Upper and Lower Sorbian tracks For both Upper and Lower Sorbian tracks, TartuNLP was the overall winner with high results in both MT and QA. Looking at the tasks of translation and question answering separately, all systems outperformed the baseline for translation, while one system remained below the baseline for question answering. Indeed, if we focus on the translation results only, NRC obtained similar or better performance than TartuNLP, but it showed noticeably lower results for the QA task, since the team chose to focus on MT performance. As they reported, exclusively fine-tuning for MT affects the QA performance negatively, with lower accuracy than the baseline. This confirms our initial assumption and answers our first research question. On the other hand, the NRC submission relies on the smaller 1.5B model and manages to compete with the larger 3B model effectively. This is a promising result for low-resource MT.

For QA, the improvements remain more modest in comparison, with the accuracy increasing by 15 and 11 points, for Upper and Lower Sorbian, respectively. The lack of dedicated training data in the language and the variety of the exercises seem to be the main reasons preventing the models from reaching higher scores.

Ukrainian track For the Ukrainian track (Table 8), only one team (SDKM) participated, achieving results that slightly outperformed the baselines for both MT and QA. In MT, the gains were rather for the closely-related cs→uk pair than for the more distant en→uk pair. Despite accounting for differences in input style between the development and test sets, the results indicate that translating more complex, document-level content remains a substantial challenge for Ukrainian. In QA, the team also surpassed the baseline. For broader comparison, in the UNLP2024 shared task (Romanyshyn et al., 2024), the best-performing model based on Mistral-7B achieved an accuracy of 49, highlighting that smaller models still struggle to reach competitive performance on this task.

6 Deeper Analysis and Discussion

This section focuses on a few analyses of the results. For Ukrainian, to approximate a more advanced evaluation, we compared the participants and the baseline MT results with xCOMET (Guerreiro et al., 2024) (§6.1). For the Sorbian language tracks, we check the QA accuracy per language level (§6.2), contrast the translation performance against other MT approaches (§6.3.1), namely against the current Sorbian-German translator, and perform a manual annotation of translation outputs (§6.3.2).

	cs→uk		en→uk		uk-QA		final
	chrF++	points	chrF++	points	acc.	points	points
SDKM	**8.09**	2	**2.98**	2	**35.82**	2	6
baseline	3.48	1	0.34	1	31.16	1	3

Table 8: Results for the primary submissions for the **Ukrainian** track.

6.1 Evaluating Ukrainian MT with xCOMET

Since the xCOMET metric (Guerreiro et al., 2024) has demonstrated strong performance as a neural-based automatic MT evaluation method and supports Ukrainian, we employed it to gain a deeper insight into the Ukrainian MT results.

We tried both xCOMET-XL[9] and xCOMET-XXL[10] to estimate the difference in significance between the baseline and SDKM team results. The results from xCOMET models are presented in Table 9.

lang. pair	x-wins	y-wins	stat.	p-value
xCOMET-XL				
cs→uk	0.09	0.88	-1.80	0.07
en→uk	0.44	0.48	-0.13	0.89
xCOMET-XXL				
cs→uk	0.01	0.97	-3.17	0.00
en→uk	0.42	0.48	0.04	0.96

Table 9: Comparison of the xCOMET results for the baseline (x) and SDKM (y) **Ukrainian MT** submissions with t-test results.

For the en→uk pair, both XL and XXL models confirmed that the differences between systems were not statistically significant. In contrast, for the cs→uk pair, the XL model results were borderline with respect to the null hypothesis, while the XXL model clearly indicated a significant difference. These findings confirm that the SDKM team achieved better performance for cs→uk translation.

In addition, we conducted a qualitative analysis of the MT outputs at the sample level. A native Ukrainian speaker evaluated the translations for both fluency and adequacy. Representative examples from both models are included in the Appendix B.2. We observe that both models struggled with paragraph-level translation. In several cases, the baseline system failed to generate any output at all. The SDKM team's results, however, are particularly interesting: although their translations did not reproduce the full paragraphs, they captured the main content, resembling a blend of translation and summarisation. This suggests that, with more granular input pre-processing, the model could potentially produce more accurate translations.

6.2 Detailed Sorbian QA results

model	A1	A2	B1	B2	C1
Upper Sorbian					
TartuNLP	**86.67**	**82.14**	**56.82**	37.50	**51.92**
NRC	50.00	32.14	22.73	19.64	30.77
SDKM	80.00	78.57	**56.82**	**41.07**	42.31
baseline	70.00	57.14	40.91	26.79	38.46
Lower Sorbian					
TartuNLP	**89.66**	71.43	**56.82**	**41.07**	**50.00**
NRC	55.17	42.86	18.18	26.79	31.25
SDKM	82.76	57.14	50.00	37.50	47.92
baseline	65.52	**75.00**	43.18	26.79	41.67

Table 10: Accuracy on the QA datasets per language level for **Upper and Lower Sorbian**.

Table 10 presents the details of the Sorbian QA results for each language level (A1 to C1). We observe that the accuracy drops overall with more difficult question levels for both Upper and Lower Sorbian, except for the B2 level. The lower score at the B2 level for all models compared to the technically more difficult C1 level could be explained by the question types. We recall here that since the questions come from an actual language certification, they are diverse in terms of question type and number of possible answers (cf. §3.1). This also means that we gave equal weight to comparatively more difficult and simpler questions in the main evaluation. If we choose a passing accuracy of 50, most submissions reach a B1 level approximately.

6.3 Detailed Sorbian MT Results

6.3.1 Comparing Sorbian MT

For both Upper and Lower Sorbian, we compare the performance of the submitted systems with existing MT-specific models and quantised versions of LLMs. We present two types of models: the current MT model from the WITAJ-Sprachzentrum (sotra) and a quantised version of the TartuNLP model.

sotra Sotra[11] is the Machine Translation platform developed by the WITAJ-Sprachzentrum since 2019. Dedicated models translate from and to four languages: Upper Sorbian, Lower Sorbian, German, and Czech (except the German-Czech pair), as of 2025. It is based on 800MB fairseq models (Ott et al., 2019), and 50MB quantised versions (INT8 with CTranslate2) have been used for the online version for notably faster outputs. We present the scores for both systems.

Quantised version of the TartuNLP submission Since the sotra website relies on the quantised version for faster inference, we also quantised the model submitted by the TartuNLP team in two different ways. More precisely, we consider a Q4_K_M and a Q8_0 quantised GGUF version of the model.

	de→hsb	de→dsb
NRC	**87.20**	**78.24**
TartuNLP	86.33	78.20
SDKM	75.73	64.34
baseline	13.88	12.21
sotra quantised	79.07	75.92
sotra unquantised	81.52	77.38
TartuNLP Q4_K_M	83.96	75.55
TartuNLP Q8_0	84.83	76.65

Table 11: Comparison of the chrF++ scores on the Upper and Lower Sorbian test dataset for different MT systems.

Results Table 11 presents the MT results on the same test dataset for sotra models and the quantised TartuNLP models. We first observe that the best MT submissions (NRC and TartuNLP) are better than the current Sorbian translator, sotra, for both languages and even with the unquantised version. The gap is larger for Upper Sorbian than Lower Sorbian. We note, however, that the sotra models are older and are thus trained with less data. They are also smaller with around 56M parameters.

Besides, as expected, more aggressive quantisation leads to worse performance. For instance, the Q4_K_M version of the TartuNLP model slightly underperformed compared to the current online sotra model in Lower Sorbian. For Upper Sorbian, the systems still performed better. The inference time is, however, still in favour of the sotra model.

6.3.2 Manual rank annotation of Sorbian MT

As more advanced and reliable automatic metrics are not available for both Sorbian languages, we also evaluate the machine translation outputs through manual rank annotation, despite the high human and time cost associated with it.

Annotation methodology For each Sorbian language, one native speaker ranked the translations from the four systems (including the baseline) for 60 sentences, thanks to the joint organisation with WITAJ-Sprachzentrum. To select the sentences, we first filter the test set (and translations) to avoid cases where two or more systems output the same or too similar sentences (especially for short sentences) or obtain extreme chrF++ scores (e.g., issues with the generation or perfect translation). Then, we randomly select 60 sentences and shuffle the translations before the manual annotation, to reduce bias from the order of the systems.

The two annotators were given the same instructions regarding the ranking. Ranks are assigned to the four translations of the sentence, from 1 for the best translation to 4 for the worst. If two translations are of similar quality, the same score rank can be given (e.g., 1, 2, 2, 4). The reference translation is also given for information purposes. Annotators can additionally put comments beside each machine translation.

Results Table 12 compares the MT system rankings produced according to our main metric (chrF++ score) and the human evaluation for both languages. Unsurprisingly, the baseline model is consistently ranked last by the human annotator for both Sorbian languages; the higher ranks achieved in Lower Sorbian are only due to a large number of ties (e.g., [1, 2, 2, 2]), which blur their poor absolute performance here. The best submitted system is, however, more difficult to conclude; as with the chrF++ score, the annotators also found the NRC and TartuNLP model outputs to be of higher and

[11] https://sotra.app

	rank	chrF++				human			
		NRC	TartuNLP	SDKM	base.	NRC	TartuNLP	SDKM	base.
Upper Sorbian	1st	28	22	10	0	23	26	11	0
	2nd	18	29	13	0	24	25	12	0
	3rd	14	9	37	0	13	9	37	0
	4th	0	0	0	60	0	0	0	60
Lower Sorbian	1st	34	22	4	0	45	37	22	1
	2nd	24	32	4	0	14	18	16	7
	3rd	2	6	52	0	1	5	22	15
	4th	0	0	0	60	0	0	0	37

Table 12: System rankings according to the chrF++ score and the human evaluation for 60 sentences. For instance, the NRC translations in Upper Sorbian were ranked first among the four systems for 28 sentences according to chrF++, while it was 23 times according to the human evaluation.

similar quality. Interestingly, for Upper Sorbian, the latter model seems to be better with the human evaluation.

We also count how often the rankings according to human annotations and chrF++ perfectly match. 27 system rankings (out of 60) are identical for Upper Sorbian and 3 for Lower Sorbian. This difference is due to the higher number of ties given to the systems in the manual annotation of Lower Sorbian.

Qualitatively, the Lower Sorbian annotation comments also showed that the output machine translations still remain unsatisfactory overall, even for the best-ranked system. We present selected examples for both languages in Appendix B.1.

7 Conclusion

The WMT 2025 Shared Task LLMs with Limited Resources for Slavic Languages was the first attempt to evaluate two tasks *jointly*, Machine Translation and Question Answering, and to assess how they impact each other. We focused on three Slavic languages: Upper and Lower Sorbian (paired with German for MT), and Ukrainian (paired with Czech and English). Submissions were constrained to open-source datasets and Qwen 2.5 models below 3B parameters for reproducibility.

Three teams participated. TartuNLP was the overall winner by jointly fine-tuning the model using Sorbian and instruction datasets. NRC won both Sorbian MT tasks with a smaller 1.5B model by focusing on the MT task only. SDKM submitted to all three tracks using additional external datasets as well as data augmentation with machine translation and won on the Ukrainian track. All submissions improved the Machine Translation quality over the baseline Qwen 2.5 3B model. We observe that only focusing on MT negatively affects QA performance, answering our first research question. However, improving the model capabilities on two different tasks remains possible even for small LLMs. This first shared task paves the way for an extension to other tasks and low-resource languages.

Ethics Statement

The shared task focused specifically on smaller models, limiting the submissions to LLMs below the milestone of 3B parameters. This lowers the computational barrier for participants, fostering accessibility and a smaller ecological footprint.

We also strove to have the results reproducible by ensuring that the teams only use both open-source models and datasets. Participants were encouraged to make their model public.

For the Sorbian tracks, the shared task relies on the partnership with the WITAJ-Sprachzentrum. They provided all new Sorbian datasets for both tasks. For the manual evaluation experiment of the Sorbian MT outputs, both annotators were contacted through the WITAJ-Sprachzentrum.

Limitations

The main limitations of this shared task come from the restricted resources. In-domain training data was scarce overall, if not completely lacking, as in the Sorbian QA task, compared to other high-resource languages. Hence, participants needed to resort to data augmentation or external data with machine translation to circumvent this constraint.

Besides, diverging data formatting might have added another layer of complexity, which is orthogonal to our research question. For Ukrainian MT, the sentence-level training data contrasted with the document-level input in the test set, and for Sorbian QA, the exercise variety in type and number of possible answers proved to be a challenge.

Finally, the shared task focused on track-based (i.e., language-specific) approaches for models and not a fully multilingual LLM for all three Slavic languages. The submissions to the Sorbian tracks showed that fine-tuning with both languages proved to be mutually beneficial.

Acknowledgements

This work has received funding from the European Research Council (ERC) under grant agreement No. 101113091 - Data4ML, an ERC Proof of Concept Grant.

We thank the UNLP 2024 Shared Task team: Roman Kyslyi, Mariana Romanyshyn, and Oleksiy Syvokon, for sharing the Ukrainian QA resources.

Moreover, we are grateful for our cooperation with WITAJ-Sprachzentrum for Upper and Lower Sorbian. Beyond the datasets they provided for the previous WMT shared tasks on MT for low-resource languages, this first edition relied on QA data. We thank Tomaš Šołta for providing the language certificate exercises in that regard. We also thank the annotator of Lower Sorbian MT outputs for his time and comments.

Finally, we thank the organisers of the WMT 2025 shared tasks. Firstly, we highly appreciate the help from Martin Popel, Tom Kocmi, Katia Artemova, and Mariya Shmatova for sharing test sets for the Ukrainian MT track with us. We are also especially grateful to Vilém Zouhar and Daniel Deutsch for their advice, Philipp Koehn for helping us with Softconf, and Roman Grundkiewicz for setting up the leaderboard on OCELoT.

A Baseline Prompts

We show the examples of the MT and QA prompts used in the baseline. Below, we first show the MT prompt for Czech to Ukrainian. The other translation directions match this template, with the language names and ISO-3 codes substituted.

```
Translate the following Czech text to Ukrainian.
Put it in this format <ukr> Ukrainian translation </ukr>.
<cze> {{src_text}} </cze>
```

Below is the QA prompt. The possible answers for Ukrainian are А, Б, В, Г, and Д, so the output of the model is constrained to these 5 options in our evaluation of the baseline. Similarly, the Upper and Lower Sorbian answers are constrained to 1 to 16. While there are not always 16 possible options for each question, we did not observe the baseline model ever choosing a value outside the actual range given in the prompt.

B Illustrative MT Examples per Language Track

We provide several illustrative examples per language track to showcase major successes or problems of the submitted models.

B.1 Upper Sorbian and Lower Sorbian MT Examples

Tables 13 and 14 present two examples of both Upper and Lower Sorbian machine translation. We selected sentences for which notable phenomena are visible; they are, however, not representative of the overall system performance. Hence, we provide the chrF++ score and the translation rank from the human evaluation for information purposes.

The main issue with the baseline translations for both tracks is the language of the output sentence: it frequently features words from the German sentence (sometimes corrupted) or non-existing words in the Sorbian languages or German.

All three submissions improve largely on this issue. We observe a high similarity overall between the translations; if it was easy to identify the baseline output, annotators had to differentiate the other translations sometimes based on how well some nuances were captured.

We also present an output from the SDKM submission in Lower Sorbian (first sentence in Table 14) where non-Latin script characters suddenly appeared. This happened only once in the annotated sentences (i.e., out of 60).

Abstract

Efforts towards better machine translation (MT) for Creole languages have historically been isolated, due to Creole languages' geographic and linguistic diversity. However, most speakers of Creole languages stand to benefit from improved MT for low-resource languages. To galvanize collaboration for Creole MT across the NLP community, we introduce the First Shared Task for Creole Language Machine Translation at WMT25. This Shared Task consists of two systems tracks and one data track, for which we received submissions from five participating teams. Participants experimented with a wide variety of systems and development techniques. Our evaluation campaign gave rise to improvements in MT performance in several languages, and particularly large improvements in new testing genres, though some participants found that reusing subsets of pretraining data for specialized post-training did not yield significant improvements. Our campaign also yielded new test sets for Mauritian Creole and a vast expansion of public training data for two Creole languages of Latin America.

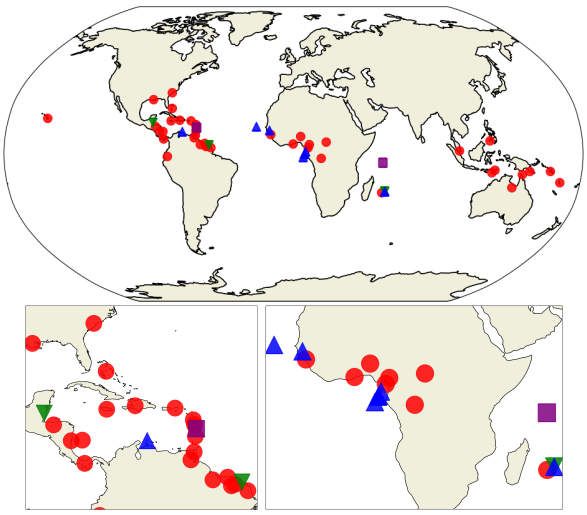

Figure 1: Creole languages included in the shared task, plotted geographically. Purple squares are languages for which we received *constrained* system submissions. Blue up-triangles are those with *unconstrained* system submissions, and green down-triangles are for *data* submissions. Red circles are for remaining Creoles for which we supported submissions but received none.

1 Introduction

Insufficient training data remains a pronounced barrier for creating natural language processing (NLP) systems that cater to lower-resourced languages. This is particularly pronounced for the task of machine translation (MT), due to the importance of aligned bitexts. For Creole languages, a geographically and linguistically diverse group (see Figure 1), the lack of training data brings some challenges common to other low-resource scenarios, but also offers unique opportunities, due to the role of contact in shaping them.

Many Creole-speaking communities have expressed interest in having MT support for their language (Lent et al., 2022). However, efforts to create NLP systems for them have largely been fragmented. This is in part due to the truly expansive scope of the term "Creole". By definition, a Creole language exhibits linguistic influence from an amalgamation of languages, typically both high- and low-resource (Kouwenberg and Singler, 2009). Naturally, the Creole languages of Africa (*e.g.* Nigerian Pidgin and Sango) are often viewed with different historical and cultural lenses than those of the Caribbean (*e.g.* Haitian Creole and Papiamento) or Pacific (*e.g.* Bislama and Tok Pisin).

However, this geographic and cultural fragmentation misses some of the notable commonalities among Creole languages. Many of the Creole languages of Africa and the Caribbean have a shared linguistic history: most of the languages in both groups emerged from European colonialism and slavery in Africa, and languages in both groups are strongly influenced by European and African

Proceedings of the Tenth Conference on Machine Translation, pages 520–531
November 8-9, 2025

(typically Niger-Congo) languages in similar ways (Gilman, 1986; Robinson et al., 2024). While Pacific Creole languages are not connected to Africa, they are also influenced by largely the same European colonial languages (*e.g.*, English, French, Portuguese, Dutch, *etc.*), and many show comparable and sometimes even more pronounced grammatical influence from Oceanic languages (Keesing, 1988). Perhaps even more important than their linguistic commonalities, Creole languages across the globe are subject to similar stigmas and play similar linguistic roles in relation to high-resource languages (DeGraff, 2003). Hence, speakers of Creole languages everywhere may have shared experiences in connection to their language and could benefit similarly from improved language technologies.

Only recent publications have addressed the data scarcity of large numbers of Creole languages, a necessary hurdle to create systems that truly serve speakers. (See Section 2.) These recent efforts have been ground-breaking (Lent et al., 2024; Robinson et al., 2024). However, their large scope allowed only for treatment of Creole languages as a conglomerate without particular attention to specific language communities and their distinct needs. To build technologies for the wide array of Creole language speakers, participation from a variety of communities is needed. In an effort to foster collaboration in NLP across these communities, we hold the first Shared Task for Creole Language MT held at WMT25.[1] We detail prior publications that inspired the need for this shared task in Section 2, and we overview the task organization in Section 3. The shared task consists of two subtasks: a call for **System Submissions**—itself consisting of two tracks, namely **Track 1** (Constrained), **Track 2** (Unconstrained)—and a call for **Dataset Submissions**. Five teams participated. Submissions and evaluation results are discussed in Sections 4 and 5, respectively.

2 Related Work

Creole languages are a product of intense linguistic contact. They usually draw most of their vocabulary from a single source language that is often referred to as the Creole language's lexifier.[2] Typologically, Creole languages tend to be more isolating than these lexifier relatives. However, attempts to define them as distinct typological class (*e.g.* Bakker et al., 2011) are contested (*e.g.* Fon Sing, 2017). In light of the typological debate, some (*e.g.* Mufwene, 2001) prefer to define Creoles by their history, which is closely associated with the long-term movement of people speaking mutually unintelligible languages.

Today, languages recognized as Creoles are spoken by over 180 million people (Lent et al., 2021). For some speakers, a Creole language is their mother tongue, and these speakers may be monolingual; for others, a Creole language can serve as a lingua franca within the broader, multilingual community. In surveying Creole language speakers, Lent et al. (2022) find that they highly desired MT support for their languages. Bird (2022) further highlights the opportunity for Creole language technology to serve as a bridge between higher and lower-resourced communities. He emphasizes that in contexts where Creoles act as a lingua franca, it may be more viable to develop language technologies for them, rather than going straight to even lower-resourced highly localized languages.

Despite the demand and utility of MT for Creole languages, they occupy a small portion of works in the broader MT community. When they are included, works tend to focus on individual languages. For example, the 2010 earthquake in Haiti prompted the rapid development of MT systems for the French-related Haitian language (Lewis, 2010). Early work by Dabre et al. (2014); Dabre and Sukhoo (2022) on Mauritian Creole acknowledged this trend, though they too developed technologies for a single language. Similarly, MT systems for West African Pidgin (Ogueji and Ahia, 2019) are highly relevant for other English-related Creole languages, like Guyanese Creolese (Clarke et al., 2024), but it has been difficult to coordinate multi-continental efforts.

The first effort towards a joint, large scale MT project for Creoles was proposed in CREOLEVAL (Lent et al., 2024) with the CREOLEM2M model, covering N-way translation between English and 26 Creoles. Building on this work, Robinson et al. (2024) contributed KREYÒL-MT for 41 Creole languages, including the first public, extensively multilingual MT dataset for Creole languages, and focusing on those spoken by the African diaspora. The resulting models have set the current state-of-the-art for Creole language MT.

Even with these advances, efforts to build Creole

[1] https://www2.statmt.org/wmt25/creole-mt.html

[2] This nomenclature is contested, however, as some academics argue it advances the misconception that Creole languages are fundamentally different from other languages (DeGraff, 2003).

technologies are not strongly unified. For instance, while Robinson et al. (2024) focus on Africa and the Americas, the potential relevance of these languages for MT efforts for Pacific Creoles (*e.g.*, Chavacano) (Vicente et al., 2024) remains an open question. Perhaps most pertinently, because both CREOLEVAL and KREYÒL-MT advanced developments for Creole languages as a conglomerate, focus on specific languages and their distinct needs was outside the scope of efforts. In organizing this shared task we hope to foster the beginnings of broader collaboration in Creole NLP. This way, members of specific Creole language communities may have a place to develop their own communities' desired technologies.

3 Shared Task Overview

3.1 Call for Systems Submissions

We solicited MT systems for translation between any number of Creole languages and English or French, for which we have paired data. (We also welcomed submissions for other pairs of a Creole and non-Creole language each, asking participants to justify how translation between such languages would be relevant to the affected community.)

The official train and dev sets provided to participants were the public KREYÒL-MT train and dev splits available on HuggingFace.[3] Participants were not permitted to use the data designated as *test* data from this dataset. We also provided, to any participants who requested them, additional training bitexts with English translations of Haitian, Papiamento, and Sango text from the Church of Jesus Christ of Latter-day Saints, still pending release on LDC.[4] We solicited submissions of systems in both **constrained** and **unconstrained** tracks. To construct our official evaluation sets for both tracks, we selected a random seed (kept private) and shuffled the public KREYÒL-MT test sets.

Constrained Track The purpose of this track was to explore better ways to model Creole MT with limited resources and allow researchers to explore smarter configurations than the simple ones that were used in past Creole language MT models. For instance, Robinson et al. (2024) focused primarily on their presentation of the KREYÒL-MT dataset without justifying all engineering choices used to train the KREYÒL-MT model. Thus, while their model was trained on 41 Creole languages at once, it was not clear whether this model was trained *optimally* for all 41 languages given the resources available. To have a track which is directly comparable to the original KREYÒL-MT model, therefore, we only accepted submissions in one of the 40 Creole languages included in the KREYÒL-MT set, with translation into or out of English and/or French only. The baseline model for this track was the `kreyol-mt-pubtrain` model available on HuggingFace,[5] which is the model trained on the public KREYÒL-MT dataset (Robinson et al., 2024). We note that this model was not trained on any data that was not made available to the participants. Moreover, participants were permitted to use this model however they wished in the constrained track, including as an initialization for fine-tuning, but they were not be permitted to use any other pre-trained models.

Unconstrained Track The purpose of this track was simply to encourage creation of state-of-the-art Creole language MT systems. In the unconstrained track, teams were allowed to use data from any source, and leverage any pre-trained models or LLMs. As the relaxed constraints in this track allowed participants to develop systems for any Creole language, we used two baseline models: `kreyol-mt-pubtrain` (the same as the constrained track)[6] and CREOLEM2M (Lent et al., 2024) (available on HuggingFace,[7] which covers a number of Creole languages not supported by the former[8]). That said, this track allowed for submission of any of the Creole languages supported by either of the baseline models; with translation into/out of English and/or French permitted for languages supported by KREYÒL-MT, and translation into/out of English only permitted for the languages supported by CREOLEM2M, accordingly. We used the same evaluation sets as in the constrained track for any languages supported by KREYÒL-MT, and were prepared to furnish additional eval sets for any other Creole languages.

[3] https://huggingface.co/datasets/jhu-clsp/kreyol-mt

[4] Further details: https://huggingface.co/datasets/jhu-clsp/kreyol-mt/blob/main/README.md

[5] https://huggingface.co/jhu-clsp/kreyol-mt-pubtrain

[6] Due to a miscommunication on our part, the EHOW team used `kreyol-mt`, the KREYÒL-MT model trained on both public and private data, as their baseline model throughout their experiments. Hence we used `kreyol-mt` as the baseline for their submissions.

[7] https://huggingface.co/AAU-NLP/CreoleVal-CreoleM2M

[8] https://github.com/hclent/CreoleVal/

For this unconstrained track, we were also prepared to accommodate submissions for Creole languages not supported by either baseline model, in which case we would require the participants to submit an evaluation set of their own creation, and we would employ the baseline models in a zero-shot setting to calculate baseline scores. However, this circumstance did not arise.

3.2 Call for Data Submissions

We also solicited contributions to Creole language MT training and evaluation sets. We requested data submissions to be in bitext formats with translations into *any* other language – not only English or French. (Again, we stipulated that submissions should justify why the non-Creole language would be relevant for the Creole language-speaking community).

We thus established the following requirements for any submitted datasets:

- Participants must show that 100% of translations were either translated or post-edited by competent native or proficient speakers of the source and target languages.
- Participants must prepare a data card[9] with each submitted dataset.
- Participants must be able to show that one of the languages in each submitted bitext is considered a Creole language, by citing adequate academic sources or other sufficiently convincing means.
- If submitting training data, we strongly encouraged participants to also develop an accompanying MT system and evaluate this system on a test set (either a test set of their own creation, which must be submitted along with the training data, or a previously published test set). Ideally, participants should show significant ($p < 0.05$) improvements in chrF++ (Popović, 2017) over the previous state-of-the-art open-source MT system for the given language pair. (To do this they must identify the previous SOTA model and make a compelling case for why it would be considered SOTA.) We committed to provide software to assist meeting this requirement as needed. If participants were not able to meet this requirement, we required that they provide other convincing evidence of the utility of their training set.
- If submitting a test set, participants must use it to evaluate performance of an MT model and provide compelling evidence that the model's performance on the test set aligns with conventional wisdom regarding the model's performance in the translation direction.

[9] See https://oldi.org/guidelines

3.3 Support for participants

During the course of the shared task, we aimed to support participants wherever possible. To this end, we provided tutoring, paper workshopping, and a dataset for manual translation (i.e. FLORES-200 English (NLLB Team et al., 2022)).

4 Shared Task Submissions

4.1 Constrained system submissions

We received two submissions for the constrained track, in which participants were only permitted to use provided training data: **KREY-ALL** (Ayasi, 2025) for Seychellois Creole translation into English, and **LUDOVIC MOMPELAT** (Mompelat, 2025) for translation between Martinican Creole and French.

4.1.1 KREY-ALL

KREY-ALL investigated joint training on typologically related Creole languages. They focused on Seychellois Creole (`crs`), and selected four additional languages known to be structurally similar, due to both shared francophone vocabulary and historical migration patterns: Mauritian Creole (`mfe`), French Guianese Creole (`gcr`), Louisiana Creole (`lou`) and Réunion Creole (`rcf`) (Papen, 1978).

Translation data from these languages were used in conjunction with Seychellois Creole data, with two tagging strategies: "All Kreyol" where all languages used the same language tag tag (`crs`), and "Specialized" where each language used its own tag. For each strategy, both full and partial (last 4-6 layers) fine-tuning were compared.

KREY-ALL found that using the same language tag for all languages and fine-tuning all model parameters were most effective. They also found that, although Mauritian Creole data was an order of magnitude more plentiful than Seychellois data, upsampling the Seychellois segments by more than 5x relative to the other languages was ineffective. Analysis of the model's embeddings revealed a distinct cluster for each language, with Seychellois having close proximity and overlap with Mauritian. However, there was no discernible Indian Ocean group, as Mauritan also overlapped with Louisiana

Creole, while Seychellois showed commonalities with Guianese. The other Indian Ocean language, Réunion Creole, did not overlap with any of the four.

4.1.2 LUDOVIC MOMPELAT

LUDOVIC MOMPELAT (LM) submitted two MT systems: from Martinican Creole (mart1259) to French and vice-versa. Their approach was to fine-tune kreyol-mt-pubtrain using LoRA (Hu et al., 2021). LM experimented with a different train/dev data ratio (70/30 vs. 90/10) and explored a few values of LoRA rank and scaling factor. Their final system for into-French MT used weighted BLEU scores for a curriculum sampling training set-up with difficulty ranking. Models for both translation directions were trained with label smoothing and a weighted BLEU criterion for checkpoint selection, and both employed a newly trained tokenizer with new language tags.

