specific features.

With the advent of pretrained language models, neural techniques such as TAPAS (Herzig et al., 2020) and TaBERT (Yin et al., 2020) introduced joint encoders for table-question pairs, enabling end-to-end reasoning without intermediate formal representations. These models directly perform operations like cell selection and aggregation. More recently, RHGN (Yang et al., 2023) proposed a two-stage strategy involving row selection followed by row-level comprehension, further improving QA accuracy over tables.

Despite these advances, many existing models require full-table encoding and extensive task-specific finetuning, which can be computationally expensive and less adaptable across domains.

2.2 Executable Code Generation for QA

A complementary direction involves generating executable programs as intermediate representations for QA. This paradigm enables complex reasoning using the expressiveness of programming languages. Chen et al. (Chen et al., 2021) showed that pretrained LLMs can generate Python code to answer multi-step questions, providing interpretability and improved control.

Rajkumar et al. (Rajkumar et al., 2022) extended this idea by proposing a framework to query tables using Python and the Pandas framework. Their results demonstrated that Python-based generation can outperform SQL-based parsing for complex queries, especially those involving arithmetic, filtering, or nested logic.

Building on these insights, our work adopts a prompt-based approach that leverages LLMs to generate Python code for tabular QA without requiring model finetuning. We focus specifically on the SemEval-2025 Task 8 (Osés Grijalba et al., 2025), introducing a schema-aware prompting strategy that bridges structured inputs and executable reasoning via interpretable code generation.

3 System Overview

This work proposes a three-stage framework powered by Large Language Models (LLMs) to generate executable Python code to answer questions on tabular data sets. The overall architecture, depicted in Figure 1, comprises the following sequential components:

(a) **Question Transformation**: The input question is first transformed into a schema-aware representation. This step employs prompt

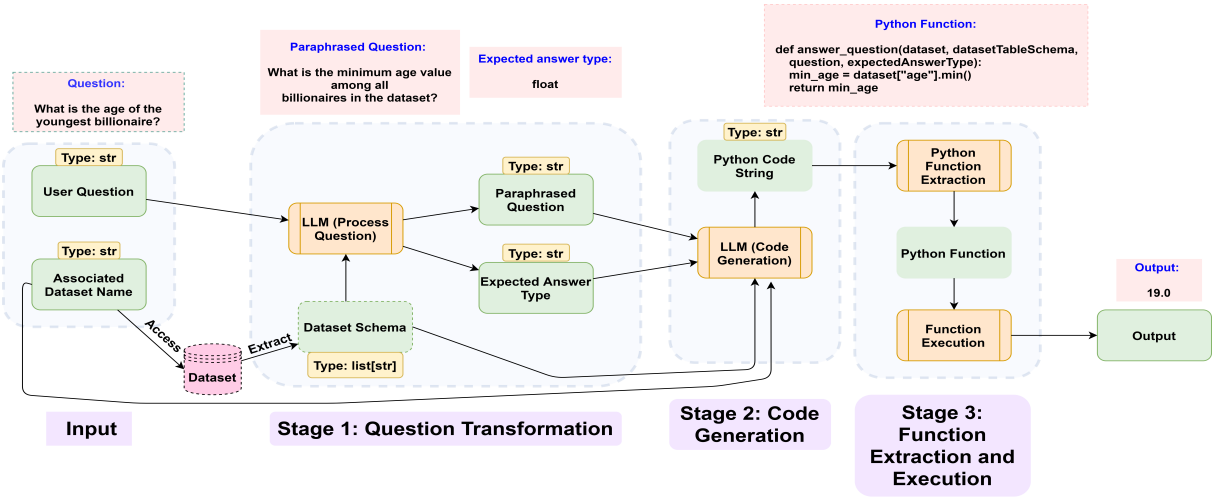

Figure 1: Architecture diagram for proposed system

engineering techniques that incorporate the structure of the dataset, including column names and data types. The LLM is guided to infer the expected answer type (e.g., scalar, list, boolean) and reformulate the question to enhance compatibility with code generation in subsequent stages.

(b) **Code Generation**: The reformulated question is passed to the LLM to generate Python code, typically using the Pandas library. The generated code is crafted to query the input table effectively and extract the relevant answer. This stage bridges natural language understanding with executable logic.

(c) **Execution and Result Formatting**: The generated code is executed on the tabular dataset, and the resulting output is post-processed to conform to the desired answer format. This may include standardizing numeric precision, formatting lists, or converting values into natural language responses, depending on task-specific requirements.

3.1 Question Transformation Prompt Design

This section elucidates the methodology through which the prompt template shown in Figure 3 of Appendix B was crafted. The objective is to paraphrase the natural language question into a form infused with keywords from the table schema, and which is in a format more suitable for code generation. The prompt consists of:

- **Precise instructions regarding the goal** The prompt defines two key tasks for the model: first, to predict the expected answer type of the question; and second, to paraphrase the question into a form that is more suitable for code generation while preserving its original semantic meaning.
- **Explicit marking of expected answer types** The set of possible data types for the answer (boolean, category, number, list[category], list[number]) is designated in the prompt.
- **Few-shot prompting** Two input-output examples are provided that demonstrate the dual task of predicting answer types and paraphrasing questions. This enables the LLM to infer the task structure and generalize to unseen queries within the same format.

3.2 Code Generation using Prompt Engineering

In the code generation step, the system approach employed another customized prompt that takes the paraphrased question and produces Python code that can be executed. The prompt consists of:

- **Information about the prompt structure** The prompt first informs that the model will be provided with four pieces of information - dataset name, schema, question, and expected answer type.
- **Information about main objective** The following requirements to generate the necessary Python code are mentioned in the prompt:
  (a) The name of the dataset and schema description (column names along with data types)

(b) The paraphrased question from the prior stage of question transformation

(c) The anticipated answer type (also from the prior stage)

- **Guidelines on output formatting** To obtain a more precise output, the expected answer type obtained from the output of stage 1 as shown in Figure 1 is mentioned.

- **Expected output function definition** The model is explicitly instructed to generate only the function definition, assuming the presence of the required code base and pandas library.

- Owing to some of the larger models, such as Llama and DeepSeek, there was a need for specific instructions to prevent additional Markdown and explanatory content in the output.

Following this, manually crafted few-shot examples have also been provided. An illustrative example of the prompt designs has been presented in Appendix B.

3.3 Execution and Function Extraction

In the last stage, the system runs the code produced with the table as input, providing all global and local scope variables to the execution. We used Python's built-in interpreter function `exec()`. The execution environment consists of essential libraries, such as the pandas library, for handling data, and the result is presented according to the requirements of the task. The result, or error, produced by running this code is then formatted suitably. This is expected to allow:

- Ensuring proper answer data type (boolean, category, number, or lists)

- Correct list formatting with proper brackets and separators

- Handling exceptions and errors in system output

4 Experimental Setup

This paper evaluates proposed framework using the dataset from SemEval-2025 Task 8 (Osés Grijalba et al., 2025), made available through the DataBench platform (Grijalba et al., 2024). The dataset includes both training and development splits, and spans diverse domains and table schemas. This diversity enables robust testing of the system's generalization ability across different question types and data formats.

LLMs Used: This paper evaluates six LLMs with sizes ranging from 7B to 671B parameters, which includes general LLMs and open-source models : gemma-3-12b-it (Team et al., 2025), llama-3.3-70b-instruct-turbo, qwen2.5-7b-instruct-1m (Yang et al., 2025), qwen2.5-coder-14b-q5, c4ai-command-r-plus-08-2024 (Cohere Labs, 2024), deepseek-v3 (DeepSeek-AI, 2024).

System Components: The experimental pipeline incorporates the following core components:

- **Prompt Engineering:** Carefully crafted prompt templates with few-shot examples are used for both question paraphrasing and code generation, ensuring schema-awareness and context preservation.

- **Answer Type Prediction:** The system identifies the expected answer type—boolean, category, number, list[category], or list[number]—to guide the formatting and structure of the generated output (Codabench, 2025).

- **Code Execution:** Python code generated by the LLM is executed using a controlled environment powered by `exec()`. Execution is sandboxed with scoped global and local variables, and includes exception handling mechanisms to ensure safe and consistent evaluation.

Inference Configuration: All model inferences were performed through the Together AI API, with models such as `gemma`, `deepseek`, and others accessed via its hosted endpoints. For API-based calls, the `stream` parameter was set to `False` to ensure consistent output handling. Code generation tasks were configured with a maximum token limit of 1000 and a temperature range between 0.5 and 0.7 to balance creativity and determinism.

Evaluation Protocol: The proposed model is evaluated using the **DataBench** *eval* function. Accuracy is measured as the ratio of correctly answered questions to the total number of questions in the development set. In addition, output formatting is evaluated to ensure alignment with the expected data type and structure. To assess robustness, this work analyses model performance across varying levels of question complexity.

5 Results and Observations

The comprehensive analysis conducted demonstrates the system's feasibility and robustness, as detailed below.

5.1 Dataset Overview

Table 1 summarizes the characteristics of the DataBench dataset (Grijalba et al., 2024), comprising 65 tables across domains such as Business, Health, Social, Sports, and Travel. Additionally, a condensed version, **DataBench Lite**, includes all tables with only the first 20 rows, facilitating rapid prototyping. The dataset's questions are categorized into five answer types: `boolean`, `category`, `number`, `list[category]`, and `list[number]`.

Domain	Datasets	Rows	Columns
Business	26	1,156,538	534
Health	7	98,032	123
Social	16	1,189,476	508

Table 1: Domains of Tables in Dataset (Grijalba et al., 2024)

5.2 Question Complexity Analysis

To assess the complexity of the question, we used spaCy[3], a Python NLP library, analysing syntactic and lexical features. This analysis enabled categorization of questions into complexity levels based on factors such as sentence length, syntactic depth, and lexical diversity. Figure 2 illustrates the distribution of questions across complexity levels and the corresponding performance of the `deepseek-v3` model, as contrasted to others. The complexity-wise distribution of the questions and the performance of deepseek-v3 for each are presented in Table 2.

5.3 Model Performance Across Complexity Levels

Figure 2 presents the accuracy of various models across different complexity levels of the question. All models exhibited a decline in performance with increasing complexity. In particular, `qwen2.5-7b-instruct-1m` consistently performed beyond complexity level 0. In contrast, `deepseek-v3` achieved the highest accuracy at all levels of complexity. This discussion is expanded in the Appendix A.

[3] https://spacy.io/

	Question		Accuracy
S.No	Complexity	Count	Accuracy (%)
1	0	2	100.00
2	1	194	83.51
3	2	292	81.85
4	3	275	73.45
5	4	174	70.11
6	5	51	74.51

Table 2: Systematic Performance Analysis of question complexity vs accuracy

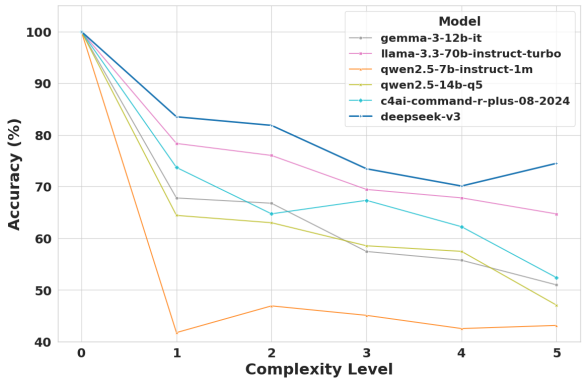

Figure 2: Complexity Wise Model Performance

5.4 Evaluation Using DataBench Eval Function

We utilized the `databench_eval` package (Grijalba et al., 2025) to compare generated answers with ground truth. This evaluation metric accommodates minor formatting discrepancies, such as item order in lists and numerical representations (e.g., integer vs. float), focusing on semantic correctness.

5.5 Error Analysis

A careful inspection of the generated code errors revealed several recurring issues. Table 3 summarizes the total number of errors produced by each model.

- **Special Character Handling:** Smaller models struggled to process inputs containing emojis or special characters (e.g., the euro symbol '€'), often resulting in incomplete or failed code execution.
- **Data Type Mismatches for Categorical Columns:** The most frequent error

across all models involved misinterpretation of categorical columns as string types. For example, in response to the question *"List the 2 most common host verification methods"*, the model incorrectly treated the column `host_verifications` (of type `list[category]`) as a string, leading to incorrect logic in the generated code.

- **Schema Ignorance and Improper Type Assumptions:** Despite having access to the column schema, models sometimes assumed incorrect data types and applied incompatible functions. For instance, for the question *"Are there any players who joined their current club before they were 18 years old?"*, the model misinterpreted columns `Joined<gx:date>` and `Age<gx:number>` as strings, resulting in erroneous function calls such as `str()` on numeric values.

- **Use of Deprecated Functions:** Some models generated outdated code involving deprecated functions or parameters, resulting in warnings or compatibility issues during execution. For example, when answering *"What are the bottom five number of replies?"*, the generated code included the deprecated Pandas parameter `observed=False`, triggering a `FutureWarning` due to changes in the default behavior of the library.

- **Correlation with Model Size:** We observed a negative correlation between model size and the number of errors. The smallest model, `qwen2.5-7b-instruct-1m`, generated 371 errors, whereas the largest model, `deepseek-v3` (671B parameters), produced only 44. This trend suggests that larger models better generalize schema understanding and generate more reliable code.

6 Conclusion and Future Work

This paper presents a three-stage LLM-based framework for SemEval-2025 Task 8: Question Answering over Tabular Data. The proposed three-stage framework comprises question transformation and answer type prediction, followed by code generation and code execution utilizing an LLM-based code prompting and a few-shot learning based approach to tabular reasoning. The system achieves an overall accuracy of 77.43% using the deepseek-v3 model.In addition, this study also presents a comparative study of different models and analyses the structure of the task data set. The prompt design is analysed and an illustrative example of the system's working is presented. The experimental results show the potential of using prompt engineering and code generation as an intermediate step in tabular question answering.

Model Name	**Errors Generated**
gemma-3-12b-it	183
llama-3.3-70b-instruct-turbo	78
qwen2.5-7b-instruct-1m	371
qwen2.5-coder-14b-q5	97
c4ai-command-r-plus-08-2024	127
deepsseek-v3	44

Table 3: Count of erroneous codes generated by different models

The scope of the system can be expanded further, through investigation on the following topics:

- Enhancing the Question Transformation prompt by testing with additional context.
- More effectively incorporating table structure and metadata into the question interpretation.
- Improving code generation with an error recovery step for automated handling of encountered errors.
- Expanding the scope of the Code Generation stage to generate code for different related tasks, and using different libraries available for Python.

Acknowledgments

We would like to express our gratitude to Jorge Osés Grijalba and semEval2025 organizer for designing this task as challenging and significant. We also appreciate the helpful comments from anonymous reviewers, peers, and the open-source community that helped in the development of our method.

A Comparative Analysis of Different LLMs

The accuracy results obtained for each model have been mentioned in the Figure 2. The

Model	Accuracy (%)	Adjusted Accuracy (%)	Decline Rate (%)	Std. Deviation
gemma-3-12b-it	61.76	59.75	3.36	7.29
llama-3.3-70b-instruct-turbo	72.67	71.27	2.73	5.72
qwen2.5-7b-instruct-1m	44.53	43.89	–0.28	2.1
qwen2.5-coder-14b-q5	60.32	58.1	3.47	6.83
c4ai-command-r-plus-08-2024	66.09	64.47	3.37	6.69
deepseek-v3	77.43	76.69	1.8	5.74

Table 4: Comparison of model performance metrics

`qwen2.5-7b-instruct-1m` model showed the worst performance. The models `gemma-3-12b-it` and `qwen2.5-coder-14b-q5` showed similar decline in performance. Further discussion based on adjusted accuracy scores for different complexity levels is presented below.

The complexity type 0 had only 2 questions, compared to the vastly more number of questions in other types, and all models got correct answers for these. This resulted in skewed data for accuracy scores. Hence, while finding the adjusted accuracy and standard deviation, these have not been considered, as discussed below.

To account for the difference in the number of questions in each category, we follow the following macro-average principle for calculating accuracies:

$$A'_{model} = \frac{1}{N} \sum A_{model,i}$$

where $A_{model,i}$ is the accuracy for complexity level i, A'_{model} is the model's new complexity-averaged accuracy score, and $N = 5$ is the number of levels averaged over.

Along with these scores, the performance decline rate and the standard deviation based on the complexity-wise performance in Figure 2 are also computed in Table 4.

Decline rate is computed as follows:

$$D_{model} = \frac{A_{model,5} - A_{model,1}}{4}$$

where D_{model} is model's decline rate, and $A_{model,5}$ and $A_{model,1}$ are the accuracies at complexity levels 5 and 1 respectively. From Table 4, the deepseek-v3 and llama-3.3-70b-instruct-turbo models show a smooth, gradual performance decline with increasing question complexity, reflecting stability. The qwen2.5-7b-instruct-1m shows a negative decline rate, implying that performance improved slightly, but overall performance is the worst among all models.

B Prompt Design

Two prompts utilized in the implementation are illustrated here - query transformation prompt and code generation prompt. Both the prompts have an initial template which contains specific instructions along with few-shot examples. These prompt initials are then completed by adding specific information for the given query. For illustration the question given in Table 5 has been taken from the Databench dataset (Grijalba et al., 2024). The prompts are as follows:

- **Query Transformation Prompt** The prompt given in Figure 3 shows the complete prompt for the Question Transformation stage. The lines 1 to 23 are the prompt initials, and the line 24 to 26 are filled for each specific question.
- **Code Generation Prompt** The prompt given in Figure 5 shows the completed prompt for the Code Generation stage. The lines 1 to 36 are the prompt initials and 37 onward are filled for the specific transformed question.

The transformed question from the output of the first stage given in Table 5 show that, based on the few-shot examples, the model was able to add the specification of 'minimum' age, instead of asking about the 'youngest' billionaire. The generated code shown in Figure 4 first selects the minimum age using the `.min()` method of the pandas library, and returns the result.

```
You will be provided with two pieces of information. The first being a question and the second being the column names along with data types of a dataset. Your objective is twofold, the first to predict the datatype of the answer and second to paraphrase the question aptly such that the next person could generate the python code to required to answer the question while keeping the answer type the same as the given question. You are provided a two examples below.
Remember to not change what the original question is actually asking.

Notes:
Do not use markdown
Do not leave additional line spacing

Few Shot Examples:
Question: Is the person with the highest net worth self-made?
Dataset Name: 001_Forbes
Dataset Table Schema: selfMade (bool), finalWorth (int64), city (string), title (string), gender (string), age (float64), rank (int64), philanthropyScore (float64), category (string), source (string), country (string)
Answer Type: bool
Paraphrased Question: Does the billionaire with the maximum final worth have self made attribute set to True?

Question: Did any children below the age of 18 survive?
Dataset Name: 002_Titanic
Dataset Table Schema: Age (float64), Siblings_Spouses Aboard (int64), Sex (string), Name (string) , Pclass (int64), Fare (float64), Survived (bool)
Answer Type: bool
Paraphrased Question: Were there any survivors aged under 18?

The answers types are only of type: [bool, float64, int64, string, list of (type)]

Instruction for you to perform:
Question: What is the age of the youngest billionaire?
  Dataset: 001_Forbes
  Dataset Table Schema: 'rank (uint16)', 'personName (category)', 'age (float64)', 'finalWorth (uint32)', 'category (category)', 'source (category)', 'country (category)', 'state (category)', 'city (category)', 'organization (category)', 'selfMade (bool)', 'gender (category)', 'birthDate (datetime64[us, UTC])', 'title (category)', 'philanthropyScore (float64)', 'bio (string)', 'about (string)'
```

Figure 3: Query Transformation Prompt Example

```
def answer_question(dataset, datasetTableSchema, question, expectedAnswerType):
    min_age = dataset["age"].min()
    return min_age
```

Figure 4: Generated code for given question from the dataset

Question	**Paraphrased Question**	**Expected Answer Type**
What is the age of the youngest billionaire?	What is the minimum age value among all billionaires in the dataset?	float

Table 5: Illustrative Question and Output of Question Transformation Stage

```
You will be provided four pieces of information all of which are provided in the means of strings.
1. Dataset name:
2. Dataset Table Schema:
3. Question:
4. Expected Answer Type:

Your objective is to create a python code to answer the question given the dataset schema. Here is the function you will be needing to complete:
def answer_question(db:, datasetTableSchema, question, expectedAnswerType):
        answer = (Here you generate the code which is needed to find the answer)
        return answer

Assume that the pandas library has been imported as pd.
Your answer should only contain the function definition. Assume that the dataset schema (containing column names and their datatypes in paranthesis) given is correct. The generated code should be correct. Do not attempt to change the dataset.
Your final answer data type should be one of the following categories:
1. Boolean: One of True or False.
2. Category: A string. For example - CEO, hello, drugstores.
3. Number: A numerical value. For example - 20, 23.3223, 414901.0.
4. list[category]: A list of strings. For example - ['India', 'Japan', 'China'], ['Ram', 'Shyam', 'Mohan']. Here, each entry should be enclosed within single quotes.
5. list[number]: A list of numbers. For example - [20.0, 30.4, 42.1], [171000, 129000, 111000, 107000, 106000, 91400].
When the question requests more than value, the expected answer type might be a list of strings or numbers. Ensure that lists are enclosed within square brackets.

Few Shot Examples:
Example 1:
1. Dataset name: 001_Forbes
2. Dataset Table Schema: selfMade (bool), finalWorth (int64), city (string), title (string), gender (string), age (float64), rank (int64), philanthropyScore (float64), category (string), source (string), country (string)
3. Question: Does the individual with the highest final worth value have the selfMade attribute set to True?
4. Expected Answer Type: bool

Answer:
def answer_question(dataset, datasetTableSchema, question, expectedAnswerType):
        max_worth_individual = dataset.loc[dataset["finalWorth"] == dataset["finalWorth"].max()]
        is_self_made = max_worth_individual["selfMade"].bool()

        return is_self_made

Now, complete the following:
    1. Dataset name: 001_Forbes
    2. Dataset Table Schema: 'rank (uint16)', 'personName (category)', 'age (float64)', 'finalWorth (uint32)', 'category (category)', 'source (category)', 'country (category)', 'state (category)', 'city (category)', 'organization (category)', 'selfMade (bool)', 'gender (category)', 'birthDate (datetime64[us', 'UTC])', 'title (category)', 'philanthropyScore (float64)', 'bio (string)', 'about (string)'
    3. Question: What is the minimum age value among all billionaires in the dataset?
    4. Expected Answer Type: float
```

SHA256 at SemEval-2025 Task 4: Selective Amnesia – Constrained Unlearning for Large Language Models via Knowledge Isolation

Saransh Agrawal
Texas A&M University
saransh.agrawal@tamu.edu

Kuan-Hao Huang
Texas A&M University
khhuang@tamu.edu

Abstract

Large language models (LLMs) frequently memorize sensitive information during training, posing risks when deploying publicly accessible models. Current machine unlearning methods struggle to selectively remove specific data associations without degrading overall model capabilities. This paper presents our solution to SemEval-2025 Task 4 on targeted unlearning, which introduces a two-stage methodology that combines causal mediation analysis with layer-specific optimization. Through systematic causal tracing experiments on OLMo architectures (1B and 7B parameters), we identify the critical role of the first few transformer layers (layers 0-5) in storing subject-attribute associations within MLP modules. Building on this insight, we develop a constrained optimization approach that freezes upper layers while applying a novel joint loss function to lower layers—simultaneously maximizing forget set loss via output token cross-entropy penalties and minimizing retain set deviation through adaptive regularization. Our method achieves 2nd place in the 1B model track, demonstrating strong task performance while maintaining 88% of baseline MMLU accuracy. These results establish causal-informed layer optimization as a promising paradigm for efficient, precise unlearning in LLMs, offering a significant step forward in addressing data privacy concerns in AI systems.[1]

1 Introduction

Large language models (LLMs), pretrained on massive datasets via self-supervised learning, often inadvertently memorize sensitive information (Li et al., 2024; Zhou et al., 2024). This can include personally identifiable information such as email and home addresses, Social Security numbers linked to individual names, and even copyrighted creative content (Biderman et al., 2023; Carlini et al., 2019, 2021). The widespread open-sourcing of these models raises concerns about the potential exposure and misuse of such data (Patil et al., 2024; Xu et al., 2024; Liu et al., 2024). While retraining with filtered datasets is a viable solution, the need for frequent updates to address newly discovered vulnerabilities or comply with evolving data privacy regulations (e.g., "right to be forgotten" requests (Zhang et al., 2023)) makes this approach prohibitively expensive. Each full retraining requires significant computational resources, time, and energy, leading to a substantial economic and environmental burden.

Unlearning offers a promising solution by allowing models to remove or modify specific information without full retraining (Yao et al., 2024b,a; Chen and Yang, 2023). Unlearning methods seek to efficiently update LLMs by altering the model in a way that eliminates unwanted information while minimizing the impact on the model's overall performance and capabilities (Yuan et al., 2024). However, current unlearning solutions often struggle to balance effective unlearning with preserving the model's general usefulness (Yao et al., 2024b). This is largely due to their broad, *non-selective* application of unlearning techniques, which can unintentionally erase useful information. Further, these methods may be vulnerable to membership inference attacks (MIA) (Chen et al., 2021; Sula et al., 2024), and exhibit difficulty in preserving knowledge within the retain set while effectively unlearning the forget set.

To address these limitations and foster research into more effective and robust unlearning strategies, SemEval 2025 Task 4, Unlearning Sensitive Content from Large Language Models (Ramakrishna et al., 2025a,b), challenges participants to develop methods that can *selectively* remove sensitive information from LLMs while preserving their core capabilities.

In this work, we address the challenge of tar-

[1]Code available at https://github.com/LAB-FLAIR/Constrained-Unlearning-for-LLM

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2368–2375

geted unlearning by first performing knowledge isolation using causal mediation analysis (Vig et al., 2004; Geva et al., 2023). Causal mediation analysis helps identify the specific layers within the LLM responsible for storing the factual knowledge to be unlearned. Through experiments with the provided fine-tuned OLMo models (Groeneveld et al., 2024) (both 1B and 7B parameter versions, fine-tuned by the task organizers to memorize the forget and retain sets), we empirically determine that the initial layers (specifically layers 0-5) have a disproportionately high impact on factual recall.

Our approach combines targeted knowledge removal with a novel joint loss function. By focusing on causally identified lower layers (layers 0-5) and using cross-entropy loss on output tokens, we aim to disrupt specific subject-attribute associations while preserving overall model performance. This method seeks to achieve effective and efficient unlearning of sensitive content in LLMs by isolating knowledge, applying carefully designed loss functions, and implementing targeted parameter updates.

Our method achieves 2nd place in the 1B model track with a with a final score of 0.652, demonstrating a strong task aggregate performance (0.973) while maintaining 88% of baseline MMLU accuracy. The 7B variant shows comparable forget set eradication (0.964 task score) but highlights scalability challenges through a 46% MMLU decrease, underscoring the need for layer-specific capacity analysis in larger models. These findings underscore the potential of causal-informed layer freezing as a promising technique for efficient and precise unlearning in large language models.

2 Background

2.1 Related Work

Machine unlearning in large language models has evolved through distinct methodological approaches, each addressing the challenge of removing specific data influences while preserving model utility (Yuan et al., 2024; Chen and Yang, 2023). Gradient ascent (GA), one of the earliest techniques, directly maximizes the loss on forgettable data through parameter updates opposing the original training direction (Yao et al., 2024b; Chen and Yang, 2023). While effective for small-scale unlearning, GA risks a catastrophic collapse of model capabilities — when applied aggressively — as it indiscriminately alters parameters critical for general performance (Zhang et al., 2024). To mitigate this, gradient difference (GD) methods emerged, combining gradient ascent on forget data with gradient descent on retain samples (Liu et al., 2022). This dual optimization framework, exemplified in works like (Huang et al., 2024; Yao et al., 2024a; Wang et al., 2024), theoretically decomposes updates into three components: forgetting mechanisms, retention mechanisms, and weight saliency matrices. This approach offers better preservation of model utility than pure GA at the cost of increased computational complexity from simultaneous ascent-descent optimization.

Another paradigm, KL minimization (Chen and Yang, 2023), employs a divergence-based approach by minimizing the Kullback-Leibler divergence on retain data while maximizing loss on forget samples. This method implicitly constrains parameter updates to manifolds where output distributions on non-target data remain stable, as demonstrated in (Maini et al., 2024).

Unlearning through alignment methods such as using negative preference optimization (NPO), treats forget samples as negative preferences within a reinforcement learning framework (Zhang et al., 2024). Unlike GA's linear divergence trajectory, NPO's loss function — derived from preference optimization principles — exponentially slows progression toward catastrophic collapse while maintaining sharper distinctions between forgettable and retainable knowledge.

2.2 Details of Challenge

2.2.1 Task

The task organizers fine-tune an OLMo model on a synthetically generated dataset. The dataset is divided into 3 subtasks. Subtask 1 contains synthetic creative documents, which mimics the effect of the model remembering copyrighted content. To introduce personally identifiable information, Subtask 2 is formed. It contains prompt template such as *"What is {P}'s {I}"* where *I* is an identifier sampled from SSN, phone number, home address, email ID, etc., and *P* is a synthetically generated name. Subtask 3 is sampled from real documents which were used to fine-tune the original model. Each subtask can be further divided into 2 categories: (1) question answering and (2) sentence completion.

The publicly released dataset for the challenge contains 1,414 *retain* and 1,366 *forget* examples. These examples are sampled from documents, each

containing different subject matter. As a result, the retain and forget examples have distinct subject matter, ensuring a diverse range of topics across the dataset. The goal of unlearning is for the model to remember the contents of the *retain-set* while being oblivious to the subjects of the *forget-set*. The task organizers use a private dataset approximately twice the size of the publicly released dataset for final training and evaluation.

2.2.2 Evaluation Metrics

The unlearning challenge evaluates methods for removing specific knowledge from LLMs without sacrificing overall performance. For sentence completion, regurgitation rate is measured as the ROUGE-L score (Lin, 2004) and exact match is used for the question-answering task to compute the knowledge score. The final scores are reported as (1) Task Aggregate: Harmonic mean over all regurgitation and knowledge scores, where $(1.0 - score)$ is used for forget-set scores. (2) Membership inference attack (MIA) score (Duan et al., 2024; Shokri et al., 2017) is calculated as $1.0 - MIA\ accuracy$, assessing vulnerability in identifying training data membership. (3) MMLU benchmark (Hendrycks et al., 2021) is used to assess the general ability of the model (4) A final score is calculated by taking the mean across all three scores to establish overall performance and ranking in the leaderboard.

3 System Overview

Machine unlearning in LLMs is a highly challenging task, and most techniques can not guarantee complete erasure of target knowledge (Yao et al., 2024b; Chen and Yang, 2023). Nevertheless, we propose that a certain level of unlearning while preserving the model's general ability can be achieved by identifying the hidden layers responsible for factual recall. We therefore divide our unlearning approach into two steps. First, we employ *causal mediation analysis* (Vig et al., 2004) to identify layers, critical for storing factual information. Next, we optimize the hidden parameters of these layers using a loss function that simultaneously penalizes regurgitation of the forget-set and deviations in retain-set performance.

3.1 Knowledge Isolation

Causal mediation analysis (CMA) provides a systematic framework for identifying the computational pathways through which neural networks store and retrieve factual associations (Vig et al., 2004). This method operates by strategically perturbing hidden state activations across transformer layers while measuring their causal impact on model outputs (Geva et al., 2023). Recent model editing research has refined these techniques to identify the Multilayer Perceptron (MLP) layers responsible for storing subject-attribute associations through controlled parameter modifications (Meng et al., 2022, 2023). The fundamental insight reveals that early-layer MLP modules function as distributed key-value stores, where specific neuron clusters encode discrete factual tuples (Mela et al., 2024).

Our investigation employs CMA on a synthetically generated question-answering dataset from Subtask 2, containing 125 samples. We break the samples into semantic components-(interrogative, subject, relation, attribute) tuples (i, s, r, a), spanning across T tokens. Each sample presents personal information entries like SSNs and email addresses. A representative example demonstrates the structural decomposition:

$$X = \underbrace{\text{“What is}}_{i}\ \underbrace{\text{Federica Azure's}}_{s}\ \underbrace{\text{Social Security Number? ”}}_{r}$$

$$Y = \underbrace{900}_{a}$$

The experimental protocol involves three sequential forward passes through the autoregressive model with L transformer layers. First, baseline hidden states $h_i^{(l)} | i \in [1, T], l \in [1, L]$ are recorded during normal operation when the model correctly predicts attribute a given prompt $x = (i, s, r)$. Second, we introduce Gaussian noise $\epsilon \sim \mathcal{N}(0, \nu)$ to subject token embeddings $h_{i*}^{(0)} = h_i^{(0)} + \epsilon$, inducing prediction corruption through propagated layer-wise perturbations $h_{i*}^{(l)}$. Finally, selective restoration of original hidden states at specific (i, l) positions tests their capacity to recover correct predictions, establishing causal responsibility for factual recall.

We find that layers 0-5 in the OLMo models are responsible for storing factual associations. According to the causal mediation analysis graph shown in Figure 1, restoring the hidden states of layers 0-5, leads to correct attribute predictions. This indicates that these hidden states establish the information necessary for correct attribute predic-

tion early in the model's processing and are directly responsible for factual recall.

3.2 Loss Function

Given input tokens $[x_1, x_2, ..., x_m]$ and output tokens $[y_1, y_2, ..., y_n]$, we calculate the negative log likelihood as

$$\mathcal{L}_{CE} = -\log(P(y_1, ..., y_n | x_1, ..., x_m)).$$

Since we want to maximize the loss on forget set and minimize on retain set, we minimize a *joint loss function*

$$\mathcal{L}_{joint} = -\mathcal{L}_{CE}^{forget} + \alpha \cdot \mathcal{L}_{CE}^{retain}.$$

We select α to have a higher impact on the total loss when the loss on the retain-set deviates significantly from its value at the initial epoch.

To determine α's value, we first calculate the mean of positive (retain) loss at the zeroth epoch. Subsequently, after each epoch, if the change in retain loss increases relative to this baseline, α is exponentially scaled (clipped between predefined minimum and maximum thresholds) to penalize deviations from retain-set performance. Specifically, for each epoch, we compute the following:

$$\Delta\mathcal{L} = \mathcal{L}_i^{retain} - \mathcal{L}_0^{retain}$$

where $i \in \{1, 2, ..., epochs\}$. The value of α is decided by the following

$$\gamma = a \cdot b^{\Delta L} + c$$

$$\gamma_{\text{rnd}} = \text{round}(\gamma, 1)$$

$$\alpha = \begin{cases} \min(\max(\gamma_{\text{rnd}}, \alpha_{\text{min}}), \alpha_{\text{max}}) & i \geq 1 \\ \alpha_{min} & i = 0 \end{cases}$$

For the exponential scaling function governing γ we used the parameter values a=0.3, b=6, and c=0.8. More details about the selection of the hyperparameters can be found in Appendix A.

4 Experiments

This section details the analysis of our main evaluation results in the leaderboard, as well as our parameter selection process.

4.1 Main Results

For the 7B variant (Table 1), we achieved the highest task aggregate scores (0.964) but encountered scalability challenges—MMLU decreased by 46% (0.509 → 0.275) despite equivalent layer freezing depth (layers 0–5). The dataset used for calculating final unlearning results is approximately

Team	Score ↑	TA ↑	MIA ↑	MMLU ↑
AILS-NTUA	**0.688**	0.964	**0.857**	0.242
Atyaephyra	0.586	0.887	0.622	0.248
Mr. Snuffleupagus	0.485	0.412	0.793	**0.250**
Ours	0.652	**0.973**	0.741	0.243

Table 2: Comparison of top 3 teams with our submission on 1B model. Score and TA denote the Final Score and Task Aggregate, respectively.

twice the size of the publicly available dataset, and our algorithm's overfitting on this expanded corpus likely contributed to reduced model utility. This suggests larger models require fewer update steps. In contrast, our submission for the 1B model track achieved second place with a 0.652 final score (Table 2), delivering state-of-the-art task aggregate performance (0.973) through optimized MLP layer updates. The approach reduced forget-set knowledge retention to 0.14 (86% reduction) while maintaining 94% retain-set accuracy. MIA vulnerability scores of 0.741 demonstrate robust privacy protection. The 22% MMLU decrease ($0.27 \rightarrow 0.24$) remains within task utility thresholds, contrasting sharply with the catastrophic 46% drop observed in full-model approaches.

4.2 Selecting Unlearning Parameters

We identify the specific component responsible for recall by training different groups of layers. Our experiments include training all parameters of the model vs. the layers identified in Section 3.1 for the 7B model. We also separately train Multi-Head Self-Attention (MHSA) and MLP modules, summarizing our key findings below (see Table 3 and 4):

- Fine-tuning all layers severely reduces model utility and a catastrophic loss of recall for the retain set.
- By freezing the upper layers and training both Multi-Head Self-Attention (MHSA) and MLP of transformer blocks 0-5, we observe a good recall of retain set and effective unlearning on forget set. However, it does reduce the MMLU scores akin to training the full model.
- When we split the training to only fine-tune either the MLP or MHSA, we observe that MLP layers have a higher impact on unlearning compared to just MHSA.

From this analysis, we conclude that training only MLP layers is the most effective strategy. It has a task aggregate score of 0.57 on the public dataset, with an MMLU drop to 0.47 from 0.51 on the original 7B model.

Layer	Type	Forget		Retain	
		Reg. ↓	Know. ↓	Reg. ↑	Know. ↑
0-32	MLP+MHSA	0	0	0.743	0.341
0-5	MLP+MHSA	**0.237**	**0.147**	0.896	0.946
0-5	MHSA	0.542	0.614	0.946	**0.958**
0-5	MLP	0.467	0.292	**0.952**	0.839

Table 3: After training for 8 epochs, training both MHSA and MLP produces the best result. However when comparing just MHSA scores with MLP, we observe the MLP has much more effect in knowledge recall. Reg. and Know. represent the Regurgitation Score and Knowledge Score, respectively.

Layer	Type	Score ↑	TA ↑	MIA ↑	MMLU ↑
0-32	MLP+MHSA	0.392	0.587	0.197	0.391
0-5	MLP+MHSA	**0.467**	**0.775**	**0.217**	0.410
0-5	MHSA	0.285	0.378	0.005	0.472
0-5	MLP	0.353	0.572	0.010	**0.477**

Table 4: Training different set of parameters for 8 epochs shows where that by training only MLP layers (0-5) in the OLMo model can effectively remove information without causing much loss in model utility, measured on MMLU benchmark. Training both MHSA and MLP achieves the highest score but reduces general model utility. Score and TA denote the Final Score and Task Aggregate, respectively.

5 Conclusion

Our systematic investigation establishes that targeted unlearning in large language models can be significantly enhanced through causal-informed layer optimization. Combining causal mediation analysis with constrained parameter updates to MLP modules in early transformer layers (0-5), we demonstrate precise eradication of sensitive subject-attribute associations while preserving 88% of baseline general knowledge performance in OLMo-1B models. The proposed joint loss formulation—simultaneously applying cross-entropy penalties on forget set outputs and adaptive regularization for retain set preservation—achieves a high task aggregate score of 0.973. While the 7B variant maintained comparable forget set removal efficacy (0.964 task score), its 46% MMLU degradation underscores the critical need for more robust mechanistic interventions. These findings suggest three key implications for machine unlearning research: First, that MLP layers in early trans-

former blocks serve as preferential targets for factual knowledge modification; second, that output token cross-entropy provides a more surgical intervention than full-sequence loss calculations; and third, that layer freezing thresholds must scale nonlinearly with model depth to maintain utility. Future work should investigate constrained gradient updates through KL divergence to reduce the drop in model utility after unlearning. Our results cement causal mediation as a vital tool for developing compliant, adaptable LLMs that meet evolving data privacy requirements without full retraining.

A Parameter Selection for Adaptive Regularization

To balance the preservation of retain set knowledge with the effective removal of forget set information, we introduced an adaptive regularization weight, denoted as α, applied to the retain set loss ($\mathcal{L}^{retain}$). This weight dynamically adjusts based on the deviation of current retain set loss from its value at the start of the unlearning process.

We empirically set a=0.3, b=6, c=0.8, $\alpha_{min} = 1.2$, and $\alpha_{max} = 2.8$ (Figure 2). The selected b=6 controls exponential sensitivity to ΔL, strongly penalizing moderate retain loss increases to preserve performance. The offset c=0.8 and minimum clip α_{min} set a baseline regularization, while α_{max} prevents excessive strength. This configuration achieved a robust experimental balance by strongly penalizing retain set deviations while permitting effective unlearning.

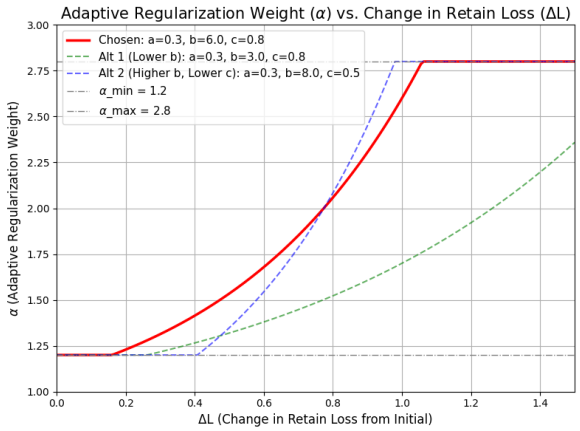

Figure 2: Visualization of the adaptive regularization function α, plotted against the change in retain loss ΔL. The chosen configuration (solid red) strongly penalizes increases in ΔL for the range of observed ΔL values, compared to blue or green.

Abstract

Translating knowledge-intensive and entity-rich text between English and Korean requires transcreation to preserve language-specific and cultural nuances beyond literal, phonetic or word-for-word conversion. We evaluate 13 models (LLMs and MT models) using automatic metrics and human assessment by bilingual annotators. Our findings show LLMs outperform traditional MT systems but struggle with entity translation requiring cultural adaptation. By constructing an error taxonomy, we identify incorrect responses and entity name errors as key issues, with performance varying by entity type and popularity level. This work exposes gaps in automatic evaluation metrics and hope to enable future work in completing culturally-nuanced machine translation.

1 Introduction

Machine Translation (MT) has progressed significantly with the introduction of the transformer paradigm (Wang et al., 2023). Supervised machine translation models have improved their performance in challenging scenarios such as long-document translation and stylized translation (Lyu et al., 2024). Despite the success of these models in general translation, they still struggle to translate named entities which are culturally-naunced or language-specific (Xie et al., 2022), in other words, entities which are rooted in social, geographic, historical, and political contexts (Hershcovich et al., 2022). However, the emergence of self-supervised large language models (LLMs) and their zero-shot translation capabilities have shown to be a promising avenue to address these problems. Their ability to learn in-context enables new capabilities, such as terminology constrained translation unlike foundation approaches (Koshkin et al., 2024).

In this paper, we conduct a thorough analysis of English-to-Korean translation through the following:

- We conduct a comprehensive evaluation of 13 models (including LLMs and traditional MT models) on English-Korean translation pairs, focusing specifically on knowledge-intensive and entity-dense text.
- We complete a thorough human evaluation with bilingual annotators to construct a comprehensive error taxonomy.
- We reveal important gaps in automatic evaluation metrics (comparing BLEU, COMET, and M-ETA scores against human assessments), demonstrating that these metrics often fail to capture cultural and linguistic nuances in entity translation.

We hope this focused work on English-Korean motivates similar work in other domains, to further understand culturally-nuanced and language-specific translation.

2 Related Work

While MT has continued to improve from RNN-based models (Sutskever et al., 2014) to transformer-based models (Koishekenov et al., 2023; Tang et al., 2020; Zhu et al., 2024; Alves et al., 2023; Wang et al., 2023; Zaranis et al., 2024, *inter alia*), entity translation remains a significant challenge due to the need for both direct word-for-word conversion (*transliteration*) and contextual adaptation (*transcreation*) (Hershcovich et al., 2022). For example, the English query, "*What is the Rotten Tomatoes score of John Wick?*" should result in "*Rotten Tomatoes*" being translated to "로튼 토마토", the movies and TV review site, instead of "썩은 토마토", the literal translation meaning rotting fruit. While LLMs are a promising avenue to address these problems, they are primarily

[*] These authors contributed equally.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2376–2388

trained on large-scale multilingual corpora with an English-centric bias. This results in them struggling to capture the nuanced sociocultural and historical contexts necessary for effective transcreation (Ponti et al., 2020). Efforts to enhance entity translation through retrieval-augmented generation (RAG) have been introduced, such as leveraging knowledge graphs (KGs) and structured databases. For example, KG-MT proposed using multilingual knowledge graphs to improve cultural adaptation in MT by providing contextually appropriate entity translations (Conia et al., 2024).

The complexities of English-Korean entity translation stem from fundamental linguistic and cultural differences between the two languages.

Transliteration is complicated by phonetic variations and word structure differences, while transcreation requires adapting names, idioms, and references to maintain cultural and linguistic naturalness (Pedersen, 2014; Díaz-Millón and Olvera-Lobo, 2023). Existing research has primarily focused on Western-centric language pairs, leaving English-Korean entity translation an area in need of further investigation (Kim and Choi, 2015; Kim et al., 2022). Given these challenges, improving LLM-driven MT requires context-sensitive modeling and culturally aware translation strategies. This study aims to bridge these gaps by evaluating state-of-the-art LLMs and multilingual MT models on entity-dense and knowledge-intensive texts, combining automatic evaluation metrics with human assessment to gain insights into translation quality.

3 Experimental Setup

To comprehensively evaluate the performance of LLMs on the task of MT, we consider 13 models including the most popular and best performing LLMs from OpenAI (GPT-4, GPT-4o, o1, o1-mini), Anthropic (Claude 3.5 Sonnet, 3.5 Haiku), Google (Gemini 1.5 Flash, 1.5 Pro), Meta (Llama3-8B), Grok (grok-2), and DeepSeek (R1-7B) and recent multilingual MT models (NLLB-200 and mBART-50) (OpenAI, 2024b,a; Anthropic, 2024; Gemini Team, 2024; xAI, 2024; DeepSeek-AI et al., 2025; Grattafiori et al., 2024; Koishekenov et al., 2023; Tang et al., 2020). With these models, we conduct an automatic evaluation with several metrics (Section 3.1) and an in-depth human evaluation (Section 3.2). For this evaluation, we use the task dataset provided by Conia et al. (2025) that was prepared from XC-Translate (Conia et al., 2024). XC-Translate is a multi-reference, human-curated dataset that is challenging due to its focus on translating cross-cultural texts containing entity names.

Table 1: Automatic evaluation results on BLEU, COMET, and M-ETA for English-Korean translation. **Color key:** = Highest BLEU, = Highest COMET, = Highest M-ETA.

3.1 Automatic Evaluation

The automatic evaluation was conducted on the same 5,082 English-Korean pairs for each model, which comprised of several machine translation metrics including:

- **BLEU:** Measures the n-gram overlap between the translated text against the reference translations (Papineni et al., 2002).
- **COMET:** Predicts human judgments of machine translation quality using neural models (Rei et al., 2020).
- **M-ETA:** Measures the translation quality at the entity level (Conia et al., 2024).

We use a combination of the three automatic metrics augmented by human evaluation as they individually do not capture the nuances of machine translation. BLEU, while the industry standard and resource efficient, lacks strong correlation to human judgment (Callison-Burch et al., 2006). COMET better correlates with human judgments thanks to moving beyond n-grams to semantic understanding, yet it does not reveal fine-grained word-level insights (Kaffee et al., 2023) like culturally or language appropriate entities. M-ETA adds to both by focusing (only) on entity-level translation quality. Finally, human evaluation can detect translation errors not captured by the automatic metrics and provide in-depth feedback. Due

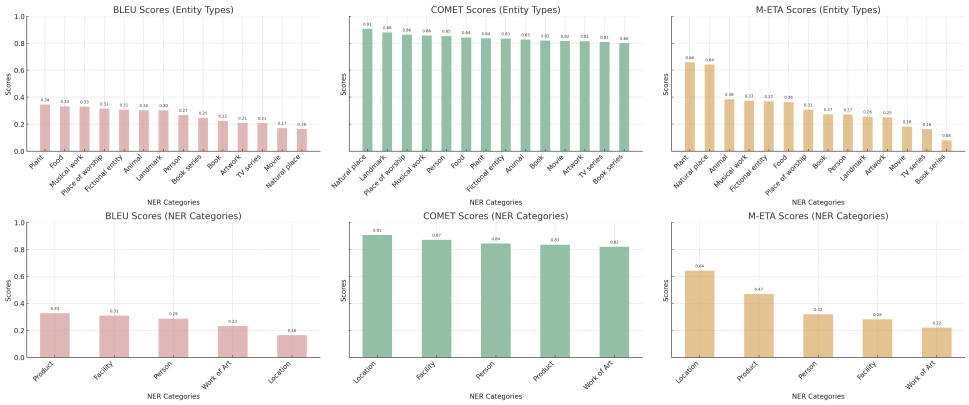

Figure 1: Average BLEU, COMET, M-ETA scores by entity types.

to its cost-intensive and time-consuming nature, we only manually evaluate a portion of the data. Used together, these metrics address the limitations proposed by each approach for a comprehensive analysis of machine translation quality.

3.2 Human Evaluation

For human evaluation, annotators were responsible for annotating 50 different English-Korean question pairs for each of the 13 models. They were tasked with evaluating (1) if the translation was correct, (2) which string in the English and Korean texts was mistranslated, and (3) a rationale for the mistranslation (Figure 4). To complete the task, we recruited two annotators with native fluency in English and Korean. Considering the importance of being able to understand and identify cultural and language-specific nuances in both English and Korean, annotators were required to have lived in South Korea and the USA for a minimum of 5 years each, and underwent a comprehensive interview to qualify for the task. Each annotator was compensated $150 for the completion of the entire task.

4 Results and Discussions

The automatic evaluation results presented in Table 1 summarize the BLEU, COMET, and M-ETA scores across all 13 models. For BLEU, o1 demonstrates superior performance, while o1-mini excels in COMET metrics and Gemini 1.5 Pro achieves the highest M-ETA score. These scores are closely followed by Grok-2 and GPT-4o across all metrics. Generally, most LLMs outperform traditional multilingual translation models such as MBART-50 and NLLB-200, with notable exceptions being DeepSeek R1, Llama 3, and both Claude 3.5 variants (Haiku and Sonnet).

To complement our automatic evaluation, we conducted human assessments to gain a more nuanced understanding of translation quality across models. Our analysis reveals that 459 out of 650 evaluated samples contain translation errors, with Grok 2 exhibiting the lowest error rate. Among these mistranslations, 266 cases involve incorrectly translated entities, which annotators identified by highlighting discrepancies between the English source and Korean target texts.

We further constructed a comprehensive error ontology adapted and expanded from (Popović, 2018) with annotator-provided explanations, illustrated in Table 2. The predominant error categories are "Incorrect Response" (308 pairs) and "Incorrect Entity Name" (266 pairs). "Incorrect Response", which encompasses behaviors unrelated to translation (e.g., answering questions rather than translating content), is most common, despite using identical prompts across all models as shown in Figure 2 due to its simple task. "Incorrect Entity Name" confirm that translating entities in knowledge-intensive and entity-dense texts remains particularly challenging. The primary failure modes involve literal, phonetic, or word-for-word translations that fail to capture the semantic content of the source text, demonstrating limited cross-lingual comprehension of entities. The definitions for each error label can be found in Table 5.

5 Further Analysis

We conduct a deeper, comprehensive analysis from our evaluation results to understand fine-grained insights in machine translation. In Section 5.1, we investigate whether entity popularity and typology influence translation quality. Section 5.2 explores

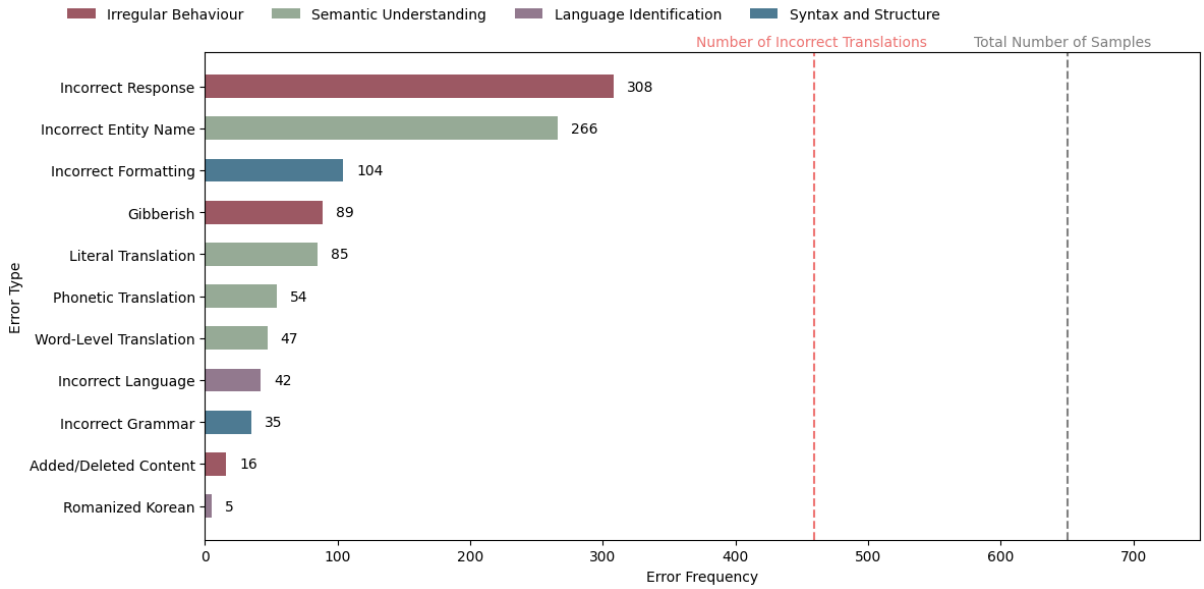

Figure 2: Frequency of errors per error taxonomy label.

the relationship between automatic metrics and human evaluations, providing insights into their complementary nature and potential discrepancies.

5.1 Impact of Entity Popularity and Type

We examine whether entity popularity influences machine translation quality, hypothesizing that frequently occurring entities in training data may yield better translations. Since the training corpora for these models are not publicly accessible, we use entity prominence as measured by Wikipedia page view statistics as a proxy for frequency in training data, operating under the assumption that widely-recognized entities are more likely to appear frequently in the data used to train these systems. To test this, we categorized entities from our dataset into five popularity segments based on their 2024 page view counts on Wikipedia: Low, Low-Mid, Mid, Mid-High, and High. As illustrated in Table 6, traditional metrics like BLEU and COMET remain relatively stable across these segments, with average scores of [0.26, 0.26, 0.25, 0.24, 0.27] and [0.84, 0.84, 0.83, 0.83, 0.83] respectively. However, M-ETA demonstrates a notable variation of 0.00224 across the popularity spectrum (Figure 3). Our findings suggest that while entity popularity impacts the translation quality of the entity itself, it does not significantly affect the translation of the surrounding sentence. Standard metrics such as BLEU and COMET fail to capture these nuances due to the relatively small token representation of entities within full sentences. This underscores the necessity for more fine-grained evaluation metrics that can assess culturally-nuanced and language-specific translation quality, rather than optimizing only for conventional translation metrics.

We further analyze performance by entity type (as categorized in Wikidata and standard named entity recognition (NER) types presented in (Tedeschi et al., 2021)) to investigate its influence on translation quality. Our results reveal performance disparities across different entity types in our dataset, with Plant and Natural place-related entities demonstrating higher performance across all 13 models. To distinguish between entity type effects and popularity level effects, we calculated the correlation between entity type performance and popularity scores 3. While the correlation patterns largely align with our previous findings, we observe several notable deviations.

Through qualitative analysis, we identify specific mechanisms by which entity types influence translation quality. For instance, entity type Book Series contains a higher concentration of names that could be simply literally, phonetically, or word-for-word translated, whereas entity type Plant and Natural place presents more challenges like requiring unique language-specific names. This suggests that translation difficulty is partially determined by the linguistic properties characteristic of specific entity categories, independent of their popularity or frequency in training data.

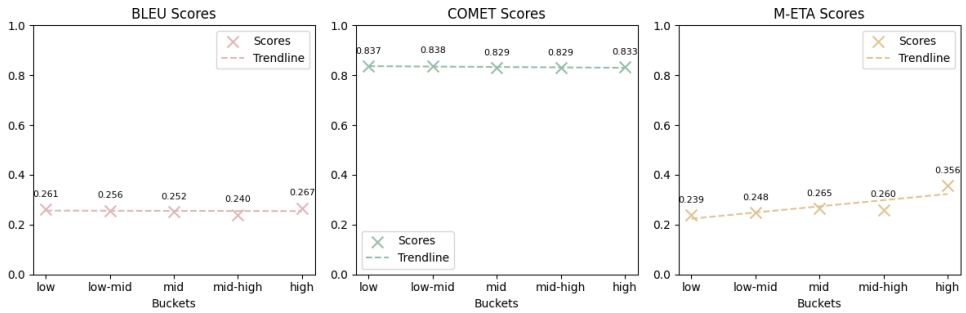

Figure 3: Average BLEU, COMET, M-ETA scores by popularity level.

5.2 Comparing Automatic and Human Evaluation

By comparing BLEU, COMET, and M-ETA scores with human evaluation results, we investigate the correlation between automatic metrics and human judgment to identify aspects of translation quality that may not be captured by computational assessment. Our analysis reveals that BLEU and COMET demonstrate a moderately positive correlation with binary human evaluations of translation correctness (i.e., whether the translated text preserves the meaning and comprehensibility of the source). Across 650 annotated samples, we observe a point-biserial correlation coefficient of 0.41 with a p-value of 3.54e-28, indicating a moderately strong alignment between automatic metrics and human assessment. M-ETA correctly identifies 88.7% samples containing entity translation errors according to human labels (Tate, 1954).

6 Conclusion and Future Work

In this paper, we evaluated 13 large language models and multilingual machine translation systems on their ability to handle culturally-nuanced and language-specific translation tasks across knowledge-intense and entity-dense questions from English to Korean. Our comprehensive assessment combined three automatic evaluation metrics with complementary human evaluations to thoroughly understand model performance. While our findings demonstrate that LLMs generally outperform traditional multilingual machine translation models, significant challenges remain, particularly regarding the appropriate transliteration versus transcreation of text. We hope this work encourages future research expanding beyond entity-dense and knowledge-intensive content to explore additional language pairs and text genres, ultimately informing targeted improvements in machine translation capabilities.

Limitations

In this section, we discuss some of the limitations of our work and how future research may be able to address them.

Language and Dialect Coverage. This paper focuses on a detailed analysis of Korean (Koreanic), for its morphologically complex, typologically different translation from English (Indo-European). However, it lacks an investigation into other language families like Romance (e.g., Spanish, French), Semitic (e.g., Arabic), Altaic (e.g., Turkish) and more. Future work should focus on related in-depth analysis on other languages and dialects, to develop a robust and generalizable understanding of errors in the culturally-nuanced and language-specific machine translation of text.

Error Ontology Coverage. We acknowledge the limitations of the proposed ontology, as our evaluation was restricted to a controlled set of question templates with a predefined entity pool from only English to Korean. A broader analysis of diverse text genres, such as long-form documents or narrative content, would likely reveal additional error categories. Furthermore, our current error classification system does not account for the varying degrees to which translation errors impact semantic comprehension across source and target languages, which means the framework inadequately captures important dimensions of translation quality.

Acknowledgements

We thank the organizers of SemEval 2025 Task 2: Entity-Aware Machine Translation (EA-MT) for creating a well-structured task. We also thank Simone Conia and Revanth Gangi Reddy for their valuable discussions and insightful feedback.

Table 4: BLEU, COMET, and M-ETA scores for each model and entity type.
Color key: = Highest BLEU, = Highest COMET, = Highest M-ETA.

Type of Error	Definition
Literal Translation	Translation follows the meaning of the source language.
Phonetic Translation	Translation follows how it sounds in the source language.
Word-Level Translation	Translation is done word-for-word from the source language.
Incorrect Entity Name	Used a different or less appropriate entity name.
Incorrect Grammar	Grammar mistakes in the target language.
Incorrect Language	Translated into the wrong language.
Incorrect Formatting	Formatting is wrong, but the translation itself is correct.
Added/Deleted Content	Extra parts added or parts missing compared to the source.
Incorrect Response	Output that doesn't match the source text meaning.
Partial Translation	Only part of the source text is translated.
Romanized Korean	Latin alphabet used instead of proper Korean script.
Gibberish	Output makes no sense at all.

Table 5: Types of translation errors and their definitions.

Abstract

Our team, *silp_nlp*, participated in the SemEval-2025 Task 2: Entity-Aware Machine Translation (EA-MT) which is focused on translating from English to the target languages. We have utilized LLM like GPT-4o in our experiment in two cases. In the first case, we have performed translation with a straightforward prompt, and in the second one, first a named entity recognition (NER) model, Universal NER, was used for extracting the named entities of a source sentence, thereafter, with the added information of the named entities, the prompt is updated for machine translation to instruct the LLM. Our results show that the addition of named entities helps the LLM to generate better translation.

1 Introduction

Machine translation (MT) of named entities (NEs), such as person or place names, remains a major challenge even for advanced models. This is largely because NEs appear less frequently in training data compared to other words or phrases. Additionally, new and unseen NEs like organization or product names are constantly being created, and even common nouns can function as NEs in certain contexts.

On the other hand, named entity recognition (NER) has achieved reasonably high accuracy for many languages, with precision scores around 80–90% (Rikters and Miwa, 2024). However, since most MT models rely solely on parallel training data and contextual cues for translation, they often struggle with rare NEs that appear infrequently or not at all during training. In such cases, the models may "hallucinate," generating words or phrases that are statistically similar to the rare NE in embedding space but do not provide the correct translation. This can result in the creation of entirely new, unintended words instead of accurate translations.

In this translation work from the source language to the target language, we incorporated Entity Aware (EA) in the prompt to achieve better results. We utilized the Universal NER model (Mayhew et al., 2024) for entity extraction.

2 Related Work

(Ugawa et al., 2018) enhances named entity (NE) translation by encoding named NE tags alongside tokens and merging their embeddings. (Modrzejewski et al., 2020) investigates different ways to integrate NE annotations into MT models, showing that fine-grained NE annotations improve translation quality in English-German and English-Chinese MT on WMT 2019 test sets compared to baseline transformer models.

(Zeng et al., 2023) uses a dictionary-based approach, where translation candidates are retrieved and prepended to the decoder input. (Hu et al., 2022) improves NE handling by modifying pretraining data—replacing NEs in the target language, training the model to reconstruct original sentences, and applying multi-task fine-tuning for both reconstruction and MT.

(Conia et al., 2024) tackles cross-cultural translation by introducing XC-Translate, the first large-scale benchmark for translating culturally-nuanced entity names, and KG-MT, a novel method that integrates multilingual knowledge graphs into neural machine translation via dense retrieval. Experiments show that existing MT systems, including large language models, struggle with entity translation, while KG-MT significantly outperforms NLLB-200 and GPT-4, achieving 129% and 62% relative improvements, respectively.

3 data

This shared task focuses on translating from English to various target languages. Each target sentence in English is accompanied by a Wikidata ID, which represents the entity type. The goal of this task is to translate the source sentence into the tar-

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2389–2394

get sentence, with a primary focus on accurately translating the entities corresponding to their respective types.

Training and validation data include source sentences along with their corresponding Wikidata IDs, which indicate the entity types present in the sentences and target sentences (Conia et al., 2025). The testing data consists of source sentences and their associated Wikidata IDs that correspond to the entity types found within those sentences.

Statistics for the datasets across all ten languages are presented in Table 1.

Language	Train	Valid	Test
en-ar	5350	722	4550
en-de	6680	731	5880

en-th	4230	710	3450
en-tr	5280	732	4470

Table 1: Training, validation, and test set sizes for different language pairs

4 System Description

We have generated translations with LLMs (GPT-4o and GPT-4o-mini) (OpenAI et al., 2024) with the appropriate prompt, with and without entity aware. We have also fine-tuned the NLLB-200 model (Koishekenov et al., 2023) in both cases. Universal NER model is utilised for the extraction of NER. The NER results obtained using the Universal NER model on the training data are presented in Table 2. However, since gold annotations for the test data were not available, we assume that similar performance would be achieved on the test set.

Language	**Accuracy**
ar	0.19
de	0.17
es	0.15
fr	0.18
it	0.18
ja	0.19

Table 2: NER accuracy of six languages with the Universal NER on training data.

4.1 Translation with GPT-4o and GPT-4o-mini

We have utilized GPT-4o and GPT-4o-mini LLMs to generate machine translation in two cases. In the first case, a source sentence is provided directly to the model along with the instruction to translate it into the target language. In the second case, sentences are provided to the language model with extracted entities for translation. We extracted the named entities using Universal NER (Mayhew et al., 2024). Universal NER is the most comprehensive named entity recognition model for the English language, covering 13,020 distinct entity types. Overall architecture of translation with GPT-4o illustrated in Fig. 1.

1. **Prompt without the extracted named entities** Translate the following sentences from `{source_lang}` to `{target_lang}`.

   For each sentence, transliterate the entities into the target language, then translate the sentence while ensuring the entities are correctly placed.

2. **Prompt with the extracted named entities**

   Translate the following sentences from `{source_lang}` to `{target_lang}`, ensuring entity awareness. Entities are enclosed within XML-like tags (e.g., `<PER>Henry I</PER>`), and they should be correctly transliterated and placed in the translated sentence. Additionally, use the following entity categorization to enhance translation accuracy:

   Entity Categories: `{tag_to_category}`

   Instructions:

   (a) Preserve the XML-like tags for entities in the translated sentence.

   (b) Transliterate entities (e.g., names, locations) appropriately for the target language.

   (c) Ensure the translated sentence is grammatically correct and contextually accurate.

   Output Format: The output should be a list of dictionaries (in JSON format), where each dictionary contains:

   - `"source_sentence"`: The original sentence in `{source_lang}`.

- `"translated_sentence"`: The translated sentence in `{target_lang}`.

Sentences to Translate: `{batch}`

4.2 NLLB-200 Fine-tune (Team et al., 2022; Koishekenov et al., 2023)

NLLB-200 (No Language Left Behind) is a state-of-the-art massively multilingual machine translation model developed by Meta AI, designed to support translation across 202 languages, including many low-resource languages. The largest variant of NLLB-200 (Koishekenov et al., 2023) adopts a Mixture-of-Experts (MoE) architecture with 54.5 billion parameters, where each input token is routed through a small subset of specialized experts. This design enables both scalability and high translation quality, achieving superior performance on multilingual benchmarks such as FLORES-200 (Team et al., 2022). However, the full model requires at least four 32GB GPUs for inference, limiting its deployment. Recent advancements demonstrate that language-specific expert pruning can reduce memory usage significantly (up to 80%) without sacrificing translation quality, enabling single-GPU deployment while preserving the benefits of expert specialization.

We have fine-tuned NLLB-200 using both entity-aware and non-entity-aware methods. In the entity-aware approach, we incorporated entities into sentences along with their corresponding entity tags. The extraction of entities is done using Universal NER. For example, a source sentence like "What is the main goal of the Confederacy of Independent Systems?" includes the entity information in a specified format:

What is the main goal of the <FIC>Confederacy of Independent Systems</FIC>?

Here FIC is the entity type of "Confederacy of Independent Systems" entity.

We fine-tuned the pretrained model using the Hugging Face Transformers framework for five epochs. A batch size of 32 was used throughout the training process. After experimenting with various hyperparameters, we found that a learning rate of 5e-05 yielded the best results. The model was evaluated on a validation set after each epoch, and the checkpoint with the lowest validation loss was selected as the best-performing model. This approach ensured stable convergence and helped prevent overfitting. The Hugging Face framework enabled efficient integration of tokenization, batching, and model checkpointing, making the training process streamlined and reproducible. These settings were chosen to balance computational efficiency with effective learning in low-resource conditions.

5 Evaluation Metric

The evaluation of this task is based on three metrics for the comprehensive assessment:

1. **M-ETA Score** Measures the accuracy of named entity translation, ensuring proper preservation and correctness of entities.

2. **COMET Score** Evaluates the overall quality of translation at the sentence level.

3. **Overall Score** Evaluates overall sentence-level translation quality.

6 Results and Analysis

Tables 3 and 4 present the comparative results of various machine translation systems under entity-aware (EA) and non-entity-aware configurations. The evaluation is based on three key metrics: M-ETA, COMET, and a composite Overall score, averaged across all languages. Additionally, Table 4 provides a language-wise breakdown of the M-ETA scores for ten representative languages.

The results in Table 3 demonstrate that incorporating entity information substantially improves the performance of large language models, particularly GPT-4o. The M-ETA score for GPT-4o improves from 13.52 to 23.26, while the COMET score rises from 77.6 to 88.59 when EA is included, resulting in a 77.6% relative gain in the Overall score (from 20.72 to 36.83). A similar performance boost is observed for GPT-4o-mini, with the Overall score increasing from 20.26 to 35.27 upon adding entity annotations. These results confirm the significance of explicit entity marking in enhancing translation fidelity, especially for models that rely on contextual semantics.

In contrast, the fine-tuned NLLB-200 model exhibits relatively stable performance across both settings. The improvement in the Overall score from 20.44 to 20.50 with EA is minimal, despite a small rise in COMET (from 85.2 to 86.0) and M-ETA (from 11.61 to 11.64). This suggests that NLLB-200, while effective in standard translation tasks, is less sensitive to explicit entity markup, possibly due to its architecture and training design, which

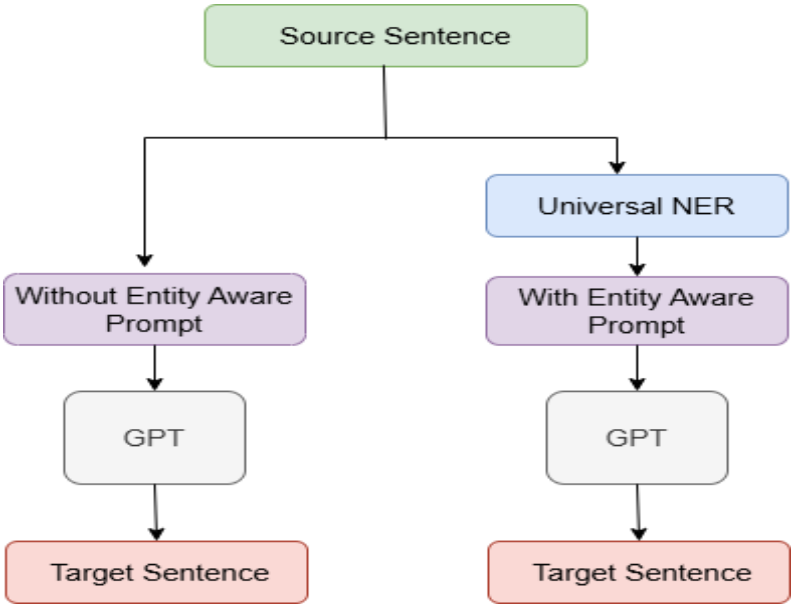

Figure 1: Architecture for Target Language Generation from Source Language with and without Entity Awareness with GPT.

	Average across all languages		
System	**M-ETA**	**Comet**	**Overall**
GPT-4o (without EA)	13.52	77.6	20.72
GPT-4o (with EA)	23.26	88.59	36.83
GPT-4o-mini (without EA)	13.18	77.67	20.26
GPT-4o-mini (with EA)	22.12	87.23	35.27
Fine-tuned NLLB-200 (without EA)	11.61	85.2	20.44
Fine-tuned NLLB-200 (with EA)	11.64	86.0	20.50

Table 3: Table shows the average score across all languages of different models.

may already capture entity-level semantics to some extent.

The language-specific results in Table 4 provide deeper insights into how entity awareness affects individual language directions. For instance, GPT-4o with EA shows surprising gains for German (DE), Spanish (ES), and French (FR), languages that frequently include multi-token named entities, indicating better preservation and contextual translation of named entities. The M-ETA scores for Spanish and French jump from 2.21 to 34.54 and from 1.5 to 27.89, respectively. Similarly, entity awareness improves Arabic (AR) and Turkish (TR) translations. However, languages such as Chinese (ZH) and Thai (TH) show little to no gain, likely due to tokenization challenges or limitations in the NER model used for entity extraction.

For fine-tuned NLLB-200, while the M-ETA scores are generally lower, entity awareness does show marginal improvements across Italian, Arabic, and French, though the gains are not consistent across all languages.

In summary, the results highlight the effectiveness of entity-aware translation in improving multilingual translation quality, particularly in transformer-based generative models like GPT-4o. While both models benefit from entity incorporation, the gains are significantly more pronounced in autoregressive generative models than in encoder-decoder models like NLLB-200. This underscores the importance of integrating named entity tagging as an auxiliary signal, especially in settings where entity fidelity and factual grounding are critical.

7 Conclusion

This study explored the impact of entity-aware translation on multilingual machine translation performance using both GPT-based models (GPT-4o

System	AR	DE	ES	FR	IT	JA	KO	TH	TR	ZH	Avg
GPT-4o (without EA)	28.24	0.92	2.21	1.5	32.97	31.15	28.85	0.09	9.21	0.12	13.52
GPT-4o (with EA)	29.29	24.03	34.54	27.89	26.09	30.15	25.9	6.12	28.55	0.12	23.26
Fine-tuned NLLB-200 (without EA)	15.6	21.77	22.32	27.03	22.32	8.89	-	-	-	-	11.61
Fine-tuned NLLB-200 (with EA)	19.39	19.87	21.02	21.20	26.26	8.73	-	-	-	-	11.64

Table 4: M-ETA score of different methods on the task across different languages. Language codes: Arabic (AR), German (DE), Spanish (ES), French (FR), Italian (IT), Japanese (JA), Korean (KO), Thai (TH), Turkish (TR), and Chinese (ZH).

and GPT-4o-mini) and the fine-tuned NLLB-200 model. Our results demonstrate that incorporating explicit entity information significantly enhances translation quality in GPT models. The models exhibited particularly strong gains in languages with rich named entity structures, such as Spanish, French, and German. In contrast, the NLLB-200 model showed only marginal improvements, indicating that while it may implicitly learn entity representations, it does not benefit substantially from direct entity injection using the current architecture.

These findings highlight the suitability of GPT-style autoregressive models for prompt-based entity-aware enhancements, whereas encoder-decoder architectures like NLLB-200 may require structural changes to leverage entity information more effectively.

For GPT-based models, future research could explore advanced prompting strategies, such as multi-turn dialogue prompts, chain-of-thought reasoning, or contextual expansion around named entities. Additionally, integrating retrieval-augmented generation (RAG) or few-shot in-context learning using entity-rich examples could further boost translation fidelity.

For NLLB-200 and similar encoder-decoder models, future work may focus on architectural enhancements, such as entity-aware attention mechanisms, adapter layers for entity embedding, or multi-task learning frameworks that jointly train on translation and NER objectives. In conclusion, this work emphasizes the importance of integrating structured entity knowledge into multilingual translation systems and opens up promising directions for enhancing translation quality in low-resource and entity-rich contexts.

clujteam at SemEval-2025 Task 10: Finetuning SmolLM2 with Taxonomy-based Prompting for Explaining the Dominant Narrative in Propaganda Text

Anca Marginean
Technical University of Cluj-Napoca, Cluj-Napoca, Romania
anca.marginean@cs.utcluj.ro

Abstract

XAI has been a long-standing goal of AI. Explaining why a text can be considered to have a dominant narrative, where the narrative is known, is of great importance for dealing with propaganda in the news. This paper reports on the participation of the system *clujteam* in Subtask 3 of Task 10 of Semveal 2025. The system obtained 7th place with a value of 0.72464 for F1macro, at 0.026 distance from the 1st place. The key components of the solution are the given taxonomy for the narratives and supervised fine-tuning of SmolLM2.

1 Introduction

Unfortunately, propaganda detection has become a crucial task in today's world. Understanding the dominant narrative and subnarratives, as well as identification of the different roles an entity can play, are two key aspects of propaganda identification.

Task 10 of Semeval 2025 (Piskorski et al., 2025), *Multilingual characterization and extraction of narratives from online news*, introduces 3 main subtasks in five languages: Entity Framing, Narrative Classification, and Narrative Explanation. This paper reports the results obtained by the system *clujteam* in the official competition for Subtask 3 in English. Additionally, post-competition experiments are reported for Subtask 1.

2 Background

Subtask 2 and 3 of Task 10 propose a taxonomy of narratives and subnarratives for two important topics for the online news: Ukraine-Rusia War (URW) and Climate Change. For each narrative and subnarrative, the taxonomy includes a definition for the relevant statements, instructions for the annotators, and possible examples. Figure 1 presents the narratives and subnarratives for URW topic. It can be observed that some subnarratives have quite similar meanings.

Subtask 3 is framed as a text-generation task where the input is a news text and a dominant narrative, and in some cases, the dominant subnarrative. The expected text must capture the explanation for having this subnarrative/narrative as the dominant one from the taxonomy. The evaluation relies on *bertscore* and the primary metric is *F1macro*.

3 System overview

Our solution for Subtask 3 is based on supervised fine-tuning (SFT) of a small language model using the data provided in the competition. Specifically, we use SmolLM2 1.7B-Instruct and 360M-Instruct (Allal et al., 2025), which offer a favorable balance between model size and performance.

3.1 SFT parameters

For SFT, we use the library trl[1] (Transformer Reinforcement Learning) from huggingface. The SFT on the 360M model was done on GPU 3090 (24GB) with $batch\_size = 4$ and $gradient\ accumulation\ steps = 4$. The used optimizer is *adamw_torch*. Differently, the SFT for the 1.7M model was done on 4 Nvidia V100 (32GB), with $batch\_size = 1$ per device, $gradient\ accumulation\ step = 2$. To reduce the GPU memory required by the 1.7B model, we changed the optimizer to *adamw_8bit* from *bitsandbytes* library, and we used mixed precision $fp16$. For both models, the learning rate was $2e-5$ and the number of epochs was 3. The parameters for the text generation were maintained consistently throughout all the experiments.

In terms of training data, we used 203 examples from the competition *training* set, while the 30 examples from the competition dev set were used for validation. The official *test* set of the com-

[1] https://huggingface.co/docs/trl/en/index

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2395–2399

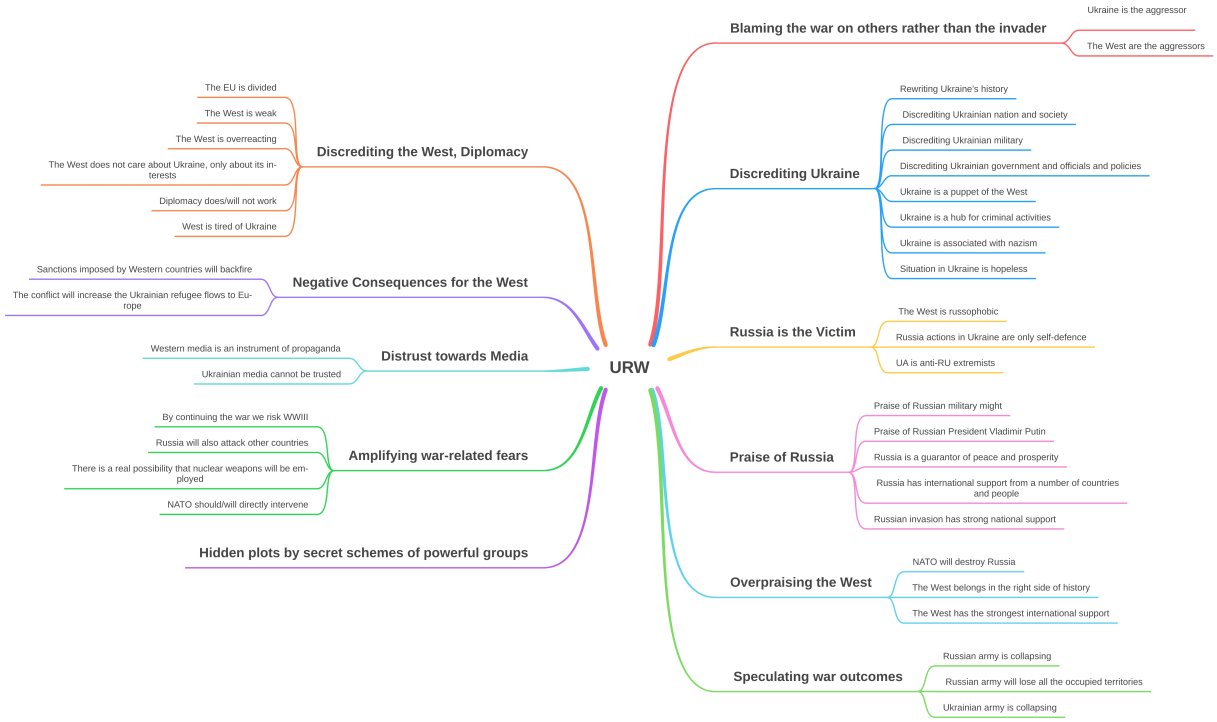

Figure 1: Ukraine War label taxonomy

petition includes 68 examples. We can observe that the training dataset is extremely small, yet the SFT works mainly because the SmolLM2-instruct models support tasks such as text rewriting and summarization.

3.2 SFT dataset preparation

Our SFT for Subtask 3 is done with distinct system and user prompts. In the prompts, square brackets [] indicate optional elements, while curly braces represent variables.

The user prompt includes the given text, the main narrative, and, if present, the subnarrative:

```
User prompt:

###News Text:
{content}

###Main narrative:
{main narrative}
[###Subnarrative
{subnarrative}]
```

For the system prompt, we experimented with two versions. One that is general for all the examples, respectively, one that is customized according to the given subnarrative (narrative). For the latter, we extracted the *Definition* of the subnarrative/narrative from the given Narrative-taxonomy. If the subnarrative is given, its definition is added at the end of the system prompt, otherwise, the *Definition* is taken from the narrative. Table 1 includes examples of such definitions for some narratives from URW and CC topics, respectively, for some URW subnarratives.

```
System prompt:

You understand propaganda in news about
Ukraina-Russia War and Climate Change,
and you know how to explain why a text
has as its main narrative a given one.

You get a news text and its main narra-
tive. In some cases, you also get a
subnarrative.
Generate a very brief explanation of the
 main narrative. The explanation MUST be
 grounded in text fragments that provide
 evidence for the given narrative's
claims. The evidence can only include
facts and opinions from the given text.

[Taxonomy-dependent part
In order to build the explanation,
analyze the {taxo[subnarrative] if
subnarrative else taxo[narrative]}].
```

4 Results

In the official leaderboard of Subtask 3 of Task 10, our system *clujteam* is positioned in the 7th place with a value of 0.72464 for F1macro. The best system obtained a value of 0.75040.

As expected, the SmolLM2 1.7B obtained the best results, even though mixed precision is used

Domain	Narrative/Subnarrative	Definition included in the taxonomy
		Narrative Definitions
URW	Blaming the war on others rather than the invader	statements attributing responsibility or fault to entities other than Russia in the context of Russia's invasion of Ukraine.
URW	Discrediting Ukraine	statements that undermine the legitimacy, actions, or intentions of Ukraine or Ukrainians as a nation.
CC	Scientific community is unreliable	statements discrediting scientists, the scientific community and their actions.
CC	Controversy about green technologies	statements that express skepticism or criticism of environmentally friendly technologies.
		Subnarrative Definitions
URW	Ukraine is the aggressor	statements that shift the responsibility of the aggression to Ukraine instead of Russia and portray Ukraine as the attacker.
URW	The West are the aggressors	statements that shift the responsibility for the conflict and escalation to the Western block.
URW	Ukraine is a puppet of the West	statements that claim that Ukraine is controlled or heavily influenced by Western powers, particularly the United States and European Union.

Table 1: Examples of Definitions included in the taxonomy-dependent system prompt. Observation: only the Definition for the given narrative/subnarrative is included in the prompt.

dataset	model version	system prompt	Precision	Recall	F1-macro
dev	360M	taxo-dependent	0.713	0.706	0.709
test	360M	taxo-dependent	0.703	0.709	0.706
dev	360M	taxo-independent	0.712	0.710	0.712
test	360M	taxo-independent	0.707	0.716	0.711
dev	1.7B	taxo-dependent	0.731	0.718	0.725
test	1.7B	taxo-dependent	**0.723**	**0.726**	**0.725**
dev	1.7B	taxo-independent	0.721	0.715	0.718
test	1.7B	taxo-independent	0.709	0.715	0.712

Table 2: Results for Subtask3 in Semeva2025 Task 10

compared to the 360M model, and an 8bit optimizer is used. Due to hardware limitations, SFT of 1.7B model was not possible with 32bit precision. Table 2 presents Precision, Recall, and F1Macro for different experiments. We report both the values on the *dev* and *test* set.

The first observation is that the 360M model performance is not significantly lower than that of the 1.7B model. When comparing the performance of the 360M model to that of the 1.7B model, it's important to note that the SFT for the larger model was conducted using mixed precision and an 8-bit optimizer.

The second observation is that the 360M model achieves acceptable performance despite the limited size of both the training dataset and the model itself. This is justified by the fact that all versions of SmolLM2 are prepared for text summarization and rewriting.

The third observation is that the taxonomy-dependent prompt does not improve the performance of the 360M model, but rather slightly the opposite. We can just assume that this is due to the size of the model and the increased length of the system prompt. The 360M model obtained better performance when the taxonomy-independent prompt is used, at least according to the used metrics that rely on Bert score. Nonetheless, the text generated by the models that use the taxonomy-dependent prompt is more meaningful.

The fourth observation, and the most important in our view, is that the taxonomy-dependent prompt

increases the performance for the 1.7B model. The model using taxonomy-dependent prompts is significantly more precise than the one with a general prompt (0.723 vs 0.709 on the *test* set).

The fifth observation is that even though the metrics do not show a significant difference between the quality of the SFT with the taxonomy-dependent prompt compared to SFT with the independent one, the generated text tends to be more meaningful when the Definition of the narrative statements is included. For example, the following text is generated by the taxonomy-dependent model: `The text suggests that the climate agenda has hidden motives, such as depopulation and population control. The author argues that the climate agenda is a tool for globalists to control the population and implement their plans for a one-world government. The text also criticizes the media.` The Taxonomy-independent model explains the dominant narrative of the same text with: `The text discusses the climate agenda and its hidden motives. The text also talks about the agenda of powerful groups and their hidden plots. The text also talks about the agenda of the powerful groups and their hidden motives.`

5 Post-competition experiments

In this section we describe our post-competition experiments for Subtask 1 using the same SFT on SmolLM2. The input for Subtask 1 is a news article and a list of entity mentions; it is required to classify the role and the subrole of the given entities using a predefined taxonomy of fine-grained roles. The subrole is not unique, so it is a multilabel classification. The same entity mention can occur several times in one text, not necessarily with the same role or subrole.