4.2 Unconstrained system submissions

Two teams submitted to the unconstrained track, in which participants were allowed to use external data and pre-trained models: **EDINHELSOW** (EHOW) (Rowe et al., 2025) and **KOZKREOLMRU** (Rajcoomar, 2025).

4.2.1 EDINHELSOW

EHOW submitted systems that translated between English and seven lusophone Creole languages: Angolar (aoa), Annobonese (fab), Guinea-Bissau Creole (pov), Kabuverdianu (kea), Papiamento (pap), Principense (pre) and Sãotomense (cri). The team conducted an incredibly thorough analysis of numerous techniques for enhancing Creole MT, and even leveraged the linguistic relationship between Portuguese and related Creoles.

Notably, EHOW collected additional parallel and monolingual data to supplement the provided data sources. These additional parallel data came from various sources: online Bible translations (pap and pov); the Jehovah's Witnesses' Watchtower magazine (kea, pap, and pov); text sourced from an online educational sentence generator (pap); and gloss text from a dictionary (pov). They used the monolingual corpora to create synthetic parallel data generated through back-translation, using the kreyol-mt model. For some of their experiments, the English sentences from the pap, kea, pov and cri bitexts were also forward-translated for Sequence-Level Distillation (Kim and Rush, 2016) of kreyol-mt. Again for some experiments, training data were further augmented using 112k high-quality English-Portuguese sentences, extracted from the Tatoeba Translation Challenge203 Dataset (Tiedemann, 2020).

Using these curated data sources, the EHOW team fine-tuned various pretrained multilingual base models: two sizes of NLLB (NLLB Team et al., 2022), three configurations of mBART (Tang et al., 2020), and kreyol-mt. EHOW experimented with inclusion of the Portuguese and distillation data mentioned in the previous paragraph, as well as with initializing language token embeddings with the Portuguese token embedding, to explore 14 combinations of training practice. They then merged six combinations of the resulting models to produce final systems. EHOW's *primary* submission for each language pair was the overall best performing merged model for each generalized direction (XX→eng or eng→XX), while *contrastive1* submissions were the best trained model (merged or otherwise) for each language pair. They found that post-editing of system outputs using LLMs and bilingual lexicons was typically not helpful, but they submitted some systems that incorporated this practice as *contrastive2*.

4.2.2 KOZKREOLMRU systems

KOZKREOLMRU took a unique three-step approach to translation between Mauritian Creole and English. Their first step was continuous pretraining of Llama 3.1-8B over 500k monolingual Mauritian Creole tokens (18k lines) sourced from (Dabre and Sukhoo, 2022), with an additional 100k monolingual tokens each of English and French data. Step two was then fine-tuning the model for MT. This was done on $\tilde{4}$0k lines of bitext, sourced again from Dabre and Sukhoo (2022); Robinson et al. (2024); 4.9k lines of synthetic data from prompting a Claude model with text from MMLU (Hendrycks et al.); and 300 lines of bitext from community translation of English Claude outputs. The final step was parameter-efficient fine-tuning (PEFT) via LoRA (Hu et al., 2021) over newly contributed Mauritian Creole translations of FLORES-200 (NLLB Team et al., 2022). In some eperiments, only the dev set translations were used for PEFT, while the devtest set was reserved for testing. In others, KOZKREOLMRU used all FLORES-200 data for PEFT and evaluated on a newly created bitext from the LALIT newspaper. (See Section 4.3 for details of these datasets.) The

KozKreolMRU team performed ablations, to isolate the effects of monolingual continuous pretraining, vanilla fine-tuning, and PEFT.

4.3 Data submissions

Two of our participating teams submitted datasets: **KozKreolMRU** (Rajcoomar, 2025) submitted two dev/test sets for Mauritian Creole↔English MT; and **JHU** (Robinson, 2025) submitted train, dev, and test sets for Belizean Kriol↔English and French Guianese Creole↔French MT. See data cards for these submissions on GitHub.[10]

4.3.1 KozKreolMRU data

KozKreolMRU submitted two dev/test sets to evaluate translation between Mauritian Creole and English. The first consists of Mauritian Creole translations of FLORES-200 (NLLB Team et al., 2022), containing 997 `dev` lines and 1012 `devtest` lines. This dataset is particularly useful because (1) it is automatically aligned with the other language sets contained in FLORES-200 and (2) FLORES is a common benchmark to judge MT model proficiency. The second dataset is a small test set consisting of 102 sentence pairs sourced from the LALIT newspaper.

4.3.2 JHU

JHU submitted three datasets for two language pairs. The first consists of 5.5k lines of Belizean Kriol and English translations from a Belizean textbook, both automatically and manually aligned after document processing. The second dataset comes from an online Bible translation and pairs 879 French Guianese Creole lines with French translations. The third dataset consists of 792 sentences from French Guianese Creole fables, aligned with French translations (mostly manually after web-scraping the raw data). All of these datasets were divided into train, dev, and test splits with a 90-10-10 ratio. Together they increase the amount of publicly available bitext by 2,300% for Belizean Kriol↔English and 370% for French Guianese Creole↔French. JHU demonstrated improvements ranging from +3.2 chrF++ to +33.3 chrF++ on the submitted test sets via fine-tuning `kreyol-mt-pubtrain` on the submitted train sets.

5 Evaluation Results

We designed a shared evaluation process for the two system tracks. All language pairs in the received submissions were supported by Kreyòl-MT, so only our shuffled Kreyòl-MT public test sets were used for official evaluation.[11]

For every language pair and direction, we computed the chrF++ (Popović, 2017) and BLEU (Papineni et al., 2002) scores of the submission using the default parameters of the `sacrebleu` library. We compared these results to the baseline scores of `kreyol-mt-pubtrain`, `kreyol-mt`, and CreoleM2M as stipulated in Section 3.1. Note that no two teams submitted a system for the same language pair, and therefore scores could only be compared with baselines. Results for the constrained track are reported in Table 1, and for the unconstrained track in Table 2. We discuss the results for each track separately below.

5.1 Constrained system results

direction	Team	Model	chrF++	BLEU
		creole → XX		
crs→eng	**Krey-All**	contrastive2	59.0	34.5
	Krey-All	contrastive1	58.9	34.2
	baseline	`kreyol-mt-pubtrain`	57.7	33.8
	Krey-All	primary	58.4	33.7
mart1259 →fra	*baseline*	`kreyol-mt-pubtrain`	50.4	28.3
	LM	primary	49.1	25.3
		XX → creole		
fra→ mart1259	*baseline*	`kreyol-mt-pubtrain`	48.7	26.5
	LM	primary	48.7	25.8

Table 1: Results of primary, *contrastive1*, and *contrastive2* submissions to the constrained track. Systems are ordered by BLEU score.

ChrF++ and BLEU scores are reported in Table 1 for both teams, alongside the `kreyol-mt-pubtrain` baseline. The LM systems score on par with or slightly below the baseline, while *constrative1* and *constrative2* submissions of Krey-All show marginal improvements.

The *primary* **Krey-All** submission corresponds to approaches with data all merged under the Seychellois Creole language tag (`crs`); *contrastive1* represents use of language-specific tags, and *constrative2* indicates partial parameter freezing (with the last 4 encoders, all decoder layers and

[10] https://github.com/n8rob/creolemt_wmt25

[11] This led to complications with the unconstrained systems track. Because Robinson et al. (2024) originally shuffled and split their private and public test sets independently, the `kreyol-mt` model trained on the private set has been contaminated with some of the segments in the public Kreyòl-MT test sets we used to construct our eval sets. Yet as a publicly available model, `kreyol-mt` was permitted for unconstrained submissions. This is what prompted our reevaluation of EHOW submissions; see Section 5.2.1.

the shared embeddings fixed during training). The best model for crs→eng was *constrative2*, however all four submitted systems score within one BLEU point of each other. This, combined with the observation that KREY-ALL came up with a different system ranking (one in which *constrative2* performed worst of all, (Ayasi, 2025)) by using a different shuffle of the same test set, suggests that score differences are not significant.

Recall from Section 4.1.2 that **LM**'s into-French system employed curriculum learning with BLEU-based difficulty ranking. The system for opposite translation direction did not employ this, but used different train/dev split (70-30 instead of 90-10). In our official evaluation, both submissions under-performed the baseline, albeit by less than 2.0 chrF++. LM's own reporting a slight improvement over the baseline for `mart1259→fra` on a shuffling of the same test set, again gives the impression that score differences are not significant.

Both LM and KREY-ALL fine-tuned the `kreyol-mt-pubtrain` model for a single language pair. These were valuable experiments because such attempts had not been made previously. The original work of (Robinson et al., 2024) focused primarily on the KREYÒL-MT dataset and did not include extensive experiments regarding how to engineer optimal MT systems from the available data. One question left open by their work was whether, if in the absence of additional data or models, significant improvements could be achieved by post-training on a select subset of training data. Results from these two studies (Ayasi, 2025; Mompelat, 2025) now indicate no such significant improvements, suggesting that either very different methods would be needed to improve performance, or that researchers may find more promise in developing new datasets and using external models (rather than post-training on subsets of `kreyol-mt-pubtrain`'s own data).

5.2 Unconstrained system results

ChrF++ and BLEU scores are reported in Table 2 for both teams, alongside baselines.[12] The **KOZKREOLMRU** systems are unique in that they are not based on any system that was trained on the full KREYÒL-MT dataset. Both KOZKREOLMRU systems out-performed CREOLEM2M for `mfe↔eng` MT, but both under-performed `kreyol-mt-pubtrain`, with the out-of-English direction performingly comparitively worse. (This is consistent with Rajcoomar's (2025) own finding that monolingual pre-training and two steps of fine-tuning has different effectiveness

Table 3: Comparison of KOZKREOLMRU chrF scores with `kreyol-mt` on FLORES and LALIT test sets. Here *primary* is understood to refer to the version of the *primary* submitted systems that was not trained on FLORES `devtest` data, in the columns for FLORES. These are averaged sentence chrF scores across each set, consistent with Rajcoomar (2025). High scores are **bold**.

depending on language direction.) But despite its under-performance on the official evaluation, the KOZKREOLMRU systems significantly outperform `kreyol-mt-pubtrain` on the KOZKREOLMRU submitted test sets (by 8.0 chrF minimum). See Table 3, which compares chrF (Popović, 2015) scores of Rajcoomar's (2025) models with `kreyol-mt-pubtrain` performance on both FLORES and LALIT test sets.

Scores for **EHOW** are also in Table 2. As noted in Section 3.1, the EHOW team used the `kreyol-mt` model (trained on both public and private KREYÒL-MT data). For a fair comparison, we use this model as their baseline. However, since `kreyol-mt` was trained on portions of the public test sets for `cri`, `kea`, `pap`, `pre`, and `pov`, this results in inflation of scores for both EHOW systems and their baselines.

Recall from Section 4.2.1 that the EHOW *primary* and *contrastive1* submissions consisted mostly of merged models (the best model for each overall direction, and the best for each language pair, respectively). In cases where LLM post-editing improved on the *contrastive1* result, this was submitted as *contrastive2*. Scores tend to improve from *primary*→*contrastive1*→*contrastive2* for most language pairs. EHOW systems outperform the baseline in both translation directions for `pap`, `pre`, `fab`, and `aoa`. The baseline scores higher on `cri`, `kea`, and `pov`. However, note that, as mentioned in the previous paragraph, these results and the others for `cri`, `kea`, `pap`, `pre`, and `pov` may be obfuscated by dataset contamination, making it difficult to draw clear conclusions from EHOW scores. To address this issue, we set up a second round of evaluations for a subset of the EHOW submissions.

5.2.1 Reevaluation of EHOW systems

Table 4 contains the results for our accurate reevaluation of EHOW *primary* and *contrastive1* systems, avoiding data contamination. Avoiding this contamination was a challenge. The team fine-tuned some models from a `kreyol-mt` initialization, which was trained on some segments in the test set used to evaluate `kreyol-mt-pubtrain`. And for fine-tuning they used the set used to train `kreyol-mt-pubtrain`, which contains some overlap with the test set used to evaluate `kreyol-mt`. Noting that each KREYÒL-MT model's corresponding train and test sets had no overlap with each other, we decided to use the intersection of both `kreyol-mt` and `kreyol-mt-pubtrain` test sets to ensure we would not evaluate on any segments used in training. However, this intersection was incredibly small for some language pairs. Hence, we augmented any resulting test sets with fewer than 20 aligned sentences, by adding sentences that had originally been filtered out of the test sets during Robinson et al.'s (2024) test set cleaning processes. These extra segments were removed due to length or noise, so we cleaned them manually. In these decontaminated, augmented test sets, the smallest set was for `pov-eng` (with 23 aligned sentences), just as in the original test set (in which the set for this same language pair had 33 aligned sentences).

When we evaluate on decontaminated test sets, EHOW systems outperform the baseline in chrF++ for every language pair, except those involving `pap` and `pov`. See Table 4. (Note that we can conclude from Table 2 already that EHOW outperformed the baseline on `aoa` and `fab` directions, not shown in Table 4.)

It is worth mentioning here that the EHOW team found superior performance of their systems over the baseline for directions involving `pap` and `pov` when they used their own test sets—which better match the distribution of the additional training data the team curated and used for fine-tuning. See Table 5 for chrF (Popović, 2015) scores. The EHOW in-house test sets are not completely free from contamination, since they contain some of the synthetic data segments tha the team produced using the `kreyol-mt` model itself. However, this would ostensibly give the baseline mode an advantage, rather than the competitor models; and the EHOW test sets for `pap-eng` and `pov-eng` only contain 13% and 15% synthetic segments, respec-

direction	Model	chrF++	BLEU

tively. Hence we infer that the effects of this data contamination are minor, and can conclude with reasonable confidence that EHOW's own models for these language pairs would outperform the baseline model in the genres represented in the extra data they used.

Given all of this, we observe that that both unconstrained submissions (EHOW and KOZKREOLMRU) show a common pattern: employing new training datasets and different pre-trained models can expand Creole MT performance to new genres, even in cases when it does not significantly improve performance on pre-existing test sets or distributions.

6 Conclusions

The first shared task for Creole language MT convened submissions for a variety of Creole languages situated across the Caribbean, South America, and Africa. This convergence was made possible by an important acknowledgment: despite their differences, Creole languages may benefit from a united approach in developing new language technology solutions. Indeed, Creole languages are the fruit of similar sociohistorical developments, leading to shared linguistic patterns, and also have in common a paucity of corpora and MT systems. We received and evaluated four submissions for new MT systems, and two dataset submissions, representing 12 Creole languages total.

Table 5: Comparison of EHOW submitted models to the kreyol-mt baseline chrF on private EHOW test sets. Highest scores are **bold**.

We note several noteworthy observations from the contributions of the participants:

- **Creative data curation**: We observed a wide variety of approaches, including human translation, data augmentation, data up-sampling, back-translation, and synthetic data generation.
- **Harnessing linguistic information**: Submissions demonstrated the utility of linguistic considerations and relationships between languages (both between Creole languages with shared history and with relative languages).
- **Data-conscious methods**: Similarly, participants leveraged an assortment of algorithmic approaches to overcome data scarcity, including LoRa PEFT, partial freezing of layers, and model merging.
- **Adressal of directional challenges**: Participants noted that translation into a high-resource language tended to yield better results than translation into a Creole language.

Our evaluation led to some central lessons and takeaways. It was found that constrained systems, which attempted to boost MT performance for a particular language by post-training the kreyol-mt-pubtrain model on a subset of its own training data (pertaining to the language in question), did not result in significant performance improvements, even when authors searched across other training tactics and hyperparameters to maxi-

mize performance. This suggests that developing new datasets and using pre-trained models may be a more promising direction. Accordingly, our participants in the unconstrained systems track showed that such methods are often effective at improving results for some language pairs, and that even in cases where performance on the original test domain does not improve, new datasets and models can bring about expansion to new testing genres.

Takeaways and Future Ambitions The variety of training approaches developed and evaluated for this shared task provides valuable insights into the training of Creole MT systems. New data collected during the campaign can also be incorporated into future Creole MT datasets and models. In particular, this will allow us to train a new baseline model for the next iteration of the shared task. Re-training the baseline model will also give us the chance to ensure that all updated versions of KREYÒL-MT models online can be evaluated with the same test sets without contamination (a critical point for interpreting results).

We are proud that a number of this year's shared task organizers represent various Creole language-speaking communities. Our committee includes two L1 speakers of Jamaican Patois, one L1 speaker of Martinican Creole, one L2 speaker of Louisiana Creole, and one L2 speaker of Haitian. In the future, we hope to incorporate members from a broader diversity of Creole language communities, so that our efforts better serve the realistic needs of these communities.

Limitations

As noted throughout this paper, our primary limitation stemmed from issues with data contamination between the train and test sets for `kreyol-mt` and `kreyol-mt-pubtrain models`. This was an organizational failure on our part that will be rectified in future iterations of this work. A limitation not so easily overcome is simply that of genre homogeneity in the datasets for low-resource languages. As demonstrated by both unconstrained track participants, it was much easier to out-perform pre-trained baseline models on novel test sets than on existing test sets, likely due to correlations of genre and topic between training data and testing data. Though this is a significant limitation, it is one of the very problems that this shared task is intended to rectify. (Due to this year's progress, we now have more diverse datasets for Mauritian Creole, Belizean Kriol, and French Guianese Creole.)

Ethical Statement

Given the historical and ongoing marginalization of many Creole languages and their population of speakers (DeGraff, 2003), we stress that community engagement is crucial. To ensure resulting research in machine translation is in accordance with community wants and needs (Lent et al., 2022), with the goal of preserving community autonomy (Bird, 2020). That said, one common limitation of working in the low-resource space is over-reliance on religious domain data; we acknowledge the presence of data which may not be culturally relevant to Creole language speakers (Hershcovich et al., 2022; Mager et al., 2023).

Acknowledgments

This work received funding from the Inria "Défi"-type project COLaF. We would like to thank the WMT organizers for making a place for Creole languages and for the opportunity to host a shared task. We also thank all of the teams who submitted systems and datasets.

Abstract

This study proposes the results of the low-resource Indic language translation task organized in collaboration with the Tenth Conference on Machine Translation (WMT) 2025. In this workshop, participants were required to build and develop machine translation models for the seven language pairs, which were categorized into two categories. Category 1 is moderate training data available in languages i.e English–Assamese, English–Mizo, English-Khasi, English–Manipuri and English–Nyishi. Category 2 has very limited training data available in languages, i.e English–Bodo and English–Kokborok. This task leverages the enriched IndicNE-corp1.0 dataset, which consists of an extensive collection of parallel and monilingual corpora for north eastern Indic languages. The participant results were evaluated using automatic machine translation metrics, including BLEU, TER, ROUGE-L, ChrF, and METEOR. Along with those metrics, this year's work also includes Cosine similarity for evaluation, which captures the semantic representation of the sentence to measure the performance and accuracy of the models. This work aims to promote innovation and advancements in low-resource Indic languages.

1 Introduction

The Indic MT Shared Task, first organized alongside the Eighth Conference on Machine Translation (WMT) 2023[1] (Pal et al., 2023), demonstrated the critical need for sustained research attention toward low-resourced languages. That inaugural effort not only revealed the untapped potential for advancing machine translation in these linguistic contexts but also provided a robust methodological and collaborative foundation for future work. Motivated by its impact, the task was expanded and refined in the Ninth Conference on Machine Translation (WMT) 2024[2] (Pakray et al., 2024), drawing broader participation and richer system diversity. Building upon these successive advancements, the 2025 edition[3] has emerged as the most successful iteration to date—surpassing previous years in both scale and the quality of contributions—further cementing the task's role as a driving force in low-resource MT research.

India's linguistic landscape is remarkably diverse, encompassing hundreds of languages spoken across its regions. While 22 languages are officially recognized under the Eighth Schedule of the Indian Constitution and receive governmental support in terms of infrastructure, research, and funding, many others—often spoken by indigenous and minority communities—remain excluded from such provisions. These low-resource languages frequently lack standardized orthographies, adequate lexical resources (e.g., corpora), and formal linguistic documentation. Limited institutional support, declining intergenerational transmission, and minimal access to modern technologies further threaten their preservation and vitality.

To address these challenges, our initiative is dedicated to revitalizing and documenting low-resource Indic languages through targeted, technology-driven solutions. Building upon the success of the Indic MT Shared Tasks at WMT 2023 and WMT 2024, which focused on four language pairs (En-

[3] https://www2.statmt.org/wmt25/indic-mt-task.html

Proceedings of the Tenth Conference on Machine Translation, pages 532–553
November 8-9, 2025

glish–Assamese, English–Mizo, English–Khasi, and English–Manipuri) using the enriched IndicNE-Corp1.0 dataset, we have expanded the scope in 2025 to seven language pairs. These are divided into two categories: (1) Languages with moderate amounts of training data: English–Assamese, English–Mizo, English–Khasi, English–Manipuri, and English–Nyishi. (2) Languages with very limited training data: English–Bodo and English–Kokborok.

This year's task, which has already surpassed prior editions in scale and participation, continues to drive innovation in machine translation and NLP, developing solutions specifically adapted to the unique linguistic and resource constraints of low-resource Indic languages. The Indic MT Shared Task initiative is also committed to safeguarding India's rich linguistic diversity and cultural heritage by strengthening the rights and identities of minority language communities. Leveraging state-of-the-art technologies, it seeks to advance the capabilities of low-resource Indic languages, enabling them not only to survive but to flourish within today's increasingly digital and interconnected landscape.

The task is evaluated using a wide range of metrics, integrating automatic lexical evaluation metrics such as BLEU (Papineni et al., 2002), TER (Snover et al., 2006), ROUGE-L (Lin, 2004), METEOR (Banerjee and Lavie, 2005), and ChrF (Popović, 2015). In addition to the standard evaluation metrics, we used cosine similarity using Sentence-BERT(all-mpnet-base-v2) (Reimers and Gurevych, 2019) to compute the semantic similarity between the predicted and reference sentences in the English language direction. By combining traditional and semantic evaluation methods, this approach provides a thorough assessment of the performance and accuracy of translation systems.

2 Languages

This section is divided into two parts based on the availability of training data: Category 1 includes languages with moderate resources, and Category 2 includes languages with very limited resources. In the WMT 2024 edition of the shared task, the focus was limited to four languages: Assamese, Mizo, Khasi, and Manipuri. Building upon that foundation, the WMT 2025 task expanded the linguistic coverage by including three additional languages: Nyishi, Bodo, and Kokborok. This expansion reflects our ongoing commitment to improving the representation of under-resourced languages in machine translation research and to broadening the scope of technological inclusion for more linguistically marginalised communities.

2.1 Category 1: (Moderate Training Data Available)

2.1.1 The Assamese Language

Assamese, a member of the Indo-Aryan(Wikipedia contributors, 2025a) branch of the Indo-European language family, is primarily spoken in the northeastern Indian state of Assam. It holds official status in the state and functions as a vital lingua franca, bridging communication across the region's diverse ethnic communities. Recognized as one of India's 22 scheduled languages, Assamese occupies a prominent position within the nation's multilingual framework.

With literary roots dating back to the early medieval era, Assamese(Mahanta, 2012) boasts a long-standing and vibrant cultural heritage. The script currently used for the language evolved from the ancient Brahmi script, reflecting centuries of historical development. However, in the contemporary digital age, Assamese confronts a number of challenges, particularly with regard to language technology. The creation and advancement of computational resources for Assamese are essential, not only to support its practical use in modern contexts but also to ensure its continued vitality and preservation in the face of rapid technological change.

2.1.2 The Mizo Language

Mizo, belonging to the Tibeto-Burman (Wikipedia contributors, 2025d) branch of the Sino-Tibetan language family, is primarily spoken in the northeastern Indian state of Mizoram. It serves as the main medium of communication among the Mizo community and is also used by various ethnic groups across neighbouring regions such as Manipur, Tripura, Assam, and even in parts of Myanmar and Bangladesh. Known for its tonal structure and distinct phonological characteristics, Mizo stands out as a linguistically unique language within the Tibeto-Burman group.

The Mizo language (Zothanliana, 2021) is deeply rooted in a vibrant oral tradition that encompasses folklore, songs, and storytelling forms of expression that preserve and reflect the community's cultural identity. The written form of the language began to take shape in the late 19th century, when Christian missionaries

introduced the Roman script, enabling systematic transcription and laying the groundwork for written literature. Since then, Mizo has developed a strong literary presence, with works spanning traditional poetry to contemporary prose. Nonetheless, like many regional languages, Mizo faces significant challenges in the digital era, especially concerning its representation in language technology and digital communication platforms. Addressing these issues is crucial for both the preservation and advancement of the language.

2.1.3 The Khasi Language

Khasi, a language of the Austroasiatic family(Wikipedia contributors, 2025c), is predominantly spoken in the central and eastern regions (Rynjah and Lyngdoh, 2023) of Meghalaya. Prior to 1813, Khasi lacked a writing system. Between 1813 and 1814, the Bengali script was adopted for translating the Bible into Khasi, a decision influenced by the relatively high literacy in Bengali during that period. By 1816, translated excerpts from the Gospel of Matthew had been printed and circulated among Khasi speakers proficient in Bengali. However, a significant shift occurred in 1841 with the arrival of a Welsh missionary, who introduced the Roman script. This led to translations being made in the Sohra (Cherra) dialect, which later became the basis for standardized written Khasi.

Khasi is marked by notable dialectal diversity. Grierson(Grierson, 1903) identified four primary dialects: Standard Khasi, Pnar (or Synteng), Lyngngam, and War. Acharya (Acharya, 1971) reaffirmed this classification, adding that additional sub dialects such as Bhoi, spoken in Meghalaya's northern plains, also exist. Expanding on these observations, Bareh(Bareh, 1977) provides a detailed account of Khasi dialects, classified primarily by their geographical distribution:

- Amwi (southern Jaiñtia hills),
- Shella and Warding (southern Khasi hills),
- Myriaw, Nongkhlaw, Nongspung, Maram, and Mawiang (mid-western Khasi hills),
- Cherra (mid-southern Khasi hills),
- Mylliem, Laitlyngkot, Nongkrem, and Lyniong-Khasi (central Khasi hills),
- Jowai (central Jaintia hills),
- Bhoi (northeastern Khasi hills),
- Manar, Nongwah, and Jirang (northern Khasi hills),
- Khatarblang/Mawpran (mid-southern region),
- Nongstoin and Langrin (western Khasi hills).

Bareh also emphasizes that phonological variation exists within these groups. Among them, Amwi is considered a particularly distinct and conservative dialect. It is often viewed as more agglutinative and less intelligible to speakers of related dialects such as Jowai or Khatarblang. Despite its unique structure, Amwi speakers can generally understand and use neighbouring dialects for communication. Its linguistic features suggest strong retention of Mon-Khmer elements, especially in morphology and phonology.

Bareh (1977) organizes Khasi dialects into three broad branches:

1. **Eastern Dialects**:
   - Jowai (Central Highlands),
   - Amwi and the War dialects (southern region),
   - Bhoi Synteng (northern region).
2. **Central Dialects**:
   - Dialects such as Nongphlang, Cherra, Nongkrem, Mylliem, Nongspung, and others,
   - Northern varieties like Bhoi East (e.g., Mawrong, Bhoi Lymbong) and Bhoi West (e.g., Manar),
   - War Shala and Warding (southern region).
3. **Western Dialects**:
   - Nongstoin, Lyngam, and Langrin.

Within each branch, sub-dialects often display considerable variation, particularly in phonological patterns. Daladier(Daladier, 2002) notes that Khasi is a part of the Mon-Khmer subgroup of the Austroasiatic family retains conservative unwritten forms, especially in the War dialect areas. Pnar and War remain among the most prominent dialects, with War further subdivided into Nongtalang, Amvi, Tremblang, and Shella. The internal

classification of Pnar remains relatively unexplored, War dialects are further sub divided into War-Khasi and War-Jaintia, spoken in the southern regions of the Khasi and Jaiñtia hills.Grierson also provides foundational work on these dialects.

For the purposes of this shared task, we adopt the Sohra (Cherra) dialect as the standardized form of Khasi for translation. Its historical significance, combined with its widespread use in education, religion, and official discourse, makes it a practical and consistent choice. The formal adoption of the Roman script in 1841 further reinforced its position as the standard written variant, ensuring accessibility for both native speakers and learners across the Khasi-speaking population.

2.1.4 The Manipuri Language

Manipuri, also known as Meiteilon, is a Sino-Tibetan language primarily spoken in the northeastern Indian state of Manipur. It holds official status as one of the 22 scheduled languages of India and functions as a common medium of communication among diverse ethnic communities in the region, thereby playing a key role in facilitating both social interaction and cultural integration.

The language is marked by a rich literary tradition, with historical records indicating the use of written texts since ancient times. Manipuri employs both the indigenous Meitei Mayek script and, more recently, the Bengali script for written communication. Despite its cultural and historical significance, the language faces notable challenges related to preservation and modernization, particularly within the context of technological development and digital communication. The advancement of computational tools and linguistic resources is critical for ensuring the sustained vitality and broader accessibility of Manipuri in the digital age. In recent years, there has been an increasing academic and technological interest in developing natural language processing (NLP) tools tailored to low-resource languages, including Manipuri (Allen, 2003). However, several persistent issues continue to hinder progress (Gyanendro Singh et al., 2016). Chief among these is the scarcity of annotated corpora and high-quality linguistic datasets, which are crucial for training effective machine learning models. This lack of data significantly constrains the development of key NLP applications such as machine translation (Pal et al., 2023), sentiment analysis (Singh and Singh, 2017), and automatic speech recognition (Gyanendro Singh et al., 2016). Another major obstacle lies in the linguistic complexity of Manipuri itself. The language features a highly inflectional morphological system, posing difficulties for standard NLP models, which are typically optimized for morphologically simpler and better-resourced languages like English. Additionally, issues of script representation and lack of digital standardization complicate text processing, as existing tools often struggle with script conversion, normalization, and consistency across platforms.

Ongoing research is working to mitigate these challenges by building foundational linguistic resources, designing language-specific processing algorithms, and modifying existing NLP architectures to better accommodate the structural characteristics of Manipuri. Despite these promising developments, there remains a substantial gap between Manipuri and more digitally privileged languages a gap that must be addressed through sustained linguistic, technological, and policy-driven efforts.

2.1.5 The Nyishi Language

Nyishi(Kakum et al., 2023; Wikipedia contributors, 2025e), also known as Nyising, Leil, Aya, Nisi, Bangni-Bangru, or Akang, is a Tani language within the Sino-Tibetan family, spoken across eight districts in Arunachal Pradesh. It exhibits distinct typological features, including tonal phonology and context-dependent semantics.

The language uses a modified Roman script comprising seven vowels, eighteen consonants, consonant clusters, a glottal component, and a semivowel. Nyishi is tonal, employing rising, falling, and level tones to distinguish meaning an essential feature in its monosyllabic lexical system.

Syntactically, Nyishi follows a default Subject–Object–Verb (SOV) word order, with occasional Subject–Verb–Object (SVO) patterns. It blends isolating and agglutinative morphological traits. Words often carry multiple meanings based on context for instance, *taxy* may mean “squirrel”, “ginger”, or “animal lice”.

Gender is marked via suffixes rather than noun inflection, using forms like *kibu* (male dog) and *kine* (female dog). There are no plural markers or verb agreement for person or number. Negation is expressed uniformly through the particle *ma*.

Despite its cultural and linguistic value, Nyishi remains underrepresented in technological and computational domains. Expanding NLP efforts

and developing language resources are crucial for its digital preservation and broader accessibility.

2.2 Category 2: (Very Limited Training Data)

2.2.1 The Bodo Language

Bodo, also referred to as Boro (Wikipedia contributors, 2025b), is a member of the Bodo-Garo subgroup within the Tibeto-Burman branch of the Sino-Tibetan language family. It is primarily spoken by the Bodo people in the Bodoland Territorial Region (BTR) of Assam, India, with additional speaker communities in neighboring states such as Arunachal Pradesh, Meghalaya, and Nagaland, as well as in parts of Nepal and Bangladesh. According to the 2011 Census of India, the language is spoken by approximately 1.4 million people.

Bodo holds official recognition as one of the 22 scheduled languages of India(Bhattacharya, 1977), having been included in the Eighth Schedule of the Constitution in 2003. It also enjoys the status of an associate official language in Assam and is used as a medium of instruction in educational institutions within the BTR. The language was historically written in the Latin and Assamese scripts, but since 1975, the Devanagari script has been officially adopted.

Linguistically, Bodo is characterized as a tonal and agglutinative language. Its tonal system assigns semantic distinctions based on pitch, while its morphology supports the formation of complex words through the use of multiple affixes. The syntactic structure typically follows a Subject-Object-Verb (SOV) (Pathak et al., 2025) order, aligning with patterns common to Tibeto-Burman languages.

The Bodo literary tradition has developed (Boro, 2021)significantly in the modern period, particularly following the establishment of the Bodo Sahitya Sabha in 1952, which has been central to efforts in language standardization, publication, and literary development. Today, Bodo literature encompasses diverse genres, including poetry, fiction, and drama, reflecting the sociocultural life of its speakers.

Despite its official status and growing corpus, Bodo remains relatively under-resourced in the digital and computational linguistic domains. Continued initiatives in documentation, corpus building, and NLP development are essential to ensure its sustained vitality and technological integration.

2.2.2 The Kokborok Language

Kokborok, also known as Tripuri, is a Tibeto-Burman language belonging to the Bodo-Garo subgroup, primarily spoken in the Indian state of Tripura and parts of southern Assam, Mizoram, and the Chittagong Hill Tracts of Bangladesh (Debbarma et al., 2012; Nagaraja, 2015). It serves as a lingua franca among indigenous communities, including the Tripuri, Reang, Jamatia, Debbarma and other Borok tribes. According to the 2011 Census of India (Census of India, 2011), Kokborok has approximately 800,000 speakers in India, with additional speakers in Bangladesh, though exact figures for the latter are less documented. Though Kokborok is one of the official language of Tripura, but in urban areas like Agartala, there is a noticeable shift toward Bengali due to its dominance in administration, education, and media.

Linguistically, Kokborok has a rich phonological system, featuring six monophthong vowels and a consonant inventory that includes stops, nasals, fricatives, and approximants. Historically tonal, with pitch distinctions marking lexical meaning, the language is undergoing phonological simplification, particularly in urban settings, due to prolonged contact with non-tonal languages like Bengali and Hindi. Morphologically, Kokborok is agglutinative, employing affixation and compounding to form complex words(Hoque, 2014). Its syntax follows a Subject-Object-Verb (SOV) order, with a robust case system and verbal inflections for tense, aspect, mood, and person, reflecting its Tibeto-Burman roots.

Kokborok is written in both Roman and Bengali scripts, creating challenges for standardization and literacy efforts. Since 1979, Kokborok has been recognized as an official language in Tripura and is integrated into primary and secondary education curricula, with efforts to develop textbooks and teaching materials (Roy et al., 2022). The language remains a cornerstone of Borok cultural identity, expressed through oral traditions, folklore, songs, and ritual practices, such as those tied to festivals like Garia, Kharchi, Ker, and Hojagiri(Jacquesson, 2003).

Despite its cultural significance, UNESCO's Atlas of the World's Languages in danger classifies Kokborok as "vulnerable", reflecting threats from language shift and limited intergenerational transmission in urban areas(UNESCO, 2010). Revitalization efforts are ongoing, including curricu-

lum development, cultural festivals, and media programming like radio broadcasts and local television. Computational innovations, such as Linear Predictive Cepstral Coefficients (LPCC) for vowel recognition, support language documentation and preservation(Debbarma, 2012). Advocacy for Kokborok's inclusion in the Eighth Schedule of the Indian Constitution continues, emphasizing its linguistic and political significance for the Borok people.

3 Low-Resource Indic Language Translation 2025 Shared Task

3.1 Overview and Task Description

Following the success of the "Shared Task: Low-Resource Indic Language Translation" at WMT 2024, which attracted widespread international participation, the initiative will continue as part of the Tenth Conference on Machine Translation (WMT 2025). While recent advancements in machine translation (MT), particularly through multilingual modelling and transfer learning, have led to significant performance gains, developing effective MT systems for low-resource languages remains a critical challenge. This difficulty primarily stems from the limited availability of high-quality parallel corpora, which are essential for training robust and accurate translation models. The shared task aims to address this gap by fostering research and collaboration in low-resource Indic MT and promoting the creation and evaluation of translation systems for linguistically diverse and underrepresented languages.

The WMT 2025 Indic Machine Translation Shared Task aims to tackle the persistent challenges of low-resource translation by focusing on a diverse set of Indic languages drawn from multiple language families. This year, the task is organized around two categories based on the availability of training data.

- **Category 1** includes language pairs with moderate amounts of parallel data: English ⇔ Assamese, English ⇔ Mizo, English ⇔ Khasi, English ⇔ Manipuri, and English ⇔ Nyishi.
- **Category 2** consists of language pairs with extremely limited training resources: English ⇔ Bodo and English ⇔ Kokborok. By highlighting both moderately and severely resource-constrained languages, the task encourages the development of adaptable and data-efficient machine translation approaches capable of addressing the varying degrees of resource scarcity.

3.2 Categories

This year's task features two main categories based on the availability of training data:

3.2.1 Category 1: Moderate Training Data

- English ⇔ Assamese (en⇔as)
- English ⇔ Mizo (en⇔lus)
- English ⇔ Khasi (en⇔kha)
- English ⇔ Manipuri (en⇔mni)
- English ⇔ Nyishi (en⇔njz)

3.2.2 Category 2: Very Limited Training Data

- English ⇔ Kokborok (en⇔trp)
- English ⇔ Bodo (en⇔bodo)

3.3 Goal

This shared task goal is to build machine translation systems that can generate accurate translations regardless of the limitations of limited data availability. Participants are motivated to explore different innovative approaches, including:

- **Leveraging Monolingual Resources**: Utilizing monolingual corpora to improve the performance of translation systems.
- **Multilingual Strategies**: Exploring cross-lingual transfer techniques to support translation for under-resourced language pairs.
- **Cross-lingual Transfer Learning**: Employing models pretrained on high-resource languages and adapting them to low-resource scenarios.
- **Novel Methodologies**: Applying cutting-edge or customized approaches designed specifically for data-scarce environments.

3.4 Data

3.4.1 Training

This WMT 2025 Indic Machine Translation Shared Task leverages a dataset that consists of both parallel and monolingual corpora for Assamese, Khasi, Mizo, Manipuri, Nyishi, Bodo and Kokborok taken from the IndicNE-corp1.0 dataset.

3.4.2 Testing

For the testing section, we have created 2000 language pair sentences for each of the following language pairs:

- English ⇔ Assamese (en⇔as)
- English ⇔ Mizo (en⇔lus)
- English ⇔ Khasi (en⇔kha)
- English ⇔ Manipuri (en⇔mni)
- English ⇔ Nyishi (en⇔njz)
- English ⇔ Kokborok (en⇔trp)
- English ⇔ Bodo (en⇔bodo)

Out of these 2000 sentences, the first 1000 are provided in English, the participant needs to translate them into the specific target(Indic) language, and the remaining 1000 are given in the target language and are to be translated to English.

3.5 Evaluation

All the machine translation systems that are submitted by the participants are evaluated using automatic assessments to ensure balanced analysis of the translation systems. Automatic evaluation is being carried out by the following metrics such as BLEU, TER, ROUGE-L, ChrF and METEOR. Along with those metrics, this year's work also includes Cosine similarity using sentence transformer (all-mpnet-base) model based embeddings for evaluation, which captures the semantic representation of the sentences in the English language direction to measure the performance and accuracy of the models.

4 Dataset

4.1 Training

The dataset for the WMT 2024 Shared Task on Low-Resource Indic Language Translation is primarily based on the IndicNE-Corp1.0 dataset[4]. This corpus was built by aggregating datasets from previous research, including significant contributions from (Laskar et al., 2020) (Laskar et al., 2022), (Khenglawt et al., 2022), and (Laitonjam and Ranbir Singh, 2021). The compiled datasets encompass both parallel and monolingual corpora across four languages: Assamese, Mizo, Khasi, and Manipuri.

In earlier studies, we focused on developing parallel and monolingual corpora for English ⇔ Assamese (en⇔as) (Laskar et al., 2020, 2022), English ⇔ Mizo (en⇔lus) (Khenglawt et al., 2022), English ⇔ Khasi (en⇔kha) (Laskar et al., 2021), and English ⇔ Manipuri (en⇔mni) (Laitonjam and Ranbir Singh, 2021). The data was sourced from a variety of online platforms, including the Bible, multilingual dictionaries (such as Xobdo and Glosbe), multilingual question papers, PMIndia (Haddow and Kirefu, 2020), web pages, blogs, and online newspapers.

Table 1 shows the detailed statistics of the parallel datasets used for training and validation for each language pair.

Type	Sentences	Tokens (eng)	Tokens (target)
Assamese	54,000	1,033,580	878,466
Mizo	50,000	981,513	1,044,077
Khasi	26,000	778,689	948,853
Manipuri	23,687	422,522	357,524
Nyishi	60,000	337,887	323,876
Bodo	15,215	228,219	204,926
Kokborok	2,269	55,634	51,268

Table 1: Parallel data statistics for train and validation.

4.2 Testing

The testing dataset for the 2024 shared task was meticulously curated to present a substantial challenge beyond previous years' datasets. It comprised 1000 samples for each language pair, spanning four distinct and diverse domains: News, Travel, Sports, Entertainment, and Business. This domain-specific distribution aimed to comprehensively evaluate models' performance across varied and complex linguistic contexts, reflecting real-world translation demands. A collaborative approach was employed to create these testing samples, involving four specialized teams, each dedicated to one domain. These teams were provided 1000 English sentences, which they translated into their assigned target languages. The translation teams were instructed to maintain high fidelity to the source material while ensuring the translations were idiomatic and contextually appropriate for each domain.

The test set release process was intentionally staged to introduce additional complexity and rigour. In the first phase, 500 English sentences were released, requiring participants to translate these into the target languages. This forward trans-

[4] https://data.statmt.org/wmt23/indic-mt/

Language Pair	Entertainment	Sports	Healthcare	Travel	Political
English → Assamese	400	400	400	400	400
English → Mizo	400	400	400	400	400
English → Khasi	400	400	400	400	400
English → Manipuri	400	400	400	400	400
English → Nyishi	400	400	400	400	400
English → Bodo	400	400	400	400	400
English → Kokborok	400	400	400	400	400

Table 2: Domain-wise distribution of the 2025 test dataset across all language pairs. Each pair contains 2000 sentences, distributed evenly over five domains.

lation task required participants to demonstrate their models' proficiency in capturing nuances and domain-specific terminology in the target languages. In the second phase, 500 sentences in the target languages were provided, requiring translation back into English. This reverse translation task assessed the models' ability to accurately render the meaning, tone, and subtleties of the original sentences in English, thus testing bidirectional translation capability. The combined forward and reverse tasks aimed to evaluate the accuracy, fluency, and idiomatic correctness of the translations. The careful selection of diverse domains and the structured release of the test set were intended to challenge the generalization capabilities of the participating models. The goal was to ensure that only the most robust models, capable of handling a wide range of real-world scenarios, would excel.

This approach ensures a rigorous and multifaceted evaluation, capturing the subtleties of each language pair's translation performance across different domains.

5 Participants and System Descriptions

Language Pair	Submissions
English - Assamese	17 (primary), 18 (contrastive)
English - Mizo	5 (primary), 9 (contrastive)
English - Khasi	6 (primary), 19 (contrastive)
English - Manipuri	11 (primary), 7 (contrastive)
English - Nyishi	6 (primary), 12 (contrastive)
English - Bodo	6 (primary), 7 (contrastive)
English - Kokborok	3 (primary), 7 (contrastive)

Table 3: Number of participants in the low-resource Indic language translations

In this WMT 2025 Indic MT Shared Task, a total of 17 teams, as illustrated in the Table 4, registered and contributed for this year which is a huge improvement over the last year. We gathered the outputs produced by participant systems, including both primary and contrastive submissions.

A3-108: This team (Yadav and Shrivastava, 2025) system focused on translation for low-resource language pairs, combining a phrase-based SMT framework with subword segmentation through multiple BPE merge operations (500–3000 merges). Their approach involved concatenating and deduplicating segmented bitext to enhance vocabulary coverage and reduce sparsity, supported by KenLM-trained target-side language models. They submitted results for four English–X pairs: Nyishi, Manipuri, Khasi, and Assamese.

AkibaNLP-TUT: The AkibaNLP-TUT (Hamada et al., 2025) team tackled the WMT25 IndicMT task with Transformer-based models implemented in Fairseq. Their approach combined official parallel datasets with additional Bengali–English and Assamese monolingual corpora. A key technique was language-specific word-level noise injection to enhance robustness in low-resource settings, complemented by back-translation to augment English→X training data.

ANVITA: This team (Sivabhavani et al., 2025)submitted systems for three low-resource Indic languages Nyishi, Khasi, and Kokborok covering both primary and contrastive tracks. Their models were built using transfer learning, fine-tuning public pre-trained architectures such as byt5-base and nllb-200-distilled-600M with selective vocabulary expansion and targeted post-editing. The primary submissions relied on organizer-provided datasets, while the contrastive runs incorporated data augmentation through back-translation, sentence concatenation, and proprietary crawled resources. Language-specific strategies included leveraging Bodo data for Kokborok and tailoring vocabulary for Khasi.

BibaoMT: This team submission explored a

Table 4: The following table provides an overview of the teams registered for the low-resource Indic language translation task at WMT 2025.

lightweight neural MT model with just 22.4M parameters (280 MB) to tackle low-resource English-to-Indic translation. Their approach used a two-stage training pipeline: multilingual pretraining on seven task languages plus three high-resource languages, followed by fine-tuning on target languages. Training data combined official shared-task corpora with NLLB-mined bitexts, Samanantar, HPLT Bengali–English and Hindi–English, and OpenSubtitles Spanish–English datasets, enabling efficient translation despite limited resources.

BVSLP: The BV-SLP(Joshi et al., 2025) team developed MT systems for five language pairs: English⇔Assamese, English⇔Manipuri, and English→Bodo. Their pipeline integrates a rule-based named entity recognition and translation module prior to NMT training, handling organisation and location names via translation or transliteration from a knowledge base. After preprocessing, byte pair encoding (BPE) was applied to prepare data for Transformer-based NMT training, enabling improved handling of named entities in low-resource scenarios.

CITK-MT: The CITK-MT(Wary et al., 2025) team proposed an end-to-end NMT system targeting English→Bodo translation, leveraging a Seq2Seq model with GRU-based encoder–decoder layers and Bahdanau attention to enhance contextual alignment. Their pipeline included extensive data preprocessing, careful hyperparameter tuning (embedding size, hidden units, dropout), and training on Google Colab with NVIDIA A100 GPUs. The system was optimized using early stopping and evaluated via BLEU scores, demonstrating a focused approach for low-resource language translation.

DELAB-IIITM: The DELAB-IIITM(Oinam and Saharia, 2025) team addressed low-resource Indic translation for English⇔Assamese and English⇔Manipuri by fine-tuning the NLLB-200 multilingual model with synthetic parallel data augmentation. They generated synthetic corpora by leveraging bilingual pairs (Manipuri–English, Assamese–English) to create additional data for target languages, yielding 77K sentences after strict data cleaning. Fine-tuning employed the Seq2SeqTrainer framework with the Adafactor optimizer (2e-5 learning rate) and two training epochs, alongside careful train–test splits to mitigate overfitting. Evaluation showed notable BLEU score gains over baseline NLLB models across most directions (e.g., mni-as 0.45 vs. 0.10 baseline).

DoDS-IITPKD: The DoDS IIT Palakkad (Khongthaw et al., 2025) team tackled low-resource Indic language translation by participating with four languages: Khasi, Mizo, Assamese (Category-1) and Bodo (Category-2). Their primary system fine-tuned facebook/nllb-200-distilled-600M for English⇔Khasi and English⇔Mizo, while IndicTrans2 was used for Assamese and Bodo. For the contrastive system, training data was expanded with external corpora

such as PMINDIA and Google SMOL, enabling broader coverage. Both systems applied Low-Rank Adaptation (LoRA) for parameter-efficient fine-tuning within the Hugging Face Transformers + PEFT framework, along with language-specific tagging for preprocessing. This modular design balanced translation quality with computational efficiency.

DPKM: The DPKM(Kumar et al., 2025) team presents a low-resource NMT approach for English–Kokborok and English–Bodo translation, leveraging the LLaMA2-8B model with LoRA-based parameter-efficient fine-tuning. Their pipeline involves pretraining on monolingual Kokborok and English corpora (70k Kokborok / 30k English for Kokborok, and 350k Kokborok / 125k English for Bodo) prior to instruction tuning using WMT25 datasets converted into Alpaca format to suit instruction-following objectives. The fine-tuning method integrates LoRA adapters to minimize training overhead on large models.

Hope for best: This team deployed pre-trained IndicTrans2 transformer models for English–Assamese translation without additional fine-tuning, prioritizing fast deployment under CPU-only constraints. They formatted inputs with language tags and applied minimal preprocessing, achieving balanced quality with beam search and batch inference. Their system highlights how off-the-shelf multilingual models can still perform competitively in low-resource shared tasks.

JU-NLP: The JUNLP(Acharya et al., 2025) team addressed English ⇔ Assamese, Mizo, Manipuri, and Bodo translation by fine-tuning multilingual NLLB and IndicTrans2 models using parameter-efficient methods like LoRA and DORA. Their pipeline featured rigorous preprocessing, including deduplication, script harmonization, and alignment filtering to improve data quality. Evaluation on WMT datasets showed competitive BLEU/ChrF scores despite low-resource constraints.

MTHLT-BLR_Amrita: This team(Sheshadri and Gupta, 2025) tackled Assamese and Bodo to English translation using IndicTrans2 enhanced with a novel Representation Fine-tuning (ReFT) method, inserting lightweight modules into encoder layers for targeted adaptation. They optimized ReFT hyperparameters via Bayesian search with Optuna and fine-tuned only 0.5M parameters to avoid overfitting. Experiments on WMT data demonstrated competitive BLEU scores under strict low-resource constraints.

NLPTng-NITAP: The team from NIT Arunachal Pradesh addressed English ⇔ Nyishi translation using the mBART50 multilingual model with Task-Adaptive Fine-Tuning (TAFT). They introduced a custom Nyishi token (<nyi_IN>) and performed full model fine-tuning on WMT25 parallel corpora, leveraging language prefixing for direction control. Their method demonstrates effective transfer learning for new Indic languages under severe low-resource constraints.

RBG-AI: The RBG-AI(H and Ptaszynski, 2025) team developed a multilingual translation pipeline using the MADLAD-400 T5-based model, optimized for both high- and low-resource languages. Their approach employed 4-bit quantization to reduce memory usage and speed up inference on RTX3090 hardware without compromising translation quality. The system incorporated language-specific tags and beam search decoding to improve fluency and directionality. This design balanced translation accuracy with deployment efficiency, suitable for edge or resource-limited environments.

SRIB-NMT: SRIB-NMT participated in the WMT-25 Low-Resource Indic MT challenge with contrastive submissions for four language pairs: English–Assamese, English–Mizo, English–Khasi, and English–Manipuri. Their system used pre-trained NLLB models combined with LoRA fine-tuning to efficiently adapt to low-resource settings. By leveraging cross-lingual transfer techniques, they achieved notable gains in SacreBLEU on blind test sets. The submission highlights parameter-efficient adaptation strategies for multilingual translation tasks.

Transformers: This team(Gupta et al., 2025) developed NMT models for English to Assamese, Bodo, and Manipuri using the OpenNMT framework with a Transformer-based encoder–decoder architecture. Their approach included extensive pre-processing tokenisation, BPE segmentation, and vocabulary generation along with transfer learning from Samanantar v2 to boost low-resource performance. The models were fine-tuned on WMT25 Indic datasets and evaluated with BLEU and perplexity metrics. Deployment was optimised through CTranslate2 for efficient runtime translation on GPUs.

TranssionMT: This team employed a dual-model strategy using IndicTrans2_1B and NLLB_3.3B for low-resource Indic translation. Their system applied cross-iterative back-translation of monolingual data to create high-quality pseudo-parallel corpora and semantic filtering (all-mpnet-base-v2) to enhance domain similarity. Rigorous data cleaning removed noise like URLs and untranslated segments, ensuring improved training quality. The final translations combined outputs from both models to achieve optimal results.

6 Results and Discussion

The results of the WMT 2025 Indic Machine Translation (MT) Shared Task are illustrated in the tables below. For clarity, results are reported separately for each language pair and direction: Assamese–English (as–en) in Table 5 and English–Assamese (en–as) in Table 6. Similarly, results for English–Manipuri (en–mni) and Manipuri–English (mni–en) are presented in Tables 7 and 8, respectively. The English–Khasi (en–kha) and Khasi–English (kha–en) directions are summarized in Tables 9 and 10. For English–Mizo (en–lus) and Mizo–English (lus–en), results are provided in Tables 11 and 12. The English–Nyishi (en–njz) and Nyishi–English (njz–en) results are shown in Tables 14 and 13. Similarly, results for and English–Bodo (en–bodo) and Bodo–English (bodo–en) are reported in Tables 15 and 16. Finally, results for English–Kokborok (en–trp) and Kokborok–English (trp–en) are detailed in Tables 17 and 18. Each table lists the participating systems in descending order of performance, along with their respective evaluation scores. This section presents the evaluation scores of the participants and their submitted system outputs and corresponding papers. Although participants submitted results for both primary and contrastive systems, only the primary system results are highlighted in the corresponding tables.

An evaluation of the quantitative results was performed using metrics like BLEU, METEOR, ROUGE-L, ChrF, and TER. BLEU measures the precision of n-grams in candidate translations relative to reference translations. TER quantifies the number of edits required to transform the candidate translation into the reference. ROUGE-L evaluates the longest common subsequence between the candidate and reference, emphasizing recall-oriented aspects of translation quality. ChrF computes the character n-gram F-score, providing sensitivity to morphological variations. METEOR combines precision, recall, and synonym matching to capture translation adequacy and fluency. In addition to the traditional statistical metrics this year's evaluation also incorporates semantic similarity based on cosine similarity between sentence embeddings generated by the all-mpnet-base model for the Indic language to English direction.

Discussion

For the Assamese language, the team TranssionMT achieved a higher BLEU score of 23.20 in primary mode and 22.41 in contrastive mode for the as-en direction with cosine similarity of 0.92 in primary mode of evaluation. For the en-as direction, this team also achieved a higher score in both primary and contrastive with BLEU scores of 20.97 and 67.50, respectively. This team employed a dual-model strategy using IndicTrans2_1B and NLLB_3.3B for low-resource Indic translation. Their system applied cross-iterative back-translation of monolingual data to create high-quality pseudo-parallel corpora and semantic filtering (all-mpnet-base-v2) to enhance domain similarity.

For the Manipuri language, the team BVSLP achieved a higher BLEU score of 4.15 in the primary system and also achieved a higher cosine similarity of 89.60. In contrastive system submission team TranssionMT achieved BLEU score of 4.49 for the en-mni direction. Team BVSLP pipeline integrates a rule-based named entity recognition and translation module prior to NMT training, handling organisation and location names via translation or transliteration from a knowledge base. After preprocessing, byte pair encoding (BPE) was applied to prepare data for Transformer-based NMT training. For the mni-en direction team TranssionMT achieved higher BLEU scores of 13.37,14.86, and cosine similarities of 0.859, 0.860 in both primary and contrastive systems using their dual model strategy.

For the Khasi language, team DoDS-IITPKD achieved a higher BLEU score of 14.20 in primary system and TranssionMT achieved higher BLEU score of 82.56 in contrastive system for the en-kha direction. This team also achieved higher BLEU score of 4.31 in kha-en direction with their primary system submission, while Trans-

higher BLUE score of 15.83 in primary system submission and TranssionMT achieved BLEU score of 37.81 in contrastive system submissions in en-lus direction. JUNLP also achieved higher BLEU score of 12.30 with cosine similarity of 0.889 in primary mode and TranssionMT achieved higher BLUE score of 18.45 with cosinie similarity of 0.915 contrastive submissions in lus-en direction.The JUNLP team addressed English–Assamese, Mizo, Manipuri, and Bodo translation by fine-tuning NLLB and IndicTrans2 using parameter-efficient methods (LoRA and DORA). Their approach emphasized extensive preprocessing including deduplication, script harmonization, and alignment filtering to enhance data quality.

For the Nyishi language, team ANVITA achieved a higher BLUE scores of 11.59 with cosine similarity of 0.786 in primary submission out of all submissions in njz-en direction and achieved higher BLUE score of 6.21 in en-njz direction. Their models employed transfer learning by fine-tuning public pre-trained architectures such as ByT5-base and NLLB-200-distilled-600M, incorporating selective vocabulary expansion and targeted post-editing. The primary submissions utilized organizer-provided datasets, while the contrastive runs applied data augmentation through back-translation, sentence concatenation, and proprietary crawled resources.

For the Bodo language, team DoDS-IITPKD achieved higher BLEU score of 24.45,24.97 in primary and contrastive modes respectively in en-bodo direction. This team also achieved higher BLEU scores of 21.68, 22.11 in primary and contrastive submissions respectively in bodo-en direction.Team DoDS-IITPKD's primary system fine-tuned NLLB-200-distilled-600M for English–Khasi and English–Mizo, and used IndicTrans2 for Assamese and Bodo. The contrastive system incorporated additional corpora (e.g., PMINDIA, Google SMOL) to expand training data. Both systems employed LoRA-based parameter-efficient fine-tuning techniques.

For the Kokborok language, team ANVITA achieved higher BLEU scores of 2.41 in trp-en and 1.756 in en-trp directions with their primary submissions. This team also presented their higher scores in contrastive submissions also. Their models leveraged transfer learning by fine-tuning public pre-trained architectures such as ByT5-base and NLLB-200-distilled-600M, combined with selective vocabulary expansion and targeted post-editing. Primary submissions used organizer-provided datasets, while contrastive runs employed data augmentation via back-translation, sentence concatenation, and proprietary crawled resources. Additionally, language-specific strategies included leveraging Bodo data for Kokborok and tailoring vocabulary for Khasi.

7 Analysis

The evaluation results across multiple translation directions reveal a competitive landscape with significant variations in performance. A key finding is the direct correlation between the size of the parallel training data and the translation quality, although some notable exceptions exist. The figures (Figure 1, 2, and 3) illustrate these findings, providing a visual context for the observations.

Figure 1 shows the best **primary** BLEU score for

each language direction (the highest BLEU among primary submissions for that direction). Figure 2 visualizes BLEU vs. ChrF for the set of all primary submissions.

Observations

- **Correlation with Data Size:** There is a strong general trend that language pairs with larger parallel datasets, such as Assamese and Mizo, have higher translation scores. Conversely, languages with very limited data, like Kokborok, show the lowest performance. This confirms that data scarcity remains a significant bottleneck for low-resource languages.
- **Outlier Performance in Bodo:** A particularly noteworthy finding is the performance of the Bodo language pair. Despite having a relatively small dataset of only 15,215 sentences, it achieved the highest overall BLEU score of 24.45 for the $en \rightarrow bodo$ translation. This suggests that the quality of the Bodo data, or the highly effective model and training strategies employed by teams like DoDS-IITPKD, compensated for the limited size. This performance highlights that data quality and model optimization can sometimes outweigh the sheer quantity of data.
- **Dominance of Key Teams:** Teams such as TranssionMT and DoDS-IITPKD consistently delivered high-performing models, frequently securing the top spot in the language pairs they participated in.
- **Asymmetry in Translation Direction:** A consistent pattern emerged where the translation quality for one direction of a language pair was notably different from the other. This could be due to differences in data quality for each direction or inherent linguistic challenges in translating into a specific language.
- **Correlation of Metrics:** The Figure 2 scatter plot illustrates a clear positive correlation between BLEU and ChrF scores. This indicates that models that perform well on one metric of translation quality generally also perform well on the other, reinforcing the validity of these metrics as indicators of good performance.