5.1 Single-step classification of all entity mentions

One approach for this subtask was to use SmolLM2 to generate the fine-grained roles for all the entity mentions in a single step. In our user prompt, we inserted special tags $\langle start\_entity\_i \rangle$ before and $\langle end\_entity\_i \rangle$ after each given entity mention to clearly delineate them. The expected output is a json object structured as a list of objects made of $entity\ number$, $entity$, and $entity\ role$. The first part of Figure 2 includes the used system prompt.

For clarity, we give here an example of the user prompt for the single-step classification of all entities:

```
Pence calls viral clip suggesting he
cares more about Ukraine than US 'fake
news'
Former Vice President  <start_entity_1>
Mike Pence <end_entity_1> fired back on
social media after ....
In the video, former Fox News host
Tucker Carlson questions the 2024
Republican presidential candidate about
where his priorities lie after Pence
criticizes the length of time it has
taken the <start_entity_2> Biden
administration <end_entity_2>  to provide
 <start_entity_3> Ukraine <end_entity_3>
 with weapons to fend off Russia's
invasion of the former Soviet state.
```

5.2 Additional task of independent classification of each entity mention based on a chatGPT extracted summary

Since the resulting training set is small, we considered an additional task for SFT of SmolLM2: given a list of actions associated with only one entity, the model needs to return a list of fine-grained roles. The system prompt used in SFT for this additional task is included in the second half of Figure 2.

The samples for this additional subtask are obtained from the Subtask 1 data by using chatGPT 4o:

User prompt is similar to the single-step classification (each entity mention is marked out with special tags).

System prompt: *You are given a text where entities are enclosed between the tags <start_entity_number> and <end_entity_number>. For each entity, identify its actions and summarize the key information associated with it, focusing primarily on the surrounding context. Ensure the summary is concise, capturing the most relevant details related to the entity's role and actions in the text.*

Example of relevant types of actions: - Protects values, communities, or individuals from harm. - Upholds justice and ensures safety. - Takes on leadership roles (e.g., law enforcement, soldiers, community leaders). ....

Present the output in JSON format, with each entity as an object containing: - entity: The name of the entity. - entity number: the number of the entity. - summary: A list of the entity's actions, significance, or other important characterizations

```
System prompt for single step classification of all entities:
You are given a text where entities are enclosed between the tags <start_entity_num-
 ber> and <end_entity_number>.
For each entity, identify its role or roles.  The possible roles are
{list of fine-grained roles from the given taxonomy}.

Present the output in JSON format, with each entity as an object containing:
- entity: the name of the entity.
- entity number: the number of the entity.
- roles: one or more roles from the given list.
Ensure the response uses only information extracted from the given text.
```

```
System prompt for independent classification of one entity:
You are given an entity and a text describing the actions or views of that entity.
Your task is to classify the entity's behavior based on the following roles:
{list of fine-grained roles from the given taxonomy}.
Assign one or more of these roles to the entity based on the given text.
Return only the identified roles as a comma-separated list without any additional
text or explanation. If no role applies, return 'None'.
```

Figure 2: System prompts for Subtask 1: the single-step prompt was employed to classify all entity mentions at once, while the independent classification prompt considered each entity separately based on a summary of its actions.

	EMR	microP	macroR	microF1	Acc main role
v1	0.264	0.287	0.260	0.270	0.824
v2	0.319	0.382	0.340	0.360	0.890

Table 3: Subtask 1 results on *dev* set for SmolLM2 1.7B trained on: (*v1*) single-step classification vs (*v2*) single-step classification & independent

of the entity (e.g. pedophile, terrorist, martyr, ..).

Ensure the response remains precise and contextual and uses only information extracted from the given text.

5.3 Experiments and results

We run three types of experiments: *v1* - SmolLM2 is trained exclusively with samples of single-step classification; *v2* - SmolLM2 is trained on a combination of both single-step classification samples and independent classification; *v3* - SmolLM2 is trained on the data from the *v2* experiment, to which the samples from Subtask 3 are added.

The best result on the test set obtained by our system *clujteam* for Subtask 1 in the Post-competition Leaderboard is: $Exact\ Match\ Ratio = 0.2894$, $microP = 0.3447$, $macroR = 0.3057$, $microF1 = 0.3240$, $Accuracy\ main\ role = 0.8638$. It was obtained for SmolLM2 1.7M trained in mixed precision on v3. For this subtask, the differences in performance between SmolLM2 360M and 1.7B are more significant, even when we compare 32-bit precision for the small model to mixed precision for the larger model.

6 Conclusions

The paper describes the participation of *clujteam* system at Subtask 3 of Semeval Task 10. Our experiments indicate that taxonomies defined for the narratives and subnarratives play a key role in obtaining a model that generates precise explanations in resource-constrained settings.

Abstract

This paper presents our system, Homa, for SemEval-2025 Task 5: Subject Tagging, which focuses on automatically assigning subject labels to technical records from TIBKAT using the Gemeinsame Normdatei (GND) taxonomy. We leverage OntoAligner, a modular ontology alignment toolkit, to address this task by integrating retrieval-augmented generation (RAG) techniques. Our approach formulates the subject tagging problem as an alignment task, where records are matched to GND categories based on semantic similarity. We evaluate OntoAligner's adaptability for subject indexing and analyze its effectiveness in handling multilingual records. Experimental results demonstrate the strengths and limitations of this method, highlighting the potential of alignment techniques for improving subject tagging in digital libraries.

1 Introduction

Libraries are the heart of every society and a cornerstone of education, serving as repositories of human knowledge and cultural heritage. As information landscapes evolve, these institutions must adapt to the growing volume and complexity of digital resources. Therefore, technological innovation in both traditional libraries and modern digital library systems is essential to optimize workflows, enhance accessibility, and improve resource organization. With the rapid advancement of artificial intelligence (AI), particularly through Large Language Models (LLMs) (Chang et al., 2024), there is an increasing need to integrate these technologies into library systems (Cox and Tzoc, 2023). LLMs offer capabilities in natural language understanding (NLU), knowledge retrieval, and automated categorization, making them valuable tools for subject tagging, metadata enrichment, and semantic search (Kasneci et al., 2023). By leveraging LLMs, libraries can enhance cataloging efficiency, improve interoperability with controlled vocabularies such as the Gemeinsame Normdatei (GND) (German National Library, 2025) librarian collections, and enable more precise and context-aware information retrieval.

Despite these advantages, integrating AI-driven solutions into library workflows presents challenges, including model interpretability, bias in automated tagging, and multilingual processing. Addressing these issues requires developing robust frameworks that balance AI-powered automation with human oversight. LLMs4Subjects (D'Souza et al., 2025a) is the first shared task of its kind organized within SemEval-2025, challenging the research community to develop cutting-edge LLM-based solutions for subject tagging of technical records from Leibniz University's Technical Library (TIBKAT). The participants are tasked with leveraging LLMs to tag technical records using the GND taxonomy. The bilingual nature of the task is designed to address the needs of library systems that often involve multi-lingual records. Given these motivations, the LLMs4Subjects shared task consist of the following two tasks: **Task 1 – Learning the GND Taxonomy** – Incorporating the GND subjects taxonomy, used by Technische Informationsbibliothek (TIB) experts for indexing, into LLMs for subject tagging to enable LLMs to understand and utilize the taxonomy for subject classification effectively. **Task 2 – Aligning Subject Tagging to TIBKAT** – Given a librarian record, a developed system should recommend GND subjects based on semantic relationships in titles and abstracts.

Ontologies are a key building block for many applications in the semantic web. Hence, ontology alignment, the process of identifying correspondences between entities in different ontologies, is a

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2400–2406

critical task in knowledge engineering. To this end, OntoAligner (Babaei Giglou et al., 2025; Giglou et al., 2025a) is a comprehensive modular and robust Python toolkit for ontology alignment built to make ontology alignment easy to use for everyone. Inspired by this vision, we adapted its technique for Subject Indexing, where we formulated a dataset into the input data structure of OntoAligner and used the retrieval-augmented generation (RAG) technique to assess the OntoAligner capability in downstream tasks such as subject tagging. The experimental setting in this work plays a case study to analyze OntoAligner behavior toward how much it can be flexible and accurate for subject indexing and what are the bottlenecks.

2 Related Work

Subject indexing in library systems has evolved to balance precision and adaptability, incorporating controlled vocabularies, social tagging, ontology-based indexing, and hybrid approaches. Controlled vocabularies, such as the Library of Congress Subject Headings (LCSH), provide structured access to resources but require substantial intellectual effort to maintain consistency (Ni, 2010). While LCSH has expanded through cooperative contributions, it faces criticism for outdated terminology and limited flexibility (Pirmann, 2012). Social tagging, introduced with Web 2.0, allows users to generate metadata, enhancing discoverability and personalization (Gerolimos, 2013; Ni, 2010). However, its effectiveness in library systems remains inconclusive, with studies suggesting that while tags aid browsing, they lack the specificity of controlled vocabularies (Rolla, 2009; Pirmann, 2012). Ontology-based indexing enhances retrieval accuracy by linking text to structured semantic concepts, addressing limitations of traditional keyword-based indexing (Köhler et al., 2006). Hybrid models integrating these approaches are increasingly advocated. Tags can supplement subject headings rather than replace them (Gerolimos, 2013), as seen in implementations like BiblioCommons (Ni, 2010). However, usability challenges persist, particularly in supporting tag-based searches within catalog interfaces (Pirmann, 2012). This evolving landscape underscores the need for innovative indexing solutions that combine structured control with user-driven flexibility.

3 Methodology

In this study, we employ the OntoAligner library (Giglou et al., 2025b,a; Babaei Giglou et al., 2025) – a Retrieval-Augmented Generation (RAG) pipeline – to align technical records from the TIBKAT for Subject Indexing tasks. This task involves generating relevant subject suggestions that accurately reflect the content of a given technical record. The RAG pipeline is designed to handle multilingual, hierarchical data, ensuring that metadata and semantic relationships within the records are preserved for efficient retrieval. Our proposed methodology consists of two main components: 1) OntoAligner Pipeline, and 2) Fine-Tuning.

3.1 OntoAligner Pipeline

1) Data Representation. To align the technical records with the target subjects, we explore multiple levels of information from the records for representation of input data: 1) *Title-based Representation*: We start by using the titles of the technical records, capturing the most concise representation of the content. 2) *Contextual Representation*: We enhance the alignment by incorporating additional metadata, such as abstracts and descriptions, providing deeper context for each record. 3) *Hierarchical Representation*: For records with hierarchical relationships, we include parent-level metadata, enriching the alignment by reflecting the structural relationships within the ontology. These varied representations ensure that both the content and the structural relationships within the records are leveraged to accurately map to relevant subjects.

2) Retrieval Module of OntoAligner. We employ Nomic-AI embedding models (Nussbaum et al., 2024) to generate dense embeddings of the technical records and their corresponding subjects. These embeddings are used to retrieve the top-k most relevant subjects for each record by computing cosine similarity between the record's embedding and the embeddings of potential subjects. We configure the top-k to 30 subject tags.

3) LLM Module of OntoAligner. The LLM module in OntoAligner leverages advanced language models to enhance the alignment process. This module utilizes Qwen2.5-0.5B (Yang et al., 2024) to interpret and align complex ontological concepts effectively. By integrating LLMs, OntoAligner can process natural language descriptions and context, facilitating more accurate alignments. After retrieving the top-k relevant candidates for indexing a

given librarian record, the LLM evaluates whether each subject is a suitable match or not. This approach follows a RAG paradigm, seamlessly integrating ontology matching within OntoAligner.

3.2 Fine-Tuning

Within prior experimentation on three types of input representation – title, contextual, and Hierarchical – using the development set and computational resource on hand, we preferred to move forward with *title-based* input representation. In the following, we will discuss the details for retriever and LLM model finetunings.

Contrastive Learning for Retrieval Model. To fine-tune the retriever module, we constructed a Semantic Textual Similarity (STS) (Majumder et al., 2016; Giglou et al., 2023) dataset. The records were then paired with their ground truth subjects, assigning a similarity score of 1 for correct pairs. To introduce contrastive learning, we randomly selected negative samples—subjects not associated with the record—and assigned them a similarity score of 0. This resulted in a balanced dataset with *32,952* sentence pairs, ensuring the retriever learns to distinguish relevant subjects from irrelevant ones based on textual similarity. The limit of 600 pairs applied per record from the training set. This threshold is applied to reduce the number of training sets for the retriever module due to the computational resource limitation. The Table 1 represents examples of the obtained datasets for positive and negative pairs. We fine-tuned a sentence-transformer model (Reimers and Gurevych, 2019) (specifically `https://huggingface.co/nomic-ai/nomic-embed-text-v1`) using the Multiple Negatives Ranking Loss (Henderson et al., 2017). The model is fine-tuned for 3 epochs with a batch size of 32. The training process leveraged contrastive learning to distinguish between relevant and irrelevant subject pairs, optimizing the model to improve retrieval performance.

Case 2	14.02	23.39	16.33

Table 2: Quantitative and Qualitative results on TIB-Core-Subjects sets. The averaged metrics are reported.

Supervised Fine-Tuning of LLM. We followed a similar process as the retriever model fine-tuning, constructing the fine-tuning dataset with a limit of 200 pairs per record. This resulted in a total of *12,348* samples for supervised fine-tuning (SFT). Later, we fine-tuned a *Qwen2.5-0.5B-Instruct* LLM using QLoRA-based (Dettmers et al., 2023) SFT to adapt it for a classification task. The training involved processing the dataset into prompt-based inputs (we used the same as OntoAligner prompts described by Babaei Giglou et al. (2025)), where the model was tasked with determining whether the title and subject tag are match or not. The model was trained over 10 epochs using a batch size of 8, leveraging the Paged AdamW optimizer (Loshchilov and Hutter, 2017) with 8-bit precision for better computational efficiency. The fine-tuned model was then saved for further evaluation using the OntoAligner pipeline.

4 Results

4.1 Dataset

For evaluations, we use the TIB-Core-Subjects dataset, which comprises 15,263 technical records across five categories: Article, Book, Conference, Report, and Thesis, in both English and German. Language distribution includes 8,195 English records and 7,113 German records, ensuring a balanced multilingual evaluation. The dataset is split into 7,632 training samples, 3,728 test samples, and 3,948 development samples.

4.2 Quantitative Results

The Figure 1 and Figure 2 provide a comprehensive comparison of system performance across different languages, record types, and top-k candidates using quantitative metrics. Additionally, Table 2 summarizes the average precision, recall, and F1 scores for the quantitative results on the TIB-Core.

Recall Performance Across k Values. As we can see within Figure 1, the recall@k curves show

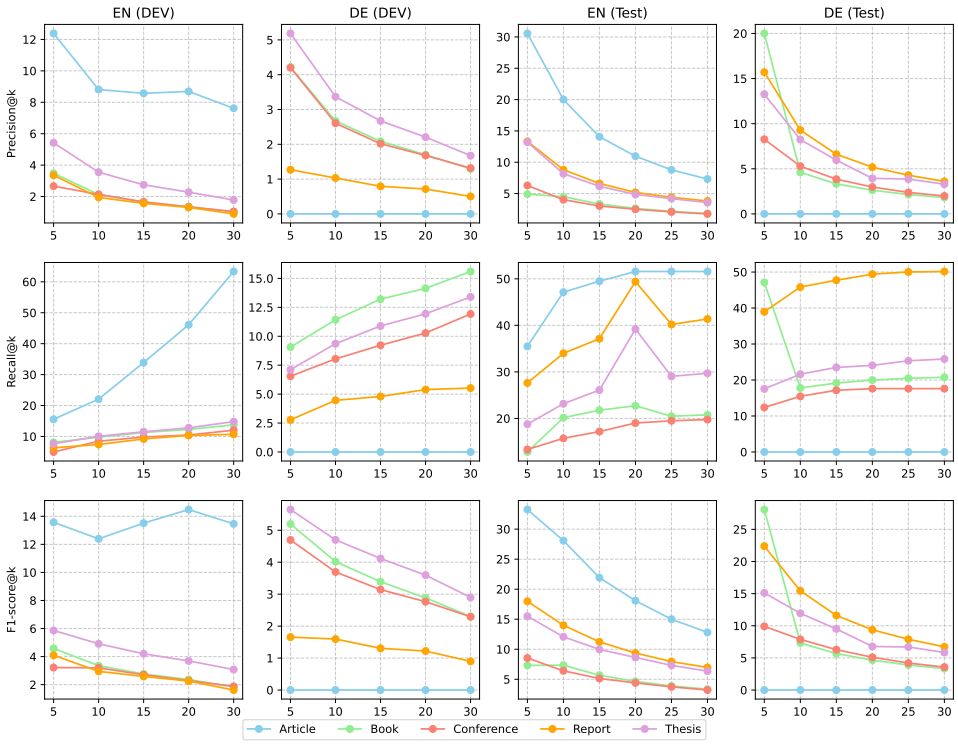

Figure 1: Results for development and test sets per language and record types.

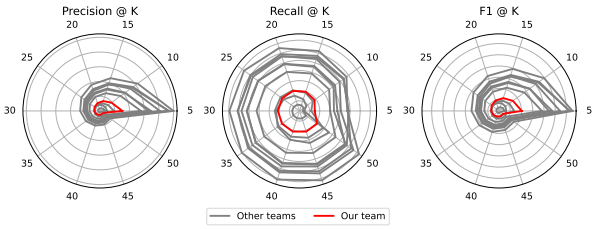

Figure 2: All the participant results on the test set.

a steady increase as k increases, with a notable jump beyond k=15. This pattern suggests that while initial ranked results contain relevant subjects, broader subject coverage improves at higher k values. The German language recall scores remain lower than English, likely due to richer training data or better linguistic resources embedded within LLMs.

Precision Trends Across Languages. The Precision@k at Figure 1 indicate that English consistently outperforms German across both the development and test sets. The English dev and test curves show higher precision values at all k values compared to their German counterparts. This suggests that the subject alignment model is more effective in English, reinforcing the earlier observation of language-based performance differences.

F1 Balance Between Precision and Recall. F1@k in Figure 1 demonstrates a balanced trade-off between precision and recall. The scores peak around k=15–20 before stabilizing, indicating an optimal range where subject retrieval achieves a balance between accuracy and comprehensiveness. Beyond k=20, recall gains do not significantly contribute to F1-score, meaning additional retrieved subjects may include more noise.

Performance Variation by Record Type. The Figure 1 shows that, among record types, *Articles* and *Books* show higher scores across all metrics, suggesting that these records have clearer subject assignments. In contrast, *Conference* and *Reports* records exhibit lower performance, likely due to ambiguous or overlapping subjects. This indicates a need for refined retrieval strategies for these document types and re-checking the ground truths for more clarity.

Impact of k Selection on Model Performance. The choice of k significantly impacts retrieval effectiveness. According to the Figure 2 and Figure 1, while lower k values (e.g., k=5) yield higher precision, increasing k enhances recall but at the cost of precision. The optimal balance is observed between k=15 and k=20, where models maintain strong performance without excessive subject list expansion. Furthermore, the distribution analysis of the number of subjects across both languages in

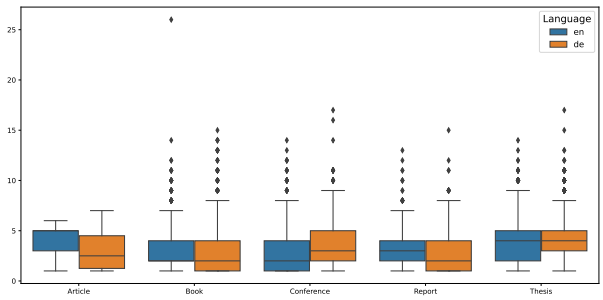

Figure 3: Distribution of number of subjects across categories using combined train and dev sets

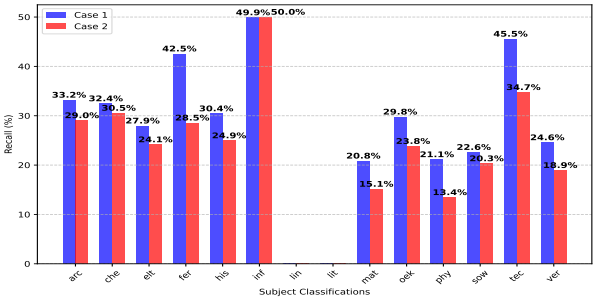

Figure 4: Recall analysis of qualitative results.

Figure 3 (combination of train and dev sets) indicates that the average number of records typically falls between 0 and 20 with mostly having an upper quartile Q3 of 5. This explains why the results for top-k values within this range vary according to the recall@k in Figure 2 for most participants.

System Performance Against Other Teams. The Figure 2 illustrates our system's performance compared to other teams across different top-k values. While precision differences are marginal, indicating similar ranking effectiveness among top models, the F1 trends show a balance between precision and recall, highlighting our system's capability in ranking relevant subjects effectively. Additionally, most teams achieved high Recall@5 but lower Precision@5 (with respect to the Figure 3 this is logical), suggesting that ranking quality is more crucial for retrieval improvements than the LLM module. This is evident in F1@5, where performance drops despite improved recall at k > 5.

4.3 Qualitative Results

The Figure 4 provides qualitative results for two case studies. Additionally, Table 2 summarizes the average precision, recall, and F1 scores for the qualitative results from two case studies.

Case 1 and Case 2 Comparison. According to the Table 2, the case 1: achieved the highest recall (24.26%) across all subject classifications, demonstrating that the system effectively retrieves relevant subjects. The F1-score of 20.06% suggests a balanced trade-off between precision and recall in this scenario, still affected due to the poor precision. However, case 2 exhibited a lower recall (19.55%) and F1-score (13.63%), indicating that the system struggled with certain subject categories, possibly due to more ambiguous or overlapping terms.

Performance Across Subject Classifications. Figure 4 further breaks down recall performance by subject classification for both case studies. The highest recall was observed in specific subject categories, such as "inf" (Informatics) – recall of 50.0% for case 1 and really of 49.9% for case 1– and "tec" (Technology) – recall of 45.5% for case 1 and recall of 34.7% for case 2 –, suggesting that the system performs well in well-structured domains with clear taxonomies. Moreover, the lowest recall of 13.4% was seen in categories like "phy" (Physics) for case 2 and lowest recall of 20.8% in "mat" (Mathematics), likely due to their abstract nature and overlapping subject boundaries. Finally, in Case 1, subject categories such as "fer" (Material Science) and "tec" (Technology) performed better compared to Case 2, highlighting the importance of context in subject alignment.

5 Limitation and Conclusion

The quantitative evaluation results in Table 2 indicate that, despite achieving a strong average recall of 20.30%, the model struggles with low precision. The low precision suggests that the system retrieves a broad set of candidate subjects, but many are not relevant. However, this is also evident in qualitative results for case-2 where the precision didn't reach the same level as recall. This limitation likely stems from the small fine-tuning dataset, suggesting that further fine-tuning could enhance performance, particularly for smaller LLMs. Additionally, OntoAligner's flexibility allows rapid pipeline construction by handling embedding storage, subject retrieval, and alignment efficiently. This enables users to focus solely on optimizing the LLM and retriever models, making it practical for subject indexing with minimal resource demands.

In this work, we explored OntoAligner as a case study for subject indexing, demonstrating its capability with minimal fine-tuning. The results highlight its effectiveness in aligning subjects, reinforcing its potential for real-world applications. However, further fine-tuning with additional computa-

tional resources and data is necessary to enhance its precision and overall performance for the subject indexing task.

Jim at SemEval-2025 Task 5: Multilingual BERT Ensemble

Jim Hahn [1,2]
[1]University of Illinois at Urbana-Champaign, School of Information Sciences, USA
[2]University of Pennsylvania, University Libraries, USA
jimhahn@illinois.edu

Abstract

The SemEval-2025 Task 5 calls for the utilization of LLM capabilities to apply controlled subject labels to record descriptions in the multilingual library collection of the German National Library of Science and Technology. The multilingual BERT ensemble system described herein produces subject labels for various record types, including articles, books, conference papers, reports, and theses. For English language article records, bidirectional encoder-only LLMs demonstrate high recall in automated subject assignment.

1 Introduction

SemEval-2025 Task 5 utilizes Large Language Model (LLM) capabilities to assign controlled subject labels to multilingual German and English record descriptions (D'Souza et al., 2025). BERT models, such as ModernBERT, are a natural fit for subject tagging (Warner et al., 2024). When trained as classifiers, such as in this submission, they are less prone to hallucination—a common challenge in generative AI models. The ModernBERT model provides improvements of increased context sequences of 8192 tokens, over prior limits of 512 tokens in the original BERT (Warner et al., 2024). Another advance in ModernBERT is the use of flash attention (Dao et al., 2022).

The emergent capabilities of LLMs are not fully explained by existing theories (Li et al., 2022). BERT utilizes a transformer architecture, but does not stack together transformers as in GPT models (Devlin et al., 2019). The research community has been able to empirically inspect why BERT works so effectively (Tenney et al., 2019; Rogers et al., 2020). Similar "mechanistic interpretability" is underway for LLMs, but is not nearly as mature as the understanding of BERT models (Sharkey et al., 2025).

The BERT ensemble developed for this task consists of four models: two multilingual BERT models, one German-only BERT model, and one English-only BERT model. All models were fine-tuned with data from the TIB Technical Library's Open-Access Catalog. See Table 1 for the model card links.

For the average recall measures in the quantitative leaderboard, the BERT ensemble ranked 7th out of 11 teams in the "All Subjects" task group. In the qualitative results, this system's highest ranking was 5th out of 13 teams. The BERT models do not mimic reasoning and cannot correct labels in the way current state-of-the-art reasoning models can, which puts purely BERT ensembles at a disadvantage. Future work will investigate combining BERT outputs with reasoning over the labels using advances in chain of thought (CoT). The code for training, testing, and inference is available on GitHub (`https://github.com/jimfhahn/SemEval-2025-Task5`).

Returning to the call to research and develop a system that could be used in practice, the system is fully reusable from the Hugging Face platform (`https://huggingface.co/`). Noteworthy for its open source hosting, the Hugging Face platform enables hosting of models and datasets and has useful inference capabilities for machine learning projects.

2 Background

The task to assign a subject to a work requires a target vocabulary. In this case, the GND vocabulary is paired with the title and abstract data from the TIBKAT collection (D'Souza et al., 2024). The language of the title and abstract was both English and German. To train the BERT models that encompassed the ensemble powering the core of the inference stack all provided data from TIBKAT are processed into JSONL format and were modeled using title and abstract text along with corresponding

DNB labels. The curated dataset is available on Hugging Face with an open source license (https://huggingface.co/datasets/jimfhahn/SemEval2025-Task5-Curated-Data).

While LLMs excel at a wide range of generative AI tasks, the specific task at hand is generating subjects, which falls under classification. Therefore, BERT models are well-suited to act as the core inference engine powering an LLM-based subject indexing system.

3 System overview

The Hugging Face software package "AutoTrain Advanced" was configured for training the component BERT models (Thakur, 2024). The input training data, sourced from the "All Subjects" folder provided by the competition organizers, was incorporated into the dataset. Additionally, the supplementary dataset, "DNB SKOS Exports of the GND," was subsequently incorporated to enrich the input data. A roughly 25/75 split was applied, allocating 78,800 rows to testing and 245,000 rows to training. This decision reflects the GND technical staff's acknowledged expertise in curating high-quality resources. A departure point for prior work in semi-automated subject indexing is to reference existing professional skills while extending professional expertise (Hahn, 2021, 2024).

The combined dataset is multilingual mixing in both German language training with English language text. For the training, the software was installed in a compute environment at the University of Illinois campus compute cluster where GPU hardware, NVIDIA A100 Tensor Core GPUs are available to be scheduled. Training time for the largest BERT models, including ModernBERT, was completed within ten hours.

The system employs an ensemble of BERT models to generate classification results. Refer to the Inference folder of the GitHub repository for the methods described herein (https://github.com/jimfhahn/SemEval-2025-Task5/blob/main/Inference/inference.py).

During inference, the `classify_text_batch` function processes input texts in batches. Each input is tokenized with truncation applied, followed by generating probability scores for all possible labels using the `torch.softmax` function.

The system then identifies the top n labels (default is 50) and their associated confidence scores using `torch.topk`. While the models are trained for single-label classification, this approach enables the generation of multiple subject labels for each input. To aggregate classification results from individual models in the ensemble, the `filter_and_aggregate` function combines confidence scores for each label across models, summing them to produce a single combined score. The system then retains the top 50 labels based on the highest accumulated scores. The `get_top_50_subjects` function finalizes the process by extracting and validating these top 50 labels for each input. By leveraging the probabilistic confidence scores, this pipeline adapts single-label models to a multi-label context, effectively simulating a multi-label classification system through confidence score aggregation.

4 Experimental Setup

The training of BERT models began with loading and processing the dataset from Hugging Face. Refer to the Train folder of the GitHub repository for the methods described herein (https://github.com/jimfhahn/SemEval-2025-Task5/blob/main/Train/train.py). The processing code filtered out underrepresented labels, ensuring that each label had at least two examples. Subsequently, the code split the dataset into training and validation sets for BERT, ensuring that all classes were represented in both sets. The AutoTrain Advanced software package included a default configuration to stop training if there was no improvement after 5 epochs, to prevent overfitting. The threshold for measuring the new optimum to continue training was set to 0.01 by default. It ensured that the training

Figure 2: The Settings for AutoTrain Advanced.

continued as long as the model's performance improved by at least 1% in each iteration. Figure 2 shows the settings of AutoTrain Advanced, as `TextClassificationParams` that were utilized to train each of the models on the curated dataset.

The AutoTrain Advanced software used Optuna for automated hyperparameter optimization (Akiba et al., 2019). In practice, two iterations of fixed learning rate settings (`lr=1e-5` and later `lr=3e-5`) were tested, with the latter yielding superior F1 scores during inference. Similarly, the trial and error included two batch size iterations in training. The initial tests used a batch size of 8, while the final, better-scoring model training parameters were trained using a batch size of 16. The BERT models were all trained as single-label classifiers where each input was assigned exactly one label.

5 Results

Recall@K was used as the central measure. Specifically, the average of Recall@K scores was used for the final leaderboard ranking of "Average Recall." According to the quantitative leaderboard, the Multilingual BERT ensemble ranked 7th out of 11 systems in the "All Subjects" category. See Table 2 for a selected set of metrics (K@50).

The system's performance on English language articles is noteworthy, as it was a standout in subject recall; the details are considered in section 5.1. Regarding the qualitative results, the system ranked 5th out of 13 systems in both Case 1 in Case 2. Detailed qualitative results are discussed in more detail in section 5.3.

5.1 Quantitative analysis

The "All Subjects" leaderboard was analyzed by record and by language. This analysis helps to identify where the BERT ensemble inference was most successful and where it was failing.

Record Type	Language	Recall
Article	de	0.2000
Article	en	**0.8329**
Book	de	0.5440
Book	en	0.5419
Conference	de	0.5165
Conference	en	0.5829
Report	de	0.5625
Report	en	0.4719
Thesis	de	0.4082
Thesis	en	0.3830

Table 2: K@50 by Record Type, Language, and Recall.

The system's standout performance was with English language articles. In the K@50 round, the system's recall for English language articles was 0.8329 of relevant subjects. Several teams in the competition had strong recall for this record type.

The BERT ensemble score of 0.8329 ranked sixth out of eleven scores for English language articles.

5.2 Why do English language article records have high recall?

An analysis was conducted on the readability of titles and abstracts in the English article record type, compared to other English language title and abstract records (Chall and Dale, 1995). Aggregated results, shown in Table 3, indicate that the title and abstract metadata from article records in the English training data is the least complex and most readable text among the record types, as evidenced by the lower Dale-Chall readability scores which indicate easier understanding. German language data was not evaluated for readability because the metric uses English language words.

Record Type	Average Readability	Record Count
Article	10.7815	1042
Book	11.5618	26966
Conference	12.5864	3619
Report	13.9757	1275

Report	13.5789	334
Thesis	12.7133	833

Table 4: Average Dale-Chall Readability Scores and Record Counts by Record Type in the English Test Data.

In both English and German, the BERT ensemble struggled the most with thesis record types. However, the readability of the training data does not seem to fully explain the difficulties with thesis records. An analysis of subject groupings per record type in the training data was instructive. Figure 3 shows the distribution of subject counts by record type in the English training data. Notably, there are outlier points beyond the outer limits of the plot, suggesting greater variability or the presence of extreme values in that record type.

Two indicators for why English language articles scored among the highest recall in the task are considered here. First, the training examples for English language articles had a more consistent number of subjects per record. In contrast, there was greater variability for Thesis and Book record types in English, which had higher subject counts. Two additional box plot figures highlight the nuanced scores of reading complexity in the training data (Figure 4) and the reading complexity of the title and abstract test data (Figure 5).

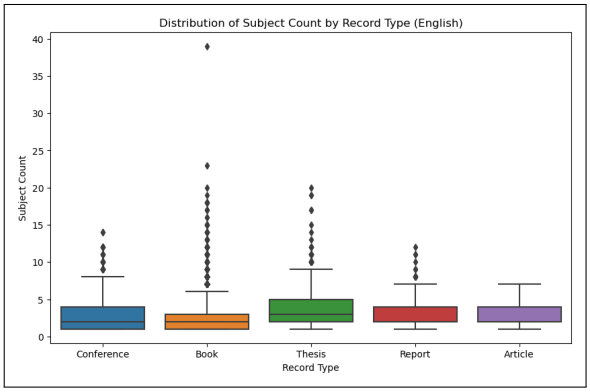

Figure 3: Subject Distribution in Training Data.

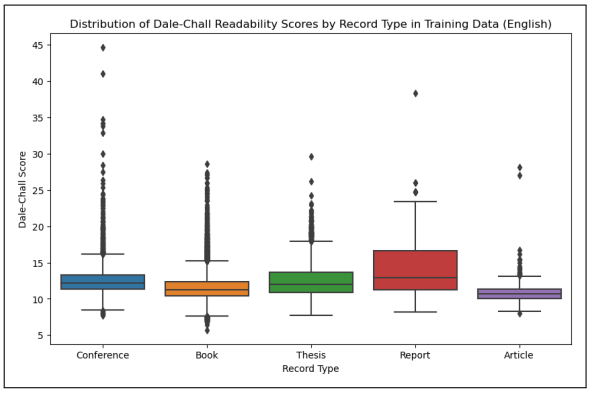

Figure 4: Readability Scores by Record Type in Training Data.

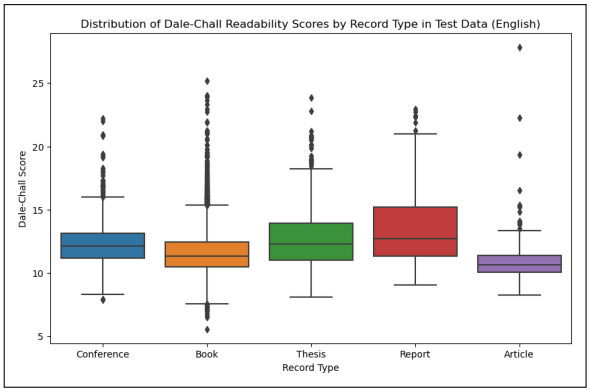

Figure 5: Readability Scores by Record Type in Test Data.

The thesis and report record types have both the most challenging readability and the lowest recall

scores by this system. When examining the scores for book and record types, which were the next two top-scoring record types for English language records, they have lower reading complexity. However, their subject distributions include a higher number of outlying values compared to article subject distributions.

This suggests that augmenting training data by rewriting abstracts for easier reading comprehension could result in performance gains at inference time. This represents a possible future use of generative AI in improving training. This needs more study particularly within those record types with a wide distribution of subjects. This analysis indicates that a lower incidence of wide subject distribution and lower complexity in abstract readability may improve recall scores.

5.3 Qualitative analysis

The highest qualitative performance, which was ranked 5th out of 13 teams, was scored by subject librarians at the TIB Technical Library. Scores are divided into two cases. In Case 1, a more expansive scoring criterion is used where both the correct keyword and irrelevant, but technically correct, subjects are considered correct. In Case 2, only correct subjects with no irrelevant subjects are scored as correct. The average of the qualitative recall scores in Case 1 (0.5263) was higher than the average score on the quantitative "All Subjects" leaderboard, which was 0.4686. However, in Case 2 (0.4258), the system did not surpass the average recall score of the quantitative leaderboard.

By design and by name, BERT is bidirectional, meaning that words are learned in context by looking both left and right. The recall performance in the results might be attributed to this bidirectional view of the training data, where the contextual notions of words are learned as part of the classification task. This idea also has theoretical grounding in the work of philosophers of language, such as Wittgenstein. In *Philosophical Investigations*, Wittgenstein theorized that context holds special importance to the meaning of words, specifically that the meanings of words are derived by their context (Wittgenstein and Anscombe, 2000). The notion of contextual relevance is particularly appropriate to consider in light of librarian scoring. Librarian expertise provides a valuable and necessary validation of the quantitative results of recall measures.

6 Conclusion

The system showed good performance in recall for English language articles. Evidence as to why these records are amenable to subject classification were considered. Specifically, an analysis of the subject distributions by record type and the readability or reading complexity of the record metadata was conducted. The system is completely portable from the Hugging Face platform. The ensemble models are all easily extensible into library systems, allowing experimentation to be taken into production without requiring extensive coding for adapting to local environments.

Abstract

The *LLMs4Subjects* shared task invited system contributions that leverage a technical library's tagged document corpus to learn document subject tagging, i.e., proposing adequate subjects given a document's title and abstract. To address the imbalance of this training corpus, team LA^{2}I^{2}F devised a semantic retrieval-based system fusing the results of ontological and analogical reasoning in embedding vector space. Our results outperformed a naive baseline of prompting a llama 3.1-based model, whilst being computationally more efficient and competitive with the state of the art.

1 Introduction

Motivation. To assist human librarians in cataloging documents with suitable subject tags from modern libraries' comprehensive subject indices (Turvey and Letarte, 2014), the SemEval-2025 shared task "LLMs4Subjects" (D'Souza et al., 2025) explores the feasibility of Large Language Model (LLM)-based automated subject tagging. The systems should exploit a human-tagged document corpus from the Leibniz University's Technical Library (TIBKAT) to learn subject tagging (Golub, 2021): Given a document's title and abstract as input, the system should propose the top-k best-matching subjects from the ontology Gemeinsame Normdatei[1] (GND) for both English (EN) and German (DE) documents.

Example Document 1

Title: Gender and creative labour
Abstract: Introduction – Sexism, segregation and gender roles – Flexibility and informality – Image-making and representation – Boundary-crossing – Notes on contributors

GND Subject Labels: Geschlechterforschung (gender studies); Künstler (artist); Kulturbetrieb (cultural sector)

[1] https://www.dnb.de/DE/Professionell/Standardisierung/GND/gnd_node.html

Example Document 1 from the training corpus illustrates the problem, showing the "ground truth" GND subject labels assigned by the librarians (original DE labels and their translations shown).

Approach. This paper describes the solution developed by the team of the *Laboratory of Applied Artificial Intelligence and Information Fusion* (LA^{2}I^{2}F), from the University of Udine, Italy, which focused on exploring novel ways to address the imbalance of the provided datasets, since highly specific subject terms typically are assigned to few documents only. Our *semantic retrieval-based information fusion system* combines complementary reasoning strategies in embedding vector space (Incitti et al., 2023): (i) an *analogical reasoning* branch proposing subject tags from the most similar documents in the training data (conceivable as case-based reasoning in vector space), and an (ii) *ontological reasoning* branch proposing subject tags from the GND based on their semantic similarity with the current document's title and abstract.

Results & Insights. While analogical clearly outperformed ontological reasoning, the *fusion* of both strategies yielded the best performance in our ablation study, surpassing a "naive" baseline of prompting an unmodified `llama 3.1:8B` model (Dubey et al., 2024) (thus agnostic of both the provided ontology and training data) which maps the extracted subjects to the GND via fuzzy string matching. Our solution achieves an average (avg.) *Recall* of **0.58** (rank $3/11$ across all submitting teams) on the reduced subject index *tib-core-subjects* and **0.48** (rank $6/11$) on the full index *all-subjects* in the task's quantitative evaluations. In the qualitative evaluation with human subject matter experts rating a sample of the proposed results, it obtained an avg. *Precision* of **0.43** on technically correct subjects, and **0.25** on correct and also relevant subjects (rank $8/13$ in both cases), demonstrating competitive performance compared to the state of the art assessed in (D'Souza et al., 2025).

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2413–2423

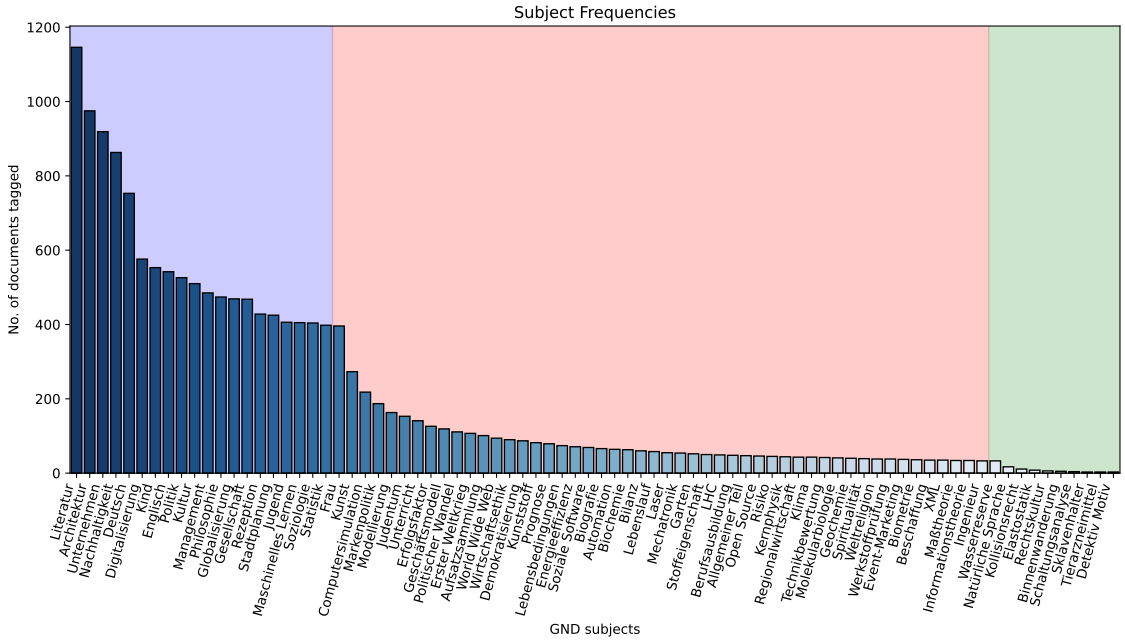

Figure 1: Ordered frequencies of subject terms. The blue shaded area represents the 20 most frequent subjects, the red and green one depict the following GND subjects sampled at sampling rates of 1:200 and 1:1000, resp.

2 Background

Data Sets. Document subject tagging is challenging for librarians due to the sheer size of the subject ontologies involved: For instance, the excerpt from the GND ontology, commonly utilized by German libraries, to be used for this shared task comprises more than 204K subjects, including additional information like their synonyms and description. Task participants should leverage a human-tagged document collection from TIBKAT for training their automated subject tagging systems, comprising five document types (article, book, conference proceedings, report, thesis) in two languages (EN and DE). This data has been split into a *development* (13666 documents) and a *training* set (81937 documents), both including the human experts' assigned GND subjects as ground truth labels, and the *test* data set (27986 documents) to tag. Task organizers made sure that the distributional characteristics between these splits were preserved.

Related Work. Fig. 1 outlines the frequency characteristics of the training corpus: While some – typically taxonomically "higher-level" – subjects have been assigned to a large number of documents, many subjects are fine-grained, specific descriptions assigned to very few documents only. Such imbalanced datasets – with sparse labels – render the training of Machine Learning (ML) classifiers challenging (Kaur et al., 2019). Typically, only very few examples will be available for the specific subject terms, while the learning process will be dominated by those few extremely frequent labels, such as the ones on the left-hand side of Fig. 1 and the subjects belonging to the most frequent macro classes in Fig. 4, like "Informatik (Computer Science)". Training an ML classifier to predict sparse labels from such a large set of possible labels is known as *eXtreme Multi-Label Classification* (XMLC) (Dasgupta et al., 2023). Document subject tagging thus typically has been framed as XMLC problem, as in related work like the system Annif (Suominen et al., 2022) developed for Finnish libraries. Processing multilingual data imposes further challenges, since linguistic variations can affect classification performance (Suominen and Koskenniemi, 2022). The improved Natural Language Understanding (NLU) capabilities of the recently introduced LLMs open up alternative solutions by converting this task into a text generation problem. However, LLMs introduce their own challenges, notably the question of how to constrain their outputs to the subjects indeed occurring in the GND (ultimately, the sought-after output needs to be given in terms of the appropriate GND ID), and moreover LLMs' limitations like the strong variance in their outputs with respect to minor variations in the prompt (Salfinger and Snidaro, 2024; Incitti et al., 2024), which we also found to be an issue in our experiments for this shared task.

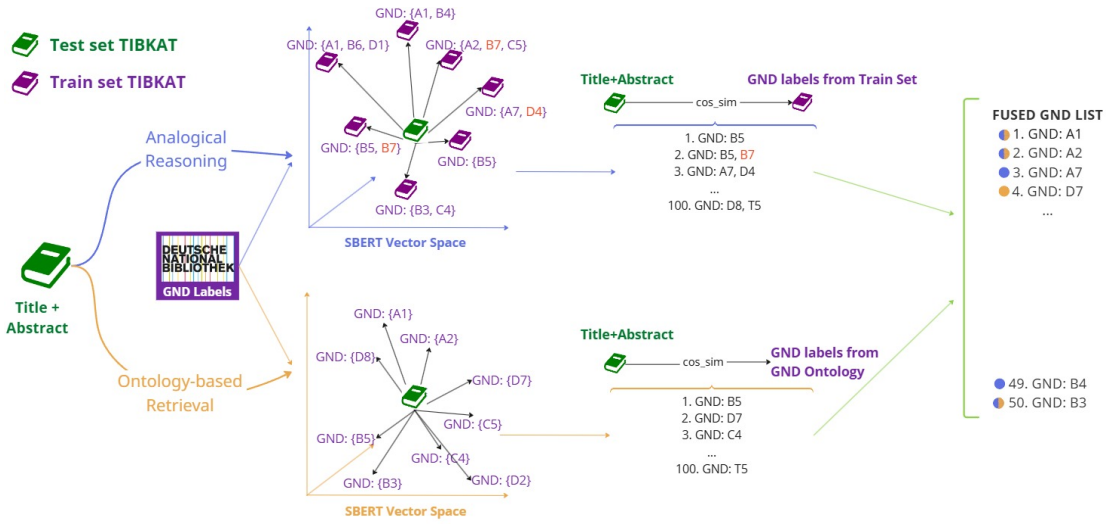

Figure 2: Processing architecture. For visualization purposes, we depict the two embedding vector spaces as 3D down-projections.

3 System overview

Motivation. Based on our insights gained from the data analysis, we aimed to address the imbalance and label-sparsity of the given datasets in a principled manner. Instead of formulating the problem as XMLC, as common in related work (see Sec. 2), we experimented with different reasoning strategies in the document and subject embedding space. These were motivated by the following findings, illustrated on Example Document 1:

1. The first GND subject label, "gender studies", could be inferred from the given title and abstract alone, with gender studies concepts concretely mentioned in the text.

2. Even for a human reader, it might not be easy to derive the other subject labels not explicitly mentioned in the text. Suitable subject tags thus could be inferred from librarians' reasoning on similar documents rather than relying solely on the text of the current document. This approach helps in identifying subject categories that are not explicitly mentioned (e.g., to link "creative labour" with the tags "artist" and "cultural sector"), which we frequently observed in the provided data.

We thus implemented both of these complementary reasoning strategies, as illustrated in Fig. 2 outlining our devised Information Fusion (IF) architecture, which we will describe in the following.

Embedding. For a given query document q (the document we seek to tag), we concatenate its title t and abstract a, forming our input text $q = [t\ a]$. We utilize the `all-mpnet-base-v2`[2] Sentence Transformer model based on MPNet (Song et al., 2020) – a multi-lingual model specifically designed for encoding sentences and paragraphs for tasks like semantic search and clustering – to map q into a 768-dimensional dense vector space. This Sentence Transformer model splits the input text into chunks fitting into its context window size, then converts each chunk into a numeric embedding vector. Finally, the mean vector is computed from these embedding vectors to form a single resulting vector space representation of q, which is then routed to two complementary "reasoning branches".

Ontological Reasoning. The *ontology-based retrieval* branch (lower half of Fig. 2) addresses finding 1., by assessing the semantic similarity of a document's title and abstract with the *subjects from the ontology*. To generate a semantic representation of the ontological concepts, we concatenate the GND subject term's name and its alternate names (such as synonyms or translations of these terms in other languages)[3] into a comma-separated list, which we map into the embedding vector space with the `all-mpnet-base-v2` Sentence Transformer model. This branch thus determines the semantic similarity between the query document q's title and abstract to all available subjects. It returns the $2k$ closest subject embeddings, which are taken as the list of $2k$ subjects returned from this branch. Hence, this

[2] https://huggingface.co/sentence-transformers/all-mpnet-base-v2

[3] Note that even more comprehensive embeddings could be created, e.g., by also including the GND descriptions or the explanations of linked Wikipedia articles, if provided. However, in our initial experiments on this, we did not find that including further information improved our results.

branch determines the *document-to-subject* similarities, and thus is purely driven by the semantic content and similarity of the query document's title and abstract with the given GND subjects.

Analogical Reasoning. Conversely, the *analogical reasoning* branch (upper row of Fig. 2) computes the *document-to-document* similarities. q's semantic similarity with *all other documents' titles and abstracts* is determined by computing the cosine similarity of q's and all training documents' embedding vectors. The rationale is that we expect documents on similar semantic content – irrespective of their titles'/abstracts' concrete textual surface forms (such as different synonyms utilized for referring to the same semantic contents) – to be mapped in the same sub-space of the embedding space, forming subject-oriented clusters. By embedding the query document q, we suppose that it will be mapped to the sub-space of topically related documents. Consequently, we assume that the subject tags assigned by domain experts to topically related documents from the training data will also be suitable for our query document q, and thus take the subject tags from the $2k$ most similar training documents as the output list of subject proposals from this branch, ranked according to their documents' similarity with q. More specifically, if document d is the closest training document to q in embedding space, we allocate its n assigned ground-truth subjects to ranks 1 to n of the resulting subject list. Since the shared task organizers clarified that the ground-truth subjects assigned to a document are not ranked, no order can be determined for the subjects *within* a document. We rank these subjects as listed in the training document, but the ordering between subjects from the same document thus can be considered random, which is reflected by all subjects stemming from the same training document sharing the same distance/similarity values. Next, the m subject labels from the second-closest training document are assigned to ranks $n+1$ to $n+m$, and so forth, until all $2k$ documents' subjects have been ranked. We then deduplicate the resulting ranked list by retaining only the first ranked occurrence of each subject (assuming that the order *across* the most similar documents matters – we assume that the earlier a subject appears, the more relevant it might be), eventually returning only the top-$2k$ ranked subjects. This strategy thus essentially implements *analogical reasoning* – or in other terms a form of *case-based reasoning in embedding space*: It identifies the most related documents from the human expert-labeled corpus under the assumption that subjects proposed for semantically similar documents will also be suitable subjects for q. Analogical inference hence allows to identify subjects not explicitly referred to in q's title and abstract, such as higher-level taxonomic subject descriptors assigned by the human domain experts. Such analogical reasoning appears thus suitable for emulating the experts' decision making in a case-based manner. This mitigates the problem of the skewed training data we observe in Fig. 1: No matter whether a document has a multitude or a limited set of similar instances in the training data – as long as *some* good examples do exist in the training data, this case-based reasoning will leverage only those for its subject inference, which thus does not get dominated by more frequent instances of other classes.

Fusion. A final *fusion* step combines the outputs retrieved from both branches: Both similarity-ranked lists are joined and re-ranked based on the *total order* of their elements' distances to q across both lists. Since the same embedding vector space, i.e., embedding model, is utilized in both branches, these distances are directly comparable. Again, duplicate subjects are removed, with only the first ranked occurrence being kept. This deduplication step is also the rationale behind the design decision of returning the top-$2k$ closest subjects from each branch, to ensure that at least k subjects are retained after deduplication and across-branch ranking. The top-k subjects of this ranked list are returned as the final result of k proposed subjects, ordered according to presumed relatedness to q.

4 Experimental setup

To estimate our models' generalization error and perform model selection, we created an internal validation split by sampling 10% of the provided training data, utilizing the remaining 90% for creating our models. This also allowed us to conduct ablation studies to measure the impact of the individual reasoning branches and the fusion approach. For producing our test set submission, we combined the provided training and development split for "training" our models, which in our approach only means embedding these corpora with `all-mpnet-base-v2`, utilized via the Sentence Transformers/SBERT framework (Reimers and Gurevych, 2019). Evaluation metrics comprise *Precision*, *Recall*, and *F1 measure* assessed for dif-

ferent cut-offs of top-k subjects[4]. In addition to the quantitative evaluation on existing *ground truth data* (which typically includes few ground truth subjects per document, usually 5-7 subjects), task organizers sampled 122 test documents across 14 subject classifications for the qualitative evaluation. The generated top-20 subject labels output by the participant systems then were marked by human subject matter experts as either *correct*, *technically correct but irrelevant*, or *incorrect* subject labels.

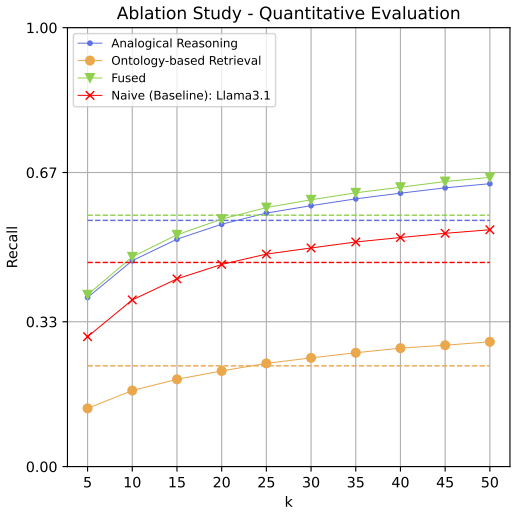

Figure 3: Ablation study comparing the individual branches, the naive baseline, and the fused results. Dashed lines represent the average values across the varied top-k values (solid lines).

5 Results

Ablation Study. Fig. 3 compares the individual performance of our two reasoning branches and the fusion approach on our own validation set. Analogical reasoning outperforms the naive baseline, and also the ontology-based retrieval branch by a large margin. Fusing the results of both branches – analogical reasoning and ontology-based retrieval – improves the metrics slightly further, suggesting that both branches extract complementary information, which is also backed by empirical evidence: Example Document 2 (document ID: 3A1649002734) shows one output from our IF system with subject predictions contributed from both reasoning branches. This highlights the feasibility of fusing the outputs of both ontological and analogical reasoning, which may retrieve complementary information. The curve of the fusion approach also surpasses the naive `llama3.1:8B`-based model, which presumably has more advanced NLU capabilities but does not incorporate the information from the ontology and the training data in its reasoning. Thus, fusing the outputs of simpler, domain-specific models – geared to the problem domain and focused on one specific reasoning approach at a time – is capable of outperforming a larger, generic and computationally far more costly model.[5]

Example Document 2

Title: Bone Densitometry in Growing Patients : Guidelines for Clinical Practice
Abstract: Focuses on the use of Clinical Densitometry in the pediatric and adolescent populations. This book, suitable for clinicians and technologists involved in the care of children and adolescents, provides expert-based guidelines to assist practitioners in performing dual-energy x-ray absorptiometry in younger patients and in interpreting the data.
GND Subject Labels: Kind (child); Osteodensitometrie (osteodensitometry);

Color coding: correct labels identified with
- ontological reasoning
- analogical reasoning

Quantitative Evaluation. Fig. 5 compares the performance obtained by our approach in the shared task's quantitative evaluation to other teams' submitted solutions. Our semantic retrieval-based reasoning fusion achieved an avg. *Recall* of **0.58** (rank $3/11$ across all submitting teams) on the reduced index *tib-core-subjects*[6], and **0.48** (rank $6/11$) on the full subject index *all-subjects*[7]. Since we employed the same model using the entire GND for submitting to both test collections, the strong performance on *tib-core-subjects* is particularly noteworthy, as limiting our predicted subjects to *tib-core-subjects* presumably would have further improved our results. Tables 1 and 3 present our language- and document type-level results, both revealing a superior performance of our model on English than on German texts. Table 2 shows the results we have obtained on our internal validation set used for model selection for *all-subjects*, in which we observe higher Recall for most document types.

Qualitative Evaluation. In the qualitative evaluation, where human subject matter experts rated a sample of the submitted test results, our IF approach obtained an average *Precision* of **0.43** on

[4] based on varying k from 5 to 50 (quantitative eval.) and from 5 to 20 (qualitative eval.), in increments of 5.

[5] On a GPU RTX A5000, avg. execution time (internal validation split): 'Analogical Reasoning': 0.32s, 'Ontology-based Retrieval': 0.74s, 'fused': 1.03s, 'Naive (Baseline): Llama3.1': 15.95s.

[6] min: 0.06, max: 0.66, $\mu = 0.41$, $\sigma = 0.2$

[7] min: 0.13, max: 0.63, $\mu = 0.44$, $\sigma = 0.17$

technically correct subjects[8] (case 1), and **0.25** on correct and also relevant subjects[9] (case 2), corresponding to rank $8/13$ in both cases (see Fig. 6 for a comparison to other teams' performance). Figs. 7 and 8 plot the obtained Recall, Precision and F1 measure of our approach for the different subject classes, according to the two cases analyzed. As expected, we observe a consistent trend across subject classes, with humanities' subjects like linguistics and history performing worse than the natural and technical sciences, which tend to use more specific custom terminology more directly related to their subject tags in their titles and abstracts, representing an easier inference problem.

Error Analysis & Future Work. As we see in Fig. 3, the IF approach is mostly driven by analogical reasoning: The final similarity ranking is dominated by document-document similarities, with similar embedded documents generally having smaller distances to q than its most similar embedded subjects. In general, even if the ontological branch retrieves a relevant subject in its top ranks, it thus may not appear at the same rank in the fused list. This is dissected in Fig. 9, depicting the fractions of subjects in the fused list proposed by the ontological branch (after fusion and de-duplication) on our *dev* set across different values of k. While we observe a low contribution *on average* (with a median of subjects from the ontological branch greater zero only for $k > 40$), the strong presence of outliers indicates that there are *specific documents* for which most and sometimes even all proposed subject labels originate from the ontological branch. Ontological retrieval complements analogical reasoning by allowing to handle novel documents which do not have good related "exemplars" in the training data yet, which thus could not be covered with analogical reasoning. In total, we observe that in 53.43 % of documents in the *dev* set, the ontological branch indeed contributes at least one subject label (irrespective of its correctness). However, for only 5.31 % of documents, ontology-based retrieval identified at least one ground truth subject, thereby increasing the performance of the fusion approach. Whilst this might appear low, we also find that in 28.17 % of documents, both branches retrieved duplicate labels, with one having been subsequently discarded by de-duplication (which is typically the lower-ranked ontological one). However, we note that a subject candidate simultaneously proposed by both reasoning branches actually would increase confidence in its relevance – for future work, we thus plan to factor this in by up-ranking such cases in the final fusion and re-ranking step.

Moreover, as illustrated by the GND IDs marked in red in Fig. 2, assuming that *all* subjects from similar documents fit q is a strong assumption which can lead to false positives, since this might not apply to *all* subjects from a similar document. This issue becomes evident in the comparably worse qualitative evaluation results, suggesting future work on further filtering the subjects output by the analogical branch.

6 Conclusion

Our proposed system explores innovative solutions to the challenging problem of document subject tagging: By operating in embedding space for identifying the semantically most similar documents and subjects, the corpus imbalance on the different subjects is not an issue: No matter whether a cluster/manifold is densely or sparsely populated, only the distances to the closest training documents and subjects are factored in. The relative frequency of documents per subject hence does not dominate or bias the "learning" process, unlike with training a neural network-based model with gradient descent or related ML classifiers. If the semantically closest document has similar contents and matching subject tags, those will be consistently proposed as the top-ranked subjects. Hence, our approach also corresponds to an interpretable and transparent strategy in terms of Explainable AI (xAI) (Longo et al., 2024). Since our model "training" only requires the embedding of the GND subjects and labeled training corpus, our approach is computationally efficient and suitable for "online learning" – if new labeled documents should be incorporated in the model, those only need to be embedded into the vector space, no "retraining" is required for dynamically growing the training corpus.

From the shared task's evaluations, we conclude that our semantic retrieval-based IF system is competitive with state-of-the-art XMLC approaches such as Annif, as comparatively evaluated in (D'Souza et al., 2025).

For future work, we aim to enhance our fusion by improving re-ranking, for instance by up-ranking results identified by both reasoning strategies.

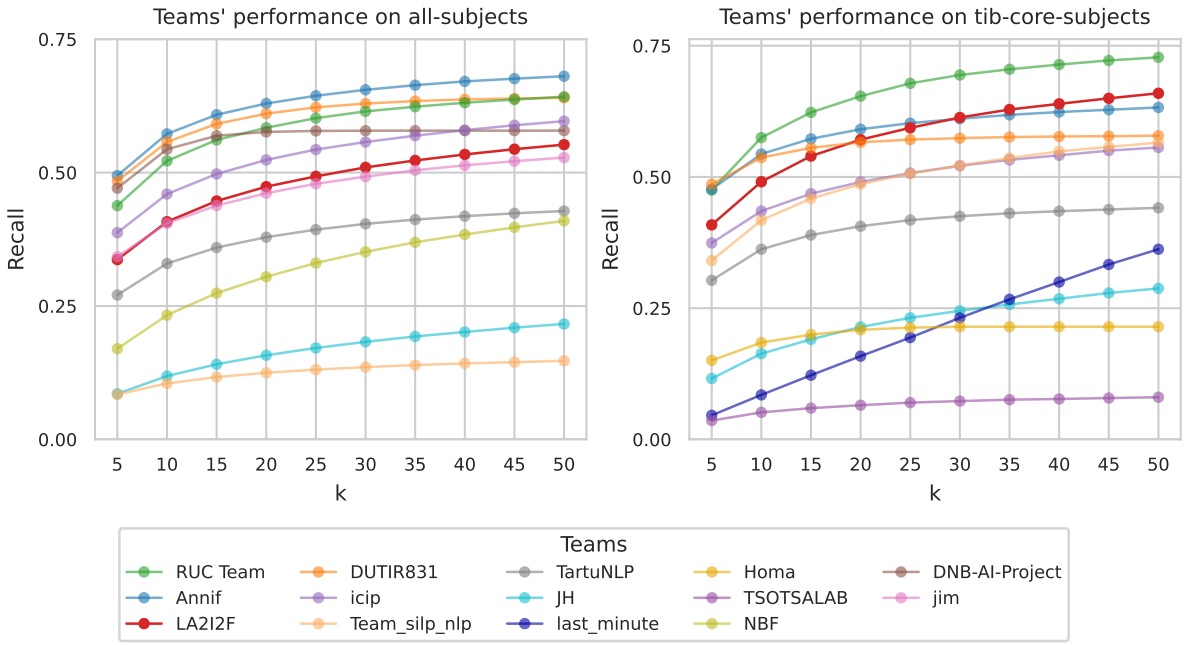

Figure 5: Performance comparison of our proposed approach (LA2I2F) to all other teams' submitted solutions for the quantitative evaluation. Note that not all teams submitted to both test collections.

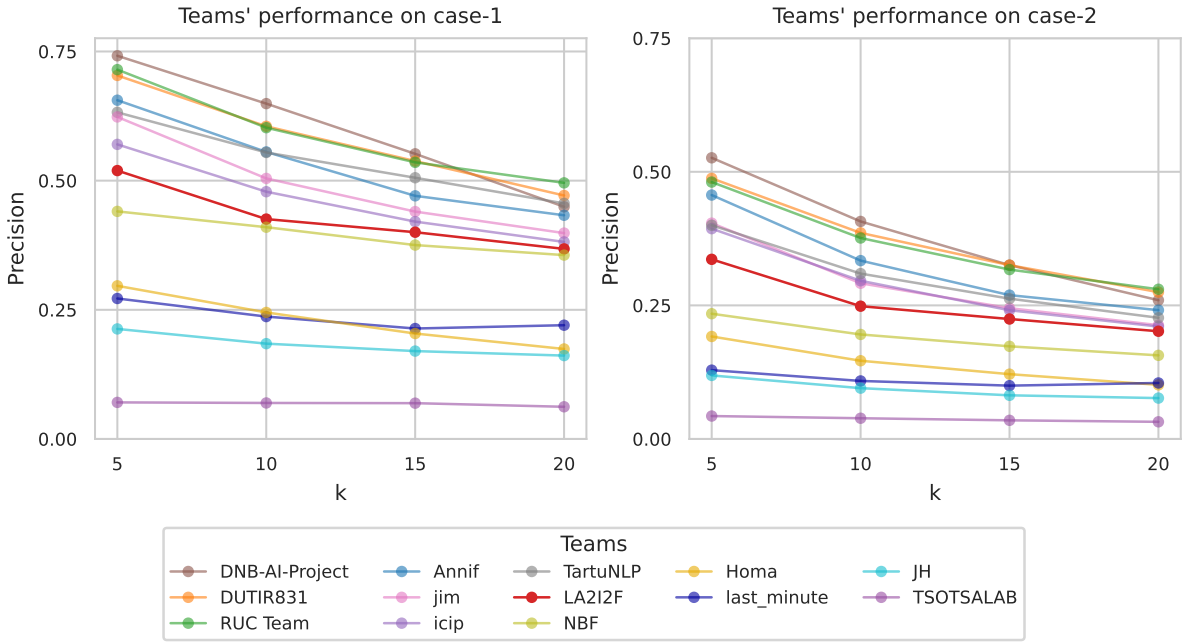

Figure 6: Performance comparison of our proposed approach (LA2I2F) to all other teams' submitted solutions for the qualitative evaluation.

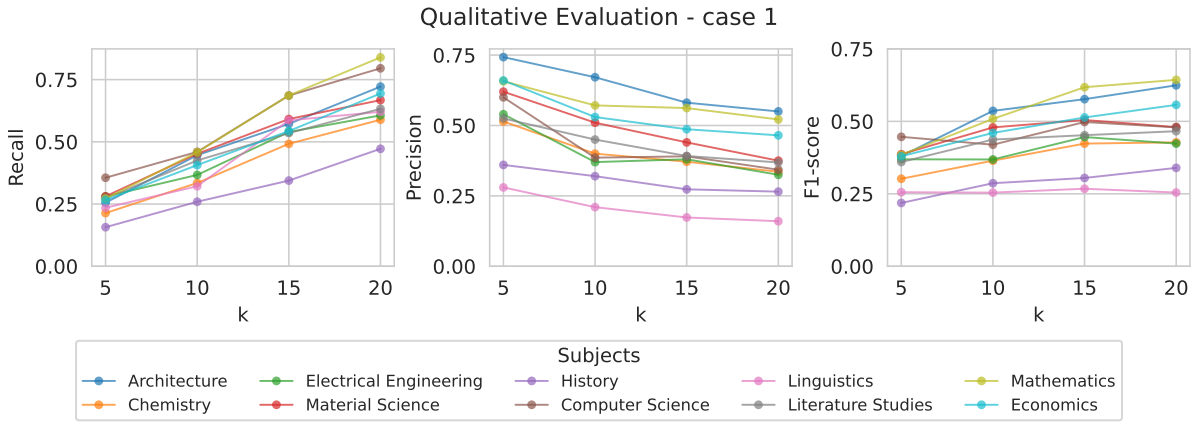

Figure 7: The qualitative evaluation of our approach on case 1 takes into consideration both types of label ratings assigned by the human experts: *correct* subjects and *technically correct, but irrelevant* subjects, and counts both of them as correct labels for determining the share of correct system outputs. The most relevant metric in this case is Precision, rating the correctness of the predicted labels as judged by the human expert.

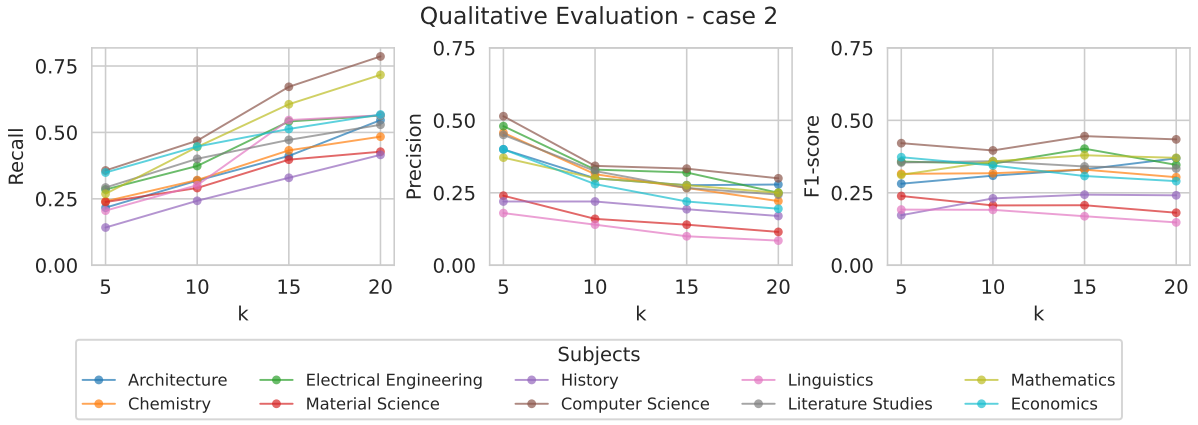

Figure 8: The qualitative evaluation of our approach on case 2 takes into consideration just those which the human experts marked as *correct*, thus, discarding subjects which are *(technically) correct but irrelevant*. As we observe, excluding the *(technically) correct but irrelevant* subjects leads to a significant drop in Precision values.

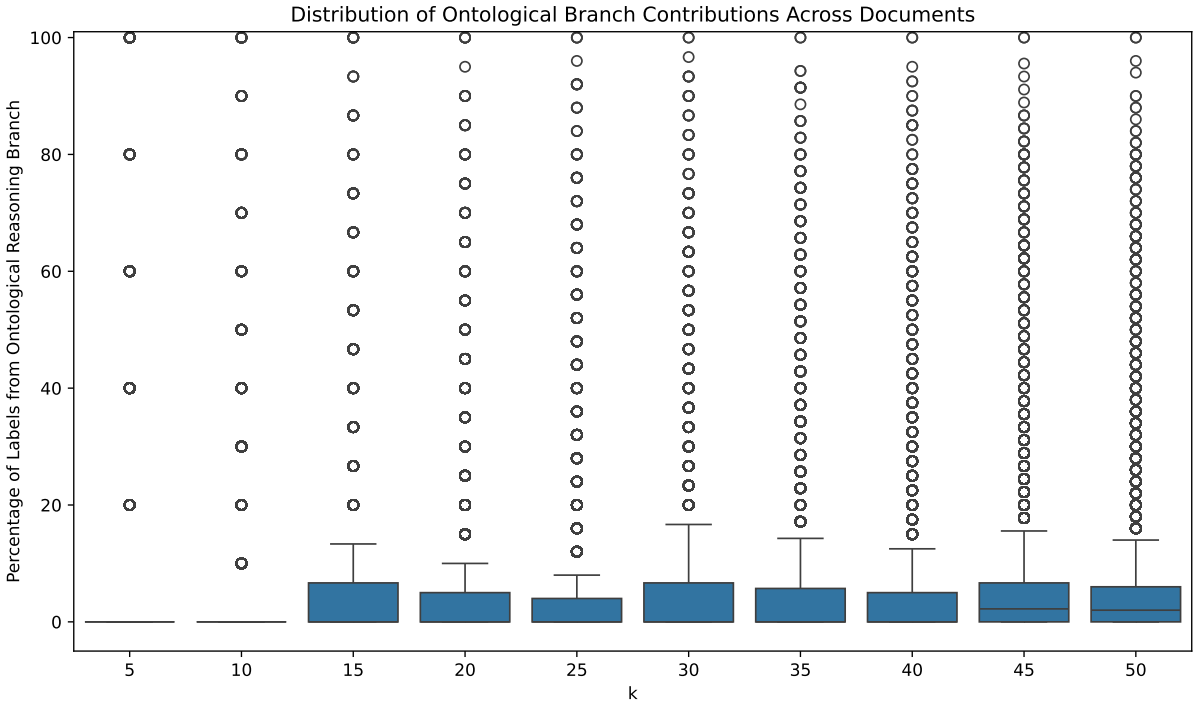

Figure 9: Fractions of subject labels in the fused list proposed by ontology-based retrieval, across varied top-k. We observe a low contribution *on average* (with a median of subjects from the ontological branch only greater zero only for $k > 40$), but the strong presence of outliers indicates documents for which most or even all proposed subject labels originate from the ontological branch.

Annif at SemEval-2025 Task 5: Traditional XMTC augmented by LLMs

Abstract

This paper presents the Annif system in SemEval-2025 Task 5 (LLMs4Subjects), which focussed on subject indexing using large language models (LLMs). The task required creating subject predictions for bibliographic records from the bilingual TIBKAT database using the GND subject vocabulary. Our approach combines traditional natural language processing and machine learning techniques implemented in the Annif toolkit with innovative LLM-based methods for translation and synthetic data generation, and merging predictions from monolingual models. The system ranked first in the all-subjects category and second in the tib-core-subjects category in the quantitative evaluation, and fourth in qualitative evaluations. These findings demonstrate the potential of combining traditional XMTC algorithms with modern LLM techniques to improve the accuracy and efficiency of subject indexing in multilingual contexts.

1 Introduction

Subject indexing is an important aspect of improving the discoverability of bibliographic databases and digital collections. Systems for automating subject indexing have traditionally been based on natural language processing (NLP) and traditional machine learning (ML) methods. The rise of generative AI and large language models (LLMs) holds some promise to revolutionise many automation tasks, yet producing accurate subject predictions using LLMs remains elusive (e.g. (Eric H. C. Chow and Li, 2024), (Martins, 2024)). The LLMs4Subjects challenge (D'Souza et al., 2025) invited teams to produce innovative solutions for LLM-based subject indexing using a data set (D'Souza et al., 2024) based on the bilingual bibliographic database TIBKAT of TIB, the Leibniz Information Centre for Science and Technology.

We have been developing the Annif[1] multilingual open source automated subject indexing toolkit since 2017 (Suominen et al., 2022). Our toolkit is mainly based on traditional NLP and ML methods. By participating in this task, we aim to provide a strong baseline using traditional methods augmented with some LLM-based techniques. The novel aspects of our work are 1) translating the subject vocabulary and metadata records using LLMs, 2) generating synthetic training data using LLMs, 3) including XTransformer in an ensemble of algorithms, and 4) generating suggestions using separate monolingual prediction pipelines and merging their results.

Our system ranked 1st in the *all-subjects* category and 2nd in the *tib-core-subjects* category in the quantitative evaluation. It was ranked 4th in qualitative evaluations. We discovered that our approach, based mainly on traditional NLP and ML, remains competitive against other systems that make heavier use of LLMs. We also found ways to efficiently translate bibliographic records and to produce additional synthetic training data using LLMs.

Our code, configuration files and customised data sets are available on GitHub[2]. The models we trained are available on Hugging Face Hub[3].

2 Background

The task involved developing LLM-based systems that recommend the most relevant subjects from the GND subject vocabulary to tag a given TIBKAT record based on its title and abstract, which is a type of extreme multilabel text classification (XMTC) problem. The organisers provided two variants of the GND subject vocabulary: *all-subjects* (all 200,035 GND subjects) and *tib-core-subjects* (a

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2424–2431

subset of 78,741 subjects especially important for TIB). We used the SKOS versions of GND provided by the German National Library (DNB).

The organisers also provided bibliographic records from the TIBKAT database as two data sets, corresponding to the two GND variants, each of them divided into train, development, and test subsets. The number of records was 81937 / 13666 / 27986 for the *all-subjects* data set and 41923 / 7001 / 6119 for the *tib-core-subjects* data set. All these subsets were further split by document type (e.g. Article or Book) and language (German or English). We did not distinguish records by these two aspects[4]. Known GND subjects were included only for the train and development records.

Although the task description suggested using LLMs, we did not use one for the core task of choosing subjects but instead relied on the traditional XMTC algorithms in Annif. However, we used LLMs to pre-process the data sets and to generate additional synthetic training data.

3 System overview

We based our system on the Annif automated subject indexing toolkit. It provides a selection of XMTC algorithms as configurable *backends* which can be used for subject indexing by setting up *projects* that define the vocabulary and specific configuration settings of a backend.

We chose three Annif backends for this task: 1) **Omikuji**[5], an implementation of a family of efficient machine learning algorithms for multilabel classification based on the idea of partitioned label trees, including Parabel (Prabhu et al., 2018) and Bonsai (Khandagale et al., 2020). We used the Bonsai-style configuration. 2) **MLLM**[6] (Maui-like Lexical Matching), a lexical algorithm for matching words and expressions in document text to terms in a subject vocabulary. It is a reimplementation of the ideas behind Maui (Medelyan, 2009), an earlier tool for automated subject indexing that uses heuristic features and a small machine learning model to select the best performing heuristics. 3) **XTransformer**, an XMTC and ranking algorithm based on fine-tuned BERT-style Transformer models that is part of the PECOS framework (Yu et al., 2022). Its Annif integration is experimental and was refined in the process of this task. We used **FacebookAI/xlm-roberta-base** as the base model.

Combinations of XMTC algorithms, called *ensembles*, often outperform individual algorithms. We combined the base backends that return lists of suggested subjects along with numeric scores into two kinds of ensembles: *simple ensembles* that merge subjects suggestions from two or more backends by averaging their scores, and *neural ensembles* that, in addition to averaging scores, also involve training a neural network model that adjusts the subject scores, for example suppressing subjects that are frequently wrongly suggested (false positives).

3.1 Translation of data sets

We used the **Llama-3.1-8B-Instruct** LLM (Grattafiori et al., 2024) for translating the titles and abstracts of all records. Each record was translated separately into a German-only and English-only record (step 1 in Figure 1). More details on LLM processing are given in Appendix D.

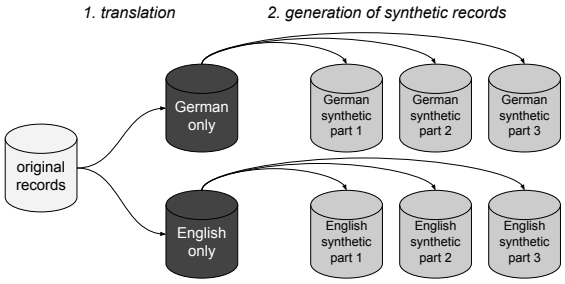

Figure 1: LLM pre-processing steps for the data sets.

The MLLM lexical backend requires that the vocabulary terms must be in the same language as the records. Therefore, we used the **GPT-4o-mini** LLM to translate all GND preferred terms in German into English and created bilingual variants of the GND SKOS files.

3.2 Synthetic training data

We found that the number of training records provided was quite small compared to the size of the subject vocabulary, so we used the **Llama-3.1-8B-Instruct** LLM to generate additional synthetic training records. We presented the LLM with each of the existing train records (its title and abstract) at a time along with its manually assigned subject labels (GND preferred terms in either German or

[4]We found that the records for different types were similar in their structure and their titles and abstracts often contained a mixture of languages regardless of the indicated language.

[5]https://github.com/tomtung/omikuji

[6]https://github.com/NatLibFi/Annif/wiki/Backend%3A-MLLM

English, matching the language of the document). We then asked the LLM to generate a similar record with the same set of subjects plus one additional, randomly chosen preferred term from the GND (step 2 in Figure 1; see also example in Figure 4 in Appendix D). This additional subject caused the LLM to generate a novel record, not just to rephrase the given example, and also helped to expand the subject coverage of the training data set to new GND subjects.

4 Experimental setup

We first set up, trained and evaluated the three kinds of base projects. We aimed to maximise their evaluation scores, measured against the development set, by exploring various approaches and settings. Once satisfied with the performance of the base projects, we combined them into ensembles that were finally used to produce our system output.

For evaluation during system development, we used two common XMTC metrics built in to the Annif toolkit: *F1@5* (F1 score calculated using the top 5 suggestions from the system) and *nDCG@10* (Normalised Discounted Cumulative Gain (Järvelin and Kekäläinen, 2002), a ranking metric calculated using the top 10 suggestions from the system).

4.1 Base projects

We set up parallel independent sets of Annif projects for the *all-subjects* data set and the *tib-core-subjects* data set. We also configured separate projects for English and German. To simplify the resulting combinatorial explosion of project configurations, we used the Data Version Control[7] tool to manage the data sets, project configurations as well as the training and evaluation processes.

For each of the four combinations (2 GND variants $\times$ 2 languages), we set up three Annif base projects: (Omikuji) Bonsai, MLLM and XTransformer (abbreviated as XTrans in tables). We trained each project on the LLM-translated monolingual records from the train set (German-only or English-only, matching the project language).

We also tested different hyperparameters. For each base project, we chose either Snowball stemming or Simplemma lemmatisation for text preprocessing. For the Bonsai projects we enabled bigram features using the *ngram=2* setting and set a *min_df* value of 2 to 5 to filter features that occur rarely in the training data. For the XTransformer projects we manually searched for model-specific hyperparameters. The final hyperparameters can be seen in the project configuration files on GitHub[8]

4.2 Adding synthetic data

We repeated the synthetic data generation process three times per language and GND variant (total $3 \times 2 \times 2$ times). The nDCG@10 scores of the Bonsai projects increased by ~0.02 when adding the first part of synthetic data, but the 2nd and 3rd synthetic sets only increased the scores modestly (see Figure 3 in Appendix A), so we stopped at 1 part original and 3 parts synthetic data. We didn't use the synthetic data for training the MLLM and XTransformer projects. MLLM does not need much training data and the XTransformer results did not improve when adding synthetic data.

The final evaluation scores for the base projects are shown in Table 3 in Appendix B. The Bonsai projects achieved the best scores in all cases, followed by XTransformer and MLLM.

4.3 Ensemble projects

We set up three kinds of ensemble projects that combined the base projects in different ways: two "BM" ensembles (simple and neural) combining Bonsai and MLLM, and a "BMX" simple ensemble that combines all three base projects (see Figure 2).

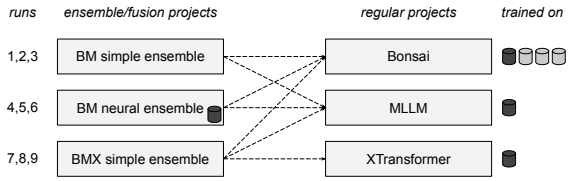

Figure 2: Overview of Annif projects and how they were combined into ensembles.

We tuned the ensembles using the automated hyperparameter optimisation facility built into Annif to select the weights used in averaging the results of base projects. We used the `annif hyperopt` command to try different combinations of weights (100 tries for the BM ensembles and 200 tries for the BMX ensembles), choosing weights that maximised the nDCG scores against the development set (see Table 4 in Appendix C). In the BM ensembles, the Bonsai model contributed 80–87% while MLLM had a minor role. In the BMX ensembles, the Bonsai model was still the most important at

[7] https://dvc.org/

[8] https://github.com/NatLibFi/Annif-LLMs4Subjects/blob/main/projects.toml

47–62%; XTransformer contributed 21–33% while MLLM again had a minor role. These optimised weights match the relative order of the evaluation of the individual base projects, where Bonsai obtained the best results, followed by XTransformer and MLLM. Omikuji Bonsai and XTransformer are both similar models in the sense that they learn to recognise each subject individually based on the training data, but they are not good at suggesting concepts which occur with a low frequency. In the ensembles, MLLM complements these models by being able to suggest any subject in the GND vocabulary as long as the term used in the text matches the preferred or alternate label in the vocabulary.

We reused the optimised weights of the BM simple ensembles also for the corresponding BM neural ensembles and trained them for 10 epochs using records from the development set. The other NN ensemble hyperparameters were left at their default values.

The results of evaluating the ensembles against the development set are in Table 1. Since the BM neural ensembles were also trained on the development set records, their evaluation results were unrealistically good. As we had not set aside any other records for this purpose, we had to wait for the official evaluation results to assess their quality.

4.4 Test set predictions

For both GND variants, teams were allowed to submit up to 10 separate *runs* (up to 50 subject predictions per test set record). We LLM-translated the test set records to produce German-only and English-only versions of each record. For each of the three ensemble types, we produced three runs: 1) using the German ensemble and the German-only record, 2) using the English ensemble and English-only record, and 3) combining the two monolingual predictions into a single prediction by summing the scores of the predicted subjects and choosing the top 50 subjects by score. This gave us a total of 9 runs per GND variant that we submitted for evaluation.

5 Results

The final quantitative and qualitative evaluations were performed by the task organisers.

5.1 Quantitative evaluation

The quantitative evaluation involved comparing the subject predictions with subject annotations in TIBKAT records using precision, recall, and F1 scores (with various thresholds from 5 to 50). The overall ranking was determined by average recall, calculated by averaging the recall scores over all threshold values. Our #9 runs, BMX simple ensemble with combined languages (de+en), ranked 1st in the *all-subjects* category with an average recall score of 0.6295 and 2nd in the *tib-core-subjects* category with a score of 0.5899 (see Table 1 for full results).

5.2 Qualitative evaluation

The qualitative evaluation was performed by subject librarians. Our *tib-core-subjects* run #9 was chosen for the qualitative evaluation. 6–10 record files from each of 14 different subject classifications were chosen, and the top 20 GND codes from the submissions were evaluated by marking the predictions as correct (Y), technically correct but irrelevant (I), or incorrect (N or blank).

Based on these ratings, two different types of qualitative results were calculated. In case 1, both Y and I were considered correct, while in case 2, only Y was considered correct. Precision, recall and F1 scores across various thresholds (from 5 to 20) were calculated. For the recall calculation, the set of correct subjects was defined as the union of TIBKAT subject annotations and all the subject suggestions from the various systems that were considered correct by the evaluators. The systems were ranked based on their average recall scores across the specified thresholds. Our system ranked 4th in both evaluations (see Table 2).