Language-wise Analysis

The key findings for each language pair are given below:

- $Assamese \leftrightarrow English$: With one of the largest datasets (54,000 sentences), this pair yielded strong results. TranssionMT was the top performer in both directions, with BLEU scores of 23.20 for $as \rightarrow en$ and 20.97 for $en \rightarrow as$. The performance here aligns with the substantial training data available.
- $Mizo \leftrightarrow English$: This pair also had a large dataset (50,000 sentences), and the results reflect this. JU-NLP consistently outperformed DoDS-IITPKD, achieving the highest BLEU scores for both $en \rightarrow lus$ (15.83) and $lus \rightarrow en$ (12.30).
- $Khasi \leftrightarrow English$: With 26,000 sentences, the performance was moderate. DoDS-IITPKD excelled in this pair, securing the highest BLEU scores in both $en \rightarrow kha$ (14.20) and $kha \rightarrow en$ (4.31). The significant performance gap between the two directions is a point of interest.
- $Manipuri \leftrightarrow English$: Despite a dataset of 23,687 sentences, the $en \rightarrow mni$ direction proved exceptionally challenging, with the top BLEU score being only 4.15. In the reverse direction ($mni \rightarrow en$), TranssionMT led with a much higher BLEU of 13.37. This disparity is a key finding, suggesting that the complexity of translating English into a tonal, agglutinative language like Manipuri is a significant hurdle.
- $Nyishi \leftrightarrow English$: This language pair had the highest sentence count (60,000), but the lowest token count among the larger datasets, suggesting shorter sentences. ANVITA's performance (11.59 and 6.21) was moderate, indicating that sentence quantity alone is not the sole determinant of success.
- $Bodo \leftrightarrow English$: This language pair is the most striking example of data quality and model effectiveness. Despite a small dataset of only 15,215 sentences, DoDS-IITPKD achieved the highest BLEU score (24.45), demonstrating that high-quality data and strong modeling can overcome the limitations of data size.
- $Kokborok \leftrightarrow English$: With the least amount of data (2,269 sentences), this pair

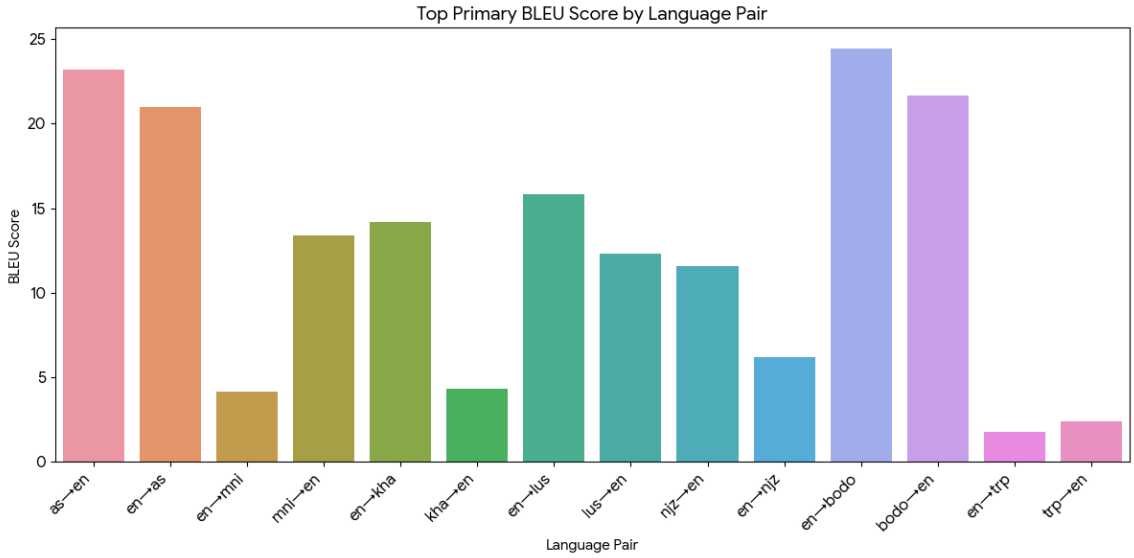

Figure 1: Top BLEU among **primary** submissions per language pair.

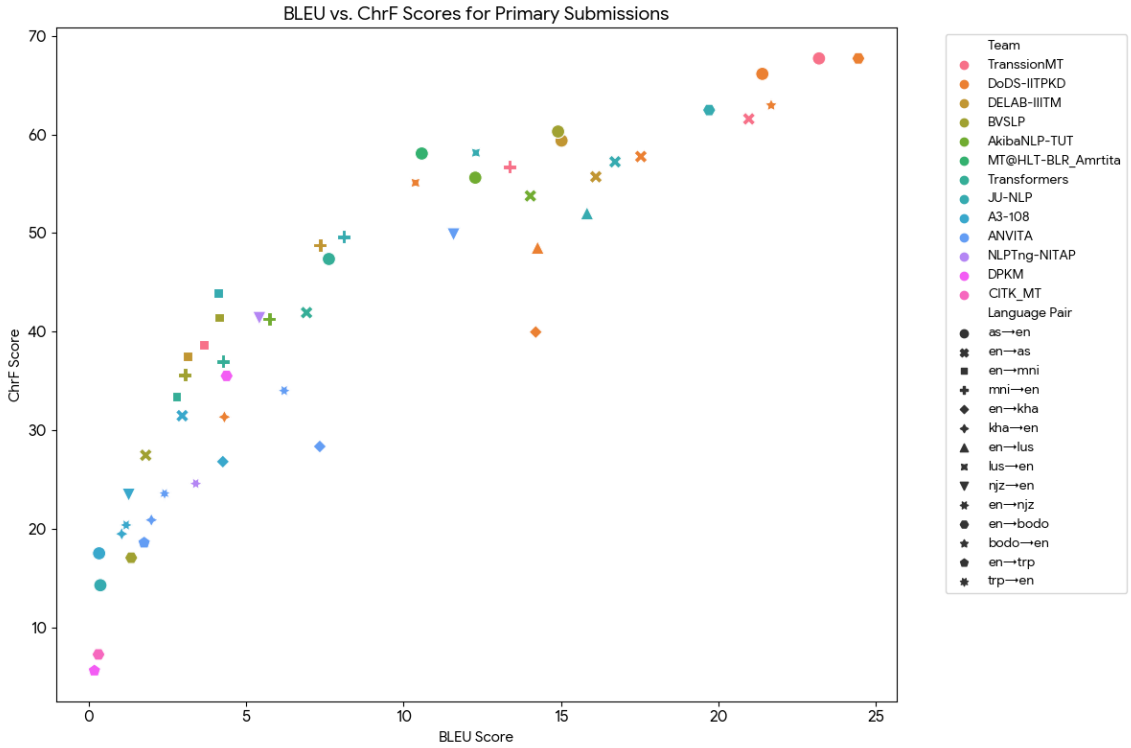

Figure 2: BLEU vs. ChrF for **primary** submissions. Each point is labelled with "team:language".

exhibited the lowest BLEU scores for both directions (1.76 and 2.41), confirming that data scarcity is the primary limiting factor for this language.

Team-wise Analysis

- TranssionMT: This team demonstrated exceptional performance in the Assamese-English and Manipuri-English pairs, consistently ranking at the top. Their models achieved the highest BLEU scores for $as \rightarrow en$ (23.20), $en \rightarrow as$ (20.97), and $mni \rightarrow en$ (13.37), highlighting their strength in these specific languages.

- DoDS-IITPKD: With the highest overall BLEU score of 24.45 for en→bodo, DoDS-IITPKD proved to be a dominant force, espe-

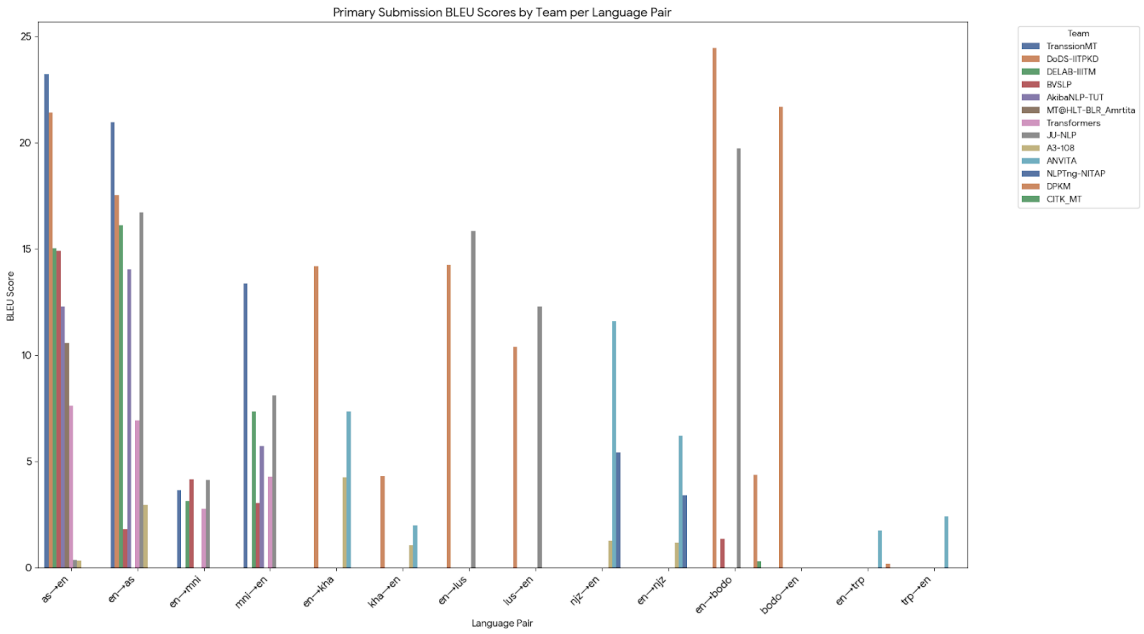

Figure 3: BLEU by team per language pair for **primary** submissions.

cially for the Bodo and Khasi language pairs, where they led in both translation directions.

- JU-NLP: This team's primary submissions were most effective for the Mizo language pairs, where they achieved the highest BLEU scores in both en→lus and lus→en.
- ANVITA: While ANVITA's performance varied, they were the clear leaders in the Nyishi and Kokborok language pairs. Their models, despite the challenges, achieved the best scores for all four directions involving these languages.
- BVSLP: BVSLP's top performance was for the en→mni translation direction, with a BLEU score of 4.15.
- Other Teams: Teams such as DELAB-IIITM, AkibaNLP-TUT, Transformers, and others participated in a number of language pairs, generally achieving lower, though still competitive, scores compared to the top performers.

Categorization of Approaches

Based on the system descriptions, the submitted approaches can be classified into the following methodological categories described in Table19. Note that some teams appear in more than one category when their systems span multiple techniques.

Language-wise Impact and Approach Trends

We further analyze the distribution of techniques across languages for primary submissions in both translation directions (Table 20).

- **>50k pairs** – Teams favored standard Transformer fine-tuning with minor augmentation. Substantial gains were observed from clean fine-tuning alone.
- **20k–30k pairs** – Back-translation and cross-lingual transfer were the most common strategies.
- **<20k pairs** – Parameter-efficient methods and transfer from related languages dominated. Data synthesis played a critical role in achieving competitive performance.

Conclusion

The outcomes of the participating teams in the WMT 2025 translation task have been comprehensively evaluated using a combination of automated metrics and semantic similarity measures. This year's shared task on low-resource Indic language translation utilized the updated **IndicNE-Corp2.0** dataset, which introduced broader domain coverage and incorporated three additional languages Nyishi, Bodo, and Kokborok extending the scope beyond the four language pairs evaluated in 2024. A newly curated test set with higher linguistic and

Category	Teams	Key Characteristics
Phrase-based SMT & Statistical Methods	A3-108	Traditional SMT with BPE, KenLM, deduplication, and focus on vocabulary coverage.
Transformer-based NMT (Standard)	AkibaNLP-TUT, BVSLP, JU-NLP, SRIB-NMT, Transformers	Transformer encoder–decoder architectures (Fairseq, OpenNMT, IndicTrans2, NLLB) with various preprocessing and fine-tuning strategies.
Parameter-efficient Fine-tuning (LoRA, DORA, ReFT)	DoDS-IITPKD, DPKM, JU-NLP, MT@HLT-BLR_Amrita, SRIB-NMT	Efficient adaptation of large multilingual models with minimal computational overhead.
Pretrained Multilingual Models (Zero/Few-shot)	Hope for Best, NLPTng-NITAP, RBG-AI	Direct use of pretrained models (IndicTrans2, mBART50, MADLAD-400) with minimal or targeted adaptation.
Back-translation / Synthetic Data Augmentation	AkibaNLP-TUT, ANVITA, DELAB-IIITM, TranssionMT	Creation of pseudo-parallel data from monolingual corpora to improve low-resource performance.
Transfer Learning & Multilingual Pretraining	ANVITA, BibaoMT, DoDS-IITPKD, Transformers	Leveraging high-resource languages or multilingual corpora to improve target language performance.
Custom Architectures / Specialized Modules	BVSLP (NER module), CITK-MT (GRU + Bahdanau), MT@HLT-BLR_Amrita (ReFT)	Architectures or modules tailored for specific challenges such as named entity handling or fine-grained adaptation.

Table 19: Categorization of submitted systems by methodological approach.

Language (Parallel Data Size)	Common Approaches Seen	Findings
Assamese (54k)	Transformer fine-tuning, direct pretrained model usage, some SMT	Largest resource size in the set; multiple teams reported strong BLEU gains with LoRA fine-tuning.
Mizo (50k)	Transformer fine-tuning + LoRA, back-translation	AkibaNLP-TUT and DoDS-IITPKD achieved consistent gains with monolingual augmentation.
Khasi (26k)	Transfer learning (ByT5, NLLB), BPE-based SMT	SMT still competitive for specific pairs; some systems leveraged Bodo data for transfer.
Manipuri (23.6k)	NLLB fine-tuning, Transformer training, back-translation	Popular among teams due to moderate resource availability.
Nyishi (60k)	SMT + mBART50 fine-tuning	Larger corpus size but fewer participating teams; most relied on transfer learning with prefix tokens.
Bodo (15.2k)	LoRA fine-tuning, ReFT, custom GRU Seq2Seq	Very low-resource; teams adopted parameter-efficient tuning or synthetic data generation.
Kokborok (2.3k)	Transfer learning from related languages, instruction-tuned LLaMA2	Extremely low-resource; innovative data sourcing and vocabulary sharing strategies applied.

Table 20: Language-wise trends in approach adoption for primary submissions in both directions.

structural complexity was also introduced, providing a more rigorous benchmark for system performance. These enhancements are aimed at capturing finer-grained differences in translation quality and reflecting more realistic application scenarios for low-resource Indic languages.

Acknowledgements

We acknowledge the use of linguistic resources and prior descriptive works on Khasi and related languages, which provided valuable background for this study. In particular, we refer to foundational contributions such as (Bareh, 1977), (Grierson, 1928), (Grierson, 1903), (Gurdon, 1904), (Gurdon, 1907), (Nagaraja, 1985), and (Pyrse, 1855).

Abstract

The WMT25 Terminology Translation Task releases new resources in high-stakes domains and investigates the capabilities of translation systems to accurately and consistently translate specialized terms. This year, we feature new domain and language coverage over previous editions, introducing two distinct tracks: (1) sentence-level translation in the information technology domain for English→German, English→Russian, and English→Spanish, and (2) document-level translation in the finance domain for English↔Traditional Chinese with a document-level one-to-many dictionary. Participants are challenged to translate texts under three modes: no terminology, proper terminology, and random terminology, allowing for a causal analysis of terminology utility. Evaluation combines overall quality, terminology accuracy, and terminology consistency. This shared task attracted broad participation, with 13 teams submitting 20 systems in Track 1 and 4 teams participating in Track 2. The results show that providing proper terminology consistently boosts both overall translation quality and term accuracy, whereas reliance on random terminology yields smaller gains. Despite the near-saturation of sentence-level benchmarks, document-level finance translation still falls short, indicating an urgent need for long-form evaluation and more robust metrics tailored to professional domains.

1 Introduction

Time flies. Since the 2023 edition of the WMT Terminology Translation Task (Semenov et al., 2023), rapid advances in machine translation (MT) and large language models (LLMs) have achieved near-human quality for general-domain translation in several languages (Kocmi et al., 2024, 2025b). Nonetheless, it remains an open question whether these powerful models or techniques can successfully address terminology translation, where the need for accurate and consistent conversion of terminologies poses extra difficulty in addition to general translation quality.

In professional fields like finance, medicine, and law, the correct use of specialized, agreed terms is critical for accuracy and clarity in communications, making terminology translation a research problem of high commercial value (Oncevay et al., 2025b). The field has seen various efforts in modeling (Hasler et al., 2018; Dinu et al., 2019), evaluation (Zouhar et al., 2020; Semenov and Bojar, 2022), and translator tool development (Vargas-Sierra, 2011; Arcan et al., 2017; Lagzdiņš et al., 2022), but recent progress seems to slow down even for high-resourced languages. For example, at the 2024 Conference on Machine Translation, only two papers were dedicated to terminology translation (Kim et al., 2024; Myung et al., 2024).

It is in this context of exciting general domain progress versus modest attention to terminology translation that we organize the WMT25 Terminology Translation Task. The task comes with two primary objectives: (1) to provide an understanding of the current landscape of terminology-aware translation, and (2) to announce and release new, human-annotated datasets to facilitate future research. We organize two tracks covering five translation directions and both sentence- and document-level translation. Particularly, the document track features large document-level one-to-many dictionaries that are more realistic in production. In terms of evaluation, we run multiple metrics that target different facets of terminology conversion, all while taking into account the general quality. Moreover, to estimate the added value (causal effect) of a provided terminology dictionary, systems are evaluated in three translation conditions: without a dictionary, with a proper terminology dictionary, and with a

November 8-9, 2025

dictionary of random words.

The main findings from the WMT 2025 Terminology Translation Task across submissions are:

★ Most systems involve an LLM in some way. Top systems achieve close to perfect terminology accuracy in the sentence-level track, indicating LLM's suitability for the task, and a saturation in the sentence benchmark. We need to move to document-level benchmarking, which is also more aligned with the practical use.

★ Contrary to the expectations based on previous research, there is little trade-off between general translation ability and terminology accuracy for most participating systems.

★ Incorporating some terminologies always benefits overall translation quality; using proper terms is more useful than random terms for top-performing systems.

2 Task Description

Our task is organized into two tracks, each focused on different domains and input sizes (of both texts and dictionaries), with a unified evaluation protocol. This allows this edition of the terminology shared task to cover wider scope of fields and input types (contrary to (Alam et al., 2021), where only medical domain and sentence-level data were provided), as well as tackling the domains in a more controlled manner (contrary to (Semenov et al., 2023), where every translation direction had its own domain of texts, from NLP abstracts to web novels).

2.1 Tracks and Domains

Track 1: Sentence-level translation

- **Domain:** Information Technology (IT), SAP
- **Translation direction:** English→German, English →Russian, and English→Spanish
- **Setup:** Participants are provided with sentence segments, each with a small terminology dictionary containing only the terms present in the segment, usually 1-2 entries.

Track 2: Document-Level Translation

- **Domain:** Hong Kong finance
- **Translation direction:** English↔Chinese[1]
- **Setup:** Participants are given documents, each accompanied by a large (up to 1K entries) document-level terminology dictionary. English input documents are capped at 2K words; for Chinese→English, the Chinese input is truncated to correspond to the English output of up to 2K words.

  Terminology constraints differ by direction: for English→Chinese, terms are one-to-one mapped, same as in Track 1; for Chinese→ English, terms may be one-to-many mapped, for instance, the target can have both full entity names and acronyms. This track tests terminology accuracy and consistency in long-form translation, reflecting real-world professional needs.

2.2 Terminology Modes

To enable a causal analysis of terminology utility and translation quality, each system is requested to translate our tests under three modes separately:

- **No Terminology (No Term):** The system translates the input text without a terminology dictionary.
- **Proper Terminology (Proper Term):** The system is provided with a dictionary of domain-specific terms; relevant to the input.
- **Random Terminology (Random Term):** The system receives a dictionary of randomly selected source words and their aligned translations from the references (the random pool excludes the proper terms).

The use of Random Term mode allows for measuring if improvements in translation quality stem from incorporating terminologies or from simply seeing part of the correct translation (Zouhar, 2023; Semenov et al., 2023).

3 Data

The data for both tracks[2] is provided in the `jsonl` format, where each instance has the following entries. See Table 1 for an example.

- Text in language 1
- Text in language 2
- Real terminology mapping dictionary (Proper)
- Random word mapping dictionary (Random)
- Dummy empty dictionary (NoTerm)

3.1 Track 1: Sentence-level IT Documentation

Data source. Our sentence-level data was produced by SAP to investigate ambiguous terminology in the IT business domain (Berger et al., 2025).[3] The data originates from their online help

[1] Traditional; henceforth only "Chinese" for brevity.

portal. Pages on the help portal are written in English, and translations are produced by post-editing machine translations to ensure proper terminology usage and adherence to corporate style guides.

Terminologies. SAP additionally maintains a one-to-many terminology dictionary across all of its production languages called SAPTerm.[4] Source and target terms were fuzzy-matched in the source and post-edited segments, with additional filtering performed to ensure post-edits made corrections of terminology usage. We make available a terminology dictionary for each segment pair, usually containing one or two entries.

The random terms were retrieved automatically by the following procedure: For every sentence pair (given input and reference translation), the pool of possible random terms is formed by all source sentence words except the terms and the stopwords (based on NLTK2024 stopword lists). Out of this pool, we sample as many words as there are in the corresponding proper dictionary. Then, we prompt ChatGPT to retrieve its translations from the reference sentence. We run an exact match search to ensure that the translation of the word is in the reference. The instruction for ChatGPT is provided in Appendix B.

Test set release. We select the English→ {German, Russian, Spanish} translation directions for the sentence track in our shared task. Per language pair, 1000 instances that contain terminology were sampled, and we split the 1000 segments into development and test sets consisting of 500 instances each. Each instance is accompanied by a terminology dictionary containing entries for that instance only. All test references are only made publicly available after the shared task submission deadline.

3.2 Track 2: Document-Level Finance

Data source. Our document track test data are sourced from the public annual reports on the official website of the Hong Kong Monetary Authority (HKMA), available in English and Traditional Chinese.[5] Each annual report contains multiple chapters, and each chapter is available to download as a standalone PDF file. In this task, we define such a chapter as a *document*. We collect all English and Traditional Chinese annual reports from 2015 to 2024. An annual report yields the same number of chapters (documents) in English and Chinese, and corresponding chapters are parallel to each other.

Document processing. We convert the chapter PDFs into markdown using MinerU (Wang et al., 2024), with table recognition, formula recognition, and optical character recognition disabled. We drop tables and formulae because they consist mostly of numbers without text, and are difficult to translate or evaluate. We then truncate each chapter to 2000 whitespace-delimited English words to keep the documents at a reasonable length for participants. Then, three authors, who are native Chinese speakers fluent in English, manually inspected and processed the markdown files. This includes truncating the Chinese side and re-aligning Chinese and English at the paragraph level in order to fix errors as a result of the automatic processing of the chapter PDFs, which are in a two-column format. As a result, each chapter (document) pair has the same number of lines in both languages.

Terminology extraction and mapping. We extract terms specific to Hong Kong finance from the source and target documents and establish a mapping via two stages. First, we prompt GPT-4.1 with a pair of source and target documents to automatically identify and align terminologies in the two languages, producing a preliminary mapping. Second, two authors independently review the generated mapping and correct it as necessary. Most revisions are removals of relatively generic named entities (e.g., Hong Kong and US dollar) that already have standard translations. The prompt used

[4] sapterm.com

[5] www.hkma.gov.hk/gb_chi/data-publications-and-research/publications/annual-report/

in this first stage is provided in Appendix A for reference. To extract a word mapping for the Random Term mode, we reuse the same technique from the sentence-level Track 1. To better approximate a real-world scenario, we merge the extracted mappings from the chapters (documents) within the same report and generate report-level mappings for both Proper and Random Term modes.

It is worth noting that the HKMA website provides a glossary for Chinese and English separately.[6] However, we did not use it because the Chinese and English lists are independently ordered, are not index-aligned, and contain different numbers of entries. Consequently, it is difficult to construct positional correspondence between entries in the two languages. This can be explored by future work.

Test set release. We release all document-level data we have prepared as the test set for this year's shared task. To avoid temporal bias and to ensure balanced representation of the translation directions, we partitioned the data so that translation direction alternates by year. Reports from odd-numbered years (2015, 2017, 2019, 2021, 2023) are used for English→Chinese tests, whereas those from even-numbered years (2016, 2018, 2020, 2022, 2024) are used for Chinese→English tests. We release each document as a single string, but paragraphs are delimited by `\n\n`, allowing participants to make their own chunking choices. With each test document, a large terminology dictionary is provided, containing mappings for all terminologies in the whole report (i.e., the dictionary is shared between all documents within the report).

4 Metrics and Evaluation

For both tracks, we run reference-based evaluation using gold translations and corresponding terminology dictionaries. We use three types of metrics in our shared task evaluation: overall quality (string match using BLEU and chrF2++; document-level MQM with LLM-as-a-judge), terminology accuracy, and terminology consistency.

This choice of metrics is motivated by two factors: (1) we wish to measure different aspects in translating terminologies, and (2) modern automated metrics can be less robust than a simple string-matching chrF, especially in domains that were not part of the metrics' training data (Lavie et al., 2025; Zouhar et al., 2024a,b).

New this year, we rank submissions based on the Pareto efficiency measured by the quality metric and the terminology. We provide terminology consistency scores as an analysis, and use the document-level AutoMQM scores for a separate ranking in Track 2, as this is not fully empirically validated.

4.1 Overall Translation Quality

BLEU and chrF2++. As an indication of overall quality, we run two reference-based metrics, BLEU (Papineni et al., 2002) and chrF2++ (Popović, 2017), as implemented in sacrebleu (Post, 2018) with default settings.[7,8] In the main paper we report chrF2++ which is tokenization-insensitive, allowing for consistent evaluation of German, Russian, Spanish, English, and Traditional Chinese outputs. Specifically to run the metrics in the document translation track, we treat each entire translation and reference document as a single string (O'Brien et al., 2025).

Doc-level AutoMQM. For document-level translation quality assessment, we use an LLM-as-a-judge: LLMs are prompted to identify translation error spans and assign severity levels, from which the final score is computed. This evaluation method is well interpretable and has been shown to correlate well with human judgment (Kocmi and Federmann, 2023; Freitag et al., 2023, 2024). An extension to the document level is focus-sentence prompting (FSP), which evaluates documents sentence by sentence (Domhan and Zhu, 2025). In FSP, the judge model is provided with the full source and translation as context, along with the specific target sentence to be evaluated. To evaluate document-level translation in Track 2, we use GPT-4o and GPT-5 as judge models, applying the FSP prompt with two modifications: (1) we evaluate three consecutive sentences at a time to improve efficiency; and (2) we provide the judge model with a terminology mapping to better assess translation quality. Details of the judge prompt are provided in Appendix C. Once the model outputs the errors and their severities, we compute the final MQM score for each annual report as a weighted average over the severity levels. We define three categories of severity: minor, major, and critical, with weights

of 1, 5, and 10, respectively. For example, an MT system receives an MQM score of 25 if it produces three major errors and one critical error.

4.2 Terminology Accuracy

We also evaluate how accurately translation systems can convert terms based on a given dictionary. We reckon that a source term usually occurs only once in a sentence input, but is more likely to appear multiple times in a document. Thus, we use different implementations for the two tracks as detailed below.

In the sentence track, for each source term appearing in the input text, we check if its corresponding target term appears in the translation, yielding a binary score. The accuracy is then computed as the sum of successful conversions divided by the total number of source words across all input instances. The algorithm is illustrated in Algorithm 1.

At the document level, the accuracy measure is modified to account for: (1) a source word can appear multiple times and thus a target word is expected as many times; (2) potential one-to-many mappings in a dictionary. The metric moves from a binary check to a percentage score. For each source term present in the source document, we calculate a ratio determined by the total number of appearances of all its possible target terms in the translation, divided by the total number of appearances of the source term itself. This ratio for each term is capped at 1 to avoid false positives, and the final document-level terminology accuracy is the average of all individual ratios across all source terms across all documents. The algorithm is shown in Algorithm 2.

The main difficulty of checking terminology accuracy lies in the terminology dictionary usually containing source and target entries in their stem form, but for many languages, we need to capture the inflected forms of the entries too. Hence, when we need to check whether a word is in a segment or count the number of appearances of the word, we always employ a two-pronged matching strategy. First, we run a direct surface-form match between the word and the segment. Second, to account for morphological variations, we check the lowercased lemmatized word against the lowercased lemmatized segment.[9] The final result is the higher value resulting from the two matching strategies—this applies to both binary outcomes or counts.

4.3 Terminology Consistency

We use the framework for the term consistency metric suggested by Semenov and Bojar (2022). The framework allows for automated (and more interpretable than LLM-as-a-judge) evaluation on how consistent the models are when choosing the translation of specialized terms. The modular structure of the framework allows for different levels of strictness in evaluation, so for the current shared task, we focused on two versions of the metric based on term frequency and the dictionary. As illustrated in Algorithm 3, the evaluation consists of the following steps:

- **Preprocessing:** This step requires sentence-level or paragraph-level alignments. Track 1 data already meets this; for Track 2, since the input texts have clear separation between paragraphs (double newline characters), we split the system outputs into segments accordingly.[10]

[9] github.com/stanfordnlp/stanza for lemmatization.

[10] For most systems, this simple preprocessing allowed for consistent alignment. The only exception was that for STITCH outputs, we additionally applied LaBSE embeddings (Feng et al., 2022) to align the split segments.

- **Source term selection:** At this step, we retrieved the subsets of terms present in a given segment. For Track 1, terminology dictionaries already meet the requirement. For Track 2, we filter the document-level dictionary to construct a segment-level dictionary for each segment using a substring match for Chinese and an exact match over lemmatized text for other languages.
- **Term translation alignment:** We then locate the exact part of the output that is a translation of the source term. The most effective way appeared to be few-shot prompting ChatGPT with additional post-processing, with details in Appendix E. We refer to the aligned term translations as "candidates".
- **Pseudo-reference choice:** To estimate the consistency of a system, we need to define "pseudo-references": translations against which we compare candidates. For the main analysis, we choose a frequency criterion: For each source term type, we order the candidate types by their frequency, and define the most frequent one as a pseudo-reference. Notably, this choice is insensitive to the term accuracy: the pseudo-reference may not be the best translation, but it should be used stably over the whole text. In an additional experiment in Appendix F, we also try another pseudo-reference option based on the Proper Term dictionary.
- **Evaluation:** For each term occurrence in each text segment, we check whether the observed translation candidate differs from the pseudo-reference. The final score is formalized as a multi-class accuracy: for each source term type (class), we count the percentage of the candidates matching the pseudo-reference in the submitted texts and run macro-averaging over the class percentages. As a result, we get a score within a range of 0 to 1, which shows the percentage of occurrences of the term translation that are consistent with the chosen pseudo-reference.

for $\text{src}_i, \text{tgt}_i \in X$ **do** # Source term selection & align.
  for $\text{term}_j \in \textsc{SrcTermSelect}(\text{src}_i)$ **do**
    $\text{cand}_j \leftarrow \textsc{Aligner}(\text{src}_i, \text{tgt}_i, \text{term}_j)$
    $\text{CandDict}_{\text{term}_j,\text{cand}_j} \leftarrow \text{CandDict}_{\text{term}_j,\text{cand}_j} + 1$
    $\text{AlgDict}_{i,\text{term}_j} \leftarrow \text{cand}_j$

for $\text{src}_i, \text{tgt}_i, \text{AlgDict}_i \in X$ **do** # Scoring
  for $\text{term}_j \in \text{AlgDict}_i$ **do**
    $\text{hit}_{i,j} \leftarrow \mathbb{1}[\text{term}_j = \text{PseudRefDict}_{\text{term}_j}]$
return $\sum_{k \in \text{PseudRefDict}} \frac{\sum \text{hit}_k}{|\text{hit}_k|}$ # Macro-average

Algorithm 3: Terminology Consistency (Track 1: sentence level) with pseudo-reference initialization of the most frequent terms. Input X is a list of source-translation pairs $\langle(\text{src}_1, \text{tgt}_1), \ldots\rangle$.

5 Participants and System Descriptions

This year, apart from our baseline, we see 20 systems in Track 1 and 4 systems in Track 2. Their descriptions are provided below. For an easier navigation over the variety of approaches, we label them with the main features and components of particular submissions, namely:

- models used:
  - NMT NMT model (encoder-decoder)
  - LLM LLM (decoder-only model)
  - multiple models (agents, preprocessing+postprocessing, etc.)
- training data:
  - DatAug data augmentation
  - DatCur data curation (filtering big corpora, enriching training data with annotation, etc.)
- model update techniques:
  - *FT fine-tuning, continuous pre-training, supervised fine-tuning, etc.
  - *PO various types of preference optimization: GRPO, PPO, DPO, etc.
- inference-time strategies:
  - code-switched prompts
  - ICL in-context learning, few-shot prompts, etc.
  - multi-metric decoding (using both general quality and term accuracy for sequence choice)
  - term injection (for NMT models)

o3-term-guide LLM The participant put terminology constraints in the form of explanatory statements and presumably prompted o3 from OpenAI.

DuTerm NMT LLM DatAug *FT This is a two-stage algorithm for terminology translation (Jaswal, 2025). It uses a terminology-aware NMT model fine-tuned from NLLB 3.3B (Costa-Jussà et al., 2022), and prompts GPT-4o for post-editing. To construct the NMT training data, they first extract bilingual terminology dictionaries from WMT25 dev sets, which are then supplemented with terminologies generated by the LLM. Then they use an LLM to synthesize parallel sentences

containing one or more terminologies. Specifically, the terms in both source and target sentences are bounded with special tags for identification. After filtering the training data for quality with COMET-QE and other rules, the NMT undergoes terminology-aware fine-tuning. Given the source, the NMT's translation and term pairs, they prompt GPT-4o to refine the translation for better fluency while keeping the constraints.

Erlendur LLM ICL Ingólfsdóttir et al. (2025) presented an LLM-based translation system using a pipeline approach that combines prompting with modular preprocessing and postprocessing components. In a preparatory stage, the LLM analyzes the source text to extract key terms and idioms, which are then matched with entries from bilingual dictionaries; user-provided glossaries can also be incorporated to enforce consistent terminology. After translation, additional post-processing steps may be applied. For example, a custom seq2seq grammatical error correction model is used to improve Icelandic translations. The system participated in both terminology tracks: for Track 1, it employed its standard pipeline with terminology mapping, while for Track 2, the backbone model was switched from Claude 3.5 to GPT-4.1, as the former refused to translate some test examples.

ISMT-TiU (TiUTerm-V0, TiUTerm-V1) LLM ICL The team submitted two systems, both relying on in-context learning of LLMs, with few-shot examples retrieved with BM25 from the dev set. TiUTerm-V0 is Llama-3-8B (Grattafiori et al., 2024) with 10 in-context examples; TiUTerm-V1 is XGLM-7.5B (Lin et al., 2022) with 12 in-context examples.

Barcelona Supercomputing Center (tower, salamandrata) LLM DatCur *PO Garcia Gilabert et al. (2025) submitted two models: Tower based on Llama2-7B (Touvron et al., 2023) and salamandrata based on Salamandra-7B (Gonzalez-Agirre et al., 2025). They use a novel approach of fine-tuning terminology translation using GRPO (Shao et al., 2024). Specifically, they introduce a terminology adherence reward, which penalizes outputs that do not contain the correct terminology. The training data are based on pseudo-terminology mined heuristically using named entities, noun phrases, and adverbial constructions. The reward during training is joined with a general MT quality reward using a quality estimation model.

IRB-MT (MeGuMa) LLM The submitted system, named MeGuMa, uses LLM agents with terminology-aware translation prompts, in combination with two MT metrics for per-translation-unit solution selection: MetricX (Juraska et al., 2023) and a custom approximation of terminology accuracy which uses an explicit alignment system by Steingrimsson et al. (2023) beyond surface mapping of lemmatized terms. Translation is done in two phases: translation and revision. Models used for translation are taken from three families: Gemma 3 (27B and 12B) by Team et al. (2025), Qwen3 (14B-thinking, 8B-thinking, 14B, 8B) by Yang et al. (2025), and EuroLLM (9B) by (Martins et al., 2025). In the second phase, three models are used to revise all translations: Gemma 3 27B with thinking, Gemma 3 12B with thinking, and Qwen 3 14B with thinking. While Qwen 3 supports thinking natively but not Gemma 3, all of the revision models were prompt-induced to first think and then produce the final solution. The final translation is selected from all of the generated solutions, both initial and revised. The selection criterion is an arithmetic mean of the arithmetic, geometric, and harmonic means of MetricX (Juraska et al., 2024) and terminology accuracy.

CommandA-WMT LLM DatCur *PO Kocmi et al. (2025a) submitted a post-trained version of Command A from Cohere. The data contains a mix of the languages the model was originally trained on, as well as machine translation data in new languages. The data was heavily filtered for quality. This was followed by preference tuning with a bespoke MTExpert dataset for all languages.

BIT LLM *PO Based on Qwen3-8B-Instruct, the participants used the PPO algorithm to perform reinforcement learning according to the terminology accuracy of the model's outputs without using any Dev Data.

Laniqo LLM DatCur *FT ICL Guttmann et al. (2025) use the EuroLLM-9B-Instruct model (Martins et al., 2025) as a foundation. Given an explicit dictionary, the terms in the source sentence in a prompt are substituted with the target language translations of it, creating a code-switched sentence. Additional prompt engineering analysis showed that two-shot prompts were the most efficient. The second modification was fine-tuning on augmented data from OPUS (Tiedemann

and Nygaard, 2004), where the randomly selected source text nouns and verbs were aligned with their translations, and were replaced with them in the same way as the prompts for the LLM. Fine-tuning was conducted with LoRA (Hu et al., 2022). The decoding is done with constraints: inspired by our announced metrics, the Pareto frontier between overall quality and term accuracy, they used epsilon sampling of 100 sentences, followed by multi-dimensional ranking by various QE metrics and term accuracy of a given segment. This approach was named Pareto-Optimal Decoding. The ablation experiments showed that the best scores were achieved by combining a fine-tuned model together with a modified prompt and few-shot examples.

Lingua Custodia (LC-primary, LC-2, LC-3) LLM DatCur *FT *PO Liu et al. (2025) submitted three systems in total: LC-primary, LC-2, and LC-3. They first filtered bilingual data from Common Crawl and WMT25 using LaBSE and applied an unsupervised terminology extraction approach, developed in their 2023 terminology task submission (Liu et al., 2023), to create terminology mappings. They then fine-tuned open-weight and efficient LLMs, Qwen3-4B (Yang et al., 2025) (with thinking mode disabled) and Gemma-3-4b-it (Team et al., 2025). They conducted supervised fine-tuning in the first stage and then applied GRPO in the second stage, using a sentence-level BLEU reward for overall quality and a constraint-following reward for terminology adherence.

CurTermNLLB NMT DatCur *FT Gonzalez-Gomez (2025)'s system is based on LoRA (Hu et al., 2022) fine-tuning of NLLB 200M (Costa-Jussà et al., 2022) on the consumer-grade Apple M3 with an automated pipeline for creating terminology containing data similar to the Track 1 dataset. They select data from OPUS (Tiedemann and Nygaard, 2004), specifically data from the `GNOME`, `KDE4`, and `WikiMatrix` projects. Sentence pairs from this subset of data were embedded with `all-mpnet-base-v2` in Sentence-Transformers (Reimers and Gurevych, 2019), and cosine similarity to Track 1 dev set sentence pairs was computed for filtering together with filtering based on part-of-speech. Source terminology was then aligned to target sentences to create a term dictionary; relevant dictionary entries were provided to the NLLB model as additional input.

UW-BENMT (ContextTerm) NMT DatCur Pong (2025) submitted a system named ContextTerm, a Transformer-based NMT model (roughly Transformer-base size) with terminology-aware data augmentation. The system identifies terminology constraints by selecting source–target alignments whose source words are judged most "important" by the encoder (measured via the norm of their hidden-state vectors) rather than merely low-frequency ones. Training data combined the IT-specific parallel corpora selected with Cross-Entropy Difference filtering and 30k synthetic English sentences generated using Aya-Expanse-8b (Dang et al., 2024), with inline soft constraints applied to 10% of the data.

Multitan (Systran-ft, EuroLLM-ft, MarianMT-ft) LLM NMT DatAug *FT The participants submitted three systems. The general approach was fine-tuning on in-domain data. Specifically, for Systran-ft, the authors used Systran Model Studio Lite to fine-tune Systran's baseline model with augmented in-domain data. For EuroLLM-ft, EuroLLM was updated with in-domain aligned segments and glossary by using LoRA (Hu et al., 2022). For the third system, MarianMT-ft, the team used two fine-tuning strategies: in No Term mode, using the dev set and other in-domain aligned segments; in Proper Term mode, in addition to fine-tuning the model with in-domain segments, they used a glossary for hard-forced training.

TranssionMT *FT This participant used training constraints and post-processing constraints to improve terminology translation accuracy.

STITCH LLM ICL The participants aimed at solving a recently highlighted problem of adding overly large context into prompts. The proposed method is named STITCH, which stands for Structured Terminology Integration for Translation with Context Handling. STITCH makes use of the observation that long-form documents are coarsely aligned on a paragraph-level and injects local terminology context in-flight during generation, while removing already integrated terminology information from the prompt. The approach leads to a task decomposition, allowing the model to perform document-level translation while being guided by local terminology information.

Baseline■ (GPT-4.1-nano) LLM The organizers prepared a baseline approach by querying GPT-4.1-nano (`2025-04-14`) with a long prompt containing

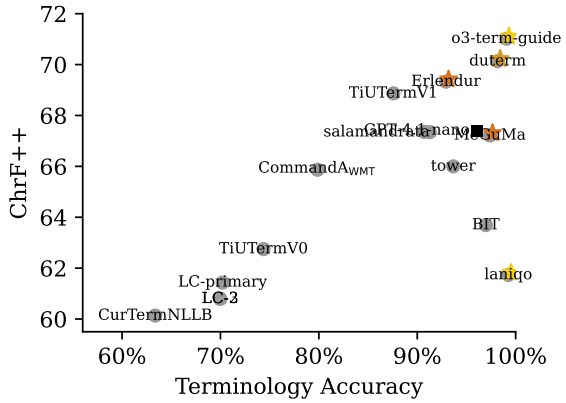

Figure 1: Tradeoff between quality (chrF++) and terminology accuracy in the proper terminology mode, averaged across three directions in Track 1. Top-performing systems are labelled as rank 1★, rank 2★, and rank 3★ according to Pareto optimality.

the input sentence or document and the entire terminology dictionary, when applicable.

6 Shared Task Results

Main results are presented in Table 2 for the sentence-level IT documentation and Table 3 for financial documents. For all three dictionary modes (Proper Term, Random Term, and No Term), the terminology accuracy is *always* measured with respect to the proper terminology dictionary. In addition to chrF++ and terminology accuracy used for system ranking, we also supply terminology consistency, which measures the consistency of the translated terminologies.

6.1 Ranking

We rank all systems in each track by a Pareto efficiency between translation quality (chrF++) and terminology accuracy in the Proper Term mode, where the systems translate real terminologies. For both Track 1 and Track 2, we average chrF++ and term accuracy across all directions for comparison.

Figure 1 visualizes the two-dimensional results for Track 1 systems. In total, there are 5 top-performing systems labelled by ★'s, namely, rank 1 (**o3-term-guide** and **laniqo**), rank 2 (**duterm**), and rank 3 (**Erlendur** and **MeGuMa**), according to Pareto optimality. In Track 2, among the 4 participants, **Erlendur** and **CommandA$_{WMT}$** are at the frontier.

6.2 Translation Quality and Terminology Accuracy

In both tracks, the quality differences between top systems are marginal, as indicated by chrF++ scores, which are usually within 1 chrF++ difference. Terminology handling exhibits sharper contrasts across the two tracks. In the sentence-level Track 1, strong systems achieve very high terminology accuracy of above 97%, implying that state-of-the-art translators can almost perfectly adhere to a few terminology constraints at the sentence level. This also implies that sentence-level terminology translation, as a rather artificial task, lacks difficulty for modern systems. By contrast, the document-level Track 2 exposes the harder challenge, as we observe that accuracy scores drop to the 70–80% range. When many terms need to be translated throughout longer contexts, systems frequently fall short.

Terminology accuracy is not uniform across translation directions. In Track 1, the best systems have similar (and very high) terminology accuracy for the three languages, but a few other systems show some divergence. Our GPT-4.1-nano baseline attains good accuracy when translating into Spanish, but not German or Russian. CommandA$_{WMT}$ and CurTermNLLB show markedly lower accuracy for Russian terminologies compared to Spanish and German. In Track 2, Erlendur delivers better quality and accuracy for English→Chinese, whereas CommandA$_{WMT}$ leads in Chinese→English.

The four systems that entered both tracks (Erlendur, MeGuMa, CommandA$_{WMT}$, and our baseline GPT-4.1-nano) enable us to compare terminology handling under different input lengths and terminology constraint loads. Given longer documents and more terminologies, we expect terminology accuracy to be lower in Track 2. However, CommandA$_{WMT}$ maintains accuracy comparable to, if not better than, its Track 1 results. Moreover, MeGuMa's accuracy is stable across the three languages in Track 1 but shows a dramatic gap of over 30 points between English→Chinese and Chinese→English in Track 2. Nonetheless, we note that the domain and translation direction also changed, which may cause the observed pattern.

Finally, as shown in Figure 1 earlier, there is no clear quality-accuracy tradeoff for many systems; chrF++ and terminology accuracy tend to rise (or drop) together. Outliers such as MeGuMa, tower, BIT, and laniqo lean towards optimizing for termi-

nology accuracy, at variable costs in chrF++. A possible explanation for that, at least for MeGuMa and laniqo, can be that the multi-metric optimization used by the authors tends to favor the terminology-specific metrics.

6.3 Terminology Consistency

Tables 2 and 3 show that, contrary to the general MT quality and success rate scores, the spreads of the consistency scores in the Proper Term mode are relatively small, ranging from 0.81 to 0.92. This shows that the models are quite stable in choosing the translations of the specific terms. The performance of the models in Track 2 is overall higher than that of Track 1: the score of 0.87 is among the highest for sentence-level translation and the lowest for document-level translation. A possible reason for that can be the contextual dependency of the generated terms: in a document-level setup, a system attends to previously generated text, and it can be more prone to copying already generated sequences, while each occurrence of a term in a sentence-level setup is translated independently. This is indirectly supported by the observation of another version of the consistency metric: with the "first-seen" pseudo-reference choice. The absolute scores in both versions of the metrics, as well as their rankings, behave in a surprisingly similar manner: the absolute scores of the "first-seen" pseudo-reference initialization are stably lower compared to the "most frequent" initialization by 0.02 on average. This suggests that the first translation of the term would tend to be the most frequent over the document.

Another observation is that, in stark contrast to the terminology accuracy, the system scores are relatively robust to different types (and presence) of explicit terminology. Yet, as was noted for the two main metrics, the difference in consistency between the proper terminology and the two other modes becomes more pronounced in the higher-scoring systems. Such a trend, however, has exceptions: while it is true for English to Russian, German (sentence level), and Chinese (document level) sentence pairs, the English to Spanish and Chinese to English outputs do not show much difference over the whole range of the systems.

Finally, we should note that if the pseudo-

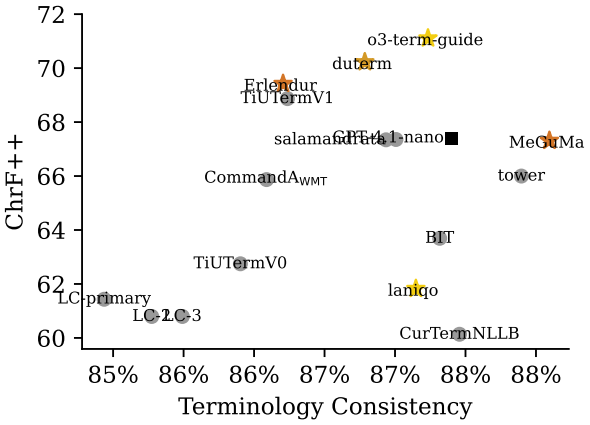

Figure 2: Relationship between quality (chrF++) and terminology consistency in the proper terminology mode, averaged across three directions in Track 1. Top-ranking systems are labelled as in Figure 1.

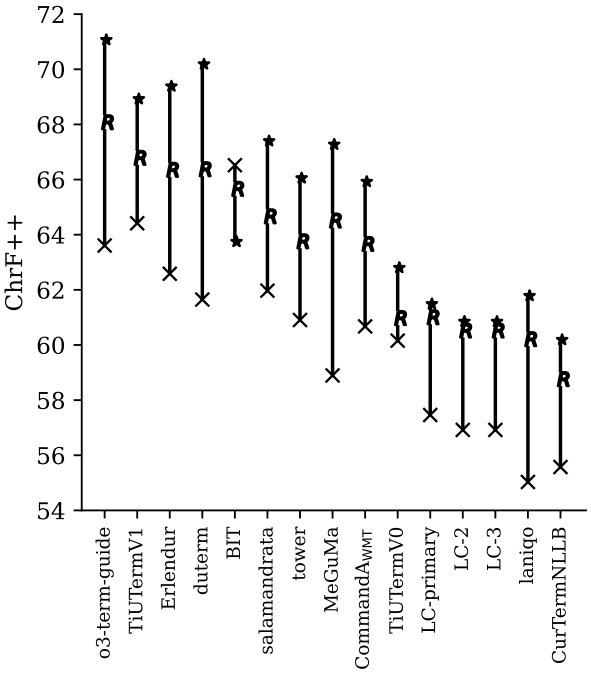

Figure 3: Effect of terminology mode on performance (measured by ChrF++) in Track 1. Legend: $\times$ denotes No Term, R denotes Random Term, and ★ denotes Proper Term.

references are initiated according to the proper terminology dictionaries, the absolute scores drop significantly (resulting in the range of 0.5 to 0.8), and the effect of the terminology mode becomes more pronounced. This is demonstrated in Appendix F, where the scores for each system in Random Term and No Term modes range between 0.2 and 0.4, while the proper terminology lies in a span of 0.5-0.8. Moreover, the difference between modes becomes more pronounced in higher-scoring systems. We conclude that the variant of the metric with dictionary-based pseudo-reference initialization may be more informative for the task of terminology translation, as it correlates with other metrics better and distinguishes between systems more clearly.

7 Analysis

Apart from reporting general translation quality, terminology accuracy, and terminology consistency, we analyze the terminology incorporation and metrics, hoping to provide insights to the community:

- A causal analysis of the impact of incorporating terminology on translation quality.
- A document-level AutoMQM using LLM-as-a-judge, all while considering a large terminology dictionary for Track 2.
- A study of the correlation between different metrics for Track 1.

7.1 Effect of Terminology Incorporation

We investigate the impact of incorporating terminologies on translation quality. Since providing a proper dictionary adds extra target-side information compared to using no dictionary, we also request participants to translate under a Random Term mode to enable a causal analysis. We plot the chrF++ scores under the three terminology modes on a vertical bar in Figure 3 for each participant in the sentence-level Track 1. This helps us easily inspect the quality gap between systems translating under different modes. It is clear that using a dictionary, either random or proper, consistently helps systems' translation quality. For top-performing systems, the benefit of using proper dictionary entries outweighs that of using a random dictionary, but for systems with a lower translation quality, there is no clear difference.

7.2 Doc-Level MQM Results

Table 4 presents the weighted MQM scores for each LLM judge, while Figures 4 and 6 visualize the distribution of error types and severities across the submitted systems in both the No Term and Proper Term settings for GPT-5 and GPT-4o, respectively.

Both LLM judges yield broadly consistent rankings among the top systems, with CommandA$_{WMT}$ and Erlendur generally outperforming MeGuMa and STITCH in terms of overall MQM scores.

	Weighted MQM score					
	GPT-4o			GPT-5		
System	**Avg**	**EnZh**	**ZhEn**	**Avg**	**EnZh**	**ZhEn**
Proper						
Erlendur	75.7	75.4	76.0	29.2	37.5	19.5
CommandA$_{WMT}$	81.2	77.6	84.8	37.7	41.0	34.5
STITCH	174.4	185.6	163.4	57.2	65.8	48.7
MeGuMa	166.8	151.2	182.2	85.1	69.5	100.5
Random						
Erlendur	76.0	81.2	71.0	35.0	49.4	20.8
CommandA$_{WMT}$	85.2	88.9	81.5	56.1	67.7	44.7
STITCH	90.5	89.6	91.3	74.4	83.3	65.8
MeGuMa	217.4	160.2	279.1	186.5	164.4	208.2
NoTerm						
Erlendur	74.0	74.6	73.5	33.1	44.4	22.1
CommandA$_{WMT}$	84.8	86.2	83.5	56.0	62.2	49.9
STITCH	104.9	110.4	99.5	90.4	103.3	77.8
MeGuMa	133.1	125.1	141.0	116.0	117.3	114.7

Table 4: Weighted MQM scores (lower is better, sorted ascending by GPT-5 Proper Avg), averaged over all, EnZh, and ZhEn documents in Track 2. Detailed counts for different error severities are presented in Appendix D.

Lower scores for the leading systems indicate fewer and less severe errors. However, while the overall patterns are similar, the judges diverge in the final ranking of the lower-performing systems in the Proper mode. Notably, GPT-5 tends to be more conservative, flagging fewer errors overall, whereas GPT-4o is stricter in its error identification.

Examining the error type distribution, Figure 4 (GPT-5) shows that most errors are classified as minor or major, with critical errors being relatively rare. The most frequent error types across all severity levels are accuracy, mistranslation, and terminology. The Proper terminology mode consistently reduces the number of terminology-related errors compared to the No Term mode, confirming the utility of providing domain-specific dictionaries.

This trend, however, is not consistently observed with GPT-4o (see Appendix Figure 6). Manual inspection revealed that GPT-4o occasionally produces false positives for terminology mismatch errors, sometimes flagging even exact matches as errors. As a result, we place greater reliance on the GPT-5 results for these outcomes. For future shared tasks, it may be beneficial to combine automated MQM with targeted manual review, or to further refine judge prompts to better accommodate acceptable variation in terminology use.

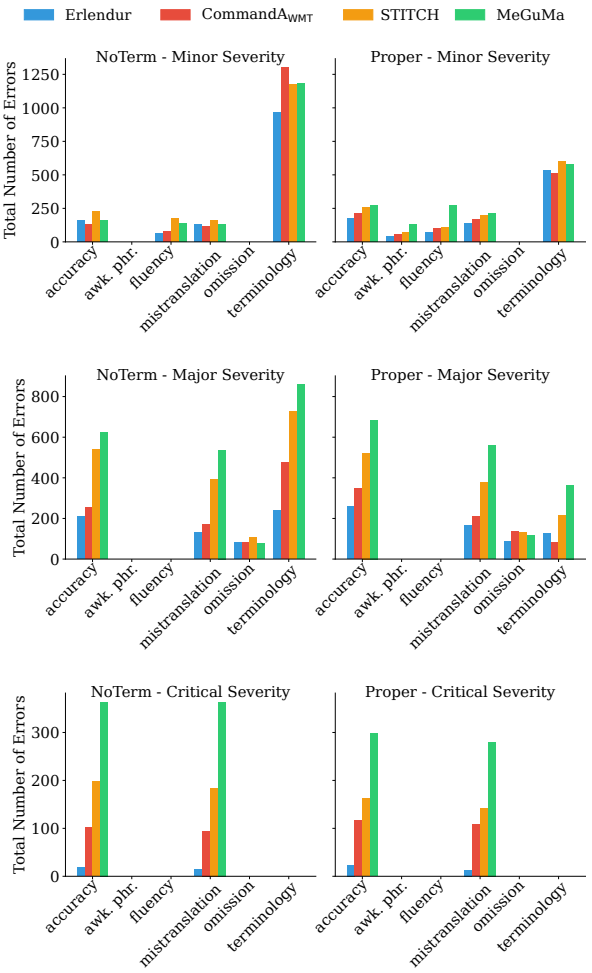

Figure 4: Distribution of error types and severities in No Term and Proper settings using GPT-5 as a judge. Total error counts indicate the number of errors each system made on the complete Task 2 test sets, comprising 10 annual reports across two translation directions. Error types with fewer than 100 occurrences across all severity levels and systems are omitted for clarity. "awk. phr." denotes awkward phrasing.

7.3 Ranking Correlation

One of the reasons for the slow progress in the field of terminology-aware translation is the lack of clarity on the best evaluation protocol(s) due to it being a multifaceted problem. We suggested several types of metrics—general quality, accuracy, and consistency—which differ significantly in the intended focus on the hypothesis and in their implementation. In this section, we analyze how differently or similarly those metrics rank the participating systems alone. This will give insights into the optimal choice of metric(s) in the future.

The comparison of the system ranking by different metrics was conducted using Kendall's τ (Kendall, 1938). We ran the correlation study only

	BLEU	ChrF++	Cons (Freq)	Cons (Dict)
ChrF++	0.81*	–		
Cons (Freq)	0.26	0.39*	–	
Cons (Dict)	0.20	0.36*	0.54*	–
Term Acc	0.22	0.39*	0.49*	0.96*

Figure 5: Kendall's τ correlation between various metrics used in the analysis, Track 1. Comparisons with $p < 0.05$ are marked with *.

for Track 1, since for Track 2, there are only 4 data points, so the τ scores will never surpass the thresholds of statistical significance. We visualize the correlation scores in Figure 5.

We can see two areas of high correlation. The first is well-known, between BLEU and ChrF++. Moreover, terminology accuracy and terminology consistency with dictionary-based pseudo-references display a near-perfect correlation. The reasons for this are clear: both metrics rely heavily on terminology dictionaries; therefore, they are aimed at finding and grouping the proper term occurrences in the system outputs. A surface-level (although lemmatized) match of translated terms is a good approximation of a more tailored system of term alignment between the input and output sequences. Therefore, considering the computational cost of running terminology consistency, future research could rely more on terminology accuracy, as it does not require any external alignment method.

The rest of the metrics show considerably weak positive correlation, in descending order: different types of consistency against term accuracy; and chrF++ against consistency and term accuracy. Although the correlation between the general quality and term-specific metrics is statistically significant, we still conclude that, as shown in Figures 1 and 2, the three types of metrics show different trends. For example, there is a 10 chrF++ gap between the best and second best system in terminology accuracy (Figure 1); top-ranking systems by chrF++ and terminology accuracy do not achieve the best terminology consistency. Therefore, using term-specific metrics is an important aspect of the evaluation of terminology-aware machine translation.

8 Related Work

Past shared tasks. Alam et al. (2021) introduced the first WMT shared task on MT using terminologies, focusing on the medical domain (including COVID-19 terminology) across five language pairs: English to French, Chinese, Russian, and Korean, as well as Czech to German. This pioneering effort established the foundation for systematic evaluation of terminology translation quality and consistency, with terminologies mined semi-automatically from parallel corpora. Building on this, Semenov et al. (2023) organized the second iteration in 2023, which expanded the range of domains (apart from medical texts, it included CL abstracts and web novels), while narrowing down the scope of translation directions: Chinese↔English, English↔Czech, and German↔English. Similar to the previous edition, their terminologies were mined semi-automatically, and they extended this line of work by contrasting random and proper terminologies. Their findings revealed that while incorporating terminology dictionaries led to improvements in translation quality, incorporating equivalent amounts of information from reference translations yielded similar results, challenging the prevailing assumption about terminologies being the crux of meaning in translation. Complementarily, Conia et al. (2025) organized the SemEval-2025 Task 2 on Entity-Aware Machine Translation, which focused on translating text containing complex named entities such as culture-specific titles, location names, and food names across 10 language pairs, introducing the XC-Translate benchmark with over 50K manually-translated sentences with entities that can deviate significantly from word-to-word translations.

Terminology translation test release. To the best of our knowledge, this shared task is among the few that release a high-quality terminology for translation in high-stakes domains such as IT and finance, with the exception of past shared tasks and a contemporary work (Oncevay et al., 2025a).

9 Conclusions

We now conclude the third iteration of the WMT Terminology Translation Task. In comparison to the 2021 and 2023 editions, this time we featured both sentence and document translation tracks with brand new data and domains. The former track ensured continuity, while the latter approximated real-life use cases better. We introduced an LLM-based document-level AutoMQM and used Pareto optimality to rank participants, but we kept the three

inference modes from 2023 for a causal analysis.

We attracted more than 20 submissions, three times more than the previous edition. The overwhelming majority used LLM-based solutions with different types of training techniques. This goes in line with a general trend in the machine translation field towards LLM-based solutions highlighted by Kocmi et al. (2024). Top-scoring systems in the sentence-level track reached good overall translation quality and nearly perfect term accuracy; the document track remains a more challenging task with respect to both metrics. The term consistency, on the contrary, shows a more stable behavior in both tracks, with overall higher scores for document-level MT. In terms of the inference modes, better systems benefit more from proper terminologies, while lower-scoring systems are less sensitive to dictionaries. Finally, we see high correlations between term-based metrics, but not between them and the overall quality, which highlights the necessity to keep at least one terminology-specific metric for this task.