Table 1: Quantitative evaluation results for the ensemble projects measured against the development and test sets. Top 5 systems included for comparison. Note that Lang refers to the project language, not to the indicated language of the records. *Unreliable score because the neural ensemble was trained on the development set it was evaluated on.

one case, the English variant achieved higher evaluation scores than its German counterpart. The quality of LLM-produced translations can have an effect on the quality of the indexing of the downstream subjects. It may be that the translations were better in English or that the analytic structure of the English language makes it easier to process for traditional NLP pipelines than German, which is more synthetic and has many compound words. Further analysis of the effect of translation quality on the quality of subject indexing is left for future work.

By generating synthetic records, we were able to mitigate the lack of sufficient training data required by traditional ML algorithms. Thanks to this, the nDCG scores of our Bonsai models increased by ~0.03 points (see Figure 3 in Appendix A).

The BMX ensembles consistently achieved higher evaluation scores than the corresponding BM ensembles, indicating that the addition of XTransformer had a positive effect. The neural BM ensembles achieved high evaluation scores against the development sets, as expected, but underperformed in the evaluations on the test set. In our experience, the neural ensemble is able to correct bias in settings where some of the training data are structurally different from the evaluation data. However, in this task, both the training and evaluation data was structurally similar so there was no need for such adjustment and the neural model simply made the predictions worse.

We tested a new "multilingual ensemble" method by generating predictions separately from German and English variants of the same records and then merging the subject predictions. The merged predictions achieved higher scores than the monolingual predictions. Had we not done this, our best runs would have been the BMX ensembles for English. In the quantitative evaluation, we would have ranked 2nd after DUTIR831 in *all-subjects* and 3rd after LA^2I^2F in *tib-core-subjects*.

Our system ranked 1st and 2nd in the quantitative evaluations, but in the qualitative evaluations, three other systems achieved higher scores. A possible explanation for this difference is that our system, based on traditional ML, was heavily guided by the

training data records. We were thus able to produce subject predictions quite similar to the existing TIBKAT subject metadata. Some other systems, in contrast, produced predictions that were not as similar to existing metadata, but were considered qualitatively better by the evaluators. Assuming that the other systems relied more on LLMs for subject assignment than our system, they were not as constrained by the available training data and instead were able to leverage the knowledge of the LLMs. None of the systems achieved a F1@5 score above 0.35 in the quantitative evaluations, possibly indicating a relative lack of consistency in the TIBKAT subject metadata[9].

Using different evaluation metrics for development and test sets introduced unnecessary complexity. In our opinion, the nDCG@50 metric would be a good choice for ranking systems that were tasked to produce 50 subject predictions per record.

6 Conclusions

In conclusion, our participation in the SemEval-2025 Task 5 (LLMs4Subjects) provided valuable insights into the capabilities and performance of Annif, particularly when augmented with large language models (LLMs) for data preparation. By leveraging traditional XMTC algorithms such as Omikuji Bonsai, MLLM, and XTransformer, and enhancing them with LLM-generated synthetic data and translations, we demonstrated competitive results across multiple categories. While this task focused only on the resulting quality of the subject indexing, we note that the computational requirements, energy consumption and processing latency of traditional ML approaches are modest in comparison to LLMs.

Acknowledgments

The authors wish to thank the Finnish Computing Competence Infrastructure (FCCI) for supporting this project with computational and data storage resources. The authors thank the University of Helsinki Scientific Computing Services staff for all the support and assistance they gave for using the HPC environment. We thank ZBW, Leibniz Information Centre for Economics, for contributing the integration of XTransformer with Annif, and DNB for their valuable insight on its hyperparameters. Finally, we thank TIB for organising this task that provided valuable insights and opportunities for comparing methods and techniques.

[9] In earlier experiments, we have been able to achieve F1@5 scores above 0.5 for some data sets that have been consistently indexed with good quality subject metadata.

D Details about LLM usage

We used the vLLM[10] inference engine to translate and synthesise records using the Llama-3.1-8B-Instruct LLM. For the processing, we used a single NVIDIA A100 GPU with 80GB VRAM from the University of Helsinki HPC cluster Turso.

For translating GND into English, we used the GPT-4o-mini LLM on the Azure OpenAI Service cloud platform.

D.1 Performance

Using vLLM, we achieved a throughput of approximately 4 records/second for translation and 8 records/second for synthesising new records.

D.2 Processing example

The process of LLM translation and record synthesis has been illustrated in Figure 4.

D.3 Prompt templates

In the following prompt templates, the system prompt is set in *italics*. Tags in the template were replaced with relevant information from the records.

D.3.1 Record translation

This prompt was used to translate records:

You are a professional translator specialized in translating bibliographic metadata.

Your task is to ensure that the given document title and description are in <LANGUAGE> language, translating the text if necessary. If the text is already in <LANGUAGE>, do not change or summarize it, keep it all as it is.

Respond with only the text, nothing else.

Give this title and description in <LANGUAGE>:

<TITLE>

<DESCRIPTION>

D.3.2 Record synthesis

This prompt was used to synthesise new records:

You are a professional metadata manager.

Your task is to create new bibliographic metadata: document titles and descriptions.

Here is an example document title and description in <LANGUAGE> with the following subject keywords: <OLD_KEYWORDS>

<TITLE_DESC>

Generate a new document title and description in <LANGUAGE>. Respond with only the title and description, nothing else. Create a new title and description that match the following subject keywords: <NEW_KEYWORDS>

---

[10] https://docs.vllm.ai

D.3.3 GND translation

This prompt was used to translate the GND preferred terms into English in batches of 100 terms:

You are a professional translator specialized in translating controlled vocabularies such as information retrieval thesauri and classifications.

Your task is to translate terms from the The Gemeinsame Normdatei (GND, Integrated Authority File), a carefully curated thesaurus known for its precise and respectful terminology. These terms are used for academic and informational purposes and are presented in German. Please maintain the list structure and translate each term into English. Only return the list of translated terms, no explanations are needed.

This translation work is part of an educational and informational project aimed at enhancing accessibility and understanding of diverse concepts across languages. It is important to handle all terms, especially those pertaining to sensitive subjects such as health conditions, with accuracy and respect as intended by the thesaurus editors.

Example input:

1. Individualisierte Person
2. Familie
3. Schlagwort
4. Sicherung

Translated output for the above examples:

1. Differentiated person
2. Family
3. Subject heading
4. Safeguarding

Now translate the following thesaurus terms to English:

<LIST_OF_TERMS>

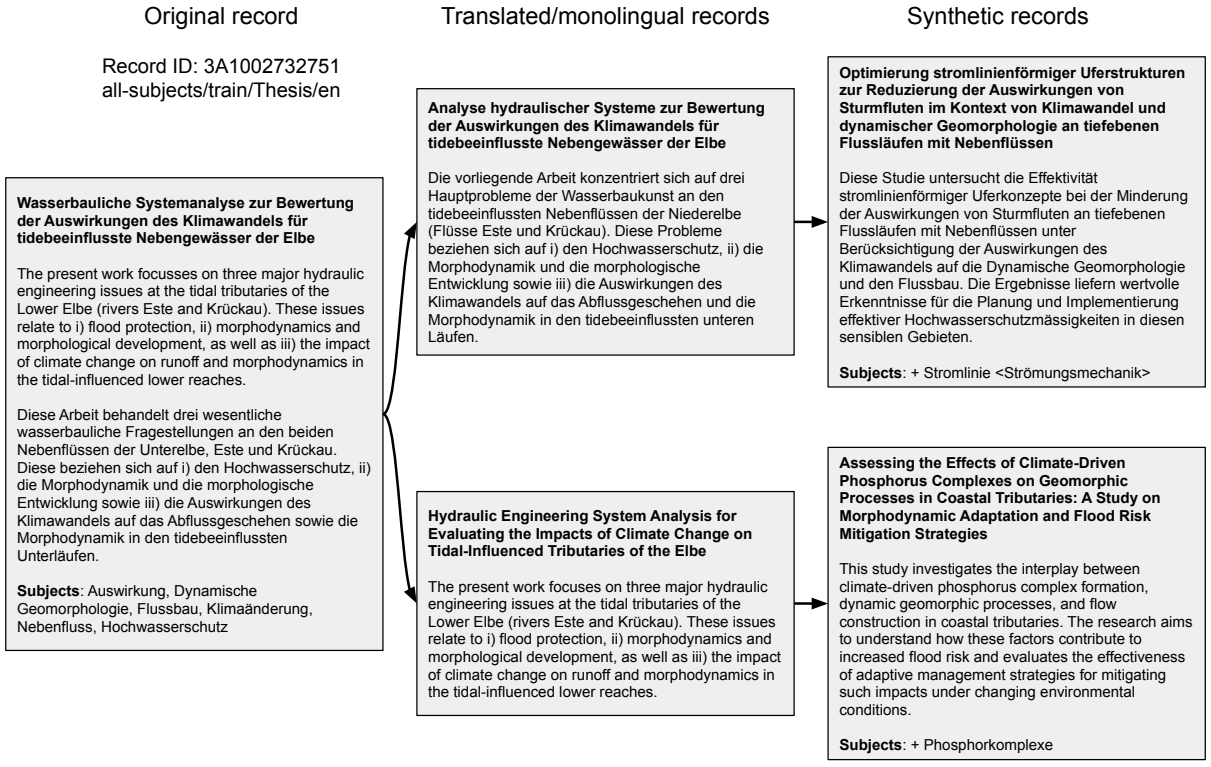

Figure 4: Example records translated and synthesised using the LLM. The example record included abstracts in both English and German, so the LLM only had to translate the German title to English. The LLM performed minor adjustment, for example changing "focusses" to "focuses" and modifying the German title. The synthetic records were generated using the translated records as one-shot examples but adding one random GND subject.

Last Minute at SemEval-2025 Task 5: RAG System for Subject Tagging

Zahra Sarlak, Ebrahim Ansari
Institute for Advanced Studies in Basic Sciences (IASBS)
Iran, Zanjan
z.sarlak@iasbs.ac.ir, ansari@iasbs.ac.ir

Abstract

The LLMs4Subjects shared task focuses on utilising Large Language Models to improve subject classification in technical records from the Leibniz University's Technical Library (TIBKAT). Participants are challenged to recommend appropriate subject headings from the GND taxonomy while processing bibliographic data in both German and English. Our approach combines RAG with contrastive learning to refine the embedding model. To further improve retrieval quality, we implement a re-ranking system. We evaluate our model on a test set of TIBKAT records, measuring its performance through precision, recall, and overall classification effectiveness. These findings contribute to the advancement of automated subject classification methodologies in digital library systems, showcasing the potential of large language models (LLMs) in managing multilingual and domain-specific bibliographic data.

1 Introduction

Subject tagging is essential for organizing and retrieving information in vast collections of technical records. The Leibniz Information Centre for Science and Technology (TIB) manages TIBKAT, an open-access bibliographic database that encompasses a significant variety of scientific and technical metadata. To enhance user accessibility, TIB aims to provide precise subject tagging based on the GND (Gemeinsame Normdatei) taxonomy, which is widely used in German-speaking libraries.

The task of manually tagging records is labor-intensive due to the vast number of different subject tags available, leading to potential inconsistencies and inefficiencies.

The LLMs4Subjects shared task(D'Souza et al., 2025) invites researchers to design models capable of processing bilingual technical documents—specifically, those written in German and English. By accurately tagging these documents, systems can significantly enhance the discoverability of information and improve research workflows.

Our study leverages the recent advances in natural language processing (NLP) made possible by retrieval-augmented generation (RAG). This method integrates retrieval mechanisms with language generation, allowing for a more context-aware approach to tagging. Despite much of the focus in NLP being on English and monolingual tasks, the demand for effective bilingual models remains high, especially in library settings.

In our approach, we utilize RAG to dynamically retrieve relevant subject headings from the GND taxonomy based on the technical record's title and abstract[1]. We also employ contrastive learning to fine-tune embedding model for subject tags and incorporate a re-ranking mechanism to optimize our recommendations. By utilizing Milvus (Guo et al., 2022) for efficient vector storage, we aim to enhance both the accuracy and speed of the subject tagging process.

2 Related Work

The integration of automated tagging and structured vocabularies in digital libraries is becoming increasingly important for improving the discoverability of academic content. Recent research has presented various strategies to enhance metadata management, which closely aligns with our use of Retrieval-Augmented Generation (RAG) for tagging in the TIBKAT database.

A key contribution in this area is by (Venktesh et al., 2021), who focus on using a hierarchical learning taxonomy to automatically tag academic questions. Their method addresses the challenges of understanding the relationships between terms in the taxonomy and the questions being tagged. Simi-

[1] https://github.com/jd-coderepos/llms4subjects

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2432–2436

larly, (Cheng et al., 2023) propose a data-driven approach for analyzing biodiversity subject metadata, using named entity recognition and word embeddings to group related terms effectively. (Aske and Giardinetti, 2023) also highlight the importance of using Artificial Intelligence tools to improve metadata creation, particularly to fix inconsistencies and outdated descriptions in digital archives.

These advances reflect a trend in natural language processing that emphasizes the need to combine retrieval methods with language models to enhance their performance on tasks that require knowledge. A key study in this area is by (Lewis et al., 2020), who introduced RAG. This approach shows that combining a pre-trained sequence-to-sequence language model with a dense vector index allows for better access to external knowledge, leading to improved performance, especially in open-domain question answering.

(Gao et al., 2024) provided a comprehensive survey of RAG methodologies, identifying the advantages of incorporating external databases into language generation. Their work emphasizes that RAG can reduce issues such as hallucination and outdated knowledge by continuously updating and integrating information from external sources. This approach not only enhances the accuracy of generated outputs but also facilitates a more transparent reasoning process, making it a robust framework for knowledge-intensive applications.

In the framework presented by (Khattab et al., 2022), the DEMONSTRATE–SEARCH–PREDICT (DSP) model outlines a sophisticated method for combining retrieval and language models. By creating a pipeline for passing information between these models, the DSP framework seeks to leverage the strengths of both retrieval and generation techniques, achieving new state-of-the-art results in various knowledge-intensive settings. This work exemplifies the potential for improving the interaction between retrieval and language generation, leading to more reliable and coherent output.

(Ovadia et al., 2023) explored the comparison between retrieval-augmented generation and traditional unsupervised fine-tuning for knowledge injection in large language models. Their findings suggest that while fine-tuning can provide benefits, RAG consistently outperforms it, particularly in integrating new knowledge and enhancing the models' overall capabilities. This study underscores the limitations of conventional methods and highlights the growing importance of retrieval-based approaches in effectively updating language model knowledge.

Lastly, (Ram et al., 2023) examined In-Context Retrieval-Augmented Language Models (RALMs), presenting a simple yet effective method for conditioning language models on relevant documents without altering their architecture. This approach focuses on maintaining the existing model while improving performance through external document incorporation, which can simplify deployment and usability. The findings suggest that leveraging retrieval mechanisms can lead to significant advantages in language modeling without necessitating extensive changes to the underlying model architecture.

These studies shows the impact of retrieval-augmented methods in enhancing the capabilities of language models, particularly for tasks that require accurate knowledge retrieval and integration.

3 Methodology

Our approach to the LLMs4Subjects shared task involved multiple key steps designed to enhance the accuracy and efficiency of subject tagging for technical records from the TIBKAT database. Below, we outline the methodology employed:

1. **Model Fine-Tuning for Embedding:** Since the main retrieval method relies on cosine similarity searching, it is crucial to have an effective embedding model that emphasizes the distinction between subject-related and unrelated content. With this in mind, we began by fine-tuning the stella-en-400M-v5 model (Zhang et al., 2025), recognized as one of the most effective lightweight models in the MTEB (Muennighoff et al., 2023) benchmark for embedding tasks[2]. The model was fine-tuned using the training data with the Multiple Negatives Ranking Loss (Henderson et al., 2017) for one epoch. Using more epochs would increase the risk of overfitting the model. The training was conducted under the following configurations:

- Number of training epochs: 1
- Per-device training batch size: 32
- Learning rate: 1e-5
- Floating point precision: bf16

[2] https://huggingface.co/spaces/mteb/leaderboard

- Gradient accumulation steps: 2

These settings were chosen to strike a balance between effective model training and generalization, ensuring that the model could learn meaningful representations without becoming overly specialized to the training data.

2. **Embedding Subject Tags:** Once the model was fine-tuned, we created embeddings for subject tags using the trained embedding model. For each subject in the GND dataset, we have the following fields: *Name* and *Classification Name*. Additionally, for a portion of the subjects, the fields *Definition* and *Related Subjects* are also available.

The embeddings for each subject tag were generated by concatenating *Name* and *Classification Name* along with *Definition* and *Related Subjects* when available. This comprehensive representation effectively captures the contextual meaning of each tag.

3. **Vector Storage with Milvus:** After embedding the subject tags, they were stored in Milvus vector storage. This enabled us to efficiently retrieve and manage the high-dimensional vectors associated with the subject tags during the later stages of our methodology.

4. **Retrieving Similar Tags:** For each record in the test dataset, the *title* and *abstract* fields were concatenated and embedded using the same embedding model that was used for subject tags. Then, we retrieved a set of 100 similar subject tags (measured by cosine similarity) from the Milvus database for the embedded representations of the test records. This retrieval process enabled us to identify potential tags that could be relevant to the given technical records based on their embeddings.

5. **Re-ranking with a Cross-Encoder Model:** To refine the initial set of retrieved tags, we employed a cross-encoder model from the MTEB benchmark (Muennighoff et al., 2023), focusing solely on its re-ranking capabilities. As of the time of writing this paper, the granite-embedding-278m-multilingual (Granite Embedding Team, 2024) model is among the top 30 low-memory models in the MTEB benchmark (Muennighoff et al., 2023) sorted by re-ranking score. We used this model to re-rank the 100 similar tags. This model evaluated the relevance of each tag in relation to the title and abstract, resulting in a more accurate ranking of the tags.

6. **Final Tag Selection:** From the re-ranked list, we selected the top 70 candidate tags. These were then passed to a large language model (Llama-3.2-1B (Grattafiori et al., 2024)) as part of a prompt to further refine the results. The LLM evaluated the tags based on contextual understanding and relevance to the input data. The prompt we passed to the model:

Given the following abstract of a technical document:

[title + abstract]

And the top retrieved subject tags:

[Retrieved tags]

Please assess the relevance of each tag in relation to the abstract provided. Sort the tags based on their appropriateness, and select the top 5 most relevant subject tags that best represent the content of the abstract.

Finally, we extracted the top 50 tags recommended by the LLM as the final output for each title and abstract. This multi-step methodology, combining embedding, tagging retrieval, re-ranking, and LLM refinement, aimed to enhance the overall accuracy and effectiveness of subject classification for the technical records in the TIBKAT database.

4 Result

The initial results of our tagging approach revealed several challenges in the subject tagging process, despite the potential of Retrieval-Augmented Generation (RAG). These challenges underscore the need for further refinement and optimization. However, they also provide valuable insights of subject classification in a multilingual and domain-specific context. In this section, we present the detailed evaluation results.

The evaluation of our subject tagging system was carried out by the SemEval team through both quantitative and qualitative assessments. Table 3 shows the overall evaluation result for quantitative and qualitative evaluation result, representing the Average precision, Recall and F1 for different evaluation methods.

The combined language and record-levels results is available at appendix A, with the separated evaluation result for different record types and languages. Tables 4-6 each represented result at k=5,10,15 respectively.

Having better recall for more @K is natural, because the more subject retrieved increase the chance of more correct tag selection.

K	Precision	Recall	F1
@5	0.0241	0.0459	0.0316
@10	0.0224	0.0848	0.0354

Table 2: Qualitative result of the proposed approach on tib-core dataset, evaluated by SemEval organizers. Rows of tables shows scores at different values of k (5, 10, and 15), where @k indicates the number of top tags retrieved by our model.

5 Challenges

One of the main reasons for the low scores is that, despite fine-tuning the embedding model, the distance between related and unrelated subject embeddings in the embedding space is still not adequate. Since extracting relevant subject tags heavily relies on cosine similarity, the distance between subject embeddings is crucial; however, achieving this distinction through fine-tuning the embedding model proves to be challenging. It is important to note that a subject may be related to one record while being unrelated to another, yet all of them may have near vectors in the vector space. Fine-tuning the model may improve some similarities, but it can also distort others, further complicating the differentiation process. Therefore, fine-tuning must be implemented with great care and involve iterative reviews of the results.

Additionally, the vast, highly imbalanced, and diverse set of subject tags, along with the need to embed and index this extensive set of tags in vector storage, makes evaluation challenging and limits our options for testing different embedding models.

Evaluation	Average Recall	Average Precision	Average F1
Quantitative	0.2099	-	-
Qualitative case 1	0.2917	0.2357	0.2471
Qualitative case 2	0.2035	0.1105	0.1359

Table 3: Result of the proposed approach on tib-core dataset, evaluated by SemEval organizers

6 Conclusion

We examined the effectiveness of Retrieval-Augmented Generation (RAG) for tagging subjects in technical records from the TIBKAT database. By fine-tuning a lightweight language model and integrating a retrieval mechanism, we aimed to improve the accuracy and efficiency of the tagging process. The challenge of accurately tagging subjects is heightened by the vast number of subject tags—over 240,000—making it difficult to achieve effective results with simple similarity searches. For future work, we propose adopting a structured approach, such as using graph-based representations, to store subject tags and utilize their hierarchical taxonomy for more precise candidate selection. Additionally, since our solution relies heavily on similarity search, evaluating its effectiveness poses challenges due to the large search space. To address this, we can implement heuristics that limit the search set for each abstract sample, ultimately improving both efficiency and accuracy in the tagging process.

Abstract

This paper presents MaRSI, an automatic subject indexing method designed to address the limitations of traditional manual indexing and emerging GenAI technologies. Focusing on improving indexing accuracy in cross-lingual contexts and balancing efficiency and accuracy in large-scale datasets, MaRSI mimics human reference learning behavior by constructing semantic indexes from pre-indexed documents. It calculates similarity to retrieve relevant references, merges, and reorders their subjects to generate index results. Experiments demonstrate that MaRSI outperforms supervised fine-tuning of LLMs on the same dataset, offering advantages in speed, effectiveness, and interpretability.

1 Introduction

With the increasing diversification of academic disciplines and the continuous influx of research outputs, the volume of documents in libraries has grown rapidly, raising the demand for efficient and accurate subject indexing techniques(Zhang et al.). Libraries use controlled vocabularies such as thesaurus and name authorities to assign subject terms for kinds of documents. However, manual indexing has high cost and low processing efficiency. With the use of Artificial Intelligence(AI), the automated subject indexing technology improves indexing efficiency. By virtue of its strong semantic processing and generalization capacity, generative Al, represented by large language models(LLMs), provides an automated path for multi-lingual subject indexing in large-scale data.

In this context, the TIB Leibniz Information Centre for Science and Technology launched the LLMs4Subjects shared task at SemEval-2025, one of the ACL 2025 Semantic Evaluation challenges(D'Souza et al., 2025). The task encourages exploring LLMs-based automated subject indexing through fine-tuning, retrieval-augmented generation (RAG), chain-of-thought prompting, and few-shot learning. This initiative serves as the motivation for our study.

Through comparative experiments with multiple AI indexing approaches English and German documents, we propose a deep learning-based embedded indexing solution that enhances automatic indexing by matching similar records and ranking related subjects. The study focuses on two key issues: 1) How to improve indexing accuracy in cross-lingual environments? 2) How to maximize accuracy while ensuring data processing efficiency in large-scale datasets?

2 Related Work

Subject indexing uses controlled vocabularies to assign subject terms to bibliographic resources, enhancing knowledge organization and retrieval. This intellectual process remains predominantly dependent on human expertise for accurate conceptual analysis. Since the 1970s, the library science and information retrieval communities have systematically investigated automated subject indexing, which primarily employ: multi-label classification, controlled term extraction and machine-assisted subject assignment. The primary methods currently in use include:

(1) Rule-based matching uses predefined syntactic, semantic, and domain-specific rules to align text terms with controlled vocabulary(Fernandez-Llimos et al., 2024), aiding subject suggestion. Methods like Maui(Medelyan, 2009) and STM(Gusfield, 1997) filter potential matches, but this approach struggles with diverse terminology and partial mismatches, leading to under-indexing.

(2) Statistical analysis-based indexing applies word frequency, associations, and co-occurrence patterns to categorize large-scale text data, facil-

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2437–2442

itating rapid retrieval in news, academia, and e-commerce(Janssens et al., 2009). Bibliometric analysis enhances visualization, reducing manual effort and rule dependence. However, lacking semantic understanding, these methods struggle to capture deep meaning.

(3) Machine learning-based automatic indexing leverages algorithms trained on annotated datasets to classify and index subjects across domains. Clustering and text mapping methods effectively classify journal articles, while algorithmic advancements have improved accuracy, driving broader adoption.

(4) Semantic computation with vector embeddings, as seen in Word2Vec and BERT(Sharma and Kumar, 2023), improves retrieval, clustering, and classification by generating semantic indexes. By mapping document features into vector space, these models enable precise indexing beyond keyword matching but require large corpora for high-quality representation(Nentidis et al., 2023).

(5) Automatic indexing using LLMs benefits from their advanced semantic understanding and strong performance in tasks like multi-label classification and keyword extraction. With prompt engineering, models like ChatGPT can infer relevant labels from few-shot examples. However, directly applying LLMs to document indexing(Kasprzik, 2024), which adheres to specific classifications and controlled vocabularies, often results in suboptimal performance.

In general, each automatic subject indexing method has its own strengths and limitations, with no universally perfect solution. Therefore, the study proposes a comparative experiment across three representative approaches-semantic embedding, supervised fine-tuning (SFT), and retrieval-augmented generation (RAG) to explore automatic such solutions from both qualitative and quantitative perspectives

3 Methods and Design

3.1 Research Question

This study frames subject indexing as the process of finding a specific function or model, f, where the title t_r and abstract a_r of a document r are input, and the model outputs the expected subject list, i.e.

$$f(t_r, a_r) = subjects(r) \quad (1)$$

The function f can internalize relevant knowledge by learning from existing data, typically through supervised fine-tuning (SFT) of LLMs.Using a labeled corpus, the model learns to map titles and abstracts to subject lists. However, due to the large number of subjects in the LLMs4Subjects task compared to the available training samples, SFT proves ineffective, as confirmed through experiments.

To address this, we propose MaRSI (Match and Rank Subject Indexing), a fast indexing method inspired by human imitation learning. MaRSI utilizes expert-generated indexing results to automatically index new documents. For a given document r,, we first identify pre-indexed samples similar to its content. The indexing results of these similar samples are treated as a candidate set, which is then ranked, and the top k, results are selected as the subject terms.

Let the indexed document set be $\mathrm{D} = \{d_1, d_2, \ldots, d_n\}$, where each document d_i has an associated set of indexed subjects $\mathrm{S}_i = \{s_{i1}, s_{i2}, \ldots, s_{im_i}\}$, with m_i representing the number of subjects for the document d_i. The function $\mathrm{sim}(d, r)$ measures the similarity between document d and the target document r for indexing. By calculating the similarity between all documents in d and r, a similarity ranking is obtained, and the top k documents are selected as reference results, forming the set $\mathrm{C} = \{c_1, c_2, \ldots, c_k\}$, where $c_i \in \mathrm{D}$, and $\mathrm{sim}(c_i, r) \geq \mathrm{sim}(c_j, r) \geq \mathrm{sim}(d, r)$ (for any $i < j$, $d \in \mathrm{D} \setminus \mathrm{C}$).

Next, the subjects from the reference set C are merged into a set $\mathrm{T} = \{t_1, t_2, \ldots, t_n\}$, containing m distinct subjects. The subjects in T are then ordered using a sorting algorithm, and the sorted result is used as the final prediction, defined as:

$$f(t_r, a_r) = rank(T|r) \quad (2)$$

In this process, the similarity function $\mathrm{sim}(d, r)$ and the ranking function $\mathrm{rank}(d|r)$ are critical to the prediction outcome. The following section will outline the specific approaches for these functions.

3.2 Main Framework of MaRSI

The overall workflow is illustrated in Figure 1. After discovering similar documents, two processing approaches are possible: direct sorting and output through the subject ranking module, or enhancing retrieval using LLMs, where the indexing results of similar documents serve as reference inputs for

few-shot learning, as shown in the gray background of the figure. After manual analysis, RAG methods did not yield better results, so the first approach was adopted in practice. Note that LLM filtering (gray area) not used in final system.

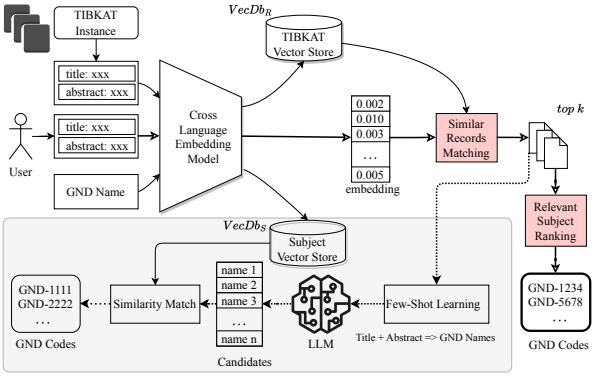

Figure 1: MaRSI Workflow.

(1) Vector Database Construction. We first embed the indexed documents records and subject sets of TIBKAT to construct the documents vector database $VecDb_R$ and the subject vector database $VecDb_S$. Given that the TIBKAT dataset contains both English and German data, the multilingual embedding model Arctic-Embed 2.0(Yu et al., 2024) was used. Based on the Transformer architecture and pretrained on a large multilingual corpus, this model is specifically optimized for semantic representation in both German and English, enabling it to efficiently capture semantic features and perform well in cross-lingual tasks.

When computing embedding vectors, the title and abstract of each document are concatenated as follows:

```
"""
title: {title}
abstract: {abstract}
"""
```

The subject calculation template is as follows:

```
"""
Subject: {name}
Related subjects: {related_subjects}
Classification Name: {classification_name}
"""
```

By iterating through TIBKAT's training set and subject list, two vector databases are generated. The TIBKAT document vector database is used to compute similar documents, while the subject vector database maps output subject terms from large language models to the most similar subject codes.

(2) Processing Workflow. Once the vector database is constructed, for a given document r, the following steps are performed: the title and abstract of document r are concatenated and input into a cross-lingual embedding model to generate its semantic vector. Using a vector-based nearest neighbor search algorithm, similar documents are retrieved from $VecDb_R$. The indexed results of these documents are merged to form a candidate set of subjects, which are then ranked to obtain the final results.

3.3 Similar Document Retrieval

To identify similar documents, this study employs an inner product-based similarity search algorithm. Given two documents d1 and d2, their semantic vectors d_1 and d_2, are derived from the embedding model, and their similarity is calculated as follows:

$$sim(\mathbf{d}_1, \mathbf{d}_2) = \sum_{i=1}^{N} v_i(\mathbf{d}_1) \cdot v_i(\mathbf{d}_2). \quad (3)$$

Where N is the vector length (1024 in this study), and $v_i(d)$ epresents the i-th component of the semantic vector for document d.

For efficient computation, the semantic vectors of indexed documents are stored in a Faiss index using the IndexFlatIP structure. This structure stores vectors in a flat data structure, calculates the inner product between the query vector and all indexed vectors, sorts them based on the inner product values, and returns the Top k most similar vectors, ensuring globally optimal results.

3.4 Candidate Subjects Ranking

The subject ranking is based on three assumptions: (1)The more similar a document d is to the target document r, the more important the subjects in d are; (2) A subject s in document d is more important the earlier it appears in the document's list of subjects; (3) A subject's name or a candidate name appearing in the title or abstract of d increases its importance. Based on these assumptions, we propose the following ranking algorithm for candidate subjects.

Algorithm 1: Candidate Subject Ranking Algorithm

Input: $C, title, abstract$

scores $\leftarrow$ defaultdict(0.0)
for $i \leftarrow 1$ **to** len(C) **do**
  $d \leftarrow C[i-1]$
  for $j \leftarrow 1$ **to** len$(d$.gnd_codes$)$ **do**
    score $\leftarrow 1.0 + \frac{1.0}{j}$
    if $i \leq$ PARAM1 **then**
      names $\leftarrow d$.alt_names $\cup \{d$.name$\}$
      for name **in** names **do**
        if name $\in$ title **then**
          score $\leftarrow$ score + PARAM2
        end if
        if name $\in$ abstract **then**
          score $\leftarrow$ score + PARAM3
        end if
      end for
    end if
    value $\leftarrow \frac{\text{len}(C)}{i}$
    score $\leftarrow$ score $\times (1 + \log(\text{value}))$
    scores$[d$.gnd_codes$[j-1]] \leftarrow$ score
  end for
end for=0

In Algorithm 1, C is the set of similar documents to the target document r, with title and abstract representing $r's$ title and abstract. The algorithm iterates over each related document and its subjects, accumulating scores in the scores dictionary. After sorting the scores, the ranked list of subjects is returned as the indexing result. Three hyperparameters are used in the algorithm: PARAM1 determines how many top documents are weighted for subject occurrence, defaulting to 5; PARAM2 and PARAM3 provide additional scores when subject names appear in the title and abstract of the target document, set to 2 and 1, respectively, in the experiment.

4 Experiment and Results

4.1 Datasets and Evaluation Methods

The dataset used in this study consists of three parts: the Train, Dev, and Test sets. For the full subject indexing task in TIBKAT, the training, validation and test sets contain 163,874, 27,332, and 55,972 items, respectively. For the core subject indexing task, the sets contain 83,804, 13,960, and 12,348 items, respectively. The datasets include five types of literature: articles, books, conference papers, reports, and theses-written in German or English.

Evaluation is carried out using three metrics: Recall, Precision, and the harmonic mean of both (F1 Score). Quantitative evaluation: Indexing results and average recall are calculated every five output subject terms. Qualitative evaluation: Documents are indexed by subjects, and random sampling is performed for expert evaluation to assess the indexing quality across different subjects.

4.2 Indexing Methods Compared

For the cross-lingual subject indexing task, three approaches-Supervised Fine-Tuning (SFT), Retrieval-Augmented Generation (RAG), and Vector Semantic Embedding-were compared, as follows:

LoRA-based Supervised Fine-Tuning with default parameters: Using the LlaMa 8b model, the training datasets for both tasks were combined for fine-tuning. Retrieval-Augmented Generation (RAG): The Chat GLM 4 (130b) model, known for strong text comprehension, knowledge reasoning, and multilingual support, was used to build an external knowledge base from the GND vocabulary and the training set's indexed documents. MaRSI: The final method used, based on document similarity matching and relevant subjects ranking, termed MaRSI.

4.3 Results and Analysis

(1) Results and Analysis on Dev set. Three approaches were used to generate about 50 subject terms for each document in the development set (Dev). Initial random sampling checks revealed that, due to factors such as model performance and external knowledge base construction, the RAG indexing approach performed poorly. Therefore, only two approaches-LLMs fine-tuning (SFT) and semantic embedding (MaRSI)-were compared on the merged validation set. The results are shown below:

As shown in Table 1, MaRSI consistently outperforms SFT in the top 30 results, with a significant decline in SFT's performance from the 10th result onward, possibly due to the factors mentioned earlier. In addition to better indexing performance, MaRSI follows a human-like processing approach, similar to manual subject indexing, where relevant documents are matched to the target subjects through semantic computation. Furthermore, MaRSI is a fast and scalable method, well-suited for large document datasets.

(2) Results and Analysis on Test Set. The test set

P@K	SFT	MaRSI
P_1	38.03%	52.43%
P_2	21.10%	38.65%
P_3	14.09%	30.50%
P_4	10.57%	25.00%
P_5	8.46%	21.25%
P_6	7.05%	18.69%
P_7	6.04%	16.28%
P_8	5.23%	15.12%
P_9	4.67%	13.86%
P_10	4.23%	12.78%
Avg_MAP	20.90%	41.19%

Table 1: SFT & MaRSI Dev Comparison (Top 10).

Task	**@5**			**@10**		
	P	R	F1	P	R	F1
Core	24.94%	47.51%	32.71%	15.81%	57.49%	24.80%
All	22.99%	43.81%	30.15%	44.21%	52.20%	22.41%

All	10.43%	56.12%	17.59%	8.25%	58.41%	14.45%

Table 2: Quantitative Analysis of MaRSI Indexing.

consists of two parts: Core and All, corresponding to two distinct indexing tasks. For each part, the MaRSI method outputs 50 subjects per document. Quantitatively, the core subject indexing achieved an average recall rate of 65.68%, ranking 1st in the task, while the full subject indexing had an average recall rate of 58.56%, ranking 3rd. Generally, precision and F1 scores decline as the number of subjects increases (Table 2). The overall low accuracy may be attributed to the fact that the number of subjects in the Train and Dev sets was much smaller than the entire GND vocabulary, making it difficult for some unused subjects to be matched through semantic embedding.

Qualitatively, LLMs4Subjects task incorporated expert analysis. This explanation references Case 1 results(D'Souza et al., 2025), which assess only the technical correctness of indexing without strict subject relevance requirements. MaRSI achieved an average precision of 52.13%, ranking first in the task. The precision of subject assignmentvaried significantly across disciplines (Table 3). Architecture, social sciences and economics showed the highest indexing accuracy (approximately 78%, 78%, and 74% respectively), respectively, demonstrating the method's robustsemantic capture capability inthese

Table 3: Subject Indexing Results for Different Classifications.

fields, likely due to the semantic richness and accuracy of subject terms of them. Semantic embedding methods also performed well in engineering, literature studies and physics, where subject terms are typically more specialized and precise. However, the results were more moderate inmaterial science , mathematics, computer science and chemistry , and poorer inelectrical engineering, linguistics, traffic engineering medicine, and history. This can be attributed to the semantic complexity and ambiguity in these fields, where subject terms tend to be more nuanced and multifaceted, and the subject terms are often highly specialized and complex, making semantic similarity matching less effective.

5 Conclusion and Future Research

This study compares three automated subject indexing methods: RAG, SFT, and MaRSI. It finds that MaRSI, which emulates the cognitive patterns of human indexers , is an efficient and high-quality method. Its performance improves with the richness and diversity of subject terms in the training set. However, indexing results exhibit clear disciplinary variations due to different semantic characteristics across fields. These methods are not mutually exclusive, and future work will explore the synergistic use of semantic embedding, LLMs, and rule-based reasoning. By adjusting fusion output weights according to disciplinary semantic traits, we aim to enhance the accuracy, efficiency, and consistency of automated subject indexing in libraries.

Abstract

This paper describes YNU-HPCC (Alias JH) team's participation in the sub-task 2 of the SemEval-2025 Task 5, which requires fine-tuning language models to align subject tags with the TIBKAT collection. The task presents three key challenges: cross-disciplinary document coverage, bilingual (English-German) processing requirements, and extreme classification over 200,000 GND Subjects. To address these challenges, we apply a contrastive learning framework using multilingual Sentence-BERT models, implementing two training strategies: mixed-negative multi-label sampling, and single-label sampling with random negative selection. Our best-performing model achieves significant improvements of 28.6% in average recall, reaching 0.2252 on the core-test set and 0.1677 on the all-test set. Notably, we reveal model architecture-dependent response patterns: MiniLM-series models benefit from multi-label training (+33.5% zero-shot recall), while mpnet variants excel with single-label approaches (+230.3% zero-shot recall). The study further demonstrates the effectiveness of contrastive learning for multilingual semantic alignment in low-resource scenarios, providing insights for extreme classification tasks. Our implementation is publicly available at https://github.com/Jiangnaio/SemEval2025Task5.

1 Introduction

This task emerges in response to the challenges associated with manually tagging library bibliographic records (D'Souza et al., 2025). Our team is primarily involved in Task 2, which is dedicated to aligning GND Subjects with TIBKAT records. This task involves two datasets: the core dataset, which contains 79,427 subject labels, and the all dataset, comprising 204,739 subject labels. The data for the entire task is presented in two languages, German and English, necessitating the consideration of multilingual characteristics during the modeling process.

Data analysis highlights two critical characteristics that have significant implications for the task. Firstly, there is severe label underutilization, with only 31.9% (25,371 out of 79,427) of the core dataset labels and 16.5% (33,898 out of 204,739) of the all dataset labels appearing in the training and development subsets. Secondly, there is extreme subject sparsity, as over 50% of the topics contain two or fewer documents. This situation creates high-dimensional semantic space challenges.

Given the large number of subjects to classify in this task, traditional topic-classification approaches like Latent Dirichlet Allocation (LDA, (Blei et al., 2003; Jelodar et al., 2019)) struggle due to complex, non-parallelizable probability calculations that result in low computational efficiency.

Although BERT (Devlin et al., 2019; Koroteev, 2021; Zhou et al., 2024) can capture sentence semantics effectively, its generated sentence vectors suffer from anisotropy, being unevenly distributed in the vector space and concentrated in a narrow cone, leading to generally high calculated vector similarities. Most Transformer-based pre-trained models face this issue in the learned sentence-vector space (Gao et al., 2019; Ethayarajh, 2019).

Researchers (Cer et al., 2018; Conneau et al., 2018) have developed sentence-vector encoders using a "dual-tower" structure with sentence-task training datasets. With the advent of Sentence-BERT (Reimers and Gurevych, 2019), sentence vector representation has advanced significantly (Chi et al., 2023; Wang et al., 2025; Tavares and Ayres, 2025). It modifies BERT's structure and fine-tunes it via supervised tasks (Luo et al., 2022) , overcoming BERT's limitations in sentence-vector representation. Subsequently, (Gao et al., 2021) proposed contrastive learning for sentence-related tasks, often used to fine-tune Sentence-

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2443–2448

BERT. (Huang et al., 2024) found that the loss function during Sentence-BERT training differs from that during prediction, causing poor performance in similarity determination. (Nielsen and Hansen, 2023) identified a hubness problem in Sentence-BERT's semantic space, which may also exist in this task. Future research could improve the loss function and optimize the training set to address these issues.

The pre-trained models used here are based on Sentence-BERT. The following sections detail our work and results.

2 Related Work

To address this task, we carried out a series of investigations. First, training datasets were created using three methods: the multi-label sample scheme, the single-label sample scheme with mixed negative samples, and the multi-label sample scheme with mixed negative samples. The prepared datasets were then utilized. Simultaneously, we explored and experimented with several pre-trained models from sentence-transformers (https://www.sbert.net/) and, prior to fine-tuning, tested them according to the official metrics (4.3). The test results are presented in Table 1.

Subsequently, we trained several sentence-transformers models using contrastive learning and reported the training results along with their analysis. Eventually, the average recall scores on the all-test and core-test datasets were 16.8% and 22.5% respectively (see Table 3). Moreover, we provided detailed experimental methodologies, procedures, some experimental results, and their analysis.

Furthermore, we proposed leveraging a translation model (Tiedemann and Thottingal, 2020) to conduct bidirectional translation between German and English, thus achieving data augmentation, and performing fine-tuning verification on the augmented data.

Lastly, we concluded the experiment, analyzed its limitations, and proposed subsequent improvement plans.

3 Methodology

Our architecture combines Sentence-BERT with contrastive learning to address the extreme classification challenge. As shown in Figure 1, the system processes TIBKAT-GND pairs through dual encoders with shared parameters.

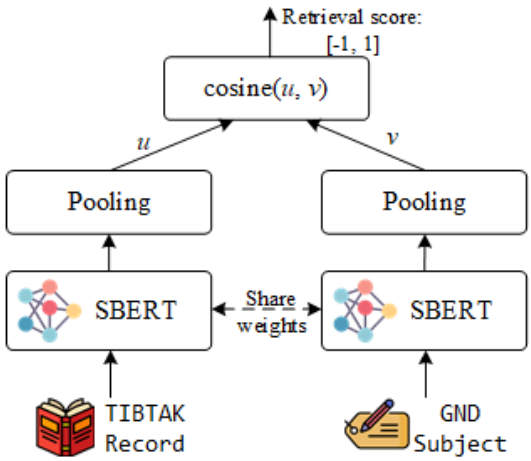

Figure 1: Flowchart illustrating the use of the Sentence-BERT model and cosine similarity to measure the similarity between two text segments: TIBTAK Record and GND Subject.

Semantic Encoding For a TIBKAT record d and GND subject s, we compute their embeddings:

$$\mathbf{h}_d = \text{SBERT}([d_{\text{title}}; d_{\text{abstract}}]) \quad (1)$$

$$\mathbf{h}_s = \text{SBERT}([s_{\text{Name}}; s_{\text{Alternate Name}}]) \quad (2)$$

where $[;]$ denotes concatenation and SBERT represents our fine-tuned model.

Balanced Sample Construction We create training pairs maintaining 1:1 positive-negative ratio:

- Positive: (d, s^+) where $s^+ \in \mathcal{S}_d^{\text{true}}$
- Negative: (d, s^-) where $s^- \in \mathcal{S}_d^{\text{false}}$

where $\mathcal{S}_d^{\text{true}}$ represents the set of all s that are related to d. S represents the set of all s or the GND Subjects used in the train and dev datasets. $\mathcal{S}_d^{\text{false}}$ represents $\mathcal{U}(\mathcal{S} \setminus \mathcal{S}_d^{\text{true}})$. (Li et al., 2024, 2025) We design two sampling paradigms for extreme classification scenarios:

Aggregate Multi-label Sampling: Aggregate all the true subjects of $\mathcal{S}_d^{\text{true}}$ into a single sample $(d, Aggregate(\mathcal{S}_d^{\text{true}}), 1)$, and randomly sample an equal number of $\mathcal{S}_d^{\text{false}}$ into a negative sample $(d, Aggregate(\mathcal{S}_d^{\text{false}}), 0)$ to construct 1:1 positive-negative pairs.

Instance-wise Disaggregated Sampling : Individually construct a positive sample $(d, s_i, 1)$ for each true subject s_i, and randomly select a negative subject s_i' from the candidate set $\mathcal{S}_d^{\text{false}}$ to create a negative simple $(d, s_i, 0)$.

Training Objective We optimize a temperature-scaled contrastive loss:

$$\mathcal{L} = -\frac{1}{N}\sum_{i=1}^{N}\log\frac{e^{\text{sim}(\mathbf{h}_d^{(i)},\mathbf{h}_s^{(i)+})/\tau}}{\sum_{j=1}^{K}e^{\text{sim}(\mathbf{h}_d^{(i)},\mathbf{h}_s^{(i)j})/\tau}} \quad (3)$$

where $\tau = 0.05$ is learned during training, and $K = 2$ for our 1:1 sampling.

4 Experiments

4.1 Experimental Setup

We conducted systematic evaluations across three dimensions: (1) baseline performance of pre-trained models, (2) effectiveness of multi-label simple, and (3) effectiveness of single-label simple. Our implementation leveraged four multilingual Sentence-BERT variants from the sentence-transformers library, selected based on their zero-shot performance (Table 1).

Training Configuration

- **Batch size:** 32 (multi-label) / 16 (single-label)
- **Learning rate:** 2×10^{-5} with AdamW optimizer
- **Temperature parameter τ:** 0.05 (learned)
- **Training epochs:** 3 (core dataset) / 20 (all dataset)
- **Hardware:** 1×NVIDIA RTX 3060 GPU

4.2 Data Strategies

Upon analyzing the datasets, we discovered that even the GND subject covered by the datasets in the tib-core-subjects directory might not be found in the GND-Subjects-tib-core.json file. Therefore, we utilized the GND-Subjects-all.json file to create the datasets for training and evaluation.

4.3 Evaluation Metric

We employ three standard metrics for system evaluation:

$$Precision = \frac{Count(true\_set \cap pred\_set)}{k} \quad (4)$$

$$Recall = \frac{Count(true\_set \cap pred\_set)}{Count(true\_set)} \quad (5)$$

$$F1 - score = 2 \times \frac{Precision \times Recall}{Precision + Recall}, \quad (6)$$

Model	P	R	F1
all-distilroberta-v1	0.0086	0.0820	0.0146
all-MiniLM-L6-v2	0.0112	0.1031	0.0190
all-mpnet-base-v2	0.0110	0.1043	0.0187
P-MiniLM-L6	0.0049	0.0439	0.0083
PM-MiniLM-L12	**0.0185**	**0.1751**	**0.0317**
P-mpnet-base-v2	0.0081	0.0773	0.0138
PM-mpnet-v2	0.0113	0.1069	0.0192

Table 1: Zero-shot performance comparison (Precision/Recall/F1 averages for k=5-50), the P of models represents "paraphrase" and M represents "multilingual".

Among them, the set of true GND Subjects is represented as $true\_set$, and the set of the top k most relevant GND Subjects predicted by our model is represented as $pred\_set$. The number of elements in a set is counted by $Count(*)$, and the intersection of sets is denoted by $\cap$. $F1 - score$ will be 0 when $Precision + Recall = 0$.

For comprehensive analysis, we compute metric averages across k-values from 5 to 50 (incrementing by 5), reporting: Avg. Precision@k, Avg. Recall@k and Avg. F1-score@k

4.4 Baseline

We select the metrics of the PM-MiniLM-L12 (paraphrase-multilingual-MiniLM-L12-v2) model in Table 1 as the baseline.

5 Results and Analysis

5.1 Zero-shot Performance Baseline

Table 1 presents the zero-shot performance of various pre-trained models, establishing baseline metrics for subsequent comparisons. The paraphrase-multilingual-MiniLM-L12-v2 (PM-MiniLM-L12-v2) model demonstrates superior zero-shot recall (17.51%), outperforming other candidates by 63.8% relative to the second-best PM-mpnet-v2 model. This baseline analysis reveals significant performance variance across architectural variants, with MiniLM-series models showing particular promise for the target task.

5.2 Training Strategy Effectiveness

Table 2 compares the impact of different training approaches. The multi-label sampling strategy improves performance for all-distilroberta-v1 and P-MiniLM-L6, while both the all-MiniLM-L6-v2 and

Table 2: Training strategy comparison (Average Recall@k)

Model	Strategy	P	R	F1
all-distilroberta-v1	Multi-label	0.0135↑	0.1749↑	0.0238↑
all-MiniLM-L6-v2	Multi-label	0.0057↓	0.0573↓	0.0098↓
P-MiniLM-L6	Multi-label	0.0060↑	0.0586↑	0.0102↑
PM-mpnet-v2	Multi-label	0.0086↓	0.0889↓	0.0149↓
PM-mpnet-v2	Single-label	0.0336↑	0.3531↑	0.0578↑

PM-mpnet-v2 models exhibited performance degradation. The PM-mpnet-v2 model demonstrated significant performance improvement under the single-label training strategy. This dichotomy suggests an architecture-dependent optimization landscape where model capacity interacts with sampling strategy effectiveness.

5.3 Competition Results and Analysis

Our official submission results, presented in Tables 3, demonstrate the performance of the fine-tuned PM-MiniLM-L12-v2 model on both all-test and core-test datasets. It should be noted that due to an operational oversight, the potentially superior fine-tuned PM-mpnet-v2 model was inadvertently excluded from the final submission.

The fine-tuned PM-MiniLM-L12-v2 model achieved significant improvements, with a 28.6% enhancement in average recall on the core-test dataset (0.2252). However, its performance on the all-test dataset (0.1677) was comparatively lower, likely due to the model's exclusive training on the core dataset. This suggests potential domain adaptation challenges when transitioning from core to all datasets.

Metric Analysis Across Top-k Thresholds Figure 2 reveals three key patterns in metric behavior across different top-k values (k = 5, 10, 15, 20):

- **Precision** exhibits a clear negative correlation with k
- **Recall** demonstrates a strong positive correlation with k
- **F1-score** shows a moderate positive trend

These trends suggest that optimal k-value selection should be application-dependent, balancing the trade-off between precision and recall based on specific use case requirements.

Dataset	Avg. Recall	Relative Imp.
Core-Test	0.2252	+28.6%
All-Test	0.1677	-

Table 3: Comparative performance analysis across test datasets (Average Recall@k for k=5–50)

5.4 Improvement

Moreover, we tested the Alibaba-NLP/gte-multilingual-base (Zhang et al., 2024; Chen et al., 2024; Saad-Falcon et al., 2024) model and found that it still performs well before training.(0.0275 on Avg. Precision@k, 0.2508 on Avg. Recall@k, 0.0468 on Avg. F1-score@k) The multi-stage training method of the gte-multilingual-base model provides inspiration for subsequent research on this task. In the evaluation, we found that the accuracy of the model is not high. A two-stage prediction method can be adopted: First, use Sentence-BERT to select the top 500 most relevant Subjects, and then let the large model select the top 50 most relevant Subjects with prompt words. The relevant test code has been submitted to `https://github.com/Jiangnaio/SemEval2025Task5`.

6 Conclusion

In this study, we constructed training datasets using both multi-label and single-label sample methods, mixed them with negative samples at a 1:1 ratio, and then fine-tuned several pre-trained models based on the Sentence-BERT architecture using contrastive learning. Ultimately, we implemented and validated a solution for the subtask 2 of the SemEval-2025 Task 5 under low GPU memory conditions. Our approach enables efficient and rapid topic retrieval with limited computational resources. The best results of our model submitted for official evaluation achieved an average recall rate of 0.1677 on the all-test dataset and 0.2252 on the core-test dataset (performance demonstrated

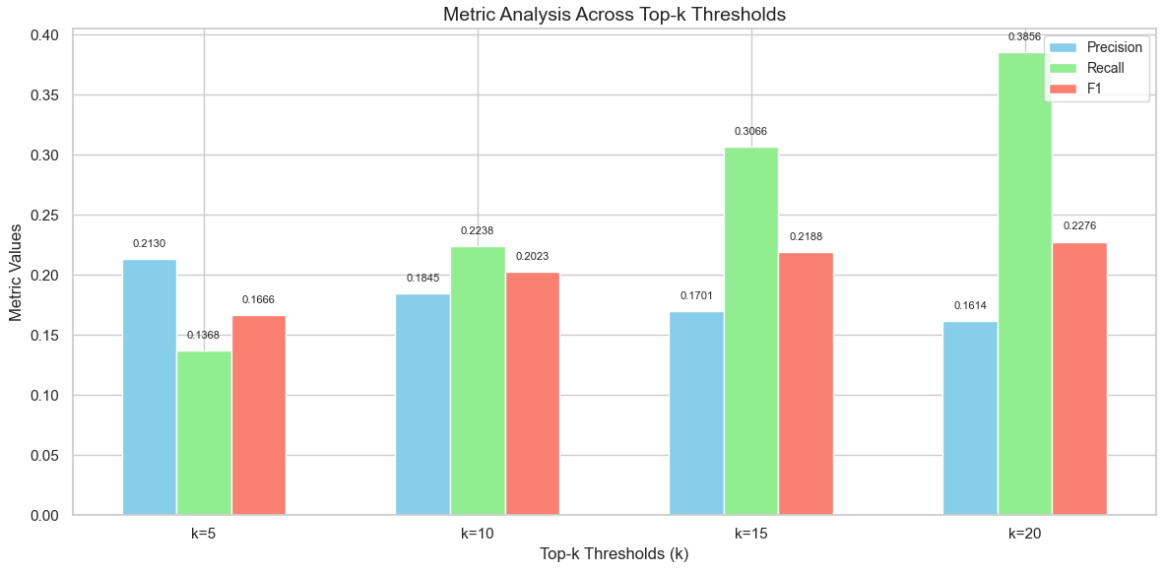

Figure 2: Bar chart of official test results

only in pre-trained models with fewer than 300M parameters).

For future research, bidirectional translation can be employed for data augmentation to address the issue of insufficient sample numbers in certain subjects. During inference, a two-stage approach combined with LLMs can be adopted. Detailed steps for these subsequent tasks are provided in the results and analysis section.

TartuNLP at SemEval-2025 Task 5: Subject Tagging as Two-Stage Information Retrieval

Aleksei Dorkin and Kairit Sirts
Institute of Computer Science
University of Tartu
{aleksei.dorkin, kairit.sirts}@ut.ee

Abstract

We present our submission to the Task 5 of SemEval-2025 that aims to aid librarians in assigning subject tags to the library records by producing a list of likely relevant tags for a given document. We frame the task as an information retrieval problem, where the document content is used to retrieve subject tags from a large subject taxonomy. We leverage two types of encoder models to build a two-stage information retrieval system—a bi-encoder for coarse-grained candidate extraction at the first stage, and a cross-encoder for fine-grained reranking at the second stage. This approach proved effective, demonstrating significant improvements in recall compared to single-stage methods and showing competitive results according to qualitative evaluation.

1 Introduction

SemEval-2025 Task 5 aims to produce a technical solution to annotate a large collection of documents with relevant subject tags (D'Souza et al., 2025). Subject tags come from the GND (Gemeinsame Normdatei in German or Integrated Authority File in English) subject taxonomy. For example, an article dealing with seismic resistance of industrial buildings may have subject tags such as "Industrial Plant Technology (General)" and "Earthquake Safety Construction Engineering".

Systematic and precise metadata annotation, subject tagging in particular, is essential for digital collections of documents to be usable and useful for the end-users as information retrieval and knowledge discovery sources. However, producing such metadata, especially at scale, requires an immense amount of specialist time and effort. For instance, a recent prototype at the National Library of Estonia, Kratt, found that even with machine assistance catalogers still needed to validate many tags, highlighting the labor bottleneck (Asula et al., 2021).

The core idea behind our system is that given a tag definition and a document to tag, it should be possible to predict whether the given tag is suitable for the document by measuring how similar their representations are using a pre-trained language model. This can be thought of as an information retrieval problem.

Bi-encoder and cross-encoder models are two common ways to approach this problem (Reimers and Gurevych, 2019; Nogueira and Cho, 2019; Karpukhin et al., 2020), both with their strengths and weaknesses. A bi-encoder processes documents and queries independently to produce their vector representations. Then, cosine similarity is measured between the document and query vectors to score relevance. Bi-encoder allows for efficient retrieval in large document collections as the document representations can be pre-computed. The downside, however, is that it is impossible to capture token-level similarities between documents and queries with this approach. Meanwhile, a cross-encoder processes document and query pairs simultaneously, capturing such similarities and producing more fine-grained similarity scores. The computational cost of using a cross-encoder is significantly larger compared to that of a bi-encoder, making it generally unsuitable for large document collections. Accordingly, we combine both in a single two-stage system to produce the optimal result.

Our system scored closer to the middle of the quantitative leaderboard (Table 1); however, it surpassed many of the participants with a similar rank in the qualitative leaderboard (Table 2), especially in Case 1, where "technically correct, but irrelevant" tags were counted in favor of the teams. This is likely due to our system not considering the tag-to-tag relations, thus missing a more complex knowledge structure in the dataset and being unable to distinguish more intricate cases. More specifically, we consider each document/tag pair independently of each other. However, we hypothesize that some

subject tags may be mutually exclusive.

We release the code for training and inference and the models.[1]

2 Background

In the shared task, the participants were given a collection of English and German documents containing a title and an abstract. The goal was to recommend the top N subjects most relevant from a predefined set of subjects. Each subject was represented by an alphanumeric code, a name in German, and an optional definition in German. Training and validation data provide ground truth tags for each document.

Two subtasks were offered to the participants: a complete collection of subjects (tibkat) and a smaller subset of the collection (tibkat-core). The former also contained a larger number of documents. In our experiments, we used the smaller tibkat-core dataset. However, we submitted the final results for both subtasks.

3 System Overview

Our system is based on the two-stage approach to information retrieval. We consider the available texts of the documents (usually, just the title and the abstract) to be the *queries*, while the subject definitions act as the *documents* to be retrieved. In the first stage, we employ an approximate nearest neighbors (ANN) search algorithm (Dasgupta and Freund, 2008) over pre-computed subject embeddings. In the second stage, these N retrieved subject descriptions are re-ranked using a cross-encoder model (Nogueira and Cho, 2019).

3.1 First Stage

The first stage of our system is a pre-trained bi-encoder model. We did not perform any additional fine-tuning, relying on the strength of pre-trained multilingual embeddings, which have been shown to handle cross-lingual retrieval effectively (Dorkin and Sirts, 2024a). The only modification we made was to provide a task-specific prompt for the model. For each document, we queried the model with the document text and retrieved top N subject descriptions.

The model is only used once to obtain representations for each document and subject, which are then stored and reused as needed, making the model relatively cheap and fast to use. However, performing the semantic search over a large collection of subject representations remains computationally expensive. To mitigate that, we employed an approximate nearest neighbors algorithm to create a fast search index for the subjects as a data structure separate from the pre-computed representations. Accordingly, the index is then queried with document representations to retrieve subject candidates.

The first stage efficiently retrieves a coarse set of

Table 2: Average recall for both cases of qualitative evaluation.

N candidate subjects. The efficiency stems from leveraging ANN indices; while increasing the number of trees (n_trees) enhances the index accuracy and thus retrieval quality (higher recall), it also increases memory usage and the time required to build and query the index. Varying this parameter provides flexibility in tuning Stage 1 performance against computational resources.

3.2 Second Stage

In the second stage, we employ a cross-encoder model to re-rank the subject candidates initially selected by the first-stage model. Specifically, pairs are formed where each instance consists of the target text and one candidate subject description. Each such pair is fed into the cross-encoder model.

This model functions as a classifier trained to assess the relevance or similarity between the paired texts (target text and candidate definition). It outputs a probability score indicating the likelihood of relevance, which we interpret directly as a normalized similarity score between 0 and 1. This scoring allows us to refine and reorder the list of subject candidates.

Cross-encoder models are well-suited for this task due to their proven ability to generalize across highly heterogeneous text collections (Thakur et al., 2021; Dorkin and Sirts, 2024b; Petrov et al., 2024). They excel at capturing subtle nuances by jointly processing document-query-like pairs to compute fine-grained relevance scores.

Given the specificity of this shared task problem, no suitable pre-trained off-the-shelf models existed. Consequently, we developed our cross-encoder model through a fine-tuning process: we took a large, multilingual text encoder pre-trained on general data and adapted it by training on the provided dataset.

While cross-encoders offer superior ranking performance—demonstrated by their ability to significantly boost recall (nearly doubling values in Table 3) compared to bi-encoder approaches—they are computationally expensive. This is primarily because generating predictions requires processing each candidate pair individually. This represents a key scalability consideration for this approach.

4 Experimental setup

The shared task data underwent minimal transformations to be suitable for our approach. For each document, the title and the abstract were concatenated. Similarly, the name and definition (when available) were concatenated for each subject. Thus, each document and each subject was represented by a single string, which served as input to our models.

Our solution primarily relied on the Sentence-Transformers[2] library for both stages of the system. We employed multilingual-e5-large-instruct[3] (Wang et al., 2024) as the first stage model to produce document and subject representations. We customized the prompt used to encode the documents to include the following: *"Instruct: Given the following title and abstract for the document,*

[2] https://www.sbert.net/

[3] https://huggingface.co/intfloat/multilingual-e5-large-instruct

Recall at k	Bi-encoder	Bi-encoder → Cross-encoder

35	0.2496	0.3661
40	0.2590	0.3732
45	0.2655	0.3791
50	0.2719	0.3837

Table 3: Recall values per k for the submitted runs.

retrieve the relevant subjects classifying the document". The query prompt remained unchanged from the default prompt *"Query:"*. We used the Annoy[4] library to build the approximate neighbors index with a somewhat large number of trees equal to **100** to maximize the recall at the cost of some performance. When selecting candidates for the second stage we the search_k parameter to **50000** for the same purpose. Finally, for each document we selected N equal to **512** subject candidates for re-ranking.

For the second stage, we fine-tuned a cross-encoder based on mdeberta-v3-base[5] (He et al., 2021) with default parameters using Sentence-Transformers. We trained on positive examples from document-subject pairs in the training set and constructed negative examples by pairing documents with randomly sampled subjects not explicitly linked to them. The model achieved high performance quickly during training; we stopped after one epoch as the F-score plateaued near 0.97. The resulting model was used to make predictions on the validation split. The model is available on HuggingFace[6].

5 Results

With our submission to the shared task, we aimed to build a hackathon-like proof-of-concept system to test the feasibility and measure the benefits of applying a two-stage information retrieval approach to match document contents with a structured knowledge resource. More specifically, our interest lied in the improvements attained by the second stage model at the cost of added complexity and computational requirements compared to using only bi-encoder representations for retrieval.

With that purpose in mind, we submitted two runs for final evaluation: bi-encoder retrieval and two-stage retrieval. The results in Table 3 demonstrate the substantial benefit of incorporating the cross-encoder re-ranking stage. Adding the second stage nearly doubles the recall across various cut-off points k, significantly improving performance over using only the Stage 1 bi-encoder retrieval. This highlights the effectiveness of leveraging sentence similarity between documents and subject definitions as relevance signals.

However, the enhanced performance comes with computational implications. Both stages involve parameters that directly impact scalability:

- **Stage 1 (Bi-Encoder + ANN)**: While the initial candidate retrieval is relatively fast due to approximate nearest neighbor search, increasing the n_trees parameter used in Annoy's index construction enhances recall by building more accurate indices. Additionally, the search_k parameter determines how many nodes in the index are explored during the search, thus also improving recall. These improvements come at the cost of an increased memory footprint and longer indexing and querying times.

- **Stage 2 (Cross-Encoder)**: The primary computational bottleneck lies in applying the cross-encoder to re-rank all N candidates for each document. This step is significantly more computationally demanding than Stage 1, especially as N grows large. While feasible for annotating documents individually on local CPU hardware, deploying such a system at extreme scale—e.g., processing millions of documents in real-time or with strict resource limits—would necessitate careful management of parameters like n_trees and N, potentially requiring optimization techniques (like quantization or using a shallow cross-encoder).

Upon examination of the results of the qualitative evaluation, we discover that the errors made by our system are primarily related to subjects with similar names and no definitions. The incorrectly assigned subject seems to be generally vaguely related to the document. However, they define a different subfield of a relevant subject.

[5] https://huggingface.co/microsoft/mdeberta-v3-base

[6] https://huggingface.co/adorkin/llms4subjects-cross-encoder

For example, for an article titled *"Model-based engineering of an automotive adaptive exterior lighting system: realistic example specifications of behavioral requirements and functional design"*, some of the tags that are considered correct are "Automotive Engineering, Vehicle Construction, Conveyor Technology, Aerospace Technology" and "System Planning IT, Data Processing". Meanwhile, "Lighting technology Electrical engineering, Electrical power engineering: Calculation, Design and Construction of Lighting Systems" and "Outdoor Lighting Electrical Engineering, Electrical Power Engineering" are only technically correct. Finally, "Adaptive Process Model Measurement, Control and Regulation Technology" and "Model-Based Testing Computer Science, Data Processing" are assigned incorrectly to this document by our system.

The main limitation of our approach is the reliance only on text representations. Using additional information such as related subjects and tag co-occurrence could have improved the performance of our system.

6 Conclusion

This paper described our solution to SemEval-2025 Task 5 based on a two-stage information retrieval system, where we used the documents to annotate as queries to retrieve candidate subject tags from a large collection of subject tags. For both stages we view sentence similarity between document texts and subject tag descriptions as the relevance score. Our system demonstrates moderate performance. However, we confirmed our hypothesis that a second-stage re-ranker substantially improves the performance of the system compared to using a bi-encoder as the only stage.

Abstract

Our team, *silp_nlp*, participated in the SemEval-2025 Task 5: LLMs4Subjects, which focuses on subject recommendation based on the given title and abstract. This task provided bilingual data in English and German for training and evaluation purposes. It consists of two data sets: one for all subjects and the other for technical subjects. We utilised statistical models, including TF-IDF and Sentence Transformers, to generate embeddings, and employed cosine similarity for recommendations. Our results show that JinaAi (sentence transformer) performed better than other sentence transformers and TF-IDF.

1 Introduction

The LLMs4Subjects shared task (D'Souza et al., 2025) aims to develop a subject recommendation system. The goal is to predict the most relevant subjects from the entire GND [1] subject collection to tag a given TIB technical record [2]. Each system will receive a technical record's title and abstract as input, and it must generate a customizable top-k list of relevant GND subjects. Since the input records may be in English or German, the systems should support bilingual semantic processing.

This task explores the potential of language model solutions for subject classification and tagging. It is based on the open-access TIB collection, specifically TIBKAT, which includes over 100,000 records such as technical reports, publications, and books, primarily in English and German. These records are classified according to the GND subjects taxonomy.

Leveraging statistical methods and transformer-based architectures for subject classification offers significant advantages. Semantic indexing with other vocabularies has gained attraction (Kazi et al., 2021; Wu et al., 2014). Notably, the prediction of Medical Subject Headings (MeSH) for biomedical literature has experienced significant advancements through the application of deep learning and machine learning techniques (Jin et al., 2018). In recent years, transformer-based models have demonstrated remarkable success across various Natural Language Processing (NLP) tasks. Among them, Sentence Transformers have attracted significant attention, particularly for tasks involving sentence similarity measurement. In this work, we employed Sentence Transformers to compute sentence similarity, leveraging cosine similarity as the distance metric. The datasets provided for the task encompass five distinct types of documents: articles, books, conference papers, reports, and theses.

2 Datasets

As part of the shared task, we were provided with datasets (D'Souza et al., 2024) containing two versions of the GND taxonomy:

GND Subjects - TIB Core: A focused subset containing subjects relevant to the core technical domains of TIB.

Full GND Subjects Collection: The complete set of GND subjects offers a broader classification range.

The total number of training, development, and testing samples for both the language and each document type is summarized in Tables 1 and 2, respectively, for both datasets (All Subjects and Tib-Core Subjects). Additionally, Tables 3 and 4 present the total number of unique subjects for each dataset.

3 Methodology

3.1 Embedding based cosine similarities

In this method, we converted all titles and abstracts into stored embeddings of the titles and abstracts using a sentence transformer (Reimers and Gurevych,

2019). During testing, the titles and abstracts of the test data were converted to embeddings. We determined the best matches on the basis of the cosine similarities between the embeddings of the test data and those of the training data. We converted the titles and abstracts into embeddings using two Sentence Transformer models. Furthermore, we conducted experiments using TF-IDF embeddings for comparison.

JinaAi/jina-embeddings-v3 (Sturua et al., 2024) JinaAi's jina-embeddings-v3 is a multilingual text embedding model supporting 89 languages, designed to process up to 8,192 input tokens and produce 1,024-dimensional embeddings. Based on a pre-trained XLM-RoBERTa (Conneau et al., 2020) with 559 million parameters, it incorporates five LoRA adapters (Hu et al., 2021) tailored for specific tasks: retrieval (separate adapters for queries and documents), clustering, similarity assessment, and classification. The model employs Matryoshka representation learning (Kusupati et al., 2024), which allows control over embedding dimensions with minimal performance loss.

distiluse-base-multilingual-cased-v2 (Reimers and Gurevych, 2020) The distiluse-base-multilingual-cased-v2 model is a multilingual sentence embedding model developed by the Sentence-Transformers team. It encodes sentences and paragraphs into a 512-dimensional dense vector space, enabling tasks such as clustering and semantic search across more than 50 languages. The model is optimized for efficient processing, with a maximum sequence length of 128 tokens.

In embeddings-based top-50 classification for subject indexing, this model can encode texts into 512-dimensional embeddings that capture semantic

3.2 Hierarchical Clustering

In this hierarchical framework (Kavyasrujana and Rao, 2015), the dataset comprised approximately 16,000 subjects across nearly all data types. Comparing the similarity of all 16,000 subjects with an article by extracting embeddings can be inefficient and may result in suboptimal performance. To address this, we divided the data into three levels of clusters, with the number of clusters varying at each level. Our objective was to reduce the number of subjects for comparison, focusing on filtering out the most relevant ones rather than comparing the article with all subjects. Architecture of a two-level cluster given in Fig. 1.

First, we extracted embeddings for all subjects in each dataset using the JinaAI embedding model, a specialized multilingual model for English and Ger-

man. After obtaining the embeddings, we clustered the subjects at each level, with each subsequent level containing half the number of subjects as the previous one. Cluster embeddings were calculated by averaging the embeddings of all subjects within each cluster.

After clustering, we compared the article's embeddings (derived from both the text and abstract) with the embeddings of one relevant cluster at each level, except at the final level, where we adopted a different approach. At the preceding level, we identified the most relevant cluster. If that cluster contained more than 50 subjects, we compared the article's embeddings with the embeddings of each subject within that cluster and selected the top 50 subjects based on similarity. If the cluster had fewer than 50 subjects, we included an additional cluster—the second most similar to the article—ensuring that the total number of subjects compared exceeded 50.

We repeated this process using the Distiluse-base-multilingual model as well.

Table 8 displays the clusters for the TIB dataset, while Table 7 shows the clusters for the complete subjects dataset. We have also included a table outlining the number of clusters utilized at each level for each dataset.

4 Results & Analysis

Table 9 presents the overall average results for each model across different levels. Additionally, the average results for each level are summarized at the end of the table. The JinaAi sentence transformer model outperforms the other models based on cosine similarities. JinaAi sentence transformer model was pretrained for the English and German languages; therefore, it showed better results.

Table 7 displays the top-5 results for each language and document type across all subjects in the dataset, highlighting the superior performance of the JinaAi sentence transformer model compared to the other models.

Similarly, Table 8 shows the top-5 results for each language and document type for the TIB subjects dataset, also demonstrating that the JinaAi sentence transformer model outperforms all other remaining models.

5 Conclusion

This work explored subject recommendation using sentence transformers within the SemEval-2025 Task 5 (LLMs4Subjects) challenge. Our approach leveraged embedding-based cosine similarity and hierarchical clustering to predict relevant GND subjects for TIB technical records in English and German. By experimenting with different models, including JinaAi, Distiluse-base-multilingual, and TF-IDF, we found that the JinaAi sentence transformer consistently outperformed other methods in terms of precision, recall, and F1-score.

Our results highlight the effectiveness of transformer-based embeddings in semantic similarity tasks for subject classification. Additionally, hierarchical clustering helped reduce computational complexity by narrowing down candidate subjects efficiently. Despite the improvements, future work can focus on fine-tuning domain-specific embeddings, exploring knowledge graph integration, and enhancing multilingual capabilities for better generalization.

Abstract

While extensive research exists on misinformation and disinformation, there is limited focus on future-oriented commitments, such as corporate Environmental, Social, and Governance (ESG) promises, which are often difficult to verify yet significantly impact public trust and market stability. To address this gap, we introduce the task of promise verification, leveraging natural language processing (NLP) techniques to automatically detect ESG commitments, identify supporting evidence, and evaluate the consistency between promises and evidence, while also inferring potential verification time points. This paper presents the dataset used in SemEval-2025 PromiseEval, outlines participant solutions, and discusses key findings. The goal is to enhance transparency in corporate discourse, strengthen investor trust, and support regulators in monitoring the fulfillment of corporate commitments.

1 Introduction

In an era characterized by rapid information dissemination and increasing reliance on public statements from influential figures–such as corporate executives and political leaders–the balance between freedom of speech and ethical responsibility has become a critical societal concern. While freedom of speech empowers individuals to express opinions and make commitments, it also raises complex challenges when these statements impact public trust, financial decisions, or social stability. Only a small number of political leaders, such as the president, may be tracked manually (Waller and Morieson, 2025).[1] However, when this extends to legislators or even corporate-level individuals, the number of targets increases significantly, making automated tracking a necessary and inevitable approach.

Although there has been extensive discussion on disinformation (Alam et al., 2022; Vykopal et al., 2024; Pan et al., 2024) and misinformation (Qazvinian et al., 2011; Wu et al., 2022; Yang et al., 2023; Ma et al., 2024), there is relatively little focus on statements related to the future. While some analyses of forward-looking statements (Chen and Takamura, 2024; Lin et al., 2024) address future events, promises represent visions for the future that are more abstract in nature and difficult to verify. For example, a forward-looking statement might forecast the next quarter's earnings per share (EPS), which can be verified once the quarter concludes. However, a promise may be less specific, such as "the company will continue to strive to reduce carbon emissions in the coming years." Such a promise can create a positive impact for the company but also poses regulatory challenges.

Public figures often make promises that shape societal expectations and influence critical decisions. These promises are typically based on the information available at the time. However, when such commitments go unfulfilled, the consequences extend beyond personal accountability to affect broader public trust and market stability. The challenge lies in discerning whether these unfulfilled promises result from unforeseen circumstances, representing legitimate changes in strategy, or if they were knowingly misleading from the outset. In the financial field, the regulatory framework governing corporate disclosures has long established sophisticated guidelines for forward-looking statements, yet remains underdeveloped in addressing ESG commitments and promises.

This regulatory asymmetry persists despite ESG commitments increasingly resembling financial forward-looking statements in their market impact. More companies now disclose climate transition plans with quantified milestones, and some institutional investors use ESG forward-looking metrics in capital allocation decisions. Yet, unlike financial forward-looking statements, ESG-related

Table 1: Dataset Statistics

promises face significant legal and ethical risks. Some climate-related statements have been alleged as cases of "greenwashing."

As an early step in assessing the integrity and fulfillment of the company's ESG promises, we introduce a new task: promise verification, which considers multinational, multilingual, and multi-industry aspects. We propose leveraging natural language processing (NLP) techniques to automatically detect ESG commitments made by companies, identify supporting evidence, and evaluate the alignment between the stated commitments and the corresponding evidence. Furthermore, this approach aims to infer or detect potential time points at which these commitments can be verified. This fine-grained analysis ensures transparency and accountability in corporate ESG discourse. Through multilingual and multi-industry scalability, the system is designed to operate across geopolitical boundaries and sector-specific nuances, making it adaptable to diverse regulatory environments and cultural expectations. This research aims to foster a more informed and accountable public sphere.

In this paper, we present the details of the dataset used in SemEval-2025 PromiseEval, the solutions from task participants, and the findings of this round's shared task. We believe that this dataset and the proposed systems can not only assist regulators but also help companies prepare reports that are more trustworthy to investors, as well as support companies in detecting any incompleteness in the information disclosed through natural language.

2 Task and Dataset

2.1 Task Definition

We propose four core tasks–Promise Identification, Actionable Evidence, Clarity of the Promise-Evidence Pair, and Timing for Verification–to serve as a foundational framework for evaluating corporate Environmental, Social, and Governance commitments. Table 1 lists the label design for each task.

1. **Promise Identification**: This is a boolean label (*Yes/No*) used to determine whether a promise is present in the statement. A promise can take the form of a declaration outlining a company principle (e.g., diversity and inclusion), a commitment (e.g., reducing plastic waste, enhancing health & safety), or a strategic initiative (e.g., protocol descriptions, establishing partnerships with associations and institutes) that aligns with ESG (Environmental, Social, and Governance) criteria. It is crucial to distinguish between substantive promises and superficial statements, as companies may make broad claims without tangible backing, which is particularly important when assessing the risk of greenwashing. If there is no foundational statement describing a principle or commitment, it should not be classified as a promise.

2. **Actionable Evidence**: This boolean label (*Yes/No*) evaluates whether concrete evidence exists that demonstrates the company is actively working towards fulfilling its promise. Valid evidence includes specific examples, implemented measures, quantitative data, reports, or third-party audits that support the promise. Documentation such as tables, pie charts, or statistical reports serve as quantified evidence, enhancing the credibility of a textual core promise. The absence of such supporting material raises concerns about the company's transparency and accountability.

3. **Clarity of the Promise-Evidence Pair**: This

Industry	English	French	Chinese	Japanese	Korean
Energy	✓	✓	✓	✓	✓
Finance	✓	✓			✓
Luxury	✓	✓			
Semiconductor			✓		✓
Technology			✓		✓

Taiwan			✓		
Japan				✓	
South Korea					✓

Table 3: Country-based statistics

criterion is evaluated using three possible labels (*Clear/Not Clear/Misleading*) and focuses on the strength of the connection between the promise and its supporting evidence. A *Clear* label indicates that the provided evidence is both specific and sufficient to substantiate the promise. A *Not Clear* label reflects ambiguity or insufficient detail, making it difficult to confirm the company's commitment. The *Misleading* label is applied when the evidence appears intentionally deceptive or when it misrepresents the actual fulfillment of the promise. Both the quantity and quality of evidence are critical in this assessment.

4. **Timing for Verification**: Adhering to Morgan Stanley Capital International (MSCI) guidelines[2] and prior research (Tseng et al., 2023; Chen et al., 2024), this label outlines when stakeholders should re-evaluate the promise to verify its fulfillment. The following time frames are used: *within 2 years*, *2-5 years*, *longer than 5 years*, and *other*. The *other* category is used when a promise has already been verified, is ongoing without a definitive timeline, or when no specific future verification is required. This labeling ensures that stakeholders can monitor ESG-related actions within an appropriate timeframe, promoting accountability and long-term impact assessment.

2.2 Data Analysis

Table 1 presents the distribution of labels across the dataset. The distribution of labels for the Promise Identification task indicates that most samples in English, French, Japanese, and Korean were identified as containing a promise. In contrast, the Chinese data exhibited a significantly lower proportion of promises, with the majority labeled as "No."

For the Actionable Evidence task, Korean and French samples showed a higher presence of actionable evidence, suggesting that commitments in these languages are often accompanied by concrete supporting details. English and Japanese demonstrated moderate levels of actionable evidence. The Chinese data again reflected a lower presence, primarily due to differences in the annotation approach. While the Chinese subset marks each page of the ESG report, other languages focus on specific sections where promises are more likely to appear. This discrepancy stems from annotation coverage rather than report structure.

In terms of the clarity between promises and their corresponding evidence, the Korean data exhibited exceptionally high clarity, indicating strong alignment between commitments and supporting details. English, French, and Japanese showed moderate clarity levels, while Chinese maintained a relatively high level despite lower rates in previous tasks. The "Misleading" label was minimal across all languages.

Regarding the timing of commitments, Korean data strongly favored short-term verifications. Chinese data also leaned toward shorter timelines. French data showed a preference for long-term commitments. A substantial portion of English data was classified as "Other," suggesting either indefinite timelines or commitments not bound by explicit temporal constraints.

This analysis reveals distinct linguistic and cultural patterns across the dataset. Korean data is characterized by high clarity and a short-term orientation, while French commitments tend to imply long-term planning. These findings underscore the importance of considering language-specific characteristics in promise analysis and may reflect broader cultural norms.

We provide industry-based and country-based statistics in Tables 2 and 3. These tables reveal

Task	Label	Market Cap		
		High	Medium	Low
Promise Identification	Yes	52.78%	40.12%	23.23%
	No	47.22%	59.88%	76.77%
Actionable Evidence	Yes	25.14%	29.01%	16.54%
	No	74.86%	70.99%	83.46%
Clarity of Promise-Evidence Pair	Clear	66.29%	59.14%	80.49%
	Not Clear	32.58%	40.86%	19.51%
	Misleading	1.12%	0.00%	0.00%
Timing for Verification	Within 2 years	54.64%	78.21%	78.79%
	2-5 years	4.92%	12.82%	21.21%
	Longer than 5 years	40.44%	8.97%	0.00%

Table 4: Distribution across different market capitalization – Chinese

that the dataset covers a wide range of sectors and geographic regions, highlighting the diversity and representativeness of the collected promises.

From an industry perspective, the Energy sector is selected across all languages. The Finance and Luxury industries are primarily covered in English and French datasets, consistent with the prominence of European and North American firms in these sectors. Meanwhile, high-technology industries such as Semiconductors, Technology, and Biomedical are particularly prominent in the Chinese dataset, aligning with the strategic economic focus in Taiwan. Automotive and Trading industries are notably present in the Japanese dataset, reflecting Japan's global leadership in these areas.

Country-wise, the English dataset aggregates statements from a diverse range of countries including the United Kingdom, United States, Jordan, South Africa, Switzerland, and Canada, showing a broad international spread. French data mainly originates from France, Canada, and Luxembourg, reflecting the global Francophone economic landscape. Chinese, Japanese, and Korean datasets are primarily sourced from Taiwan, Japan, and South Korea respectively.

This wide coverage ensures that the dataset is not only multilingual but also multicultural and multisectoral, allowing researchers to study promise verification in a variety of economic, regulatory, and cultural contexts. Such diversity is crucial for building robust, generalizable models and for enabling fine-grained analyses that account for regional and sector-specific nuances in corporate ESG discourse.

2.3 Market Capitalization

Previous studies (Cormier and Magnan, 2003; Hahn and Kühnen, 2013) have indicated that the quality of sustainability and ESG reporting may be related to company size. Larger companies, measured by asset size, number of employees, and market capitalization, tend to produce higher-quality and more transparent ESG reports due to their abundant resources and greater external pressures from investors, governments, and media scrutiny. In contrast, smaller companies, which typically face limited resources and lower external pressure, may produce ESG reports that are less detailed and accurate. Therefore, when selecting companies for our analysis, we categorized firms within each industry into high, medium, and low market capitalization groups. Table 4 presents the statistical summary of the Chinese dataset. Analysis of the distribution reveals notable differences across company sizes. For the Promise Identification task, large companies had a higher number of positive identifications than medium-sized and small companies, indicating that larger firms are more likely to explicitly make ESG promises. In the Actionable Evidence task, the proportions were relatively similar across company sizes, suggesting that regardless of company size, firms demonstrated comparable levels of effort in providing concrete evidence to support their ESG promises.

Regarding the Clarity of the Promise-Evidence Pair, small companies demonstrated the highest clarity rate, followed by large and then medium-sized companies. This suggests that although smaller companies make fewer promises, the ones they do make tend to be more clearly supported by evidence, possibly due to more focused ESG initiatives or simpler reporting structures. For the Timing for Verification, small and medium-sized companies favored short-term verifications within two years, whereas large companies had a more balanced distribution between short-term verification and longer-term goals extending beyond five years. This pattern indicates that larger corporations often set long-term sustainability objectives, while smaller firms prefer immediate or near-term

Task	Label	Industry		
		Semiconductor	Energy	Biomedical
Promise Identification	Yes	48.90%	58.24%	18.11%
	No	51.10%	41.76%	81.89%
Actionable Evidence	Yes	28.61%	30.00%	14.17%
	No	71.39%	70.00%	85.83%
Clarity of Promise-Evidence Pair	Clear	60.00%	62.38%	88.57%
	Not Clear	40.00%	36.63%	11.43%
	Misleading	0.00%	0.99%	0.00%
Timing for Verification	Within 2 years	59.87%	70.27%	66.67%
	2-5 years	1.27%	14.41%	19.05%
	Longer than 5 years	38.85%	15.32%	14.29%

Table 5: Distribution across different industry – Chinese

demonstrable achievements.

Overall, the findings suggest that company size plays a critical role in shaping ESG communication practices. Larger firms are more proactive in making promises and pursuing long-term strategies, while smaller firms emphasize clarity and short-term execution in their commitments.