Outlook. The lessons from the shared task also hint at the possible directions for its future iterations:

- Data: continue with document-level terminology translation evaluation
- Metrics: investigate suitable ranking measures and the trade-off between informativeness and computational costs of term-oriented metrics.
- Human evaluation: run human judgment on terminology translations and analyse its correlation with automatic scores. This, to our knowledge, has not been explored before.
- Language: extend the task to more, especially lower-resourced languages, while preventing contamination.

We are open to collaborations, and we especially welcome resources that can be used towards test sets or human evaluation. Stay tuned!

Limitations

The sentence-level test sets have been used in line with their original translation directions; for the document track, we are unsure of the original translation direction, so one of the two directions has the potential problem of translating translated/post-edited text back to its original language.

In terms of evaluation, while we have used several best metrics we can design, there could be some room for considerations and improvements: 1) document-level AutoMQM, especially with terminologies, has not been validated against human judgment; 2) although our terminology match runs lowercasing and lemmatization before string matching, it may not capture all occurrences of an intended word; and 3) certain correlation exists between metrics, e.g. surface string match and terminology match, so they are not fully orthogonal.

Finally, we used a quality-terminology tradeoff to rank participating systems, but as LLMs are more often deployed in practice, cost-effectiveness has become another important aspect.

Acknowledgments

We thank all participants for their submissions.

The document-level finance data used in this shared task is derived from the publicly available annual reports on the Hong Kong Monetary Authority (HKMA)'s website. We acknowledge HKMA as the source and owner of the reports, and we are grateful for the availability of these materials for research purposes.

A Automatic Terminology Extraction

We prompt GPT-4.1 (`gpt-4.1-2025-04-14`) to automatically extract terminology from the source text and align it with the terminology used in the reference translation. Our prompt is shown in Table 5. Extraction and mapping are performed at the document level. The mappings of documents from the same annual report are then merged into a single terminology mapping for the entire report. In the data release, each source document is accompanied by this report-level terminology mapping, simulating realistic scenarios in which terminology mappings are predefined for a specific domain or task. In such cases, the predefined terms may or may not appear in the source document requiring translation.

B Automatic Random Terminology Alignment

The random terms were aligned with the help of GPT-4o. First, we randomly sample the words from the sentence that are not in the set of the proper terms, then we prompt GPT-4o with the text demonstrated in Table 7. To avoid hallucinations, we post-check the target sentence on whether it contains a highlighted word.

C Focus-Segments Prompting (FSP)

Focus-Sentence Prompting (FSP) was originally proposed by Domhan and Zhu (2025) as a method for using LLMs as judges in long-form translation evaluation while mitigating length bias, which is the tendency of LLMs to underreport errors when evaluating an entire long translation in a single pass. Their approach evaluates one sentence at a time while still providing the entire source and target documents as context. Although effective, the original FSP is costly because it requires many inference calls. To reduce this cost, we introduce Focus-Segments Prompting, in which a segment of three sentences is evaluated at once. This modification reduces the computational cost of FSP by approximately a factor of three. In our meta-evaluation on the WMT'24 Metrics Shared Task data, Focus-Segments Prompting performed comparably to the original FSP.

Another modification we introduced is adapting FSP to better suit our terminology-focused task. We consider accurate terminology translation a key quality dimension that the LLM judge should evaluate. However, even an LLM judge may not always know the correct translations of certain terms. To address this, we provide the judge with a ground-truth terminology mapping for reference. Recall that our original mapping was report-level and included many terms that might not appear in the segment under evaluation. To avoid unnecessary distraction for the judge, we tailor the mapping so that it only retains terms present in the source segment. Furthermore, the judge is explicitly instructed to evaluate terminology usage. Note that providing the mapping means our metric is not entirely reference-free and may correlate more with other terminology-focused metrics. To study this effect, we also tested a standard FSP prompt without access to the terminology mapping across all submissions and settings. We found that the system rankings remained unchanged with the standard FSP prompt, suggesting that the inclusion of the terminology mapping primarily improves the interpretability and focus of the evaluation without fundamentally altering its outcomes.

Our terminology-aware FSP prompt is presented in Table 6.

D MQM Error Count

The output of the MQM judges using the FSP prompt is a list of errors. Each error is assigned a severity of minor, major, or critical. Table 8 reports the number and severity of errors produced by each submitted system, averaged across all documents in Track 2.

E Automatic Term Alignment in the Output Texts

The initial edition of the consistency metric (Semenov and Bojar, 2022) suggested that for term translation, specialized word alignment methods would be used. However, our preliminary analysis shows that both popular solutions, FastAlign by Dyer et al. (2013) and AwesomeAlign by Dou and Neubig (2021) show a lack of robustness with respect to morphological variation of the words, as well as casing and punctuation. Therefore, we used GPT-4o to retrieve the aligned terms from the system outputs. Our experiments showed that few-shot prompting was helpful for the quality of the term retrieval; therefore, we used 20-shot prompts. An example of the alignment prompt can be found in Table 9. For Track 2, we first split the documents into smaller paragraphs and retrieved the subsets of the terms for each segment, i.e., applied the same

```
TASK:
You are an expert linguist and terminologist.

Your job is to:
1. Analyze the source document and identify all domain-specific terminology and key terms (e.g. technical terms, product names,
named entities, etc.).
2. Find the corresponding translations in the translated document.
3. Output the result as a Python dictionary in the format:
{
    "source_term_1": "translated_term_1",
    "source_term_2": "translated_term_2",
    ...
}

RULES:
- Both source and translated documents are in Markdown format and may include image paths (e.g. ![image](path/to/image.png)) or
links. Ignore such elements.
- Only extract relevant terminology – avoid common words, function words, and markdown/control elements.
- If a translation is ambiguous or missing, set the value to null.
- Follow Python dict syntax strictly.
- Do NOT include explanations or extra text – only output the Python dictionary.

{{'-'*40}}
SOURCE DOCUMENT:
{{ source_document }}
{{'-'*40}}
TRANSLATED DOCUMENT:
{{ translated_document }}
{{'-'*40}}

OUTPUT:
(Please provide only the Python dictionary below)
```

Table 5: Prompt used for automatic terminology extraction in Track 2.

preprocessing schema as described in Section 4.3. To avoid hallucinations, every output is compared to a system output (by simple substring search).

We noticed that, while being able to correctly identify the part of the sentence containing a term translation, GPT-4o tends to return an overly long string (for example, if the ground truth term correspondence for English-Spanish sentence is "predefined"-"predeterminado", GPT, given a sentence "Es el valor predeterminado." would return the phrase "**valor** predeterminado" (lit. "predefined **value**". To overcome this, we used the following post-processing schema: each GPT output is compared against the reference term translation. If the number of words in the aligned term is more than it is in the reference translation, we run AwesomeAlign (Dou and Neubig, 2021) on the sentence pair and retrieve the word mappings of each word. Then, we check if the words selected by GPT (lemmatized) indeed correspond to the (lemmatized) source sentence tokens. If not, we cut these words out and leave only the part that corresponds to the exact term translation.

F Consistency Scores with Dictionary-Defined Pseudo-References

Figures 7 and 8 show the term consistency scores of the submitted systems with respect to pseudoreference initialization based on terminology dictionaries. We see that, firstly, the difference between the proper terminology mode, on one side, and random terminology and no terminology modes, on the other side, is significantly larger than in case of most frequent pseudoreference initialization. We also observe the increasing deltas between the proper terminology mode and two other modes in the best scoring systems.

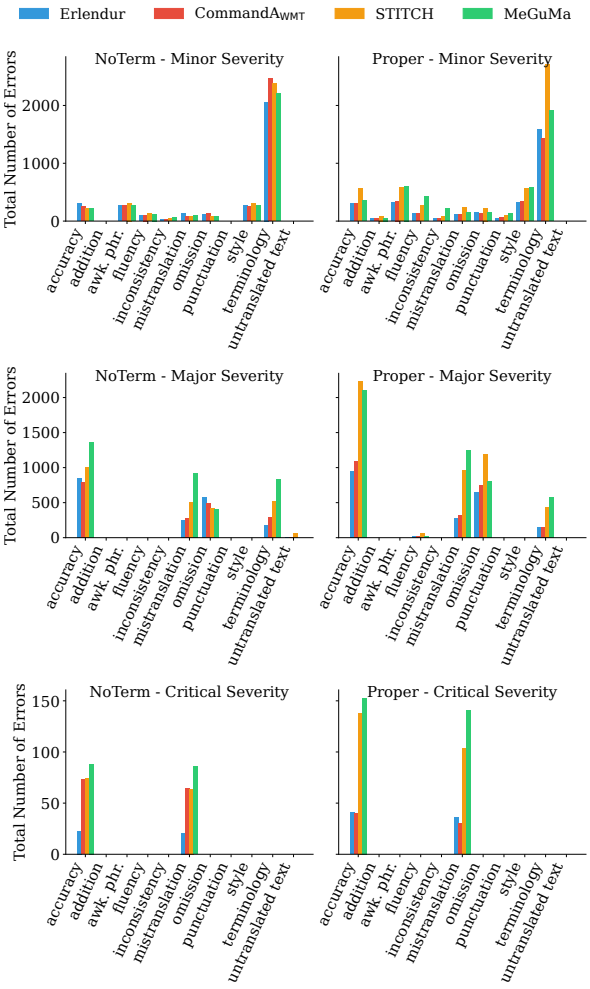

Figure 6: Distribution of error types and severities in No Term and Proper settings using GPT-4o as a judge. Total error counts indicate the number of errors each system made on the complete Task 2 test sets, comprising 10 annual reports across two translation directions. Error types with fewer than 50 occurrences across all severity levels and systems are omitted for clarity. "awk. phr." denotes awkward phrasing.

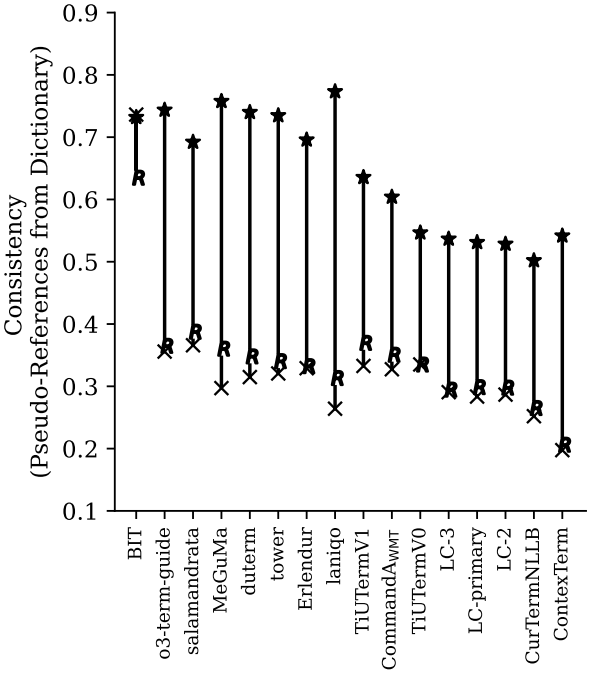

Figure 7: Effect of terminology mode on performance (measured by consistency score with dictionary-defined pseudo-references); Track 1. Legend: × denotes No Term, R denotes Random Term, and ★ denotes Proper Term.

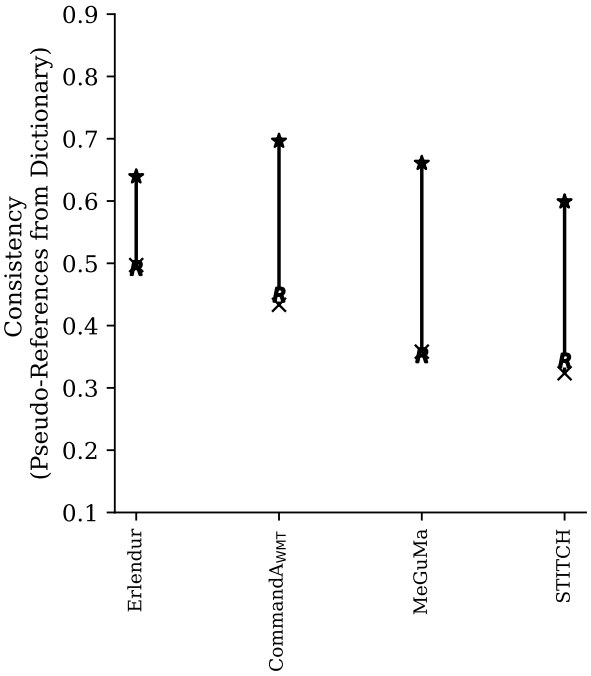

Figure 8: Effect of terminology mode on performance (measured by consistency score with dictionary-defined pseudo-references); Track 2. The legend is identical to that of the Figure 7.

```
You are an annotator for the quality of machine translation. Your task is to identify errors and assess the quality of the
translation using MQM. Based on the source text (in <source></source> tags) and the machine translation (surrounded by
<translation></translation> tags), identify error types in the translation and classify them.

The categories of errors are:
- accuracy (addition, mistranslation, omission, untranslated text, wrong language)
- fluency (character encoding, grammar, inconsistency, punctuation, register, spelling)
- style (awkward phrasing)
- terminology (see subcategories below)
- other

Each error, including omissions or untranslated content, is classified as one of three categories:
- Critical: Errors that make the text incomprehensible or misleading.
- Major: Errors that disrupt flow or distort meaning, but the text is still understandable.
- Minor: Errors that do not affect comprehension but are grammatically, stylistically, or formally incorrect.

The source text must be fully covered, and any omissions should be annotated as errors.
If the error is an omission (missing translation), set "error_span": "" and describe the missing content in "explanation".
Only include spans with errors; exclude correct text.

You will be given a full document and its translations. Only score the sentence in <target_segment></target_segment>, but use the
rest of the document for context. Consistency issues may be flagged per segment, even if similar issues are repeated in other
segments.

Terminology use (if <terminology> is provided; it will be a dictionary and may be empty `{}`):
- Treat <terminology> as a useful reference, not an absolute rule. Prefer its entries when appropriate, but do not penalize
natural, domain-correct alternatives.
- Ignore very minor variations such as capitalization, plural/singular, or the presence/absence of articles (``a,'' ``the'')
unless they clearly change the meaning and/or cause translation errors.
- If an entry in <terminology> seems implausible or clearly incorrect in context, do not enforce it.
- Terminology error subcategories:
  • terminology_mismatch: a correct entry exists in <terminology> for the context, but the translation uses a meaningfully
  different wording that diverges from the provided or established term.
  • terminology_omitted: a source term with a required translation is left untranslated.

            if necessary."
          },
          "error_category": {
            "type": "string",
            "enum": ["accuracy", "fluency", "style", "terminology", "other"],
            "description": "The main category of the error."
          },
          "error_type": {
            "type": "string",
            "description": "The specific type of error (e.g., omission, mistranslation, punctuation, terminology_mismatch,
            terminology_omitted)."
          },
          "severity": {
            "type": "string",
            "enum": ["critical", "major", "minor"],
            "description": "Critical: incomprehensible or misleading. Major: distorts meaning but is understandable. Minor: does
            not affect comprehension but is incorrect."
          }
        },
        "required": ["error_span", "explanation", "error_category", "error_type", "severity"]
      }
    },
    "quality_score": {
      "type": "integer",
      "description": "Overall quality score of the translation for the target segment. Use any integer between 0 and 100.
      Guidance: 0 = No meaning preserved, nearly all information is lost. 33 = Some meaning preserved but significant parts are
      missing or garbled; hard to follow. 66 = Most meaning preserved, with only minor grammar/fluency issues; understandable
      overall. 100 = Perfect meaning and grammar, fluent and natural."
    }
  },
  "required": ["errors", "quality_score"]
}

Please score the following input: <input>
<source_language>{{ src_lang }}</source_language>
<source>{{ src }}</source>
<target_language>{{ tgt_lang }}</target_language>
<translation>{{ output_seq }}</translation>
<target_segment>{{ target_segment }}</target_segment>
<terminology>{{ terminology_dict }}</terminology>
</input>

Output requirements:
- Respond with valid JSON only (no text before or after the JSON).
- Produce strings as plain text without Markdown formatting.
```

Table 6: The FSP prompt used to identify MQM errors in the translation.

```
You are a professional translator from {{ source_language }} to {{ target_language }}. You need to help the user with finding the
corresponding words in the {{ target_language }} sentence translated from {{ source_language }}.

Below you are given the {{ source_language }} sentence and its translation, and a list of words to which you need to find the
corresponding words.

You need to return the words and their translations in the form of the Python dictionary, where keys are {{ source_language }}
words and values are their translations, for example, {{ 4-shot example dictionary }}.
DO NOT PRETTIFY THE DICTIONARY, return the raw dictionary in one string.

Source sentence: {{ source sentence }}
Target sentence: {{ target sentence }}
Words that need correspondence: {{ randomly selected words }}
Dictionary of correspondences:
```

Table 7: Prompt for automatically mapping randomly selected words from the source text to the target text.

```
You are a professional {{ source_language }}-{{ target_language }} translator, teaching the students the course on technical
translation. You are checking a student's translation of a sentence that contains a technical term. You are given an {{
source_language }} term (it can be a word or an expression), a source {{ source_language }} sentence containing this term (it may
be cased differently or contain additional punctuation), and a student's {{ target_language }} translation. You need to find how
the student has translated the term in question in {{ target_language }}, and return only that term.

Important: do not change the translated term anyhow, copy it straight from the sentence! For example, keep the casing and the
grammar form of the translated term as is.

When completing the task, follow the examples below:

        {{ source_language }} sentence: {{ sentence in source language }}
        {{ source_language }} term: {{ source language term }}
        {{ target_language }} translation: {{ reference translation }}
        Translated term: {{ reference term translation }}

                .
                .
                .

        {{ source_language }} sentence: {{ sentence in source language }}
        {{ source_language }} term: {{ source language term }}
        {{ target_language }} translation: {{ reference translation }}
        Translated term:
```

Abstract

We present Miðeind's system contribution to two shared tasks at WMT25 – Tenth Conference on Machine Translation: The General Machine Translation Task and the WMT25 Terminology Translation Task. Erlendur is a multilingual LLM-based translation system that employs a multi-stage pipeline approach, with enhancements especially for translations from English to Icelandic. We address translation quality and grammatical accuracy challenges in current LLMs through a hybrid prompt-based approach that can benefit lower-resource language pairs. In a preparatory step, the LLM analyzes the source text and extracts key terms for lookup in an English-Icelandic dictionary. The findings of the analysis and the retrieved dictionary results are then incorporated into the translation prompt. When provided with a custom glossary, the system identifies relevant terms from the glossary and incorporates them into the translation, to ensure consistency in terminology. For longer inputs, the system maintains translation consistency by providing contextual information from preceding text chunks. Lastly, Icelandic target texts are passed through our custom-developed seq2seq language correction model (Ingólfsdóttir et al., 2023), where grammatical errors are corrected. Using this hybrid method, Erlendur delivers high-quality translations, without fine-tuning. Erlendur ranked 3rd-4th overall in the General Machine Translation Task for English-Icelandic translations, achieving the highest rank amongst all systems submitted by WMT25 participants (Kocmi et al., 2025a). Notably, in the WMT25 Terminology Shared Task, Erlendur placed 3rd in Track 1 and took first place in the more demanding Track 2 (Semenov et al., 2025).

1 Introduction

While large language models (LLMs) exhibit strong cross-lingual understanding and can produce high-quality translations from lower-resource languages into major languages like English, gaps in the models' vocabulary and limitations in their grammatical knowledge (Arnett and Bergen, 2025) often become apparent when translating into lower-resource languages (Robinson et al., 2023). Here we describe Erlendur, a multilingual LLM-based translation system designed to address these challenges by enhancing the quality and grammaticality of Icelandic translations. Our main contribution is a hybrid, multi-stage pipeline that combines preparatory text analysis, dictionary lookup, glossary integration, careful prompting, seamless handling of longer texts, and grammatical error correction.

We deployed Erlendur for our submissions to WMT25. In the General Machine Translation Task (unconstrained track)[1] for English-Icelandic translations, Erlendur achieved the highest performance among participating systems for the language pair, ranking 3rd overall behind a human translation (1st) and Gemini 2.5 Pro (2nd). Erlendur marginally outperformed GPT-4.1, though within the margin of statistical significance (Kocmi et al., 2025a). In the WMT25 Terminology Translation Task[2], where participating systems must correctly incorporate glossary terms into their translations, Erlendur placed third in Track 1, which tests injection of glossary terms into short text chunks, and secured first place in Track 2, which tests the scalability of the terminology approach, with much longer glossaries and corpus-level texts (Semenov et al., 2025).

2 System description

Erlendur (see Figure 1) is a translation service provided through Málstaður[3] (Miðeind, 2025), an integrated platform for language technology solutions aimed at Icelandic. Users can access translation

[1] https://www2.statmt.org/wmt25/translation-task.html
[2] https://www2.statmt.org/wmt25/terminology.html
[3] https://malstadur.is

Proceedings of the Tenth Conference on Machine Translation, pages 577–582
November 8-9, 2025

capabilities through Málstaður's editor interface, or through a speech recognition system where they can speak directly and receive translations of the transcribed text. The translation service is also provided commercially through an API.

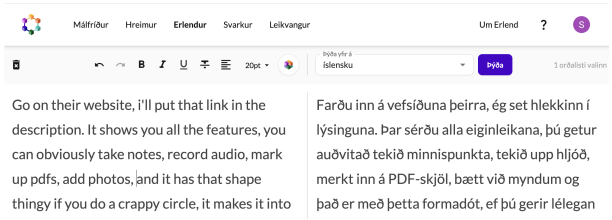

Figure 1: The Erlendur translation interface (in Icelandic) in the Málstaður platform. The user selects the target language; the source language is inferred. "1 orðalisti valinn" indicates that one glossary is selected for use during translation.

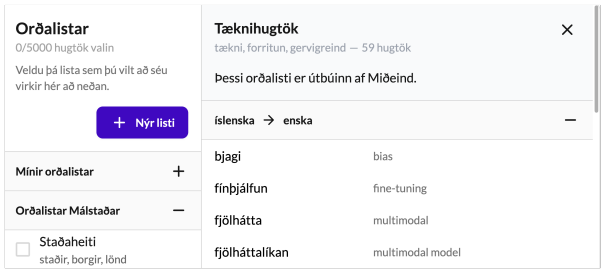

Figure 2: The user interface for the glossary integration in Erlendur (in Icelandic). The user can upload own glossaries or make use of glossaries shared by others in their Málstaður user group.

All the enhancement measures described in this section are intended to improve the translation capabilities beyond a baseline LLM translation. These measures are language-agnostic, unless otherwise stated. The modular nature of the system allows for most of these to be turned on and off. For the WMT25 submissions, all enhancements were used.

2.1 Model selection

While the general language quality of major languages such as English has seen diminishing returns in the latest generation of LLMs, the models still exhibit notable performance gaps when working with many lower-resource languages, and subtle or even significant differences can be noticed between different versions of the same model. We find, for example, that Claude 3.5 Sonnet (Anthropic, 2024) still surpasses other Claude model versions in Icelandic capabilities, even the more recent Claude 4 Sonnet/Opus (Anthropic, 2025). This is supported by Miðeind's Icelandic LLM leaderboard[4] (Miðeind, 2025) results, where Claude 3.5 Sonnet ranks highest of all models in the Claude model family in Icelandic language capabilities.

This motivated our selection of Claude 3.5 Sonnet as the underlying model in Erlendur at the time of system development, and this is the model used for all our WMT25 submissions. The system's API-based architecture makes it straightforward to substitute alternative models as Icelandic language capabilities advance.[5]

2.2 Preparatory analysis and lookup

For translation, the system only needs an input text and a target language; the source language is inferred if none is provided (optional parameters may be supplied). Once the input text is received, it is sent for analysis in a separate pass through the LLM. This is to gain a better understanding of the text, its style, subject domain, and general tone of voice. Key terms and named entities are extracted, and for English-to-Icelandic translations, a list of words is compiled for lookup in Ensk.is, an open-source dictionary[6] (Zoëga and Þórðarson, 2025). The LLM also identifies fixed expressions and idioms that may require special consideration in translation. The results are then prepared for incorporation into the main translation prompt along with the dictionary results provided through the dictionary API. The aim of this preparatory step is to provide the model with richer information on the type of text to translate, and to guide its focus on aspects of the text that require careful translation. This two-pass approach decouples analysis from generation, allowing for more explicit and targeted instructions in the final translation prompt. This step can be further enriched with more versatile tool use, such as dictionaries in other language pairs, or by providing explanations for complex concepts or idioms in the text.

2.3 Glossary integration

An important part of translations in a professional environment is consistent use of terminology. Busi-

[4] https://huggingface.co/spaces/mideind/icelandic-llm-leaderboard

[5] This architecture allowed us, after the WMT25 preliminary results were released (Kocmi et al., 2025b), to easily change the translation model to the high-scoring Gemini 2.5 Pro (https://deepmind.google/models/gemini/pro/), and now, at the time of publication, Gemini 2.5 Pro is the underlying model of Erlendur.

[6] https://ensk.is

nesses often compile glossaries of terms to ensure brand consistency, technical accuracy, and adherence to industry-specific language standards across all translated materials. Erlendur accepts custom glossaries (see Figure 2), where each term can be assigned a subject domain ("finance", "pharmaceutical", etc.) and even a special note on the usage of the term if needed. In the Erlendur editor, the glossary can be provided as a TSV file.

For longer glossaries, it is not feasible to inject them as a whole into the translation prompt, so we need to filter out the terms that appear in the input text. We also need to account for multi-word terms, and properly match those in the input text. Highly-inflected languages present unique challenges for term matching due to morphological variations. We developed a hybrid approach combining fuzzy matching and n-gram analysis, informed by the morphological characteristics of such languages.

The system generates n-grams of lengths 1 through `max_ngram_size` (determined by the longest glossary term) from the input text, then compares each n-gram against glossary terms of the same word count using a string-matching library (RapidFuzz[7]). The algorithm prioritizes longer n-grams first when selecting matches to favor multi-word term matches over shorter partial matches, and uses position tracking to avoid overlapping selections. Fuzzy matching is based on Levenshtein distance between text sequences, with a minimum similarity threshold of 0.75, established through iterative refinement during system development. The goal is to achieve high recall without generating an overly long list of candidate terms. We limit the list to a maximum of 50 terms per text chunk to translate, though this is adjustable, based on the chunk size (see Section 2.4). Once a list of term candidates has been compiled, the terms and their translations are incorporated into the translation prompt as an important resource for the LLM to follow when translating. This curated list of terms likely contains some false positives, but those can simply be ignored by the LLM. This methodology of fuzzy string matching of n-grams allows even inflected terms to be correctly matched, such as when the nominative term "sérstök áætlun" ("specific programme") matches the same term when it appears in the genitive case; "sérstakrar áætlunar". This ensures consistent term use throughout, even for longer documents.

[7] https://github.com/rapidfuzz/RapidFuzz

The glossary functionality is language-agnostic, and since the term matching module was developed to accommodate an inflectional language, it is flexible and should benefit many other morphologically rich languages. While in-house experiments indicate this, formal evaluations remain future work. Of note is that Erlendur placed first in the Terminology Translation Task, Track 2 (see Section 3.2), which tests terminology between Traditional Chinese and English, with Chinese being structurally and morphologically very different from Icelandic. In addition to providing terminological consistency, another benefit of injecting custom glossary terms when translating into lower-resource languages is that they can help fill the vocabulary gaps observed in LLMs for these languages.

2.4 Context-handling and translation

The translation prompt is an information-dense text with clear instructions on how to translate, along with the compiled analysis results, optional dictionary results and relevant glossary terms. An additional information string can be added, with special instructions or information about the text. For longer texts, whose translation might surpass the output token limit of the LLM in question, the system splits the text into fragments or chunks, and translates each chunk separately, while providing a snippet of the previous source text chunk as context to ensure text cohesion.

2.5 Post-processing

LLM-generated texts in Icelandic still contain ungrammatical sentences and made-up words. To remedy this, after translation, we run Icelandic target texts through our in-house grammatical error correction tool, Málfríður (Ingólfsdóttir et al., 2023). This helps catch ungrammatical sentences and correct them, mostly incorrect inflections or unconventional preposition use.

3 WMT submissions

We used Erlendur for both the general and the terminology shared tasks, with the same enhancements. The following sections describe the details of each submission.

3.1 General Machine Translation Task

In our submission, our aim was to use the features already present in Erlendur, without special handling for specific texts in the test set, to demonstrate

the robustness of the system and mimic realistic user behavior. The API offers the option of adding special instructions or information for the task at hand, as mentioned in Section 2.4. This option was used to relay some metadata from the test set, namely the domain, the `doc_id`, and a shortened version of the prompt string provided for each of the four focus domains (*news*, *speech*, *social*, *literary*).

One task-specific instruction was added: A considerable part of the test set data is in the first person (the *speech* domain in particular), and the speaker's gender is not always evident from the text. This calls for some decision-making when translating into Icelandic, to ensure gender agreement in the translation. Icelandic has inherent grammatical gender (masculine, feminine, or neuter), and adjectives change according to gender, so "I'm worried" translates into "Ég er áhyggjufull" (feminine) or "Ég er áhyggjufullur" (masculine), depending on the subject's gender. Instead of inferring the gender from the limited context of the source text, for the *speech* domain, we opted to ask the model to output the standard abbreviated gender notation, "Ég er áhyggjufull(ur)."

Another model-specific limitation is that Claude 3.5 Sonnet cannot produce Icelandic closing quotation marks (“); to remedy this we ask the model to instead output French quotation marks (guillemets, « ») and then we convert them to Icelandic ones („“) in post-processing.

For the translation, we used our standard glossary of place names and organizations in English, and their official Icelandic translations, compiled in-house. This glossary is available for use by Erlendur users.

3.2 Terminology Translation Task

The WMT25 Terminology Translation Task tests the inclusion of a given dictionary of terms when translating, to ensure correct and consistent terminology in specialized domains. This task has two tracks: Track 1 involves translating short text chunks from English into Russian/Spanish/German, and correctly incorporating term translations from a short list of terms that appear in the text. Track 2 better mimics real-life conditions, where the texts are corpus-level and the glossaries are considerably larger. The language pairs are English→Traditional Chinese and Traditional Chinese→English. In both tracks, there are three modes: no terminology, random terminology (the glossary terms are words randomly drawn from input texts) and proper terminology (domain-specific terminology).