2.4 Industry-Wise Analysis

To further understand sector-specific differences in ESG communication, we conducted an industry-wise analysis based on the Chinese dataset, focusing on Semiconductor, Energy, and Biomedical sectors. The statistics are provided in Table 5.

In the Promise Identification task, the Energy sector exhibited the highest proportion of promises, followed by the Semiconductor sector, and finally the Biomedical sector. This suggests that Energy companies are more proactive in articulating their ESG commitments, likely due to increasing regulatory and societal pressures regarding environmental impact. In contrast, Biomedical companies demonstrated a notably lower rate of ESG promise articulation, possibly reflecting a more cautious or conservative disclosure strategy. For the Actionable Evidence task, both Semiconductor and Energy sectors showed moderate levels of actionable evidence, indicating that although promises are made, the provision of concrete supporting evidence remains limited. Biomedical companies further highlight the challenges in demonstrating tangible ESG progress in highly regulated and research-driven industries.

Regarding the Clarity of the Promise-Evidence Pair, the Biomedical sector stood out with the highest clarity, significantly surpassing both Semiconductor and Energy sectors. This result implies that although Biomedical companies make fewer promises, they tend to ensure a strong and clear linkage between their commitments and supporting documentation, possibly due to stricter compliance standards in the healthcare domain. In terms of Timing for Verification, all three sectors heavily favored short-term verification within two years, particularly the Energy sector. This trend suggests a focus on near-term accountability, driven by stakeholder demand for demonstrable ESG progress. Semiconductor companies showed a notable proportion of long-term commitments, reflecting the sector's need for longer innovation cycles and infrastructure development to achieve sustainability goals.

Overall, the industry-wise analysis reveals that sector-specific dynamics significantly influence how ESG promises are formulated, supported, and communicated. The Energy sector, under intense scrutiny, emphasizes frequent and near-term disclosures; the Semiconductor sector balances short- and long-term perspectives; while the Biomedical sector prioritizes clarity over quantity in its ESG messaging. These findings underline the importance of tailoring ESG verification systems to industry-specific characteristics to ensure fair and accurate assessments.

3 Participants and Methods

The SemEval-2025 Task 6 attracted various innovative approaches from participating teams, reflecting the diverse strategies used to tackle multilingual ESG promise verification. Ten teams shared their experimental results on the Kaggle leaderboard, and seven teams submitted a method description paper. Some teams participated only in the Promise and Evidence verification tasks, while others focused on specific languages. We summarize their methods in this section. Please refer to the paper for more details.

CSECU-DSG (Hossain and Chy, 2025) proposed a Bi-LSTM-based model, which leverages

Team Name	Method
CSECU-DSG (Hossain and Chy, 2025)	Bi-LSTM (LASER and Universal Embedding)
CSCU (Leesombatwathana et al., 2025)	GPT-4o, SVM, DistilBERT (Data Augmentation)
CYUT (Wu et al., 2025)	Llama-3.1 (Structured Prompt) & RAG
Oath (Khubaib et al., 2025)	DeBERTa (Data Augmentation)
QM-AI (Sun and Sobczak, 2025)	Ensemble BERT (Data Augmentation)
WC Team (Nishi and Takagi, 2025)	BERT (CamemBERT, Tohoku-BERT)
YNU-HPCC (deng et al., 2025)	BERT (R-Drop)

Table 7: Experimental results

both LASER and Universal Sentence Encoder embeddings to capture multilingual semantic features. By combining these embeddings and using Bi-LSTM to capture sequential patterns, their approach focuses on improving cross-lingual promise identification performance.

CSCU (Leesombatwathana et al., 2025) focused on data augmentation, particularly through Paraphrase Augmentation and Synthesis Augmentation generated by Gemini-2.0-Flash. They compared multiple classifiers, including GPT-4o (zero-shot and six-shot), Support Vector Machine (SVM) using Multilingual E5 embeddings, and fine-tuned DistilBERT. Their results highlight that synthetic data augmentation significantly boosts classification performance, especially for identifying promises and supporting evidence.

CYUT (Wu et al., 2025) adopted a Structured Prompting with Retrieval-Augmented Generation (RAG) approach, using Llama 3.1 to systematically evaluate promises. Their framework employs structured definitions, examples, and step-by-step reasoning, combined with retrieval of relevant context, to enhance ESG promise verification across multiple languages.

Oath (Khubaib et al., 2025) introduced a DeBERTa-based pipeline, enhanced with contrastive learning and data augmentation to handle class imbalance and subtle differences between promise-related and non-promise text. This approach significantly improved evidence classification and timeline verification performance.

QM-AI (Sun and Sobczak, 2025) proposed an ensemble BERT framework, combining four different BERT variants (original, augmented, translated, and mixed-language versions). This ensemble approach leverages both multilingual training and language-specific fine-tuning to improve robustness, particularly for non-English data.

WC Team (Nishi and Takagi, 2025) adopted a

language-specific BERT strategy, training individual BERT models for each language—BERT-base-uncased for English, CamemBERT for French, and Tohoku-BERT for Japanese. This monolingual fine-tuning approach emphasizes capturing each language's unique syntactic and semantic characteristics, achieving strong performance for high-resource languages.

Finally, YNU-HPCC (deng et al., 2025) introduced a BERT model regularized with R-Drop, a regularization technique that forces consistent predictions across different dropout applications. This method stabilizes the model's predictions in low-resource and noisy environments, particularly benefiting smaller language datasets within the task.

These methods collectively demonstrate the importance of data augmentation, multilingual embeddings, structured prompting, and regularization techniques when developing robust promise verification systems for ESG reports across diverse languages.

4 Evaluation Results

Each team was allowed to submit multiple entries. The public leaderboard reflected performance on 70% of the test set, while the remaining 30% was kept private by the organizers. The values presented in Table 7 were recalculated based on each team's highest-scoring entry on the private leaderboard, using the entire test set (both the public and private portions). Therefore, these recalculated results may differ slightly from the original public leaderboard results. Additionally, since some teams only participated in predicting specific columns, scores for columns without submissions are marked as "–." Ten teams shared their experimental results on the Kaggle leaderboard, and seven teams submitted a method description paper. Some teams participated only in the Promise and Evidence verification tasks, while others focused on specific languages.

As shown in Table 7, Team CSCU ranked first for English data, achieving high overall scores on all tasks using synthetic data augmentation and GPT-4o (final submission) which outperformed the fine-tuned DistilBERT model and SVM (Leesombatwathana et al., 2025). For French, Team CYUT placed 1st using LLaMA 3.1:70b, enhanced by structured prompting along with RAG and CoT strategies (Wu et al., 2025). Team QM-AI placed first for both Korean and Japanese data using an ensemble of fine-tuned BERT-base models with data augmentation (Sun and Sobczak, 2025). For Chinese, Team SemanticEval placed first (no paper was submitted).

The participants experimented diverse approaches, ranging from transformer architecture to LLM-based framework, revealing important insights about effective multilingual NLP strategies. Most results demonstrate the effectiveness of models designed with multilingual capabilities and the potential of advanced LLM techniques such as RAG, CoT, GoT Structured Prompting when properly implemented. Additionally, Team WC achieved encouraging results with a monolingual approach using separate models for each language, while Team Oath experimented with different approaches for each subtask, showing promising scores compared to the multilabel classification approach.

The varying effectiveness of data augmentation and ensemble methods across languages and tasks highlights the need for language/task-specific strategies rather than one-size-fits-all approaches. For English and French, data augmentation showed minimal benefits contrary to the Japanese, Korean and Chinese datasets for which data augmentation using an LLM like GPT-4o provided meaningful improvements. The best-performing approaches combined targeted data augmentation, fine-tuning on large models like BERT, DeBERTa and XLM-RoBERTa and an LLM framework, which is obviously a viable alternative to traditional fine-tuning.

For Korean, the highest performance was achieved by Team QM-AI, which utilized an ensemble of multilingual BERT models directly trained on original texts without English translation (Sun and Sobczak, 2025). A notable challenge specific to the Korean dataset was that texts were provided as PDF pages rather than extracted snippets, requiring additional preprocessing to extract clean textual inputs. Although data augmentation using GPT-4o generally improved results for Korean, excessive synthetic augmentation negatively affected performance, as observed with Team CSECU-DSG (Hossain and Chy, 2025). This indicates the importance of carefully balancing data augmentation and preserving linguistic nuances specific to Korean.

For Japanese, three teams—QM-AI, CSECU-DSG, and WC Team—participated. Their approaches included:

	Promise						Evidence

Table 8: Fine-grained comparison of models in the Chinese dataset.

- QM-AI: BERT-based ensemble models with data augmentation and machine translation
- CSECU-DSG: Dual embedding models (Laser and Universal Sentence Encoder) combined with LSTM and MLP
- WC Team: Japanese-specific Tohoku BERT

From the results, QM-AI achieved the highest scores in the Promise Identification and Clarity of Promise-Evidence Pair subtasks, CSECU-DSG led in Timing Verification, and WC Team excelled in Actionable Evidence Identification. QM-AI's insights suggest that while data augmentation and machine translation were ineffective, their ensemble approach generalized well for certain subtasks. Conversely, universal sentence embeddings were particularly effective for timing verification, while a Japanese-specific approach performed well for evidence identification, likely due to language-specific writing styles. Notably, machine translation to English was less effective than in previous tasks (Chen et al., 2024), possibly because the Promise Verification task required deeper language-specific knowledge.

5 Discussion

5.1 Data Imbalance and Labeling Challenges

We observe that participants encountered data imbalance issues both between languages and across subtasks, as most experimented with multilingual and multilabel classification approaches. This is also reflected in the final scores as shown in Table 7: the Promise Identification subtask showed consistently high scores across languages, which also coincides with higher agreement among annotators. In contrast, other labels, particularly Clarity (Clarity of Promise-Evidence Pair) and Timing (Timing for Verification), posed greater challenges, likely due to higher subjectivity and lower agreement among annotators.

To address data imbalance, future work should go beyond collecting more balanced datasets and refining guidelines - given that ESG data preparation requires expert involvement and validation - by also exploring and leveraging LLM-based cross-lingual data augmentation techniques (Whitehouse et al., 2023) to enhance representation in low-resource languages.

5.2 Comparison of Models

Table 8 presents the performance of different systems for the Chinese subtask, including SemanticEval, CSECU-DSG, QM-AI, and an ensemble voting method. The metrics cover precision (P), recall (R), and F1-score (F1) for both *Yes* and *No* labels under each task. The main findings are summarized as follows:

- **QM-AI excels in identifying promises and evidence**: QM-AI achieves the highest F1 for the *Yes* class in both tasks, demonstrating its superior ability to detect substantive promises and concrete evidence.
- **CSECU-DSG is reliable for rejecting non-promises and missing evidence**: CSECU-DSG achieves the highest F1 for the *No* class, indicating strong performance in identifying irrelevant or unsupported statements.

The ensemble model, built by majority voting, does not significantly outperform the strongest single system (QM-AI). In particular, its F1 for the *Yes* class is lower than that of QM-AI, indicating that ensemble voting diluted the strength of QM-AI's positive predictions. While ensemble voting slightly improves the *No* class F1, this gain does not offset the drop in identifying positive cases.

This result highlights a fundamental limitation: simple voting ensembles are not effective when there is a large performance gap between models. The weaker models (e.g., SemanticEval) pull down the overall performance, especially in the crucial *Yes* class. This is problematic for ESG promise detection, where identifying actual promises and evidence is more critical than filtering out irrelevant content. The findings suggest that a better ensemble strategy would apply weighted voting, where

QM-AI contributes more to the *Yes* class decisions, while CSECU-DSG could contribute more to the *No* class. We further provide Heuristic results in Table 8. This adaptive weighting would better reflect each model's strengths, potentially leading to a more robust and interpretable final system.

In conclusion, QM-AI is the most effective standalone system, especially for detecting positive cases, which is crucial for identifying real ESG commitments and evidence. The current ensemble approach, however, fails to add value and may even hurt performance. Future work should explore weighted or task-specific ensemble strategies to better combine the complementary strengths of different models. The choice of method and the aspect to prioritize ultimately depends on the specific application scenario. For instance, if the goal is to verify the existence of promises, detecting the presence of a promise (the *Yes* class) becomes the primary objective. On the other hand, for regulatory agencies, the focus might shift toward identifying cases where no concrete evidence is provided (the *No* class), as such instances signal potential transparency issues or greenwashing risks. Therefore, the relative importance of detecting *Yes* versus *No* should align with the intended use case and stakeholder needs.

5.3 Case Studies – Misleading

Although misleading cases are relatively rare in the dataset, they represent significant risks to transparency and accountability. One common pattern involves presenting superficial evidence, such as emphasizing trust with suppliers to imply material quality without objective proof. In other instances, companies announce future policies alongside unrelated past data, creating an illusion of responsiveness. Ambiguous promises, like support for low- and moderate-income communities, sometimes cite general charity work rather than directly addressing the original ESG goal. Similarly, companies may highlight employee training without clearly linking it to the technical innovations previously mentioned. In each case, the misalignment between promise and evidence can mislead stakeholders, inflating perceptions of progress without substantive backing.

5.4 Future Directions

To further enhance the depth and effectiveness of the proposed direction, two additional dimensions can be incorporated: Risk of Greenwashing and Stakeholder Impact. These dimensions should also be aligned with the proposed four tasks to ensure a comprehensive and cohesive approach.

The Risk of Greenwashing expands the assessment by evaluating the likelihood that a company's ESG claims are misleading or lack substantive backing. By categorizing promises into *Low*, *Moderate*, or *High* risk based on the consistency between the stated commitment and supporting evidence, the clarity of communication, and the involvement of third-party verification, this criterion helps stakeholders critically appraise the authenticity of Environmental, Social, and Governance statements. A *High* risk rating signals vague promises with little or no verifiable data, while a *Low* risk reflects transparent and substantiated claims.

In parallel, the Stakeholder Impact dimension assesses the extent to which an ESG promise directly or indirectly benefits stakeholders. Classifications of *Direct*, *Indirect*, or *Minimal* impact allow for a nuanced understanding of the promise's reach and relevance. *Direct* impacts refer to immediate effects on employees, customers, or local communities (e.g., enhancing workplace safety), while *Indirect* impacts relate to broader societal or environmental outcomes (e.g., reducing carbon emissions). *Minimal* impact reflects limited or negligible stakeholder benefits.

Together, these extended dimensions complement the original four tasks, providing a more comprehensive evaluation of Environmental, Social, and Governance commitments. They enable stakeholders to not only verify the authenticity and clarity of corporate promises but also assess their broader societal implications and the risk of misleading information.

6 Conclusion

This paper presents SemEval-2025 Task 6, a multilingual, multi-industry shared task on verifying corporate ESG promises—a shift from misinformation research to future corporate commitments critical for public trust. We introduced a novel dataset in five languages annotated for promise identification, evidence detection, clarity, and timing. Results from diverse methods, including multilingual transformers and LLM-enhanced prompting, highlight challenges like data imbalance and linguistic variation. We propose expanding research to greenwashing risk and stakeholder impact, aiming to strengthen ESG transparency and accountability.

Abstract

We present the Mu-SHROOM shared task which is focused on detecting hallucinations and other overgeneration mistakes in the output of instruction-tuned large language models (LLMs). Mu-SHROOM addresses general-purpose LLMs in 14 languages, and frames the hallucination detection problem as a span-labeling task. We received 2,618 submissions from 43 participating teams employing diverse methodologies. The large number of submissions underscores the interest of the community in hallucination detection. We present the results of the participating systems and conduct an empirical analysis to identify key factors contributing to strong performance in this task. We also emphasize relevant current challenges, notably the varying degree of hallucinations across languages and the high annotator disagreement when labeling hallucination spans.

1 Lets a-go! Introduction

As generative AI systems become increasingly integrated into real-world applications we expect them to produce fluent and coherent text (e.g., Rohrbach et al., 2018; Lee et al., 2018). However, a critical issue undermines their reliability: these models frequently generate outputs that are highly fluent but factually incorrect, a phenomenon known as hallucination. Hallucinations, as presently observed, are characterized by a disregard of the truth value of statements in favor of persuasive or plausible-sounding language, carrying consequences such as the spread of misinformation, and erosion of user trust (Hicks et al., 2024). Compounding this issue is the tendency of hallucinations to "snowball": when models are prompted to provide evidence or explanations for a false claim, they often generate coherent but false statements, further entrenching misinformation (Zhang et al., 2023b; Hicks et al., 2024). Addressing hallucinations is crucial for building systems that the public can trust. Despite its significance, detecting hallucinations at scale remains a major challenge, with no clear universally effective solution currently available.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2472–2497

The Mu-SHROOM task[1] aims to contribute to advancing research in this direction. Mu-SHROOM builds on the SHROOM shared task (Mickus et al., 2024), expanding its scope and addressing key limitations. Unlike SHROOM which focused solely on English, Mu-SHROOM incorporates multilingual data across 14 languages to account for potential variations in hallucination rates (Guerreiro et al., 2023). It also addresses general-purpose LLMs, reflecting the dominance of such models in current research, and introduces token-level annotations for more precise hallucination detection. By providing a richly annotated multilingual dataset and evaluation metrics, Mu-SHROOM aims to advance research on hallucination patterns, improve detection methodologies, and foster community collaboration in NLG and factual consistency assessment.

The Mu-SHROOM dataset consists of a collection of prompts, model outputs, logits, and identifiers for openly available LLMs. The dataset encompasses 10 languages with validation and test data (Modern Standard Arabic, German, English, Spanish, Finnish, French, Hindi, Italian, Swedish and Mandarin Chinese), 4 test-only ("surprise") languages (Catalan, Czech, Basque and Farsi), as well as unlabeled training data for English, Spanish, French, and Chinese. Supplementary metadata, including raw annotations before post-processing and the Wikipedia URLs used as references, as well as the scripts used to generate model outputs for all 14 languages and code for the annotation and submission interfaces are all publicly available.[2]

The shared task attracted a total of 43 teams, resulting in over 2,600 submissions during the three-week evaluation phase. The strong participation and diverse methodologies signal the task's success. Notably, many teams relied on a few key models, often using synthetic data for fine-tuning or zero-shot prompting. While 64–71% of the teams outperform our baseline, top-scoring systems perform at random for the most challenging items. We present the results and provide a thorough analysis of the strengths and limitations of current hallucination detection systems.

2 Down the warp pipe: Related works

Hallucination in NLG has been widely studied since the shift to neural methods (Vinyals and Le, 2015; Raunak et al., 2021; Maynez et al., 2020; Augenstein et al., 2024). Despite significant progress, there remains minimal consensus on the optimal framework for detecting and mitigating hallucinations, partly due to the diversity of tasks that NLG encompasses (Ji et al., 2023; Huang et al., 2024). Recent advances further highlight the urgency for addressing this issue, as hallucinations can lead to the propagation of incorrect or misleading information, particularly in high-stakes domains such as healthcare, legal systems, and education (Zhang et al., 2023a,b). This has led to a recent but flourishing body of work interested in detecting and mitigating hallucinations (Farquhar et al., 2024; Gu et al., 2024; Mishra et al., 2024), as well as studies on how to best define and articulate this phenomenon (Guerreiro et al., 2023; Rawte et al., 2023; Huang et al., 2024; Liu et al., 2024).

More immediately relevant to our shared task are pre-existing benchmarks and datasets. Li et al. (2023) introduced HaluEval which is focused on dialogue systems but relies on closed, non-transparent models, limiting reproducibility. Other benchmarks, such as those by Liu et al. (2022) and Zhou et al. (2021), use synthetic data for token-level hallucination detection. The SHROOM dataset (Mickus et al., 2024) provides 4k multi-annotated datapoints for task-specific NLG systems. Recently, Niu et al. (2024) introduced RAGTruth, a large-scale corpus with 18,000 annotated responses for analyzing word-level hallucinations in RAG frameworks. Chen et al. (2024) proposed FactCHD to specifically study hallucinations due to fact conflation. Additionally, Rawte et al. (2023) introduced a comprehensive dataset and a vulnerability index to quantify LLMs' susceptibility to hallucinations. Most of these datasets focus on English (or Chinese, Cheng et al., 2023).

3 Collecting the coins: Data

We begin with a description of the general process, and then note specific *ad-hoc* departures from this process for each language. The dataset covers 38 LLMs over 14 languages, out of which 4 (CA, CS, EU, FA) are test-only with about 100 datapoints. The other 10 languages (AR, DE, EN, ES, FI, FR, HI, IT, SV, ZH) include both a validation split of

50 datapoints and a test split of 150 datapoints.[3]

The construction of the dataset started with an automatic extraction of 400 Wikipedia pages, with a focus on pages available in multiple languages of interest. We eventually increased this extraction to 762 links to guarantee a large number of Wikipedia pages for all languages. From this point, the process we follow for creating the Mu-SHROOM dataset is divided into two phases: datapoint creation and data annotation.

Data creation. The datapoint creation for each language was spearheaded by one of our organizers proficient in the language. Appendix B.3 (esp. Figure 7) describes the process in detail. In short, we manually selected and read 200 Wikipedia pages (100 for test-only languages), and wrote for each page one question that could be answered with the information it contained. Due to variations across Wiki projects, the set of selected pages and the constructed questions vary across languages.[4] Questions had to be *factual* (i.e., not a matter of opinion) and *closed* (i.e., answerable with a closed set of answers, such as numbers, places, names, etc).

For each question, we then generated multiple LLM answers: We identified existing open-weight instruction-tuned LLMs capable of handling the languages of interest (cf. Table 8 in Appendix for a list), and produce multiple outputs for each question by varying generation hyperparameters (top p, top k, temperature). We then manually selected one output to annotate for each question which satisfied a set of criteria: It was fluent and in the language of interest; it was relevant to the input question; it appeared to contain hallucinations or data worth annotating. A subset of the remaining outputs was set aside to serve as an unlabeled training set.

Data annotation. We frame the data annotation task as a span-labeling task where human annotators are asked to highlight text spans in the model output that contain an overgeneration or hallucination. Within this task, we define hallucination as "*content that contains or describes facts that are not supported by a provided reference*".

Annotation were collected using a custom platform displaying the input question, the answer output by the model, and the source the Wikipedia page from which the question was derived. The annotators' task was to highlight all spans of text in the answer that were not supported by information present in the Wikipedia page, which corresponds to an overgeneration or hallucination.

In order to accommodate the complete set of languages in the Mu-SHROOM task using a common set of annotation guidelines, and to cover all eventualities, the annotators were instructed to highlight the minimum number of *characters* that would need to be edited or deleted in order to provide a correct answer. The annotators were encouraged to be conservative when highlighting spans, and to focus on content words rather than function words.

With the aim of constraining the scope of the task and ensuring the reliability of the source information used, the annotators were restricted to consulting Wikipedia in order to identify hallucinated content. Whilst the reference Wikipedia page provided should ideally be sufficient for the task, annotators were permitted to browse other Wikipedia articles in order to verify information the reference might not contain, as long as they provided details of any such pages. The complete set of annotation guidelines given to the annotators is provided in Appendix B.2. All selected outputs from the datapoint creation phase were annotated by at least three annotators, usually with the same three individuals handling all 200 datapoints; exceptions are listed in Appendix B.4.

	AR	CA	CS	DE	EN	ES	EU
Val.	0.77	—	—	0.75	0.45	0.58	—
Test	0.76	0.80	0.71	0.72	0.49	0.51	0.74
	FA	**FI**	**FR**	**HI**	**IT**	**SV**	**ZH**
Val.	—	0.74	0.73	0.80	0.85	0.74	0.57
Test	0.75	0.79	0.81	0.80	0.87	0.78	0.58

Table 1: Annotator agreement measured as Intersection over Union (IoU, cf. eq. (1)).

Annotator agreement. An overview of the agreement rates obtained by our annotators is shown in Table 1, computed as the intersection over union (IoU) of the characters marked as hallucinations by the annotators. To measure this, assuming C_n is the set of character indices marked as hallucination by our n^{th} annotator, we compute

$$\text{agg} = \frac{1}{n \cdot |C_{\text{all}}|} \sum_{n} \sum_{c_i \in C_{\text{all}}} \mathbb{1}\{c_i \in C_n\} \quad (1)$$

where $C_{\text{all}} = \bigcup C_n$. This is equivalent to a multiset-based IoU, where we keep one copy of

[3] Due to technical and replicability issues, we manually removed 1 datapoint from EU test, 1 from SV val and 3 from SV test. A handful of languages contained extra test items.

[4] E.g., $\approx 75\%$ of HI datapoints have no equivalent in other languages.

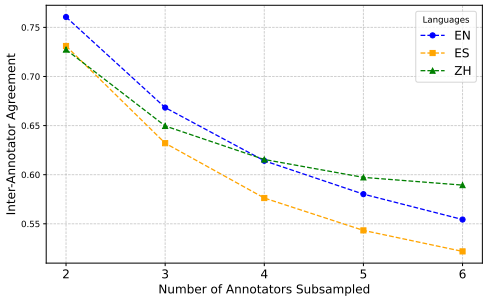

Figure 2: Effects of annotator pool size on inter-annotator agreement (100 random samples, $\sigma \leq 0.01$)

a character index for each annotator that marked it as a hallucination.

Empirically, we observe that ES, EN and ZH yield lower agreement rates, which we can partly link to the higher number of annotators: Remark that a character index marked by a single annotator penalizes the agreement rate by $\frac{n-1}{n \cdot |C_{\text{all}}|}$, which tends to $\frac{1}{|C_{\text{all}}|}$ as n grows. In fact, if we subsample a lower number of annotations per item for EN, ES and ZH, we obtain the curve in Figure 2 which empirically demonstrates this effect. It is still worth highlighting that not all of the disagreement we observe can be reduced to this effect, suggesting that the different annotation conditions (see Appendix B.4) may also play a significant role, or that there is something fundamentally distinct regarding hallucinations in higher–resource languages.

Error type	Language								
	AR	CA	CS	ES	EU	FI	FR	IT	ZH
Fluency	7	18	24	1	68	16	1	3	11
Factuality	97	79	82	66	46	87	57	70	96

Table 2: Number of factuality and fluency mistakes in random samples of LLM productions ($n = 100$).

Fluency vs. factuality. One assumption we have adopted thus far, but which needs further verification, is the extent to which hallucinations are indeed a major problem for LLMs. To assess this, we manually re-annotated 100 independently sampled LLM outputs from different languages, distinguishing between fluency and factuality errors. Results in Table 2 show that factuality issues are more pervasive than fluency mistakes, except in Basque. This explains the shift in NLG evaluation priorities, with factual accuracy now outweighing grammaticality as a primary challenge. Additionally, the results reveal a coverage gap across languages: while Spanish, French, Italian and perhaps also Arabic outputs are nearly perfectly fluent, Czech, Catalan, Basque and Finnish offer a more challenging picture, perhaps due to the fewer available resources; with Basque standing out as an exception, with 68 fluency errors compared to 46 factuality errors. Notably, at least half of the outputs across all languages in this small-scale study contain errors, underscoring the unreliability of instruction-tuned LLMs and the need for cautiousness when deploying them in real-world applications.

4 It's a me, Wario: Metrics and baselines

Metrics. We compare the participants' submissions using two metrics: an intersection-over-union metric (IoU) and a correlation metric (ρ). In order to apply the IoU metric, we first binarize annotations by considering whether a majority of annotators ($> 50\%$) marked a character as hallucinated, and then compare the set of indices marked by the system being rated to this binarized set of annotations. Formally, for one datapoint:

$$C_{\text{bin}} = \left\{ c_i \;\middle|\; 0.5 < \sum_n \frac{1}{n} \mathbb{1}\left\{c_i \in C_n\right\} \right\}$$
$$\text{IoU} = \left|\hat{C}_{\text{bin}} \cap C_{\text{bin}}\right| \,/\, \left|\hat{C}_{\text{bin}} \cup C_{\text{bin}}\right| \qquad (2)$$

where C_{bin} is the set of binarized character-level annotations derived from the n different sets of annotations C_n, and $\hat{C}_{\text{bin}}$ is the set of characters that the system predicts as hallucinated.

On the other hand, the ρ metric tries to factor in the lack of thorough consensus we observed in Section 3. A drawback of the binarized annotation scheme is that it assumes a single ground truth, which may prove inaccurate or overly simplistic (Aroyo and Welty, 2015; Plank, 2022). To sidestep this issue, we consider whether the empirical probability of a character being marked by our annotators aligns with the probability derived from the participants' models. For a given datapoint of length k, we formally measure:

$$\Pr_{c_i} = \sum_n \frac{1}{n} \mathbb{1}\left\{c_i \in C_n\right\}$$
$$\mathbf{c} = (\Pr_{c_1}, \ldots, \Pr_{c_k})$$
$$\hat{\mathbf{c}} = (p(c_1 \mid \theta), \ldots, p(c_k \mid \theta))$$
$$\rho = \text{Spearman}(\mathbf{c}, \hat{\mathbf{c}}) \qquad (3)$$

where $p(c_i \mid \theta)$ stands for the probability that character c_i is in a hallucinated span, as assigned by a

given participating system, and $\Pr_{c_i}$ is our empirical probability. The ρ metric assesses how well the model captures the relative likelihood of hallucination rather than just the binary decision. In effect, we are measuring the human calibration of the participants' systems (Baan et al., 2022).[5]

The two metrics make different assumptions regarding our data. With the IoU metric, we assume that annotators can reach a consensus as to what counts as hallucination, whereas with the ρ metric, we expect that models should be able to match human variation closely. In the interest of lowering the barrier to entry for the shared task, we rank participating systems according to their highest IoU scores and break eventual ties depending on the ρ scores.[6] In the same vein, we also allowed participants to submit binary predictions ($\hat{C}_{\text{bin}}$), continuous predictions ($\hat{\mathbf{c}}$), or both. If a submission was missing either binary or continuous predictions, we applied default heuristics to derive the missing prediction from the other. We converted continuous predictions $\hat{\mathbf{c}}$ into binary predictions by applying a cutoff of 0.5, and binary predictions $\hat{C}_{\text{bin}}$ into continuous predictions by assigning a probability of 1 or 0 based on membership. Formally:

$$\hat{C}_{\text{bin}} = \{\, c_i \mid p(c_i \mid \theta) > 0.5 \,\}$$
$$\hat{\mathbf{c}} = \left(\mathbb{1}\left\{ c_1 \in \hat{C}_{\text{bin}} \right\}, \ \ldots\ , \mathbb{1}\left\{ c_k \in \hat{C}_{\text{bin}} \right\} \right)$$

Baselines. To lower the barrier to entry to the shared task, we provided participants with an XLM-R-based baseline system *neural* fine-tuned on the entire test set for token-level classification.[7] This classifier directly maps tokens in an LLM's answer to binary probabilities, without any intermediate fact verification step. In addition to this neural baseline, we consider two heuristics: *mark-all* where all characters are marked as hallucinated with probability 1, and *mark-none* where no hallucination is found, i.e., all characters get a probability of 0.

The neural baseline is meant first and foremost as a tool for participants to build upon and demonstrate how to map characters to tokens. Without any means of verification of the facts underpinning an LLM output, we have low expectations that this baseline will perform well, especially in zero-shot settings. The two heuristics assign probabilities of 0 or 1 uniformly to all characters, which entails that every LLM output is mapped to a constant series of probability. This corresponds to a correlation score of $\rho = 0$ in most cases. As for IoU scores, given our data selection protocol (cf. Section 3), we expect our dataset to be biased towards samples that contain hallucinations. Therefore, the mark-none baseline should yield lower IoU scores than the mark-all baseline.

5 It's a me, Mario: Participants' systems

43 teams submitted their systems during the evaluation phase, and 35 teams wrote a paper describing their system. In total, we received 2,618 submissions across all languages. In average, 27.2 teams participated in each language. 41 teams submitted systems for English (EN), followed by 32 for Spanish (ES) and 30 for French (FR). The languages with the least number of participants were our surprise languages: Catalan (CA) with 21 teams; Czech (CS), Basque (EU) and Farsi (FA), with 23 teams each. Overall, we remark a wide variety of approaches, ranging from QA– or NER–based finetuning, to time series–based analyses of logits (Aryal and Akomoize, 2025) and to zero-shot RAG-based approaches. We present an overview of the participating systems in Table 3 and spotlight a few approaches below, noteworthy in that they portray clearly different methodologies that nonetheless performed reasonably well within the shared task.

The **UCSC** system (Huang et al., 2025b) is designed as a three-stage pipeline: (i) context retrieval, wherein they retrieve relevant pieces of information to assess the factuality of the LLM outputs; (ii) hallucinated fact detection, wherein they identify the incorrect facts based on the retrieved contexts; and (iii) span mapping, wherein the incorrect facts are mapped onto specific segments of the output. The approach furthermore employs prompt optimization to maximize performances. Multi-stage frameworks were also deployed by other teams, for instance, **iai_msu** (Pukemo et al., 2025) developed a three-step approach, with a retrieval-based first step, a self-refine second step, and an ensembling third step.

Another noteworthy entry is that of **CCNU** (Liu and Chen, 2025) — whose report also incorporates information about unsuccessful attempts and some

[5] A handful of datapoints do not contain hallucinations. In such cases, we assign an IoU of 1 if the system's predicted set is also empty, 0 otherwise, and a ρ of 1 if the model assigns the same probability to all tokens, 0 otherwise.

[6] We also provide alternative rankings based on ρ scores in Appendix C.2.

[7] We used `FacebookAI/xlm-roberta-base`. We fine-tuned for 5 epochs with a learning rate of 2e-5.

Team & Paper	Languages	Overview
Advacheck (Voznyuk et al., 2025)	EN	NER-based keyword extraction, Wikipedia-based RAG, LLM edition-based prompting.
AILSNTUA (Karkani et al., 2025)	All	Translate-test (to EN and ZH) prompt-based approaches using synthetic few-shot examples.
ATLANTIS (Kobus et al., 2025)	DE, EN, ES, FR	RAG + LLM prompting; RAG-based approaches; token-level classifiers.
BlueToad (Pronk et al., 2025)	AR, CS, DE, EN, ES, EU, FA, FI, FR, HI, IT, SV, ZH	QA-finetuned base PLMs; fine-tuning on synthetic data
CCNU (Liu and Chen, 2025)	All	Prompting & RAG
COGUMELO (Creo et al., 2025)	EN, ES	NER-finetuning; perplexity-based assessments
CUET_SSTM	AR	NER-finetuning.
Deloitte (Chandler et al., 2025)	All	Binary token-level classifiers, trained using web-search results, task instruction and datapoint as inputs.
DeepPavlov	All	White-box approaches
DUTJBD (Yin et al., 2025)	EN	—
FENJI (Alberts et al., 2025)	All	Dense passage retrieval for Flan-T5 prompting.
FiRC-NLP (Tufa et al., 2025)	All	Prompt-based approaches, incorporating external references.
FunghiFunghi (Ballout et al., 2025)	EN, ES, FR, IT, SV	Translate-train (to EN) and synthetic datasets.
GIL-IIMAS UNAM (Lopez-Ponce et al., 2025)	EN, ES	Wikipedia-based RAG.
HalluRAG-RUG (Abdi et al., 2025)	EN	Wikipedia-based RAG, followed by a summarization step and a zero-shot prompting to annotate the items.
HalluSearch (Abdallah and El-Beltagy, 2025)	All	Factual statement decomposition and verification through real-world context retrieval.
HalluciSeekers	AR, DE, EN, ES, FA, FR, IT, SV	—
Hallucination Detectives (Elchafei and Abu-Elkheir, 2025)	AR, EN	Semantic role labeling, dependency parsing, and token-logit confidence scores to construct spans
HausaNLP (Bala et al., 2025)	EN	Finetuning approaches.
Howard University - AI4PC (Aryal and Akomoize, 2025)	All	Time-series anomaly detection across the sequence of logits.
iai_MSU (Pukemo et al., 2025)	EN	RAG
keepitsimple (Vemula and Krishnamurthy, 2025)	All	Multiple LLM generated responses are compared with model output text by modeling information entropy for detecting uncertainty.
LCTeam (Maldonado Rodríguez et al., 2025)	All	Label transfer via translate-train (to CA, CS, ES, FR, IT, ZH, & between phylogenetically related languages); Wikipedia-based RAG and summarization approaches.
MALTO (Savelli et al., 2025)	EN	Logits of a larger model are used to assess the truthfulness of the sentence predicted by the single smaller model.
MSA (Hikal et al., 2025)	All	Weak supervised fine-tuning approaches
NCL-UoR (Hong et al., 2025)	All	Keyword extraction and Wikipedia-based retrieval, detection using closed-source APIs, post-processing with non-linear probability optimization or stochastic prompt-based labeling.
NLP_CIMAT (Stack-Sánchez et al., 2025)	AR, CA, CS, EN, ES, EU, FA, FI, FR, IT, SV	MLP-based classifiers probing the hidden layers of a Llama 3.1 model; few shot inference with chatGPT3.5-turbo using Wikipedia contexts.
nsu-ai	All	prompt based approaches
RaggedyFive (Heerema et al., 2025)	EN	RAG + NLI across trigrams in LLM answers.
REFIND (Lee and Yu, 2025)	AR, CS, DE, EN, ES, EU, FI, FR, IT	Context sensitivity-based token-level identification matched against externally retrieved documents; FAVA-based pipeline.
S1mT5v-FMI	DE, ES, FI, FR, SV, ZH	—
SmurfCat (Rykov et al., 2025)	All	Qwen-based approach, deriving continuous annotation through repeated sampling.
Swushroomsia (Mitrović et al., 2025)	AR, DE, EN, ES, FI, FR, HI, IT, SV, ZH	Prompting-based approach
Team Cantharellus (Mo et al., 2025)	AR, CA, CS, DE, EN, ES, EU, FA, FI, FR, HI, IT, ZH	Prompting-based approach (GPT-4o-mini) to find hallucinated words/parts of text in each datapoint; fine-tuning on synthetic data.
TrustAI	AR, DE, EN, ES, FI, FR, HI, IT, SV, ZH	Variations on the neural baseline
tsotsalab	All	GPT-4 finetuning; counterfactual comparisons with external references.
TU Munich	AR, DE, EN, ES, FI, FR, HI, IT, SV, ZH	Synthetic data generation (MKQA-based).
TUM-MiKaNi (Anschütz et al., 2025)	All	Wikipedia-based retrieval used as input for prompting-based approaches; BERT-based regression.
UCSC (Huang et al., 2025b)	All	Elaborate prompting approaches (CoT, few-shot reasoning); pre-translation (to EN) before RAG-based prompting; token masking-based approaches.
uir-cis (Huang et al., 2025a)	All	Comparison of extracted triples to external references.
UMUTeam (Pan et al., 2025)	All	Classifier-based, compare outputs to be annotated with those from larger LLMs.
UZH (Wastl et al., 2025)	All	Prompting to generate a set of answers, using either an external model (GPT-4o-mini) or the model that produced the datapoint, followed by a embedding similarity–based detection step to mark counterfactual spans.
VerbaNexAI (Morillo et al., 2025)	EN	Retrieval-based approaches
YNU-HPCC (Chen et al., 2025)	EN, ZH	Prompting, RAG; MRC.

Table 3: Summary of 43 participating teams (listed in alphabetical order). First column contains the team handle, second column contains languages the team participated in, and the last column briefly describes their respective approaches.

discussion of the working definition of 'hallucination' we used within this shared task. The CCNU system attempts to emulate a crowd-sourcing approach by utilizing multiple LLM-based agents with different expertise and different knowledge sources. Such crowd-emulation approaches turned out fairly popular within the shared task and were also deployed by a.o. UCSC (Huang et al., 2025b) or **Swushroomsia** (Mitrović et al., 2025).

Lastly, the **SmurfCat** system (Rykov et al.,

2025) offers an interesting perspective on external knowledge incorporation: Rykov et al. constructed a synthetic dataset derived from Wikipedia, viz. PsiloQA, so as to finetune LLMs for hallucination span detection. They further refine their models' raw predictions using white-box techniques derived from uncertainty quantification, a perspective also explored, e.g., by **MALTO** (Savelli et al., 2025).

The variety of approaches deployed by the participating teams is a clear indicator of the potential for future improvements.

6 Rainbow Road Completed: Results

We include an overview of the highest scoring systems from each team per language in Figure 3. In the interest of space, we defer tables of ranking to Appendix C. Most teams outperformed the baselines. The mark-none and neural baselines rank extremely low, both in terms of IoU and ρ. The mark-all baseline performs better in terms IoU, but remains far below the top teams, highlighting the need for more sophisticated strategies.

The most consistent top performers coincidentally made submissions to all 14 languages.[8] **UCSC** (Huang et al., 2025b) appears in the top 3 teams for 11 languages, securing 5 wins (CA, DE, FI, IT, SV) and 5 second-place finishes (CS, EN, EU, FA, HI). Their systems demonstrate a stable IoU-to-ρ ratio mean(IoU/ρ)= 1.01. **MSA** (Hikal et al., 2025) ranks in the top 3 for 8 languages, winning in 2 (AR, EU) and securing second place in 3 others (DE, FI, SV) and mean(IoU/ρ)= 1.03. **AILS-NTUA** (Karkani et al., 2025) performs well across multiple languages, winning in 2 (CS, FA), but showing a less balanced performance between the two metrics: mean(IoU/ρ)= 0.93. **CCNU** (Liu and Chen, 2025) ranks first in HI and appears in the top-5 in 9 languages with mean(IoU/ρ)= 0.93. **Deloitte** (Chandler et al., 2025) ranks first in FR and places the top-5 in 3 languages. **SmurfCat** (Rykov et al., 2025) consistently ranks in the top-5 across 7 languages and never falls out of the top-10. **ATLANTIS** (Kobus et al., 2025) participated in 4 languages and won the 1st place in ES. However, their ρ scores are near zero in three of their languages, including ES and EN, where they placed 1st and 3rd, respectively. Due to this imbalance, we report the inverse ratio: mean(ρ/IoU)= 0.2. **iai_MSU** (Pukemo et al., 2025) competed only in EN, where

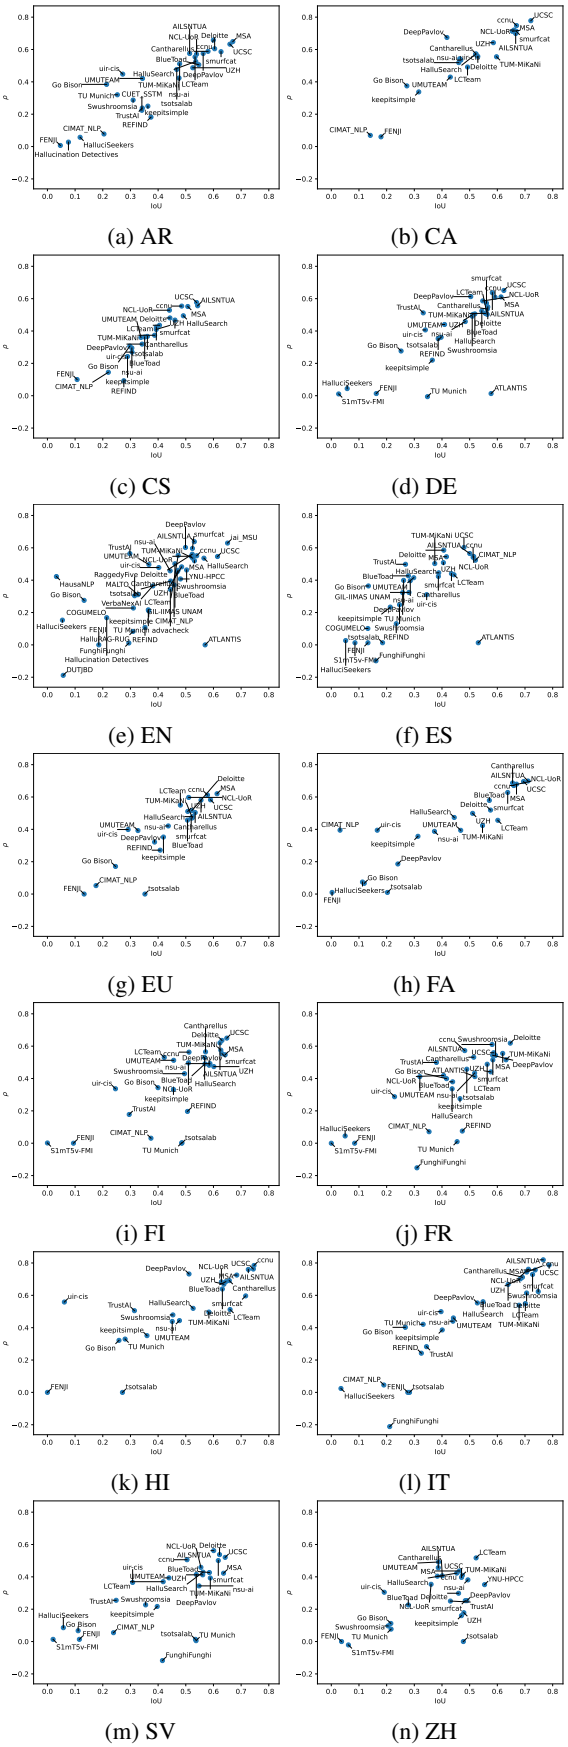

Figure 3: Overview of the performance by the best systems from each team in each language.

[8]Note that we generally do not find evidence that rank differences are statistically significant, cf. Appendix C.

it secured the 1st place with a system that performs well in both metrics: mean(IoU/ρ)= 1.03. **YNU-HPCC** (Chen et al., 2025) participated in ZH and EN, placing 1st and 15th, respectively. While strong in IoU, its systems struggle in ρ, particularly for ZH, resulting in a mean(IoU/ρ) = 1.38.

Table 4 presents the average performance of systems across languages, highlighting the difficulty differences across languages. We compute the mean IoU and ρ across all teams (excluding baselines) for each language and rank them accordingly based on the average IoU. IT and HI emerge as the highest-ranked languages, with both high IoU and ρ, suggesting that systems perform well in both precision and ranking reliability. Conversely, ES, ZH, and CS rank lowest, with ES standing out due to its top-performing system achieving an almost zero ρ. This suggests that certain languages pose greater challenges for models, potentially due to dataset properties, linguistic complexity, or limitations in training data. However, as shown in Table 5, while the most challenging languages tend to have lower $\bar{\rho}$ values, the overall rankings indicate that these datasets are not unreliable.

Rank	Lang	$\overline{\text{IoU}}$	$\bar{\rho}$	Top team		
				Name	IoU	ρ
1	IT	0.51	0.46	UCSC	0.78	0.78
2	HI	0.50	0.52	ccnu	0.74	0.78
3	CA	0.49	0.53	UCSC	0.72	0.77
4	FI	0.48	0.39	UCSC	0.64	0.64
5	DE	0.44	0.41	UCSC	0.62	0.65
6	FR	0.44	0.36	Deloitte	0.64	0.61
7	EU	0.44	0.40	MSA	0.61	0.62
8	SV	0.43	0.29	UCSC	0.64	0.52
9	FA	0.43	0.43	AILSNTUA	0.71	0.69
10	AR	0.42	0.40	MSA	0.66	0.64
11	EN	0.40	0.37	iai_MSU	0.65	0.62
12	ZH	0.37	0.27	YNU-HPCC	0.55	0.35
13	CS	0.37	0.37	AILSNTUA	0.54	0.55
14	ES	0.31	0.33	ATLANTIS	0.53	0.01

Table 4: Ranking of the languages based on the mean IoU ($\overline{\text{IoU}}$), presenting also the mean ρ ($\bar{\rho}$) and the top performing team with their scores.

Figure 4 further illustrates team performance by scatter-plotting IoU against ρ for teams competing in the top two and bottom two languages from Table 4. Most high-performing teams (circled in red) cluster in the top-right corner, exhibiting strong results for both metrics, while lower-ranked teams are spread towards the bottom-left. While only a subset of languages is displayed for clarity, we observe similar trends across the full dataset. Notably, IoU scores tend to be higher than ρ, as indicated by the majority of points falling below the red dotted line. This highlights the importance of considering ρ for evaluating ranking consistency.

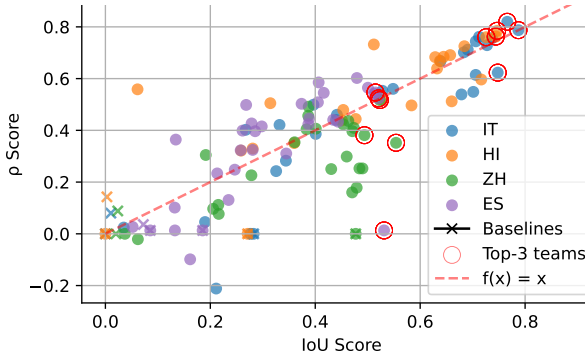

Figure 4: Scatter plot of IoU versus ρ scores for all participating teams in the top two and bottom two performing languages, ranked by average IoU scores.

Some teams show high ρ but low IoU, suggesting they are good at ranking hallucinations but struggle with binary classification. An example from the table is HausaNLP (Bala et al., 2025; EN: $\rho = 0.42$, IoU= 0.03), with highly correlated predictions but almost no correct identifications. When the gap between IoU and ρ is small — for teams like UCSC and AILSNTUA — shows the reliability of both metrics not just in raw intersection but in their robustness in ranking, implying that high IoU does not always correlate with high ρ. A big gap in these two metrics when $\rho \ll$ IoU, as we observe for ATLANTIS, indicates that the models are good at making binary decisions but poor at ranking how hallucinated a character is compared to others. Conversely, we observed for teams with IoU $\ll \rho$ that their models can rank characters well in terms of hallucination but fail in making the correct binary selections. For instance, HausaNLP shows an extremely low IoU despite a decent ρ, meaning its predictions are correlated but far from accurate. Other trends we observe from the general ranking are: TrustAI and Swushroomsia (Mitrović et al., 2025) present con-

Lang	$\bar{\rho}$	σ_ρ	Min (ρ)	Max (ρ)
IT	0.47	0.28	−0.21	0.82
HI	0.53	0.21	0.00	0.78
ES	0.34	0.21	−0.10	0.60
CS	0.38	0.14	0.09	0.58
ZH	0.28	0.16	−0.02	0.52

Table 5: The mean ($\bar{\rho}$), standard deviation (σ_ρ), maximum and minimum ρ values for the top-2 (IT, HI) and the worse 3 languages: ES, CS, ZH.

sistent gaps between IoU and ρ in the same ballpark as $\rho = 0.54$, IoU$= 0.28$; DeepPavlov performs well in CA and EN ($\rho = 0.67$, IoU$= 0.41$; $\rho = 0.61$, IoU$= 0.44$) but has significantly lower IoU in ES ($\rho = 0.42$, IoU$= 0.21$), indicating poor precision; and NLP_CIMAT (Stack-Sánchez et al., 2025) show highly inconsistent performance across languages (ES: $\rho = 0.54$, IoU$= 0.47$; FI: $\rho = 0.04$, IoU$= 0.37$; AR: $\rho = 0.09$, IoU$= 0.14$).

7 1-UP! Discussion

In order to deepen our understanding of the factors relevant to the success of participating teams within our shared task, we now turn to an analysis of metadata collected during the shared task. Participants were asked to fill in a form to describe how their systems worked and what type of resources they used.[9] The trends we discuss below are therefore based on self-reporting. We z-normalize performance per language before analysis so as to factor out the varying intrinsic difficulty of the different language datasets.

A first obvious trend in our results is that 36.98% of the submissions are reported as prompt-based. The IoU scores of prompt-based submissions are not statistically distinct from the IoU scores of other submissions, but we do find a statistical difference for ρ scores, which are usually lower than in other submissions (Mann-Whitney U test: p-value < 0.002, common language effect size: $f = 45.96\%$). This echoes findings in the previous iteration of the shared task (Mickus et al., 2024), which pointed out that fine-tuning based approaches were usually more successful on hallucination detection.

Even more prominent is the use of RAG: 52.60% of the submissions report using RAG, and are assigned statistically higher IoU scores (Mann-Whitney U, p-value $< 10^{-59}$, $f = 69.80\%$) and ρ scores (p-value $< 10^{-39}$, $f = 66.16\%$). On a related note, if we focus on the data used by participants, we find that 34.88% of submissions which primarily used the data we provided tend to have lower IoU (Mann-Whitney U, p-value $< 10^{-21}$, $f = 37.60\%$) and ρ scores (p-value $< 10^{-22}$, $f = 37.28\%$). The preponderance of retrieval-based approaches and their noteworthy success along with the limited performance of submissions relying mainly on the provided data, both showcase that one of the key challenges of the task is finding appropriate references for assessing LLM outputs.

Model family	% subs	IoU p-val.	IoU f (%)	ρ p-val.	ρ f (%)
BERT	12.12	$< 10^{-4}$	42.47	0.09	—
Claude	3.02	$< 10^{-5}$	65.87	$< 10^{-14}$	78.23
DeepSeek	2.32	$< 10^{-11}$	77.87	$< 10^{-13}$	80.15
Flan-T5	5.78	$< 10^{-18}$	26.61	$< 10^{-13}$	30.28
GPT	16.02	$< 10^{-7}$	59.11	$< 10^{-2}$	55.07
Llama	12.34	$< 10^{-15}$	35.17	$< 10^{-29}$	29.08
Qwen	18.03	$< 10^{-16}$	63.06	$< 10^{-21}$	65.27
XLM-R	10.33	0.01	44.96	$< 10^{-2}$	44.35

Table 6: Overview of main PLM families used by participating teams, proportion of relevant submissions, and their effects on scores (Mann-Whitney U tests comparing the scores of submissions using PLMs of the given model family vs. other submissions, along with common-language effect size f where significant).

Another factor of interest is whether specific PLMs stand out as more or less appropriate for the task of detecting hallucinated spans. In Table 6, we provide an overview of the PLMs most frequently used by participants to tackle the shared task, along with the results of U tests comparing scores assigned to submissions using this PLM vs. submissions not relying on it. This allows us to get insights regarding which PLMs tended to yield comparatively higher scores. Given the large number of models, we group them by family, i.e., the GPT family contains GPT-3, GPT-3.5, GPT-4 and other variants, while some other families include multilingual variants (e.g., Flan-T5 includes MT5). The BERT family is used as a catch-all for large group of language-specific models (e.g., CamemBERT), and smaller encoder-based PLMs (e.g., ALBERT or DeBERTa). Several submissions mentioned multiple PLMs and a handful mentioned using none. For the sake of clarity, we do not include PLMs that were only used in a small minority (<1%) of submissions. Overall, we find that Llama-based, Flan-T5 and BERT-based systems tended to perform less well than other systems. The DeepSeek family appears to be highly competitive, as there is a 78% chance that any DeepSeek-based submission will outrank a randomly selected non-DeepSeek-based submission. Here as well, ρ and IoU performances appear roughly in line with one another.

The last factor we explore is related to our earlier observations regarding inter-annotator agreement (reported in Section 3, Table 1). We would expect

[9] We manually excluded partially filled responses. Metadata was collected for each *submission* rather than for each *system*, i.e., a system may correspond to multiple submissions (e.g., when the system has multilingual capabilities, or when participants tested multiple hyperparametrizations).

Lang.	IoU		ρ	
	p-val.	correl.	p-val.	correl.
AR	$< 10^{-323}$	0.24	$< 10^{-323}$	0.24
CA	$< 10^{-207}$	0.26	$< 10^{-60}$	0.14

ZH	$< 10^{-323}$	0.37	$< 10^{-10}$	0.04

Table 7: Spearman correlation of inter-annotator agreement (Equation (1)) vs. datapoint-level scores.

different levels of inter-annotator agreement across languages to impact performance. This line of thought should also apply at the datapoint level: Items where annotations are less consensual, as per Equation (1), might lead to lower scores. We explicitly evaluate this by computing the Spearman correlation between the inter-annotator agreement metric and the scores assigned to a given datapoint. The results are summarized in Table 7. We observe low to moderate correlations across all setups. In other words, while annotator agreement rates do impact the success of a model, other factors of variation still play an important role.

8 The Princess is in another article: Conclusions

The Mu-SHROOM multilingual shared-task was an overall success. We received 2,618 submissions from 43 teams, including a handful of participants from the first iteration of the SHROOM shared task. Whilst the level of participation varied by language, over 20 teams competed in each of the 14 languages. Participating teams deployed a vast array of methodologies, ranging from QA– or NER–based pretraining to synthetic data generation and RAG approaches, which will serve as starting points for future research. We also observed a high number of student-lead teams. One of the goals of the shared task is to lower the barrier to entry to current challenges in NLP, hence we take the interest of students as a further indicator of success.

Beyond these participation numbers, the data collected for Mu-SHROOM also allowed us to highlight a number of often-overlooked points in the literature. The prevalence and severity of hallucinated outputs varies across languages (see Table 2); for some languages, we in fact observe fluency to be a more pressing challenge for LLMs than factuality. The metadata collected from participants' submissions (see Section 7) also allowed us to highlight some of the challenges underpinning hallucination detection. The ability to retrieve accurate references matters, but so do the base pretrained LM used by participants and (to a lesser extent) the agreement rates of annotators. Regarding this latter point, it is worth stressing that we find genuine disagreement among our annotators as to where a hallucination begins and ends.

If Mu-SHROOM has allowed us to establish the importance of multilingual data for hallucination detection, much remains to be done in order to fully assess LLM technologies' tendency to produce non-factual information. One other aspect we have left outside the scope of this shared task is that of mitigating hallucinations, a step that is however necessary and complementary to our endeavors. We have constructed the present shared task as a means to draw the attention of the community towards some challenges tied to hallucination detection — and attention is indeed needed, given that even top-scoring teams do not detect 20% or more of the hallucination spans.

The Boo's we avoid: Limitations and Ethical considerations

We strive to uphold the principles outlined in the ACL Code of Ethics.

Terminology. One important limitation of our work is the terminology surrounding hallucinations in AI-generated text. Hicks et al. (2024) argue that this metaphor can be misleading, implying that AI models perceive information incorrectly rather than simply generating outputs based on probabilistic patterns without any underlying understanding or intent. This framing may contribute to misconceptions among policymakers, investors, and the general public, shaping unrealistic expectations about AI systems' capabilities and failures. While we use the term hallucination in this work due to its established presence in the literature, we acknowledge its limitations and the broader implications of language in shaping discussions around AI reliability.

Broader Impact. Hallucinated outputs from large language models pose a significant risk, as they can be exploited to propagate disinformation

and reinforce misleading narratives. Detecting such outputs is a critical step toward understanding the underlying causes of this phenomenon and contributing to ongoing efforts to mitigate hallucinations. By addressing this challenge, we aim to support the development of more reliable and trustworthy generative language models.

Data and Annotators. The dataset we release may contain false or misleading statements, reflecting the nature of the task. While annotated portions of the data are explicitly labeled as such, unannotated portions may include unverified or inaccurate content. To ensure a respectful and safe annotation process, we manually pre-filtered the data provided to annotators, removing profanities and other objectionable material. However, the unannotated portion of the dataset has not undergone the same level of scrutiny and may include offensive, obscene, or otherwise inappropriate content.

Acknowledgments

The construction of the Mu-SHROOM dataset was made possible thanks to a grant from the Otto Malm foundation. This work was also supported by the ICT 2023 project "Uncertainty-aware neural language models" funded by the Academy of Finland (grant agreement № 345999). Liane Guillou was funded by UK Research and Innovation (UKRI) under the UK government's Horizon Europe funding guarantee [grant number 10039436 (Utter)] whilst working at the University of Edinburgh. Alessandro Raganato thanks Morteza Ghorbaniparvariji for their contribution to the Farsi annotations. Raúl Vázquez and Timothee Mickus thank Malvina Nissim, along with the students in her "Shared Task" class at the University of Groningen — her commitment to this course is one of the reasons that Mu-SHROOM was able to reach a broad audience. Timothee Mickus also thanks the volunteers for testing the annotation interface, especially Jean-Michel Jézéquel. Shaoxiong Ji received support from the CA21167 COST action UniDive, funded by COST (European Cooperation in Science and Technology).

A The super Mu-SHROOM party jamboree: Organizers' roles

Our long line of mushroom friendly people behind this edition of the SHROOM Shared task are as follows:

Raúl Vázquez: Grant application writing & accounting, Spanish data creation & selection, datapoint creation guidelines, annotation guidelines, annotator recruitment & briefing sessions, annotator training, advertisement, overall leadership, paper writing, reviewing process.

Timothee Mickus: Websites development, French validation data creation & selection, English data creation & selection, German data creation, datapoint creation guidelines, annotation guidelines, annotator recruitment & briefing sessions, data analysis, advertisement, overall leadership, paper writing, reviewing process.

Elaine Zosa: Baseline system development.

Teemu Vahtola: Finnish data creation & selection.

Jörg Tiedemann: German data selection, advertisement.

Aman Sinha: Hindi data creation & selection, advertisement, annotator recruitment, reviewing process.

Vincent Segonne: French test data creation & selection.

Fernando Sánchez-Vega: Spanish data annotator recruitment, advertisement.

Alessandro Raganato: Italian & Farsi data creation & selection, annotation guidelines, annotator recruitment, advertisement.
Jindřich Libovický: Czech data creation & selection, data analysis.
Jussi Karlgren: Swedish data creation & selection.
Shaoxiong Ji: Chinese data creation & selection, advertisement, reviewing process.
Jindřich Helcl: Czech data creation & selection, data analysis.
Liane Guillou: English data selection, lead role for annotation guidelines development, paper writing.
Ona de Gibert: Catalan data creation & selection, advertisement, reviewing process.
Jaione Bengoetxea: Basque data creation & selection, advertisement.
Joseph Attieh: Arabic data creation & selection, advertisement.
Marianna Apidianaki: Annotator recruitment, paper writing.

B The map of the Mu-SHROOM kingdom: Supplementary information on dataset creation

B.1 Dataset details

In Table 8, we provide an overview of the models used for every language in the shared task. There are a total of 38 different LLMs, all available through the HuggingFace platform.[10] In practice, a number of these models correspond to variants of the same base model or family, including language-specific fine-tuned versions, incremental releases, or models with different parameter counts from the same model family. It is worth stressing that the models themselves are not balanced: for instance, over 85% of the Hindi test set correspond to a single model (viz. `nickmalhotra/ProjectIndus`).

B.2 Annotation guidelines

In Figures 5 and 6, we provide an exact copy of the annotation guidelines and the illustrative example given to the annotators. These guidelines are based on five of the organizers' experience of annotating the trial set, and were provided to annotators recruited for the validation and test splits. For all languages except EN and ZH, we also organized a briefing session for annotators so as to ensure the guidelines were properly understood and that participants were aware of existing communication channels through which they could ask for clarifications.

B.3 Datapoint creation guidelines

In Figure 7, we provide an exact copy of the annotation guidelines given to the organizers in charge of each language.

B.4 Departures from the general guidelines

In practice, some ad-hoc modifications to the data creation process were adopted, depending on the challenges intrinsic to individual languages. We list the exceptions to these rules for each language below, and the available means for annotation:

- **CS:** The Czech split was built from Wikipedia pages with no equivalent in other languages.
- **EN:** The dataset was annotated with a large pool of annotators that individually annotated about 20 datapoints. In total, some datapoints were annotated by up to 12 annotators.
- **ES:** The test split was annotated by 6 annotators; the first release of the validation split contained only 3 annotations, which was increased to 6 in the final data released.
- **SV:** Due to replicability concerns, a handful of datapoints were removed. One of the SV models is not instruction-tuned.
- **ZH:** The dataset was annotated with a large pool of annotators that individually annotated about 20 datapoints. In total, some datapoints were annotated by up to 6 annotators. A subset of items correspond to the same questions, with answers from different LLMs (or different settings).

Table 8: LLMs considered for each language. N. val.: corresponding number of datapoints in val; N. test: corresponding number of datapoints in test.

Mu-SHROOM Annotation Guidelines

Introduction
In this annotation project you will be shown a series of question-answer pairs plus a relevant Wikipedia article. The answer will be a passage of text produced by a Large Language Model (LLM) in response to the question. You will be asked to identify, with respect to the Wikipedia article: which tokens in the answer constitute the overgeneration or "hallucination".

Annotation Guidelines

1. Carefully read the answer text.
2. Highlight each span of text in the answer text that is not supported by the information present in the Wikipedia article (i.e. contains an overgeneration or hallucination). Your annotations should include only the **minimum** number of characters* in the text that should be edited/deleted in order to provide a correct answer (*in the case of Chinese, these will be "character components"). As a general "rule of thumb" you are encouraged to annotate ***conservatively*** and to focus on ***content words*** rather than ***function words***. Please note that this is not a strict guideline, and you should rely on your best judgements when annotating examples.
    - In the annotation platform: To highlight a span of one or more characters in the text, click on the first character and drag the mouse to the last character - it will change to red text. To remove highlighting, click anywhere on the highlighted red span - it will revert to black text.
3. If the answer text does not contain a hallucination, write "NO HALLUCINATION" in the comment box.
4. If you are unsure about how to annotate an example, write "UNSURE" in the comment box. Please only use this option as a last resort.
5. Ensure that you double-check your annotations prior to moving to the next example. From the "See previous annotations" link you can ***edit*** or ***delete*** previous annotations.

Note:

- You should not consult any other sources of information, e.g. web searches, other web pages, or your own knowledge. Use only Wikipedia as your source.
- Ideally, the wikipedia entry provided should suffice for the annotation, however, you are allowed/encouraged to browse other Wikipedia articles to verify information that is not contained in the provided article.
- If you do consult other Wikipedia articles, please add a comment to this effect and include links to the articles that include information that informed your annotation.
- You are encouraged to leave comments where relevant e.g. if the annotation of an example is not straightforward, or if there is anything else you wish to bring to our attention
- You are encouraged to ***review*** your annotations prior to finishing the task

Hallucination Definition
Hallucination: content that contains or describes facts that are not supported by the provided reference. In other words: hallucinations are cases where the answer text is more specific than it should be, given the information available in the Wikipedia page.

Content/Function Word Definition
Content words contribute to the meaning of the sentence in which they occur. Nouns (Barack Obama, cake, cat etc.), main verbs (eat, run, think etc.), adjectives (small, red, angry etc.) and adverbs (quickly, loudly etc.) are usually content words.

Function words are structural and typically have very little substantive meaning. Auxiliary verbs (could, must, need, will etc.), articles (a, an, the etc.), prepositions (in, out, under etc.), and conjunctions (and, but, till, as etc.) are usually function words.

Figure 5: Annotation guidelines: Instructions.

Example

Question: During which centuries did William II of Angoulême live?
Answer: William II, also known as Guillaume II or "William the Good," was a French nobleman who lived from around 1099 to 1137. He was Count of Angoulême and Poitou from 1104 until his death in 1137. Therefore, William II lived during the 11th and 12th centuries.

William II of Angoulême

8 languages

Article Talk | Read Edit View history Tools

From Wikipedia, the free encyclopedia

"William IV of Angoulême" redirects here. For the later count sometimes given this numbering, see William VI of Angoulême.
For the second William in the dynasty of Angoulême, see William Taillefer I.

William Taillefer (c. 952 – March 1028), numbered **William II** (as the second with the sobriquet Taillefer) or **William IV** (as the fourth William in his family), was the Count of Angoulême from 987. He was the son of Count Arnald II *Manzer* and grandson of Count William Taillefer I. He stood at the head of the family which controlled not only the Angoumois, but also the Agenais and part of Saintonge.[1] By the time of his death he was "the leading magnate in [the west] of Aquitaine[, but his] eminence ... proved temporary and illusory," evaporating on his death in succession squabbles, revolts and the predations of his erstwhile allies.[2] The principal sources for William's career are Ademar of Chabannes and the anonymous *Historia pontificum et comitum Engolismensium*.[3]

Between 994 and 1000 William married Ermengarde-Gerberga, widow of Conan I of Brittany and sister of Fulk III of

Annotated Example
In the **William II of Angoulême** example, we find that the answer text contains information that is not present in the Wikipedia article.

Question: During which centuries did William II of Angoulême live?
Answer: William II, also known as Guillaume II or "William the Good," was a French nobleman who lived from around 1099 to 1137. He was Count of Angoulême and Poitou from 1104 until his death in 1137. Therefore, William II lived during the 11th and 12th centuries.

We therefore annotate the example as follows:

William II , also known as **Guillaume II** or " **William the Good** , " was a French nobleman who lived from around **1099 to 1137** . He was Count of Angoulême and **Poitou from 1104 until his death in 1137** . Therefore , William II lived during the **11th and 12th** centuries .

(Explanation: in the text above, spans highlighted in bolded red text are overgenerations / hallucinations as the information that they contain is not supported by the Wikipedia article)

Figure 6: Annotation guidelines: Illustrative example.

How to generate data points for Mu-Shroom

Start from our wikipedia URL spreadsheet, under the 'sorted per existing val' tab (Wiki URLs spreadsheet). See the next point for a succinct explanation of what is going on there.

1. Structure of the spreadsheet.
    a. **URL-idx**: general index of the whole mushroom dataset
    b. **Primary Wikipedia URL**: URL where we fetched the wiki entry from
    c. **title**: Title of the wikipedia page
    d. **langs**: languages in which this entry is available
    e. **Link in <LANG>**: URL to the specific language wiki entry
    f. **<LANG code> question**: questions asked about this page in the relevant language SV questions ZH questions
    g. **comments** (misc, tracks some of the datapoints assigned to the trial set, etc.)
    h. **Priority**: indicates whether a page should be prioritized for the dev split (when negative) or the val set (when positive).
    [*Under the hood, the magnitude is the number of languages with a question in the same split*]
    i. **<LANG code>-idx**: automatic language-specific counters. Anything below 50 is assigned to val.
2. selecting entries for filling in the spreadsheet with new datapoints :
    a. pick pages with >= 4 of languages
    b. go read wikipedia pages manually,
    c. skip pages with no concrete information
    d. if necessary, go down to pages available >= 3 languages
    e. prefer pages that are already used (with a high absolute priority value)
    f. ignore pages marked as being part of the sample split (column T)
3. Come up with questions
    a. pretty involved, try to come up with questions answerable given the page
    b. pretty hard to make systematic
    c. some cases are feasible: e.g., area / population of a city, but they might not be exactly great
    d. in general, this is enough to get hallucinations
    e. make sure the question is factual and closed
    f. **note:** adding the question in the spreadsheet will update the language counters and priority
4. Generate answers with LLM(s)
    a. Overview:
        i. test several generation configurations (varying top K, top P, temperature, etc.),
        ii. seed your experiments for replicability
        iii. targeting 2~4 LLMs
        iv. select one answer per datapoint
        v. keep the rest of the datapoints for them to be in the unlabeled train sets
        vi. answers need not be evenly balanced across LLMs
        vii. format: in jsonl (see point d. for the variables needed.)
        viii. cf. example scripts available on github (see e.g. spanish, where there are scripts to generate with llama, qwen2 and neurona, and a helper_function to select the answer to be annotated.)
    b. Creation of the **Dev & Test sets**
        i. please remove answers without hallucinations (this step is not needed for training sets)
        ii. please remove answers that are not fluent (remove off-target productions in another language than the one asked for…)
        iii. please remove answers that are completely irrelevant to the questions (keep it as long as it's something you could encounter in a conversation, and that can be annotated with respect to the wikipage)
        iv. format: a jsonl file (see point 3.d. below)
    c. Creation of the **unlabelled Train set** ---SKIP THIS IF YOU ARE WORKING ON A "SURPRISE" TEST LANGUAGE---
        i. Only focus on the questions included in the Dev set (if you don't know them, then check them here)
        ii. Take away the ones that you chose to be annotated for the Dev
        iii. Pack all the other ones, and send them to the main organizers, or upload them on the git, under data/<your language>
        iv. format: a jsonl -- same as the Dev (point 3.d. below)
    d. Data to include: the jsonl file should have the following variables
        i. **'url'**: wiki url
        ii. **'localized-url'**: localized wiki url (the one from the lang you are working with)
        iii. **'lang'**: language
        iv. **'model_id'**: model identifier (as found in HF)
        v. **'input_question'**: input question prompted to the model
        vi. **'output_text'**: output answer in plain text
        vii. **'output_tokens'**: output answer segmented in word pieces
        viii. **'output_logits'**: logits for each word piece in the output answer (only that of the generated token),

Figure 7: Datapoint creation guidelines.

C The Lost Levels: detailed rankings

C.1 Official IoU-based rankings

In Table 9, we provide detailed rankings across all languages. We also include the probability $\Pr(\text{rank})$ of any given submission outranking the submission one rank below, which we compute through random permutation: We re-sample with replacement the datapoints in both submissions 100 000 times, and then compute the proportion of samples where the higher-ranking submission still outperforms the lower-ranking submission, based on IoU scores. For instance, team MSA (ranked 1st on Arabic) outranks team UCSC (ranked 2nd on Arabic) in 65.24% of the random samples we perform, suggesting that the advantage of team MSA's approach is in part contingent on the test data. More broadly, this bootstrapping approach reveals that the rankings are not stable — in most case, we find the probability of a lower-ranking submission outranking the next best submission under resampling to be greater than $1 - \Pr > 0.05$, i.e., we find limited statistical evidence that performances are significantly better within higher ranked submissions.

Table 9: Official rankings, all languages, all teams. Column Pr(rank) tracks a bootstrapped probability of a given team outranking the team one rank below.

C.2 Alternative ρ-based rankings

In Table 10, we provide alternative rankings of participating teams based on their best ρ submission. We also include the probability Pr(rank) of a ρ-based ranking being stable, which as previously we

compute through bootstrapping. Here again, we find that stable rankings (where $\Pr(\text{rank}) > 0.95$) are the exception and not the norm.

One key observation to be stressed is that the rankings are significantly impacted by the metric we use.

Abstract

The rapid spread of online disinformation presents a global challenge, and machine learning has been widely explored as a potential solution. However, multilingual settings and low-resource languages are often neglected in this field. To address this gap, we conducted a shared task on multilingual claim retrieval at SemEval 2025, aimed at identifying fact-checked claims that match newly encountered claims expressed in social media posts across different languages. The task includes two subtracks: (1) a monolingual track, where social posts and claims are in the same language, and (2) a crosslingual track, where social posts and claims might be in different languages. A total of 179 participants registered for the task contributing to 52 test submissions. 23 out of 31 teams have submitted their system papers. In this paper, we report the best-performing systems as well as the most common and the most effective approaches across both subtracks. This shared task, along with its dataset and participating systems, provides valuable insights into multilingual claim retrieval and automated fact-checking, supporting future research in this field.

1 Introduction

The sheer amount of disinformation on the Internet is proving to be a societal problem (Vosoughi et al., 2018). Fact-checking organizations have made progress in manually and professionally fact-checking various contents (Vlachos and Riedel, 2014; Micallef et al., 2022). However, manual fact-checking at scale is too costly. To reduce some of the fact-checkers' manual efforts and make their work more effective, recent studies have examined their needs and identified tasks that could be automated (Nakov et al., 2021; Zeng et al., 2021; Hrckova et al., 2024), such as evidence retrieval (Schuster et al., 2020; Liao et al., 2023) and verdict prediction (Nakashole and Mitchell, 2014; Thorne et al., 2018a).

	Original text (German)	English translation
Social media post	*Wer an Wahlen glaubt, ist auch der Meinung, dass das Ordnungsamt die Küche putzt.* Wussten Sie eigentlich das Das Besatzerstatut besagt: dass die Fremdverwaltung allein Durch die Wahlen vom Wahler akzeptiert wird ** Bei unter 50% Wahlbeteiligung wäre dies hinfällig Denn es gabe dann ein rechtliches Problem Das Besatzerstatut wäre ungültig...	*Anyone who believes in elections also believes that the regulatory office cleans the kitchen.* Did you actually know that? The occupier statute states: that the foreign administration is only accepted by the voters through the elections ** If the turnout is less than 50%, this would be obsolete Because then there was a legal problem The occupier statute would be invalid...
Claim	Deutschland ist ein besetztes Land.	Germany is an occupied country.

Table 1: An example from our dataset. The **social media post** was written by a user. The main text of the post is in *italics*, the OCR transcript from an attached images is in regular font. The **claim** comes from the fact-check assigned by a fact-checker.

In this work, we put focus on the task of *claim retrieval*, also called *claim matching* (Kazemi et al., 2021), *searching for fact-checked information* (Vo and Lee, 2020), or *fact-checked claim detection* (Shaar et al., 2020). Claim retrieval is an NLP task that addresses one significant problem that fact-checkers face: How to find out whether a similar claim has already been fact-checked before, even in a different language (Hrckova et al., 2024). Solving this problem would reduce duplicate work and improve the efficiency of fact-checking efforts. Previously, this task was mostly done in English. Other languages that have been considered include Arabic, Bengali, Hindi, and Tamil (Kazemi et al., 2021; Nakov et al., 2022). However, many other languages or even entire major language families have not been considered at all.

To close this gap, we organized the SemEval 2025 Task 7 "Multilingual and Crosslingual Fact-Checked Claim Retrieval". We formulate claim retrieval task as an information retrieval task: Based on an input text (we use social media posts), the

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2498–2511

goal is to find an appropriate claim from a database of claims that have been already fact-checked by professional fact-checkers. Consider the example in Table 1. A user has written a post making a claim worth fact-checking. The idea of *claim retrieval* is for a model to find a semantically similar claim from a list of previously fact-checked claims. We base the task on our already published multilingual dataset *MultiClaim* (Pikuliak et al., 2023) that consists of two parts: (1) A list of 206k fact-checked claims, and (2) 28k social media posts (SMPs) with references to relevant fact-checked claims from the list. With these data, we can simulate a situation where a fact-checker is asked to fact-check an SMP, and they want to search through the list of already available fact-checks to see whether the same claim was fact-checked before. Our task features subtracks on both a monolingual and a crosslingual setup. To construct the training and development sets, we use a subset of the MultiClaim data set covering 8 different languages in the monolingual track and 14 different languages (52 combinations) in the crosslingual track. We further collect new resources to construct a test set which covers two additional previously unannounced languages and more than 4,000 new SMP-Claim pairs.

Our shared task attracted 179 participants. There were in total 52 test submissions by 31 teams, and 23 teams submitted system description papers. In this paper, we describe in detail the setup and implementation of our shared task along with datasets and submitted machine learning systems. These systems tackling the multilingual and crosslingual claim retrieval task provide valuable insights on applying state-of-the-art techniques to the real-world task and highlight future directions on better solving the claim retrieval problem.

2 Related Work

The increasing prevalence of disinformation on the Internet has prompted extensive research on fact-checking. A number of tasks have been proposed accordingly to examine different aspects of the process (Kotonya and Toni, 2020; Guo et al., 2022), including claim detection (Arslan et al., 2020; Konstantinovskiy et al., 2021; Eyuboglu et al., 2023), verdict prediction (Nakashole and Mitchell, 2014; Thorne et al., 2018a; Kumar et al., 2024), evidence retrieval (Schuster et al., 2020; Liao et al., 2023), and justification production (Lu and Li, 2020; Russo et al., 2023).

Prior shared tasks and competitions have touched on claim verification, such as the well-known FEVER shared task (Thorne et al., 2018b; Christodoulopoulos et al., 2020; Akhtar et al., 2023), and AVeriTeC shared task (Schlichtkrull et al., 2023, 2024). Evidence retrieval has also attracted significant attention. Jullien et al. (2023) organized the shared task on evidence retrieval on clinical trial data. SemEval 2020 Task 9 (Wang et al., 2021) focuses on evidence finding for tabular data in scientific documents. Similarly, shared tasks are organized to tackle claim retrieval in social media posts, such as the CheckThat! Lab 2023 shared task (Barrón-Cedeño et al., 2024), and in a multi-modal and multigenre content, such as CheckThat! Lab 2024 (Alam et al., 2023) and Factify 2 (Suryavardan et al., 2023).

3 Task Description

The shared task is formulated as an information retrieval task. Given social media posts, the goal is to retrieve the most relevant claims from a list of claims that are previously fact-checked. We set up two tracks for the shared task. In the **monolingual track**, matched posts and claims are always in the same language and the search pools for candidate claims are language specific to the post. In the **crosslingual track**, the search pool of candidate claims is not restricted and the matched claims can be in languages that are different from the post.

3.1 Dataset

The dataset used in the shared task is available for research purposes at Zenodo[1]. The training and development sets are based on the MultiClaim (Pikuliak et al., 2023) dataset. The test set contains additional data, which are not part of the original MultiClaim dataset, but which were collected using the same methodology.

Training and Development Sets. The original MultiClaim dataset consists of two parts:

1. *Fact-checked claims*. The dataset contains 205,751 fact-checked claims extracted from fact-checks created by 142 fact-checking organizations. Claims are usually one sentence long summaries of the main idea that is being fact-checked.

2. *Social media posts*. The dataset contains 28,092 SMPs spanning 27 different languages, collected from Facebook, Instagram, and Twitter by

Table 3: Combinations of languages in SMP-Claim pairs for train and dev sets of the crosslingual track.

following the links to these platforms given in the fact-checking articles. This way, 31,305 SMP-Claim pairs (each SMP has at least one claim assigned) were established. All posts in MultiClaim were published before 2023.

To make sure that only relevant SMPs are considered, two filtering techniques were used: (1) We use links from the `ClaimReview` json schema that the fact-checkers use. (2) We use the fact-checking warnings provided by the Facebook and Instagram platforms. When a visitor visits SMPs that were flagged as disinformation, the warnings contain a link to relevant fact-checks. In both cases, we can be sure that the link between a claim and an SMP is correct, because a fact-checker left an explicit signal confirming it. Manual inspections of the connections (done by three authors on a random sample of 100 pairs; see Pikuliak et al., 2023 for more details) confirmed the absence of false positives. However, roughly 15% of the connections rely on visual information present in either attached images or videos, making it impossible to match the SMP with an appropriate claim based on the text data only.

An additional manual inspection (of claims retrieved for a sample of 87 posts done by three authors; see Pikuliak et al., 2023 for more details) also revealed that there are many potential connections between SMPs and claims that are missing in the dataset due to the employed collection procedure, especially crosslingual connections. To at least partially mitigate this, we added to the dataset additional SMP-Claim pairs created by following *transitive connections*: If two SMPs p_i and p_j share a link to the same fact-checked claim and one of those (p_i) is also linked to a different claim c_k, we add the link (p_j, c_k), if missing. This way, we were able to identify 3,351 additional SMP-Claim pairs.

To construct high-quality training and development sets covering different languages, we filter out languages that have less than 500 SMP-Claim pairs. After filtering, the dataset contains 8 languages (Arabic, English, French, German, Malay, Portuguese, Spanish, and Thai) for the monolingual track. For the crosslingual track, we include all SMP-Claim pairs, where the language of the claim is different than the language of the post and at the same time, both of the languages are already included in the monolingual pairs; additionally, all pairs with a language combination appearing at least 200 times are included even if these languages do not appear in the monolingual pairs. There are still only 8 claim languages, but there are 6 additional post languages as compared to the monolingual track (Hindi, Korean, Sinhala, Tagalog, Urdu, and Chinese). There is a total of 52 different combinations that are covered in the crosslingual track. To prevent an exploitation of the data design in the crosslingual task (e.g., by ignoring the language of

Table 4: Combinations of languages in SMP-Claim pairs for test set of the crosslingual track.

the post, if the matched claim is always in a different language), we assign a randomly selected 10% of monolingual pairs into the crosslingual subset of the data. The development set was created by holding out a randomly selected 10% of pairs for the monolingual and the crosslingual tracks. The final numbers of selected posts, claims, and pairs are reported in Table 2. Table 3 shows the combinations of languages in SMP-Claim pairs for the combined training and development sets.

Test Set. Our test set consists of additionally collected data containing posts that are not a part of the original MultiClaim dataset and which were published until March 2024. For fact-checked claims, the test set contains the ones already present in the training and development sets, as well as newly collected ones (ranging until May 2024). The same data collection methodology was applied as in the original MultiClaim dataset, while being extended to more sources (more fact-checking organizations and also including Telegram in case of SMPs). Similarly, the same data cleaning and pre-processing was applied as described in Pikuliak et al. (2023) to ensure consistency.

For the monolingual track, the same 8 languages were used as in the training and development sets. Additionally, we added two unannounced languages: Polish and Turkish, which both meet the criteria imposed on the number of SMP-Claim pairs and which did not appear in the prior phases of the shared task in either of the subtracks. We select a random set of 500 posts (where available; only 93 and 183 posts were available for Malay and Thai, resp.) for each language and all fact-checked claims available for that language.

To construct a test set for the crosslingual track, we again apply the same criteria as for the training and development sets, resulting in 11 languages for

Table 6: An example of a fact-checked claim. There are four fields for each claim.

claims (10 from the monolingual track plus Hindi), 14 languages in SMPs – the ones not contained in the monolingual track being Hindi, Urdu, Chinese, and Bengali – and 60 language combinations in total. The complete statistics for the test set are reported in Table 2. Table 4 shows the combinations of languages in SMP-Claim pairs contained in the test set. It is worth noting that despite the language diversity, most crosslingual pairs still contain English as either a language of a post or of a claim. This is one of the limitations of the dataset and it needs to be taken into consideration when interpreting the results of the crosslingual track.

Details on Data Format. Each post has five fields as illustrated in Table 5. The *post_id* refers to the id of the post in our dataset. The *instances* field is used to indicate the timestamp of the post and its social platform. The *ocr* field is filled with transcribed texts if there are any associated images

in the post. The *verdict* is assigned by professional fact-checkers. The *text* field contains the content of the post, its translation to English and a list of detected languages.

Each claim has three fields as illustrated in Table 6. The *fact_check_id* is the identification of the fact-check (claim) in the dataset. The *claim* field contains the content of the claim, its translation to English and a list of identified languages. Similar to the structure of posts, the *instances* field is used to indicate the timestamp of the claim and its relevant URL. The *title* field contains the original title of the fact-check, its translation to English and a list of identified languages.

We utilize the Google Vision API and Google Translate API to obtain the texts in the image associated to posts and the translations of non-English texts respectively.

3.2 Evaluation

The participants were asked to provide top 10 results for each SMP. The lists of fact-checked claims are provided as a search pool. We calculate *success@10* to evaluate the performance of all systems:

$$\text{success@10} = \frac{1}{N}\sum_{i=1}^{N} \mathbf{1}(\text{relevant claim in top10})$$

where N is the total number of examples (SMPs), and $\mathbf{1}(\cdot)$ is an indicator function that returns 1 if the condition is met for the post i, otherwise 0. We count a retrieval as success if at least one relevant claim is ranked in the top 10.

4 Baselines

We selected four approaches as baselines:

BM25. BM25 (Robertson and Zaragoza, 2009) is used as a default retriever in many prior works on claim matching (see, e.g., Vo and Lee, 2020; Shaar et al., 2020, 2022) and it also achieved competitive results especially in monolingual evaluation performed in Pikuliak et al. (2023). We use it with the English-translated version of the dataset.

GTR-T5-Large. GTR-T5-Large (Ni et al., 2022) was the overall best performing model in Pikuliak et al. (2023) in monolingual as well as crosslingual settings. Since it is an English-only model, we use it with the English-translated version of the dataset.

Paraphrase-Multi-v2. We use the Paraphrase-Multilingual-MPNet-Base-v2 model, which is a part of the Sentence-BERT set of pre-trained models (Reimers and Gurevych, 2019). We selected this model as one of the baselines, since it was the best multilingual model in Pikuliak et al. (2023), although having lower performance than both BM25 and GTR-T5-Large (which, however, work on the English translations). The original multilingual version of the dataset is used with this model.

E5-Large. We use Multilingual-E5-Large model (Wang et al., 2024a), which belongs to the best performing multilingual text embedding models under 1B parameters based on public benchmarks[2] (2nd for reranking task, 6th for retrieval and sentence similarity tasks) and it had competitive results in our initial experiments. Being a multilingual model, it works with the original multilingual version of the dataset.

5 Participating Systems and Results

The high-level overview of approaches utilized by individual systems is summarized in Table 7. The results presented in Tables 8 and 9 reflect the performance of test submissions by the end of the test phase. In their system papers, participants may provide additional post-test analysis that achieve further improvements.

5.1 Monolingual Track

In the monolingual track, posts and claims are in the same language, and multilingual data cover ten different languages. Two (Turkish and Polish) out of ten are unannounced languages – i.e., no examples in these languages appear in the training and development sets.

21 out of 27 teams have submitted their system description papers on the monolingual track. The results are summarized in Table 8. Out of all teams that submitted system description papers, we describe the top-5 performing systems.

TIFIN India. Inspired by Khan et al. (2024), Devadiga et al. (2025) first translate all posts and claims into English and utilize English-focused models for the claim retrieval task. They employ the Aya-expanse-8B (Dang et al., 2024) model for the translation. Then, a two-stage pipeline is implemented. The Stella 400M embedding model

Table 8: The results (success@10) on Monolingual Track. Teams are ranked by their average performance across all languages. The best results for each language and the average are in bold. The rows with gray background and * indicate the performance of four baselines. Teams with reference have submitted system papers.

(Zhang et al., 2024) is first used to retrieve top 50 claims using cosine similarity. These are fed into an LLM-based re-ranker, Qwen2.5-72B-Instruct (Yang et al., 2024). The re-ranking is performed in

a prompting style. The top 10 candidates from the re-ranker are then combined with the top 10 results from the embedding model by Reciprocal Rank Fusion (Cormack et al., 2009), producing the final top 10 results. They further fine-tune the embedding model by adding hard negatives, demonstrating that 20 negatives per post give the best performance.

RACAI. Chivereanu and Tufis (2025) adopt a single-step strategy to tackle the task without re-ranking. All posts and claims are used in their original languages. The BGE-Multilingual-Gemma2-9B model (Xiao et al., 2023; Chen et al., 2024), is used to provide embeddings for posts and claims. They explored different strategies to optimize and adapt the general-purpose embedding model on the given task. They first utilize LoRA (Hu et al., 2022) with a contrastive learning objective with in-batch negatives to fine-tune the base model. Additionally, they use prompt-tuning to adjust the embeddings for instructions. To reduce the computational requirements, Matryoshka representation learning (Kusupati et al., 2022) is employed to produce embeddings of different dimension sizes.

QUST_NLP. Liu et al. (2025) propose a three-stage retrieval framework. A group of six different retrieval models is utilized in the retrieval stage to coarsely identify relevant claims for each post. In the re-ranking stage, six different re-ranking models are employed to provide top 10 candidates from the retrieved results. For each language, a set of re-ranker models are fine-tuned with training data in that language. Finally, the weighted voting stage combines the top 10 candidates from each re-ranker and weight them by their performance on the dev set to obtain the final top 10 results. They also find that the combination of the original text and corresponding English translations can further improve the overall performance.

UniBuc-AE. Enache (2025) utilize both the original text and English-translated text for retrieval. Two embedding models (English one: e5-large-v2, Wang et al., 2022, and multilingual one: multilingual-e5-large-instruct, Wang et al., 2024b) are employed to provide corresponding embeddings after contrastive learning with in-batch negatives. They further fine-tune the two models with hard negatives, resulting in two hard fine-tuned models. All four models are used to vote for the final top 10 retrieval claims in a weighted manner. The optimal weights are discovered by their performance on the development set.

UWBa. Lenc et al. (2025) present a zero-shot claim retrieval approach with all posts and claims translated into English. Five embedding models without any further fine-tuning are utilized to provide embeddings for posts/claims. A model combination strategy is employed to produce the final top 10 candidates. The models are firstly ranked in term of performance on dev set. Their top 5 retrieval results are then combined to produce the top 10 results after potential de-duplication.

Discussion. We can see that most systems outperformed the baselines. On the other hand, a clear pattern is that the two unseen languages, Turkish and Polish, show a generally worse performance than the languages observed in the training data. This indicates that the **generalization ability to unseen languages is still a big challenge**.

Approximately half of the submissions to the monolingual track did not apply any data filtering or pre-processing techniques, including many good-performing competitors. This does not mean that these techniques (e.g., using LLMs for data augmentation) do not improve performance, but others, such as fine-tuning, have a higher impact. On the other hand, a common and successful strategy (used by three out of top-5 described systems) was to improve base embedding models by **fine-tuning them in a contrastive learning manner** with in-batch negatives and using hard-negatives for further improvements.

Many systems utilized a one-stage approach (retrieval with fine-tuned or vanilla embedding models) to tackle the retrieval task, while some systems built two- or three-stage pipelines (adding a re-ranking or a weighted voting stage) that demonstrated a better performance in some cases. However, the results do not provide a conclusive evidence whether adding them is in general better, especially since we do not compare the systems in terms of their computational requirements.

In the monolingual track, there are subsets for different languages. Yet, most systems chose to train one model for all languages. This was achieved by either translating everything into English and utilizing an English-focused model, or, more often, utilizing a multilingual embedding model with the original data. When comparing the former (e.g., TIFIN India) with the latter (e.g., RACAI), we can see that **the differences between**

Table 9: The results (success@10) on Crosslingual Track. Teams are ranked by their performance. The best result is in bold. The rows with gray background and * indicate the performance of baselines. Teams with reference have submitted system papers.

the two approaches are negligible, which clearly shows the recent improvements in multilingual models compared to the situation reported in Pikuliak et al. (2023). A small number of systems trained a set of models for each language specifically. Some other models utilized both texts in original language and their English translations, reporting improved performance.

5.2 Crosslingual Track

20 out of 28 teams submitted system description papers for the crosslingual track. The results are summarized in Table 9. We describe the top 5 performing systems of those teams that submitted system description papers.

RACAI. The same pipeline is employed as for the monolingual track, where the base embedding model is improved by contrastive learning with in-batch negatives and prompt-tuning. They demonstrate that it brings much higher improvements in crosslingual compared to monolingual setup.

TIFIN India. They translate everything into English and use the same two-stage pipeline as in the monolingual track. Their high performance shows that this strategy is effective in both monolingual and crosslingual setups.

fact check AI. Rastogi (2025) uses the English translations. Base embedding models (mul-e5-large-instruct, Stella-400M, and mxbai-embed-large-v1) are fine-tuned with contrastive learning. The fine-tuning is performed in a K-fold manner to increase the robustness and prevent over-fitting. The final 10 candidates are produced by models' voting. They also conduct pre-processing such as removing noise (e.g., url, emoji, extra space) and filtering out too-short texts.

QUST_NLP. The same three-stage framework is utilized for the crosslingual track. Different from the language-specific fine-tuning strategy for re-rankers in the monolingual track, they use English translations and employ one set of re-rankers for refined re-ranking. They also demonstrate that though the combination of the original text and English translations are helpful in the monolingual track, such combination often causes performance decrease in the crosslingual track.

UniBuc-AE. They adopt the same strategy for the crosslingual track where four embedding models are used for weighted voting. They show that fine-tuning with hard negatives brings larger improvements in the crosslingual setup.

Discussion. We can see that most systems outperform the baselines, but **they achieve a worse performance compared to the monolingual track (more than 10 percentage points difference)**, highlighting the challenge of this setup. Also, most systems that were submitted to both tracks do not consider a new approach but adopt the same pipeline, which seems to work quite well, given that it is the case for all top-5 best performing systems in the crosslingual track. However, they also highlight some performance inconsistencies of different techniques when applied across the tracks. For example, the **improvements brought in by additional re-ranking and weighted-voting seem to be larger** in the crosslingual setup. On the other hand, as indicated by Liu et al. (2025), the combination of original text with English translations instead has a negative impact on the performance

in the crosslingual setup. This raises questions on the transferability of such techniques and models to the crosslingual scenario, which a future research should examine more comprehensively.

6 Conclusion

This work presents an overview of SemEval 2025 Task 7 on multilingual and crosslingual fact-checked claim retrieval. It provides a comprehensive analysis of the dataset and submitted systems. The task has attracted 179 participants. In the final test phase, 31 teams submitted test systems, of which 23 submitted system description papers.

Our analysis reveals that the most common strategy to improve base embedding models is to fine-tune them in a contrastive learning manner with in-batch negatives. As demonstrated by many systems, further improvements can be obtained by adding hard negatives and training on diverse subsets. A multi-stage pipeline is adopted by a large number of systems that additionally include a re-ranking and a weighted voting stage, which can bring improvements in both crosslingual and monolingual setups. An effective strategy to tackle different languages is still to translate them into English and utilize an English-focused model, but using multilingual models with the texts in original languages already gives comparable results. Several systems have discovered that some techniques which work well in one track have a different impact in the other track, suggesting the difficulty of transferability.

We believe our shared task along with participating systems provides valuable insights into multilingual and crosslingual claim retrieval, supporting future research in this field.

Ethical Considerations

Most of the ethical, legal and societal issues tied to the MultiClaim dataset were already described in the Ethical Considerations section of the accompanying paper (Pikuliak et al., 2023). The most severe risks were tied to a Terms of Service (ToS) violation, various types of privacy intrusions, the possibility of third-party misuse, or the erosion of some privacy rights such as the right to erasure. For the shared task organization we also discussed the possibility of the emergence of new issues that were not assessed before with respect to the most affected stakeholders, especially researchers who will participate in the shared task, social media users, and social media platforms.

We have reassessed the risk of a potential violation of the ToS of the social media platforms in light of the new EU digital regulations. Exploratory research on very large online platforms is now legally permitted by Article 40 (12) of the EU Act on digital services (DSA) if the research concerns systemic risks. As the spread of disinformation is clearly a systemic risk as foreseen by Recital 83 of the DSA (Commission, 2022), we see this as an argument in favor of the further use of the MultiClaim dataset.

During the shared task, new methods were proposed, trained and published by the participants. As strictly research-oriented models, they should not be deployed without further assessment regarding their potential misuse, privacy concerns, or the occurrence of various forms of algorithmic biases (Lee and Singh, 2021). To avoid the risk that participants do not understand the limitations and further uses of data and methods used in our shared task, we prepared a set of guidelines to inform participants from the beginning of the task about the purpose of the task, its possible limitations, and the admissible uses of the outputs,

In the process of analyzing data, researchers participating in our shared task may have been exposed to several risks tied to their well-being, moral integrity, or safety. Disinformation may contain some sensitive societal topics regarding the LGBTQIA+ community, war, or humanitarian crises, child abuse, terrorism, or other political and theological topics. However, since the participants focused on improving retrieval performance rather than direct content analysis of the posts, we expect possible negative impacts to be minimal.

To minimize the risks of third-party misuse or revealing incorrect, highly sensitive, or offensive content, we still maintain the right to restrict the use of the shared task dataset. Participants were not allowed to use any external datasets other than the dataset prepared for the shared task, to enable fair evaluation. To ensure that any residual privacy concerns are adequately addressed, contact persons were designated, through which participants were able flag potential data issues.

Abstract

We introduce the findings and results of SemEval-2025 Task 8: Question Answering over Tabular Data. This shared task featured two subtasks, DataBench and DataBench Lite. DataBench consists on question answering over tabular data, and DataBench Lite comprises small datasets that might be easier to manage by current models by for example fitting them into a prompt.

In this paper, we present the task, analyze a number of system submissions and discuss the results. The results show how approaches leveraging LLMs dominated the task, with larger models exhibiting a considerably superior performance compared to small models. Open models proved competitive with respect to proprietary LLMs, but further work would be required to improve the performance of smaller models.

1 Introduction

Large Language Models (LLMs) have demonstrated emerging capabilities (Wei et al., 2022), with one of the latest recognized tasks being Question Answering (QA) on Tabular Data (Chen, 2023). **QA on Tabular Data**, as illustrated in Figure 1, involves responding to natural language queries using structured information stored in tables. Different approaches exist for retrieving answers, including translating natural language questions into formal programming languages like SQL, which can then be used to interact with databases (Nan et al., 2022a; Aly et al., 2021; Nan et al., 2022b). Since these models are widely applied across various domains, ensuring their accurate evaluation is essential. However, the research community currently lacks a comprehensive evaluation benchmark to assess and compare different LLMs and prompting strategies for this task.

Benchmarking in Tabular QA has traditionally relied on a limited set of collections, such as (Zhong et al., 2017; Pasupat and Liang, 2015; Kweon et al., 2023), which are predominantly based on tables extracted from Wikipedia.

Name	Subject	Score
Alice	Math	92
Bob	Science	85
Charlie	History	78
Diana	Math	88
Ethan	Science	95

Q: Who scored highest in Math?
A: Alice

Q: What is the mean score for Science?
A: 80

Figure 1: Examples of correct and wrong answers to simple and factual questions made on Tabular Data

While these datasets have been widely used, they exhibit common characteristics—such as low data variety and a small number of columns—that make them less representative of the complex tabular data encountered in real-world applications. Additionally, Wikipedia tables often pose challenges related to scale, data cleanliness, and structural limitations.

To address these shortcomings, we introduced DataBench at LREC-COLING 2024 (Osés-Grijalba et al., 2024), a novel benchmark designed to provide a more diverse and realistic evaluation framework for question answering on tabular data. DataBench consists of real-world datasets from various domains, featuring large and heterogeneous tables, along with a rich collection of annotated question-answer pairs.

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2512–2522

Domain	Datasets	Rows	Columns
Business	26	1,156,538	534
Health	7	98,032	123
Social	16	1,189,476	508
Sports	6	398,778	177
Travel	10	427,151	273
Total	65	3,269,975	1615

Table 1: Domains and statistical data of DataBench.

The availability of DataBench encourages us to challenge the research community to design QA on tabular data models with the ability of processing and answering questions about data stored in tables. Accordingly, we propose the Tabular QA task with the enough freedom to encourage the creativity of researchers to provide solutions to this challenge. As we will describe hereinafter, we provide two versions of DataBench, and one of them is oriented to facilitate the use of models that are not able to process large contexts by presenting datasets small enough to fit whole into a single prompt by whatever representation the users desire.

The task has arisen the participation of more than 100 teams, with 35 research teams having submitted a system description paper. The top-ranked models evidence the superiority of models leveraging LLMs, and among them those with large size of parameters. However, the approaches also followed evidence that the task needs smart prompting strategies, hence the size of the models is not the only important feature at play. The top ranked systems for each kind are described further in the results section.

Codabench. The competition has been hosted on Codabench[1] where you can find more details, examples and links for the relevant test set data.

2 Datasets

DataBench was introduced in Osés-Grijalba et al. (2024) to provide a dataset for Question Answering over Tabular Data, addressing challenges commonly found in real-world data that are often absent from existing datasets, which primarily consist of Wikipedia tables. By incorporating these complexities, DataBench offers a more reliable benchmark for developing models capable of handling such data.

The dataset includes 65 datasets spanning various domains, as detailed in Table 1. These domains include **Business**, covering topics such as churn prediction and market basket analysis; **Health**, featuring datasets on diseases and treatments; **Social**, containing data from surveys and social networks; and **Travel**, which focuses on the travel industry.

DataBench also includes 1,300 tagged QA pairs, providing insights into the types of columns being used. The questions, as illustrated in Table 2, are concise and objective, each targeting specific pieces of information expected in a particular format.

DataBench Lite DataBench Lite was also introduced along DataBench and it contains sampled versions of all datasets and answers for each sampled version. The size of this is essentially the same as Table 1 but with only 20 rows per dataset. Everything else stays the same, except for the answers to the questions which have been adapted to fit the sampled data. We created DataBench Lite because of the limitation of most language models to a given context window. This smaller version of the data can help explore fitting the whole data within the prompt following an In-Context Learning approach, or to test models which have not been able to fully scale up to large sizes yet.

DataBench and DataBench Lite are hosted publicly on HuggingFace.[2]

Train and Development sets The full set of DataBench was divided in two sets: the **Train Set**, containing the first 40 datasets, and the **Dev set**, containing the last 15. This artificial distinction was made in order to facilitate evaluating on the development set during the first phase of the competition, but otherwise participants were encouraged to use the two sets as they found best fit.

Test set The test set released in the competition phase comprises 522 QA pairs over 15 datasets. In Table 3 we can see that the number of total rows of data is 438,909 and the number of columns is 391. The original five domains from DataBench have been included here as well. Table 4 shows the data types of the columns of the datasets. This full test set was used for Subtask A, while a reduced version (*lite*) with up to twenty rows per dataset was used for Subtask B.

The language of the datasets is primarily English, and only understanding English is required in order to retrieve the appropriate answers.

3 Pilot Task

In the original DataBench paper (Osés-Grijalba et al., 2024), we compared two approaches based on LLaMA (Touvron et al., 2023) (including the code version) and ChatGPT. Specifically, we examined two different zero-shot approaches and tested multiple prompts for each over DataBench Lite. These models were evaluated in the 65 datasets included in DataBench Lite.

The first approach, referred to as *In-Context Learning*, involved including the entire dataset in the prompt, formatted as a CSV, and then directly asking the intended question while specifying the expected response format.

The second approach, called *Code*, functioned as a Python code-completion task, where the model was instructed to complete a function. This function was given a structured representation of the dataset—including at least its column names—and could only use PANDAS and NUMPY to perform the task.

Overall, the *In-Context Learning* approach produced worse results and exhibited more hallucinations. However, it performed relatively better on certain subsets (such as boolean datasets) and was generally faster since it did not rely on a code interpreter. In contrast, the code-based approach interacted with the data by generating code through completion models to execute the required operations.

A key challenge with the first approach was managing hallucinations and ensuring that users could verify the correctness of the response in real-world applications. On the other hand, the main challenge with code-based methods was providing sufficient information about the dataset to allow accurate code generation. For example, it was often necessary to supply the model with column names to enable proper data access.

A summary of the results in the pilot task is provided in Table 12 in the Appendix. Overall, the results indicated that the task remained unsolved, with accuracy scores in the early tests generally below 50% for small open source models, which were the focus of our approach. This made the approaches unreliable for most applications. However, there was potential for improvement through more grounded methods, including more refined strategies and fine-tuning techniques that were not explored in the pilot study.

4 Task Organization

The task was run in two phases, making use of the Codabench platform. Both DataBench and DataBench Lite were evaluated on all submissions at the same time, but participants could make a submission with either of them, or both.

In the platform we only evaluated accuracy against a ground truth set for both subtasks, allowing participants to freely build any systems they would like to solve the task. They were informed of requirements to share the type of model used, code and general descriptions in order to qualify for the final ranking. Rankings for both subtasks were also made separately, and special rankings were provided for small models of up to 9 billion parameters and open source models in general.

Evaluation script. Participants were also provided with a Python package (databench_eval[3]) to make the process of making a submission more streamlined in case they wished to use it. Due to the open-ended nature of the task, we opted for an open-source evaluation function that heuristically evaluates the output provided by the users against the ground truth depending on the type expected. The function returns either *true* or *false* for a given pair of response and ground truth and according to the expected semantic value of the response. We then add up the percentage of *true* values to compute the accuracy. This evaluation carries a number of checks to allow for smaller models to commit some small format errors that would otherwise hinder their performance, such as trimming down extra spaces in the response or allowing for drifts in calculations smaller than the second decimal position for numerical values. This function was open-sourced from the start and received feedback from participants which resulted in a number of small changes which can be seen through the history of the GitHub repo.

Given that LLMs generate text of any kind, and the almost infinite possibilities of format changes for a given answer, we also performed a manual evaluation of the results shown in the final ranking in order to ensure small formatting mistakes were mitigated as much as possible. This manual evaluation in the competition phase was done for the top 10 results for each category, and resulted only in very small changes which did not in the end affect the rankings.

[3] https://github.com/jorses/databench_eval

Development Phase Running from the 8th of September 2024 to the 9th of January 2025. In this phase participants were only provided with the full train and development sets, including tags on the columns where the answer was to be extracted from and the type expected of the answer. They were free to make as many submissions as they wanted and had full access to their scores. A public ranking was available on the platform where participants could freely choose to display their results, but were not forced to do so. Participants were provided with a minimal **baseline** script that could be executed locally without any GPU on most consumer hardware and yielded 28.05 and 30.22 of accuracy for DataBench and DataBench Lite respectively with the use of a 4bit quantized version of the stable-coder-3b model (TheBloke and StabilityAI, 2023). This baseline is still available in the GitHub page for the evaluation benchmark.

Competition Phase The full blind test set, including only the questions from the test set, was released on 9 January 2025. The competition ran until 31 January 2025. During this phase, participants were allowed only three submissions and the public ranking was not available. After the competition, participants who wished to take part in the final ranking had to fill out a Google form containing the information on their system described earlier.

5 Participating systems

106 teams submitted valid results to the Codabench January Competition phase. All of them were informed of the requirement to complete a form describing their approach in order to participate in the ranking. Out of those 106 teams, 51 chose to fill the form, which are the teams included in this paper. Finally, 35 teams submitted a system description paper to be included in the proceedings, and more details about the approaches can be found on their specific articles.

Among all participants, thirty-five teams used an approach based purely on open-weight models, while sixteen teams used a proprietary model. A separate category was created for open-source models with fewer than 9 billion parameters, as these models can efficiently run after 4-bit quantization is performed run on CPU on modern consumer hardware and were the focus of our pilot task.

In general, most successful teams implemented a code-based LLM approach with few-shot prompt-

ing, coupled with some innovations such as self-correction and table-tailored prompting. In the following, we describe the teams that achieved the highest scores in each of the categories (see the following section for more details on the experimental results).

TeleAI The team from the Institute of Artificial Intelligence (TeleAI), China Telecom Corp Ltd, achieved the highest accuracy in the DataBench benchmark, with 95.02% on DataBench and 92.91% on DataBench Lite. Their approach leveraged a structured reasoning framework combining program-aided query refinement and code generation to enhance structured data understanding.

According to their own description provided in the *Google Form*, the task is implemented using the ReAct prompting approach (Yao et al., 2023). First, Python processes table data, and an LLM generates natural language descriptions that provide an overview of the table's content, explain column names, identify data types, define value ranges, and include row examples. This process is referred to as *Table Schema Generation*. Within each reasoning cycle in ReAct prompting, the *thought* component represents the original or refined query. The *action* stage follows a structured, program-assisted approach involving the *Query Expansion & Linking - Schema Refinement - CoT Generation - Code Generation & Execution* pipeline. Query Expansion decomposes the original query into finer subqueries, identifying relevant columns and entity values. Schema Refinement extracts key structures from the dataset to simplify large tables. The *observation* step records the results of program execution. After completing each thought-action-observation cycle, the LLM determines whether the answer can be inferred. If the answer is sufficient, the process transitions to the *Answer Summary* module, which generates a structured response; otherwise, the query is refined for another iteration.

Table 6: Subtask B) DataBench Lite Rankings - Proprietary models marked with an asterisk after accuracy, small open source models under 9billion parameters with sm.

To improve query expansion and linking, the team fine-tuned their model using the DataBench train and dev sets. Data distillation from advanced LLMs, combined with Rejection Sampling, was applied to construct and select supervised fine-tuning (SFT) data. For model selection, they utilized the *Mistral-Large-Instruct-2407* LLM for the code generation module, while the *Qwen2.5-72B-Instruct* LLM handled other components. Their structured approach demonstrated superior performance in accurately interpreting and processing structured queries.

AILS-NTUA According to their own description in the google form, the AILS-NTUA team topped the ranks for the used code generation with exemplars for few-shot prompting, utilizing the proprietary *anthropic.claude-3-5-sonnet-20241022-v2:0* model. Their accuracy on DataBench was 89.85%, and on DataBench Lite, it was 88.89%.

ScottyPoseidon This team used the *unsloth/phi-4-unsloth-bnb-4bit* model with 8.48 billion parameters. They tackled the problem using code generation by providing the dataset schema and sample rows to the engine. Their approach leveraged multiple LLM models to build a system with Chain-of-Thought (CoT) reasoning, integrating an explainer, coder, and reviewer LLMs. This system collaboratively generated and refined code to produce an effective solution. They used the development set for validation.

6 Results

In this section, we present the main results of the competition for those that chose to submit a Google Form. Table 5 shows the results in the DataBench test set, while Table 6 shows the results in the reduced DataBench lite test set. Overall, the scores vary widely, which is expected given the large diversity of models and the completely different ap-

Table 8: Subtask B) Only open models under 9 billion parameters.

proaches.The biggest open source models ranked overall on par with the closed-source approaches, and small models came behind.

The best small open source approach, ScottyPoseidon, ranked 25th in the competition, and they become more common as we approach the bottom of the ranking. The best approach overall claims to use exclusively big open source models.

Baseline results. The result of executing the baseline we provided the participants with (see Section 4 for more details) over the test set data yielded 26.00 and 27.00 accuracy scores for DataBench and DataBench Lite respectively, making the difficulty of this task approximately the same as the proposed development set. The baseline used was intentionally very simple, mimicking the approach followed for the pilot task and getting similar results as the ones displayed in our original paper (Osés-Grijalba et al., 2024).

Results by answer type. We have also averaged all of the results of all submissions by type in Table 9. Performance across submissions seems to vary for each type, with lists of categories proving the hardest and boolean questions proving the easiest in both rankings.

In the following, we provide more details of participants' ranking in two additional categories we enabled in the task: (1) open models (including methods that rely on non-proprietary models and have at least their weights available) and (2) small models (with models consisting of lower than 9 billion parameters).

(1) Ranking of open models. Large open models in general rank pretty similarly to the proprietary ones as can be observed in Table 5 and Table 6.

Category	DataBench (Acc)	DataBench Lite (Acc)
boolean	63.90	61.94
category	52.85	52.13
list[category]	46.93	45.89
list[number]	50.56	48.96
number	56.42	54.41
Overall	55.43	53.82

Table 9: Average accuracy in both suites across all submissions by type in the test set

Open-only rankings are displayed in Table 10 and Table 11. The first 10 positions on both rankings contain 5 and 6 open models respectively, and in both the best performing team uses a purely open source approach. Large open source models have established themselves as a solid alternative to proprietary approaches for both subtasks.

(2) Ranking of small open models. Small open-weights models under 9 billion parameters lag behind both their open source and proprietary larger counterparts as we can see in Table 7 and Table 8. The best performance for these models, the **ScottyPoseidon** team, ranks 25th in the general ranking for subtask A) and in the 26th position for task B). Only three others achieve over 60% accuracy in any of the task. This further showcases the need for more research to be done for small models in the field of Tabular QA in order to achieve performances similar to large models.

7 Conclusions and Future Work

In this paper, we presented the SemEval task on Question Answering over Tabular Data. The test set consisted of tabular datasets from different domains and questions about different types. The results of the competition suggest that existing models can answer these types of questions reliably, as long

Table 11: Subtask B) DataBench open rankings including small models and baseline without rank.

as they are tailored and specialized in the task. In general, out of the box models cannot solve the task and struggle for the most part, and the results suggest there is a need for specialised and in-domain trained solutions beyond LLMs. Moreover, smaller LLMs (below 9B parameters) are far from the best performing models, and reinforce the challenging nature of the task for general-domain models.

In addition to this task, we are looking at expanding this benchmark to other language and domains, as well as other types of questions, including those ones that require different types of reasoning. This reasoning can be in the form of requiring information from different columns, or to perform operations beyond what is actually displayed in the table, for example.

Regarding the expansion of DataBench to languages different from English, we also released

DataBenchSPA for the Spanish language (Osés Grijalba et al., 2024), including an accompanying shared task[4]. This is an example of an expansion to a different language, but in general most languages do not have a suitable benchmark, and therefore there is plenty of room for future work in this area.

Limitations

The questions asked in this task are in general short and factual and do not require complex reasoning over the datasets, in large part because of the difficulty in developing a standard evaluation framework for longer more complex questions over tabular data that can be used in a competition. These questions are meant to provide a general baseline for models, but are by no means comprehensive of all types of questions that can be answered using tabular datasets.

Also, the sheer scope of different datasets used in a myriad of use cases would require us to keep growing our collection in order to provide a benchmark that is of relevance to most users. At the moment, the test set is rather small and would not be representative of all tabular data.

Abstract

In this challenge, we explored text-based food hazard prediction with long tail distributed classes. The task was divided into two subtasks: **(1)** predicting whether a web text implies one of ten food-hazard categories and identifying the associated food category, and **(2)** providing a more fine-grained classification by assigning a specific label to both the hazard and the product. Our findings highlight that large language model-generated synthetic data can be highly effective for oversampling long-tail distributions. Furthermore, we find that fine-tuned encoder-only, encoder-decoder, and decoder-only systems achieve comparable maximum performance across both subtasks. During this challenge, we gradually released (under CC BY-NC-SA 4.0) a novel set of 6,644 manually labeled food-incident reports.

1 Introduction

The Food Hazard Detection Challenge at SemEval 2025 evaluated classification systems for titles of food-incident reports collected from the world wide web. Algorithms like these could, for example, be used to help automated crawlers find and extract food issues from publicly available sources like social media. Since such systems could have a high economic impact (specific food items may need to be recalled, leading to financial damage for the producers), transparency is extremely important. Human experts using data from these crawlers need to be well-informed about how the respective food issues are extracted.

Prior work has shown that a major challenge in food-hazard and food-product classification from text is the large number of possible classes, combined with a long-tail distribution (Randl et al., 2024b). To address this, we define two subtasks:

- **Subtask 1 (ST1)** focuses on training models for coarse-grained "category" prediction.

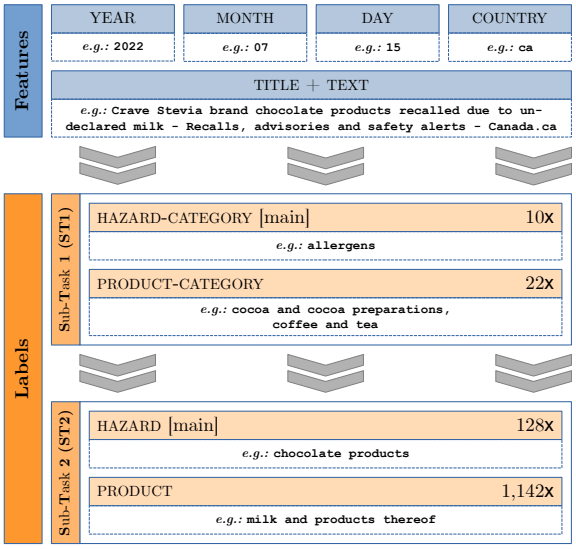

Figure 1: The columns in the blue boxes were available to the participants to serve as model input, while the orange boxes comprised the ground truth labels per subtask. The number on the right of each label indicated the number of unique values per label.

- **Subtask 2 (ST2)** is a more fine-grained "vector" prediction task.

A prior SemEval challenge by Kirk et al. (2023) framed a similar setup as an initial step toward explainability. While this interpretation may be somewhat broad, we recognize that a "vector" prediction task is particularly valuable for automated information extraction, as it provides more specific information.

An overview of the SemEval-Task is shown in Figure 1. It includes **two sub-tasks**: **(ST1)** text classification for food hazard prediction, predicting the type of hazard (HAZARD-CATEGORY) and the type of product (PRODUCT-CATEGORY); **(ST2)** food hazard and product "vector" detection, predicting the exact hazard (HAZARD) and product (PRODUCT). The task was primarily concerned with detecting the hazard (more important than the product), hence a two-step scoring metric based

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2523–2534

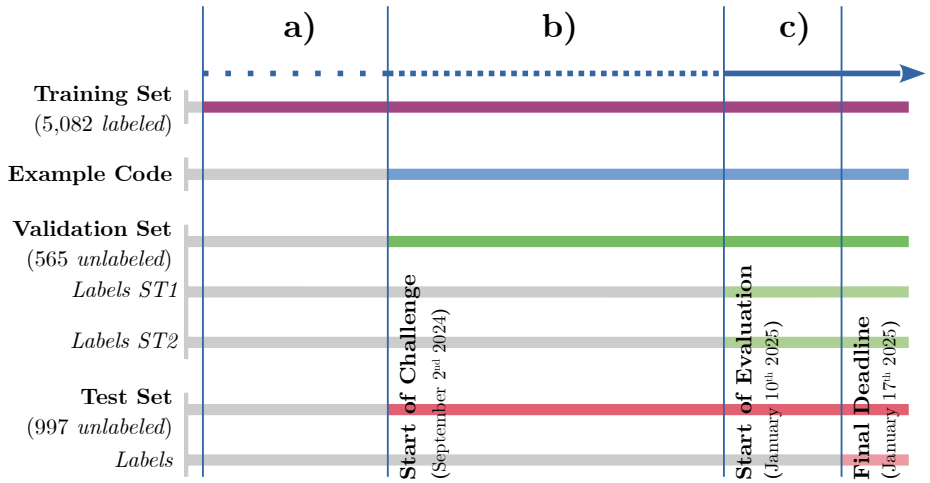

Figure 2: Timeline of the challenge: **(a) Trial Phase**: Training data was provided before the challenge commenced. **(b) Conception Phase**: Example code, along with unlabeled validation and test data, was released at the beginning of the challenge. During this phase, participants could submit separate trial entries for ST1 (category classification) and ST2 ("vector" classification) using the validation data. **(c) Evaluation Phase**: The validation data was made available, and final submissions for both tasks were accepted on the test data to determine the final ranking.

on the macro F_1 score was used, focusing on the respective hazard label per sub-task (see Section 4).

2 Task Organization

The detailed timeline of the project is illustrated in Figure 2. Participants were provided with training and validation data to develop, train, and evaluate their systems before the evaluation phase. The challenge was conducted on Codalab[1] (Pavao et al., 2023), adhering to the framework of previous competitions (Kirk et al., 2023).

The validation data was made available at the start of the challenge, enabling participants to submit to the leaderboards and compare their systems during the conception phase. However, these rankings did not influence the final results. The test set was released at the beginning of the challenge with labels concealed until its conclusion. During the evaluation phase, models could be trained on both the training and validation data but were evaluated exclusively on the test set to get the final ranking. After the evaluation phase, participants were required to submit a brief system description specifying the dataset features used, with this information made public alongside the final ranking.

Participants could submit up to five times per day and 100 times in total during the conception phase, whereas in the evaluation phase, each participant was limited to a single valid submission.

Table 1: Sample of texts along with their labels.

Additionally, participants were required to share their code (e.g., via GitHub) along with their system description papers.

3 Dataset

The dataset we used in the challenge is a subset of the data described in Randl et al. (2024b) and publicly accessible on zenodo (Randl et al., 2024a). It consists of 6,644 TITLEs (length in characters: *min=5, avg=88, max=277*), and full TEXTs (length in characters: *min=56, avg=2329, max=48318*) of

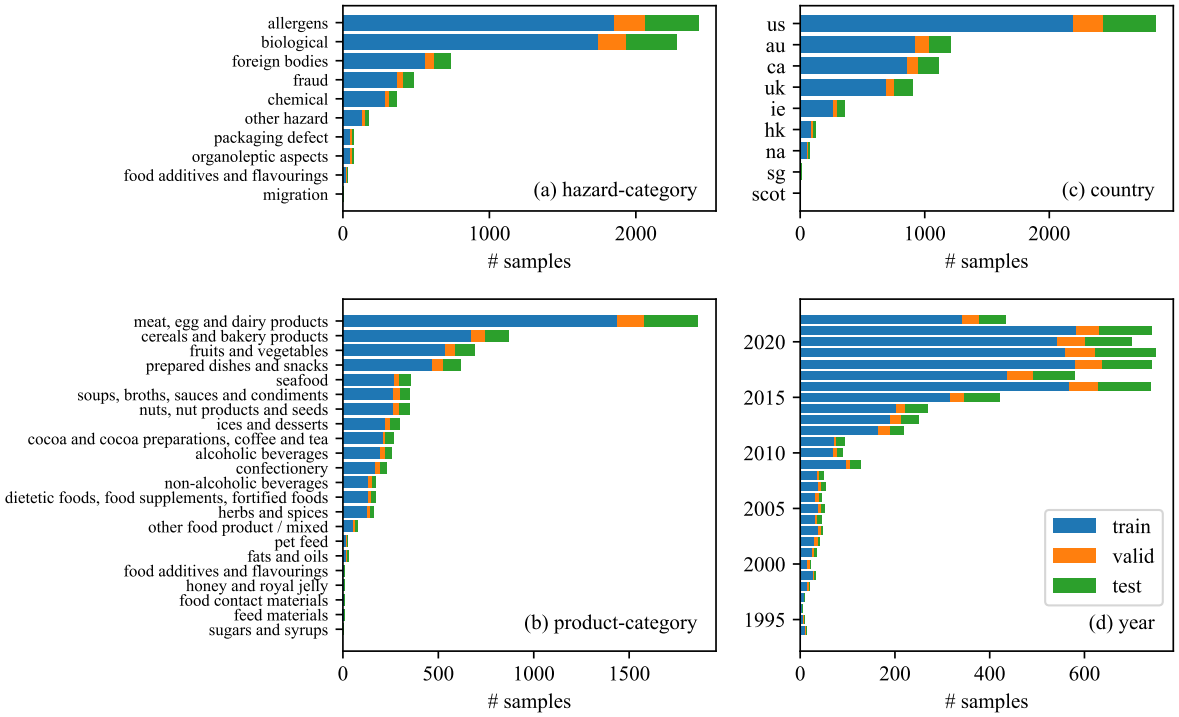

Figure 3: Overview over the data used in the challenge

English food recall announcements from the official websites of food agencies (e.g. the FDA's website). In addition, the dataset contains meta information such as date of download and country of issue. These texts were primarily gathered between 2012 and 2022 from domains based in the United States, Australia, Canada, and the United Kingdom (see Figure 3 (c) and (d)). The data was manually labeled with the reason for recall (HAZARD) and the recalled PRODUCT. Although neither TITLE nor TEXT individually is guaranteed to contain information about the product and hazard involved in a recall, their combination reliably provides the necessary details for classification. The distribution of this information between TITLE and TEXT varies across the dataset and largely depends on the issuing authority. Each pair of TITLE and TEXT has been assessed by two experts on food science or food technology from Agroknow[2]. Some sample TITLEs are shown in Table 1.

The data was stratified based on the more important hazard "vectors" (HAZARD) and divided into three subsets: 5,082 samples for training, 565 for validation, and 997 for evaluation. The training data, which was already published on zenodo (Randl et al., 2024a), also contains additional non-English texts that could be used by participants to train their classifiers. Nevertheless, our evaluation was only based on English texts. As the texts contain varying degrees of information on the HAZARD, we considered careful pre-processing of the data as part of the challenge. Upon completion of the task, the complete dataset was made available under the Creative Commons BY-NC-SA 4.0 license.

One sample of the dataset is shown in Figure 1. As described above, the data includes the features YEAR, MONTH, DAY, COUNTRY, TEXT and TITLE. Participants performed their text analysis primarily on the TITLE or TEXT fields, while additional features were available if needed. The task was to predict the labels PRODUCT-CATEGORY and HAZARD-CATEGORY, as well as the vectors PRODUCT and HAZARD. The dataset comprises 1,256 different PRODUCT values (e.g., "*ice cream*," "*chicken based products*," "*cakes*") sorted into 22 categories (e.g. "*meat, egg and dairy products*," "*cereals and bakery products*," "*fruits and vegetables*") with the help of ontologies. In addition, there are 261 distinct values for HAZARD (e.g., "*salmonella*," "*listeria monocytogenes*," "*milk and products thereof*") , which are grouped (again using ontologies) into the following 10 values of the la-

[2] https://agroknow.com

bel HAZARD-CATEGORY: "*allergens*," "*biological*," "*foreign bodies*," "*fraud*," "*chemical*," "*other hazard*," "*packaging defect*," "*organoleptic aspects*," "*food additives and flavourings*," "*migration*." The class distribution in the data is heavily imbalanced with the above examples being ranked from the most to the least common in Figure 3.

3.1 Baselines

In our challenge, we provided participants with three jupyter-notebooks for training and evaluating baseline models for both subtasks[3]:

(i) We provide a traditional pipeline consisting of a TF-IDF embedding in combination with a logistic regression classifier based on the `scikit-learn` Python module (Pedregosa et al., 2011).

(ii) A second baseline implementation fine-tunes an encoder-only transformer, specifically `bert-base-uncased` (Devlin et al., 2019), using the `transformers` Python module (Wolf et al., 2020) by huggingface.co.

(iii) Finally we provide a more sophisticated baseline based on the CICLe method (Randl et al., 2024b). It relies on prompting larger transformers such as GPT-4 without further fine-tuning (Brown et al., 2020) in combination with conformal prediction (Vovk et al., 2005). In our baseline we use the `crepes` Python module to implement conformal prediction (Boström, 2022).

Baseline performance of different classifiers on the whole dataset used in this challenge was also reported by Randl et al. (2024b). The results showed that the classification of hazards and products was a non-trivial task, and the classification of the "vector"-label, which we aimed to address in this challenge, was particularly challenging.

4 Evaluation

We computed the performance for ST1 and ST2 by calculating the macro F_1-score on the participants' predicted labels $\hat{\mathbf{y}}$ using the annotated labels $\mathbf{y}$ as ground truth. This measure is the unweighted mean of per-class-F_1-scores over the n classes. Both $\hat{\mathbf{y}}$ and $\mathbf{y}$ are vectors of m samples:

$$\text{F}_1(\mathbf{y}, \hat{\mathbf{y}}) = \frac{2}{n} \sum_{i=0}^{n} \frac{\text{RCL}_i(\mathbf{y}, \hat{\mathbf{y}}) \cdot \text{PRC}_i(\mathbf{y}, \hat{\mathbf{y}})}{\text{RCL}_i(\mathbf{y}, \hat{\mathbf{y}}) + \text{PRC}_i(\mathbf{y}, \hat{\mathbf{y}})} \quad (1)$$

where RCL_c is the recall and PRC_c is the precision for a specific class c. In order to combine the predictions for the HAZARD and PRODUCT labels into one score, we took the average of the scores:

$$\text{S}(Y, \hat{Y}) = \frac{\text{F}_1(\mathbf{y}^h, \hat{\mathbf{y}}^h) + \text{F}_1(\mathbf{y}^{p|h}, \hat{\mathbf{y}}^{p|h})}{2} \quad (2)$$

Here $Y = [\mathbf{y}^h, \mathbf{y}^p]$ is the $2 \times m$ matrix with the HAZARD label $\mathbf{y}_h$ and the PRODUCT label $\mathbf{y}_p$ as column vectors. The vector $\mathbf{y}^{p|h}$ is defined as the entries of $\mathbf{y}^p$ where $\mathbf{y}^h$ is correctly predicted:

$$\mathbf{y}^{p|h} = \{\mathbf{y}^p_j \mid \hat{\mathbf{y}}^h_j = \mathbf{y}^h_j\},\ j \in \{1, 2, ..., m\} \quad (3)$$

The scalar $\mathbf{y}^*_j$ is the j-th element of $\mathbf{y}^*$. $\hat{Y}$ and $\hat{\mathbf{y}}^{p|h}$ are defined accordingly. With this measure we based our rankings predominantly on the predictions for the HAZARD classes. Intuitively, this means that a submission with both $\mathbf{y}^h$ and $\mathbf{y}^p$ completely right would have scored 1.0, a submission with $\mathbf{y}^h$ completely right and $\mathbf{y}^p$ completely wrong would have scored 0.5, and any submission with $\mathbf{y}^h$ completely wrong would have scored 0.0 independently of the value of $\mathbf{y}^p$.

5 Participant Systems and Results

In total, our task attracted approximately 260 participants and received 99 valid submissions during the evaluation phase. Among these, 27 system description papers were submitted for peer-review. These 27 systems form the basis of our analysis and the official ranking, as they are accompanied by detailed system descriptions, enabling a thorough evaluation. The full, unofficial ranking – including all submissions to codalab – is available on the task's website.[4]

5.1 Popular Methods

Figure 4 illustrates the frequency distribution of system attributes. Each subplot corresponds to a distinct attribute, highlighting key trends among the systems. We observe that the majority (16 systems) of stystems uses both TITLE and TEXT features, while three systems incorporated all available dataset features. Furthermore, the majority (21 systems) treated the tasks separately, with only five systems leveraging a combined approach to exploit the correlation between the tasks. In terms of model choice, most systems (19) relied on encoder-only transformer models, while two used traditional machine learning models. Among the systems that

[3] https://food-hazard-detection-semeval-2025.github.io/code/

[4] https://food-hazard-detection-semeval-2025.github.io/

used transformer-based models, open-source models (24 systems) were preferred. Furthermore, the majority (14 models) opted for a single model for classification rather than an ensemble strategy (11 systems). Finally, regarding the data sources, 12 systems incorporated synthetic data, for example oversampling with LLM-generated texts, to address the tasks.

5.2 Leaderboard Results

ST1 Table 2 presents the results and the ranking of the systems that submitted system a description paper in ST1. The scores lie between 0.1426 and 0.8223, with the largest gap in performance observed between the first and second-ranked systems among the top three. Systems ranked between fifth and 16th exhibit relatively similar scores, while a distinct widening of the gap is evident in the lower ranks. Furthermore, the top two systems used richer feature sets compared to the lower-ranked systems, indicating that the richer feature sets may have contributed to their scores, while most systems relied on both textual features, i.e., TITLE and TEXT, rather than focusing on one of them.

RANK	TEAM NAME	SCORE	FEATURES
Baselines:	TFIDF + LR	0.498	TITLE

Table 2: ST1 ranking for systems of teams that submitted a system description paper. Gray entries are outperformed by the best baseline.

ST2 Table 3 presents the results and the rankings of the systems for ST2 that submitted a system description paper. The results show significantly lower performance compared to ST1, with the highest score of SRCB (0.5473) being considerably lower than the top score in ST1 (0.8223), which indicates that ST2 is a more challenging task. A sharp drop in scores is observed after the top three teams and again after the 12th team (BitsAndBites), with the lowest-ranked system (Anaselka) receiving 0.0049 score. Notably, the top three teams in both subtasks – except for the Anastasia team, which focused only on ST1 – performed well in both, consistently ranking among the top teams in each subtask. Among the top 15 systems, while a few systems, such as Anastasia and BitsAndBites, performed better on ST1, a larger number of systems, including MINDS, Fossils, PuerAI, and BrightCookies, achieved significantly higher rankings in ST2.

Table 3: ST2 ranking for systems of teams that submitted a system description paper. Gray entries are outperformed by the best baseline.

5.3 Best Systems

In this section, we outline the key methods employed by the top three systems for each subtask.

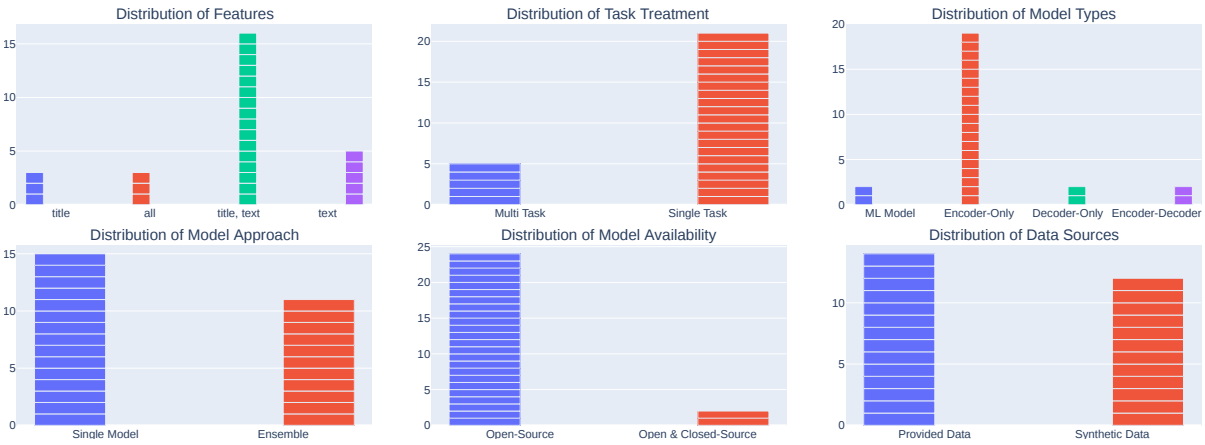

Figure 4: Frequency distribution of system attributes. Each subplot represents a distinct attribute, illustrating the choices made by the participating systems in terms of features, task treatment, model types, ensemble strategies, model availability, and data usage.

Since the teams "MyMy" and "SCRB" rank among the top three in both evaluations (see Tables 2 and 3), we analyze a total of four systems.

SRCB (**ST1:** 3^{rd}, **ST2:** 1^{st}) The first place in ST2 comes from Ricoh Software Research Center. Zhang et al. (2025) concatenated the TITLE and the TEXT in lower case, and followed a two-step approach. In the first step, they used BERT to reduce the label space and include only the most probable ones. In a second step, then, all the possible labels (possibly along with examples) were fed to a large language model (LLM) to predict the correct one. This approach follows the paradigm of Randl et al. (2024b), who suggested reducing the possible labels by quantifying the uncertainty with conformal prediction (Vovk et al., 2005). Infrequent categories were furthermore augmented with an LLM, while approx. 10% of the data was truncated.

Anastasia (**ST1:** 1^{st}, **ST2:** 21^{th}) The best system in ST1 is by Le et al. (2025) from VNUHCM – University of Information Technology and focuses on ST1, while neglecting ST2. After a simple text normalization step, they chunk the texts into snippets of consecutive sentences that fit the context windows of their applied models. Following this, they fine-tune two encoder-only transformers, specifically `DeBERTa-v3-large` and `RoBERTa-large`, using focal loss (Lin et al., 2017) with class weights. For training, they compare two setups: **(i)** They try **multi-task** fine-tuning of `DeBERTa-v3-large` to get a combined model for both HAZARD and PRODUCT prediction using oversampling for underrepresented classes and undersampling for overrepresented classes. **(ii)** Additionally, they try **single-task** fine-tuning of both `DeBERTa-v3-large` and `RoBERTa-large`, this time addressing the class-imbalance by creating synthetic samples by prompting `gemini-2.0-flash-exp` to paraphrase texts in underrepresented classes. They report that multi-task training leads to slightly worse performance on ST1 compared to single-task. This may be owed to the different resampling approaches, though. Finally, they combine all of their trained models (single- and multi-task) in one ensemble, using soft voting with a weighted sum. The weights were based on grid search on the validation set.

MyMy (**ST1:** 2^{nd}, **ST2:** 2^{nd}) Phan and Chiang (2025) from the Department of Computer Science and Information Engineering, National Cheng Kung University employ a retrieval-augmented generation (RAG) approach to address both subtasks separately by intergrating domain-specific external knowledge. It first retrieves relevant documents for each data sample from PubMed,[5] following the RAG paradigm: it uses GPT- 3.5 Turbo3,[6] Gemini Flash 2.0 (Team et al., 2023), Llama 3.1 8B (Touvron et al., 2023), and Mistral 8x7B (Jiang et al., 2023) LLMs to simplify the original data sample; it then retrieves documents from the PubMed API, encodes them into embeddings using `nomic-embed-text-v1` (Nussbaum et al., 2024) and stores them in a Chroma embedding database; cosine similarity scores are then computed to retrieve the top-K most relevant documents. These

[6] https://platform.openai.com/docs/models/gpt-3-5-turbo

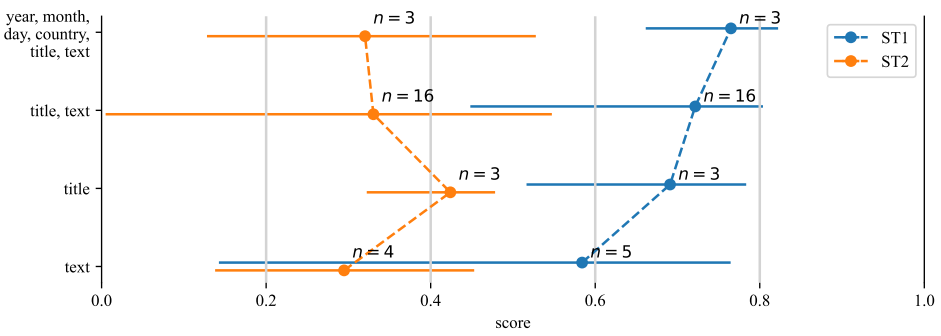

Figure 5: Average score achieved and number of submissions per combination of input features used (– ST1, – ST2). The horizontal bars show minimum and maximum score and the number of samples is annotated as n.

documents are then combined with the original input and paraphrased using the same LLMs to generate augmented data. A validation step incorporating the same LLMs is used to filter the generated samples based on relevance, ensuring data quality. The enriched dataset is then used to fine-tune classification models (Gemini Flash 2.0 (Team et al., 2023), PubMedBERT (Gu et al., 2021), and ModernBERT (Warner et al., 2024)). Finally, predictions are obtained through a weighted soft voting strategy, where class probabilities from multiple models are combined using weighted sums to determine the final label.

PATeam (**ST1:** 4^{th}, **ST2:** 3^{rd}) Wan et al. (2025) begin with data cleaning using regular expressions, followed by text augmentation, where LLM-generated summaries are concatenated with the TEXT feature. To address data imbalance, SMOTE (Chawla et al., 2002) is applied to underrepresented categories (fewer than five samples, a threshold determined through tuning) to ensure a minimum of five samples per class. The system employs a bagging approach with bootstrapping to generate five subsets of the training data, fine-tuning five `microsoft/phi-4 models`[7] using low-rank adaptation (LoRA) (Hu et al., 2021) to reduce trainable parameters. Predictions from all five models are integrated via an ensemble voting mechanism. The system employs the multi-dimensional type-slot label interaction network (MTLN) (Wan et al., 2023) to capture the correlation between the two subtasks. It first classifies ST1 and then utilizes these predictions to inform the classification of ST2. An ablation study confirmed that this multi-task approach outperforms treating the tasks independently.

[7] https://huggingface.co/microsoft/phi-4

5.4 What Worked Well

A prevalent strategy among these systems is the use of generative LLMs for synthetic data creation to mitigate class imbalance. Specifically, three approaches stand out: (i) **paraphrasing** (Le et al., 2025), (ii) **summarizing** and appending generated text to the original (Wan et al., 2025), and (iii) **generating** new samples by combining information from two instances of the same class (Zhang et al., 2025). Additionally, Le et al. (2025) and Phan and Chiang (2025) incorporate class-weighted loss functions to increase the impact of underrepresented classes during training.

Another common technique among top-ranking systems is the use of ensemble methods. Le et al. (2025) employ a soft voting approach, optimizing weights of different models during grid search on a validation set, while Phan and Chiang (2025) adopt a max voting strategy, selecting the prediction from the most confident model. Wan et al. (2025) fine-tune five classifiers using bootstrapped subsets of their preprocessed training data.

In contrast to these shared strategies, there is no clear consensus on the use of multi-task learning (joint modeling of both subtasks) versus single-task learning (treating subtasks separately). Three out of four systems opt for a single-task approach, but Wan et al. (2025) experiment with both strategies in a prompting-based classification setup. Their results suggest that multi-turn prompts, where both subtasks are addressed within a single interaction, outperform single-turn prompts, which handle the subtasks separately.

As discussed in Section 5.2, richer feature sets tend to support stronger models across both subtasks. This observation is further illustrated in Figure 5, where systems leveraging multiple input fea-

tures consistently outperform those using only a single feature (according to maximum achieved score). Notably, models utilizing only TITLEs tend to achieve better results than those using only TEXTs. A plausible explanation is that TITLEs often contain more concise and targeted information compared to the broader and potentially noisier content in TEXTs. Interestingly, the three approaches that utilize all available features achieve better results in ST1, but underperform slightly in ST2, suggesting that their design was primarily optimized for the former.

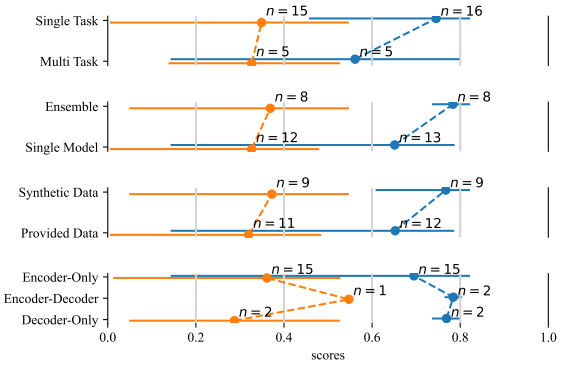

Figure 6: Average score achieved and number of submissions per combination per design choice (– ST1, – ST2). The horizontal bars show minimum and maximum.

Figure 6 presents a detailed comparison of design choices based on evaluation scores. Interestingly, treating the subtasks separately leads to better performance than multi-task approaches that use a shared model for ST1 and ST2. Additionally, leveraging an ensemble of multiple models proves more effective than relying on independent models.

As discussed in Section 3, one major challenge participants faced was the extreme class imbalance in the dataset. It is therefore unsurprising that oversampling underrepresented classes with artificially generated data significantly improved performance compared to using only the provided training set. As noted in Section 5.3, this artificial data was typically generated by prompting LLMs. Finally, an interesting finding is that no transformer architecture – whether encoder-only (e.g. BERT), encoder-decoder (e.g. BART), or decoder-only (e.g. Llama) – consistently outperforms the others. Across all three architectures, the highest achieved scores remain approximately equal within each subtask.

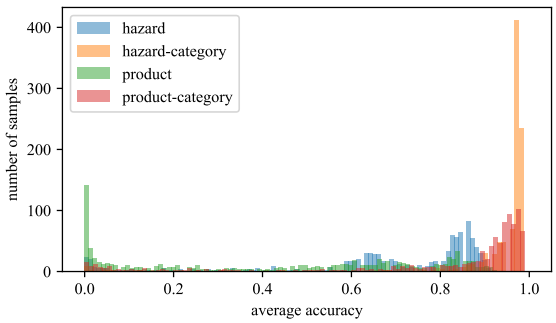

Figure 7: Histogram of the frequency (vertically) across the fraction of systems correctly predicting a specific sample (horizontally).

6 Discussion

6.1 Task Difficulty Estimation

We show an instance-based difficulty analysis in Figure 7. The figure shows that across categories/vectors most samples are more likely to be predicted correctly than not. Nevertheless, we also see a spike at zero accuracy, which is most prevalent for the vector PRODUCT, but seen for all categories/vectors. This indicates that several samples were never correctly classified, indicating that they are extremely difficult or even missing information. To make it easier to identify such instances in our data, we include an instance difficulty score, ranging linearly from 0 (*instance was classified correctly by all submissions*) to 1 (*instance was never correctly classified*), for all instances in the train and test set in our dataset on zenodo.

6.2 Error Analysis

Figure 8 shows the pairwise error rate between the submissions per category. The error is considerably higher in ST2 for the two plots on the right compared to the two of ST1. This is partly due to the fewer number of possible labels in the latter and the higher likelihood of mistakes on the former.

A more detailed analysis is shown in the confusion matrices in Appendix A. For HAZARD-CATEGORY, we see that precision and recall are relatively high except for the classes "*migration*" and "*food additives and flavourings*" (see Figure 9). While samples of the class "*migration*" are predicted to the very similar class "*chemical*" in 90% of the cases, predictions for "*food additives and flavourings*" are divided between the true class (49%), "*other hazard*" (28%), "*fraud*" (13%), and "*allergens*" (13%).

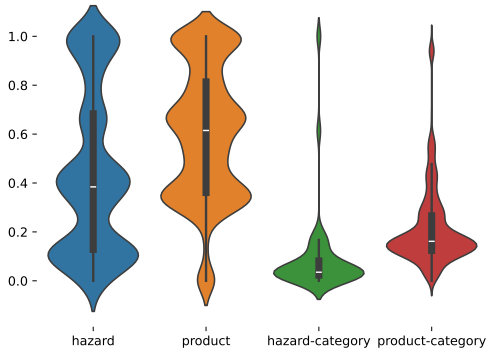

Figure 8: Pairwise error rate (vertically) of submissions (horizontally)

We see a similar picture for PRODUCT-CATEGORY in Figure 10. Most classes show good performance, while "*food additives and flavourings*," "*honey and royal jelly*," and "*other food product / mixed*" show high misclassification rates. "*Food additives and flavourings*" is most commonly confused with "*meat, egg and dairy products*" (22%) and "*cereals and bakery products*" (18%). "*Honey and royal jelly*" is confused with the most supported class "*meat, egg and dairy products*" in 40% of the cases. As an overarching class for leftover samples, "*other food product / mixed*" is misclassified to multiple other classes, most prominently "*soups, broths, sauces and condiments*" (18%), and "*fruits and vegetables*" (18%). All of these commonly mislabeled classes are highly underrepresented in the dataset and/or easy to confuse with other, higher-supported classes in the data.

7 Conclusion

In conclusion, our task demonstrates that LLM-generated synthetic data can be highly effective for oversampling in long-tail distributions. A second, albeit expected, finding is that ensemble strategies significantly enhance classification performance. Additionally, while combined approaches for vector and category classification can be beneficial in prompting scenarios, they do not generally lead to performance improvements. More notably, we do not observe a clear winner among transformer architectures: fine-tuned encoder-only, encoder-decoder, and decoder-only models achieve comparable maximum performance across both subtasks.

Future research on our dataset should prioritize the more challenging vector classification task. Our analysis indicates that classification errors often stem from low class support and that food recall texts contain ambiguous instances, with semantically similar classes contributing to misclassification. We argue that debugging classifiers using explainability techniques may help improve performance.

Despite its potential to assist human validation and enable meta-learning approaches, such as clustering or pre-sorting examples, explainability in text-based food risk classification remains underexplored. However, explanations can vary significantly depending on the model and task. Existing literature addresses both model-specific (Assael et al., 2022; Pavlopoulos et al., 2022) and model-agnostic (Ribeiro et al., 2016) explainability approaches, which should be further investigated in this domain.

Limitations

(i) A limitation of our evaluation process is that, while we enforced a one-submission-per-user policy during the evaluation phase, some participants have circumvented this by registering multiple accounts. We chose not to remove suspicious accounts, as identifying all of them would have been impractical and likely only encouraged more covert attempts to bypass the restriction.
(ii) We chose to release the unlabeled test set at the beginning of the challenge, as this was easier to set up with codalab. While this ensured transparency throughout the challenge, participants strongly determined to win could peak (e.g., manually annotating the test data).
(iii) We found 42 duplicate entries in our dataset after the start of the challenge. These were introduced due to an error in one of our preprocessing scripts and resulted in six entries that are present in both the training and validation set as well as seven entries that are present in both the training and test set. As this concerns less than 1% of the data, we argue that it is not severely impacting our results.

Ethical Statement

All texts are collected from official and publicly available sources, hence no privacy-related issues are present. All annotations have been provided by Agroknow experts. System application is intended to complement and not substitute the human expert in preventing illness or harm from food sources.

Acknowledgments

We thank Giannis Stoitsis and Agroknow for collecting and providing the data for this task.

Abstract

Translating text that contains complex or challenging named entities—e.g., culture-specific book and movie titles, location names, proper nouns, food names, etc.—remains a difficult task for modern machine translation systems, including the latest large language models. To systematically study and advance progress in this area, we organized the first edition of **Entity-Aware Machine Translation**, or *EA-MT*, a shared task that evaluates how well systems handle entity translation across 10 language pairs. With EA-MT, we introduce XC-Translate, a novel gold benchmark comprising over 50K *manually*-translated sentences with entity names that can deviate significantly from word-to-word translations in their target languages. This paper describes the creation process of XC-Translate, provides an overview of the approaches explored by our participants, presents the main evaluation findings, and points toward open research directions, such as contextual retrieval methods for low-resource entities and more robust evaluation metrics for entity correctness. We hope that our shared task will inspire further research in entity-aware machine translation and foster the development of more culturally-accurate translation systems.

1 Introduction

Background. The emergence of multilingual large language models (LLMs) and the wide availability of massive multilingual datasets have significantly advanced the field of Machine Translation (MT) (Fan et al., 2021; Tang et al., 2021; Costa-jussà et al., 2022; Kudugunta et al., 2023, inter alia). These developments have led to MT systems that not only perform exceptionally well in high-resource languages but also support a growing number of low-resource languages (Fan et al., 2021; Tang et al., 2021; Costa-jussà et al., 2022; Kudugunta et al., 2023, inter alia). Nevertheless, the research community still faces several unresolved challenges in MT. Among these, the translation of text that contains entities is still a hard task, especially with particular categories of entities, e.g., movies, books, food, locations, and sometimes even people, to name a few. Indeed, *word-for-word*, or *literal*, translations of their names may not be suitable due to culture-specific references, which can vary depending on social, geographical, and historical contexts, among other factors (Hershcovich et al., 2022).

Motivation. In this context, the challenge lies in accurately identifying when and how to translate entities whose names are significantly different across languages, not because of differences in the script (e.g., English and Chinese) but because of differences in the cultural context. This step is crucial, as relying on literal translations may not convey the intended meaning, risking the effectiveness of the entire translation process (Gaballo, 2012; Díaz-Millón and Olvera-Lobo, 2023; Conia et al., 2024). For example, if we were to translate word-for-word "Qual è la trama de *Il Giovane Holden*?" from Italian to English, we could obtain "What is the plot of *The Young Holden*?", which is grammatically correct but semantically incorrect. The correct translation "What is the plot of *The Catcher in the Rye*?"

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2535–2557

necessitates not only fluency in both the source and target languages but also knowledge of the cultural contexts involved. Current systems often struggle with this task; however, the research community lacks i) a comprehensive benchmark specifically designed to evaluate the performance of MT systems in translating text containing entities, and ii) evaluation metrics that can accurately measure the quality of the translations produced by these systems, as current metrics (e.g., BLEU and COMET) are not designed to capture the quality of entity translations.

Summary of the task. To address this challenge, we organized the first edition of **Entity-Aware Machine Translation (EA-MT)**, a new shared task whose goal is to track the progress and encourage the development of MT systems that can better handle the translation of text containing entities with names that are significantly different across languages. Given a sentence s in English containing an entity e, the task is to translate s into a target language while adapting the name of e to the target language to preserve the original meaning of the sentence. The first edition of EA-MT focuses on:

- text containing entities from various categories, such as movies, books, food, locations, and people, among others;
- entities whose names are significantly different across languages, e.g., *Il Giovane Holden* and *The Catcher in the Rye*;
- translating simple sentences, as the challenge shall lie in the translation of the entity names rather than in the complexity of the sentence structure.

In this task, we provide participants with a dataset containing English sentences with entities and their translations into 10 other languages: *Arabic*, *Chinese*, *French*, *German*, *Italian*, *Japanese*, *Korean*, *Spanish*, *Thai*, and *Turkish*.

Contributions. The first edition of EA-MT attracted around 50 teams, who submitted around 300 runs. Among these, 25 teams submitted their final results for the official leaderboard and 18 of them illustrated their approaches and results in system description papers. In summary, the main contributions of the first edition of EA-MT are:

- **XC-Translate**, a novel benchmark for evaluating the performance of MT systems in translating text containing entities with names that are significantly different across languages;
- **M-ETA**, a new evaluation metric that can accurately measure the quality of the translations produced by MT systems, focusing on the translation of entity names;
- an analysis of the approaches introduced by the participants and their results, highlighting the strengths and weaknesses of current MT systems in handling entity translation.

We release the benchmark and the evaluation metric to the research community, with the hope that they will encourage further research in this area.

2 Entity-Aware Machine Translation

Task definition. We introduce Entity-Aware Machine Translation (EA-MT), a new shared task that evaluates how well systems handle entity translation across 10 language pairs. More formally, EA-MT is defined as follows: given a source sentence s_e in English that contains an entity mention e, the goal is to produce a translation t in a target language l_{target} that correctly adapts the entity to its culturally-appropriate equivalent e' in that language. For each sentence s_e in English, we have:

$$f(s_e, l_{\text{target}}) \rightarrow t \quad (1)$$

where f represents the translation function, l_{target} is one of the 10 target languages in our benchmark, and t contains the culturally-appropriate equivalent e' of the entity e.

Key challenges. The main challenge of EA-MT lies in the fact that we selected a set of entities whose names are significantly different across languages, e.g., *The Catcher in the Rye* (English), *Il Giovane Holden* (Italian), *El guardián entre el centeno* (Spanish), and *L'attrape-cœurs* (French).[1] To address this challenge, an MT system must ensure that the entity name is adapted to its culturally-appropriate equivalent in the target language, which may require a transcreation step instead of a literal translation. To stress the importance of translating the entity names correctly, we also introduce M-ETA, a new evaluation metric that focuses on the quality of the translations of entity names, as described in Section 4. With M-ETA, systems that

[1] We provide more details about how we selected "challenging" entities in Section 4.

produce fluent translations but fail to adapt the entity names correctly are strongly penalized, revealing the limitations of current MT systems—and evaluation metrics—in handling entity translation.

Differences with previous MT tasks. EA-MT differs from previous MT tasks in that it focuses on the translation of text containing entities with names that are significantly different across languages, which is a challenge that has not been systematically studied before with a dedicated shared task, across multiple languages and at a significant scale. Previous benchmarks and shared tasks on MT have focused on other aspects, such as low-resource languages (Pal et al., 2023; Sánchez-Martínez et al., 2024), multimodal translation (Specia et al., 2016; Barrault et al., 2018), code-switched data (Chen et al., 2022), and general translation.

3 XC-Translate: A Novel Gold Benchmark for Entity-Aware MT

In this section, we introduce XC-Translate, a novel gold benchmark for evaluating the performance of MT systems in translating text containing entities with names that are significantly different across a set of 10 diverse languages. Creating XC-Translate represents a core contribution of this SemEval task, as it was specifically designed to address the challenges of entity-aware machine translation. While we encourage readers interested in the full technical details to refer to our dedicated publication (Conia et al., 2024), we provide an overview of the benchmark creation process in this section. To create XC-Translate we employ a four-step process:

1. **Entity selection:** We first select the entities of interest for the task. These entities were chosen to be significantly different across languages, e.g., *Il Giovane Holden* and *The Catcher in the Rye*.

2. **Sentence generation:** We generate sentences containing the selected entities. These sentences are simple, as the challenge should lie in the translation of the entities rather than in the complexity of the sentence.

3. **Multi-reference translation:** Each sentence is translated into 10 target languages by at least three native translators.

4. **Translation validation:** Each translation is reviewed by one native speaker of the target language, who checks both the overall quality of the translations and the translations of the entity names.

Language Pair	Sample	Dev	Test	Total
EN → Arabic	70	722	4,546	5,338
EN → Chinese	73	722	5,181	5,976
EN → French	75	724	5,464	6,263
EN → German	70	731	5,875	6,676
EN → Italian	73	730	5,097	5,900
EN → Japanese	73	723	5,107	5,903
EN → Korean	73	745	5,081	5,899
EN → Spanish	72	739	5,337	6,148
EN → Thai	73	710	3,446	4,229
EN → Turkish	75	732	4,472	5,279
EN → XX	727	7,278	49,606	57,611

Table 1: Statistics of the EA-MT benchmark provided to participants, divided by language and split. The values indicate the number of instances in each split. The last row shows the total number of instances in the benchmark, where XX indicates all the languages combined.

In the following, we describe each step in detail, and provide an overview of the resulting benchmark. We also provide a summary of the statistics of the benchmark in Table 1.

3.1 Selecting "Challenging" Entities

Since the focus of EA-MT is on the translation of text containing entities, we do not randomly select sentences to translate; previous MT tasks that have relied on random sentence selection have been shown not to i) include enough entities to evaluate the translation of entities, and ii) contain entities whose names are significantly different across languages (Zeng et al., 2023). Instead, we will first select the entities of interest for the task, and then generate sentences containing these entities. Although Wikidata (Vrandečić and Krötzsch, 2014) has been shown to be incomplete in terms of entity name coverage (Conia et al., 2023), we use it as a starting point to select entities for EA-MT, and then manually verify the selected entities.

Criteria for entity selection. To avoid entities whose names are similar across languages, we select a random sample of entities that satisfy the following criteria: an entity is valid if and only if its English name and its word-for-word translations have less than a 50% character overlap with the corresponding names in French, German, Italian, and Spanish. Our assumption is that, if the entity has a name in these five languages, then it is a rel-

atively well-known entity, i.e., not belonging to a niche domain or to the tail of the popularity distribution. Moreover, if it satisfies these criteria across these five languages, which mostly share the script (unlike, for example, English and Chinese), then there is a high chance that the translation of such entity requires more than a word-for-word translation. We refer to this set of entities as *challenging* entities, i.e., entities whose names are significantly different across languages and are likely to require a transcreation step instead of a literal translation.

3.2 From Entities to Sentences

Having selected the entities, we generate sentences containing these entities using an LLM, namely, GPT-4. More specifically, given an entity name and its Wikidata description that provides some context about the entity, we prompt the model to generate a simple question pertaining to the entity in English.

Generating a simple question rather than a statement allows us to i) keep the sentence structure simple and short (less than 25 words), ii) ensure that the entity is the most important part of the sentence to translate, iii) provide just enough context to disambiguate the entity, and – most importantly – iv) avoid issues related to the factuality of the generated text. Keeping the sentence structure simple and short is important in our case, as the most challenging part of the task should be the translation of the entity names rather than the complexity of the sentence structure. Moreover, generating a question like "Is *The Catcher in the Rye* a book?" is less likely to generate factuality-related issues than a statement like "*The Catcher in the Rye* is a book", which may be factually incorrect if the entity is not a book.

Calibrating the complexity of the task. Although factuality is not the main focus of this task, we want to avoid generating sentences that are factually incorrect or misleading, as this would not only affect the quality of the translations but also make it difficult to evaluate the performance of the systems. Future editions of EA-MT or future work could explore the use of more complex sentence structures, such as longer sentences or paragraphs, to evaluate the performance of MT systems. Given the current complexity of the task for traditional MT systems and modern LLMs as shown in the results of the first edition of EA-MT (see Section 6), we believe that the current task is already challenging enough without introducing additional complexity. Furthermore, increasing the length of the sentences may introduce additional challenges from the perspective of the evaluation metrics, as longer text may include more entities and require coreference resolution and disambiguation of the entities by the evaluation metrics.

3.3 Creating High-Quality Translations

Finally, we translate our set of simple questions in English into the 10 target languages using native translators. To ensure the quality of our translations, we employ a 4-step translation process: first, we check the validity of each generated question; second, each sentence is translated by at least three native translators; third, each translation is reviewed by a native speaker of the target language; and finally, we ask the translators to provide valid aliases for each entity name in the target language.

Multi-reference translation. The entire translation process is guided by a set of instructions and guidelines that we provide to the annotators. Moreover, we require the annotators to be fluent in English, native speakers of the target language, and resident in a country where the target language is spoken.[2] Before starting the translation process, we also require the annotators to pass an entrance test to further verify their language proficiency and their comprehension of the instructions and guidelines; otherwise, they are not allowed to participate in the annotation task. Finally, the annotators are periodically evaluated on a set of test questions: if they fail on them, they are excluded from the pool of annotators. Since each English question is formulated from a given entity, we aid the translators by providing the entity name(s) from Wikidata in the target language as a hint, the English and target language descriptions of the entity from Wikidata, and the English and target language Wikipedia pages of the entity, which are fundamental resources to grasp the context and background of each entity.

Translation validation. To ensure the quality of our translations, we ask a pool of native speakers to review the translations.[3] Similar to the translation step, we provide the reviewers with a set of instructions and guidelines to follow, asking them to check both the overall quality of the translations (e.g., fluency, adequacy, and correctness) and the translations of the entity names (e.g., whether the

[2]We are not able to verify the residency of the annotators; residency is self-reported.

[3]The pool of reviewers and translators may overlap.

entity names are translated correctly, whether the most common translation is used, whether the entity name has been adapted to the context of the sentence, etc.). Each translation is reviewed by at least one annotator: if the reviewer finds any issue with the translation, the translation is discarded and the sentence is re-inserted into the pool of sentences to be translated.

Focusing on entity names and aliases. Since our focus is on the translation of entity names, we include an additional step in the translation process: we ask the annotators to provide valid names for each entity in the target language, i.e., other names that can be used to refer to the same entity in the target language. These names must be valid translations of the entity name that can be used interchangeably with the main translation. Importantly, we require the annotators to provide at least one valid name for each entity *in the given context*, i.e., the name must be valid in and adapted to the context of the translated sentence. Sometimes the annotators may deem that there is only one valid name for the entity—i.e., the one used in the translation—and they are allowed to do so: in this case, they must provide the name used in the translation as the only valid name for the entity, and the list of valid names for the entity will contain only one name. Having a list of valid names and aliases for each entity is important for our evaluation, as described in Section 4. It also allows annotators to indicate borderline cases, increasing the robustness of the evaluation process and agreement among annotators.

We provide more details about the benchmark creation process in Conia et al. (2024), including the guidelines provided to the annotators.

3.4 Benchmark Overview

As shown in Table 1, the resulting benchmark, XC-Translate, contains over 50K sentences in English with their translations into the following 10 languages: *Arabic*, *Chinese (Traditional)*, *French*, *German*, *Italian*, *Japanese*, *Korean*, *Spanish*, *Thai*, and *Turkish*. Since multiple valid translations are possible for each sentence, we provide multiple references for each sentence in the benchmark, resulting in a total of over 100K manually-created and manually-verified translations. We split XC-Translate into:

- **Sample:** a small sample of sentences for each language pair, which participants were encouraged to use for rapid prototyping;
- **Development:** a small development set for each language pair, which participants were encouraged to use for tuning and testing their systems, as the gold references were available;
- **Test:** the official test set for each language pair, which participants were not allowed to use for tuning their systems, as the gold references were released only after the end of the evaluation period.

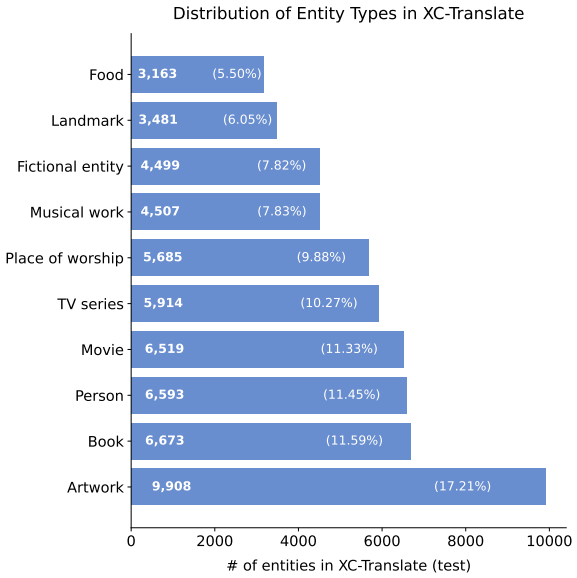

Figure 1: Distribution of the entities in XC-Translate by entity type (top-10 entity types by frequency).

The split is performed randomly, ensuring that the same entity is not present in two different splits. XC-Translate also indicates a coarse-grained type for each entity, which can be used to group the entities by category, as shown in Figure 1.

4 Evaluation Metrics

To evaluate translation quality, we employ a combination of two metrics: COMET and M-ETA.

Dealing with multiple references. XC-Translate contains multiple references for each sentence, which is a often considered a best practice in MT tasks to account for the fact that there are multiple valid ways to convey the same meaning in a target language. When evaluating the translations produced by the systems, we use the best reference approach, which selects the best reference translation for each system output based on the highest

score of the evaluation metric, instead of using the average score across all references.

COMET. COMET (Rei et al., 2020) is a neural metric that evaluates overall translation quality by comparing system outputs against human references. Unlike traditional lexical overlap metrics such as BLEU, COMET leverages contextualized embeddings to capture semantic similarity between translations. We use COMET-22 (Rei et al., 2022), which has shown strong correlation with human judgments across multiple languages. However, while COMET measures general translation quality, it may not specifically capture entity translation accuracy.

M-ETA. To address this limitation, we introduce Manual Entity Translation Accuracy (M-ETA), a simple specialized metric that focuses exclusively on entity translation correctness. Given a set of gold entity translations and predicted translations, M-ETA computes the proportion of correctly translated entities. Importantly, M-ETA accounts for valid aliases of entity names, recognizing that entities often have multiple acceptable translations in a target language. This is crucial for culturally-specific entities where literal translations would be inaccurate. Formally, we define M-ETA as follows:

$$\text{M-ETA} = \frac{1}{N}\sum_{i=1}^{N}\mathbb{I}(e_i \in \mathcal{E}_i) \quad (2)$$

where N is the number of entities in the test set, e_i is the predicted translation of the i-th entity, and $\mathcal{E}_i$ is the set of valid aliases for the i-th entity.

Overall score. The final evaluation score is the harmonic mean of COMET and M-ETA:

$$\text{Overall Score} = \frac{2 \times \text{COMET} \times \text{M-ETA}}{\text{COMET} + \text{M-ETA}} \quad (3)$$

This combined score ensures that systems must perform well on both general translation quality and entity translation accuracy, preventing systems from achieving high rankings by excelling in only one dimension. The harmonic mean particularly penalizes systems that perform poorly in either metric, emphasizing the importance of balanced results.

5 Overview of Participating Systems

In total, 54 participants registered for the task on our CodaBench competition and submitted 322 runs on the test set, each run containing the predictions of a single system on at least one language pair. Among these, 25 teams submitted the final results of 53 systems for the official leaderboard and 18 teams submitted system description papers. We provide an overview of the systems at EA-MT in Table 3.

As shown in Figure 2, we can observe a clear trend toward the use of large language models (LLMs) for entity-aware machine translation, as 86.8% of the systems are based on LLMs and only 13.2% of the systems are based on traditional NMT models. Moreover, retrieval-augmented generation (RAG) is one of the most common techniques used by the participants, as 26.4% of the systems use this technique to improve their performance. There is still a significant number of participants (47.2%) who opted to fine-tune their models on a training dataset, which is a considerable proportion since only open-source models can be directly fine-tuned. Not surprisingly, the most used LLMs for this task align with the most popular and best-performing LLMs in the general NLP community, i.e., GPT-4o, Qwen-2.5, and LLaMA-3.

6 Results, Analysis, and Discussion

The number of submissions to the official leaderboard allows to provide a birds-eye view of the performance of different systems on the task, and analyze a few interesting trends, which are discussed in depth in Appendix B.

General results. We report the results of the official leaderboard in Table 2, which reports the scores of the systems obtained during the main evaluation phase.[4] We distinguish between two main categories of systems: systems that use "gold" information during the translation process (i.e., systems that take in input the manually-identified Wikidata ID of the entity appearing in the sentence to be translated) and "end-to-end" systems that do not use this information. In other words, the first category reflects scenarios where the entity to be translated is known in advance, while the second category reflects a more general scenario where it is not known in advance if the sentence to be translated contains an entity and which entity it is. Among the systems using "gold" information, `Qwen2.5-72B-LoRA` by Pingan Team achieves the best score, with a COMET of 94.7 and an M-ETA of 89.1. Instead, among the

[4] Partipants were also allowed to submit additional results during the post-evaluation phase, but these results are not included in the official leaderboard.

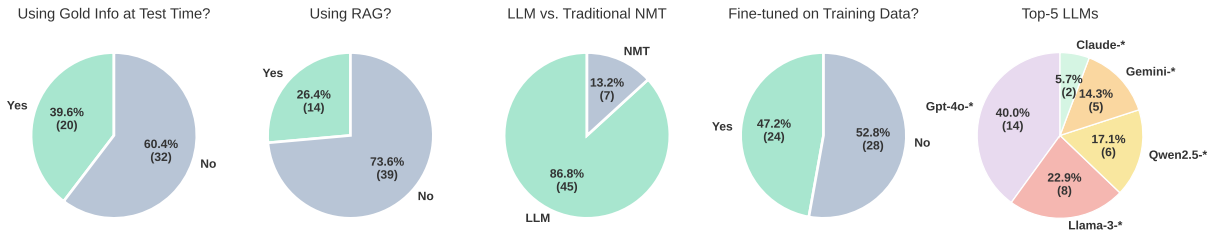

Figure 2: Overview of the systems submitted to EA-MT. Here, we distinguish between systems that: 1) use "gold" information during the translation process; 2) employ RAG; 3) are based on traditional NMT or modern LLMs; 4) are fine-tuned on a training dataset. We also report the top-5 LLMs used among the participants.

EA-MT – Official Leaderboard						Average across all languages			Rank

Table 2: Official leaderboard for the EA-MT shared task, showing the top-15 systems divided into two sections. 🟠: System uses gold information at test time. 🔍: System uses retrieval-augmented generation. 🤖: System uses a large language model. 📚: System is fine-tuned on training data. *: Scores averaged over a subset of the 10 languages.

"end-to-end" systems, `Salt-Full-Pipeline` by SALT achieves the best score, with a COMET of 91.8 and an M-ETA of 77.1, –2.9 and –12.0 points lower than the best system using "gold" information

in terms of COMET and M-ETA, respectively.

Gold information is not enough. An interesting finding is that state-of-the-art LLMs are not perfectly able to translate entities, even when provided with "gold" information, e.g., using the manually-identified Wikidata ID of the entity appearing in the sentence to be translated to retrieve the correct entity name in the target language from Wikidata. The M-ETA scores for the top-10 systems using "gold" information range between 87.3 and 89.1, showing that there is a hard core of entities whose names are difficult to adapt to the context of the translated sentence. Notably, there are two orthogonal aspects to consider: i) sometimes systems disregard the provided "gold" entity name in the target language because the transcreation process resulted in a completely different name, leading the MT systems to prefer a word-for-word translation; ii) sometimes systems fail to adapt the provided "gold" entity name to the context of the translated sentence, e.g., its morphology and syntax.