In this task, we participated in both Track 1 and Track 2, making use of the native glossary functionality of Erlendur described in Section 2.3. The system's existing capabilities, particularly its efficient term matching and enforcement of terminological consistency, were sufficient to meet the task requirements without further modification. We, however, encountered an unexpected challenge in Track 2. The underlying model, Claude 3.5 Sonnet, refused to consistently generate Chinese translations of the test data, returning a "Content blocked" message. No prompt adjustments we tried could properly bypass this content filter, so we utilized our system's modular architecture to replace the underlying model with GPT 4.1 (OpenAI, 2025), which successfully processed the translations and has solid multilingual capabilities. As the source text itself was innocuous, we concluded that the filter was likely triggered by a policy related to the generation of the target language itself.

This is an example of unforeseen issues that may arise when using external, closed-source models over which the user has no control. It also underscores the value of a flexible system design that permits rapid adaptation, such as swapping the core LLM, to ensure robustness against external constraints.

3.3 WMT results

As briefly mentioned in the introduction, Erlendur ranked 3rd in the WMT25 General Machine Translation Task (Kocmi et al., 2025a) in English-Icelandic translations, with a human translator taking top place and Gemini 2.5 Pro taking second. GPT-4.1 was a close 4th, within the margin of statistical significance. Erlendur thus scored the highest out of all WMT25 participants for this language pair, even with a model that is relatively old and close to being deprecated (Claude Sonnet 3.5). Gemini 2.5 Pro, included for comparison, was the high-scoring model across most languages in the general MT task, also for Icelandic; this has been our cue to replace it as the underlying model in the current version of Erlendur. While Claude 3.5 Sonnet without enhancements was not evaluated in the task, Claude 4 ranked 8-10 for the language pair.

In the Terminology task, Erlendur was the only

system scoring in the top 5 in both Track 1 and Track 2, taking third place in Track 1 and first place in Track 2. This is a clear indicator that our terminology approach, developed with a focus on Icelandic and English, has a solid foundation that works for a range of languages, as different from Icelandic as Russian and Chinese. It also demonstrates its robustness with both longer input texts and its practical value in industry scenarios, where extensive glossaries are commonly used.

4 Conclusion

We have presented Erlendur, a multilingual LLM-based translation system that addresses the challenges of translating into lower-resource languages through a hybrid multi-stage approach. By combining preparatory text analysis, dictionary lookup, glossary integration, and grammatical error correction, the system demonstrates how targeted enhancements can significantly improve translation quality for languages like Icelandic without requiring model fine-tuning. The language-agnostic design of most system components makes this approach applicable to other lower-resource language pairs, while the modular architecture allows for flexible adaptation to different translation scenarios and future model improvements.

Limitations

The translation process of Erlendur is a hybrid pipeline that involves two passes through an LLM, some processing of terms, API lookup and a grammatical correction pass through a separate model, which means that the translation time is longer than in smaller models and simpler solutions. For a faster translation turnaround, each of the preprocessing steps can be included or skipped in the API. The bulk of the overall time, however, is spent on text generation by the model when producing the translation, while the preprocessing steps and dictionary lookups add minimal overhead. Concurrent handling makes time measurements of each step challenging, so while this information would be useful, it has not been reported in this work.

While we hypothesize that our approach, carefully developing a system to translate to and from a morphologically rich language, will benefit other languages of varying morphological complexity, this has not been confirmed with formal experiments.

A Preliminary Study of AI Agent Model in Machine Translation

Ahrii Kim
AI-Bio Convergence Research Institute
South Korea
ahriikim@gmail.com

trotacodigos/MultiAgentMT.git

Abstract

We present IR_Multi-agentMT, our submission to the WMT25 General Shared Task. The system adopts an AI-agent paradigm implemented through a multi-agent workflow, Prompt Chaining, in combination with RUBRIC-MQM, an automatic MQM-based error annotation metric. Our primary configuration follows the Translate–Postedit–Proofread paradigm, where each stage progressively enhances translation quality. We conduct a preliminary study to investigate (i) the impact of initial translation quality and (ii) the effect of enforcing explicit responses from the Postedit Agent. Our findings highlight the importance of both factors in shaping the overall performance of multi-agent translation systems.

1 Introduction

An AI agent is a computational system that operates autonomously, guided by environmental observations, and often equipped with adaptive learning capabilities (Russell and Norvig, 2010). Large Language Models (LLMs), which have become central to the development of AI agents, demonstrate advanced reasoning, contextual understanding, and flexible workflows across a wide range of tasks, including Machine Translation (MT) (Briva-Iglesias, 2025). Recent work by Briva-Iglesias (2025) explored a multi-agent system composed of four agents—a Translator, Fluency Reviewer, Adequacy Reviewer, and Editor—highlighting its potential for driving future advancements. Inspired by this line of research, we participate in this year's MT track with a multi-agent workflow. Our goal is to leverage smaller models to achieve performance competitive with, or even superior to, larger models, while simultaneously reducing computational costs.

2 Participating Task

The shared task aims to evaluate translation performance across a broad range of languages, domains, genres, and modalities. We participate in the multilingual subtask, which covers 30 target languages, with Czech, English, and Japanese serving as the source languages. Our system is categorized as unconstrained. The source data consists of 29,957 segments, corresponding to 102,060 paragraphs. Our approach performs translation inference on a segment-by-segment basis. In cases where paragraph boundaries are ignored in the original segmentation, we re-split the data into paragraphs and translate them independently.

3 IR_Multi-agentMT

3.1 Design

AI agents enable dynamic workflows through configurable architectures. We adopt the concept of Prompt Chaining, in which the output of each step serves as the input to the next, fostering systematic reasoning and iterative refinement (Briva-Iglesias, 2025). While iterative refinement may theoretically improve translation quality, cost constraints motivate us to employ a unidirectional configuration. Accordingly, we experiment with two workflow variants: Translate–Postedit (TP Workflow) and Translate–Postedit–Proofread (TPP Workflow), both of which are submitted to the competition.

3.2 Translate Agent

The Translate Agent generates target text from the given source using the official prompt provided by the organizers. We use the GPT-4o-mini model to obtain the initial translation.

3.3 Postedit Agent

The Post-edit Agent refines the translation with reference to the source text. We build upon RUBRIC-MQM (Kim, 2025), which, like its counterpart

Proceedings of the Tenth Conference on Machine Translation, pages 583–586
November 8-9, 2025

GEMBA-MQM (Kocmi and Federmann, 2023), identifies MQM-style error categories, severities, and spans. Unlike Gemba-MQM, however, Rubric-MQM reduces biases associated with the MAJOR and MISTRANSLATION labels, improves recognition of NO-ERROR cases, and increases precision in error detection.

We introduce three modifications to the original Rubric-MQM:

Transformation into a post-editor The model is instructed to propose corrected translations for each identified error span.

Severity scale adjustment The original 100-point scale is simplified to a 4-level scale, since severity is not our primary focus. While Kim (2025) stressed that the rubric scheme is essential for model effectiveness, we reduce the rubric complexity in the prompt to streamline usage.

Multilingual configuration While preserving the original in-context examples, we replace one instance from English–German with Japanese–Korean to support broader X–Y translation directions. This modification improves detection of NO-ERROR cases and prevents erroneous corrections of already error-free phrases.

Finally, the model's suggested spans are manually integrated into the sentence, and the revised output is considered the final version.

3.4 Proofread Agent

The Proofread Agent further examines and refines the translation using a Chain-of-Thought prompting strategy (Wei et al., 2022). First, the model identifies potential errors; then it is asked to propose five alternative phrasings that prioritize fluency while maintaining alignment with the source. The best alternative is selected as the final translation. This procedure is designed to resolve awkward expressions introduced during earlier manual edits and to further polish the final output.

4 Model Details

We employ prompt engineering for all agents, using `GPT-4o-mini-2024-07-18` as the primary baseline. The model is configured with a temperature of 1 and a maximum token length of 1024. Although this setup is suboptimal in terms of reproducibility, our iterative pilot studies suggest that these parameters allow the model to explore a wider error space and generate more effective modifications, thereby improving overall translation quality. Future work will focus on developing a more stable and reproducible experimental environment.

5 Experiment

We evaluate our multi-agent pipeline through experiments on the WMT24 English–Spanish dataset (Kocmi et al., 2024). We take a subset of 304 unique source segments with balanced domain distribution (literary, news, social media, and speech) and use 23 translations, summing up to 6,992 segments for analysis.

Our experiments are structured in two parts. First, we obtain initial translations from DeepL (DeepL) and MarianMT (Junczys-Dowmunt et al., 2018), cost-efficient models, and GPT-4o-mini, our baseline model, and compare the final translation quality produced by the multi-agent workflows. We use ChrF++ (Popović, 2017) and COMET (Rei et al., 2020). Second, we analyze translations generated with both the original and the refined versions of Rubric-MQM, with particular attention to cases where (i) no-error labels are produced and (ii) source phrases are erroneously marked as errors.

5.1 Analysis: Initial Translation Quality

Table 1 shows that both the initial and final translation quality are highest when using GPT-4o-mini across the two metrics. Regardless of the initial quality, the general trend in our multi-agent workflow is that translation quality decreases after the Postedit stage and increases again after Proofread, with few exceptions. For instance, the surface-level quality measured by ChrF++ drops from 78.55 to 68.18 with GPT-4o-mini, while COMET scores remain stable, indicating that the revisions primarily involve semantic edits within a similar structural framework. These findings suggest that increasing the extent of semantic-level edits can result in higher overall translation quality.

5.2 Analysis: Response of Postedit Agent

We analyze the erroneous responses produced under the original Rubric-MQM setting. As shown in Table 2, 55.38% of the model outputs are empty, indicating that the system deemed the translation perfect. In 2.8% of the cases, spans were incorrectly labeled as "no-error." Furthermore, in 36.7% of the cases, the model identified source errors, which can disrupt the agent workflow. The revised

Language	Metric	Translate	Postedit	Proofread	Final Δ
DeepL	ChrF++	45.99	38.04	40.62 ↑	-5.37
	COMET	65.72	59.96	59.71	-6.01
MarianMT	ChrF++	60.01	55.92	60.53 ↑	+0.52
	COMET	89.66	87.25	88.40 ↑	-1.26
GPT-4o-mini	ChrF++	78.55	78.93 ↑	68.18	-10.37
	COMET	94.38	91.69	96.05 ↑	+1.67

Table 1: Performance scores of the IR_Multi-agentMT system with different baselines for the initial translation (*Translate*). ↑ indicates gains over the previous stage. The gains from *Translate* to *Proofread* are reported in the *Final* column.

	NaN	No-error	Source error
#	3872	200	2567
%	55.38	2.86	36.71

Table 2: Distribution of erroneous response of Postedit Agent. Raw counts (#) and the percentage (%) are given.

version, however, mitigates these issues through improved prompt engineering.

6 Conclusion

Our experiments on the multi-agent pipeline indicate that higher initial translation quality leads to better final outcomes. Furthermore, enforcing the Postedit Agent to identify more errors is essential for ensuring meaningful revisions within the workflow. In this way, IR_Multi-agentMT demonstrates the potential to achieve translation quality comparable to that of larger models, while operating at roughly half the cost. A more detailed discussion of these findings will be provided in the main system paper.

Abstract

This paper presents the **Marco-MT-Algharb** system, our submission to the WMT2025 General Machine Translation Shared Task from **Alibaba International Digital Commerce** (AIDC). Built on a large language model (LLM) foundation, the system's strong performance stems from novel quality-aware training and decoding techniques: (1) a two-step supervised fine-tuning (SFT) process incorporating data distillation, (2) a two-step reinforcement learning (RL) framework for preference alignment, and (3) a hybrid decoding strategy that integrates word alignment with Minimum Bayes Risk (MBR) re-ranking to improve faithfulness. These approaches jointly ensure high accuracy and robustness across diverse languages and domains. **In the official human evaluation, our system secured six first-place finishes, four second, and two third-place results** in the constrained category across the 13 directions we participated in. Notably, for the **English-Chinese**, our results surpassed all open/closed-source systems.

1 Introduction

The Conference on Machine Translation (WMT) continues to be the primary arena for benchmarking the advancements in machine translation technology (Kocmi et al., 2024; Freitag et al., 2023). For years, the field was dominated by the Transformer architecture (Vaswani et al., 2017), which set a high standard for translation quality through its powerful attention mechanism. However, the recent advent of Large Language Models (LLMs) has sparked a paradigm shift. These models, pre-trained on vast amounts of text data, have demonstrated remarkable capabilities in understanding context, generating fluent text, and leveraging world knowledge, making them exceptionally promising candidates for complex multilingual translation tasks (Achiam et al., 2023; Ouyang et al., 2022; Ming et al., 2024; Alves et al., 2024). However, adapting these powerful, general-purpose LLMs for high-fidelity, specialized translation presents a significant challenge (Jiao et al., 2023; Hendy et al., 2023). To bridge this gap, we propose quality-aware training and decoding techniques designed to systematically enhance both the fluency and faithfulness of LLM-based translation. To this end, we present the Marco-MT-Algharb system.

Marco-MT-Algharb is our submission to the WMT 2025 General Machine Translation Shared Task. Our participation covers 13 diverse language pairs.[1] Built upon the Qwen3-14B foundation

[1]The 13 language pairs are: English to Chinese (en→zh), English to Japanese (en→ja), English to Korean (en→ko), English to Egyptian Arabic (en→arz), English to Bhojpuri (en→bho), English to Czech (en→cs), English to Estonian (en→et), English to Russian (en→ru), English to Ukrainian (en→uk), English to Serbian (Latin script) (en→sr_Latn), Czech to German (cs→de), Czech to Ukrainian (cs→uk), and Japanese to Chinese (ja→zh).

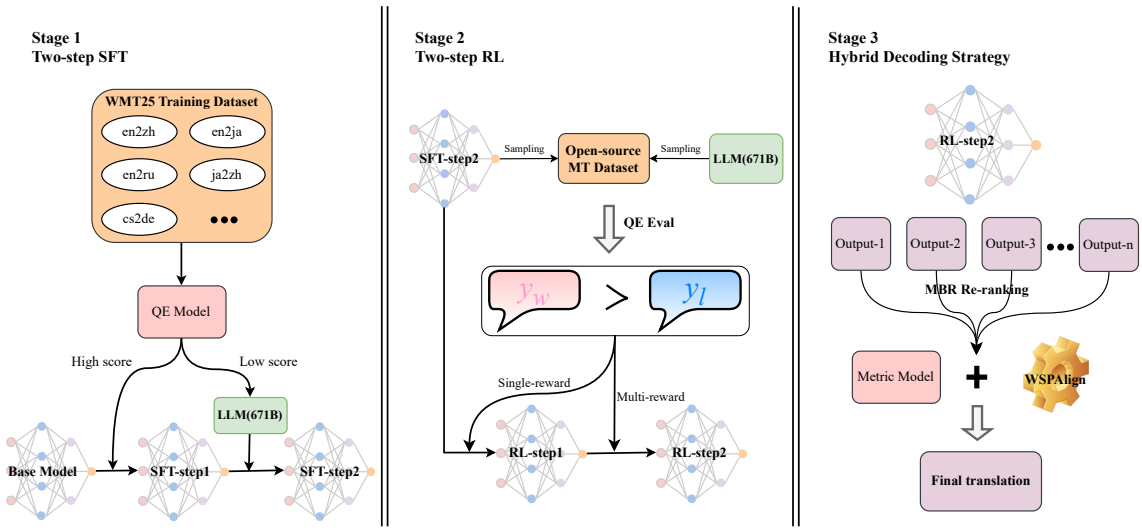

Figure 1: Overall pipeline of the Marco-MT-Algharb system. **SFT Stage:** Fine-tuning on QE-filtered and teacher-distilled data. **RL Stage:** Preference alignment via CPO and dynamic multi-reward optimization. **Decoding Stage:** Hybrid MBR re-ranking with a WSPAlign faithfulness score.

model (Yang et al., 2025), we propose quality-aware training and decoding techniques to enhance translation quality through three key phases: (1) a two-step Supervised Fine-Tuning (SFT) process with data distillation to expand data coverage; (2) a two-step Reinforcement Learning (RL) framework to align the model with quality estimation metrics; and (3) a hybrid decoding strategy that combines quality scores with word alignment to improve faithfulness.

Our work makes several key contributions to the development of state-of-the-art, LLM-based translation systems:

- **A progressive, two-step supervised fine-tuning (SFT) strategy.** We begin by training on high-quality, rigorously cleaned parallel data. Subsequently, we employ data distillation, using a powerful teacher model to regenerate translations for the data filtered out during the cleaning process. This allows our model to learn from a broader data distribution without being compromised by noise.
- **A two-step reinforcement learning (RL) framework for preference alignment.** We first utilize Contrastive Preference Optimization (CPO) (Xu et al., 2024) for initial alignment. We then introduce a novel dynamic multi-reward preference optimization method, which leverages a combination of quality metrics to achieve a more holistic improvement in translation adequacy and fluency.
- **A novel hybrid decoding strategy to mitigate omission errors.** We observed that models optimized heavily on neural quality estimation (QE) metrics like COMET (Rei et al., 2020) can sometimes produce fluent but incomplete translations. To address this, we developed a hybrid decoding algorithm that integrates a word-alignment-based penalty into the Minimum Bayes Risk (MBR) re-ranking framework, ensuring both semantic fidelity and lexical completeness.

In the official human evaluation (Kocmi et al., 2025), our system achieved top-3 rankings in 10 out of 13 participated directions within the constrained category, including five first-place finishes (see Table 1). Notably, our English-Chinese system surpassed all other submissions, including proprietary systems.

The remainder of this paper is structured as follows: Section 2 provides a detailed overview of our system's architecture and training methodology. Section 3 presents our experimental setup and results. Finally, Section 4 concludes the paper.

2 System Overview

Our translation system, Marco-MT-Algharb, is an end-to-end pipeline built upon a powerful foundation model. The overall workflow consists of four key stages: (1) selection of a base model architecture; (2) a two-step SFT process to impart translation capabilities; (3) a two-step RL process to align outputs with automated translation quality metrics; and (4) a hybrid decoding strategy for

robust and accurate inference. A schematic of our system is shown in Figure 1.

2.1 Model Architecture

We selected Qwen3-14B-base[2] as the foundation for our system. Qwen3 is a series of advanced, multilingual large language models known for their strong performance across a wide range of natural language understanding and generation tasks. The 14-billion parameter variant provides a powerful balance between model capacity and computational feasibility for fine-tuning. Its extensive pre-training on a diverse corpus of multilingual data makes it an excellent starting point for developing a high-quality, multilingual translation system, as it already possesses a rich cross-lingual representation space. For our tasks, we utilized the base model and tailored it specifically for translation through the subsequent training stages.

2.2 Two-step Supervised Fine-tuning

The goal of our SFT process is to effectively adapt the general capabilities of Qwen3-14B to the specific domain of machine translation. We designed a two-step approach to maximize data utilization and model performance.

Step 1: SFT on High-Quality Parallel Data. In the first step, we focused on building a robust translation baseline using high-quality data. We collected all parallel data provided by the WMT 2025 organizers for the 13 language directions we participated in. This raw data underwent an intensive cleaning pipeline, which included:

- Normalization: Standardizing punctuation, spacing, and casing.
- Filtering: Removing sentence pairs based on length ratio mismatches and identifying sentence pairs with a high proportion of non-alphabetic characters.
- Language Identification: Ensuring that the source and target sentences correctly match their designated language labels.
- Quality Estimation Filtering: Employing a pre-trained QE model (CometKiwi-XXL[3]) to score sentence pairs and discarding those with predicted low translation quality.

After cleaning, the resulting high-quality dataset was used to perform a single, comprehensive multilingual SFT run. For 12 of our high-resource language directions, we compiled a substantial dataset of 10 million parallel sentences each. Due to data scarcity for the English-to-Bhojpuri (en→bho) direction, its data volume was significantly smaller. In total, this initial SFT step utilized a massive training corpus of approximately 120 million sentence pairs, training the model on all 13 language pairs simultaneously. This large-scale multilingual training encourages the model to develop robust shared representations and effectively leverage cross-lingual transfer learning.

Step 2: SFT with Distilled Noisy Data. A significant amount of data is typically discarded during aggressive cleaning. While noisy, this data often contains valuable lexical and syntactic diversity. To leverage this, we designed a second SFT step based on data distillation. We took the parallel data that was filtered out in Step 1 and used a powerful teacher model, DeepSeek-V3[4] (Liu et al., 2024), to regenerate the target-side translations. For each of the 13 language directions, we distilled approximately 800,000 sentence pairs. This process effectively "cleans" the noisy target text while preserving the original source text's diversity. The resulting distilled dataset was then used for a second round of SFT. This allowed our model to learn from a much broader set of source inputs, guided by the high-quality outputs of the teacher model, thereby enhancing its robustness and domain coverage.

2.3 Preference Alignment via Two-step Reinforcement Learning

Following SFT, we employed a two-step RL to further refine the model's output. The goal of this stage is to directly align the model's generations with scores from automated translation quality estimation metrics, which serve as a proxy for human judgment. This approach moves beyond the token-level supervision of SFT to optimize the holistic quality of the entire translated sentence based on established evaluation standards.

Step 1: Contrastive Preference Optimization with Diverse Candidate Translations. We began with CPO to align our model with high-quality translation preferences. The foundation for our RL training is a curated dataset of source sentences, created by randomly sampling 15,000 entries for each source language from high-quality, open-source

[2]https://huggingface.co/Qwen/Qwen3-14B-Base

[3]https://huggingface.co/Unbabel/wmt23-cometkiwi-da-xxl

[4]https://huggingface.co/deepseek-ai/DeepSeek-V3

corpora, including Flores-200 (nll, 2024) and historical WMT test sets (WMT08-23). We reuse this same dataset for both of our RL steps, not only for methodological consistency, but more importantly, due to the limited availability of high-quality data that closely mirrors the test domain.

To construct preference pairs for these source sentences, we adopted a teacher-augmented strategy. For each source sentence, we generated a pool of candidate translations populated from two distinct sources: (1) multiple sampled outputs from our own SFT-trained model, and (2) a high-quality translation from a powerful, external teacher model, DeepSeek-V3.

We then used a reference-free QE model CometKiwi-XXL to score every candidate in this combined pool. The preference pair was formed as follows:

- The **"chosen"** translation was the candidate with the highest evaluation score. In many cases, this was the output from the DeepSeek-V3 model, providing a strong, high-quality target.
- The **"rejected"** translation was a candidate from the same pool with a significantly lower evaluation score, often one of the less successful samples from our own model.

This teacher-augmented approach is highly effective as it provides a robust learning signal, allowing our model to learn from responses that are often superior to its own initial capabilities. This CPO step provided a stable initial alignment towards the quality standards set by a strong translation model.

Step 2: Dynamic Multi-Reward Optimization with Self-Distillation. To achieve more nuanced control and move beyond reliance on a single, static metric, we introduce a novel training framework in our second RL step. This framework combines a dynamic, hybrid reward signal with a knowledge distillation objective, encouraging the model to internalize the principles of translation quality.

First, our reward function is not static but a dynamic composite of two sources: an external QE metric (CometKiwi-XXL) and the model's own internal reward signal. The total reward R_{total} for a generated translation y from source x at training step t is defined as:

$$R_{\text{total}}(x, y, t) = (1 - w_{\text{self}}(t)) \cdot R_{\text{QE}}(x, y) + w_{\text{self}}(t) \cdot R_{\text{self}}(x, y) \quad (1)$$

where R_{QE} is the score from the QE model, and $R_{\text{self}}(x, y)$ is the model's own sequence log-probability ($\log P_\theta(y|x)$), serving as a measure of its confidence. The weight of the self-reward, $w_{\text{self}}(t)$, is annealed to increase gradually with the training step t. This curriculum strategy allows the model to initially anchor its learning on the reliable external metric and progressively trust its own refined judgment as it improves.

Second, to accelerate the refinement of the model's internal judgment, we introduce a Kullback-Leibler (KL) divergence loss term. This term explicitly distills the relational quality knowledge from the QE model into the model's probability space. For a pair of translations (y_w, y_l) where QE scores y_w higher than y_l, we define a target preference distribution based on their score difference. The KL loss then minimizes the divergence between the model's predicted preference probability and this QE-derived target distribution:

$$\mathcal{L}_{\text{KL}} = D_{\text{KL}}\left(\sigma(\tau \cdot \Delta\text{QE}) \parallel \sigma(\Delta \log P_\theta)\right) \quad (2)$$

where ΔQE is the difference in QE scores for the pair (y_w, y_l), $\Delta \log P_\theta$ is the difference in the model's log-probabilities for the same pair, σ is the sigmoid function, and τ is a temperature parameter controlling the sharpness of the target distribution.

The final objective combines the preference optimization loss with $\mathcal{L}_{\text{KL}}$. This synergistic approach allows the model to not only generate better translations based on the hybrid reward but also to simultaneously internalize the very principles of translation quality evaluation. This makes the self-reward signal more reliable over time and leads to significant, stable performance gains.

2.4 Hybrid Decoding Strategy

A notable pitfall of optimizing Large Language Models towards neural metrics is their tendency to produce translations that are highly fluent yet lexically or semantically incomplete (Freitag et al., 2022; Moghe et al., 2022). To combat this, we developed a hybrid decoding strategy that fuses the MBR re-ranking algorithm with a reward for lexical faithfulness.

Our approach is built upon Minimum Bayes Risk (MBR) decoding (Freitag et al., 2021). In standard MBR, we first generate a set of N candidate translations $\{y_1, y_2, \ldots, y_N\}$ for a given source text x. The optimal translation y^* is the one that has the highest expected utility score against all other can-

didates:

$$y^* = \underset{y_i}{\text{argmax}} \sum_{j=1}^{N} U(y_i, y_j) \tag{3}$$

where the utility function $U(y_i, y_j)$ is realized using the COMET-22 metric model[5].

Our innovation is to incorporate an alignment-based score into this framework to explicitly reward source faithfulness. The final score for each candidate is a hybrid of its peer-based MBR utility and its source-based alignment score. We define the standard MBR score for a candidate y_i as:

$$S_{\text{MBR}}(y_i) = \sum_{j=1}^{N} U(y_i, y_j) \tag{4}$$

The alignment score, $S_{\text{align}}(x, y_i)$, is computed using our tool, `WSPAlign` (Wu et al., 2023), which measures the lexical faithfulness between the source x and the candidate y_i. A higher score indicates better faithfulness. The final hybrid score is then calculated as:

$$S_{\text{hybrid}}(y_i) = S_{\text{MBR}}(y_i) + \lambda \cdot S_{\text{align}}(x, y_i) \tag{5}$$

where λ is a hyperparameter that balances the MBR and alignment terms. During inference, we generate N candidates, compute S_{hybrid} for each, and select the one with the highest score as the final translation. This approach significantly reduces the frequency of omission errors in our final submissions.

3 Experiments

3.1 Experimental Setup

Implementation Details. For the Supervised Fine-Tuning (SFT) stage, we perform full-parameter fine-tuning. In contrast, for the Reinforcement Learning (RL) stage, we employ a parameter-efficient LoRA strategy (Hu et al., 2022), configuring the adapters with a rank of 64 and an alpha of 128. For the optimization process, we use the Adam optimizer (Kingma and Ba, 2014) with $\beta_1 = 0.9$ and $\beta_2 = 0.99$. We adopt a carefully designed learning rate schedule that decreases with each stage of our pipeline: the learning rate was set to 2×10^{-5} for the first SFT step, 1×10^{-5} for the second SFT step, 2×10^{-6} for the first RL step (CPO), and 1×10^{-6} for the final RL step. A global batch size of 64 was maintained throughout all training phases. For our dynamic multi-reward

[5]We use the `Unbabel/wmt22-comet-da` implementation from Hugging Face.

optimization step, key hyperparameters include a KL distillation temperature τ of 0.3, and a self-reward weight w_{self} that is linearly annealed from an initial value of 0.05 to 0.8. In the subsequent Hybrid Decoding stage, the balancing weight λ is set to 0.5.

Evaluation Setup. We evaluate our final model on the official test sets for the WMT25 General Machine Translation Shared Task. Our participation covers 13 language pairs: en→{zh, arz, bho, cs, et, ja, ko, ru, uk, sr_Latn}, cs→{uk, de}, and ja→zh. Our decoding procedure implements the proposed hybrid re-ranking strategy. For each source sentence, we generate 100 candidate translations via stochastic sampling using the `vllm` library (Kwon et al., 2023) for efficient inference, which are then scored and re-ranked using our hybrid scoring function (Equation 5) to select the final output. The quality of this final translation is measured using the state-of-the-art reference-free metric XCOMET-XXL[6] (Guerreiro et al., 2024).

3.2 Main Results

Baselines. To demonstrate the effectiveness of our multi-stage pipeline, we compare our final system against several key baselines. We conduct an ablation study with two internal models: (1) Two-step SFT, our model after only the two SFT step, to measure the combined impact of our RL and hybrid decoding steps; and (2) Two-step RL, the model after full SFT and RL training, to isolate the performance gain from the hybrid decoding strategy. Furthermore, we benchmark our system against leading proprietary models, including GPT-4o and Claude 3.7 Sonnet.

Table 2 presents the main findings of our evaluation. The results clearly demonstrate the superiority of our final Marco-MT-Algharb system. On average, our final system achieves an XCOMET-XXL score of 79.33, significantly outperforming all other models in the comparison.

The effectiveness of our multi-stage pipeline is validated by the ablation study. Our full RL framework (Two-step RL) improves upon the SFT-only baseline by a substantial margin of 1.5 points on average. The final addition of our hybrid decoding strategy (Hybrid Decode) provides a further 1.3-point gain, highlighting the crucial and cumulative contribution of each component to the final performance.

[6]https://huggingface.co/Unbabel/XCOMET-XXL

Most notably, Marco-MT-Algharb not only surpasses the strong proprietary baselines of GPT-4o and Claude 3.7 Sonnet by a large margin (over 5.1 points on average), but it also achieves the highest score across every individual language pair. This consistently strong performance highlights the effectiveness of our specialized training and decoding approach. These results suggest that a carefully refined, open-source model can produce translations of exceptional quality, capable of outperforming even leading general-purpose proprietary systems on this benchmark.