State-of-the-art LLMs lack cross-lingual and cross-cultural knowledge. Recent LLMs have shown impressive performance on a wide range of tasks, including machine translation. Although LLM-based translations are often fluent, coherent and grammatically-correct, XC-Translate demonstrates that they still struggle with entity translation. Indeed, if we based the evaluation of the systems on COMET only, we would conclude that LLMs are able to translate entities correctly. However, the M-ETA score shows that this is far from the truth, especially for current LLMs, e.g., not fine-tuned on a training dataset or using retrieval-augmented generation. There are two main reasons for this: i) XC-Translate contains a large number of entities that are not well-known, and ii) XC-Translate contains a large number of entities whose names are difficult to adapt to the context of the translated sentence. Therefore, we believe that XC-Translate will be valuable in future research not only for MT but also for benchmarking cross-lingual and cross-cultural knowledge in LLMs.

How did the participants address the limitations of current LLMs? As current LLMs still do not encode the cross-lingual and cross-cultural knowledge required to translate entities correctly, retrieval-augmented generation (RAG)—often combined with fine-tuning—is one of the most common techniques used by the participants to improve

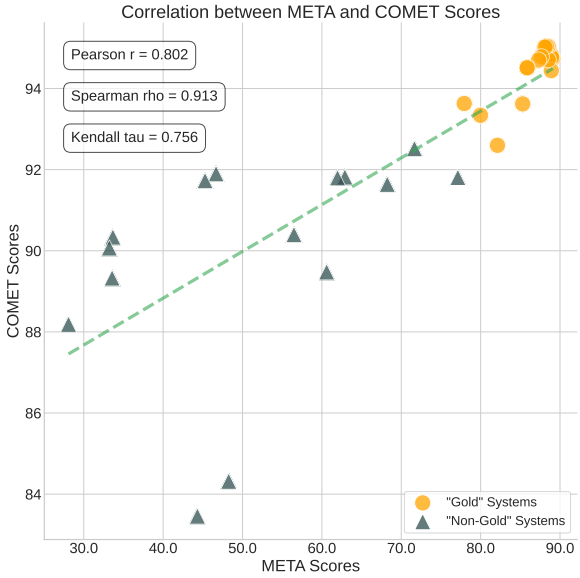

Figure 3: Correlation between M-ETA and COMET using Pearson r, Spearmen rho, and Kendall's tau.

their performance. Different participants used different retrieval strategies to retrieve different types of information (e.g., entity names, descriptions, Wikipedia pages, etc.). For instance, the SALT team used a SQL-based approach to retrieve the entity name in the target language from Wikidata before translating the sentence, whereas the Lunar team took advantage of the function calling capabilities of recent LLMs to retrieve entity-related information. Alternatively, some teams used external tools for entity recognition and linking, e.g., WikiNEuRal (Tedeschi et al., 2021) and ReLiK (Orlando et al., 2024). Finally, some teams used a combination of these techniques, e.g., the UAlberta team used both retrieval-augmented generation and ensemble learning to improve their performance. We provide more details about the systems submitted to the EA-MT shared task in Appendix A.

COMET is not a good proxy for entity translation. We can observe that the systems that achieve the best overall scores are not necessarily the ones that achieve the best M-ETA scores. Interestingly, the "gold" systems with the best COMET scores rank in 5th, 7th, and 8th place in terms of M-ETA scores, namely `GPT-4o + Wikidata + RAG` by RAGthoven, `WikiEnsemble` by UAlberta, and `WikiGPT4o` by UAlberta. This is even more evident for the "end-to-end" systems: `Salt-Full-Pipeline` by SALT—the 1st system in terms of M-ETA score—is only separated by 0.1 points in terms of COMET score (91.8 vs 91.7) from `GPT-4o`

+ RAG by RAGthoven, which ranks 10th in terms of M-ETA score (77.1 vs 45.3). As shown in Figure 3, COMET and M-ETA are correlated; however, even if we remove the outliers, a small shift in the value of COMET can lead to a very large shift in the value of M-ETA. This suggests that COMET is not a good proxy for entity translation, as COMET is often affected more by the fluency and coherence than by the correctness of the entity translation.

Not a universal solution across all languages. Independently of the evaluation metric, different systems do not perform equally well across all languages, as shown by the average rank of the systems across all languages in Table 2, which is computed by averaging the ranks of the systems across all languages. For instance, the best "gold" system, `Qwen2.5-72B-LoRA` by Pingan Team, only ranks 1st in 2 languages out of 10, achieving only 8th and 9th place in Arabic and Korean, respectively. Vice versa, `WikiEnsemble` by UAlberta ranks 1st in Arabic but only 6th on average across all languages. Similar to the best "gold" system, the best "end-to-end" system, `Salt-Full-Pipeline` by SALT, ranks 1st only in 5 languages. Therefore, among the many systems proposed by the participants there is no universal solution for entity-aware machine translation, showing that there is room for improvement in two areas: i) combining the different techniques used among the task participants, and ii) leveraging language-specific features and resources to create better models for each language.

Different research directions and open questions for different settings. The results of the EA-MT shared task show that there are still many open questions and challenges in the field of entity-aware machine translation. Here, we highlight some of the most important ones that emerged from the task, divided into two main categories: i) "gold" systems and ii) "end-to-end" systems.

- For "gold" systems: (1) even with gold entity annotations, *language-specific optimization* seems necessary for now, as no single system uniformly excels across all languages; (2) *knowledge retrieval quality* is uneven across languages, motivating language-specific retrieval strategies rather than a universal approach; and (3) *script adaptation mechanisms* are still an important challenge, as many systems struggle to achieve consistent results across languages with different scripts.
- For "end-to-end" systems: (1) *entity recognition and linking* is a crucial step for improving the performance of these systems, as it allows to identify the entities in the source sentence and link them to their corresponding entity names in the target language; (2) *hybrid systems* are a promising direction for improving the performance while reducing the computational cost; and (3) *cross-lingual and cross-cultural knowledge* is still a challenge for these systems, as they often struggle to adapt the entity name to the context of the translated sentence.

We provide an in-depth analysis of these challenges in Appendix B. In general, we believe that these challenges will be valuable for future research in the field of entity-aware machine translation, and we encourage researchers to explore these directions to improve the performance of their systems.

7 Conclusion and Future Work

In this paper, we presented the Entity-Aware Machine Translation (EA-MT) shared task, which was part of SemEval-2025. The goal of EA-MT is to evaluate the ability of machine translation systems—traditional NMT and modern LLMs—to translate text that contains challenging entities, e.g., entities that are affected by cultural and linguistic differences across languages. To this end, we created XC-Translate, a benchmark for entity-aware machine translation that contains over 50K sentences in English with their translations into 10 languages, with a total of over 100K manually-created and manually-verified translations. We also proposed a new evaluation metric, M-ETA, which focuses exclusively on entity translation correctness. Finally, we analyzed the results of the official leaderboard and discussed the key trends in the systems submitted to the EA-MT shared task. In general, XC-Translate has shown that state-of-the-art LLMs still struggle with entity translation, and that different approaches are needed to bridge the gap between LLMs and human translators. In the future, we plan to extend XC-Translate with additional language-pairs—including pairs where the source language is different from English—and domains, and to introduce new challenges, such as code-switching, low-resource languages, and larger coverage of emerging entities.

Limitations

XC-Translate. XC-Translate is a benchmark for entity-aware machine translation that contains over 50K sentences in English with their translations into 10 languages, with a total of over 100K manually-created and manually-verified translations. However, XC-Translate is limited in several ways. First, XC-Translate only provides translations from English to 10 languages, which limits its applicability to other language pairs. We avoided reversing the translation direction to avoid the risk of introducing noise in the translations and dealing with known issues in back-translation, including the increase of translationese artifacts. Second, XC-Translate only contains translations of entities that are present in Wikidata and feature at least one alias in the source and target languages. This means that XC-Translate may not be representative of entities belonging to domains that are not well covered by Wikidata. Third, while we strived to cover as many languages as possible, we focused on the most widely spoken languages. Increased attention to low-resource languages is needed to ensure that XC-Translate is representative of the diversity of languages spoken around the world. Fourth, XC-Translate only includes questions (see Section 3). This means that XC-Translate may not be representative of other types of text, such as narratives or technical documents.

M-ETA. M-ETA is a specialized metric that focuses exclusively on entity translation correctness. We introduced M-ETA to address the limitations of other metrics, such as COMET and BLEU, which do not specifically capture entity translation accuracy. However, M-ETA also has limitations. First, M-ETA only considers the correctness of entity translations and does not account for other aspects of translation quality, such as fluency and coherence. Therefore, M-ETA should be used in conjunction with other metrics to provide a comprehensive evaluation of translation quality. Second, M-ETA relies on the availability of valid aliases for entity names in the target language, which is a manually-intensive process and may not be feasible for all entities.

Systems. The systems submitted to the EA-MT shared task are based on a variety of approaches, including traditional NMT, retrieval-augmented generation, and large language models. Although the prevalence of LLMs in the submitted systems is a promising trend, it also raises concerns about the reproducibility and generalizability of the results. Many of the systems are based on proprietary LLMs, which limits their accessibility and reproducibility. Additionally, systems based on closed-source models are difficult to analyze and understand, making it challenging to identify potential biases in the models, which can lead to unfair treatment of certain groups or individuals. Finally, the reliance on large-scale pre-trained models raises questions about the environmental impact of training and deploying these models. Therefore, solutions based on smaller and open-source models may still be competitive and more sustainable in the long run if we consider other factors, such as reproducibility, latency, and energy consumption.

Acknowledgements

We would like to thank the participants of the EA-MT shared task for their valuable contributions and for sharing their systems and results with us. We would also like to thank the annotators and reviewers for their hard work in creating and validating the XC-Translate benchmark. Finally, we would like to thank the organizers of SemEval-2025 for their support, availability, and flexibility, and for providing us with the opportunity to organize this shared task.

Simone Conia gratefully acknowledges the support of the PNRR MUR project PE0000013-FAIR, which fully funds his fellowship. Roberto Navigli also acknowledges the support of the PNRR MUR project PE0000013-FAIR, which partially funds his research.

A Participating Systems

In this section, we provide an overview of the systems submitted to EA-MT, sorted by team name. For each system, we briefly describe the approach used by the participants to tackle the task and summarize their main findings. For more details, we refer the reader to the corresponding system description papers.

Arancini: *"Multilingual Translation Enhanced by Lightweight LLMs, NER, and RAG for Named Entities"* (Zenotto et al., 2025). This work introduces a multilingual translation pipeline that combines lightweight large language models (LLMs), a dedicated NER module, and a retrieval-augmented generation (RAG) mechanism to improve named-entity handling. The authors benchmark several models (e.g., M2M100 variants, Qwen2.5, Gemma2-9B) and show that integrating entity linking with Wikidata resources, guided by either gold IDs or automatically detected entities, significantly boosts M-ETA (entity-level accuracy) and maintains strong COMET scores (overall fluency). The authors demonstrate that even when NER introduces errors, the retrieval-based approach preserves high semantic fidelity, underscoring the pipeline's robustness for real-world scenarios in which perfectly labeled data is unavailable.

CHILL: *"You Can't Just Throw Entities and Hope — Make Your LLM to Get Them Right"* (Lee et al., 2025b). The authors present a system that enhances entity-aware translation by fusing retrieval-augmented generation (RAG) with an iterative self-refinement mechanism. In particular, they retrieve entity labels and descriptions from Wikidata, embedding these details into prompts for GPT-4o to ensure accurate handling of named entities. Crucially, the system self-evaluates each translation on both entity correctness and overall linguistic quality, iterating until it meets a predefined performance threshold or exhausts the allotted refinement steps. This feedback-driven procedure, grounded in large language models, consistently yields improvements in entity accuracy (M-ETA) without sacrificing global translation quality (COMET). A further analysis reveals minimal correlation between label similarity (quantified via Levenshtein distance) and entity-translation precision, underscoring that the critical gains stem from leveraging oracle entity context and iterative revision rather than label similarity alone.

Deerlu: *"Wikidata-Driven Entity-Aware Translation — Boosting LLMs with External Knowledge"* (Xu, 2025). The authors introduce an entity-aware machine translation system that enhances large language models (LLMs) with external knowledge from Wikidata. Their approach involves two strategies: one that uses gold Wikidata IDs for cross-lingual entity retrieval, and a practical alternative that leverages ReLiK to identify and link entities automatically with an external knowledge base. Experiments across multiple language pairs demonstrate significant improvements in named entity translation accuracy with up to a 63-point gain in M-ETA while maintaining strong overall translation quality as measured by COMET. Notably, the system ranks third overall and first among non-finetuned entries on the SemEval-2025 Task 2 leaderboard. Further enhancements tailored to specific linguistic nuances, such as simplified-to-traditional character conversion for Chinese, boost performance and highlight the practical applicability of external-knowledge integration for robust and accurate entity-aware machine translation.

FII the Best: *"Steering State-of-the-art Machine Translation Models with Strategically Engineered Pipelines for Enhanced Entity Translation"* (Grigorita et al., 2025). The authors propose two complementary pipelines for enhancing entity-aware machine translation, with a shared emphasis on integrating structured knowledge into large language models. In the first approach, a multilingual NER module (mBERT trained on WikiNEuRal) identifies entities in the source text, which are then aligned with Wikidata translations and merged back into placeholders to preserve context. Notable refinements include punctuation normalization and replacing general MT with the Gemini API to address grammatical coherence issues. The second approach leverages LLMs (Qwen 2.5 Instruct) guided by carefully engineered prompts to separate named entities, fetch accurate translations from Wikidata, and maintain fluency when reinserting them into the transformed text. Comparative results show that the second strategy consistently yields stronger COMET and M-ETA scores across ten languages, especially for underperforming cases like Chinese. Future work involves substituting Gemini 1.0 with more advanced LLMs and unifying both strategies into a single, robust framework for entity-centric translation.

GinGer: *"Challenges in Entity-Aware Machine Translation with Fine-Tuning and Zero-Shot Prompting"* (Naebzadeh, 2025). The authors tackle named entity translation by experimenting with two distinct strategies: 1) parameter-efficient fine-tuning (PEFT) of multilingual seq2seq models, and 2) zero-shot prompting using open-source LLMs. Their PEFT approach uses LoRA-based low-rank updates to mitigate heavy computational requirements, and applies it to various Transformer-based NMT backbones. They also explore zero-shot translation with models under 10 billion parameters, using carefully constructed prompts that emphasize preserving entity integrity. Empirical results on Arabic, Italian, and Japanese highlight the persistent difficulty of accurately translating named entities, especially under data-scarce conditions or model size constraints. While both PEFT and prompt-based approaches yield improvements over naive baselines, entity translation remains suboptimal, suggesting that more robust integration of external knowledge or domain adaptation is needed. Nonetheless, the work underscores how smaller NMT or LLM models can be practically adapted for entity-aware translation, even with limited computational resources.

HausaNLP: *"Entity-Aware Fine-tuning vs. Prompt Engineering in Entity-Aware Machine Translation"* (Abubakar et al., 2025). The authors explore both fine-tuning a distilled NLLB-200 model and zero-/few-shot prompt-based methods with Gemini for entity-aware machine translation from English into ten target languages. Their fine-tuning strategy includes augmenting training data with named entities (NE) extracted from Wikidata to refine translation performance, while prompt-based approaches either rely on minimal instructions (zero-shot) or incorporate a few examples (few-shot) to promote correct NE usage. By comparing these strategies, they uncover that Gemini consistently achieves higher M-ETA (entity accuracy) than the fine-tuned NLLB-200 model, particularly for European languages. Their findings highlight that the gap between zero- and few-shot prompting is small, suggesting that extensive prompt engineering may not be necessary for robust entity-centric translations.

Howard University-AI4PC: *"Improving Machine Translation With Context-Aware Entity-Only Pretranslations with GPT4o"* (Aryal and Agyemang-Prempeh, 2025). The authors propose a three-step pipeline that combines external knowledge from Wikidata and structured GPT prompts to improve named entity translation. First, they extract target-language labels and descriptions for each entity via Wikidata lookups, ensuring that contextually specific translations are available. Second, they refine these entity translations with a dedicated GPT prompt, guiding the model to produce accurate named entities. Finally, they feed both the original source text and the refined entity translations into a context-aware GPT prompt, generating a translation that preserves semantic integrity while accurately handling named entities. Experiments indicate that this multi-pass strategy yields substantial gains over baseline GPT-only approaches, especially for languages with distinctive tokenization or orthographic conventions (e.g., Arabic, Japanese). Although dependent on Wikidata coverage, the proposed method demonstrates how systematically bridging large language models with external entity information can significantly enhance the quality of cultural- or domain-specific named entity translations.

🏆 **Pingan Team:** Best "gold" system — *"LoRA-Augmented Qwen2.5 with Wikidata-Driven Entity Translation"* (Chen, 2025). The authors present a system for entity-aware translation that leverages a LoRA-based fine-tuning of the 72B-parameter Qwen2.5 model, augmented by a synthetic data generation pipeline. Specifically, they incorporate Wikidata entries to retrieve multilingual entity labels, then synthesize sentence pairs containing these labels to improve named entity translation coverage. LoRA focuses on low-rank updates while maintaining the original model's generalization ability, enabling domain adaptation without excessive resource overhead from a computational point of view. Experimental results across ten languages show that their approach achieves state-of-the-art performance on the SemEval-2025 Task 2 leaderboard, evidenced by both high COMET scores for global translation quality and substantially improved M-ETA scores for named entity translation accuracy. Notably, the system demonstrates effective handling of rare or culturally specific references, suggesting that combining structured knowledge (Wikidata) with large language models (Qwen2.5) and targeted LoRA fine-tuning can robustly address complex cross-lingual entity mappings.

RAGthoven: *"Enhancing Entity-Aware Machine Translation with Large Language Models, Re-*

trieval Augmented Generation and Function Calling" (Skottis et al., 2025). The authors describe a lightweight, high-impact approach to entity-aware machine translation that combines GPT-4o with Wikidata-based named entity translations, retrieval-augmented generation, and function calling. Implemented in the RAGthoven framework, their system first enriches the source sentence with any existing named entity data from Wikidata. It then retrieves similar (English→Target) sentence pairs from a small parallel corpus to as contextual examples, and finally, uses GPT-4o to generate a final translation that incorporates this information. When the gold entity is not pre-identified, the system invokes a multi-step procedure in which the LLM identifies the named entity, queries the Wikidata API for translations, and re-injects them into the prompt. Empirical results on ten languages show strong gains over a baseline GPT-4o, up to a twenty-point boost when Wikidata entity IDs are provided. The proposed method highlights that carefully orchestrating calls to external knowledge can effectively mitigate typical LLM weaknesses in handling culturally specific or domain-limited entity references.

Sakura: *"Enhancing Named Entity Translation with Fine-Tuning and Preference Optimization"* (Poncelas and Htun, 2025). The authors explore two techniques to incorporate dictionary-based knowledge for named entity translation from English into Japanese: 1) fine-tuning on either individual or batched dictionary entries, and 2) applying preference optimization to rerank the model's output toward the dictionary references. While fine-tuning with single entries maximizes entity-level accuracy (M-ETA), it can degrade overall quality (COMET, CHRF). Aggregating entries into lists mitigates this trade-off, but still affects fluency and coverage. In contrast, preference optimization yields more balanced improvements, boosting named entity fidelity without significantly harming broader translation performance. Experiments using a curated Wikidata-derived dictionary and a pre-trained RakutenAI-7B model demonstrate that both strategies are effective, with distinct trade-offs in preserving entity translations and maintaining global translation quality.

🏆 **SALT:** Best end-to-end system — *"A SQL-based Approach for LLM-Free Entity-Aware-Translation"* (Völker et al., 2025). The authors propose a lightweight two-stage pipeline, SALT, that bypasses large language models for entity-aware translation and instead uses SQL-based retrieval in combination with constrained neural decoding. The proposed approach identifies source sentence spans via n-gram matching, retrieves corresponding entity translations from a SQL-indexed knowledge base, and then injects these matches into a distilled NLLB-200 model augmented with logit biasing to favor the provided entity translations. Ablation studies reveal that simple string-based retrieval rivals more complex neural methods, that limiting each entity to a single candidate avoids confusion in generation, and that logit biasing effectively improves name-entity accuracy without harming overall translation quality. Despite using far fewer parameters than LLMs, SALT achieves state-of-the-art performance among systems without gold data, narrowing the performance gap with LLM-based methods to less than one percentage point in harmonic mean metrics.

SheffieldGATE: *"Multi-Stage Reasoning with Knowledge Fusion for Entity Translation"* (Yang et al., 2025). The authors introduce a multi-agent entity-aware machine translation system, focusing on precise handling of named entities. Their approach employs a three-stage reasoning pipeline involving entity extraction, knowledge enhancement, and translation decision-making. In the first stage, an LLM identifies named entities and relevant context within the source text. The second stage uses Wikidata-based retrieval, guided by refined LLM-generated queries, to gather candidate entity information with descriptions and alternate names. Finally, in the translation stage, a fine-tuned LLM selectively integrates these candidate entities to produce contextually accurate translations. An additional verification module detects reasoning failures and refines outputs, guarding against omissions or semantic shifts. Experimental results across four language pairs (English–German, English–French, English–Italian, and English–Spanish) confirm significant gains in entity translation accuracy, as measured by M-ETA, while maintaining strong overall translation quality (COMET).

silp_nlp: *"An effect of Entity Awareness in Machine Translation using LLM"* (Singh et al., 2025). The authors propose two strategies for entity-aware translation from English into various target languages: prompting GPT-based models (GPT-4o and GPT-4o-mini) directly, and fine-tuning an NLLB-200 model with LoRA adaptation. An external

Universal NER module identifies named entities in the source text, which are then incorporated into the LLM prompts or appended to the training data for NLLB-200. Automatic results on M-ETA and COMET demonstrate that adding entity annotations boosts overall performance for both approaches, though success is highly dependent on the accuracy of the entity extraction stage. GPT models outperform a fine-tuned NLLB-200, but both approaches benefit from explicit named entity information, reinforcing the value of entity-awareness to resolve the common pitfalls of incorrectly handling rare or ambiguous entities.

Team ACK: *"Beyond Word-for-Word Machine Translation for English-Korean Pairs"* (Lee et al., 2025a). The authors focus on translating English text into Korean by evaluating thirteen models (LLMs and MT systems) on knowledge-intensive question-answer pairs. Their setup combines three automatic metrics, namely, BLEU, COMET, and M-ETA, to measure fluency, general translation quality, and entity-specific accuracy. Notably, they also conduct a comprehensive human annotation of 650 samples to identify error types and construct an interesting error taxonomy. Empirical results highlight that LLMs generally outperform traditional MT approaches but still often fail to preserve cultural nuances when adapting entity references between English and Korean. The authors classify the most frequent error types (e.g. incorrect responses, misaligned or phonetic entity translations), and further note how entity popularity and type can influence outcomes. They conclude that current automatic metrics often overlook finer cultural nuances, underscoring the continued need for human-in-the-loop evaluations and specialized techniques for culturally grounded, entity-focused machine translation.

UAlberta: *"Prompting and Ensembling for Entity-Aware Translation"* (Shi et al., 2025). The authors develop a new strategy for entity-aware translation, focusing on large language model (LLM) prompting and ensemble methods to boost performance on named entities. First, they combine retrieval-augmented generation with in-context learning, ensuring that LLM outputs align with external knowledge bases (e.g., WikiData or BabelNet). Structured prompts include named entity translations, role alignment (an "expert translator" framing), and example source-target pairs. Second, they explore ensemble mechanisms that combine outputs from multiple translation systems, including both LLM and commercial MT engines. The core ensemble approach prioritizes any candidate containing a valid named entity translation, while optional semantic overlap features also favor translations with improved word-level alignment. Experiments reveal that both carefully designed LLM prompts and ensembling yield significant gains in producing accurate entity translations.

VerbaNexAI: *"Enhancing Entity-Aware Translation with Wikidata-Enriched MarianMT"* (Peña Gnecco et al., 2025). The authors present a resource-efficient system for English–Spanish entity-aware translation that enriches MarianMT with a static collection of 240,432 Wikidata entity pairs. This setup aims to address named-entity coverage (e.g., "*Águila de San Juan*") while maintaining stable fluency on general content. Despite achieving a solid COMET score (87.1), the proposed system underperforms on M-ETA (24.6)—a shortcoming traced to rigid, non-adaptive reliance on Wikidata and the inherent difficulty of exact-match scoring for rare or context-sensitive entities. In contrast, dynamic, retrieval-based large language model methods excel by integrating flexible external knowledge. Their findings emphasize that while static knowledge bases improve translation for well-documented entities, effective cross-domain entity accuracy likely requires adaptive retrieval-augmented or on-demand fine-tuning strategies.

YNU-HPCC: *"Local Cache and Online Retrieval-Based method for Entity-Aware Machine Translation"* (Li et al., 2025). The authors introduce a multi-faceted approach that leverages both traditional and large language model (LLM) architectures to improve entity-aware translation. Specifically, they propose four methods that integrate named entity recognition (NER) modules (BERT or Qwen-based), a local cache of entity translations, and an online retrieval mechanism for unseen entities. By systematically incorporating Wikidata lookups and performing careful prompt engineering for Qwen models, the system achieves higher entity-specific accuracy (M-ETA) and maintains strong overall translation quality (COMET). Notably, a ReAct-based framework further enhances interpretability by explicitly separating reasoning steps from execution, allowing the model to iteratively refine entity translations or query additional resources when encountering ambiguous cases. Ex-

perimental results across ten languages demonstrate the viability of these methods, underscoring that LLM-driven pipelines can surpass traditional MT systems in both robustness and adaptability for entity-centric text.

Zero: *"Entity-Aware Machine Translation: Fine-Tuning NLLB for Improved Named Entity Translation"* (Gundam et al., 2025). The authors address the challenge of translating named entities by fine-tuning a distilled NLLB-200 model with LoRA on a "silver dataset" derived from Google Translate outputs, focusing on efficient adaptation rather than relying on large general-purpose models. This methodology enables the system to learn entity-specific patterns while preserving overall translation quality, as demonstrated by improvements in BLEU, COMET and M-ETA. Notably, while certain languages (e.g., Spanish, Turkish) achieve robust performance, others (e.g., Chinese) remain difficult due to structural complexity and rare entities. Nevertheless, the work underscores that specialized training on moderately sized data can substantially enhance entity translation accuracy, suggesting a cost-effective alternative to massive language models for entity-aware machine translation.

B Extended Results

In this section, we provide additional results for the systems submitted to the EA-MT task. We include the full ranking of all systems across all the 10 languages, as well as the average ranking across all languages. The results are divided into two tables: one for the "gold" systems and one for the end-to-end systems. For all the numerical results, we redirect the reader to the official leaderboard of the task, which is available at `https://huggingface.co/spaces/sapienzanlp/ea-mt-leaderboard`.

B.1 Gold Systems

Table 4 shows the ranking of the "gold" systems submitted to EA-MT for each language pair and on average across languages. The systems are sorted by average ranking, with the best-performing system at the top. We can observe significant cross-lingual performance variations among systems that leverage gold entity information, highlighting that even with perfect entity identification, translation quality remains language-dependent.

The Qwen2.5-based systems from Pingan Team consistently outperform other approaches, achieving top average rankings (3.70 and 4.20). However, their performance exhibits substantial cross-lingual variance—particularly for Korean (9th and 8th place) versus Germanic languages (1st and 4th place). This pattern suggests that despite using identical model architectures and training methodologies, certain linguistic families present inherently different challenges for entity name translation. The effectiveness of parameter-efficient fine-tuning methods is also evident, as LoRA-based approaches occupy three of the top five positions. Notably, these approaches maintain representational capacity across languages while specifically adapting to entity-translation tasks, outperforming both full fine-tuning and zero-shot prompting strategies, even though different participants employed different underlying models, which may have contributed to the observed performance differences.

Knowledge Integration Mechanisms. The systems submitted to the EA-MT task employed various knowledge integration mechanisms, including retrieval-augmented generation (RAG), ensemble methods, and LLM-only approaches. The performance of these systems varied significantly across languages, indicating that the choice of knowledge integration mechanism plays a crucial role in entity-aware translation.

- **RAG-based systems** (Deerlu, RAGthoven, CHILL) demonstrate strong average performance (4.80–6.30) but with high variance across languages. For instance, RAGthoven's system ranks 1st for Chinese but 9th for Japanese, despite their writing system similarities. This suggests that knowledge retrieval quality varies significantly by language, potentially reflecting disparities in Wikidata coverage or retrieval accuracy.
- **Ensemble methods** (UAlberta's WikiEnsemble) show particular strength for Arabic (1st) but mediocre performance for Romance languages like Italian (10th) and French (10th). This pattern indicates that ensemble advantages are most pronounced for languages with greater structural divergence from English, where aggregating multiple translation hypotheses proves valuable.

Language-Specific Challenges. The rank distribution reveals three distinct language clusters with different system behaviors:

- **Germanic and Romance languages** (German, French, Spanish, Italian) show relatively

Table 5: Ranking of end-to-end systems submitted to EA-MT for each language pair and on average across languages.

consistent rankings across systems, suggesting more predictable entity translation patterns.

- **East Asian languages** exhibit the highest variability. For Japanese, the ranking difference between the best and worst performing systems (Deerlu's Qwen2.5-Max-Wiki at 1st vs. Howard's DoubleGPT at 15th) is striking. Similar patterns emerge for Korean and Chinese. This suggests that entity handling for languages with non-Latin scripts and different naming conventions benefits differently from various knowledge integration strategies.

- **Turkish and Thai** display unique patterns where CHILL's GPT4o-RAG-Refine performs exceptionally well (1st for both), despite middling performance on European languages. This system's iterative refinement approach appears particularly effective for agglutinative languages (Turkish) and languages with unique script properties (Thai).

Key Findings and Research Directions. These findings have several methodological implications for entity-aware translation research:

1. **Language-specific optimization** appears necessary even when using gold entity information, as no system achieved consistent top-tier performance across all languages.

2. **Knowledge retrieval quality** likely varies substantially across languages, suggesting the need for language-specific retrieval strategies rather than one-size-fits-all approaches.

3. **Script adaptation mechanisms** deserve focused attention, as the most dramatic performance variations occur between languages with different writing systems.

These insights indicate that accurate entity translation remains challenging even with gold entity information, reflecting deeper cross-cultural and linguistic adaptation issues that extend beyond simply retrieving correct entity mappings.

B.2 End-to-End Systems

Table 5 shows the ranking of end-to-end systems submitted to EA-MT for each language pair and on average across languages. The systems are sorted by average ranking, with the best-performing system at the top. The results indicate that the best-performing end-to-end systems (SALT, SheffieldGATE, and FII-UAIC-SAI) achieve high average rankings (1.60–2.70), demonstrating the effectiveness of their approaches in entity-aware translation. However, there is still significant room for improvement, as the average ranking across languages remains relatively high.

The systems submitted to the EA-MT task employed various approaches, including fine-tuning, prompting, and ensemble methods. The performance of these systems varied significantly across languages, indicating that the choice of approach plays a crucial role in entity-aware translation.

- **Retrieval-augmented generation (RAG) and function calling** (SheffieldGATE, SALT, LUnar) demonstrate strong average performance. For instance, SheffieldGATE's system leveraged an agentic approach to enhance entity translation, achieving the best average ranking (1.00) across all languages, while SALT's system used a SQL-based approach to achieve the second-best average ranking (1.60). Lunar also performed well with RAG and function calling, achieving an average ranking of 5.30.

- **Fine-tuning approaches** (SALT, FII-UAIC-SAI, Lunar, UAlberta) show that fine-tuning models with entity-specific data can significantly improve translation quality, but the question on how to efficiently adapt the model to the task and how to produce high-quality entity-specific data remains open.

Non-LLM vs. LLM-based Approaches. A fascinating trend in the results is the competitive performance of specifically engineered non-LLM systems against larger language models:

- **SALT's SQL-based approach** consistently outperforms many LLM-based systems across almost all languages (ranking 1st or 2nd in 9 out of 10 language pairs), demonstrating that lightweight, specialized pipelines can be highly effective when explicitly designed for entity handling. This challenges the assumption that ever-larger models are necessary for complex cross-lingual tasks.

- **FII-UAIC-SAI's Qwen2.5-Wiki-MT** shows remarkable language-specific adaptability, ranking 1st for Chinese while maintaining strong performance (3rd-5th) across other languages. This suggests that targeted knowledge integration can offset raw model size advantages.

Language-Specific Observations. The end-to-end systems exhibit distinct patterns across language families:

- **Chinese** shows the highest divergence from patterns observed in other languages. FII-UAIC-SAI's system ranks 1st for Chinese but only 4th overall, while SALT's top-performing system ranks only 3rd for Chinese despite leading in most other languages. This suggests unique challenges in Chinese entity translation that benefit from specialized approaches.

- **Thai** yields particularly strong results for Lunar's LLaMA-RAFT-Plus (2nd place), significantly outperforming its average ranking (5.30). This contrasts with Romance languages where the system performs less effectively (6th-7th places), indicating that the

proposed approach might have specific advantages for non-latin script and linguistic properties.

- **Korean** demonstrates a significant variability across systems. Team ACK's extensive Korean-specific analysis produced a detailed error taxonomy, highlighting how language-specific insights can inform system design.

Key Findings and Research Directions. The results from the end-to-end systems provide several key insights and directions for future research in entity-aware translation:

1. **Entity detection quality** appears to be the critical bottleneck in end-to-end performance, as the gap between gold-information systems and end-to-end systems remains substantial (best M-ETA of 89.1 vs. 77.1).

2. **Computational efficiency tradeoffs** deserve more attention, as lightweight systems like SALT demonstrate that clever architectural choices can outperform resource-intensive approaches in specialized tasks.

3. **Cross-lingual consistency** remains elusive, with the top-5 systems showing performance variations across languages. This suggests that truly universal entity-aware translation systems may require language-family-specific components rather than pure monolithic approaches.

These findings suggest that future research may focus on modular, knowledge-enhanced architectures that can specialize for different language families while maintaining computational efficiency. The success of lightweight but informed systems indicates that architectural innovation may yield more immediate benefits than simply scaling up model size for entity-aware translation.

C XC-Translate: Addendum

Here, we provide an overview of the contents of XC-Translate, our novel gold benchmark dataset for entity-aware machine translation.

C.1 Data Format

The data is provided in JSONL format, where each line in the file contains a JSON object.
The JSON object contains the following fields, as shown in Figure 4:

```
{
    "id": "Q2461698_0",
    "wikidata_id": "Q2461698",
    "entity_types": [
        "Fictional entity"
    ],
    "source":
        "Who are the main antagonistic forces
            in the World of Ice and Fire?",
    "targets": [{
        "translation":
            "Chi sono le principali forze
                antagoniste nel mondo delle
                Cronache del ghiaccio e
                del fuoco?",
        "mention":
            "mondo delle Cronache del ghiaccio
                e del fuoco"
    }],
    "source_locale": "en",
    "target_locale": "it"
}
```

Figure 4: Example of a data entry from XC-Translate showing the JSON structure. Note how the entity "World of Ice and Fire" is translated to "mondo delle Cronache del ghiaccio e del fuoco" in Italian, demonstrating the non-literal translation characteristic of the dataset.

- **id**: A unique identifier for the entry.
- **wikidata_id**: The Wikidata ID of the entity being translated.
- **entity_types**: A list of entity types associated with the entity.
- **source**: The source sentence containing the entity to be translated.
- **targets**: A list of target translations, each containing:
  - **translation**: The translated sentence in the target language.
  - **mention**: The mention of the entity in the translated sentence.
- **source_locale**: The locale of the source sentence (e.g., "en" for English).
- **target_locale**: The locale of the target sentence (e.g., "it" for Italian).

This format allows for easy parsing and processing of the data, making it suitable for training and evaluating machine translation systems.

Entity ID	Type(s)	Text	Mention(s)	Locale
Q746666	Musical work	Can you sing the chorus of the folk song Ring a Ring o' Roses ?	Ring a Ring o' Roses	English
		Puoi cantare il ritornello della canzone popolare Girotondo ?	Girotondo	Italian
Q157073	Person	How long was Mary of Burgundy married to Emperor Maximilian I?	Mary of Burgundy	English
		Per quanto tempo Maria di Borgogna è stata sposata con l'imperatore Massimiliano I?	Maria di Borgogna	Italian
Q850522	Movie	Who are the main characters in the movie Little Women ?	Little Women	English
		¿Quiénes son los personajes principales de la película Mujercitas ?	Mujercitas	Spanish
Q1204366	Book	Who is the author of the book A Room of One's Own ?	A Room of One's Own	English
		¿Quién es el autor del libro Una habitación propia ?	Una habitación propia	Spanish

Table 6: Examples of Entity Translations in XC-Translate Dataset. For each example, we display the entity ID (Wikidata ID), the entity type(s), the source text with the entity mention highlighted in light blue, the target text with the translated entity mention highlighted in light peach, and the locale of the source and target texts. The examples illustrate the diversity of entities and their translations across different languages, even when the languages mostly share the same script.

C.2 Examples from XC-Translate

Table 6 shows some examples of entity translations in the XC-Translate dataset. The examples illustrate the diversity of entities and their translations across different languages, highlighting the challenges and complexities involved in entity-aware machine translation even when the languages are closely related and share mostly the same script. The examples also demonstrate the non-literal translations that are often required for proper entity translation, as seen in the translations of "Ring a Ring o' Roses" to "Girotondo" and "Mary of Burgundy" to "Maria di Borgogna".

Abstract

We present our shared task on text-based emotion detection, covering more than 30 languages from seven distinct language families. These languages are predominantly low-resource and are spoken across various continents. The data instances are multi-labeled with six emotional classes, with additional datasets in 11 languages annotated for emotion intensity. Participants were asked to predict labels in three tracks: (a) multilabel emotion detection, (b) emotion intensity score detection, and (c) cross-lingual emotion detection.

The task attracted over 700 participants. We received final submissions from more than 200 teams and 93 system description papers. We report baseline results, along with findings on the best-performing systems, the most common approaches, and the most effective methods across different tracks and languages. The datasets for this task are publicly available.

1 Introduction

People use language in diverse and sophisticated ways to express emotions across languages and cultures (Wiebe et al., 2005; Mohammad and Kiritchenko, 2018; Mohammad et al., 2018a). Emotions are also perceived subjectively, even within the same culture or social group. Recognising these emotions is central to language technologies and NLP applications in healthcare, digital humanities, dialogue systems, and beyond (Mohammad et al., 2018b; Saffar et al., 2023). In this work, we use *emotion recognition* to refer to *perceived* emotions, i.e., the emotion most people believe the speaker might have felt based on a sentence or short text snippet.

Despite the linguistic diversity of regions such as Africa and Asia, which together account for more than 4,000 languages, few emotion recognition resources exist for these languages. Prior SemEval shared tasks on emotion recognition have primarily focused on high-resource languages such as English, Spanish, and Arabic (Strapparava and Mihalcea, 2007; Mohammad et al., 2018a; Chatterjee et al., 2019). In this task, we provide participants with new datasets covering more than 30 languages from seven distinct language families, spoken across Africa, Asia, Latin America, North America, and Europe (Muhammad et al., 2025). Our manually annotated emotion recognition datasets, curated in collaboration with local communities, consist of over 100,000 multi-labeled instances drawn from diverse sources, including speeches, social media, news, literature, and reviews. Each instance is labeled by fluent speakers and annotated with six emotion classes: *joy, sadness, anger, fear, surprise, disgust*, and neutral. Additionally, eleven datasets include four emotional intensity levels ranging from 0 to 3 (i.e., absence of emotion to high intensity).

The task consists of three tracks: (a) multilabel emotion detection, (b) emotion intensity detection, and (c) cross-lingual emotion detection. The languages for each track are listed in Figure 1. Each team could submit results for one, two, or all three tracks in one or more languages. Our official evaluation metrics were the average F-score for Tracks A and C and the Pearson correlation coefficient for Track B, which measures how well system-

[*]Equal contribution

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2558–2569

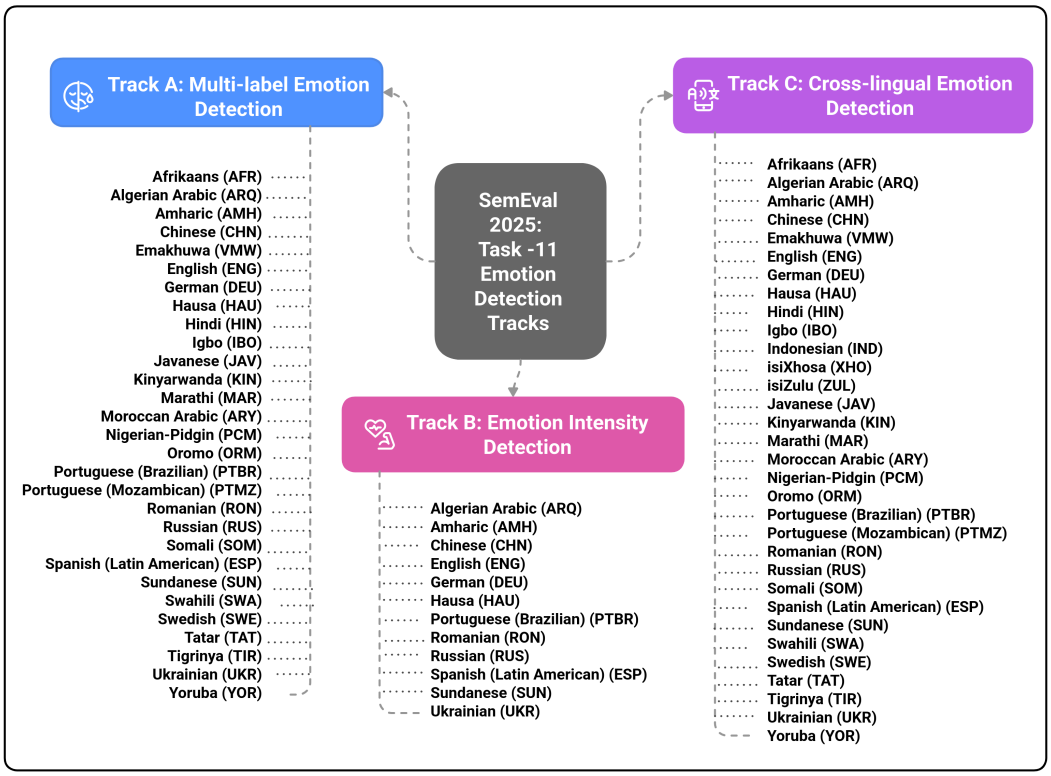

Figure 1: Languages in the three tracks (A, B, and C) of SemEval 2025 Task 11.

predicted intensity scores align with human judgments.

Our task attracted over 700 participants, with 220 final submissions and 93 teams submitting system description papers. Track A (multi-label emotion detection) received the most submissions (114), followed by Track C (cross-lingual emotion detection) with 51, and Track B (emotion intensity detection) with 32. Most teams participated in multiple languages, averaging 11 languages per team. Our task was the most popular competition on CodaBench in 2024.All task details and resources are available on the task's GitHub page.

2 Related Work

NLP work on emotion detection is predominantly Western-centric, with a few exceptions for languages other than English (e.g., Italian (Bianchi et al., 2021), Romanian (Ciobotaru et al., 2022), Indonesian (Saputri et al., 2018), and Bengali (Iqbal et al., 2022)). While multilingual datasets (e.g., (Öhman et al., 2020) and XLM-EMO (Bianchi et al., 2022)) exist, they do not fully capture cultural nuances in emotional expressions due to their reliance on translated data (e.g., XLM-EMO), as emotions are highly contextualized and culture-specific (Havaldar et al., 2023; Mohamed et al., 2024; Hershcovich et al., 2022). Furthermore, most datasets are single-labeled, and to the best of our knowledge, there are no multilingual resources that capture simultaneous emotions and their intensity across various languages.

Additionally, most prior emotion recognition shared tasks have focused on high-resource languages such as English, Spanish, German, and Arabic (Strapparava and Mihalcea, 2007; Mohammad and Bravo-Marquez, 2017; Mohammad et al., 2018b; Chatterjee et al., 2019). In contrast, this shared task covers more than 30 languages, including several low-resource languages.

3 Data

3.1 Data Collection

As our task includes more than 30 different datasets, curated and annotated by fluent speakers, we selected data sources based on: 1) the availability of textual data potentially rich in emotions, and 2) access to annotators. Since finding suitable data is challenging when resources are limited, we typically combine sources. The main textual sources used to build our dataset collection are:

- **Social media posts**: Data collected from var-

Table 1: Languages and data split sizes. Datasets with no training splits (-) were only used in Track C (crosslingual) only.

ious platforms, including Reddit (e.g., eng, deu), YouTube (e.g., esp, ind, jav, sun, tir), Twitter (e.g., amh, hau), and Weibo (e.g., chn).

- **Personal narratives, talks, speeches**: Anonymised sentences from personal diary posts. We use these in eng, deu, and ptbr, mainly from subreddits such as IAmI. Similarly, the afr dataset includes sentences from speeches and talks.
- **Literary texts**: The language lead manually translated the novel *La Grande Maison* (The Big House) by the Algerian author Mohammed Dib from French into Algerian Arabic (arq), and post-processed the translation to generate sentences for annotation by native speakers. Note that the translator is bilingual and a native speaker of Algerian Arabic.
- **News data**: Although we prefer emotionally rich social media data from different platforms, when such data is scarce, we annotated news data and headlines in some African languages (e.g., yor, hau, and vmw).
- **Human-written and machine-generated data**: We created a dataset from scratch for Hindi (hin) and Marathi (mar). Annotators were asked to come up with emotive sentences on a given topic (e.g., family). A small portion of the Hindi dataset was automatically translated into Marathi and manually corrected by native speakers to fix translation errors. Finally, we augmented both datasets with a few hundred quality-approved instances generated by ChatGPT. Note that these constitute less than 1% of the total number of data instances.

3.2 Data Annotation

We ask the annotators to select all the emotions that apply to a given text. The set of perceived emotion labels includes: *anger, sadness, fear, disgust, joy, surprise*, and *neutral* (if no emotion is present). The annotators further rate the selected emotion(s) on a four-point intensity scale: 0 (no emotion), 1 (low intensity), 2 (moderate intensity), and 3 (high intensity). We provide the definitions of the categories, annotation guidelines, and more details in Muhammad et al. (2025). We expected some level of disagreement, as emotions are complex, subtle, and perceived differently, even by people within the same culture, especially in the absence of full context. Hence, the final emotion labels were determined based on the emotions and associated intensity values selected by the annotators. Specifically, the given emotion is considered present if:

1. At least two annotators select a label with an intensity value of 1, 2, or 3 (low, medium, or high, respectively).
2. The average score exceeds a predefined threshold T. We set T to 0.5.

Once the perceived emotion labels are assigned, the final intensity scores for Track B are determined by averaging the selected intensity values and rounding up to the nearest whole number. Intensity scores are assigned only for datasets in which most instances were annotated by at least five annotators to ensure robustness. Table 1 shows the total number of instances in each dataset, as well as the number of instances in the training, development, and test splits for all languages.

3.3 Annotators' Reliability

We report the reliability of the annotation using the Split-Half Class Match Percentage (SHCMP; Mohammad, 2024) as described in Muhammad et al. (2025). SHCMP extends the concept of Split-Half Reliability (SHR), traditionally used for continuous scores (Kiritchenko and Mohammad, 2016), to discrete categories like ours (i.e., intensity scores per emotion). Overall, the scores vary from 60% to

more than 90%, indicating that our datasets are of high quality.

4 Task Description

Participants were given text snippets and asked to determine the emotions that people may attribute to the speaker based on a sentence or short text snippet uttered by the speaker. The task consists of three tracks, and participants could participate in one or more of these tracks.

4.1 Tracks

Track A: Multi-label Emotion Detection Participants were asked to predict the perceived emotion(s) of the speaker and label each text snippet based on the presence (1) or absence (0) of the following emotions: joy, sadness, fear, anger, surprise, and disgust.

Track B: Emotion Intensity Detection Given a text and six emotion classes (i.e., joy, sadness, fear, anger, surprise, and disgust), participants were required to predict whether the intensity of each emotion was 0 (no emotion), 1 (low), 2 (medium), or 3 (high). Note that Track B does not include all languages, as intensity scores were only released for datasets with at least five annotators per instance to ensure more robust and reliable labels.

Track C: Cross-lingual Emotion Detection Similar to Track A, participants were required to predict the presence or absence of each perceived emotion, but without using any training data in the target language. Instead, they were permitted to use labeled dataset(s) from at least one other language. For instance, one could use German data for training when testing on English. This track focuses on cross-lingual transfer and explores how data from various languages can support emotion detection in low-resource settings, as well as the ability of models to generalise across domains.

4.2 Task Organisation

We used Codabench as the competition platform and released pilot datasets before the start of the shared task to help participants better understand the task (i.e., the datasets, the languages involved, and the labels). We provided participants with a starter kit on GitHub, resources for beginners, and organised a Q&A session along with a writing tutorial for junior researchers. Our participants were based in different parts of the world, as shown in Figure 2, with many coming from underrepresented regions. The task consisted of two phases: (1) the development phase and (2) the evaluation phase. During the development phase, the leaderboard was open, allowing a maximum of 999 submissions per participant. In the evaluation phase, the leaderboard was closed, and each participant was allowed up to three submissions, with the last submission being considered for the official ranking.

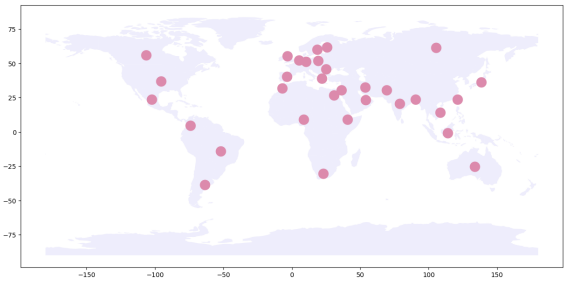

Figure 2: The official affiliations of some of our participants. The list includes 33 countries: Argentina, Australia, Bangladesh, Brazil, Canada, Colombia, Egypt, Ethiopia, Finland, Germany, Greece, India, Indonesia, Iran, Japan, Jordan, Mexico, Morocco, the Netherlands, Nigeria, Pakistan, Poland, Romania, Russia, South Africa, Spain, Sweden, Taiwan, the UAE, the UK, the USA, and Vietnam.

4.3 Evaluation Metrics and Baselines

Evaluation Metrics For Tracks A and C, we use the average macro F-score calculated based on the predicted and the gold-standard labels. For Track B, we use the Pearson correlation coefficient, which captures how well the system-predicted intensity scores of test instances align with human judgments. We provided the participants with an evaluation script on our GitHub page.

Our Baselines We run a simple majority class baseline for each language across all three tracks. Further, for Tracks A and B (Tables 2 and 3, respectively), we fine-tuned RoBERTa using the training data for each language. Table 2 shows the average macro F-scores of the top-performing systems compared to our baseline in Track A, and Table 3 shows the Pearson correlation scores for Track B. For Track C (Table 4), we fine-tuned RoBERTa by training on all languages within a language family while holding out one target language used for testing, e.g., all Indo-European languages except `eng` when testing on it. For language families with only one language, we trained on the Slavic languages (`rus` and `ukr`) and tested on `tat`; on the

Niger-Congo languages (swa and yor) and tested on pcm; and trained on rus when testing on chn.

5 Participating Systems and Results

5.1 Overview

Our task attracted more than 700 registered participants and was featured in the Codabench newsletter as the most popular competition hosted on Codabench in 2024.

In the development phase, 153 submissions were made for Track A, 52 for Track B, and 25 for Track C. In the test phase, 220 submissions were made for Track A, 96 for Track B, and 46 for Track C. The official results include more than 220 final submissions from 93 teams. While the English subtracks received the highest number of submissions, we note that other languages, including underserved ones, were comparable in terms of popularity.

We report results only for teams that submitted a system description paper. **??** presents the results for Track A, which had 87 participating teams. **??** shows the results for Track B, with 38 participating teams, while **??** reports the results for Track C, which had 21 participating teams.

5.2 Track A: Multi-label Emotion Detection

5.2.1 Best-Performing Systems

Team Pai proposes one of the most effective models in the competition. They consistently rank as the top approach in Track A for 20 out of 28 languages. For their system, they combine several base models (ChatGPT-4o (OpenAI, 2024), DeepSeek-V3 (DeepSeek-AI et al., 2025), Gemma-9b (Team et al., 2024), Qwen-2.5-32b (Yang et al., 2024), Mistral-Small-24B (Jiang et al., 2024)) using multiple ensemble techniques (neural networks, XGBoost, LightGBM, linear regression, weighted voting). They fine-tune Gemma-9b and Qwen-2.5-32b using AdaLoRA. For prompting the LLMs, they used an iterative prompt-optimisation technique that generates prompt variations.

Team Chinchunmei ranks in the top 10 in 16 languages in Track A and 12th in English. They use sample contrastive learning, where performance is enhanced by comparing sample pairs, and generative contrastive learning, where the models learn to distinguish correct from incorrect predictions. Their samples are randomly selected from the

task dataset (no external augmentation). They use LLaMa3-Instruct-8B (AI@Meta, 2024) for their fine-tuning.

5.2.2 Takeaways

Most of the teams that rank well on Track A experiment with essentially two methodologies: 1) fine-tuning BERT-based models such as DeBERTa (Siino, 2024), mBERT (Dolev, 2023), and XLM-R (Conneau et al., 2020); and/or 2) instruction-fine-tuning using LoRa methodologies in combination with prompt design and data augmentation techniques on LLMs (ChatGPT-4o, DeepSeek-V3, Gemma-9b, Qwen-2.5-32b, Mistral-Small-24B). For instance, Team Telai (3rd in Chinese), Team Empaths (2nd in Hausa and Somali, and 1st in Swahili), Team NYCU-NLP (2nd in English), Team JNLP (1st in Hindi and among the best four across 10 languages), Team Unibouc (1st in Emakhuwa), Team Heiderdinger (2nd in Mozambican Portuguese, German, Spanish, Brazilian Portuguese, and Yorùbá; 1st in Russian), and Team Maomao (2nd in Afrikaans).

Few teams focus on only a subset of languages or explore language-related knowledge in their methodology. For instance, Team Lazarus NLP redefined and reformulated the multi-label classification into multiple binary tasks to expand training samples. They also explored how knowledge could potentially be transferred between Indonesian languages. All the top 10 teams performed significantly better than our baseline model, with an improvement that is more notable in a few low-resource languages, such as Oromo, where Team Tewodros obtained an average macro-F1 score of 0.616 compared to a baseline of 0.126. The same was observed for Yorùbá, where Team Pai scored 0.461 compared to a baseline score of 0.092.

5.3 Track B: Emotion Intensity Detection

5.3.1 Best-Performing Systems

Team Pai Similar to Track A, Team Pai ranked at the top across all languages in Track B, except for Amharic. They used an ensemble of LLMs, combining several base models (ChatGPT-4o(OpenAI, 2024), DeepSeek-V3 (DeepSeek-AI et al., 2025), Gemma-9b (Team et al., 2024), Qwen-2.5-32b (Yang et al., 2024), Mistral-Small-24B) with multiple ensemble techniques (neural networks, XGBoost, LightGBM, linear regression, weighted voting). They fine-tuned the Gemma and Qwen models using AdaLoRA. For prompting the LLMs, they employed an iterative prompt-optimisation technique to generate prompt variations.

Table 3: Pearson correlation scores for our baselines (Majority: $M_{baseline}$ and RoBERTa: $R_{baseline}$) and the top two performing systems in Track B (shown in bold) for each language.

Team CSECU-Learners CSECU-Learners ranked at the top in Amharic by fine-tuning language-specific transformers (XLM-Roberta (Conneau et al., 2020) for Amharic) with a classification layer and multi-sample dropout.

5.3.2 Takeaways

Teams Deepwave, Teleai, and JNLP also ranked highly across various languages using prompt engineering approaches similar to those in Track A. Additionally, Team NYCU-NLP ranked second in English by aggregating instruction-tuned small language models. All these teams outperformed our RoBERTa baseline, which achieved moderate Pearson correlation coefficient scores overall, but performed poorly in languages such as Algerian Arabic, Hausa, Ukrainian, and even Brazilian Portuguese -highlighting the difficulty of the task.

Overall, we observe that most teams adopted approaches similar to those used in Track A, with only minor adjustments to the prompts. Notably, even the best-performing teams achieved a Pearson correlation coefficient of no more than 0.65

Table 4: Average macro-F1 scores for our baselines ($M_{baseline}$ and $R_{baseline}$, referring to the Majority Vote and RoBERTa baselines, respectively) and the top two performing systems in Track C (shown in bold) for each language.

on Algerian Arabic, likely due to the novelty and complexity of the dataset.

5.4 Track C: Cross-lingual Emotion Detection

5.4.1 Best-Performing Systems

Team deepwave Team Deepwave fine-tuned Google Gemma-2 (Team et al., 2024) using tailored data augmentation and Chain-of-Thought (CoT) prompting. They decomposed the task into two sub-tasks: (1) sentiment keyword identification and (2) sentiment polarity recognition.

To address the challenge of limited data, they employed k-fold (k=5) cross-validation and used model merging—a strategy that combines the predictions of multiple models to improve generalization—by averaging the prediction probabilities of each model, assigning equal weights of 0.2. In this track, a dedicated LoRA module was trained for each target language. The training dataset for each module comprised data from all other languages in Track A, excluding the target language L_i. They exclusively used augmented data generated through CoT prompting for training.

Team maomao Team maomao experimented with different setups for fine-tuning LLMs. The base models used were Qwen2.5-7B-Instruct, GPT-0544o Mini2, and LLaMA-3.2-3B-Instruct (AI@Meta, 2024). They applied Direct Preference Optimisation to refine their model -a technique that selects high-quality instances from lower-quality ones within a dataset. After this step, they retrained the model using the refined dataset. They also explored random sampling and retrieval-augmented generation (RAG) methods for training, primarily on DeepSeek-V3, Qwen-Max5093, and Grok-V2.

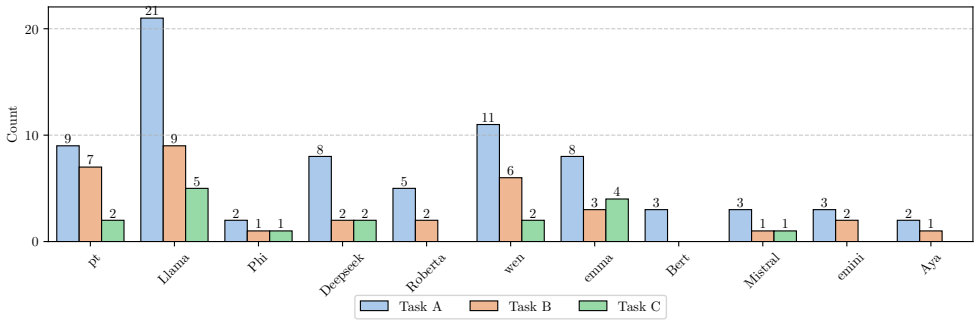

Figure 3: Top LLMs used by participants across tracks (A, B, and C).

5.4.2 Takeaways

Other top-performing systems include Team Ozemi, who fine-tuned a multilingual BERT model and applied machine translation to enhance performance across all languages. They used the Synthetic Minority Oversampling Technique (SMOTE) with TF-IDF to address class imbalance in Russian. They translated all the datasets into a common language using Google Translate before processing -except for Nigerian Pidgin and Emakhua, where they used a multilingual BERT model for translation. They also leveraged two Kaggle competition datasets for data augmentation.

Team heimerdinger, who ranked highest in Javanese, built their approach using various LLMs (LLaMA 3.1 8B, Qwen 2.5 7B, DeepSeek-7B, MistralV0.3-7B, and Gemma2-9B) for Track C. They employed in-context learning with multilingual examples from high-resource languages such as English and Spanish.

Overall, the participating teams outperformed our baselines. However, the average scores for this track are notably lower, particularly in low-resource languages, due to the additional challenges posed by limited data and resources. As shown in Table 4, there are significant performance gaps -even the top systems did not achieve an F-score higher than 0.50 in languages such as Javanese, Somali, Sundanese, Xhosa, Yorùbá, isiZulu, and Emakhuwa (where the top system achieved an F-score of only 0.21).

6 Discussion

Popular Methods Unsurprisingly, most top-performing teams favored fine-tuning and prompting large language models (LLMs) such as Gemma-2, Mistral, Phi-4, Qwen-2.5, DeepSeek, LLaMA-3, GPT, and Gemini models. For fine-tuning, both full fine-tuning and parameter-efficient fine-tuning were the most commonly used strategies to enhance performance.

For prompting, few-shot, zero-shot, and chain-of-thought prompting were the most frequently used techniques.

Many participants also experimented with traditional transformer-based models, particularly XLM-RoBERTa, mBERT, DeBERTa, and IndicBERT (Kakwani et al., 2020) (see Figure 3 and **??** in the Appendix).

Best Performing Systems The results from the top-performing submissions suggest that while LLMs achieve strong overall performance, their effectiveness is heavily dependent on prompt engineering techniques and wording.

Additionally, performance varies significantly by language. Across all tracks, LLM-based approaches and the best-performing systems consistently yielded better results for high-resource languages such as English and Russian. In contrast, performance dropped notably when tested on low-resource languages such as Swahili and Emakhuwa.

Furthermore, most teams did not incorporate additional datasets to enhance performance (see Appendix), as few-shot and zero-shot approaches proved highly effective.

7 Conclusion

We presented our shared task on text-based emotion recognition, which covered three tracks and a total of 32 languages. The submitted systems were ranked based on macro F1-scores for Tracks A and C, comparing predicted labels to gold labels, and based on the ranking of predicted intensity scores for Track B.

We summarised the reported results, discussing the best-performing and most innovative methods.

Overall, performance varied significantly across languages. Our results highlight that emotion recognition remains an open challenge, particularly for under-served languages and in low-resource settings.

8 Limitations

Emotions are subjective and subtle, and they are expressed and perceived differently. We do not claim that our datasets capture the true emotions of the speakers, fully represent language use across the 32 languages, or cover all possible emotions. We discuss the ethical considerations extensively in Section 9.

We acknowledge the limited data sources available for some low-resource languages. Therefore, our datasets may not be suitable for tasks requiring large amounts of data in a given language. However, they serve as a valuable starting point for research in this area.

9 Ethical Considerations

Emotion perception and expression are subjective and nuanced, as they are influenced by various factors (e.g., cultural background, social group, personal experiences, and social context). Thus, it is impossible to determine someone's emotions with absolute certainty based solely on short text snippets. Our datasets explicitly focus on perceived emotions—identifying the emotions that most people believe the speaker may have felt. We do not claim to annotate the speaker's true emotions, as these cannot be definitively determined from text alone. We recognise the importance of this distinction, as perceived emotions may differ from actual emotions.

We acknowledge potential biases in our data, as we rely on text-based communication, which inherently carries biases from data sources and annotators. Additionally, while many of our datasets focus on low-resource languages, we do not claim they fully represent these languages' usage. Further, although we took measures to filter inappropriate content, some instances may have been overlooked.

We explicitly urge careful consideration of ethical implications before using our datasets. We prohibit their use for commercial purposes or by state actors in high-risk applications unless explicitly approved by the dataset creators. Systems built on our datasets may not be reliable at the individual instance level and are susceptible to domain shifts. Thus, they should not be used for critical decision-making, such as in health applications, without expert supervision. For a more in-depth discussion, see Mohammad (2022, 2023).

Finally, all annotators involved in the study were compensated above the minimum hourly wage.

SemEval-2025 Task 5: LLMs4Subjects - LLM-based Automated Subject Tagging for a National Technical Library's Open-Access Catalog

Jennifer D'Souza, Sameer Sadruddin, Holger Israel, Mathias Begoin, and Diana Slawig
TIB Leibniz Information Centre for Science and Technology, Hannover, Germany
{firstname.lastname}@tib.eu

Abstract

We present SemEval-2025 Task 5: LLMs4Subjects, a shared task on automated subject tagging for scientific and technical records in English and German using the GND taxonomy. Participants developed LLM-based systems to recommend top-k subjects, evaluated through quantitative metrics (precision, recall, F1-score) and qualitative assessments by subject specialists. Results highlight the effectiveness of LLM ensembles, synthetic data generation, and multilingual processing, offering insights into applying LLMs for digital library classification.

1 Introduction

Subject classification within library systems involves organizing books and resources based on their content and subject matter to facilitate easy retrieval and access. Automated methods for classifying scientific texts include Springer Nature's CSO classifier (Salatino et al., 2019), which uses syntactic and semantic analysis to categorize papers based on the Computer Science Ontology (CSO) using abstracts, titles, and keywords. Other approaches have utilized citation metadata for classification (Mahdi and Joorabchi, 2011), while research like New Mexico State University's application of topic modeling on digital news releases (Glowacka-Musial, 2022) demonstrates the diversity of techniques. Methods range from embeddings (Buscaldi et al., 2017; Růžička and Sojka, 2021) and deep learning (Ahanger and Wani, 2022) to citation analysis (Small et al., 2014) and topic modeling (Bolelli et al., 2009; Griffiths and Steyvers, 2004). Thus, while the use of NLP in digital library subject classification is well-established (Gooding et al., 2019), the potential for leveraging Large Language Models (LLMs) for their extensive knowledge representation remains largely unexplored.

Several open-source toolkits integrate machine learning (ML) and NLP for automated subject indexing, notably ANNIF (https://annif.org/), developed by the National Library of Finland, as a DIY automated subject indexing tool supporting the training of multiple traditional machine learning algorithms (Suominen, 2019). ANNIF allows users to train models on a chosen subject taxonomy and metadata to generate subject headings for new documents. It has performed well on scientific papers and books but struggles with older or diverse materials like Q&A pairs or Finnish Wikipedia. European national libraries, including Sweden's National Library, the Leibniz Information Centre for Economics, and the German National Library, have adopted ANNIF. Supporting multiple languages and vocabularies, it offers command-line, web, and REST API interfaces, demonstrating the adaptability required for effective subject classification.

With these insights, as a SemEval 2025 shared task, we organized Task 5 — LLMs4Subjects — to explore the untapped potential of LLMs for subject classification and tagging. The task was defined on the catalog of the TIB – Leibniz Information Centre for Science and Technology, Germany's national library for science and technology. Its catalog, TIBKAT, holds 5.7 million records (as of March 2025), including bibliographic data and metadata from freely available electronic collections. A subset of around 100,000 records is available as open access, and the task focused on this subset. The collection includes various record types such as technical reports, publications, and books, primarily in English and German. Regardless of full-text language, records are consistently annotated using subject terms from the Gemeinsame Normdatei (GND), the integrated authority file and subject taxonomy used in the German library system. LLMs offer promising opportunities for subject classification through their ability to process natural language at scale and capture the nuances of complex, interdisciplinary topics. This can significantly improve the accuracy and efficiency of organizing

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2570–2583

large collections, enhancing the accessibility and discoverability of information. The solutions developed in this task serve as a benchmark for applying LLMs in digital library systems, fostering innovation and setting new standards in the field. Moreover, the task aligns with the goals of the SemEval series by evaluating a novel application of computational semantics essential for effective information organization and retrieval.

While the shared task focused on practical systems development, it was also driven by the following four research questions. **RQ1** Multilingual vs. Monolingual Models in Subject Tagging: How do multilingual pre-trained models compare to monolingual models in bilingual subject tagging tasks?, **RQ2** Effect of Training Data Size and Diversity: How does the size and diversity of training data affect LLM performance in subject tagging?, **RQ3** Role of Augmented Generation: How impactful are RAG approaches versus finetuning?, and **RQ4** Efficiency of Language Models: How effective are small versus large LMs in performing the task?

A key observation from the systems submitted to this shared task is that the advantages of LLMs over traditional machine learning algorithms for subject indexing remain debatable (Kluge and Kähler, 2024). While the first iteration of this shared task brings this question to light, to further explore the possibilities offered by LLMs, we will reorganize the LLMs4Subjects shared task a second time and this time with a theme to build solutions based on *energy- and compute-efficient LLMs*.

2 Background

About TIB. TIB – the Leibniz Information Centre for Science and Technology and University Library – promotes free access to knowledge, information sharing, and open scientific publications and data. As Germany's national library for science and technology, including Architecture, Chemistry, Computer Science, Mathematics, and Physics, it maintains a globally unique collection, including audiovisual media and research data.

About the TIBKAT Open-access Subset. A subset of TIB's collection—including bibliographic data in science and technology from its library catalog (TIBKAT Data), metadata from freely available electronic collections, and metadata with thumbnails from the TIB AV-Portal—is made available under the CC0 1.0 Universal Public Domain Dedication, allowing unrestricted use. More here.

The GND Taxonomy. The Gemeinsame Normdatei[1] (GND, German for "integrated authority file") is an international authority file used primarily by German-speaking library systems to catalog and link information on topics, organizations, people, and works. It is publicly available for download[2] in various formats under a CC0 license. The GND's records specifically cover entities such as persons, corporate bodies, conferences, geographic locations, subject headings, and works, relevant to cultural and scientific collections.

For the LLMs4Subjects shared task, only the GND subject heading (Sachbegriff) records are of interest. Since accessing the GND for the first time for new users can be overwhelming, for the convenience of our participants, we have created a how-to guide to download the latest GND file.

3 Source Dataset

We queried the TIBKAT service to restrict its metadata to records containing abstracts and GND subject indexing. The query is fully reproducible via this persistent search link. It returned 189,665 records at the time of dataset creation. The TIB open-access catalog spans nine media types: Book (136,434), Thesis (31,859), Conference (12,212), Report (6,711), Article (2,080), Collection (188), AudioVisualDocument (167), Periodical (57), and Chapter (11), detailed in Appendix A. Using the `langdetect`[3] Python library, we identified 48 languages. The top five were German (108,637), English (76,735), French (1,741), Indonesian (945), and Spanish (311).[4] For the official shared task corpus, we retained only records in German and English and excluded the four least represented media types, resulting in a dataset of 123,589 records. The excluded data is available as supplementary data. The final shared task dataset is available at: `https://github.com/jd-coderepos/llms4subjects/tree/main/shared-task-datasets`.

3.1 How are subject annotations obtained?

Subject annotations in the TIB catalog are continuously created by a dedicated team of

[1] `https://www.dnb.de/EN/gnd`

[2] The GND is available for download at `https://www.dnb.de/EN/Professionell/Metadatendienste/Datenbezug/Gesamtabzuege/gesamtabzuege_node.html`.

[3] `https://pypi.org/project/langdetect/`

[4] Reflecting the real-world nature of the corpus, many records contain mixed-language content and are not reliably classifiable under a single language.

statistics	lang	Article	Book	Conference	Report	Thesis
num. records	en	1,042/253	26,966/17,669	3,619/2,840	1,275/896	3,452/2,506

Table 1: Train dataset statistics (all-subjects/tib-core collections) for the LLMs4Subjects shared task.

17 expert subject specialists covering 28 disciplines—including Architecture, Chemistry, Electrical Engineering, Mathematics, Traffic Engineering, and others—ensuring broad and expert-driven subject classification.

In libraries, content is typically described using controlled vocabularies. In Germany, the GND is used for cataloging literature. In addition to descriptive cataloging (e.g., author, title, year, publisher), subject cataloging is performed by subject librarians. Based on the title, abstract, and full text, librarians assign appropriate GND keywords to describe the content as precisely as possible. This collaborative work is carried out across various libraries and national library networks.

With TIB adding around 15,000 new titles each month, subject cataloging is a labor-intensive task. Integrating AI-driven solutions—especially LLMs—can significantly boost efficiency, partially automate workflows, and improve usability, all while maintaining cataloging quality. Such innovations are key to modernizing information management and supporting research at scale.

4 Shared Task Description and Dataset

The LLMs4Subjects shared task challenged participants to develop LLM-based systems for recommending relevant subjects from the GND taxonomy to annotate TIB technical records. Given a record's title and abstract as input, systems were expected to generate a customizable top-k ranked list of relevant GND subjects. Since the dataset included records in both English and German, systems were required to support bilingual semantic processing. The task was defined over two dataset collections.

4.1 Dataset Collections

all-subjects.[5] This dataset comprises the full TIBKAT open-source collection, with predefined splits: 81,937 records for training and 13,666 for development. A detailed dataset overview is available in the shared task repository. Participants also received the accompanying GND subject taxonomy,[6] which included 204,739 subjects, with coverage and distribution frequencies published online.

Due to the large dataset size (>100,000 records), participants could opt for a smaller subset focused on TIB's core subject classification.

tib-core.[7] This subset includes only records annotated with at least one GND subject from the so-called TIB core domains. It contains 41,902 training and 6,980 development records across 14 domains: Architecture (arc), Civil Engineering (bau), Mining (ber), Chemistry (che), Chemical Engineering (cet), Electrical Engineering (elt), Materials Science (fer), Information Technology (inf), Mathematics (mat), Mechanical Engineering (mas), Medical Technology (med), Physics (phy), Engineering (tec), and Traffic Engineering (ver). A refined GND subject taxonomy[8] with 79,427 subjects accompanied this dataset, along with subject coverage and frequency distributions.

Participants could choose between the all-subjects dataset for comprehensive indexing, the tib-core dataset for a more focused classification task, or even attempt both.

4.2 Dataset Format and Statistics

Both datasets were released in JSON-LD format and include metadata such as title, type, abstract, and authors. The key attribute for the task, `dcterms:subject`, holds the GND subject headings assigned to each record. Example records are available in English here and in German here. Table 1 provides a detailed dataset breakdown. Books were the most common record type in both language collections, with each record annotated with an average of 3 to 7 subjects.

[8] https://github.com/jd-coderepos/llms4subjects/blob/main/shared-task-datasets/GND/dataset/GND-Subjects-tib-core.json

5 Task Setup

The shared task offered multiple communication channels: a dedicated website,[9] a Google Group for FAQs, and direct email support (llms4subjects@gmail.com). The organizing team included two Computer Scientists and three TIB subject specialists who supported participants throughout. The task timeline spanned four months, from October 2024 to January 2025. A Declaration of Interest for Participation (DIP) survey initially recorded **33 teams**; of these, **14 teams** submitted system outputs, and **12** also contributed system description papers to the SemEval workshop. The next section summarizes their approaches.

6 Shared Task Participant Systems

The participant systems are described with a focus on their key methodological contributions. Teams are listed in alphabetical order of their names. An overview of the systems is provided in Table 2.

1. Annif (Suominen et al., 2025) The key ideas in this system's subject tagging approach were: 1) **Traditional extreme multi-label text classification (XMTC)** implemented in the Annif toolkit (2022) – Using Omikuji Bonsai (Khandagale et al., 2020), a tree-based machine learning approach; MLLM (Maui-like (Medelyan, 2009) Lexical Matching), a lexical matching algorithm; and XTransformer, a transformer-based classification model (Yu et al., 2022) for XMTC. 2) **Ensemble Models** – Combining individual classifiers into simple averaging and neural ensembles to improve predictions. 3) **LLM-Assisted Translation** – Using the Llama-3.1-8B-Instruct LLM (2024) to translate bibliographic records and subject vocabularies into English and German. 4) **Synthetic Data Generation** – Expanding training data with the same LLM by generating new records with modified subject labels. And 5) **Multilingual Merging** – Combining monolingual predictions to form a multilingual ensemble, improving overall performance.

2. DNB-AI-Project (Kluge and Kähler, 2025) This was an LLM-driven ensemble approach which achieved top qualitative scores without fine-tuning and few-shot prompting. Key steps included: 1) **LLM Ensemble for Keyword Generation** – Multiple off-the-shelf LLMs use few-shot prompting with 8-12 examples to improve recall and precision. 2) **Map** – A BGE-M3 embedding model (Chen et al., 2024) maps LLM-generated free keywords to controlled GND subject terms via nearest neighbor search. 3) **Summarize** – Predictions from the LLM ensemble are aggregated, with similarity scores summed and normalized into a confidence-based score. 4) **Rank** – A new LLM, Llama-3.1-8B-Instruct (2024) assesses relevance of each predicted term on a 0-10 scale, refining rankings beyond frequency-based measures. And 5) **Combine** – Ensemble and relevance scores are weighted and combined to optimize subject ranking.

3. DUTIR831 (Tian et al., 2025b) The key steps of this system are: 1) **Data Synthesis and Filtering** – The Qwen2.5-72B-Instruct LLM is used to generate synthetic data to expand training sets by selecting related subject terms and creating titles and abstracts. The LLM is then applied to filter low-quality samples based on coherence and relevance. 2) **GND Knowledge Distillation** – The LLM is then finetuned on GND subject collections improves its understanding of subject hierarchies and relationships. 3) **Supervised Fine-Tuning and Preference Optimization** – LoRA-based (Hu et al., 2022) fine-tuning on TIBKAT data is combined with Direct Preference Optimization (DPO) (Rafailov et al., 2023) to align model outputs with human-like subject assignments. 4) **Subject Term Generation** – A multi-sampling ranking strategy improves diversity, LLM-based keyword extraction selects high-confidence terms, and BGE-M3 (2024) embedding-based vector retrieval adds missing terms to ensure 50 subject labels per record. And 5) **Re-Ranking for Final Selection** – Subject terms from multiple sources are re-ranked using LLMs to prioritize the most relevant terms, improving recall and ranking consistency.

4. Homa (Bayrami Asl Tekanlou et al., 2025) Subject tagging is tackled using retrieval-augmented generation (RAG) (Lewis et al., 2020) to match TIBKAT records with GND subjects leveraging the OntoAligner toolkit (Giglou et al., 2025). The key methods steps are: 1) **Multi-Level Data Representation** – Records are represented at three levels: title-based, contextual (including metadata), and hierarchical (parent-level relationships) to improve subject mapping. 2) **Retrieval with Embeddings** – Nomic-AI embeddings (Nussbaum et al., 2024) are used to retrieve the top-k relevant subjects by computing cosine similarity between records and subject embeddings. 3) **LLM-Assisted Subject Selection** – Qwen2.5-0.5B-Instruct LLM (Yang et al., 2024) assesses retrieved subjects, verifying rele-

Team	Method	LLMs Used	Ranking
Annif	LLM-based synthetic data generation and XMTC traditional classifier models ensemble	Llama-3.1-8B-Instruct	1st all-subjects, 2nd tib-core, 4th qualitative
DNB-AI	Few-shot prompting to an LLM ensemble	Llama-3.2-3B-Instruct, Llama-3.1-70B-Instruct, Mistral-7B-v0.1, Mixtral-8x7B-Instruct-v0.1, OpenHermes-2.5-Mistral-7B, Teuken-7B-instruct-research-v0.4, LLama-3.1-8B-Instruct	4th all-subjects, N/A tib-core, 1st qualitative
DUTIR831	Synthetic data generation, GND knowledge distillation, and supervised finetuning	Qwen2.5-72B-Instruct	2nd all-subjects, 4th tib-core, 2nd qualitative
Homa	RAG-based ranking and retriever fine-tuning	Qwen2.5-0.5B	N/A all-subjects, 10th tib-core, 10th qualitative
Jim	BERT model ensemble	German BERT, Multilingual cased/uncased, ModernBERT base	7th all-subjects, N/A tib-core, 5th qualitative
LA²I²F	Transfer of concepts from similar documents to target and concept similarity to target document	Llama-3.1-8B as baseline, all-mpnet-base-v2 Sentence Transformer	6th all-subjects, 3rd tib-core, 8th qualitative
last_minute	Subjects are ranked, then re-ranked with embeddings, and refined with an LLM	stella-en-400M-v5, granite-embedding-125m-english, Llama-3.2-1B	N/A all-subjects, 9th tib-core, 11th qualitative
NBF	Finetuned embeddings using Burst Attention and multi-layer perceptron	all-mpnet-base-v2, german-roberta	9th all-subjects, N/A tib-core, 9th qualitative
RUC Team	Retrieves pre-indexed similar records and uses their subject tags as candidates	Arctic-Embed 2.0, Llama-8B, Chat GLM 4 (130B)	3rd all-subjects, 1st tib-core, 3rd qualitative
silp_nlp	Multilingual sentence transformer-based embedding similarity	jina-embeddings-v3-559M, distiluse-base-multilingual-cased-v2	11th all-subjects, 6th tib-core, N/A qualitative
TartuNLP	Bi-encoder candidate subject retrieval, and finetuned cross-encoder re-ranking model	multilingual-e5-large-instruct, mdeberta-v3-base	8th all-subjects, 7th tib-core, 7th qualitative
YNU-HPCC	Combines Sentence-BERT with contrastive learning	distilroberta, minilm, mpnet	10th all-subjects, 8th tib-core, 12th qualitative

Table 2: Overview of teams, methods, LLMs used, and rankings from quantitative scores over the two dataset collections and from the qualitative evaluations. The full leaderboard is released on our shared task website.

vance in a RAG-based ranking framework. And 4) **Fine-Tuning with Contrastive Learning** – The retriever is fine-tuned using contrastive learning, training on positive and negative record-subject pairs to improve distinction between relevant and irrelevant subjects.

5. Jim (Hahn, 2025) The key method steps of this system are: 1) **Multilingual BERT Ensemble** – The system uses an ensemble of four BERT models (two multilingual m1 & m2, one German-only, one English-only). 2) **Fine-Tuning on TIBKAT and GND Data** – The models are finetuned on TIBKAT records paired with GND subject labels, leveraging the AutoTrain framework (Thakur, 2024) for efficient optimization. 3) **Ensemble-Based Inference** – Subject predictions are ranked by summing confidence scores across models.

6. LA^{2}I^{2}F (Salfinger et al., 2025) The system retrieves subjects based on document similarity (analogical reasoning) and semantic similarity with ontology concepts (ontological reasoning), combining both for optimal subject tagging. The key steps are: 1) **Embedding-Based Retrieval** – MPNet sentence embeddings (Reimers and Gurevych, 2019) are used to represent documents and GND subjects in a shared vector space, enabling similarity-based matching. 2) **Analogical Reasoning for Subject Transfer** – The system identifies semantically similar training documents and transfers their human-assigned subject labels to the target document. 3) **Ontology-Based Subject Matching** – GND subjects are embedded and matched to documents based on semantic closeness, retrieving the most conceptually relevant subjects. And 4) **Final Fusion and Re-Ranking** – Predictions from both methods are merged and ranked by similarity, ensuring complementary information is integrated.

7. last_minute (Sarlak and Ansari, 2025) The system followed a rank, rerank, and refine approach using contextual vector embeddings stored in the

Milvus vector database for efficient retrieval. The key steps are: 1) **Finetuned Embedding Model** – The stella-en-400M-v5 model (Zhang et al., 2024) is finetuned on the training data with Multiple Negatives Ranking Loss (Henderson et al., 2017). 2) **Re-Ranking with a Cross-Encoder Model** – A granite-embedding-125m model (Granite Embedding Team, 2024) re-ranks the top 100 retrieved subject tags from the prior step, refining predictions before LLM processing. And 3) **LLM Refinement** – The Llama-3.2-1B LLM (2024) evaluates and selects the top 50 most relevant subject tags from the re-ranked list using prompt-based filtering.

8. NBF (Islam et al., 2025) The system introduces the use of Burst Attention (Sun et al., 2024), a lightweight self-attention mechanism that treats each embedding dimension as a token, capturing inter-dimensional dependencies to enhance subject retrieval. The methodology consists of four key steps. 1) **Sentence Transformer Embeddings** (2019): Articles and GND subjects are embedded using all-mpnet-base-v2 for en and german-roberta-sentence-transformer-v2 for de, aligning them in a shared space. 2) **Margin-Based Retrieval with BurstAttention**: The model is trained with a margin-based ranking loss, leveraging BurstAttention to refine embeddings by bringing relevant subjects closer and pushing irrelevant ones away. 3) **Feed-Forward MLP for Refinement**: A multilayer perceptron (MLP) further refines embeddings to improve subject retrieval accuracy. 4) **Top-k Search**: At inference, cosine similarity between article and subject embeddings is computed, selecting the top-k closest subjects as final predictions.

9. RUC Team (Tian et al., 2025a) This team used a retrieval-based method, prioritizing accuracy, speed, and scalability over heavy LLM inference. Key steps are: 1) **Cross-Lingual Embeddings for Retrieval** – Uses Arctic-Embed 2.0 (Yu et al., 2024), a multilingual embedding model, to match documents across English and German in a shared semantic space. 2) **Vector-Based Nearest Neighbor Search** – Computes inner product similarities between document embeddings using Faiss indexing to efficiently retrieve the most relevant records. And 3) **Ranking Relevant Subject Terms** – Merges and re-ranks candidate subjects based on document similarity, term position, and term occurrence in the title/abstract.

10. silp_nlp (Singh et al., 2025) This system utilizes **sentence transformer embeddings** (2019) for titles and abstracts, retrieving subjects based on cosine similarity. It employs JinaAi/jina-embeddings-v3 (Sturua et al., 2024), a **novel multilingual model supporting 89 languages**, to process both en and de text. Performance was compared against distiluse sentence transformers, with JinaAi embeddings achieving superior results.

11. TartuNLP (Dorkin and Sirts, 2025) The system first retrieves a coarse set of candidate subjects using a **bi-encoder**, viz. multilingual-e5-large-instruct (Wang et al., 2024), then refines the selection with a **cross-encoder re-ranking model**, viz. mdeberta-v3-base model (He et al.), finetuned on the task dataset. The key insight being the two-stage approach nearly doubles recall compared to using the bi-encoder alone, confirming the cross-encoder re-ranking's impact on performance.

12. YNU-HPCC (Mao et al., 2025) The system fine-tuned multilingual sentence-BERT models, such as paraphrase-multilingual-MiniLM, -mpnet, and mpnet-base, using contrastive loss, to improve semantic alignment between the records and subjects. Key was their **Balanced Positive-Negative Sampling** – Two strategies were tested: multi-label sampling, aggregating all true labels per document, and single-label sampling, constructing 1:1 positive-negative pairs to improve classification.

The shared task attracted a diverse range of systems. A review of the 12 submissions revealed unique methodological contributions, including Burst Attention (Islam et al., 2025), analogical/ontological reasoning (Salfinger et al., 2025), the use of toolkits like Annif (2022) (Suominen et al., 2025) and OntoAligner (2025) (Bayrami Asl Tekanlou et al., 2025), and multi-stage prompt engineering. Some teams (Tian et al., 2025a; Singh et al., 2025) also evaluated newer embedding models such as Arctic-Embed and JinAI. As shown in Table 2, top-performing systems went beyond standard sentence transformer embeddings (2019). Key strategies among the leading teams—Annif (Suominen et al., 2025), DNB-AI (Kluge and Kähler, 2025), DUTIR831 (Tian et al., 2025b), RUC Team (Tian et al., 2025a), and Jim (Hahn, 2025)—included: (1) model ensembles, (2) synthetic training data generation, and (3) multilingual language models, the latter being common across submissions. Notably, DUTIR831 and RUC Team deployed very large LLMs—Qwen2.5-72B-Instruct and ChatGLM 4 (130B)—while others used models with 8B or fewer parameters.

In the next section, we present the leaderboard results for the shared task.

7 Shared Task Leaderboard Results

In this shared task, we provided two leaderboards: 1) quantitative results and 2) qualitative results.

Quantitative Metrics. System performance was evaluated using average precision@k, recall@k, and F1-score@k at multiple cutoffs (k = 5, 10, 15, ..., 50). These metrics were chosen as subject tagging was treated as a bag-of-words among applicable subjects, making precision, recall, and F1-score more suitable. Given the dataset structure of the LLMs4Subjects shared task, evaluation scores were released at varying levels of granularity: (1) language-level, separately for en and de, (2) record-level, across five types of technical records, and (3) combined language and record-levels, offering a comprehensive performance breakdown. This approach provided deeper insights into system performance and facilitated detailed discussions in the task overview and system description papers. To ensure transparency, the shared task evaluation script was publicly released.

Qualitative Metrics. To assess system-generated results in real-world scenarios, a qualitative evaluation was conducted over three weeks. TIB subject specialists manually reviewed 122 test records common to both all-subjects and tib-core, sampling 10 records from each of 14 subject classifications. The top 20 GND codes from teams' submissions were extracted, and subject librarians labeled them as Y (correct), I (irrelevant but technically correct), or N/Blank (incorrect). Two evaluation criteria were used: case 1 - treating both Y and I as correct, and case 2 - considering only Y. Results were summarized using average P@20, R@20, and F1@20.

Detailed results leaderboards are released on the shared task website.

7.1 Quantitative Evaluations

The primary evaluation metric was recall, with the overall leaderboard ranking based on average recall scores across k values from 5 to 50. For practical use by subject specialists, systems should predict relevant subjects at lower k values, ideally between 5 and 10, with a maximum of 20. Table 3 presents the results for both collections: all-subjects and tib-core. The top teams consistently predicted over half of the subject annotations in both collections. A caveat here is that our precision score would never amount to one and heavily penalizes actual system performance.[10] Despite this, they were included to provide a comparison. The top three teams based on average recall for all-subjects were Annif, DUTIR831, and RUC Team, while for tib-core, the top three were RUC Team, Annif, and LA^{2}I^{2}F. Notably, the top-performing teams on all-subjects maintained strong rankings on tib-core, with DUTIR831 placing fourth. LA^{2}I^{2}F, ranking third on tib-core, appeared more effective on the smaller subjects taxonomy of tib-core.

At the record-type level (Figure 1a), most systems achieved high recall@5 for articles in both collections, while books, conference papers, and reports showed similar performance. The weakest results were observed for theses. For the top teams on all-subjects (Annif, DUTIR831, and RUC Team), precision scores across record types were similar (Figure 1b). RUC Team demonstrated consistently high precision on articles in both collections. On tib-core, LA^{2}I^{2}F's boost to third place stemmed from its high precision on articles—second only to RUC—despite comparable recall scores to other teams. At the language level, results from both recall (Figure 2a) and precision (Figure 2b) showed no significant difference between processing de or en records across all teams. The only consistent variation was that RUC Team performed slightly better on de records, while LA^{2}I^{2}F for en records.

7.2 Qualitative Evaluations

We now turn to the qualitative manual evaluations from the shared task's evaluation phase.

Table 4 shows results for both qualitative evaluation cases. Based on subject librarian assessments, both Y (correct) and I (irrelevant but technically correct) labels were counted as correct in case 1, while only Y was considered correct in case 2. The top 4 teams ranked consistently across both cases, with minor changes among the remaining teams. Case 1 accounts for situations where models predicted multiple semantically similar subjects as top-ranked, leading to generally higher precision scores. However, in practice, it is preferred that models predict semantically distinct and relevant subjects as top-ranked. Therefore, the remainder of this section focuses on case 2, where only Y labels are treated as correct.

[10] Precision@k is the number of correct predictions among the top-k, divided by k. Since TIBKAT records average around 5 true GND subjects, precision is inherently limited at higher k. Even a perfect system would achieve at most 0.5 precision at $k = 10$, as only 5 of 10 predictions can be correct.

Table 4: Qualitative performance comparison across teams for two cases: case 1 — treating both Y and I as correct, and case 2 — treating only Y as correct. Metrics reported are precision and recall at k. The 'Ov. R@k' columns represent the average recall across $k = 5, 10, 15, 20$.

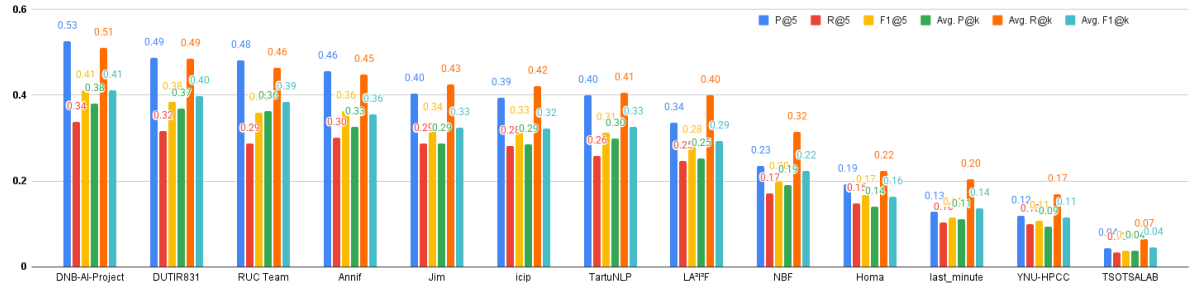

Figure 3: Overall qualitative evaluation results w.r.t. metric@5 and averages per metric@k where k = 5, 10, 15, and 20. On the x-axis, teams are listed in ranked order of performance based on average recall@k.

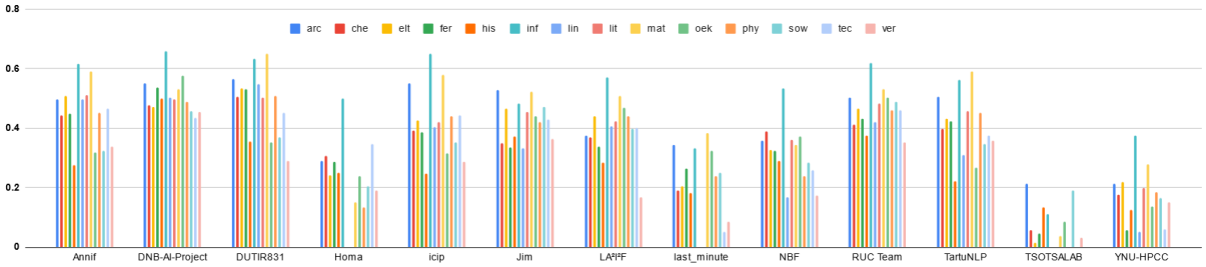
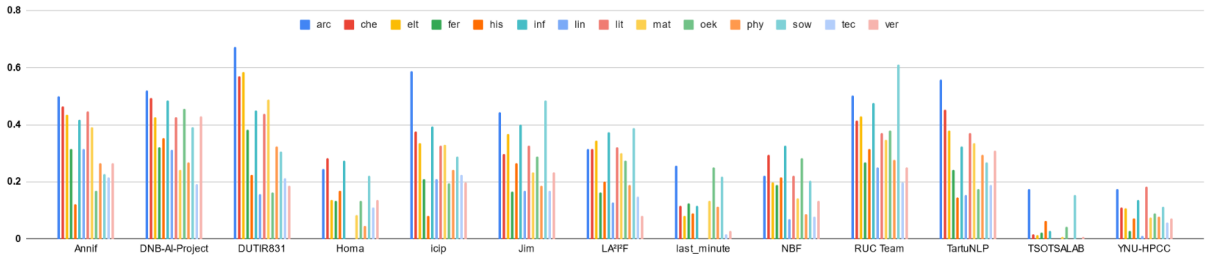


(a) Average recall@k scores per domain over k = 5, 10, 15, and 20.



(b) Average precision@k scores per domain over k = 5, 10, 15, and 20.

Figure 4: Qualitative results per 14 distinct domains. Acronyms used: Architecture (arc), Chemistry (che), Electrical Engineering (elt), Material Science (fer), History (his), Computer Science (inf), Linguistics (lin), Literature Studies (lit), Mathematics (mat), Economics (oek), Physics (phy), Social Sciences (sow), Engineering (tec), and Traffic Engineering (ver). On the x-axis, teams are listed in alphabetical order of names.

The overall results, shown in Figure 3, report six metrics: P@5, R@5, F1@5, Avg. P@k, Avg. R@k, and Avg. F1@k, with k ranging from 5 to 20 in the qualitative setting. These results do not distinguish between all-subjects and tib-core since the 122 evaluated records were shared across both collections.[11] The top teams from the quantitative leaderboard (DUTIR831, RUC Team, and Annif) remained among the top four, with the DNB-AI-Project emerging as the best-performing system in qualitative evaluations. Here, precision reflected true system performance, measuring the proportion of predicted subjects marked correct by subject librarians. Recall was adjusted to account for any newly identified correct subjects not present in the gold standard. DNB-AI-Project stood out for its high precision among the top 20 recalled subjects, employing a purely LLM-based approach with an ensemble of LLMs and few-shot prompting, requiring no fine-tuning. This supports the premise of the shared task—assessing whether LLMs can generalize effectively compared to traditional machine learning approaches that rely on extensive fine-tuning. Among the 14 evaluated domains, Computer Science (inf) consistently had the highest average recall (Figure 4a), while Linguistics (lin) and Literature Studies (lit) showed no predictions from Homa and last_minute. Most teams struggled with Engineering (tec) and Traffic Engineering (ver) records, and Annif and DUTIR831 also exhibited low recall for History (his) and Economics (oek). In contrast, the DNB-AI-Project and RUC Team demonstrated consistent performance across all domains. Finally, as shown in Figure 4b, precision did not always align with recall rankings; the Architecture (arc) domain, however, exhibited the top 2 highest precision among all domains.

8 Discussion

To establish a reference point for the LLMs4Subjects shared task, we developed a baseline system using OpenAI's GPT-4o via the Assistant API.[12] Two assistants were configured—one for all-subjects and another for tib-core—each equipped with the respective GND subject taxonomies stored in OpenAI's vector stores. For each TIBKAT record, the assistants embedded the title and abstract and queried the vector store to retrieve 50 GND subjects.

Both assistants followed an identical prompt that defined their role as a subject matter expert in a technical library using the GND taxonomy. The prompt instructed them to select exactly 50 valid, semantically relevant subject tags based on the input title and abstract, and return them in a strict JSON format. It also enforced constraints such as avoiding duplicates and non-matching entries, and supported bilingual input in German and English.

Despite using a GPT LLM and structured prompt, the Assistant API showed reliability issues: some outputs broke schema constraints or included malformed GND codes, requiring multiple runs. Still in beta, its stability at scale is uncertain. This baseline ranked below all participant submissions on the leaderboard, underscoring that while the API enables quick prototyping, effective subject tagging demands more specialized, robust systems like those of the top teams.

9 Conclusion

SemEval-2025 Task 5: LLMs4Subjects presented the first evaluation of LLMs for GND-based subject indexing in bilingual (German/English) technical library records, combining quantitative metrics with expert assessments. The task revealed four key takeaways: multilingual models and training data outperformed monolingual ones (RQ1, RQ2); synthetic data and retrieval-augmented pipelines improved performance, underscoring the value of data diversity and system design (RQ3); and smaller, well-engineered systems often rivaled large instruction-tuned LLMs, highlighting trade-offs between scale and specialization (RQ4).

All data, code, and evaluation resources are openly available at `https://github.com/jd-coderepos/llms4subjects`. A second edition[13] of the task is planned, with an emphasis on *energy- and compute-efficient* LLM systems.

Acknowledgments

The SemEval Task-5 LLMs4Subjects shared task was jointly supported by the TIB Leibniz Information Centre for Science and Technology, the SCINEXT project (BMBF, Grant 01IS22070), and the NFDI4DataScience initiative (DFG, Grant 460234259).

[11] The silp_nlp team output was not evaluated qualitatively since it was submitted after the deadline.

A TIBKAT media types

Book: A comprehensive written work published as a volume or a series of volumes.
Thesis: A document submitted in support of candidature for an academic degree or professional qualification, presenting the author's research and findings.
Conference: Proceedings or collections of papers presented at academic conferences or symposiums.
Report: Detailed and systematic accounts of research findings, often prepared for a specific audience or purpose.
Article: A written composition on a specific topic, usually intended for publication in a journal or magazine. Collection: A curated assembly of documents or works, typically related by theme, subject, or author.
AudioVisualDocument: Media content that combines both sound and visual components, such as videos or films.
Periodical: Publications issued at regular intervals, such as journals, magazines, or newspapers.
Chapter: A specific section or segment of a book, usually focusing on a particular topic within the larger work.

B TIBKAT Language Distribution

There are 48 different languages in the TIBKAT with abstracts. Their distributions are listed below.

de (German): 108637; en (English): 76735; fr (French): 1741; id (Indonesian): 945; es (Spanish): 311; it (Italian): 294; nl (Dutch): 167; da (Danish): 129; sq (Albanian): 100; ro (Romanian): 93; ca (Catalan): 86; fi (Finnish): 80; so (Somali): 67; sv (Swedish): 65; no (Norwegian): 50; unknown (Unknown): 41; tl (Tagalog): 31; et (Estonian): 24; pt (Portuguese): 16; sw (Swahili (macrolanguage)): 15; pl (Polish): 15; hr (Croatian): 12; lt (Lithuanian): 10; hu (Hungarian): 10; af (Afrikaans): 10; tr (Turkish): 8; sk (Slovak): 7; sl (Slovenian): 4; cy (Welsh): 4; cs (Czech): 3; lv (Latvian): 3; vi (Vietnamese): 2; he (Hebrew): 2; ko (Korean): 1; ru (Russian): 1.

C Additional details about the GND

At TIB, the GND is used as follows. The subject specialists are usually using online services like GND-Explorer (https://explore.gnd.network/) or OGND (https://swb.bsz-bw.de/) for searching the GND. There you can also restrict to Sachbegriff/Topical term (saz), which is the term class we are using for subject indexing (there are some additional term classes used, like geographical terms (swg), but to start topical terms (saz) should be sufficient). New terms are added in a cooperative process and are searchable as soon as they passed a review process. For more general details you can also have a closer look here. There is also a way to get complete sets of the GND that are updated on a regular basis. Details can be found here. A centralized resource pool and a guide for accessing the GND are provided in the LLMs4Subjects GitHub repository https://github.com/jd-coderepos/llms4subjects/tree/main/gnd-how-to.

Note, all terms in GND usually are in German and every TIB record regardless of its language is described by it. But there are some cases, where a term is e.g. English, if the preferred naming is English. In this case a German naming can be listed under synonyms. The synonyms are also important for the subject classification, as many relevant terms are listed under synonyms. These are not always synonyms in a strong sense, as the GND is a growing database and meanings of terms once created do change or shift and larger corrections are rarely realized, if terms are not wrong in sense of content. The GND's purpose extends to enhancing the discoverability of literature in bibliographic systems, where synonyms are also utilized, emphasizing their importance in indexing.

D Pilot Task

At TIB, ANNIF has been used in production code since the start of 2024 for the use case of assigning items from the TIB portal discovery system to one or several subject facets. The TIB portal employs a multi-stage algorithm to attribute a record to one of the 28 TIB's different subjects, viz. Architecture, Civil Engineering, Biochemistry, Biology, Chemistry, Chemical Engineering, Electrical Engineering, Energy Technology, Educational Science, Earth Sciences, History, Information Technology, Literary Studies and Linguistics, Mechanical Engineering, Mathematics, Medical Technology, Plant Sciences, Philosophy, Physics, Law, Study of Religions, Social Sciences, Sports Sciences, Theology, Environmental Engineering, Traffic Engineering, Materials Science, and Economics, the last of which is the so-called automatic stage. If no more salient information is available, machine learning methods are used to assign the subject(s). Note, the subjects reference here can be seen directly akin to fields of study or scientific disciplines, whereas LLMs4Subjects includes a much broader scope for its subjects. Previously utilizing a commercial algorithm, TIB switched to ANNIF for its customization potential and community-driven improvements. The training data of ANNIF algorithms consists of document metadata from the TIB catalog, partially overlapping with the training dataset for LLMs4Subjects. Since the documents to be indexed by ANNIF include many cases where abstracts or fulltexts cannot be accessed programmatically, we only consider the the titles and publishers. ANNIF has shown good overall results in assigning the 14 subjects is has so far been incrementally trained on, with an overall F1 score of ≈ 0.65 for several algorithms. Both English and German-language documents were considered, with little difference in performance when training both languages combined or separately. Leveraging the capabilities of LLMs as a complementary approach to ANNIF marks a logical next step in the automation of subject indexing.

SemEval-2025 Task 4: Unlearning sensitive content from Large Language Models

Anil Ramakrishna[1], Yixin Wan[2], Xiaomeng Jin[3], Kai-Wei Chang[1,2], Zhiqi Bu[1], Bhanukiran Vinzamuri[1], Volkan Cevher[1,4], Mingyi Hong[1,5], Rahul Gupta[1]
[1]Amazon AGI, [2]UCLA, [3]UIUC, [4]EPFL, [5]University of Minnesota

Abstract

We introduce SemEval-2025 Task 4: unlearning sensitive content from Large Language Models (LLMs). The task features 3 subtasks for LLM unlearning spanning different use cases: (1) unlearn long form synthetic creative documents spanning different genres; (2) unlearn short form synthetic biographies containing personally identifiable information (PII), including fake names, phone number, SSN, email and home addresses, and (3) unlearn real documents sampled from the target model's training dataset. We received over 100 submissions from 26 teams and we summarize the key techniques and lessons in this paper.

1 Introduction

Large Language Models (LLMs) have achieved enormous success recently due to their ability to understand and solve various non-trivial tasks in natural language. However, they have been shown to memorize their training data (Carlini et al., 2019) which, among other concerns, increases risk of the model regurgitating creative or private content. Often, such issues are discovered post model training during testing or red teaming. Furthermore, stakeholders may sometimes request to remove their data after model training to protect copyright, or exercise their right to be forgotten (General Data Protection Regulation). In these instances, retraining models after discarding such data is one option but doing so after each such removal request is prohibitively expensive.

Machine unlearning is a promising line of research for removing sensitive information from models' parametric memory. While unlearning has been studied for sometime in classification problems, it is still a relatively underdeveloped area of study in LLM research since the latter operate in a potentially unbounded output label space. Current algorithms often fall short of effectively and efficiently unlearning sensitive information from LLMs, without impacting model utility. Further, there is a need for benchmarks which can provide thorough evaluations of new unlearning algorithms in removing different categories of sensitive information.

To address these needs and to spur further research on this topic, we developed a new challenge (and an associated benchmark) for LLM Unlearning as part of the SemEval 2025 competition. This document provides a summary of our challenge[1] along with the benchmark, results and key takeaways.

2 Related work

Given the nascent stage of unlearning research in LLMs, few prior works exist which address the task of robustly evaluating the success of unlearning. (Triantafillou et al., 2023) presented a new challenge task in which the goal was to to unlearn information contained in select images within the task of image based age prediction. While successful, the specific task addressed in this challenge was narrow, focusing only on image based age prediction - a classification problem with 10 classes with limited applicability in the unbounded text generation task of large language models.

(Maini et al., 2024) released a new evaluation framework named TOFU which partially addressed this task of evaluating LLM unlearning algorithms. Their framework was evaluated on question answering task applied on biographies of synthetically created fake authors. They train target models on this synthetic data and evaluate the ability of unlearning algorithms to forget a portion of this synthetic dataset. While being a promising first step, this work has a few key limitations: unlearning the targeted information required for the QA task is unlikely to cause loss of any other substantial information, specially linguistic attributes such

[1]llmunlearningsemeval2025.github.io

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2584–2596

as grammar. Further, this work leverages GPT4 to generate the synthetic content, which may have downstream implications owing to GPT4's proprietary license.

More recently, (Shi et al., 2024) released a benchmark named MUSE which evaluated model unlearning using real data set for containing news documents and Harry Potter book chapters. This benchmark released detailed evaluation metrics to robustly evaluate the unlearning algorithms. However since it only leverages real data set the benchmark does not provide a clean test bed to evaluate model performance. Specifically, the information contained in the unlearn documents may also appear in other disjoint training documents, limiting the effectiveness of unlearning. While the TOFU benchmark mentioned before avoids this by only using synthetic documents, the data set coverage is rather limited (it only containts biographic information). The benchmark developed in our challenge addresses both these shortcomings together and presents a single holistic testbed to evaluate model unlearning in LLMs.

3 Challenge Description

To robustly evaluate unlearning algorithms on their effectiveness in removing different categories of information from LLM, we developed[2] a new unlearning benchmark (on English language), covering three distinct sub-tasks spanning (1) creative content, (2) Personally Identifiable Information (PII) of synthetic individuals and (3) real biographies of individuals sampled from Wikipedia. Please refer to (Ramakrishna et al., 2025) for detailed information on the dataset creation process.

Within each sub-task, we further test the models for regurgitation (where model is prompted to complete partial documents) and knowledge (via generated question-answer pairs), leading to 12 different sub-tasks for the challenge. To score highly in the challenge, participants are expected to do well in all sub-tasks. In comparison, existing unlearning benchmarks such as TOFU (Maini et al., 2024) and MUSE (Shi et al., 2024) cover only a portion of the subtasks we test for.

For each subtask, we released *Retain* (R) (i.e. model should retain these documents in memory) and *Forget* (F) datasets (i.e. model should forget information from these documents) along with two target models (7 billion and 1 billion parameters in size) which were fine-tuned to memorize documents from all three tasks.

	Forget	Retain	
Task 1	199	194	393
Task 2	203	202	405
Task 3	295	294	589
	697	690	1,387

Table 1: Number of unique documents for both data subsets within each task. For each document, we create multiple regurgitation and knowledge datasets leading to 4,394 unique examples.

Participants were encouraged to explore various unlearning algorithms which enable them to remove the sensitive information present in F without affecting model knowledge on the R. Our initial data release was further split in 80:20 ratio as train and validation subsets for optional hyperparameter tuning. Participants were expected to submit working Python scripts containing their unlearning code for the evaluation phase, which were executed on privately held subsets of retain and forget sets from each sub-task. Table 1 lists overall statistics of our benchmark, and examples are shown in Figure 5.

We provide further details on our dataset creation for the three tasks below, followed by details on the evaluation phase.

3.1 Dataset Creation

3.1.1 Task 1: Synthetic creative documents

LLMs trained on Internet-scraped data are often exposed to copyrighted content, making unlearning of this information a common requirement post training. However, evaluating effectiveness of unlearning on only real creative documents (Shi et al., 2024; Eldan and Russinovich, 2023) is challenging as information to be removed may appear in other documents not being unlearned. For example, MUSE (Shi et al., 2024) uses Harry Potter books as its forget set, but this information may be exposed to the model via Wikipedia articles and social media posts. Motivated by this, in this task, we only include synthetically generated short novels, created using Mixtral 8x7B (Jiang et al., 2023) as our generator LLM.

To create each document in this task, we first randomly sample a genre from one of Action, Fantasy, Thriller, Comedy, Mystery, Science Fiction, Young Adult and Romance. Next we generate one

[2] github.com/amazon-science/lume-llm-unlearning

to four synthetic character names using a random name generator [3], and synthetic locations from the city list of a random address generator [4] for all genres except Fantasy genre. For Fantasy, we sample unique genre specific city names using a Dungeons and Dragons town generator [5]. Given this information, we prompt the Mixtral model (full prompt listed in Appendix B) to create a short story with 150-200 words. To validate the generated stories, we conducted manual reviews (each short story was reviewed by two authors) and filtered out stories with similar content to prior reviewed stories. Our final dataset for this task contained 393 unique short stories across all genres.

3.1.2 Task 2: Synthetic biographies with sensitive PII

We use various heuristics to generate 500 synthetic personal biographies with following PII fields:

- *Name*: randomly created from a name generator, includes firstname+lastname.
- *Birthday*: randomly sampled between 01/01/1964 and 01/01/1991.
- *Social Security number (SSN)*: randomly sampled within the range 900-xx-xxxx (which by policy cannot not belong to a real person (ssa, 2011)).
- *Phone Number*: 10 randomly sampled digits.
- *Email address*: Created heuristically of the form `firstname_lastname@me.com`.
- *Home address*: A non-existent physical home address obtained by combining a random street address from a US state with an alternate city and zip-code from a different state.

For each synthetic individual created above, we prompt the Mixtral model (using prompt listed in Appendix C) to create a short biography which includes all the PII information.

3.1.3 Task 3: Real biographies

To evaluate effectiveness of unlearning on real data, we include real biographies as the third task. Specifically, we sampled 750 biographies spanning 100 to 200 words from Wikipedia documents released in the Dolma (Soldaini et al., 2024) v1.6 corpus, which was part of the training dataset for the OLMo models (Groeneveld et al., 2024) we use for this task.

[3] pypi.org/project/unique-names-generator
[4] pypi.org/project/random-address
[5] perchance.org/dndtowngen

3.2 Subtasks

For each task, we additionally created prompts for two subtasks detailed below.

3.2.1 Regurgitation tests

To test for model regurgitation of documents, we created sentence completion prompts for all documents from the three tasks by sampling a random position in second half of the document with the sentences before it as the input.

3.2.2 Knowledge tests

We create question answer prompts for each document using an agentic workflow for Tasks 1 and 3 where we prompt the data generator LLM (Mixtral 8x7b) with few-shot Chain of Thought prompting (Wei et al., 2022) (prompt listed in Appendix D) to construct an unambiguous question with a single concise answer. We validate the quality of the generated QA pair by prompting three verification LLMs (Claude 3 Sonnet, Titan Text Express and Mixtral 8x7B) to answer the question with full document as grounding. We discard QA pairs if any of the three verification LLMs are unable to answer the question accurately. For Task 2, we use template based heuristics for each PII field to frame questions of the form *What is the birth date of John Smith?* with the corresponding entry as the answer.

3.3 Data Splits

We divide the dataset we created into two halves, corresponding to forget (F) and retain (R) subsets. Each unlearning algorithm is evaluated on how well it can erase sensitive information from the forget subset, without impacting information in the retain subset. We maintain a 1:1 ratio between the two subsets, which adds to the challenge. We further split both of these into private and public subsets. We released the public retain and forget subsets in September 2024, as part of the task artifacts. The private datasets were saved for the evaluation phase.

3.4 Unlearning Model Candidates

We fine-tuned OLMo-7B-0724-Instruct-hf (7 Billion parameters[6]) and OLMo-1B-0724-hf (1 Billion parameters[7]) models on documents from all

[6] huggingface.co/llmunlearningsemeval2025organization/olmo-1B-model-semeval25-unlearning
[7] huggingface.co/llmunlearningsemeval2025organization/olmo-finetuned-semeval25-unlearning

three tasks and release them as unlearning candidates. We selected OLMo because of its permissive license and open sourced training dataset (with logs) which enables downstream task specific analyses of model behavior.

3.5 Evaluation

In typical evaluation cycles, participants are invited to upload their trained model checkpoints which are evaluated on a private test set. However, since unlearning algorithms need access to the targeted information to erase from the model's memory, we would have to release the private forget and retain subsets. But this can compromise the integrity of evaluations since a participant may chose to retrain the OLMo models from scratch on just the retain data subsets, achieving high scores in our evaluation metrics.

To avoid this, in our challenge we invited each participant to develop their unlearning algorithms locally using the publicly released forget and retain subsets and upload their working code for evaluation. For each such submission, we individually call the corresponding unlearning functions with the private forget and retain subsets as arguments, and evaluate the generated checkpoints for unlearning effectiveness. During the evaluation phase, submissions were timed and those runs which take more than a pre-determined threshold of time were discarded. Further, to support diverse explorations, each team was invited to submit up to 5 distinct code files for the evaluation, of which the best performing candidate (among those which finished training and retained model utility) was selected for the leaderboard.

All evaluation experiments were conducted (with limited permissions) on an AWS EC2 p4d.24xlarge node with 8 A100 40 GB GPUs. The compute environment was pre-configured with DeepSpeed Zero (Rajbhandari et al., 2020) with additional packages installed if requested by the teams.

To evaluate the generated checkpoints, we computed following metrics:

3.5.1 Task memorization metrics

For each of our three tasks, we compute two distinct metrics listed below, corresponding to the two subtasks to evaluate the model's memorization of sensitive information:

a) Regurgitation Rate: We compute ROUGE-L (Lin, 2004) scores for the model generated outputs with respect to the expected sentence completions. We chose ROUGE since it is weighted for recall of sensitive information in model outputs.

b) Knowledge Test Accuracy: For all QA prompts, we use case insensitive exact match between model output and the expected answer to measure prediction accuracy.

Overall, we compute 12 different metrics which measure memorization. We compute the harmonic mean of these to obtain a single task-aggregate metric.

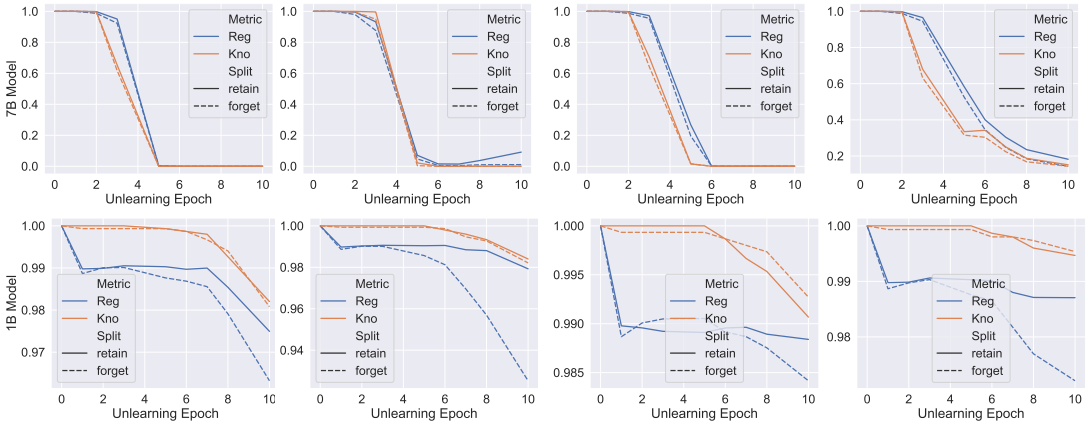
3.5.2 Membership Inference Attack success rates (MIA)

Since the model may retain some sensitive information despite showing low memorization rates after unlearning, we also compute MIA rates on the subtask prompts. We compute loss based membership inference attacks using the MIA attack framework from (Duan et al., 2024) to assess data leakage risk after unlearning. A robust unlearning algorithm should effectively remove evidence of the forget set and yield MIA success rates close to 0.5 AUC (random chance) between member v/s non-member datasets. We use a subset of the memorized Wikipedia biographies from the forget subset of Task 3 as the member set and a disjoint sample of similar biographies not exposed to the model as the non-member set. Further, we compute following MIA score to penalize any deviations from 0.5:

$$\text{MIA Score} = 1 - 2 \cdot |\text{mia\_auc} - 0.5|$$

3.5.3 Model Utility

We also test for overall model utility by computing test set accuracy for 57 STEM subjects from MMLU (Hendrycks et al., 2021), a general benchmark for LLM utility. We also threshold on this metric for the post unlearning candidate to avoid trivial solutions which completely distort general model utility but achieve high scores in the task aggregate and/or MIA (such as Gradient Ascent). Specifically for the 7B model, we only consider submissions for which the MMLU accuracy is above 0.371 (75% of the pre-unlearning checkpoint) for our official awards leaderboard. However, we did not impose this constraint for the 1B model since the performance of the base model on this dataset was already low, close to random chance.



(a) GA (b) GD (c) KL (d) NPO

Figure 1: Performance on *retain* and *forget* subsets for benchmarked unlearning algorithms. Reg: Regurgitation Rate (r), Kno: Knowledge Accuracy (t). Split refers to data subset (forget or retain) used in evaluations.

3.5.4 Aggregate Final Score

Finally, we compute arithmetic mean of the task aggregate metric, MIA score and the model utility to obtain a single numeric score to compare all submissions.

4 Benchmarked Algorithms

We benchmarked our dataset on several state of the art unlearning algorithms described below.

Gradient Ascent: This is a straightforward unlearning algorithm where we reverse the direction of model update by flipping the sign in gradient descent, in order to steer the model away from the sensitive model outputs in the forget set. While easy to implement, this approach has a significant drawback since the gradient ascent training objective is unbounded, which can lead to model divergence with nonsensical outputs for all inputs. The loss term in this algorithm reverses sign of the standard Cross Entropy training loss ($\mathcal{L}_{CE}$) and is applied only on the forget set F:

$$-\mathcal{L}_{CE}(F;\theta)$$

Gradient Difference (Liu et al., 2022): In this approach, we augment the gradient ascent objective applied on forget set, by adding a gradient descent objective on the retain set. By jointly optimizing on both sets, we steer the model away from regurgitating the sensitive information from the retain set, while ensuring it does not lose performance in the retain set. Despite being a promising alternative to Gradient Ascent, this quality of model performance on non-sensitive dataset depends on the size of the retain set used in model training, and can lead to poor generalization on new examples. The loss term jointly increases the likelihood of generating responses in the retain set R while reducing the likelihood of generating F, as shown below.

$$-\mathcal{L}_{CE}(F;\theta) + \mathcal{L}_{CE}(R;\theta)$$

KL Regularization (Maini et al., 2024) Similar to Gradient Difference, in this baseline, we augment the gradient ascent objective with a Kullback-Leibler Divergence term to ensure the model does not deviate too far from the original model.

$$-\mathcal{L}_{CE}(F;\theta) + \mathcal{L}_{KL}(R;\theta,\theta_{ref})$$

Negative Preference Optimization (Zhang et al., 2024): This baseline uses a modified version of the Direct Preference Optimization objective, adapted to remove the sensitive information from forget set.

$$\mathcal{L}_{NPO}(F;\theta)$$

4.1 Benchmark Results

Consistent with other recent benchmarks, we evaluate each algorithm described above using following hyper-parameters and provide these results to the participants for reference. We use a batch size of 32, and run the algorithms for 10 epochs using a learning rate = $1e-5$ on both models. Figure 1 plots their performance on forget and retain sets (task wise plots are shown in Appendix E). We observe over-unlearning with the 7B model but under-unlearning with the 1B model for selected hyper-parameters, suggesting room for improvements by participants over these baselines.

Table 2: Key ideas explored in participating teams, sorted based on their performance on 7B model.

5 Participant Systems

We received over 100 submissions from 24 teams with nearly 70 individuals spanning over 30 institutions across the world. We list key ideas explored by participants in Table 2.

Most teams used variations of Gradient Difference (GD), KL Regularization or Negative Preference Optimization (NPO) with specific hyperparameters coupled with clever optimizations leading to faster training within the fixed compute time. Other teams explored new and innovative solutions for unlearning by leveraging novel loss objectives, selective layer/parameter training, etc.

The best performing team, **AILS-NTUA**, leveraged a parameter-efficient unlearning method based on GD with LoRA adapters added to transformer projection layers. They carefully sampled chunks of forget set mixed with a large (resampled) retain set. The second place team, **ZJUKLAB** merged two different models unlearned with distinct hyperparameters, to balance under/over-unlearning in the two models. The third place team, **YNU** used alternating GD with randomly sampled forget labels. Team **Mr. Snuffleupagus** applied targeted unlearning using RMU on 3 layers selected using the validation set. **ishumei-Chinchunmei** explored a new inverted loss function for the forget set, which avoids the gradient explosion commonly found in GA.

SHA256 use causal mediation analysis on the OLMo models and identify the first five model layers as most relevant for unlearning, and apply re-weighted GD. While this approach achieved high unlearning performance, it considerably degraded model utility on MMLU. Team **Atyaephyra** use LoRA adapters with NPO, regularized using KL, with low memory footmark by offloading the adapters during distillation. However, their submission included an early exit bug during 7B evaluations which led to low performance with this model. This was corrected and resubmitted in time for 1B evaluation, in which their submission took the third spot. We present more detailed summaries of the core strategies used by participating teams in Table 5.

5.1 Results and Discussion

Table 3 presents performance of the top teams when their unlearning algorithms are applied to 7B and 1B models. **AILS-NTUA** achieved the best performance with both the 1B and 7B models, as their system excels across all three metrics. While **ZJUKLAB** performed better on Task Aggregate and MMLU scores for the 7B model, their submission significantly underperformed on the MIA score suggesting the unlearned information was not completely removed from model parameter space, and also highlighting a trade-off between MIA and the Task Aggregate scores (also observed in (Ramakrishna et al., 2024)).

Team	Final Score	Task Aggregate	MIA Score	MMLU Avg.
Results from 7B Models				
AILS-NTUA	0.706	0.827	0.847	0.443
ZJUKLAB	0.487	0.944	0.048	0.471
YNU	0.47	0.834	0.139	0.436
Mr. Snuffleupagus	0.376	0.387	0.256	0.485
ishumei-Chinchunmei	0.326	0.496	0	0.481
Results from 1B Models				
AILS-NTUA	0.688	0.964	0.857	0.242
SHA256	0.652	0.973	0.741	0.243
Atyaephyra	0.586	0.887	0.622	0.248
Mr. Snuffleupagus	0.485	0.412	0.793	0.25
ZJUKLAB	0.483	0.915	0.292	0.243

Table 3: Scores from the top-5 teams for 7B and 1B models. Complete results are published at llmunlearningsemeval2025.github.io.

Team	Regurgitation Score			Knowledge Score		
	Task 1	Task 2	Task 3	Task 1	Task 2	Task 3
Forget Set						
AILS-NTUA	0.963	0.986	0.979	0.966	0.998	0.951

Mr. Snuffleupagus	0.594	0.994	0.916	0.415	1.000	0.566
ishumei-Chinchunmei	0.587	0.634	0.637	0.603	0.567	0.601
Retain Set						
AILS-NTUA	0.493	0.995	0.556	0.758	0.990	0.844
ZJUKLAB	0.671	0.952	0.815	0.527	0.799	0.696
YNU	0.896	0.981	0.749	0.967	0.984	0.970
Mr. Snuffleupagus	0.485	0.290	0.145	0.582	0.167	0.526
ishumei-Chinchunmei	0.502	0.392	0.428	0.330	0.470	0.452

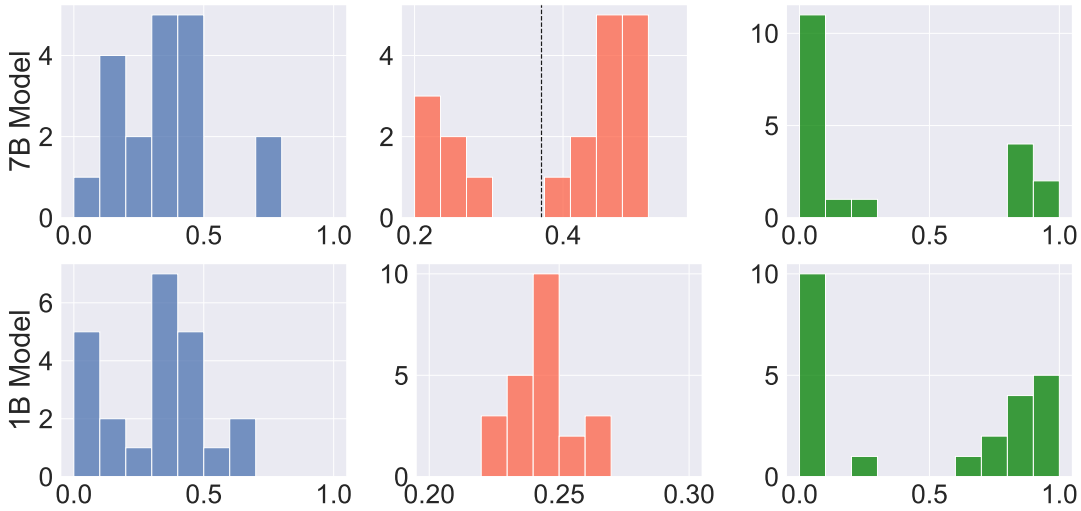
Table 4: Regurgitation and Knowledge Scores for the top-5 teams on 3 sub-tasks in the 7B model. Higher values indicate better performance in all scores.

Results for both models are largely consistent, with three teams (**AILS-NTUA**, **Mr. Snuffleupagus**, and **ZJUKLAB**) ranking in the top five positions on both leaderboards. As discussed earlier, **Atyaephyra** had a bug in their submission which was addressed before 1B evaluations thereby gaining several positions.

Finally, a handful of teams which were disqualified in 7B evals due to a drop in their MMLU utility recovered higher positions in the 1B leaderboard. Notably, **SHA256** achieved a high Final Score (0.711), Task Aggregate (0.964), and MIA Score (0.894) with the 7B model. However, their MMLU score (0.275) dropped below the pre-defined threshold of 0.371, suggesting a substantial drop in overall model utility after unlearning. As a result, their system was regrettably disqualified in 7B evals but retained for 1B.

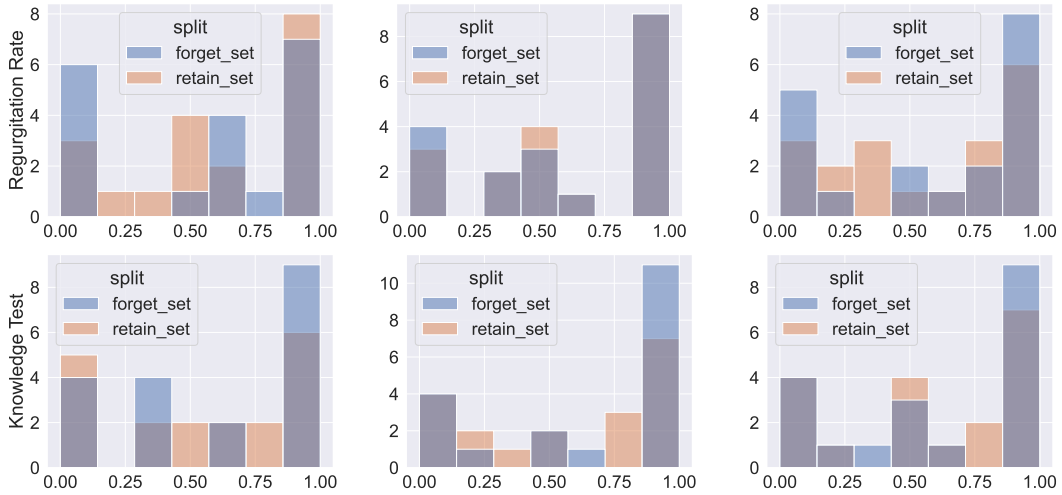
Table 4 presents task wise breakdown of top 5 teams in the 7B model. Results show that the top three systems achieve nearly perfect performance on the forget set, demonstrating the effectiveness of their methods in reducing regurgitation and removing knowledge from the LLMs. However, in several cases the performance on the retain sets drops considerably, suggesting *over-unlearning*, leading to unintended forgetting of relevant information from the model. When comparing across tasks, Task 2 appears relatively easier than the other two tasks since it largely deals with short form, factual answers, with both **AILS-NTUA** and **YNU** achieving near-perfect scores in this task.

We plot histograms of team performances for both models in Figure 2. Most teams score low on



(a) Final scores (b) MMLU (c) MIA

Figure 2: Distribution of key scores for all participants on both models. MMLU plots are zoomed in (but still contain 10 bins). Dashed line indicates threshold for 7B model utility below which submissions are discarded.

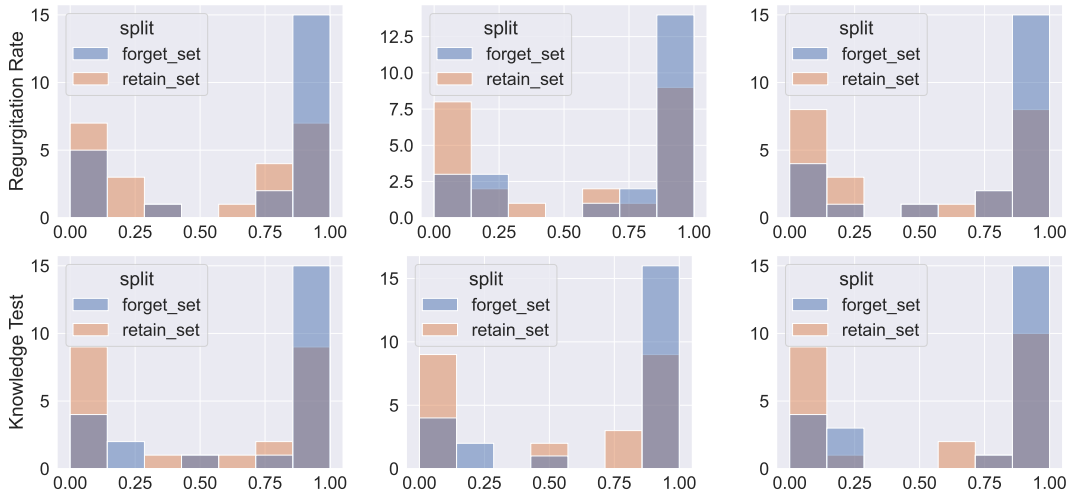


(a) Task1 (b) Task2 (c) Task3

Figure 3: Distribution of participant scores for forget and retain sets on the 7B model for all 6 sub-tasks.

MIA, with only three teams scoring high on the 7B model while most others scored close to zero, suggesting imbalanced unlearning in these submissions. The MMLU scores for the 7B model are split into two clusters above and below the pre-defined threshold for rejection, with most submissions scoring above this threshold, suggesting delibrate parameter tuning to stop unlearning before this score drops below the threshold. For 1B model, since the base model performance on MMLU was already close to random chance, there is minimal impact due to the unlearning algorithms. The final score plots show an approximately bi-modal distribution, with a majority of teams with low scores except a select few which score highly.

We also plot distributions of sub-task wise performance for all teams for the two models in Figures 3 and 4. We plot 1-test scores for the Forget set for easy comparison with the retain set. Across both models and in a majority of subtasks, the highest performing teams score considerably better with the forget set compared to retain set as observed in Table 4. This is also due to over-unlearning in low scoring submissions which would remove the sensitive information but cause substantial degradations in the retain set as illustrated by a relatively uniform spread of retain set scores. We also observe an approximately bi-modal distribution across all tasks for the 1B model while for the 7B model some teams scored intermediate values.



(a) Task1 (b) Task2 (c) Task3

Figure 4: Distribution of participant scores for forget and retain sets on the 1B model for all 6 sub-tasks.

6 Key Takeaways

What were the key strategies explored by the teams? The top team, along with a few others, applied gradient-based unlearning with low-rank adaptation (LoRA). These parameter-efficient updates enable the model to be fine-tuned efficiently, allowing for more iterations and the use of a larger retain dataset. Similarly, several teams developed selective unlearning techniques to identify and target specific parameters or layers for unlearning. Finally, balancing between over or under unlearning is critical and several teams fail to address it, causing low MMLU or MIA scores respectively.

Is the task solved? While the top-performing team achieved high scores, its utility (measured by MMLU) still experienced a notable drop, from 0.494 to 0.443. Their model checkpoint was also reported to generate garbage tokens with specific prompts, suggesting some degree of model degradation due to unlearning. In contrast, other teams maintained utility but did not improve on MIA or task aggregate scores. This highlights that balancing utility and unlearning effectiveness remains a challenging and open task for future work.

What can we do differently? Several participants reported not having access to a multi-gpu training environment, and submitted code which was not tested with Deepspeed. As a result, substantial manual effort was invested in modifying all submitted code files to train on our evaluation environment. In future work, we can avoid this by using platforms such as Huggingface competitions.

7 Conclusion and Future Improvements

This paper summarizes SemEval-2025 Task 4 on unlearning sensitive content from LLMs. Our task presents a significant challenge, as most baselines struggle to maintain model utility while unlearning unwanted information. We received several innovative solutions which made strong contributions towards solving this task. We hope our challenge and the associated benchmark inspire further research into efficient methods for unlearning sensitive content from LLMs.

We note several avenues for future exploration:

1. **Evaluation metrics.** Outside LLMs, unlearning literature typically uses some form of statistical hypothesis testing between the model posteriors from the unlearned and the retrained (i.e. trained without the sensitive information) model candidates. However, this is not always feasible for LLMs since the model would have to be trained from ground up, including pretraining which is a computationally expensive undertaking.
2. **Larger model checkpoints:** We limited our challenge to 7 and 1 billion parameter models due to limited compute availability with most participants. In future work we may expand on this challenge by inviting a subset of teams to onboard to specialized compute platforms to motivate further research on unlearning larger models.
3. **Unlearning other attributes:** Unlearning of sensitive information or a class of model capabilities (such as coding in a specific language).

A Examples

Figure 5 shows examples from all six subtasks in our benchmark.

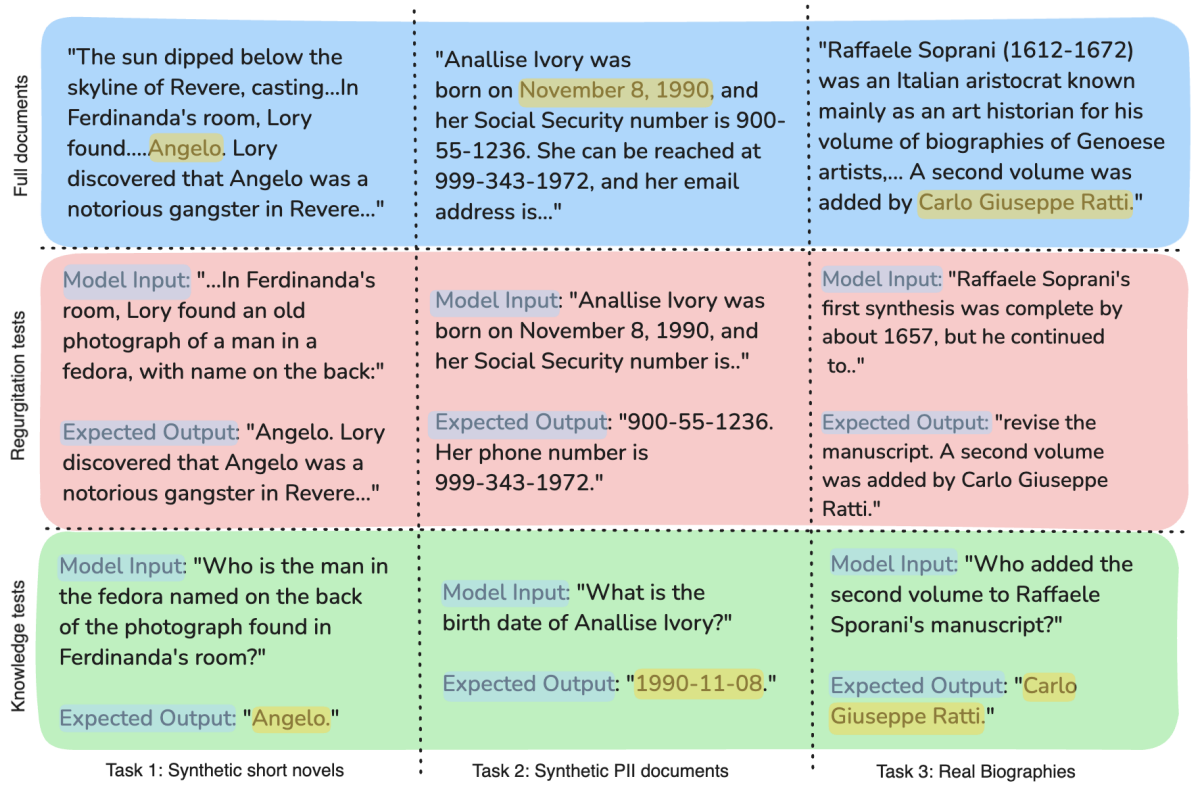

Figure 5: Examples of full documents and test prompts for the three tasks covered in this challenge. The figure is quoted from (Ramakrishna et al., 2025).

B Creative Content Generation Prompt

```
Model Input:
Create a short novel of at least 150 words. The
     novel should be from fantasy genre and set in
     the city of Atlantis. It should include
     following characters: Kyle, Stan, Kenny and
     Eric.

Model Output:
A short story about four friends lost in the magical
      realm below the oceans, known to ousiders as
     Atlantis. Kyle had always held a deep
     fascination for the deep blue ocean, and this
     naturally led him to take up a major in oceanic
      studies...
```

C Personal Biography Generation Prompt

```
Model Input:
Create a biography for Jon Smith with date of birth:
      1/2/1989, SSN: 900123456, phone number:
     0987654321, email: jon_smith@me.com, home
     address: 10 Summertime Lane, New York City, NY,
      USA.

Model Output:
Jon Smith was both in New York City on the first of
     February in 1989,...
```

D Question Generation Prompt

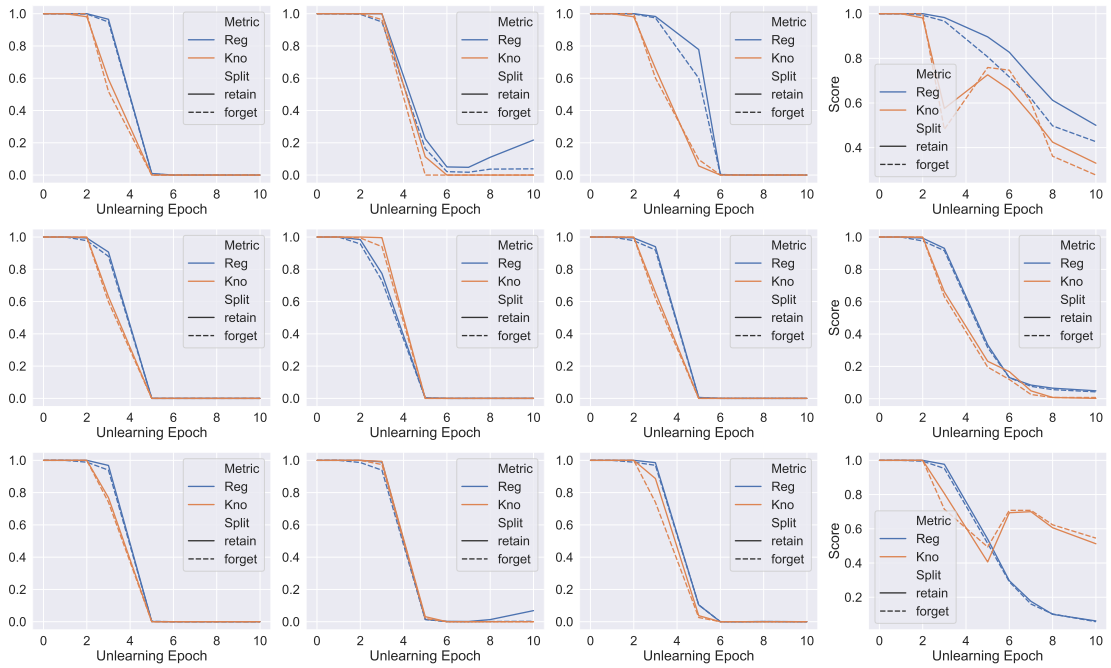
```
Model Input:
You are given a short story. First, find all the
     proper nouns in this story. If it does not
     contain a proper noun, say "I can't use this
     statement since it does not contain any proper
     nouns.". If it contains proper nouns, use your
     reasoning to create an unambiguous question,
     for which there would be *only* one answer.
     Give a concise answer (i.e. one word or phrase)
      which accurately answers the question. If you
     cannot create such an unambiguous question, say
      "I'm unable to create an unambiguous question
     for this story". Use the examples below for
     reference.

Examples:
1. Example #1
2. Example #2
3. Example #3
4. Example #4
5. Example #5

Here's the story: <input_story>. Generate a question
      with an unambiguous answer using this story.
```

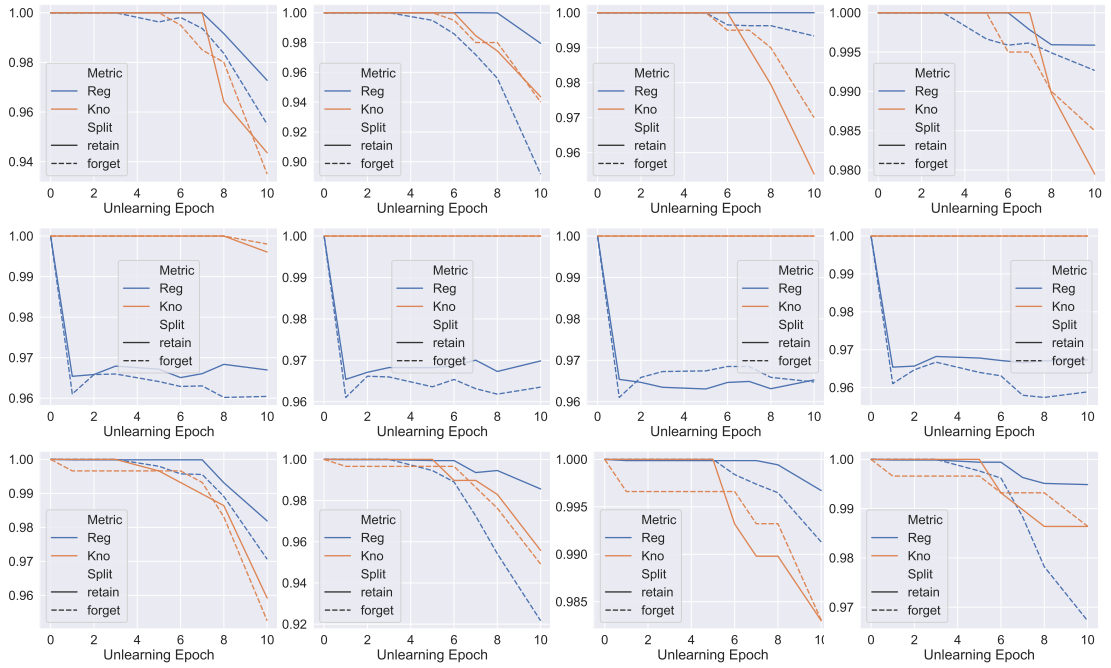
E Task Wise Benchmark Results

Figures 3 and 4 show task wise distributions on forget and retain sets for all benchmarked unlearning algorithms.



(a) GA (b) GD (c) KL (d) NPO

Figure 6: Performance on *retain* and *forget* subsets for 7B model for benchmarked unlearning algorithms for Tasks 1 to 3 (respectively from top to bottom). Reg: Regurgitation Rate (r), Kno: Knowledge Accuracy (t). Split refers to data subset (forget or retain) used in evaluations.



(a) GA (b) GD (c) KL (d) NPO

Figure 7: Performance on *retain* and *forget* subsets for 1B model for benchmarked unlearning algorithms for Tasks 1 to 3 (respectively from top to bottom). Reg: Regurgitation Rate (r), Kno: Knowledge Accuracy (t). Split refers to data subset (forget or retain) used in evaluations.

Team	*Core strategy*
AILS-NTUA	Iterative unlearning on carefully sampled chunks of forget set, mixed with a larger volume of retain set
ZJUKLAB	Two distinct NPO+KL+GD trained models are merged to balance under/over-unlearning between them.
YNU	Unlearning with random tokens followed by alternating GA/GD on forget/retain samples.
Mr. Snuffleupagus	Adaptive RMU on three layers selected using validation set.
ishumei-Chinchunmei	Alternate formulation for unlearning loss as reciprocal of gradient descent (instead of inverted sign as is done in GA).
GUIR	Unlearning with adaptive tuning of weights for forget and retain sets
GIL-IIMAS UNAM	Selective GA followed by GD (7B) and Task vector from forget set subtracted for unlearning (1B)
Atyaephyra	NPO using LoRA adapters (for compute efficiency), with reference probability obtained by removing LoRA adapters (for memory efficiency).
Lacuna Inc.	Selective parameter unlearning on parameters not relevant for retain set, selected using Fisher Information Matrix
NLPART	NPO+SFT on deflection strings.
JU-CSE-NLP'25	Normalized Gradient Difference with AutoLR (Jin et al., 2025)
SHA256	Causal mediation to identify first 5 layers as most impactful, followed by unlearning using GD on these layers.
NeuroReset	GA on forget set followed by GD on retain set (3 epochs each)
Cyber for AI	Gradient Difference followed by gradient ascent.
MALTO	Distillation from aggregated probability from incompetent (forget set) and competent (retain set) teachers.
NEKO	GA with KL regularization on retain set from reference model.
DUTir	Selective parameter unlearning on parameters identified using gradients for forget and retain sets.
AI4PC	Distillation from two models enhanced on forget and retain sets separately.

Table 5: Brief summaries of key strategys employed by all participating teams.

F System descriptions

We provide brief descriptions for submissions from all participants in Table 5.

SemEval-2025 Task 1: AdMIRe - Advancing Multimodal Idiomaticity Representation

Abstract

Idiomatic expressions present a unique challenge in NLP, as their meanings are often not directly inferable from their constituent words. Despite recent advancements in Large Language Models (LLMs), idiomaticity remains a significant obstacle to robust semantic representation. We present datasets and tasks for SemEval-2025 Task 1: AdMIRe (Advancing Multimodal Idiomaticity Representation), which challenges the community to assess and improve models' ability to interpret idiomatic expressions in multimodal contexts and in multiple languages. Participants competed in two subtasks: ranking images based on their alignment with idiomatic or literal meanings, and predicting the next image in a sequence. The most effective methods achieved human-level performance by leveraging pretrained LLMs and vision-language models in mixture-of-experts settings, with multiple queries used to smooth over the weaknesses in these models' representations of idiomaticity.

1 Introduction

Idioms are a class of multi-word expression (MWE) which pose a challenge for current state-of-the-art models because their meanings are often not predictable from the individual words that compose them (Dankers et al., 2022; Villavicencio et al., 2005). For instance, "eager beaver" is unlikely to refer to a passionate muskrat; rather, it typically describes a person who is keen and enthusiastic. These expressions may also generate ambiguity between the literal, surface meaning arising from their component words and their idiomatic meaning (He et al., 2024b). These, among other characteristics, make them a valuable testing ground for examining how NLP models capture meaning.

Advances in language modeling of such phenomena have been made in recent years (Zeng and Bhat, 2022; Zeng et al., 2023; He et al., 2024a), but large language models (LLMs) which perform well on general benchmarks (even for well-resourced languages such as English) fail to consistently exhibit good understanding of figurative language (Mi et al., 2024; Phelps et al., 2024). This has an impact on their application in natural language processing activities such as sentiment analysis (Williams et al., 2015; Spasić et al., 2020), understanding and inference tasks and machine translation (Yazdani et al., 2015; Syahrir and Hartina, 2021). For example, due to poor automatic translation of an idiom, the Israeli PM appeared to call the winner of Eurovision 2018 a 'real cow' instead of a 'real darling'![1].

Several benchmark datasets exist for the processing of idiomatic expressions in text (e.g. Chakrabarty et al., 2022; Haagsma et al., 2020; Tedeschi et al., 2022; Tayyar Madabushi et al., 2021; Garcia et al., 2021; Mi et al., 2024) but concerns have been raised that these tasks do not necessarily require that language models possess good representations of idiom meaning (Boisson et al., 2023; He et al., 2024b). More recent datasets (Yosef et al., 2023; Saakyan et al., 2025) introduce a visual modality to idiom processing tasks alongside text, and their findings indicate that this task is indeed more difficult for vision-language models (VLMs) to perform.

The task presented here builds on previous SemEval tasks exploring the evaluation of compositional models (Marelli et al., 2014), paraphrases and interpretation of noun compounds (Hendrickx et al., 2013; Butnariu et al., 2009) and idiomaticity detection (Tayyar Madabushi et al., 2022). We incorporate visual (§3.1) and visual-temporal (§3.2) modalities across two subtasks in an effort to promote the construction of higher-quality semantic representations of idioms. Our dataset incorporates items in both English (EN) and Brazilian Portuguese (PT-BR), and we focus on nominal com-

[1] metro.co.uk

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2597–2609

pounds which have interpretations in literal and idiomatic senses which are both plausible and imageable.

The AdMIRe datasets are available from doi.org/10.15131/shef.data.28436600.v1 under a CC-BY-4.0 license.

2 Dataset Construction

2.1 Target compound selection

The potentially idiomatic noun compounds used in this study were sourced from existing datasets including NCTTI (Tayyar Madabushi et al., 2021), FLUTE (Chakrabarty et al., 2022) and MAGPIE (Haagsma et al., 2020), or identified by the researchers during the project. For the purposes of this task, we filtered out compositional expressions (e.g. *olive oil*), focusing exclusively on those that exhibit duality — i.e., expressions that can be interpreted either literally or figuratively depending on the context (e.g. *silver bullet*). The candidate lists covered expressions in both English (EN) and Brazilian Portuguese (PT-BR).

The candidate expressions were then used to create two data subsets.

2.2 Static Images (Subtask A)

Native speakers of the target language were asked to write a short sentence describing a visual scene depicting each target expression in the following contexts:

- strongly figurative
- mildly figurative
- mildly literal
- strongly literal

In addition, a 'distractor' prompt was also requested - this was something unrelated to either the figurative or literal meaning of the expression. Where the annotators were unable to construct any of these scenes, the item was excluded as a candidate. For instance, it is difficult to capture the semantics of an idiomatic *kangaroo court* in an image. Candidate items therefore needed to have plausible and imageable literal and idiomatic interpretations.

For each item selected, the annotators also provided two context sentences; one in which the expression is used literally, and one idiomatic. These sentences were obtained from existing corpora (Tayyar Madabushi et al., 2021; Jakubíček et al., 2013) or were written specifically for AdMIRe. For Portuguese, we observed that many adjective-noun compounds would normally be distinguished in writing between literal and idiomatic cases since they would be hyphenated in the idiomatic instance. For instance, *ovelha-negra* means "black sheep" (with the same idiomatic sense as English), but *ovelha negra* would be a literal black sheep. To avoid creating a shortcut for the models, we removed these hyphens from the idiomatic context sentences, and a native speaker reviewed them to confirm that they still appeared to be natural.

In total, we obtained 100 English and 55 Portuguese potentially idiomatic expressions, with literal and idiomatic context sentences and visual scene descriptions for each item.

Table 1: Data Sources for Static Images.

Source	EN	PT-BR
NCTTI	54	54
MAGPIE	11	-
Crowdsourced	31	1
FLUTE	4	-
Total	100	55

2.3 Image Sequences (Subtask B)

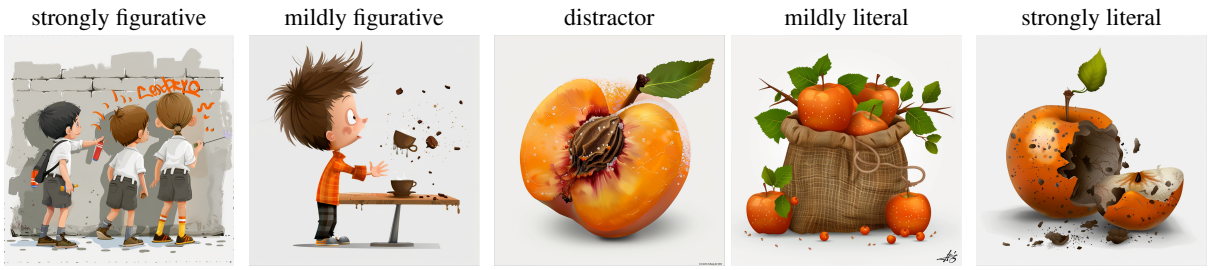
The semantics of many idiomatic expressions are difficult to capture in a single, static image, as they incorporate aspects of ongoing actions or changes over time. For instance, a *brain drain* is not an instantaneous event but something which takes place over a period of time. In order to represent some of these items in the AdMIRe dataset, we also incorporated a visual-temporal modality.

For the image sequences dataset, native speakers of English were asked to write short descriptions of three visual scenes which form a sequence representing either the literal or idiomatic sense of a given expression, akin to a three-panel comic strip. For each of the sequences, they also wrote two alternatives to the final image in the sequence. These alternatives included elements relating to the previous panels but were incompatible with the target expression, and were intended to increase the difficulty of identifying the correct completion for the sequence based solely on image similarity without using the semantic information.

A total of 30 items were collected in English. Note that 10 items appear in both of the English data subsets.

2.4 Image Generation

For each visual scene created by the annotators, we used a commercial text-to-image diffusion model



(a) The image depicts three children standing in front of a gray, textured wall...

(b) The image depicts a cartoon-style illustration of a young boy standing at a table...

(c) The image depicts a halved peach with a detailed and realistic appearance...

(d) The image depicts a rustic, burlap sack filled with several bright orange apples...

(e) The image depicts an orange-colored apple that appears to be decomposing or decaying...

Figure 1: Subtask A data example for *bad apple*. Images generated using Midjourney. Captions are displayed partially.

(Midjourney[2]) to generate a corresponding image. This choice of tool provided the fine-grained human control needed to produce high-quality, domain-specific images tailored to the task, guided by human expert supervision to ensure alignment with literal and idiomatic meanings. A consistent 'style reference' image was used, guiding the model to produce images with a consistent, cartoon-like appearance. For image sequences where the same character(s) were needed, we also employed a set of character reference images in the same style.

2.5 Caption Generation

In order to support participation in the shared task by teams who wish to work only with text models (which lowers complexity and computational costs), we generated descriptive captions for each image. These were obtained by using the *LLaVA-HF/v1.6-mistral-7b-hf*[3] (LLaVA) model, a large vision-language model specifically designed for tasks requiring multimodal reasoning (Liu et al., 2024). LLaVA integrates a vision encoder to extract semantic features from images and a large language model to process these features and generate text. By employing the prompt "*What is shown in this image?*", the model generates captions that describe the content of the input images. The workflow ensures that the visual and textual components of the model work in harmony to produce accurate and contextually relevant descriptions. To ensure the quality of the generated captions, all outputs were reviewed and verified by human evaluators. For items in Portuguese, we provide captions in both English and Portuguese.

3 Task Description

3.1 Task A: Multiple Image Choice

Subtask A uses the static image portion of the AdMIRe dataset (§2.2). Given a context sentence containing a potentially idiomatic nominal compound (NC) and a set of five images, the task is to **rank** the images based on how accurately they depict the meaning of the NC used in that sentence.

A variation of task also allows for monomodal settings, where given a sentence and five text captions (each describing the content of one of the images, as described in Section 2.5) the goal is to rank the image captions on how they capture the meaning of the NC.

Figure 1 provides an example of the Subtask A data for the expression *bad apple*.

The dataset is split into training, development and test sets, with each compound present in only one subset and one, randomly-selected, sense (literal or idiomatic). In addition, we provide an extended evaluation set, which uses all 100 compounds (and therefore overlaps with the other subsets), but selects the other sense of the NC. For example, *elbow grease* appears with its idiomatic sense in the training dataset, and literally in the extended evaluation set.

The English dataset for Subtask A includes 70 training items (350 image-caption pairs), 15 development items, and 15 test items, while the Portuguese dataset comprises 32 training items (160 image-caption pairs), 10 development items, and 13 test items.

First two of the sequence:

(a) The image shows a classroom scene with five animated characters, likely children, sitting at desks...

(b) The image shows an animated character, a young boy with red hair, sitting at a desk with a laptop...

Candidates:

(c) The image shows a group of animated characters, likely children, standing in front of a television screen that displays various cartoon animals...

(d) The image shows an animated character, a young man with brown hair, standing next to a trash can...

(e) The image shows a cartoon illustration of a young girl with red hair, wearing a white sweater with a red bow and a plaid skirt...

(f) The image shows a group of animated characters that appear to be in a state of distress or chaos...

Figure 2: Subtask B data example for *bad apple*. Images (a) and (b) form the initial part of the sequence, while images (c) through (f) serve as completion candidates. In this instance, the intended sense of *bad apple* is idiomatic.

3.2 Subtask B: Image Sequences (Next Image Prediction)

Subtask B uses the image sequence portion of the AdMIRe dataset (§2.3).

For each target expression, the first two images in either the literal or idiomatic sequence are provided, along with a set of four candidate images for completion of the sequence. The candidates consist of the intended completion, the two associated alternatives and the completion for the other sense (literal/idiomatic) of the NC. The task is to correctly identify the intended completion image, while also determining whether the depicted sense of the nominal compound (NC) is idiomatic or literal. Examples are shown in Figure 2.

As with Subtask A, we also offer two settings for Subtask B, with descriptive text replacing the images in the 'caption' setting. In the Subtask B dataset, the English set includes 20 examples for training, 5 for development, and 5 for testing. All 30 items are also included in an extended evaluation set, with initial sequences and completion candidates appropriate to the NC sense not used in the primary data.

3.3 Evaluation

3.3.1 Subtask A

For subtask A, we set an expected rank ordering of the 5 images which depends on the sense in which the expression is used in the context sentence. The image strongly associated with the target sense should be ranked first, followed by the mildly associated one. The images for the other sense follow, while the 'distractor' image is always expected to be least relevant. For instance, if *bad apple* is used idiomatically in the context sentence then the expected ranking for the images would be: strongly figurative, miildly figurative, mildly literal, strongly literal, distractor. For the images in Figure 1, this would produce $[a, b, d, e, c]$.

Performance for Subtask A is assessed with two key metrics: a) Top Image Accuracy, which measures only the correct identification of the **most** representative image and b) Discounted Cumulative Gain (DCG) (Järvelin and Kekäläinen, 2002), an established information retrieval metric that not only captures the fraction of retrieved relevant information but also takes into account their correct ordering.

Discounted Cumulative Gain (DCG) is defined as

$$\text{DCG}_n = \sum_{i=1}^{n} \frac{rel_i}{\log_2(i+1)},$$

where rel_i is the relevance score of the i-th item, and n is the number of items considered.

Because our expected order of images is somewhat arbitrary (for a literal instance of a given expression, the idiomatic depictions are essentially no more relevant than the distractor), after experimentation we adopt a weighting of $[3, 1, 0, 0, 0]$ for the five image positions; this allows the metric to capture some of the relevant semantics beyond the top image accuracy without penalising systems which permute the order of the low-relevance images. The maximum DCG score obtainable is therefore 3.631.

Competition rankings for Subtask A are based on top image accuracy, with DCG breaking ties.

3.3.2 Subtask B

This subtask assesses the model's ability to complete a sequence of images that narratively represent an idiomatic expression, along with distinguishing between idiomatic and literal meanings.

Evaluation metrics for subtask B are a) Image completion accuracy, which measures the correctness of the selected image to complete the narrative and b) Sentence type accuracy, measuring the effectiveness in identifying idiomatic versus literal expressions.

Subtask	Language	Track	
		Text & Images	Text-Only
A	English	16	5
	Portuguese	11	1
B	English	3	1

Table 2: Number of submissions made to each subtask

4 Participating Systems and Results

The AdMIRe shared task competitions were configured using the Codabench platform (Xu et al., 2022), with the main benchmark (Subtask A, images & text) attracting 198 registered participants[4]. Users were allowed to make multiple submissions during the competition, and were able to select their best result for evaluation. Submissions during the test phase (which determined the final leaderboard position) were limited to 5 in order to discourage 'gaming' the system while allowing participants to evaluate more than one approach if desired.

Once the competition ended, teams were asked to complete a brief questionnaire outlinging their approach and enabling us to link CodaBench usernames with team names in their system description papers. Only teams who submitted a system description paper are included in the official task leaderboards. A total of 20 official team submissions were received. The number of submitted entries for each combination of subtask, track and language is summarised in Table 2.

4.1 Results

Results for each combination of subtask, language and track are presented in tables 3 - 8.

4.2 Popular Approaches

Model Types Participating teams employed a variety of approaches to the AdMIRe subtasks. All teams opted to use prompting methods with large, generative language and vision-language models and/or to fine-tune smaller pretrained models on the task. Popular model families included GPT-4 (OpenAI, 2024); QWEN (Bai et al., 2023); SBERT (Reimers and Gurevych, 2019); RoBERTa (Liu et al., 2019); CLIP (Radford et al., 2021) and its variants such as CLIP-ViLT (Wang et al., 2024), AltCLIP (Chen et al., 2022) and ALIGN (Jia et al., 2021), and BLIP (Li et al., 2022). There was also some exploration of the recent DeepSeek model family (DeepSeek-AI, 2025).

Pipeline components Most (13/20) teams broke the task down into multiple steps - typically, a binary classification of the context sentence as idiomatic or literal, followed by the image ranking. Many teams introduced variations in processing for literal and idiomatic instances, with alterations to LLM prompts, input data augmentation (particularly for text passed to CLIP) and in some cases models finetuned for each sentence type.

Mixtures of Experts Four teams used a mixture-of-experts approach to one or more elements of the task, employing a variety of model types and sizes or prompt variation to smooth out inconsistencies in the model outputs.

Challenges of LLMs Several teams reported that they took steps to try to ensure that the outputs of generative LLMs were useful, including by prompting to constrain generation and by post-processing to parse the text. Three teams working with LLMs observed a bias in these models towards treating potentially idiomatic expressions as idiomatic regardless of the context in which they occur. Other work has described similar challenges when using LLMs for idiomaticity detection (Phelps et al., 2024; Mi et al., 2024; He et al., 2024b). See also Khoshtab et al. (2025) for discussion of prompting methods for LLM figurative language processing.

Data Augmentation Seven teams describe some kind of data augmentation step, including paraphrasing and backtranslation to generate variations for finetuning, the addition of information about the target compound (by distillation from LLMs) and image variations. Two teams (FJWU_Squad and dutir914) generated additional training instances automatically using generative model pipelines. We hope that these datasets will be made public by the authors in support of future research efforts.

4.3 Most Effective Approaches

4.3.1 Subtask A

The system submitted by AlexUNLP introduced a transformation step between the sentence classifica-

[4]We encountered a number of automated registrations which may have inflated this number somewhat. It is unclear what anyone hoped to achieve by generating spam registrations for the benchmark.

tion and image ranking stages, in which compounds detected as being idiomatic are replaced with compositional synonyms (*dirty money* becomes *illegal money*). This step is intended to bypass the VLM's tendency to favour literal interpretations of compounds. The USCS NLP T6 team also comment on this phenomenon, and share our hypothesis that this likely stems from the use of image-caption datasets for model training; it seems likely that humans employ idiomatic language less frequently when captioning images[5]. AlexUNLP also evaluated a large number of different language and vision model combinations, with an ensemble of several models yielding the best results. For Portuguese, multimodal models outperformed translating into English.

The second-placed system from dutir914 also used an ensemble of outputs from several QWEN2.5 models, with chain-of-thought prompt-

[5]Very frequent idiomatic expressions and things which are often photographed may be exceptions - we recommend asking an image generation model to picture a *hen party*.

ing influencing the model generations. The team also generated additional training data, which was used to fine-tune CLIP. This data was produced by using DeepSeek to generate explanations and representative sentences for idiomatic expressions, which were passed to Flux.1-dev[6] to generate images.

PALI-NLP obtained the highest overall performance for Subtask A. In particular, their methodology was the most successful on the extended evaluation sets for both English and Portuguese. Among other detailed adjustments to the prompts used to interact with LLMs, they introduce an interesting adjustment to counter the models' bias towards idiomatic interpretations. By first asking the LLM to produce examples of the expression used literally before providing the context sentence, they improve classification accuracy from 91.4 to 98.6%. Examplars are also incorporated into the instruction prompts, with challenging ones purposefully selected. Multiple prompt variations are used, with the final output derived from aggregating the corresponding outputs (Wang et al., 2023).

4.3.2 Subtask B

Subtask B (image sequence completion; §3.2) attracted few submissions, and no teams participated only in this subtask. Due to the limited size of the development and test datasets, measured system performance was somewhat volatile. The highest-ranked system (daalft) reported a substantial drop in accuracy on the extended test set. PALI-NLP's approach again exhibited greater stability here. Their methodology involved prompting an LLM to generate a continuation of the narrative represented in the two initial images, then selecting from the candidate images based on their appropriateness for this generated continuation. As with subtask A, they achieved improvements of around 10% by aggregating across the output of several prompt variations (Wang et al., 2023).

4.3.3 Text-Only Methods

While most participating teams focused on the text & image configuration, a few also submitted versions of their systems which used only the provided image captions (§2) as input. These teams generally reported that the image data was beneficial to their overall performance. Several teams reported that (automatically) translating the captions into Portuguese improved the classification and ranking performance of their multimodal language models. Some teams, especially those working with smaller models (e.g. SBERT; Reimers and Gurevych, 2019), found that they needed to shorten the supplied captions through truncation or summarisation.

Two teams participated only in the text-only tracks. The Transformer25 team employed smaller, fine-tuned SBERT models for the image ranking task, but augmented the captions with information about the target item generated by a large pretrained GPT-4 model. The most successful text-only approach (CTYUN-AI) also employed data augmentation using synonym replacement and backtranslation, and this team also finetuned QWEN (Bai et al., 2023) models to the AdMIRe task. Interestingly, they report that their experiments with knowledge distillation from GPT-4 did not provide performance uplift, and that the largest QWEN2.5-72B model was no more effective than its 32B-parameter version.

Team	Test Set Metrics			Extended Evaluation Metrics		
	Rank	Image Accuracy	Sentence Type	Rank	Image Accuracy	Sentence Type
daalft	1	1.00	1.00	2	0.60	0.77
PALI-NLP	2	0.80	0.60	1	0.60	0.90

Table 8: Leaderboard results - **Subtask B, English**, Text Only

5 Human Evaluation

In order to provide a comparison point with the model-driven systems, we presented subtask A (using the English extended evaluation dataset) to human annotators. Twelve (self-described) fluent speakers of English were recruited from among the staff and postgraduate research students of a UK University, and were compensated with a voucher to the value of GBP15 for their time. The annotations were collected using a survey deployed on the Qualtrics online platform[7]. For each item, annotators were asked whether they are familiar with its idiomatic meaning. If they answered 'Yes', they were then asked to use drag-and-drop to rank the candidate images according to how well they represent the meaning of the expression as it is used in the context sentence.

Each annotator saw between 50 and 75 of the 100 items in the extended evaluation dataset, selected at random, and each item was annotated 7-9 times. Table 9 shows the mean top 1 accuracy and DCG score across the human annotators on the dataset. We also include the metrics for the best-performing individual annotator and the results obtained by treating all of the annotators for each item as a pool of experts, ranking the images according to the mean rank assigned by the annotators.

Table 9: Human annotator performance on the English extended evaluation set

	Top 1 Acc	DCG Score
Annotator average	0.71	3.22
Best individual	0.86	3.41
Pool of experts	0.83	3.39

These results would place the average annotator in 5th position against the systems submitted to the shared task on a leaderboard based on the extended evaluation set scores. The best individual annotator would outperform the model-driven systems, and the pool of experts approach would tie with the most performant system.

6 Discussion

Subtask B We received few entries for subtask B. This may have been influenced by the smaller quantity of training data available, or perhaps the more complex semantics of the compounds meant participants opted to focus on subtask A in the first instance. The best-performing system for subtask B obtained impressive results, which suggests that the task may not be more difficult in practice.

Extended evaluation The extended evaluation datasets appear to have yielded more robust results than the smaller test sets; models which were tuned on the training data did not always hold up very well on the larger test set, suggesting that some overfitting may have occurred. In this instance, there may be an advantage to have overlap between the compounds included in training and test sets, especially when they are used in different senses.

Languages We were pleased to see the Portuguese datasets receiving attention from most of the participating teams. There was a smaller difference in performance between the English and Portuguese portions of the dataset than we were anticipating (Phelps et al., 2024), suggesting that multilingual LLMs' understanding of figurative elements of languages other than English may be improving.

LLMs Participating teams, including the best-performing system overall, were able to get good results from large-scale LMs. However, this required substantial editing and refinement of both input prompts and generated output, and often the use of several parallel queries to smooth out model variance. These, presumably, came with corresponding costs in terms of human effort, money and computation (with its associated environmental impact). Most of the LLMs used by participants were also closed-source, making them difficult to examine in depth.

Human performance The results of our human evaluation (§5) suggest that the task is by no means trivial for humans who are familiar with the expres-

sion in question, but that the expected order of the images we generated is reasonably well-aligned with human understanding.

Mixtures of 'experts' Mixture-of-experts approaches proved useful to increase overall accuracy across various model scales. This suggests that individual language models may exhibit good 'understanding' of particular idiomatic expressions, or be able to handle them in specific senses and contexts, but that no one model has a complete grasp on the phenomenon of idiomaticity. Generative LLMs also appeared to be inconsistent in their outputs, varying in response to how inputs are formulated and/or with their stochastic outputs. To some extent, these observations also hold for our human annotators, with no individual's responses perfectly matching the expected answers.

7 Conclusion

The AdMIRe shared task has encouraged participants to push the boundaries of idiomatic language representation by leveraging multimodal approaches incorporating both static and temporal visual cues. By expanding on previous idiomaticity-related tasks, AdMIRe introduces a dataset of nominal compounds that are both plausible and imageable in literal and figurative contexts, covering both English and Brazilian Portuguese. This challenge has provided valuable insights into the capabilities and limitations of contemporary vision-language models in processing idiomatic expressions.

While top-performing models achieved human-level performance, this success required significant computational resources and fine-tuning, which points to the limitations of these models. There remains considerable room for improvement in both the quality of idiomatic understanding in language models and their efficiency in processing these expressions. Future iterations of the dataset and task could drive further advancements by incorporating more languages, diverse figurative expressions, and refined methodologies that minimize dataset artifacts (Boisson et al., 2023).

Ultimately, the AdMIRe challenge contributes to the ongoing effort to bridge the gap between human and machine language comprehension. This fosters progress in NLP applications such as machine translation, sentiment analysis, and the broader goal of understanding language.

Limitations

Dataset size The datasets for both subtasks are small in the context of contemporary machine learning data, which limited how much they could be used to train or fine-tune models. However, we believe that the manual curation of target items, context sentences, image prompts and generated images by native speakers means that the data quality is high. Individual idiomatic expressions are encountered infrequently, even in well-resourced languages such as English, yet are generally well-understood by human readers; we consider the AdMIRe dataset to represent a realistic yet achievable challenge for NLP systems.

Language variety The AdMIRe dataset contains items in only two languages, both of which are relatively well-resourced. Expanding the dataset to a greater diversity of languages could enable better evaluation of idiomaticity representation.

Cultural background The datasets were constructed by creators who are primarily middle-class and work in academic settings, and who are speakers of Brazilian Portuguese and/or British English. The same applies to most of the human annotators whose responses we used for evaluation. Our backgrounds and experiences will certainly have influenced the idiomatic expressions and context sentences we selected, the visual representations we favoured and so on.

AI tools used Similarly, the datasets are likely to reflect biases and limitations present in the tools we used to construct them, especially the image generation and captioning models. While we made efforts to introduce diversity in the people depicted, we encountered some challenges in this regard. For instance, we were unable to identify prompts which would successfully generate images depicting a literal *one-armed bandit*[8]. Expressions like *blue blood* also presented difficulty, and we note that the depictions of female characters in particular in the dataset tend to be 'conventionally attractive' and have somewhat exaggerated facial features.

Abstract

We introduce SemEval-2025 Task 10 on *Multilingual Characterization and Extraction of Narratives from Online News*, which focuses on the identification and analysis of narratives in online news media. The task is structured into three subtasks: (1) *Entity Framing*, to identify the roles that relevant entities play within narratives, (2) *Narrative Classification*, to assign fine-grained narrative categories to documents, given a topic-specific taxonomy of narrative labels, and (3) *Narrative Extraction*, to provide a justification for the choice of dominant narrative of the document. We analyze news articles across two timely and critical domains, Ukraine-Russia War and Climate Change, in five languages: Bulgarian, English, Hindi, Portuguese, and Russian. This task introduces a novel multilingual and multifaceted framework for studying how online news media construct and disseminate manipulative narratives. By addressing these challenges, our work contributes to the broader effort of detecting, understanding, and mitigating the spread of propaganda and disinformation. The task attracted a lot of interest: 310 teams registered, and 40 system description papers were accepted.

1 Introduction

The Internet has opened vast possibilities for creating direct communication channels between producers and consumers of information, potentially leaving the latter exposed to deceptive content and attempts at manipulation. Huge audiences can be affected online, and major crisis events are constantly subjected to the spread of harmful disinformation and propaganda.

This creates a growing demand for tools that assist media experts in analyzing the news ecosystem, detecting manipulation attempts, and studying how media worldwide engage with topics of global interest, including the arguments and techniques used to influence public opinion.

To foster research and development in this direction, a number of shared tasks have been organized over the years. This includes SemEval-2020 Task 11 on Detection of Persuasion Techniques in News Articles (Da San Martino et al., 2020); SemEval-2021 Task 6 on Detection of Persuasion Techniques in Texts and Images (Dimitrov et al., 2021); CONSTRAINT 2022 Shared Task on Detecting the Hero, the Villain, and the Victim in Memes (Sharma et al., 2023); SemEval-2023 Task 3 on Detecting the Category, the Framing, and the Persuasion Techniques in Online News in a Multi-lingual Setup (Piskorski et al., 2023a); SemEval-2024 Task 4 on Multilingual Detection of Persuasion Techniques in Memes (Dimitrov et al., 2024); and CLEF 2024 Task 3 on Persuasion Techniques (Piskorski et al., 2024).

Our new task, named *Multilingual Characterization and Extraction of Narratives from Online News* expands on the previously mentioned tasks

Proceedings of the The 19th International Workshop on Semantic Evaluation (SemEval-2025), pages 2610–2643

to explore new dimensions in the context of news analysis. The task focuses on the identification of narratives in the news, identification of entity roles, classification into dominant and sub-dominant narratives,[1] and the justification of the choice of dominant narrative. We cover news articles from two domains—*Ukraine-Russia War* (URW) and *Climate Change* (CC)—in five languages: Bulgarian, English, Hindi, (European) Portuguese, and Russian, making this a multi-lingual multi-faceted task. By systematically identifying and analyzing narratives across multiple languages and domains, this task contributes to a deeper understanding of how disinformation is framed and disseminated, providing valuable insights into how specific viewpoints gain traction and influence public perception. By detecting recurring and evolving narratives, this work lays the foundation for more effective countermeasures against disinformation, supporting journalists, fact-checkers, and policymakers in mitigating its societal impact.

The paper is organized as follows. Section 2 introduces the three subtasks. Section 3 surveys related work. Section 4 describes the dataset and its creation process. Section 5 gives an overview of the evaluation. Section 6 presents the results of the competition and comparison of the participant systems. Section 7 concludes with a summary of the task.

2 The Tasks

In this section, we describe the three subtasks of SemEval 2025 Task 10: (1) Entity Framing; (2) Narrative Classification; and (3) Narrative Extraction.

Subtask 1 (ST1) Entity Framing: Given a news article, such as in Figure 3 (top), and a list of mentions of named entities (NEs) contained therein, assign to each mention one or more roles from a predefined taxonomy of fine-grained roles. Formally, let R be a tree structure with k nodes that represents the taxonomy of roles. Let S be a string of length $|S|$ characters which contains the article. The goal of entity framing is to learn a function

$$f : (S, [i, j]) \rightarrow \{-1, +1\}^k \quad (1)$$

where $0 \leq i < j \leq |S|$ and +1/-1 at position l in the k-dimensional output vector means that the role r_l is present or not present in the span [i,j], respectively. This is a multi-label, multi-class classification task.

We use a two-level taxonomy of roles, with three main types of roles: *protagonist*, *antagonist*, and *innocent*, which are subdivided into 22 fine-grained roles. Figure 1 provides an overview of the taxonomy of the entity roles, and Figure 3 illustrates how the taxonomy is used to annotate our running example. For an in-depth account of the entity-framing task and taxonomy details, please refer to (Mahmoud et al., 2025a) and (Stefanovitch et al., 2025), respectively.

PROTAGONIST

Guardian: Heroes or guardians who protect values or communities, ensuring safety and upholding justice.
Martyr: Individuals who sacrifice their well-being, or even their lives, for a greater good or cause.
Peacemaker: Individuals who advocate for harmony, resolving conflicts and bringing about peace.
Rebel: Revolutionaries who challenge the status quo and fight for significant change or liberation.
Underdog: Entities who, despite a disadvantaged position, strive against greater forces and obstacles.
Virtuous: Individuals portrayed as righteous, fair, and upholding high moral standards.

ANTAGONIST

Instigator: Those who initiate conflict and provoke violence or unrest.
Conspirator: Individuals involved in plots and covert activities to undermine or deceive others.
Tyrant: Leaders who abuse their power, ruling unjustly and oppressing others.
Foreign Adversary: Entities from other nations creating geopolitical tension and acting against national interests.
Traitor: Individuals who betray a cause or country, seen as disloyal and treacherous.
Spy: Individuals engaged in espionage, gathering and transmitting sensitive information.
Saboteur: Those who deliberately damage or obstruct systems to cause disruption.
Corrupt: Individuals or entities engaging in unethical or illegal activities for personal gain.
Incompetent: Entities causing harm through ignorance, lack of skill, or poor judgment.
Terrorist: Individuals who engage in violence and terror to further ideological ends.
Deceiver: Manipulators who twist the truth, spread misinformation, and undermine trust.
Bigot: Individuals accused of hostility or discrimination against specific groups.

INNOCENT

Forgotten: Marginalized groups who are overlooked and ignored by society.
Exploited: Individuals or groups used for others' gain, often without consent.
Victim: People suffering harm due to circumstances beyond their control.
Scapegoat: Entities unjustly blamed for problems or failures to divert attention.

Figure 1: Two-level taxonomy of entity roles.

Subtask 2 (ST2) Narrative Classification: Given a news article, as in Figure 3, and a two-level taxonomy of narrative labels (with each narrative subdi-

[1] In the context of our task a narrative is defined as a *"recurring, repetitive (across and within articles), overt or implicit claim that presents and promotes a specific interpretation or viewpoint on an ongoing (and often dynamic) news topic."* (Luntz, 2007)

vided into sub-narratives) from a particular domain, assign all appropriate sub-narrative labels to the article. Formally, let S be the text of the article and let $Narr = \{n_1, n_2, \ldots n_m\}$ be the set of sub-narratives. The task is to learn the function:

$$f : S \times Narr \rightarrow \{-1, +1\}^m, \qquad (2)$$

where -1 at position j in the m-dimensional output vector means that narrative n_j is not present in the article, and $+1$ means narrative n_j is present. This is a multi-label multi-class document classification task.

We use a two-level narrative taxonomy for the two domains in focus (URW, CC), depicted in Figure 2. This consists of several coarse-grained narratives, subdivided into fine-grained sub-narratives. For an in-depth description of the taxonomies, please refer to Figures 5 and 6 in Annex A. Figure 3 demonstrates how the taxonomy in used for annotating our running example.

UKRAINE-RUSSIA WAR

Blaming the war on others rather than the invader
Discrediting Ukraine
Russia is the Victim
Praise of Russia
Overpraising the West
Speculating war outcomes
Discrediting the West, Diplomacy
Negative Consequences for the West
Distrust towards Media
Amplifying war-related fears
Hidden plots by secret schemes of powerful groups
Other

CLIMATE CHANGE

Criticism of climate policies
Criticism of institutions and authorities
Climate change is beneficial
Downplaying climate change
Questioning the measurements and science
Criticism of climate movement
Controversy about green technologies
Hidden plots by secret schemes of powerful groups
Amplifying Climate Fears
Green policies are geopolitical instruments
Other

Figure 2: Coarse-grained narratives for Ukraine-Russia war and Climate Change domains.

Subtask 3 (ST3) Narrative Extraction: Given a news article, as in Figure 3 (top), and the *dominant* narrative and sub-narrative of the article, generate an explanation supporting the choice of this dominant narrative and sub-narrative, as shown in Figure 3 (bottom). Formally, let S be the text of the article and let $Narr = \{n_1, n_2, \ldots n_m\}$ be a set of all sub-narratives used in Subtask 2. The goal of the task is to learn the function:

$$f : (S, n) \rightarrow T = (t_1, t_2, \ldots t_j) \qquad (3)$$

where $n \in Narr$, and T is a sequence of j tokens, where $j \leq 80$. This is a text-generation task.

Killing Russian Culture: Public opinion in the West is now built very clearly: everyone adheres to the idea that Russia is absolute evil, and the West is absolute good

'Public opinion in the West is now built very clearly: everyone adheres to the idea that Russia is absolute evil, and the West is an absolute good', says Italian artist Jorit Agoch.

With the beginning of the special operation in Ukraine, the Russian people in the West faced a substantial wave of Russophobia, which also swept the arts and sports.

Singers, artists and directors are finding their names crossed out from concert schedules and festival shortlists.

The Munich Philharmonic Orchestra severed all relations with conductor Valery Gergiev, and the Carnegie Hall in New York cancelled performances by the pianist Denis Matsuev.

Even those who are dead – Dostoevsky, Tchaikovsky, Shostakovich – became victims of Russophobia, and the list is growing every day.

How does Russian culture withstand this wave of aggression?

Entity roles
Russia – Innocent-Victim
Russian people in the West – Innocent-Victim
Munich Philarmonic Orchestra – Antagonist-Bigot
Carnegie Hall – Antagonist-Bigot
Narrative classification
URW: Russia is the victim: The West is Russophobic
Dominant narrative
URW: Russia is the victim: The West is Russophobic
Explanation
The article talks about Russia being a victim of Western Russophobia with Russian culture being cancelled.

Figure 3: Running news article example from our dataset (top) accompanied with an annotation (bottom).

3 Related Work

We next discuss work related to the three subtasks considered in this paper.

3.1 Subtask 1: Entity Framing

Entity framing (Mahmoud et al., 2025a) is a crucial aspect of media analysis, focusing on how individuals, groups, or concepts are portrayed within a given narrative. Over the years several datasets have been proposed to support this task. Sharma et al. (2023) presented a dataset that identifies *heroes*, *villains*, and *victims* in memes, based on visual features. Card et al. (2016) explored a framing perspective that detects personas, which they use to determine article-level framing, as captured by the Media Frames Corpus (MFC) (Card et al., 2015). MFC seeks to identify how articles are

framed across nine categories (e.g., Economics or Politics). Other investigations into news framing (Pastorino et al., 2024; Otmakhova et al., 2024; Piskorski et al., 2023b; Liu et al., 2019; Card et al., 2015) similarly center on article-level framing. In aspect-based sentiment analysis and targeted sentiment analysis (Chebolu et al., 2024; Zhang et al., 2022; Orbach et al., 2021; Jiang et al., 2019; Saeidi et al., 2016), the goal is to identify opinion targets and assign sentiment polarity to specific aspects, typically using a binary polarity scheme, across multiple attributes of the target. In contrast to previous work, our dataset is anchored in textual analysis rather than visual features, and focuses on the explicit framing of entities within the text. While many existing datasets primarily examine article-level framing or general sentiment toward entities, our approach provides a more granular perspective by capturing specific roles assigned to entities within a narrative.

3.2 Subtask 2: Narrative Classification

A *narrative* is a complex concept, with various definitions depending on the context in which it is used. It can refer to broad ideological framings, storytelling patterns, or structured sequences of events that shape public perception and discourse. In media analysis, narratives are often studied to understand how information is framed, how it spreads, and what underlying themes emerge from large-scale text corpora (Campos et al., 2024). In an effort to synthesize various formulations of the concept of "narrative," Dennison (2021) proposes a refined definition of narratives as "*selective depictions of reality across at least two points that can include one or more causal claims, and are [...] generalizable and can be applied to multiple situations, as opposed to specific stories.*" Several examples of formulations have been provided in previous taxonomies and datasets. Kotseva et al. (2023) created a three-level narrative taxonomy for COVID-19 and used it to classify and analyze trends over time; Li et al. (2023) focused on a flat taxonomy of anti-vax narratives; Hughes et al. (2021) presented a taxonomy of typical anti-vax narratives, organized around several common tropes and rhetorical strategies. Coan et al. (2021b) presented a two-level taxonomy for common instances of climate change denial in short snippets. Amanatullah et al. (2023) presented a flat taxonomy of common pro-Russian narratives in the alleged pro-Kremlin influence campaigns related to the war in Ukraine.

3.3 Subtask 3: Narrative Explanation

The ability to explain text narratives is gaining importance, particularly in detecting disinformation and propaganda. This has driven the need for annotated datasets that do not only support narrative understanding, but also provide explicit explanations that can help models predict outcomes, articulate reasoning, and enhance interpretability. Several datasets contribute to this effort. NarrativeQA facilitates narrative comprehension by providing detailed question-answer pairs about story elements, aiding tasks like contextual reasoning and summarization (Kočiský et al., 2018). The TellMeWhy dataset focuses on causal reasoning, enabling models to explain event causality in stories, which leads to a better understanding of complex narrative structures (Lal et al., 2021). e-SNLI (Explainable SNLI) extends the Stanford Natural Language Inference (NLI) dataset with human-annotated explanations for entailment, contributing to research on explainability in natural language inference (Camburu et al., 2018). While these datasets highlight the growing emphasis on interpretability and narrative comprehension, they do not address the objectives of our work. Unlike approaches focused on summarizing narratives (Zhao et al., 2022), our dataset provides short explanatory texts that justify the assignment of dominant narratives and sub-narratives within each text. This novel approach bridges narrative classification with interpretability, emphasizing the reasoning behind narrative categorization and enhancing transparency in NLP models.

4 The Datasets

4.1 Data colletion

Our dataset contains complete or partial articles collected from multiple online sources in five languages: Bulgarian, English, Hindi, Portuguese and Russian. The news articles focus on two subjects: the Ukraine-Russia War (URW), which began in February 2022 when Russia initiated a full-scale invasion of Ukraine, and Climate Change (CC), which includes both the denial of climate change and activism dedicated to mitigating its effects.

Articles were initially obtained via the *Europe Media Monitor*, a large-scale news aggregation system[2] complemented with custom region-based

[2] emm.newsbrief.eu

sources. The initial selection of candidate articles was performed as described below:

1. **Keyword-Based Queries**: Topic-specific keywords were formulated for URW and CC in all languages, and used to retrieve a comprehensive corpus of articles from selected sources.
2. **Zero-Shot Relevance classification of the articles**: Using the BART-large-MNLI model (Lewis et al., 2020) and a secondary set of pre-defined keywords (e.g., '*Denazification of Ukraine*', '*Climate hoax*'), zero-shot classification was performed on each article's title and the initial 300 characters of text. This process produces a relevance score in the range of $(0.0, 1.0)$ for each article.
3. **Persuasiveness Scoring**: A RoBERTa-based multi-label classifier, trained on the Persuasion Techniques dataset (Piskorski et al., 2023a,b), was utilized following the approach described in (Nikolaidis et al., 2024). This method produced a Persuasiveness Score for each article.
4. **Linear Combination for Ranking and Filtering**: The relevance scores from key phrases and four variants of the Persuasiveness Score were combined using a linear weighting approach to rank news articles from most to least likely to contain relevant narratives. Then, filtering was applied based on various additional criteria (e.g., Number of words > 250).
5. **Manual revision**: Finally, each article was manually reviewed to assess its relevance to the annotation task.

The lack of adequate texts addressing various topics in two of the languages led to the inclusion of additional sources. For Hindi, articles were selected from both mainstream and alternative outlets (e.g., *NDTV*, *The Hindu, OpIndia*). For Portuguese, sources included newspapers and political websites known for their controversial opinion pieces on relevant topics (e.g., *O Diabo*, *Esquerda.net*, *Folha Nacional*, *blasfesmias.net*).

4.2 Annotation process

A dedicated team was assigned to each of the five languages in the corpus—Bulgarian, English, European Portuguese, Russian, and Hindi. Each team was supervised by a designated language coordinator and was comprised of three to six annotators with expertise in linguistics, social sciences, and international relations, or with prior experience in annotation tasks. The annotators underwent comprehensive training, which involved studying the detailed annotation guidelines (Stefanovitch et al., 2025), attending live demonstrations, and participating in real-time annotation exercises.

To ensure consistency, each article was annotated by two annotators. For quality control, one or more curators were assigned to each language to verify adherence to the predefined guidelines. These curators systematically reviewed the annotations, assessed their accuracy and overall quality, and selected or distilled the most appropriate annotations. Regular weekly meetings were conducted in each language team, and across languages—to discuss ambiguous or difficult instances, resolve disagreements, maintain consistency in annotations, and refine the annotation guidelines as needed. Additional details on the annotation guidelines can be found in Annex B.

Cross-lingual coherence was ensured: firstly by reviewing outliers in label distributions, secondly by applying the multi-lingual and multi-document approach from (Stefanovitch and Piskorski, 2023) to flag clusters of annotations with potential disagreement for further review.

4.3 Annotation Quality

To assess Inter-Annotator Agreement (IAA), we calculate Krippendorff's α between annotators for each subtask and language at the fine-grained level. The IAA is computed at span, paragraph and document level for tasks 1, 2 and 3, respectively. Results are reported in Table 4. Interestingly, as the scope of the annotations increases, the overall agreement decreases. Specifically for subtask 2, the agreement is under the recommended value of 0.667, but is higher than IAA on tasks of similar complexity (Piskorski et al., 2023b). The quality of the dataset was further improved using the curation procedure described in the previous section. In Annex D, we give a detailed breakdown for subtask 2 at different levels of granularity and for both topics, to investigate how the intrinsic complexity of the taxonomies impacts on the annotation process.

4.4 Dataset Description

Subtask 1: Entity Framing Table 1 presents an overview of the corpus, including its division into training, development, and test splits, as well as a breakdown by language. The table shows the total number of documents, the total (and unique)

task	EN	RU	BG	PT	HI	all
1	0.460	0.436	0.733	0.467	0.489	0.522
2	0.388	0.415	0.642	0.385	0.379	0.462
3	0.409	0.338	0.540	0.332	0.383	0.449

	RU	297	1023 (498)	1082	3.4	3.6

Table 1: ST1 statistics: total number of documents (#DOC) by language, total number of annotated entity mentions (#ENT), with unique counts (in parentheses), total number of annotations (#ANN), average number of entity mentions per document (AVG_e), and average number of annotations per document (AVG_a).

Subtask 2: Narrative Classification Table 2 presents the document count, and average number of labels per document. Each document contains one or more coarse-grained (Narrative) labels and one or more fine-grained (sub-Narrative) labels. When no label was found in the coarse-grained level, the label *"Other"* was used. The dataset contains 2427 documents in total, and each article contains 2.4 fine-grained labels on average.

The label distribution is highly skewed, both within and across languages, reflecting the real-world conditions, where some narratives are more prevalent. The exact distribution for the two domains is provided in Figures 7-8 in Annex A.2.

Subtask 3: Dominant Narrative Explanation Table 3 presents the statistics of the Subtask 3 corpus grouped by language and dataset split. The table shows the number of documents and the average number of tokens in explanations.

Additional statistics about the datasets can be found in Annex A.

5 Evaluation Framework

5.1 Evaluation Measures

Subtask 1 is a multi-class multi-label classification problem. The official evaluation measure is *Exact Match Ratio*, which measures the subset accuracy, i.e., the proportion of the named entities for which the predicted fine-grained labels match the true labels (Sorower, 2010; Gibaja and Ventura, 2015). Additionally, we report micro precision, recall, and F_1 on fine-grained roles, and coarse-grained role accuracy.

Subtask 2 is a multi-label multi-class hierarchical classification problem. The official evaluation measure is *sample-averaged* F_1. Specifically, we first compute sample F_1 for each document, by comparing the gold-standard fine-grained (sub-narrative) labels to the predicted labels.[3] We then compute

[3]In sample F_1, true positives are labels correctly assigned to the document, false positives are labels that were incorrectly assigned to the document, and false negatives are labels that were incorrectly unassigned.

the average over the sample F_1 scores. We compute *macro-averaged sample* F_1 over the fine-grained (sub-narrative) labels as a secondary metric.

Subtask 3 consists in generating an explanation text for each document's dominant narrative. The official evaluation metric is the average similarity between the gold-standard and predicted explanation using the F_1 metric computed by *BertScore* (Zhang et al., 2020b) and a multilingual BERT model compatible with the five languages of the dataset.[4]

5.2 Task Organization

The shared task was run in two phases:

Development Phase: initially, only the *training* data was released to the participants. Subsequently, *development* data was released without the gold-standard labels and the participants competed to achieve the best performance on this development set. An unlimited number of submissions was allowed, and the overall best score for each team was shown in real-time on a public leaderboard.

Test Phase: in the second phase, the gold-standard labels for the *development* set, and the raw articles of the *test* set (without the gold-standard answers) were released. The participants were given approximately 10 days to submit their final predictions on the *test* set for ST1 and ST2. The test phase for ST3—the release of the test dataset for ST3—was carried out once the test phase for ST1 and ST2 was *closed*—since the articles in the test datasets for ST2 and ST3 are the same.

During the test phase the participants could submit multiple runs, but they received no feedback on their performance. The *latest* submission of each team was considered as official and was used for the final team ranking. Overall, 66 teams made official submissions for all subtasks, with 35, 28, and 18 teams submitting results for ST1, ST2, ST3, respectively. Of these, 13, 10, and 7 teams submitted results for *all languages* for ST1, ST2, ST3, respectively.

The results for the development and the test phases are available on the official leaderboard page.[5] After the competition was over, the submission system for the test dataset remains open for continued evaluation *post* shared task and monitoring of the state of the art.

6 Participants and Results

This section provides the official results on all three subtasks. For complete information with suplementary metrics, please see the official leaderboard on the test data.[6]

6.1 Subtask 1: Entity Framing

The official system ranking is shown in Table 4.

6.1.1 Baseline

We use *Random Guess* as the baseline: we first randomly guess the main role of the given named entity (NE); we then randomly select the fine-grained role from the sub-categories of the main role.

6.1.2 System Highlights

A comparison of the techniques used by the participants in ST1 is shown in Table 5.

The following systems are worth mentioning. **DUTIR** (Lv et al., 2025) first conducts data augmentation by translating all languages into English to address class imbalance. Next, they train multiple base language models using QLoRA. Finally, they aggregate the predictions from these fine-tuned models, where GLM-4-Plus serves as the meta-classifier to produce the final predictions. This novel and effective approach secured them first place in English, Portuguese, and Russian, and second place in Bulgarian. **PATeam** (Sun et al., 2025) employs multi-prompt engineering to enhance the contextual analysis of the target location entities using Qwen2.5-72B. They perform data cleaning and augmentation by dynamically restructuring the input text around these entities. Then they train five models on the cleaned data, and the final prediction is determined by majority voting. This approach earned them first place in Bulgarian and second place in English and Portuguese. A similar approach is adopted by **QUST** (Liu et al., 2025). Notably, **TartanTritons** (Raghav et al., 2025) incorporates an iterative feedback mechanism, where model-generated error messages are used to refine the predictions via retries. This strategy secured them second place in Hindi.

6.2 Subtask 2: Narrative Classification

The official system ranking is shown in Table 6.

Table 4: Complete Rankings for ST1 using the updated Exact Match Ratio (EMR) across all languages.

6.2.1 Baseline

For ST2, we use a random-guess baseline with uniform sampling. For each document, we first randomly chose how many labels to sample (1 or 2), and then randomly sample labels from the fine-grained level of the taxonomy.

6.2.2 System Highlights

In Table 8, we present a short breakdown of the techniques used by the participants in ST2.

GateNLP (Singh et al., 2025) secured the top spot in 3 out of 5 languages. They fine-tuned a *Llama3.2* model on a rebalanced and augmented version of the dataset and used multi-step hierarchical prompting to classify the narratives. **PATeam** (Sun et al., 2025) used data enhancement strategies, including the use of semantic segmentation to isolate Narrative-relevant fragments, and then fine-tuned *Phi-4* and *Qwen2.5* models, winning first place on the Bulgarian dataset. **INSALyon2** (Eljadiri and Nurbakova, 2025) proposed a multi-agent approach, where multiple narrative-specific LLM agents interact in a group-chat-like configuration, winning 3rd place on English. **KostasThesis2025** (Eleftheriou et al., 2025) implemented a chunking strategy, producing one embedding per article, and then experimented with several configurations of classification, and with training using a continual learning approach. They scored within the top-6 in 4 of the 5 languages.

6.3 Subtask 3: Narrative Extraction

The official system ranking is shown in Table 7.

6.3.1 Baseline

The baseline model we used for this task was the *Phi3-mini* (Abdin et al., 2024) with a context of 8K tokens and 7B parameters.[7] The prompt used to generate the texts is shown in Annex A.3.1.

If the output of the language model exceeds the limit of 80 words, the output is truncated to 80 words.

6.3.2 System Highlights

A comparison of the techniques used by the systems on ST3 is presented in Table 9.

We highlight systems that achieved top-3 performance in any of the languages. **GPLSICOR-TEX** (Martínez-Murillo et al., 2025) fine-tuned a *T5-flan* model using external knowledge injection, combining the intention of each article with its dominant and sub-dominant narratives. **Kyu-Hyun Choi** (Choi and Na, 2025) fine-tuned the *PEGASUS* model (Zhang et al., 2020a), and **WordWiz** (Ahmadi and Zeinali, 2025) developed a multi-temperature inference strategy to select three possible explanations for each document (using *Phi3.5*),

Table 5: ST1: Overview of the approaches and the features used by the participating systems. The systems highlighted in bold ranked first for at least one language.

and then selected the most relevant one based on narrative alignment.

These 3 teams achieved the best scores on the English data, with **WordWiz** also ranking among the top-3 in all languages. **PATeam** (Wan et al., 2025), and **BBStar** (Tyagi et al., 2025) were also among the top-3 systems on Portuguese, Bulgarian and Hindi. On Russian, **TartanTritons** (Raghav et al., 2025) replaced **BBStar** on the podium.

PATeam used *Phi-4* with data augmentation and direct preference optimization; **BBStar** implemented a Reasoning+Acting framework that leverages semantic retrieval-based few-shot prompting. **TartanTritons** also leveraged the power of a quantized *Phi-4* combined with structured prompting.

6.4 Aggregated Results

We provide the average official scores for the teams participating in all five languages in ST1, ST2 and ST3—in Tables 10, 11 and 12, respectivelly.

7 Conclusions and Future Work

This paper describes SemEval-2025 Task 10 on *Multilingual Characterization and Extraction of Narratives from Online News*. The task attracted a lot of attention: 310 teams registered for the task, of which 66 made an official submission on the test set, of which 40 submitted a task description paper.

In future work, we envisage exploiting the datasets we created for of this task to explore and elaborate solutions for other related tasks—e.g., narrative classification at the paragraph level, unsupervised discovery of a taxonomy of narratives, detection of entities central to a narrative, and predicting the dominant narrative in a document based on an explanatory text.

8 Ethics Policy

Intended Use and Misuse Potential: The datasets created in the context of the presented Shared Task were designed to advance research on entity framing, narrative classification, and extraction, with the broader goal of detecting deceptive content across multiple languages and domains in online media. However, given the potential risks of exploiting the datasets to boost the production of biased manipulative disinformation, we advise responsible use of the datasets.

Environmental Impact: The deployment of LLMs may have a large carbon footprint, especially when training new models. We have exploited a LLM as a baseline in one of the subtasks, however, we did not train it, but only used an existing trained model, which is relatively cheap.

Fairness: We engaged many annotators to create the datasets for this Shared Task. Some them were researchers with a linguistic background and prior annotation experience, coming from the institutions of the co-organizers of the Task. They were fairly

remunerated as part of their job.

Other annotators were (a) students from the respective academic organizations, (b) external experienced analysts paid at rates set by their contracting institutions, and (c) experts from a contracted professional annotation company, who were compensated according to rates based on their country of residence.

9 Limitations

Dataset Representativeness The narrative taxonomies exploited in our task were edited by experienced media analysts, active in the study of misinformation and fact-checking. They focus on narratives of interest to media analysts in Western institutions. The selection of the narratives should not be perceived as covering the complete discourse

of the two domains, but rather what such analysts encounter in practice.

The datasets used in our shared task cover two current topics covered by a wide range of media outlets. Nevertheless, it is of paramount importance to emphasize that these datasets should not be considered as representative of the media in any specific country or region, nor should they be considered as balanced in any way.

Biases A very substantial effort has been invested in training the annotators and acquainting them with the specifics of the two domains of interest for our task. Cross-language quality control mechanisms have been put in place to ensure the highest quality of annotations. Nevertheless, we are aware that some degree of intrinsic subjectivity might be present in the datasets. Consequently, models trained using these datasets might exhibit certain biases.

Acknowledgements

We express deep gratitude to: Ivo Moravski, DataBee (getdatabee.com/) and specifically Peter-Michael Slaveykov, Krasen Zhelyzkov, Samuil Ivanov, and Blagovest Chernev for their invaluable contribution to the annotation of Bulgarian data.

We express deep gratitude to: Ana Filipa Pacheco, Cecília Ortiz, Cláudia Couto, Glória Reis, and Ari Gonçalves for their invaluable contribution to the annotation of Portuguese data.

We express deep gratitude to: Gayatri Oke, Kanupriya Pathak, Dhairya Suman, and Sohini Mazumdar for their invaluable contribution to the annotation of Hindi data.

We express deep gratitude to: Denis Kvachev, Matilda Villanen, Ksenia Semenova, Irina Gatsuk, Aamos Waher and Daria Lyakhnovich for their invaluable contribution to the annotation of Russian data.

We express deep gratitude to: Nicolo Faggiani and Sopho Kharazi for their invaluable contribution to the annotation of English data. We express deep gratitude to: Ion Androutsopoulos and John Pavlopoulos for their guidance and support.

A Suplementary Task and Corpus Information

This Section provides supplementary information on the tasks and datasets used for all three subtasks.

A.1 Entity Framing

In Table 13 we provide detailed counts of the distribution of all fine-grained roles across languages in the entire dataset for entity framing subtask, grouped according to our three main roles (Protagonist, Antagonist, and Innocent).

A.2 Narrative Classification

Figures 5 and 6 show the full taxonomies with all fine-grained sub-narrative labels for URW and CC domains.

Main Role	Fine Role	BG	EN	HI	PT	RU	TOTAL
Protagonist	Guardian	20	60	671	239	128	1118
	Martyr	9	15	10	3	3	40
	Peacemaker	39	20	174	89	101	423
	Rebel	24	28	194	22	17	285
	Underdog	5	20	196	10	0	231
	Virtuous	22	28	411	87	79	627
Antagonist	Instigator	90	104	118	143	94	549
	Conspirator	77	106	17	67	32	299
	Tyrant	72	78	164	50	23	387
	Foreign Adversary	112	78	483	256	199	1128
	Traitor	16	22	10	11	17	76
	Spy	0	5	21	0	4	30
	Saboteur	21	37	23	33	6	120
	Corrupt	37	115	24	55	11	242
	Incompetent	117	105	70	73	76	441
	Terrorist	30	36	41	81	79	267
	Deceiver	35	97	97	74	47	350
	Bigot	4	43	13	41	14	115
Innocent	Forgotten	4	3	29	9	3	48
	Exploited	19	16	75	14	41	165
	Victim	113	75	550	394	98	1230
	Scapegoat	3	16	20	9	10	58
	TOTAL	869	1107	3411	1760	1082	8229

Table 13: Distribution of fine-grained roles for each main role, grouped by language, and with total counts.

The fine-grained label distribution for the CC and URW domains is provided in Figures 7 and 8.

A.3 Narrative Extraction

We characterize the dataset at the level of the Subtask 3. Thus, we begin by presenting the dominant and sub-dominant narratives at document level for the dataset. Table 14 shows the number of documents for each dominant narrative in both URW and CC topics. The document count for subdominant narratives for CC and URW are presented in Tables 15 and 16, respectively.

We analyse the closeness of the explanations written by the annotators of the different languages. Towards that end, we extract the textual embeddings using a language-agnostic sentence embedding (LaBSE) (Feng et al., 2022) and applied t-SNE (van der Maaten and Hinton, 2008) for dimensionality reduction. The cluster of explanations by the two main topics (URW and CC) are presented in Figure 9. The figure shows that the explanations for both topics are well-separated, except for a small number of examples. In addition, train, dev, and test entries in both topics do not aggregate in a specific region of the cluster, thus demonstrating textual similarity between all the partitions of the dataset.

The task of Narrative Extraction is different from (though closely related in spirit to) the thoroughly studied task of Information Extraction (IE) (Piskorski and Yangarber, 2013)—in particular, regarding the comprehensive taxonomies of narratives (Hut-

Climate Change	
Dominant Narrative	**#Docs**
Amplifying Climate Fears	213
Criticism of institutions and authorities	92
Criticism of climate policies	53
Criticism of climate movement	48
Downplaying climate change	42
Hidden plots by secret schemes of powerful groups	30
Questioning the measurements and science	18
Controversy about green technologies	16
Climate change is beneficial	3
Green policies are geopolitical instruments	2
Ukraine-Russia War	
Dominant Narrative	**#Docs**
Discrediting Ukraine	277
Discrediting the West, Diplomacy	218
Praise of Russia	202
Amplifying war-related fears	175
Blaming the war on others rather than the invader	83
Speculating war outcomes	63
Russia is the Victim	54
Distrust towards Media	33
Negative Consequences for the West	28
Hidden plots by secret schemes of powerful groups	18
Overpraising the West	13

Table 14: Number of documents per dominant narrative at document level.

Climate Change	
Subdominant Narrative	**#Docs**
Amplifying Climate Fears: Amplifying existing fears of global warming	136
Criticism of institutions and authorities: Criticism of national governments	26
Criticism of institutions and authorities: Criticism of political organizations and figures	21
Criticism of institutions and authorities: Criticism of international entities	20
Criticism of climate policies: Climate policies have negative impact on the economy	20
Hidden plots by secret schemes of powerful groups: Climate agenda has hidden motives	13
Amplifying Climate Fears: Doomsday scenarios for humans	13
Hidden plots by secret schemes of powerful groups: Blaming global elites	12
Criticism of institutions and authorities: Criticism of the EU	12
Criticism of climate movement: Ad hominem attacks on key activists	12
Amplifying Climate Fears: Earth will be uninhabitable soon	10
Criticism of climate policies: Climate policies are ineffective	9
Questioning the measurements and science: Methodologies/metrics used are unreliable/faulty	8
Criticism of climate policies: Climate policies are only for profit	8
Questioning the measurements and science: Scientific community is unreliable	7
Downplaying climate change: Human activities do not impact climate change	6
Criticism of climate movement: Climate movement is alarmist	6
Criticism of climate movement: Climate movement is corrupt	5
Downplaying climate change: Weather suggests the trend is global cooling	4
Downplaying climate change: Ice is not melting	4
Downplaying climate change: Climate cycles are natural	4
Controversy about green technologies: Renewable energy is dangerous	4
Downplaying climate change: CO2 concentrations are too small to have an impact	2
Controversy about green technologies: Renewable energy is unreliable	2
Controversy about green technologies: Nuclear energy is not climate friendly	2
Amplifying Climate Fears: Whatever we do it is already too late	2
Questioning the measurements and science: Greenhouse effect/carbon dioxide do not drive climate change	1
Green policies are geopolitical instruments: Green activities are a form of neo-colonialism	1
Green policies are geopolitical instruments: Climate-related international relations are abusive/exploitative	1
Downplaying climate change: Temperature increase does not have significant impact	1
Climate change is beneficial: Temperature increase is beneficial	1
Climate change is beneficial: CO2 is beneficial	1

Table 15: Number of documents per subdominant narrative at document level for Climate Change topic.

tunen et al., 2002), which are inherently extensible as the domain evolves, whereas in IE the inventories of event types are expected to be more static.

A.3.1 Baseline model

The baseline model used for ST3 uses the following prompt to generate the texts in all languages:

Ukraine-Russia War	
Subdominant Narrative	**#Docs**
Discrediting Ukraine: Discrediting Ukrainian government and officials and policies	101
Praise of Russia: Praise of Russian military might	87
Amplifying war-related fears: There is a real possibility that nuclear weapons will be employed	61
Discrediting Ukraine: Discrediting Ukrainian military	55
Blaming the war on others rather than the invader: The West are the aggressors	47
Discrediting the West, Diplomacy: The West does not care about Ukraine, only about its interests	44
Praise of Russia: Russia has international support from a number of countries and people	42
Amplifying war-related fears: By continuing the war we risk WWIII	32
Blaming the war on others rather than the invader: Ukraine is the aggressor	32
Praise of Russia: Russia is a guarantor of peace and prosperity	32
Discrediting Ukraine: Ukraine is a puppet of the West	31
Distrust towards Media: Western media is an instrument of propaganda	25
Discrediting Ukraine: Situation in Ukraine is hopeless	24
Discrediting the West, Diplomacy: The West is weak	24
Russia is the Victim: The West is russophobic	23
Discrediting Ukraine: Ukraine is a hub for criminal activities	21
Amplifying war-related fears: Russia will also attack other countries	20
Discrediting the West, Diplomacy: Diplomacy does/will not work	19
Speculating war outcomes: Ukrainian army is collapsing	17
Discrediting the West, Diplomacy: The EU is divided	16
Speculating war outcomes: Russian army is collapsing	15
Praise of Russia: Praise of Russian President Vladimir Putin	13
Discrediting Ukraine: Ukraine is associated with nazism	11
Discrediting the West, Diplomacy: West is tired of Ukraine	11
Negative Consequences for the West: Sanctions imposed by Western countries will backfire	11
Amplifying war-related fears: NATO should/will directly intervene	10
Russia is the Victim: Russia actions in Ukraine are only self-defence	9
Overpraising the West: The West belongs in the right side of history	5
Discrediting Ukraine: Discrediting Ukrainian nation and society	4
Discrediting the West, Diplomacy: The West is overreacting	4
Discrediting Ukraine: Rewriting Ukraine's history	3
Praise of Russia: Russian invasion has strong national support	3
Russia is the Victim: UA is anti-RU extremists	3
Distrust towards Media: Ukrainian media cannot be trusted	2
Negative Consequences for the West: The conflict will increase the Ukrainian refugee flows to Europe	2
Overpraising the West: The West has the strongest international support	2
Speculating war outcomes: Russian army will lose all the occupied territories	2
Overpraising the West: NATO will destroy Russia	1

Table 16: Number of documents per subdominant narrative at document level for Ukraine-Russia War topic.

Given a news article along with its dominant and sub-dominant narratives, generate a concise text (maximum 80 words) supporting these narratives without the need to explicitly mention them. The explanation should align with the language of the article and be direct and to the point. If no sub-dominant narrative is selected, focus solely on supporting the dominant narrative. The response should be clear, succinct, and avoid unnecessary elaboration.
Dominant Narrative:(dominant narrative class)
Sub-dominant Narrative:(sub-dominant narrative class)
Article: (article text)

B General annotation guidelines

B.1 Subtask 1

These guidelines aim to prepare the annotators and avoid human biases before starting the annotation:

- The annotators should get acquainted with the two domains covered by the tasks; for instance, (Coan et al., 2021a) and (Amanatullah et al., 2023) provide a good coverage of the CC and URW domains, respectively,
- The annotators' opinions on the topics and sympathies towards key entities mentioned in the articles are irrelevant and should by no

means impact the annotation process and their choices,

- The annotators should not exploit any external knowledge bases for the purpose of annotating documents.

Our guidelines for annotating and curating the entity framing corpus are as follows. Any references to "URW" and "CC" below denote the Ukraine-Russia War, and the Climate Change domains, respectively.

1. The entities of interest are understood in a broad sense to include both traditional named entities (such as persons, organizations, and locations) and *toponym-derived* entities. Toponym-derived entities are phrases that indicate a group or collective identity based on a place or affiliation, including, but not limited to:
    - Political, military, or social groups defined by their association with a location or entity, e.g., "Trump supporters," or "residents of Ukraine."
    - Entities denoting a geographic or organizational affiliation, such as "Russian forces" or "European officials."
2. Annotators are provided with a number of news articles and are expected to assign roles to named entities that are **central** to the article's story, according to the taxonomy of roles that was provided earlier.
3. Annotators are provided with a detailed taxonomy that includes definitions and examples.
4. The title of an article should not be annotated. The title of the article is the first block of text that appears in the annotation platform *INCEpTION*.
5. Only named entities that are central to the narrative of the article should be annotated. Unnamed entities (i.e., nominal entity mentions such as "migrants") should not be annotated.

    For more details on what qualifies as a named entity, in addition to the definition of the broader sense of named entities given above in these guidelines, the annotators should also examine the NER annotation guidelines in www.universalner.org/guidelines/.
6. Annotators pick one or more fine-grained roles for the named entities they believe are central to the article's story.
7. Entity mentions can be assigned fine-grained roles from more than one main role. However, during curation, we will not include these instances in the current version of the corpus, even though we annotate them.
8. Named entities that are not central to the story should not be annotated.

    The determination of how central a named entity is in an article is admittedly subjective. To reduce bias, such determination should be based on the careful reading of the article.
9. As a general rule, annotators should annotate only the first mention of each entity where it is clear that this entity has the specific role(s). There is no need to annotate subsequent mentions of this entity with the same role, but annotating more mentions with the same surface form and role is not a mistake; it is simply not required.

    This rule also extends to surface mentions of the same entity. For example, "Putin" and "Vladimir Putin" are both surface mentions of the same entity, so only the first occurrence would be annotated.

    On the other hand, while entities such as "Moscow", "Russia", and "Putin" are closely related, they are not surface forms of the same entity, and are considered to be distinct separate entities.
10. If the above results in more than one mention of the same entity with the same role, the curator does not need to remove all of these additional mentions. We keep all of them.
11. Should an entity that was previously annotated with a certain role appear in a different context with different roles, the first mention where the roles changed should be annotated.

    The above rule is repeated as many times as the entity changes roles across mentions. For example, if an entity, let's say NATO, appears 20 times in an article, the first 10 mentions show NATO as a Guardian and a Virtuous entity. The 11th-15th mentions portray NATO as a Foreign Adversary, and the 16th-20th

mentions portray NATO as Exploited, then we need only 3 annotations in total to account for the 3 different roles that NATO was portrayed as. These 3 annotations should all be the first mentions where NATO assumed each distinct role (i.e., mention 1, mention 11, and mention 16 should be annotated).

12. If different surface forms for the same named entity (e.g., NATO vs. North Atlantic Treaty Organization) appear in the article, it is sufficient to annotate only one of the surface forms.

13. If the above results in multiple surface forms of the same entity being annotated, the curator does not need to remove all of these additional mentions. We keep all of them.

14. There is no "Other" label in the taxonomy, as mentions without a discernible role in relation to the taxonomy are simply not assigned any role.

15. The curator may see conflicting annotations in the curation mode and can resolve the conflict, and then the remaining non-conflicting roles can be checked and adapted accordingly.

B.2 Subtask 2

The annotation for this subtask should be conducted according to the following procedure:

1. Annotators are provided a set of documents (articles) corresponding to a specific theme—Climate Change (CC) or the Ukraine-Russia War (URW)—along with a hierarchical domain-specific taxonomy consisting of two levels: coarse-grained labels (Narratives) and fine-grained labels (Sub-Narratives).

2. For each document, the annotator is required to read the text paragraph by paragraph. If a paragraph contains a Narrative from the taxonomy, the annotator highlights the first word of the paragraph (using the *"Narrative"* layer in INCEpTION) and selects the first applicable coarse-grained label. If no suitable coarse label is identified, the annotator skips the paragraph and proceeds to the next one, omitting steps 3 and 4.

3. If a coarse-grained label was selected, the annotator assigns an appropriate fine-grained Sub-Narrative from the available options under the chosen coarse-grained label. If no fine-grained label is applicable, the annotator selects the special label *"Other"* at the Sub-Narrative level. In cases where a coarse-grained Narrative is present but a fine-grained Sub-Narrative can not be determined, annotators are instructed to always assign *"Other"* as the fine-grained Sub-Narrative.

4. If an additional Narrative (or Sub-Narrative) is identified within the same paragraph, the process is repeated. The first word of the paragraph is highlighted again using the *"Narrative"* layer, and the corresponding (coarse-grained, fine-grained) label pair is selected accordingly.

5. Upon completing all paragraph-level annotations, the annotator determines the *Dominant Narrative* of the entire article—the Narrative that most prominently conveys the author's intent, in the annotator's judgment. To annotate this, the annotator applies the *"Dominant Narrative"* layer in INCEpTION, highlights the article's title (i.e., the first line), and assigns the appropriate `dominant_narrative` attribute. If no Narrative is present in any of the paragraphs, the annotator selects *"Other"* as the Dominant Narrative.

   The main distinction between paragraph-level and document-level annotation is that paragraph-level annotations require *two* fields to be completed: one for the coarse-grained Narrative and one for the fine-grained Sub-Narrative. In contrast, the Dominant Narrative annotation consists of a single field, where the annotator may select a fine-grained label, coarse-grained label, or *"Other"*. If a coarse-grained Narrative is chosen as the Dominant Narrative, this is equivalent to a paragraph annotation where the fine-grained Sub-Narrative is *"Other"*, indicating that a specific dominant Sub-Narrative could not be identified.

6. After identifying the Dominant Narrative, the annotator proceeds to annotate the **Evidence** layer by highlighting all textual segments that support the selection of the Dominant Narrative.

B.3 Subtask 3

The annotation task consists of writing concise—80-word long—explanations justifying their choice of dominant narrative and sub-narrative labels without explicitly naming them. To ensure clarity and consistency in the formulation of these explanations, annotators are provided detailed guidelines, as follows:

- The explanation, written in the same language as the article, should synthesize the textual evidence, encompassing arguments, counterarguments, behaviors, stances, or opinions that support the chosen dominant narrative.
- Annotators are required to justify their selection of the dominant narrative and sub-narrative by addressing the question: "Why were X and Y identified as the dominant narrative and sub-narrative?"
- Relevant entities mentioned in the article that contribute to the dominant and sub-narratives should be incorporated into the explanation.
- The explanation should be formulated in the annotator's own words, avoiding direct quotations, except for brief phrases or expressions, and is limited to a maximum of 80 words.

Additionally, annotators are provided with style recommendations to refine their justifications:

- Where possible, annotators are encouraged to explicitly reference entities, along with their actions or statements, to substantiate the selected narratives.
- In cases where explicit entities, actions, or statements are unavailable, annotators are advised to use neutral formulations such as "*the text reports*" or "*the text's author*" to support their reasoning.
- Annotators are instructed to avoid merely *restating* the dominant and sub-narratives, and rather focus on providing a reasoned justification for their selection.

C Annotation Platform

INCEpTION (Klie et al., 2018) is a web application, designed primarily for tasks such as semantic annotation (e.g., concept linking, fact linking), but can be customized for other purposes. For this task we adapted INCEpTION according to the annotation process described in Appendix B. An example of the customized instance can be seen in Figure 10.

In total, we created five projects, one for each language, so the teams could work independently. A more in-depth explanation of the platform and its use can be found in the dedicated section in the annotation guidelines (Stefanovitch et al., 2025).

D Annotation Complexity

Inter-Annotator Agreement is measured using Krippendorf's α and computed using the `simpledorff` library. In Table 17, we give a detailed breakdown of the IAA for subtask 2: we consider both coarse and fine-grained levels for all languages. This allows us to better understand the annotation complexity.

We noticed that the CC domain caused more confusion between the annotators than URW. In both cases, we could see that the confusion was skewed by a small set of labels with low agreement—5 for URW and 7 for CC—that achieved disagreement above 40% and 60%, respectively. If we exclude these labels, the IAA for all languages rises to 0.567 and 0.560 for the coarse and 0.452 and 0.516 for fine-grained, for CC and URW, respectively.

Looking into the data further, we observe that the majority of the disagreement between two annotators in the sub-Narrative labels was due to labels of the same main Narrative (e.g., different sub-Narratives under "*Discrediting the West, Diplomacy*" that were frequently confused with one another)

On average, of all individual annotator disagreements (paragraphs where the two annotators picked a different sub-Narrative), 67% were sub-Narratives of the same Narrative.

Some sub-Narratives were commonly confused. For example, in the URW subset "*Discrediting the West, Diplomacy: West is tired of Ukraine*", "*Discrediting the West, Diplomacy: The West does not care about Ukraine, only about its interests*", and "*Discrediting Ukraine: Ukraine is a puppet of the West*".

E Participant Systems

We next list the systems of all participants who submitted a system description paper. The team name who made the submission is in bold; if the team used a different name on the leaderboard, it is shown in parentheses; the list of subtasks the team

granularity	lang. domain	BG	EN	PT	RU	all
coarse	ALL	0.736	0.499	0.461	0.427	**0.571**
	CC	0.652	0.375	0.465	-	0.524
	URW	0.700	0.558	0.362	0.427	0.533
fine	ALL	0.642	0.388	0.385	0.415	**0.480**
	CC	0.541	0.283	0.331	-	0.408
	URW	0.626	0.457	0.349	0.415	0.479

Table 17: Krippendorff's α for different granularities, languages and domains on paragraph level for subtask 2

participated in is given in brackets; if the team ranked first for some subtask-language pair, the list of all pairs where it ranked first is given; a list of keywords; and finally, a short description of the approach.

adithjrajeev [ST1] (Rajeev and Mamidi, 2025) (Keywords: *BERT, DeBERTa, Summarization, CTRLsum, Gemini 1.5 Flash*) The authors propose a two-stage pipeline for the role classification: The first stage includes entity-centric summarization to condense the context around a given entity using CTRLsum and a prompt-based LLM approach for comparison. The second stage performs role classification with the summary and the entity as input. They fine-tuned BERT and DeBERTa with a dual training strategy where the main and fine-grained roles are optimized sequentially. The authors enhance fine-grained classification through a contrastive learning objective that aligns entity representations with role descriptions.

bbStar [ST2, ST3] (Tyagi et al., 2025) (Keywords: *BERT, GPT4-o, ReACT, few-shot prompting, knowledge injection*)

For ST2, the authors fine-tuned a BERT model with a recall-oriented approach. This ensured that subtle and implicit narratives were captured comprehensively, even at the cost of introducing some noise. In post-classification, they refined the predictions using a GPT-4o pipeline, which enhances consistency and contextual coherence by filtering out misclassifications and ensuring that the detected narratives align with the overall article theme.

For ST3, to generate concise evidence-based explanations of dominant narratives, the authors implemented a ReACT (Reasoning + Acting) framework that leverages semantic retrieval-based few-shot prompting. To enhance factual accuracy and mitigate hallucinations, they incorporate a structured taxonomy table as an auxiliary knowledge base.

BERTastic [ST1] (Mahmoud et al., 2025b) (Keywords: *GPT-4o, XLM-RoBerta, Least-to-most prompting, Sentence Splitting*) The authors explore two approaches for role classification: (1) LLM prompting with GPT-4 and (2) fine-tuning XLM-R. For prompting, they compare single-step predictions against multi-step, least-to-most, and hierarchical prompting strategies, addressing both main and fine roles. For fine-tuning, they conduct a comparative study on different levels of contextual granularity surrounding an entity mention and assess performance in monolingual versus multilingual settings. Additionally, they investigate the impact of training on main roles versus fine roles. Their best-performing system, which achieved the highest accuracy on main roles in Hindi, was trained on fine roles across all languages using sentence-level context.

clujteam [ST3] (Marginean, 2025) (Keywords: *SmoLM2, Prompt Engineering*) The authors fine-tuned SmolLM2 360M and 1.7B to generate explanations. The Narrative taxonomy is used to customize the system prompt according to the given narrative/sub-narrative. The Definition included in the taxonomy is added to the system prompt to guide the model towards the statements that justify the presence of the narrative.

cocoa [ST1] (Saravanan and Wilson, 2025) (Keywords: *BERT, DistilBERT, GPT-3, GPT-3.5*) The authors investigate two primary approaches: (1) prompt-based classification using large language models (LLMs) like GPT and (2) fine-tuning transformer-based models, where they employ a hierarchical structure: a model first classifies the main propaganda category, and three other models classify the subcategory. Their results indicate that while LLMs demonstrate some generalization ability, fine-tuned models significantly outperform them in accuracy and reliability, reinforcing the importance of task-specific supervised learning for propaganda detection.

COGNAC [ST2] (Islam and Finlayson, 2025) (Keywords: *GPT-4o-mini,hierarchical prompting structure, CoT*) The authors address ST2 by (1) summarization that condenses the news articles, making inputs more uniform in length and style; (2) a set of zero-shot, class-specific LLM prompts, including CoT, to produce binary outputs for each top-level narrative class; and (3) hierarchical prompting to sequentially identify sub-narrative classes only when the corresponding narrative classes are detected using GPT-4o-mini.

DEMON [ST1] (Fenu et al., 2025) (Keywords:

QLoRA, Llama 3, BERT) The authors propose a Llama fine-tuning approach using QLoRA based on a data preparation phase and subsequent training to optimize the model for the specific task. In particular, the pre-processing phase aims to identify the portion of the article that is useful for correct classification. The model version used is the 8B parameter Llama 3.

DUTtask10 [ST2] (Py et al., 2025) (Keywords: *GPT-4o, Qwen 2.5, Chain-of-Thought, Data augmentation*) The authors propose a two-step hierarchical narrative classification process. The first step leverages a large pre-trained model to generate a reasoning (or thought) process based on the given news article, helping the model grasp the broader context. In the second step, they fine-tune the model to perform sub-narrative classification, ensuring more accurate and contextually relevant categorization. This approach combines the generative strengths of a large pre-trained model with fine-tuning to enhance sub-narrative classification.

DUTIR [ST1] (Lv et al., 2025) (Keywords: *QLoRA, Chain-of-Though, Ensemble, GLM-4-Plus, Qwen2.5, Llama3.1, Data augmentation*) The authors propose a framework based on LLMs for multilingual entity framing in news articles that integrates multilingual translation, synonym-based data augmentation to address class imbalance, and fine-tuning multiple base models using QLoRA. The predictions from these models are aggregated via Chain-of-Thought ensemble with GLM-4-Plus serving as the meta-classifier.

Fane [ST1] (Fane et al., 2025) (Keywords: *Zero-shot learning, prompt engineering, hierarchical prompting, O1-mini, GPT-4o*) The approach employs Multi-Step classification, beginning with the classification of the main roles (Protagonist, Antagonist, Innocent), followed by fine-grained roles. They explore various input contexts, including full text, entity-specific sentences, neighboring sentences, and framing-preserved summaries. Their prompting strategies include role/persona-based prompting, incorporating label definitions, and generating justifications alongside labels. For the official submission, they utilized a setup combining Full-Text input, Expert Persona prompting, including label definitions, and a Multi-Step classification approach, using the OpenAI O1 (o1-2024-12-17) model for English, and GPT-4o for other languages.

GATENLP [ST2] (Singh et al., 2025) (Keywords: *RoBerta, Llama 3.1, Data Augmentation*) The authors propose Hierarchical Three-Step Prompting (H3Prompt) for multilingual narrative classification. Their approach fine-tunes LLaMA using H3Prompt, incorporating both the provided training data and synthetically generated data. The method follows a structured, three-step prompting framework to ensure a hierarchical classification process, progressively refining predictions at each stage.

GPLSICORTEX [ST3] (Martínez-Murillo et al., 2025) (Keywords: *GPT-4o mini, Llama 3, FLAN-T5, Instruction vanilla*) The authors propose a narrative-aware approach that enhances explanation generation by incorporating the underlying intention and structure of texts into pre-trained models. By explicitly modeling the purpose of a text, their system produces more meaningful and contextually relevant explanations. They experimented with various instruction-tuned models, including LLaMa 3 and Flan-T5, with the latter achieving the best results. Their approach secured 3rd place in the competition.

gowithnlp [ST1] (Wang et al., 2025a) (Keywords: *CoT, GPT-3.5-Turbo,GPT-3, Claude*) The approach iteratively refines prompts and utilizes Entity-Centric Chain of Thought. Specifically, to minimize ambiguity in label definitions, they use the model's predictions as supervisory signals, iteratively refining the category definitions. Furthermore, to minimize the interference of irrelevant information during inference, they incorporate entity-related information into the CoT framework, allowing the model to focus more effectively on entity-centric reasoning.

HowardUniversityAI4PC [ST1] (Aryal and Dhungana, 2025) (Keywords: *Mistral-7B, Phi-4, Llama 3.1, Gemma 2, DeepSeek R1, Instruction vanilla, Synthetic prompting*) The authors employ an ensemble-based approach for role assignment, utilizing multiple state-of-the-art LLMs, including LLaMA 3.1-8B, Mistral-7B, Phi-4, and Gemma 2. Through prompt engineering, they optimize each model's output using Ollama's API to generate structured responses for named entities across all articles and languages. The outputs are stored as text files and subsequently combined to produce a final submission. This multi-model strategy enables them to achieve strong performance metrics by leveraging the complementary strengths of different LLMs.

iLostTheCode [ST2] (Concas et al., 2025) (Key-

words: *RoBERTa, DeBERTa, DistilBERT, MLP*) The authors propose a model that leverages multiple pre-trained models in parallel to create enriched embeddings fed into a simple machine learning model. The dataset is first translated and processed so that each sentence is treated as an individual sample, independently or with a small contextual window, depending on the language. Each sentence is passed through different models (BERT variants), and their resulting embeddings are concatenated to form a composite feature vector. This vector is then used as input for the neural network, which outputs classification probabilities. Finally, a post-processing module aggregates the probabilities of all sentences within a file and applies a threshold to produce the final classification predictions.

Irapuarani [ST2] (Assis et al., 2025) (Keywords: *GPT-4o mini, DeBERTa, mDeBERTa, Aya Expanse 8B, Instructions vanilla, Translation*) The authors explore three strategies combining Small Language Models (SLMs) and Large Language Models (LLMs) for hierarchical multi-label classification. The first approach applies a multilingual SLM for direct classification without hierarchical constraints. The second leverages an LLM for text translation into a single language before classification with a monolingual SLM. The third adopts a hierarchical strategy where an SLM filters domains, and an LLM assigns final labels. Among these, the translation-based approach proves the most generalizable across languages, improving label alignment and reducing inconsistencies caused by imbalanced label representation across different languages.

IRNLP [ST2] (Kiousis, 2025) (Keywords: *XLM-RoBERTa, DeepPavlov, Neuralmind BERT*) The authors' approach to multilingual narrative classification is based on XLM-RoBERTa Large and other bert-based models, e.g, DeepPavlov and Neuralmind BERT, fine-tuned on different language datasets. To improve generalization and ensure robust performance across languages, they employed a repeated k-fold cross-validation strategy. Their preprocessing pipeline included (1) language-specific tokenization, (2) hierarchical label structuring, and (3) dynamic batch sampling to balance label distributions. The results demonstrated that the chosen approach effectively leveraged transformer-based architectures to model complex narrative structures across languages, with strong performance gains due to repeated k-fold evaluation.

INSALyon2 [ST2] (Eljadiri and Nurbakova, 2025) (Keywords: *Zero-shot, Agentic framework*) The authors propose an agentic framework where each agent functions as a specialized binary classifier. Each agent is responsible for detecting whether a given text belongs to a specific narrative or a sub-narrative. They use AutoGen to coordinate multiple LLM agents, organized as a group chat with a user proxy agent, manager agent, and multiple narrative and sub-narrative agents. The manager limits narrative agents to a single query per classification, while the user agent initiates a group chat for every new text sample. All models were used in a zero-shot setting, with GPT-4o as the primary classification agent and GPT-4o Mini as the user proxy agent.

INSAntive [ST2] (Wang et al., 2025b) (Keywords: *BERT, translation*) The authors' framework provides a range of functional modules—including segmentation, automated translation, and standardized output—that facilitate the generation of high-quality multilingual data for subsequent classification and semantic analysis. In the multi-label setting, the framework integrates a BERT-based text classification method, utilizing automated data processing, optimized training workflows, and memory management strategies.

KostasThesis2025 [ST2] (Eleftheriou et al., 2025) (Keywords: *Continual Learning, MLP, Hierarchical classification, Ensemble, KaLM, Stella*) The authors focus on hierarchical multi-label, multi-class classification in multilingual news articles. They present an architecture that combines narrative predictions with multiple sub-narrative heads using concatenation. They experimented with different embeddings, KaLM and Stell, with KaLM outperforming Stella. The best results were achieved with the Continual Learning model with Concatenation architecture.

KyuHyunChoi [ST3] (Choi and Na, 2025) (Keywords: *PEGASUS*) The authors employ PEGASUS, a transformer-based model pre-trained specifically for summarization using the Gap Sentence Generation (GSG) method. PEGASUS large was chosen for this study, as it was trained solely with GSG, given the ineffectiveness of MLM. Fine-tuning followed a standard procedure, where training set inputs were processed by the encoder, and outputs were generated via the decoder. No special techniques were applied during fine-tuning. The model was saved at the checkpoint with the highest

BertScore F1 score.

LATE-GIL-nlp [ST1, ST2, ST3] (Diaz et al., 2025) (Keywords: *RoBERTa, XLM-RoBerta, Flan-T5, Llama 3.1, Sentence-Transformers, TweetNLP, Data augmentation*) For ST1, the authors propose a three-stage pipeline for the Entity Framing track, ensuring consistency across five languages. Context extraction captures 18 words around each entity and refines it using Llama 3.1 8B to generate English contexts. Multi-class classification fine-tunes RoBERTa with role-based labels, incorporates sentiment augmentation, and undergoes additional fine-tuning for each language. Multi-label classification preprocesses text, fine-tunes sentence transformers per language, and assigns multiple emotion labels. Finally, a K-Nearest Neighbors classifier is trained using cross-validation to classify entities based on their contextual embeddings.

For ST2, they propose a multilingual classification pipeline with different setups for Bulgarian, English, Hindi, and Russian. For the first three languages, a three-stage pipeline first classifies "Other" vs. narratives, then identifies narratives, and finally classifies sub-narratives. The Russian pipeline omits the "Other" label, using a two-stage process for narrative and sub-narrative classification. Both variants use an XLM-RoBERTa backbone for multilingual adaptability. The approach is tailored to varying label distributions across languages.

For ST3, they apply a two-step data cleaning process, removing unwanted prefixes from annotations and omitting article titles while handling duplicates. The training dataset is prepared by retrieving article content for each annotation and applying a predefined prompt. A pre-trained Google FLAN-T5 model is fine-tuned using the Hugging Face Trainer API with specific hyperparameters. Explanation generation involves extracting key sentences using spaCy and NLTK to create structured summaries. This approach ensures cleaner data, effective training, and improved text-to-text generation.

LTG [ST1] (Rønningstad and Negi, 2025) (Keywords: *XLM-RoBerta, Llama 3, Mistral-7B*) The authors investigate the optimal text segments to extract from newspaper articles to capture an entity's narrative role while minimizing distractions. Their approach is evaluated using XLM-RoBERTa large and compared against supervised fine-tuning of smaller generative language models. They investigate the optimal text segments to extract from newspaper articles to capture an entity's narrative role while minimizing distractions. Their approach is evaluated using XLM-RoBERTa-large and compared against supervised fine-tuning of generative language models. By optimizing text selection, they find that XLM-RoBERTa-large outperforms fine-tuning larger language models trained on the entire texts.

NarrativeMiners [ST1, ST2, ST3] (Khubaib et al., 2025) (Keywords: *Gemini, Mistral, Translation,*) In ST1, the authors use multiple data augmentation strategies: (1) generating similar articles with the same entities using Gemini and Mistral and (2) translating into English, the former not showing promising results. They experimented with BERT, DeBERTa, and BART, with BART-CNN emerging as the best-performing model.

In ST2, the authors applied back-translation to increase the dataset size. They experimented with BERT model fine-tuning using a multi-stage approach: (1) the first model was on topic classification - URW, CC, or Other; (2) the second classified articles in the narrative for the respective topic; (3) finally, for the predicted narrative, a sub-narrative classification model was used.

In ST3, the authors fine-tuned FLAN-T5, GPT-2, and BART-CNN. Compared to BART-CNN, GTP-2 and FLAN-T5 significantly underperformed, struggling with generating coherent and contextually grounded explanations.

NarrativeNexus [ST1, ST3] (Siraj et al., 2025) (Keywords: *BART*) In ST1, the authors employ a BART-based sequence classifier to identify and categorize named entities within news articles, mapping them to predefined roles such as protagonists, antagonists, and innocents. More specifically, their approach involved fine-tuning BART-large with hyperparameter optimization, data augmentation techniques, and confidence thresholding to improve classification reliability.

In ST3, the authors fine-tuned BART-large-cnn using a text-to-text generative paradigm to generate justifications for dominant narratives. To enhance factual consistency, they introduced a filtering step to discard low-confidence justifications. Their evaluation relied on BLEU and ROUGE scores to measure output fluency and relevance.

Narrlangen [ST2] (Blombach et al., 2025) (Keywords: *Hierarchical classification, SetFit, XLM-RoBERTa*) The authors experimented with several approaches: (1) fine-tuning encoder models, (2) hi-

erarchical classification using encoder models with two different classification heads, (3) direct classification of fine-grained labels using SetFit, (4) a zero-shot approach based on sentence similarities, and (5) prompt engineering of LLMs. Their best approach was fine-tuning a pre-trained multilingual model, XLM-RoBERTa, with two additional linear layers and a softmax on top as a classification head. They fine-tuned their multilingual model on the combined data set of all languages.

NCLTeam [ST2] (Li et al., 2025b) (Keywords: *BERT, ModernBERT, BART, all-MiniLM-L12-v2, CU-Net, Data augmentation*) The authors propose a hierarchical model architecture that aligns with the dataset taxonomy, leveraging a pretrained all-MiniLM-L12-v2 encoder and a cascaded UNet for text classification. The model jointly optimizes both components, using the last hidden state as input to the UNet. Conditional subcategory pathways refine classification, first distinguishing "Climate Change (CC)", "Ukraine-Russia War (URW)", and "Others", then further classifying CC and URW narratives. Contrastive learning enhances feature representation with positive-negative pairs and mix-up regularization. A cosine embedding loss improves intra-class similarity while ensuring distinct separation of negative samples.

NlpUned [ST1] (Caballero et al., 2025) (Keywords: *GPT-4o, Chain-of-Thought, Hierarchical classification, Summarization*) This study explores a prompt-based, non-hierarchical approach to fine-grained role classification in news narratives using Large Language Models (LLMs). Instead of traditional model training or fine-tuning, the system relies on zero-shot and few-shot prompting, leveraging structured taxonomies and contextual signals to classify named entities into fine-grained sub-roles.

nlptuducd [ST2] (Younus and Qureshi, 2025) (Keywords: *Mistral 7B, synthetic generated data*)

The system authors propose the application of a Mistral 7B model, specifically E5 model, to address the ST2 in English. Their approach frames the task as a retrieval task in a similarity-matching framework instead of relying on supervised learning. Specifically, each test article's top two similar articles are first retrieved with cosine similarity, and from those, the one with a narrative alignment is extracted using story embeddings (an embedding framework on top of Mistral-7B via synthetically generated data).

NotMyNarrative [ST2] (Faye et al., 2025) (Keywords: *XLM-RoBERTa, mDeBERTa, ModernBERT, Albertina PT-PT, MuRIL, SlavicBERT, Muril*) The authors compare multilingual models (XLM-RoBERTa, mDeBERTa) with monolingual ones and observe that, given the limited data per label per language, multilingual models perform better and can leverage information from all languages to improve general performance. Furthermore, the authors conducted an ablation study by leaving out a single language in training and then testing on all languages. Results show that XLM-RoBERTa generalizes better than mDeBERTa on new languages.

PATeam [ST1, ST2, ST3] (Sun et al., 2025) (Keywords: *Qwen2.5, Phi-4, Multi-prompting,LoRa,Data Augmentation, DPO, SFT Synthetic Data Generation*)

In ST1, the authors propose a two-stage pipeline system that enhances the accuracy of role classification for location entities in news articles. This system comprises three key components: 1) Qwen2.5-72B model leverages multi-prompt engineering techniques to focus contextual analysis on target location entities to dynamically restructure the input text around these entities, thereby reducing noise and enhancing semantic coherence. 2) Phi-4 and Qwen2.5-32B models are fine-tuned using LoRA to specialize in multi-turn conversational reasoning, enabling a nuanced understanding of role-specific patterns at both coarse and fine granularities through sequential interaction analysis. 3) Through systematic ablation studies across multiple experimental configurations, the authors evaluate the comparative effectiveness of monolingual and multilingual approaches, deriving actionable implementation guidelines. 4) The ensemble prediction was decided by majority voting, and very few cases were handled by selecting the model with the best validation performance.

In ST2, the team adopts a similar pipeline for narrative-based semantic segmentation. For each news article, they obtain a list of relevant paragraphs for each sub-narrative in its golden label set. Then, two types of models for multilabel classification are trained, the one-vs-rest classification models and the label sequence generation models. Therefore, two data aggregation approaches are employed to convert the above data into proper training data for different types of models, respectively.

In ST3, the authors used Phi-4 as the base model, with data augmentation and direct preference optimization. In addition, the authors also used synthetic data generated from Qwen2.5-72B and Llama3-70B, which proved particularly effective for lesser-known languages. They conducted experiments with several training techniques, including SFT (supervised fine-tuning), DPO, SimPO, and ORPO. The best results were achieved with the combination of SFT and DPO.

QUST [ST1] (Liu et al., 2025) (Keywords: *DeBERTa, Qwen2.5, Phi-3, Phi-4, Ensemble, GLM4*) The authors fine-tune several models, including DeBERTa, Qwen 2.5, Phi-3, Phi-4, and GLM4. For their final submission, they utilize an ensemble learning strategy that employs hard voting to combine predictions of the top 3 selected models for each language, enhancing the prediction accuracy of the final result.

TartanTritons [ST1, ST3] (Raghav et al., 2025) (Keywords: *RoBERTa, Phi-4, Llama 3.1, Instructions vanilla, Chain-of-Thought, Active prompting*) The authors present a hierarchical role extraction system built on Microsoft's Phi-4, a quantized and instruction-tuned LLM. Their approach integrates multiple techniques to enhance accuracy and robustness. By leveraging instruction tuning with a predefined taxonomy of fine-grained roles, they achieve notable performance gains. To improve entity disambiguation, they introduce special 'entity' tags, allowing the model to differentiate multiple mentions within the text. Additionally, they enhance cross-lingual performance by training on multilingual datasets. An iterative feedback mechanism further refines predictions, where model-generated error messages guide retries to improve output quality.

TECHSSN [ST3] (Premnath et al., 2025) (Keywords: *BART, DistilBART, T5, FalconAI*) The authors propose fine-tuning pre-trained summarization models using the Seq2SeqTrainer from the Hugging Face Transformers library. The model used to tackle ST3 was a fine-tuned version of DistilBART (distilbart-cnn-12-6).

Tuebingen [ST1] (Karabulut et al., 2025) (Keywords: *BERT, Data Augmentation, External Knowledge*) The authors evaluate transformer-based models(BERT-family) with minimal hyperparameter tuning to analyze their impact on classification performance. The authors also incorporated class weighting to address class imbalance and explored additional techniques, such as data augmentation and the integration of external information, to improve model robustness and enhance overall performance.

UNEDTeam [ST2] (Fraile-Hernandez and Peñas, 2025) (Keywords: *Calme-2.4-rys-78B*) The authors employ a zero-shot approach, using the knowledge embedded in Large Language Models (LLMs), specifically MaziyarPanahi/calme-2.4-rys-78b, without relying on training examples. To address linguistic barriers, they translate all news items into English using OPUS machine translation models. Classification occurs in two stages using prompts: first, each news item is categorized into one of the two main thematic categories (Climate Change or Ukraine-Russia War). Then, within each category, sub-narratives are identified, with the option to label the news item as "Other" if it does not align with any predefined sub-narrative.

WordWiz [ST3] (Ahmadi and Zeinali, 2025) (Keywords: *instruction-tuning, Phi-3.5, DFT*) The authors employed a combination of targeted preprocessing techniques and instruction-tuned language models to generate concise, accurate narrative explanations across five languages. Their approach leverages an evidence refinement strategy that removes irrelevant sentences, improving signal-to-noise ratio in training examples. They fine-tuned Microsoft's Phi-3.5 model using Supervised Fine-Tuning (SFT). During inference, they implemented a multi-temperature sampling strategy that generates multiple candidate explanations and selects the optimal response using narrative relevance scoring.

YNU-HPCC [ST1] (Li et al., 2025a) (Keywords: *DeBERTa*) The authors propose a two-stage role classification model based on DeBERTa. The proposed model integrates the deep semantic representation of the DeBERTa pre-trained language model through two sub-models: main role classification and sub-role classification, and utilizes Focal Loss to optimize the category imbalance issue.

YNUzwt [ST1,ST2] (Tan et al., 2025) (Keywords: *CoT, Phi-3.5, GPT4-o*)

The authors present a Tree-guided Stagewise Classifier with Chain of Thought to tackle ST1 and ST2 in multiple languages. This algorithm uses Hierarchical Reasoning to overcome the limitations of zero-shot classifiers guiding the LLM through the hierarchical structural annotation in ST1 and ST2. The authors experimented with this algorithm in two large language models: GPT4-o and Phi-3.5.

The following systems are listed on the official leaderboard of the Shared Task, but no paper was submitted: Synapse (ST3), Mendel292A (ST3), UMZNLP (ST3), ftd (ST3). We have not received short descriptions of the following systems: YNUzwt (ST3), DUTtask10 (ST3).

```
Other
Blaming the war on others rather than the invader
- Ukraine is the aggressor
- The West are the aggressors
Discrediting Ukraine
- Rewriting Ukraine's history
- Discrediting Ukrainian nation and society
- Discrediting Ukrainian military
- Discrediting Ukrainian government and officials and policies
- Ukraine is a puppet of the West
- Ukraine is a hub for criminal activities
- Ukraine is associated with nazism
- Situation in Ukraine is hopeless
Russia is the Victim
- The West is russophobic
- Russia actions in Ukraine are only self-defence
- UA is anti-RU extremists
Praise of Russia
- Praise of Russian military might
- Praise of Russian President Vladimir Putin
- Russia is a guarantor of peace and prosperity
- Russia has international support from a number of countries and people
- Russian invasion has strong national support
Overpraising the West
- NATO will destroy Russia
- The West belongs in the right side of history
- The West has the strongest international support
Speculating war outcomes
- Russian army is collapsing
- Russian army will lose all the occupied territories
- Ukrainian army is collapsing
Discrediting the West, Diplomacy
- The EU is divided
- The West is weak
- The West is overreacting
- The West does not care about Ukraine, only about its interests
- Diplomacy does/will not work
- West is tired of Ukraine
Negative Consequences for the West
- Sanctions imposed by Western countries will backfire
- The conflict will increase the Ukrainian refugee flows to Europe
Distrust towards Media
- Western media is an instrument of propaganda
- Ukrainian media cannot be trusted
Amplifying war-related fears
- By continuing the war we risk WWIII
- Russia will also attack other countries
- There is a real possibility that nuclear weapons will be employed
- NATO should/will directly intervene
Hidden plots by secret schemes of powerful groups
```

Figure 5: Ukraine War label taxonomy

```
Other
Criticism of climate policies
- Climate policies are ineffective
- Climate policies have negative impact on the economy
- Climate policies are only for profit
Criticism of institutions and authorities
- Criticism of the EU
- Criticism of international entities
- Criticism of national governments
- Criticism of political organizations and figures
Climate change is beneficial
- CO2 is beneficial
- Temperature increase is beneficial
Downplaying climate change
- Climate cycles are natural
- Weather suggests the trend is global cooling
- Temperature increase does not have significant impact
- CO2 concentrations are too small to have an impact
- Human activities do not impact climate change
- Ice is not melting
- Sea levels are not rising
- Humans and nature will adapt to the changes
Questioning the measurements and science
- Methodologies/metrics used are unreliable/faulty
- Data shows no temperature increase
- Greenhouse effect/carbon dioxide do not drive climate change
- Scientific community is unreliable
Criticism of climate movement
- Climate movement is alarmist
- Climate movement is corrupt
- Ad hominem attacks on key activists
Controversy about green technologies
- Renewable energy is dangerous
- Renewable energy is unreliable
- Renewable energy is costly
- Nuclear energy is not climate-friendly
Hidden plots by secret schemes of powerful groups
- Blaming global elites
- Climate agenda has hidden motives
Amplifying Climate Fears
- Earth will be uninhabitable soon
- Amplifying existing fears of global warming
- Doomsday scenarios for humans
- Whatever we do it is already too late
Green policies are geopolitical instruments
- Climate-related international relations are abusive/exploitative
- Green activities are a form of neo-colonialism
```

Figure 6: Climate Change label taxonomy

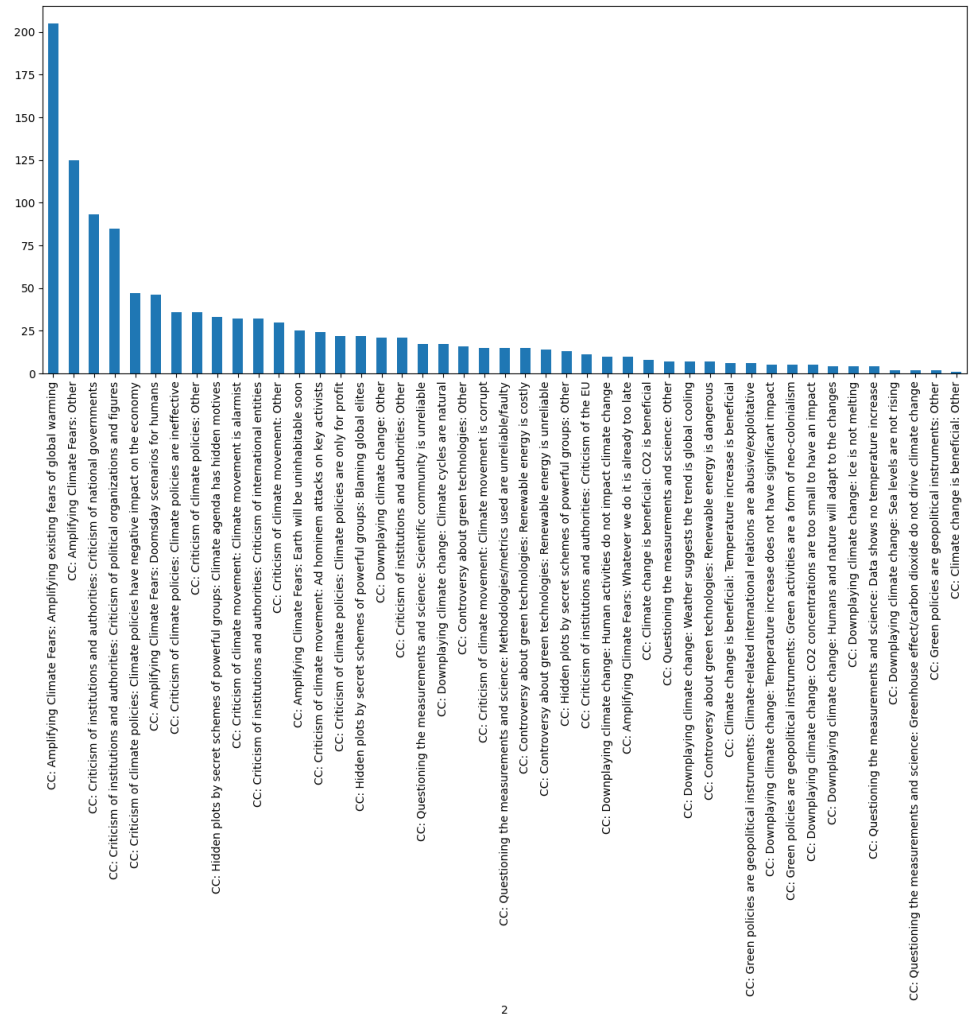

Figure 7: Label distribution statistics for the labels of Subtask-2 for Climate Change subset.

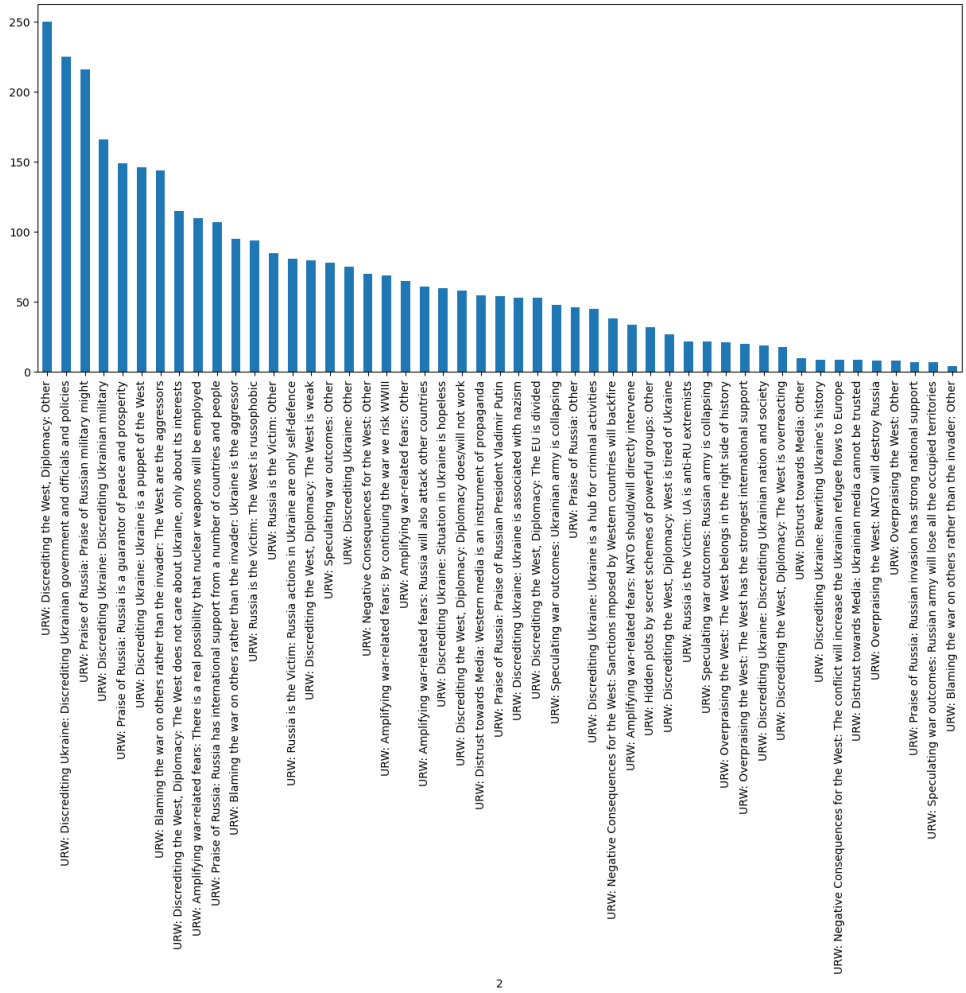

Figure 8: Label distribution statistics for the labels of Subtask-2 for Ukraine Russia War.

Figure 9: Similarity of the explanations by topic (URW in blue and CC in red) using LaBSE. In addition, the explanations of each split are represented by different symbols (train: circle, dev: diamond, test: square)

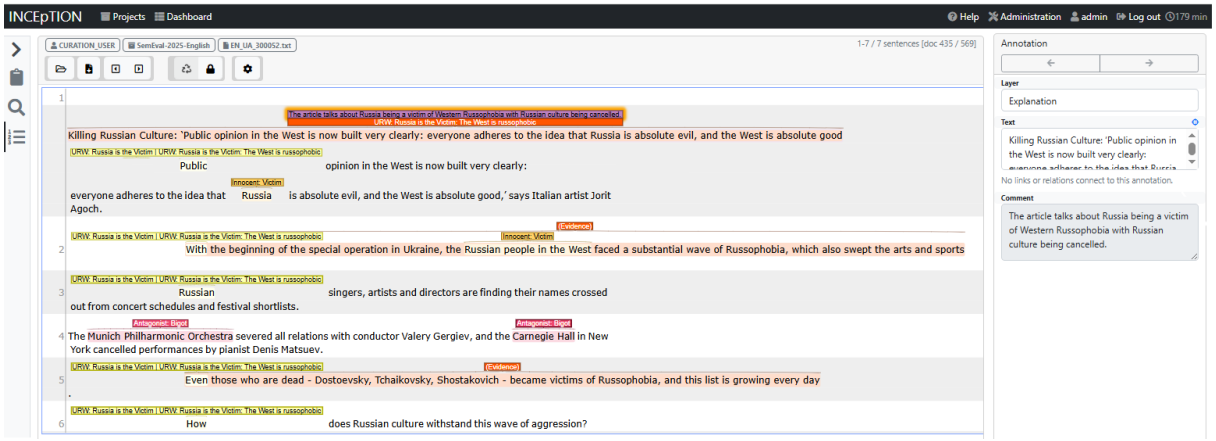

Figure 10: Annotated example from the English portion of our dataset. Entity framing is indicated in warm yellow, while narratives and sub-narratives at the paragraph level are highlighted in yellow. In the title of the article, the Dominant Narrative (*Russia is the victim*) and Sub-narrative (*The West is russophobic*) are highlighted in orange, while the explanation is highlighted in purple. Within the body of the article, the Evidence is highlighted in light orange.