4 Conclusion

This paper presented Marco-MT-Algharb, our system for the WMT25 General Machine Translation Shared Task. We introduced a novel quality-aware framework that enhances LLM-based translation through a synergistic combination of two-step supervised fine-tuning with data distillation, dynamic multi-reward reinforcement learning, and a hybrid alignment-aware decoding strategy. Our methodology was validated on the WMT25 test set, where Marco-MT-Algharb substantially outperformed strong baselines and leading proprietary models. These results were corroborated by the official human evaluation, which placed our system in the top three across 12 of our 13 language pairs, including six first-place victories. Notably, in the highly competitive English-Chinese direction, our system ranked first among all open and closed-source submissions.

Evaluation of Qwen3 for English to Ukrainian Translation

Cristian Grozea[1] * Oleg Verbitsky[2]
[1]Fraunhofer Institute FOKUS, Berlin, Germany
[2]Pidstryhach Institute for Applied Problems of Mechanics and Mathematics
Ukrainian Academy of Sciences, Lviv, Ukraine

Abstract

We report the results of evaluating Qwen3 for the English-to-Ukrainian language pair of the general MT task of WMT 2025.

In addition to the quantitative evaluation, we performed a qualitative evaluation, in collaboration with a native Ukrainian speaker - therefore we present an example-heavy analysis of the typical failures the LLMs still do when translating natural language, particularly into Ukrainian.

We report also on the practicalities of using LLMs, such as on the difficulties of making them follow instructions, on ways to exploit the increased "smartness" of the reasoning models while simultaneously avoiding the reasoning part improperly interfering with the chain in which the LLM is just one element.

1 Introduction

This submission to the general MT task of WMT 2025 from Fraunhofer FOKUS continues our series of baselines prepared for the WMT biomedical translation task, as this system was intended for preparing baselines in case the task had been organized this year. Those baselines evolved with the field: starting with training sequence-to-sequence models on biomedical corpora (Bawden et al., 2019), continuing with transformers trained by us on biomedical corpora (Bawden et al., 2020), starting using generic pretrained models like T5 – not necessarily targeting the biomedical field (Yeganova et al., 2021; Neves et al., 2022), then using one of the first widely deployed LLMs, ChatGPT 3.5 (Neves et al., 2023) and eventually using the emerging more capable locally-hosted open-model LLMs, LLama 3.1 70B (Neves et al., 2024).

Using locally hosted models keeps data away from cloud providers, leveraging the competitiveness of the locally-hosted large LLMs such as the Qwen3 (Yang et al., 2025) we used here. This is particularly important to ensure unfiltered access to the potential hiding in these models, as online services may further censor or otherwise limit the cloud-served models.

2 System Description

2.1 Hardware

The hardware this system ran on is part of the Fraunhofer FOKUS GPU cluster. It is a server with 8 Nvidia H100 SXM GPUs, each with 80 GB Video RAM (VRAM), 3 TB RAM, 192 CPU cores (384 threads). The power consumption of this server in idle mode is about 1800 W. Only 7 of the 8 GPUs were used to perform the translation task, at an average of 140 W/GPU, adding approximately 1000 W to the power consumption during the experiment.

2.2 Software

The GPU cluster is managed with Kubernetes[1]. To run the selected LLM, we have used the ollama system[2], ran as a Helm[3] deployment and limited to 7 of the 8 GPUs.

The translation itself has been controlled with a Python script that used the ollama Python API for calling the LLM, once per each paragraph to translate.

Translating the texts took approximately 12 hours.

2.3 LLM

The LLM we have employed is Qwen3, as available in the ollama library under the tag qwen3:235b-a22b-q4_K_M. It is a mixture of experts model, with 235.1e9 parameters, context length 262144, embedding length 4096. It has been used with temperature 0.6 (randomness level in decoding),

[1]https://kubernetes.io/
[2]https://ollama.com/
[3]https://helm.sh/

Proceedings of the Tenth Conference on Machine Translation, pages 594–598
November 8-9, 2025

top_k=20, top_p=0.95 and repeat_penalty=1. This is a quantized model, with Q4_K_M quantization, leading in average to the use of 4.84 bits for every parameter of the original not-quantized model.

2.4 Prompt

This is the prompt we used uniformly, regardless of the context (be it chat, or video captioning or another source):

"You are a helpful assistant specialized in translation. You will be provided with a text in English, and your task is to translate it into Ukrainian. Keep the formatting as close as possible to the source. Preserve meaning, tone, emotions, and nuances and target the cultural context of Ukrainian. For easier selection, mark the translated text with <translation-begin> and <translation-end>".

3 Results and Analysis

3.1 Quantitative Evaluation

The automated evaluation performed by the organizers(Kocmi et al., 2025) computed several metrics characterizing the performance of our system: a trained quality estimation (CometKiwi-XL) score of 0.597 (versus 0.65 for the top system), an LLM evaluation score with the Commander-A model as judge of 75.7 (versus 84.1 for the top system), and of 78.1 with GPT4.1 as judge (versus 85.3 for the top system). A metric based on the reference translation (xCOMET-XL) was computed as well; score 0.513 (versus 0.662 for the top system). These metrics resulted in an AutoRank score of 8.7.

3.2 Qualitative Evaluation

We evaluated, grouped, and classified a randomly selected subset of errors on the very test set of the WMT 2025 general MT task, hoping that the recency of this dataset prevented the LLMs from being trained on these texts. We attempted to understand how the error came to be, given the statistical nature of the LLMs.

Types and sources of errors (**be warned, Example 3 could be shocking to sensitive readers, who might want to skip reading it**; the misspelled words in the source of translation are reproduced verbatim):

- The absence of idiomatic analogs in Ukrainian:

  Example 1

  EN: Rmember, theres alot of fish in the sea!

  UKR: Пам'ятай, у морі багато риби!

  This is a word-for-word translation. Ukrainians do not say it this way. However, in internet there are a lot of translations like this, which indicates this might become idiomatic in Ukrainian as well!

  Example 2

  EN: wejt out of their way

  UKR: вийшов зі свого шляху

  This is again an incorrect word-for-word translation. Correct would be: полишив свої справи.

- Unexplainable typos:

  Example 3

  EN: boil on my ass

  UKR: присом на сракі

  Correct: прищем на сраці

- (questionable) preservation of the English acronym:

  Example 4

  EN: WTF

  UKR: WTF (not translated)

- Play of words leading to the loss of sense:

  Example 5

  EN: Basically if you didn't know what that is,it's basically an example of two sentences. One says "Lets eat granny" making it seem like someone's gonna eat their nan.However,the other example says "Lets eat,granny" implying a different meaning to the sentence. Pretty creative way to teach kids to use commas ig.

  UKR: По суті, якщо ти не знав(-ла), що це таке, це просто приклад двох речень. Одне каже: «Їдьмо, бабуся», через що здається, ніби хтось збирається з'їсти свою бабусю. А інший приклад: «Їдьмо, бабусю», — що змінює зміст речення. Досить творчий спосіб навчити дітей ставити коми, припускаю.

  Mistake: "Їдьмо" is not "Let's eat" (though this incorrect guess is still somehow plausible/natural, due to the closeness of the stems of "to go" and "to eat" in Slavic languages). The actual meaning of "Їдьмо" is

"let's go/drive", but even then "to drive someone" does not exist in Ukrainian. Thus, the sense is completely lost. Correct: "Давайте їсти бабусю" and "Давайте їсти, бабусю". This word-for-word translation would perfectly preserve the general meaning of the original.

Example 6

EN: One word I simply can't say properly is water..... It actually hurts my brain trying to add the T and I sound american if I do or still say wut-ta, IDK why it's so hard for me to say tbh. Just wondering what ppl thought are when you meet people who drop H's and have glottal stops.

UKR: Одне слово, яке я просто не можу правильно вимовити – це вода... Навіть більно у голові, коли намагаюся додати Т, і виглядає, ніби я американець, якщо так роблю, або все ще кажу "вутта". Не знаю, чому мені так важко це вимовити, щиро кажучи. Цікаво, що люди думають, коли зустрічають тих, у кого випадає "г" і є гортанні зупинки.

The sense is lost as the word "вода" (translated from "water") does not contain the letter T at all.

- Translating with a blend of Ukrainian and Russian, including made-up words:

  Example 7

  EN: innit

  UKR: а?

  Correct: га? Or even better: чи не так? правда ж?

  Example 8

  EN: BLOW

  UKR: ЗІРВЕТЬСЯ

  Correct: ВИБУХНЕ.

  ЗІРВЕТЬСЯ here seems a blend of Ukrainian and Russian stemming from the Russian word ВЗОРВЁТСЯ. In fact, ЗІРВЕТЬСЯ exists in Ukrainian but has a completely different meaning (to fall off).

- corrupted words (in the translation)

  Example 9

  EN: RN

  UKR: ПРЯМОСЬОГО ТЕПЕР

  Correct: ПРЯМО ТЕПЕР.

  The word ПРЯМОСЬОГО doesn't exist in Ukrainian, it sounds slightly like ПРЯМІСІНЬКО (infrequent, more stringent variant of ПРЯМО).

  Yet another case appears in the translation from Example 6 above, "більно" does not exist in Ukrainian, although it is formed in a plausible way: біль+но. Correct would be боляче (painful).

- missing slang equivalents

  EN: BRUH

  UKR: БРУХ

  This is a transliteration, such a word does not exist in Ukrainian.

4 Discussion

When selecting Qwen3 235B, we evaluated it briefly and informally against another truly large LLM that can be run locally on powerful machines, DeepSeek-R1 671B (DeepSeek-AI, 2025), also quantized, with the same type of quantization. Somewhat surprisingly, the Qwen3 model, which is nearly three times smaller, seemed to outperform the largest DeepSeek-R1 model on English to Romanian and English to German tasks. In the introductory blog entry[4] Qwen3 has been presented as supporting 119 languages, including Ukrainian and English, whereas the training of DeepSeek-R1 focuses on English and Chinese (DeepSeek-AI, 2025). All this made us employ Qwen3 instead of DeepSeek-R1, as the more efficient Qwen3 was also faster. In retrospect, this seems to have been a poor decision, as the organizers report better results with DeepSeek-R1 for the task of English-to-Ukrainian translation. We should have contrasted the performance of those two models on the intended language pair.

Fine-tuning a general LLM to a task like this language pair translation was an option with the smaller models, but it became much more difficult as the models grew towards the limits of the available hardware resources, especially VRAM. The hope is not to have to specialize the models, but to get good results from generalist models instead. As the system we employed was intended as a baseline,

[4] https://qwenlm.github.io/blog/qwen3/

we refrained from attempting to improve upon the standard pre-trained Qwen3 model, as published for everyone.

Despite the instructions shown in Section 2.4, the LLM we employed did not always preserve the newline structure of the source, where double newlines served as paragraph delimiter. Therefore, and to make the task easier for the LLM, although with the risk of providing too little context for the translation, we split explicitly in the Python script the text into paragraphs, translated each paragraph and recomposed the resulting text by joining the translations with the expected delimiter. Even with this procedure, 50 out of 1251 texts had to be retranslated, because the LLM introduced spurious double newlines inside the translation of single paragraphs, disrupting the correspondence of the input and the output paragraphs.

Qwen3 is a so-called "reasoning" model, meaning that before outputting the desired translation it produces "reasoning" text describing its approach and its doubts about the task. This part is delimited by the tags <think> and </think>. We deleted this part of the output by removing everything up to and including the closing </think> tag.

The LLM inconsistently used the required tags to mark the translation and separate it from various other comments it produced in addition to it. It produced randomly such alternative closing tags for the translation section: </end-translation> and </begin-translation>. Our Python script was designed to detect and accept also these alternative closing tags.

In the end, two of the outputs still contained traces indicating that something went wrong with the automatic extraction of the translated text, that is they still contained the <think> tag. We decided not to fix those, in order to get a realistic evaluation of what to expect when using a "reasoning" LLM for translation.

We expect the need for explicit well-controlled postprocessing – as described here – to remain, as none of the models we interacted with have complete adherence to the instructions.

Concerning the errors those models still produce in machine translation, it might be that successfully finetuning on a well-curated parallel corpora might eliminate some of them, but probably not all.

5 Conclusion

We have evaluated the use of one of the largest local LLMs for automatic translation of English to Ukrainian. Beyond the automated quantitative analysis performed by the task organizers, we have performed a qualitative analysis of several translation errors observed, and explained also the engineering issues one has to deal with when relying on LLMs for machine translation, such as the incomplete adherence to instructions and the subsequent need for postprocessing, especially when using a "reasoning" LLM. We conclude that, although neural machine translation of occasionally challenging texts in natural language has advanced significantly, the LLMs, as the other neural models before them, continue to be characterized by two aspects: smooth and polished output, convincing thanks to the good form, paired with instances where meaning is sometimes missed – or even reversed. Still, when a human with knowledge of the target and of the source languages is proofreading the outcome, the translation process can be significantly accelerated using such a local LLM.

6 Thanks

We thank the anonymous reviewers, whose suggestions led to improving the quality of this article.

Abstract

We present an English-to-Japanese translation system built upon the EuroLLM-9B (Martins et al., 2025) model. The training process involves two main stages: continue pretraining (CPT) and supervised fine-tuning (SFT). After both stages, we further tuned the model using a development set to optimize performance. For training data, we employed both basic filtering techniques and high-quality filtering strategies to ensure data cleanness. Additionally, we classify both the training data and development data into four different domains and we train and fine-tune with domain specific prompts during system training. Finally, we applied Minimum Bayes Risk (MBR) decoding and paragraph-level reranking for post-processing to enhance translation quality[1].

1 Introduction

Large language models (LLMs) are increasingly used in machine translation, taking advantage of their deep understanding of both source and target languages. Their training typically involves two main stages: continued pretraining (CPT) and supervised fine-tuning (SFT).

In the pretraining stage, the model is exposed to massive amounts of unlabeled text and learns by predicting the next token in a sequence. This allows the model to acquire a broad understanding of language structure, grammar, general world knowledge, and reasoning patterns. In the supervised fine-tuning stage, the model is trained on task-specific labeled datasets, where each input is paired with reference output. This targeted training enables the model to follow instructions more precisely and handle specialized tasks, such as question answering, summarization, classification, and translation, with greater accuracy.

For the WMT25 general translation task, we began with the pretrained LLM EuroLLM-9B (Martins et al., 2025) and performed additional training using bilingual corpora containing only English–Japanese sentence pairs. In this stage, we employed the two aforementioned training approaches: continued pretraining (CPT) and supervised fine-tuning (SFT), and trained separate systems using each method. Following the first stage, a reduced development dataset was employed to fine-tune (FT) the systems to the WMT translation tasks. The training architecture is shown in Figure 1 (left side).

Before generating translations, we segment the WMT25 test set into individual sentences using the newline character ("\n"), as our systems are trained to operate at the sentence level.

During inference, we apply Minimum Bayes Risk (MBR) decoding and reranking of diverse translation hypotheses produced by our two models. For each input sentence, we generate up to 300 translation candidates by combining outputs from both trained models with variations in decoding prompts (Table 6), greedy/nucleus decoding (5-best), and zero-shot/few-shot examples. A quality estimation step is then applied to these hypotheses, discarding the worst 50% for each input. From the remaining candidates, MBR decoding is used to select the most promising translation, following the approach of Rei et al. (2024). Finally, the translated sentences are concatenated back into paragraphs, which are reranked using CometKiwi[2] (Rei et al., 2022), with the top-ranked paragraph selected as the final system output. The inference post-process architecture is shown in Figure 1 (right side).

As a result, our submission is an ensemble of two open-weight, sentence-level, English-to-Japanese translation models with a combined total of 18B parameters. The following sections describe the

data preparation process as well as give additional details on the training procedures used to build our WMT25 English-Japanese system.

2 Data preparation

2.1 Bitext data

We use only parallel corpora to continue training LLMs for the machine translation task. We apply both basic and high-quality filtering methods to the WMT25 English-Japanese bitext data. From the original 225 million sentence pairs, we select approximately 10 million high-quality pairs for training. These filtered pairs are then used to train models using both CPT and SFT strategies. Similar filtering methods are also applied to the development datasets to further fine-tune (FT) the trained models. Table 1 summarizes the data statistics for the training and development datasets.

2.1.1 Basic Filtering Rules

Basic filtering rules are applied first to remove duplicates and noisy samples, such as misaligned sentence pairs and those with significantly different length ratios. Details of the filtering steps are as follows:

- **uniq:** Remove duplicated bitext examples.
- **1:1 example:** Discard examples where a single sentence is aligned to multiple sentences (1:N) or multiple sentences are aligned to a single sentence (M:1).
- **length ratio:** Discard examples where the length ratio between source and target exceeds 10 or is less than 0.2[3].
- **length:** Discard examples with length greater than 500 tokens.
- **character:** Retain sentences containing only Latin and Greek characters on the English side, and Latin, Greek, Hiragana, Katakana, and Han characters on the Japanese side.
- **LID:** Perform language identification using `lid.176.bin` (Joulin et al., 2016b,a).

2.1.2 High-Quality Filtering

The high-quality filtering process involves two main steps: first, generating translation hypotheses using a translation model; second, estimating the similarity between the source sentence and the target sentence, or between the source sentence and the generated hypothesis, using a quality evaluation model. For this purpose, we use EuroLLM-9B-Instruct (Martins et al., 2025) to translate English sentences into Japanese, and CometKiwi to assess the quality scores between English and Japanese segments in this year's WMT evaluation. Finally, we remove those samples which

$$CometKiwi(src, tgt) < CometKiwi(src, hyp)$$

2.2 Development data

Development data is used to fine-tune the pre-trained models to adapt to WMT evaluation. We first merge all development data, both English-to-Japanese and Japanese-to-English, provided by WMT25, including WMT dev/test data in previous years, NTREX (Federmann et al., 2022) and Flores (NLLB Team et al., 2024), except wmttest2024 dataset[4]. Then we apply high-quality filtering (Section 2.1.2) after deduplication. Details are shown

[3]We use basic tokenization for length and length ratio filtering: on the English side, we tokenize by spaces, while on the Japanese side, we tokenize at the character level.

[4]https://data.statmt.org/wmt24/general-mt/wmt24_GeneralMT.zip

	Bitext	Dev set
wmt25 provided	225M	20,111
uniq	132M	18,019
1:1 example	57M	-
basic rules (length, LID, etc.)	55M	-
high quality	10M	5,736

Table 1: Data statistics (number of lines) for training and development dataset filtering.

in Table 1. There are in total 5,736 sentence pairs finally used for system fine-tuning (FT in Table 1).

2.3 Data classification

In WMT2024, the test dataset covers four domains: News, Social, Speech and Literary. To perform domain classification, we fine-tune Llama-3.1-8B-Instruct[5] model on the WMT24++ dataset (Deutsch et al., 2025) and use the resulting classifier to label both the training and development data. The prompt used for classification during both training and inference is shown in Table 5.

The fine-tuned model categorizes English input sentences into one of the four domains. Within the 10M cleaned parallel corpus, the distribution across these domains is 7% (News), 74% (Social), 12% (Speech), and 7% (Literary), indicating that the Social domain constitutes the majority of the training data.

This classification model is used only for training data preparation. For decoding, we generate translation hypothesis for each input with all domain related prompts (Table 6) and rely on MBR postprocessing to select the best candidate.

Table 7 shows that domain related prompts benefit the final system.

3 Model training

3.1 Continue pretraining and Supervised fine-tuning

The pretraining stage of LLM typically requires vast amounts of unlabeled monolingual data. However, since the WMT evaluation is dedicated exclusively to machine translation, we leverage parallel corpora as a stand-in for monolingual data. Accordingly, we train LLMs independently using two approaches, continued pretraining (CPT) and supervised fine-tuning (SFT), on parallel data.

[5]https://huggingface.co/meta-llama/Llama-3.1-8B-Instruct

For CPT, we generate training examples of up to 2048 tokens by appending the corresponding Japanese sentence to the end of each English input, together with a domain-specific prompt (Section 2.3). To minimize dependency between bilingual sentence pairs in the synthetic example, we insert an "end-of-sentence" token (</s>) after each Japanese sentence. The input text format for CPT is:

```
sample = (domain_prompt)En\nJa\n</s>
input = [sample] +
```

where `input` is constructed by concatenating (+) one or more `sample` entries, each containing an English (`En`) and a Japanese (`Ja`) sentence. The actual set of `domain_prompts` used are shown in Table 6.

We apply 10% prompt smoothing to the domain-specific prompts, where each of the four prompt types — News, Social, Speech and Literary — is sampled with a 10% probability with generic domain-free prompt (default 1 and default 2 in Table 6). This helps mitigate the impact of annotation errors and enhances training diversity.

We apply similar domain-specific prompts for SFT training. The only difference is that training examples are not concatenated during SFT.

We use LLaMA-Factory (Zheng et al., 2024) to train CPT/SFT models from EuroLLM-9B. The training parameters are the same as described in GemmaX2-28 (Cui et al., 2025) except that we use 4 GPUs in parallel for both training. The effective batch size for both trainings is 128. The learning rate starts from 2.0e-5 and decays based on cosine_with_min_lr policy, with a miminum value of 1.0e-6 (Table 8).

We use full model tuning rather than parameter-efficient methods such as LoRA adapters for CPT/SFT training. This choice is motivated by the relatively small size of the training data, where full tuning has been shown to yield better performance than adapter-based methods in similar low-resource settings (Hu et al., 2021; Pfeiffer et al., 2021).

3.2 Fine-tuning with development data

To further adapt our models to the WMT task, we perform an additional round of fine-tuning (FT) on both the CPT and SFT models using the filtered previous year's development data except wmttest2024 (Section 2.2).

Given the limited dataset size of 5,736 samples and an effective batch size of 128, this fine-tuning

Policy	Prompts	zero/few-shot	Greedy	Nucleus
Adequacy	all	all	Yes	No
Diversity	all	all	Yes	Yes

Table 2: Decoding policies (Adequacy vs. Diversity) for MBR post-processing.

wmttest2024		Adequacy policy		Diversity policy	
		BLEU	CometKiwi	BLEU	CometKiwi
Baseline	EuroLLM-9B-instruct	26.3	0.7501	22.9	0.7620
	EuroLLM-9B-instruct-FT	26.4	0.7500	22.6	0.7624
Our models	EuroLLM-9B-CPT-FT	29.5	0.7504	24.5	0.7659
	EuroLLM-9B-SFT-FT	28.4	0.7515	24.9	0.7667
	Ensemble	**29.8**	0.7586	24.6	**0.7686**

Table 3: Sentence-level evaluations on wmttest2024 English-Japanese translation. Both BLEU and CometKiwi scores are the result of MBR output. BLEU is calculated by Sacrebleu (Post, 2018) with ja-mecab tokenization. CometKiwi is the reference-free score of Unbabel/wmt23-cometkiwi-da-xl.

process runs for only 45 steps (1 epoch). In this stage, training samples are also built with domain-specific prompts as in our previous training. We apply full model training instead of using LoRa adapters for fine-tuning, with a starting learning rate 2.0e-5 and inverse_sqrt decay policy. We add NEFTune noise (Jain et al., 2023), with alpha=5, in this fine-tuning stage (Table 8).

4 Decoding and Postprocessing

We follow the idea of quality-aware decoding proposed by Rei et al. (2024). First, we apply Quality Estimation (QE) to discard the translation candidates with the lowest quality. Then, we perform Minimum Bayes Risk (MBR) decoding over the remaining hypotheses, using CometKiwi (Rei et al., 2022) as the loss function. The candidate with the lowest expected risk is selected as the final output.

To generate diverse output for each input, we apply different domain-free/domain-specific prompts, zero/few-shot examples, and greedy decoding as well as nucleus decoding. Table 2 summarizes the two decoding policies that we used in this work. Note that the policies differ only in the use of nucleus sampling to generate diverse hypotheses, which favors outputs with higher diversity (lower adequacy). Table 3[6] confirms this, as the Adequacy policy achieves correspondingly higher BLEU scores, while the Diversity policy yields higher CometKiwi scores.

[6]EuroLLM-9B-instruct-FT is the model that we directly fine-tune EuroLLM-9B-instruct with the development data described in Section 2.2.

4.1 Reference-free Quality Estimation (QE)

To filter low-quality hypotheses, we employ Comet-QE (Rei et al., 2021) in a reference-free setting. Given a source sentence src and a set of N candidate translations $\{hyp_1, hyp_2, \ldots, hyp_N\}$, we use Comet-QE score to compute quality scores $s_i = \text{Comet-QE}(src, hyp_i)$ for each hypothesis hyp_i. We then retain only the top $K = \lfloor N/2 \rfloor$ candidates with the highest scores:

$$\{hyp'_1, \ldots, hyp'_K\} = \text{Top-}K\ (\{s_1, \ldots, s_N\})$$

This step serves to remove noisy or low-quality translations that may adversely affect subsequent MBR decoding (Kondo et al., 2024).

4.2 Minimum Bayes Risk (MBR) Decoding

Following QE filtering, we apply Minimum Bayes Risk decoding (Fernandes et al., 2022) using a reference-based CometKiwi score. For each sentence, we consider the remaining K candidates $\{hyp_1, \ldots, hyp_K\}$ and compute the pairwise loss between each one of them with the others using CometKiwi scores, treating each candidate as a reference for the others: $\ell(hyp_i, hyp_j) = 1 - \text{CometKiwi}(src, hyp_i, hyp_j)$. Each hypothesis is then assigned an expected loss:

$$\mathbb{E}[\ell(hyp_i)] = \sum_{j=1}^{K} p(hyp_j) \cdot \ell(hyp_i, hyp_j)$$

where $p(hyp_j) = \frac{\exp(\log P(hyp_j))}{\sum_k \exp(\log P(hyp_k))}$ is derived from the log-probabilities assigned by the model.

wmttest2025	CometKiwi	
	Adequacy policy	Diversity policy
EuroLLM-9B-CPT-FT	0.6769	0.6801
EuroLLM-9B-SFT-FT	0.6826	0.6842
Ensemble	0.6843	0.6859
Reranking (main submission)	**0.7033**	

Table 4: Paragraph-level evaluation (Kocmi et al., 2025) for wmttest2025. CometKiwi is the reference-free score of Unbabel/wmt23-cometkiwi-da-xl.

We select the hypothesis y^* that minimizes the expected loss:

$$y^* = \arg\min_{hyp_i} \mathbb{E}[\ell(hyp_i)]$$

and thus, selecting the hypothesis that is most representative of the overall candidate distribution.

4.3 Paragraph-level re-ranking (WMT25)

For the WMT25 test set, we first split each document into sentences using the newline character "\n". Then we apply MBR to select the best candidate for each sentence individually. The selected sentences are reassembled into their original paragraph structure. Finally, we compute paragraph-level CometKiwi scores and select the combination of sentences that yields the highest overall score as the final output.

Let $D = \{d_1, d_2, \ldots, d_N\}$ be the set of documents in the WMT25 test set. Each document d is split into a list of sentences:

$$S_d = [s_1, s_2, \ldots, s_{n_d}]$$

For each sentence s_i, let $y_i = \{y_{i_1}, y_{i_2}, \ldots, y_{i_k}\}$ be a set of corresponding candidate translations. Apply MBR decoding to select the best candidate $\hat{y}_i$, and reconstruct the sentence list with best translation candidates:

$$\hat{S}_d = [\hat{y}_1, \hat{y}_2, \ldots, \hat{y}_{n_d}]$$

These selected sentences are then reassembled into a paragraph structure:

$$\hat{P}_d = \text{Assemble}(\hat{S}_d)$$

Finally, among all possible sentence combinations $P \in \mathcal{P}_d$, select the one with the highest paragraph-level CometKiwi score:

$$\hat{P}_d^* = \arg\max_{P \in \mathcal{P}_d} \text{CometKiwi}(P)$$

As shown in Table 4, incorporating paragraph-level reranking further improves the quality of the final submission.

5 Conclusions

In this paper, we present our English-to-Japanese translation system for the WMT25 General Translation Task. The final output is generated by ensembling two models trained with different strategies: continued pretraining (CPT) and supervised fine-tuning (SFT). Both models are trained on a cleaned parallel corpora of 10 million sentence pairs and further fine-tuned (FT) on a development set consisting of 5,736 sentences. MBR and re-ranking inference post-processing are also successfully performed to obtain the final quality boost. Additionally, we release one classification model[7] and two translation models[8] in our HuggingFace repository.

Abstract

In this paper, we present our submission to the WMT25 shared task on machine translation, for which we propose **S**ynergy-en**h**anced polic**y** optimization framework, named **Shy**. This novel two-phase training framework synergistically combines knowledge distillation and fusion via reinforcement learning. In the first phase, we introduce a multi-stage training framework that harnesses the complementary strengths of multiple state-of-the-art large language models to generate diverse, high-quality translation candidates. These candidates serve as pseudo-references to guide the supervised fine-tuning of our model, Hunyuan-7B, effectively distilling the collective knowledge of multiple expert systems into a single efficient model. In the second phase, we further refine the distilled model through Group Relative Policy Optimization, a reinforcement learning technique that employs a composite reward function. By calculating reward from multiple perspectives, our model ensures better alignment with human preferences and evaluation metrics. Extensive experiments across multiple language pairs demonstrate that our model **Shy-hunyuan-MT** yields substantial improvements in translation quality compared to baselines. Notably, our framework achieves competitive performance comparable to that of state-of-the-art systems while maintaining computational efficiency through knowledge distillation and fusion.

1 Introduction

The field of machine translation has witnessed remarkable progress with the emergence of large language models; yet, challenges remain in consistently producing human-quality translations. This work addresses two key limitations: (1) the over-reliance on single-model supervision during fine-tuning, and (2) the difficulty of aligning machine outputs with nuanced human judgments during reinforcement learning.

Our method comprises three main phases. First, we collect diverse translations from state-of-the-art open-source large language models, including DeepSeek-V3 (DeepSeek-AI, 2024), DeepSeek-R1 (Guo et al., 2025), and Gemma across multiple language pairs. This ensemble approach provides a richer training signal than single-model distillation, exposing our base model Hunyuan-7B to varied translation strategies and stylistic choices. The collected translation outputs are carefully filtered and normalized before serving as supervision targets. Second, we perform Supervised Fine-Tuning (SFT) on Hunyuan-7B using the prior collected translation dataset. Crucially, we implement a dynamic weighting scheme that prioritizes higher-quality translations during SFT training, as determined by automatic metrics. Specifically, this phase enables the model to internalize the strengths of each contributor model while maintaining its own linguistic identity. The third phase applies Group Relative Policy Optimization (Shao et al., 2024), a sample-efficient Reinforcement Learning (RL) algorithm, to further refine the model. We employ XCOMET for its strong correlation with human judgments and DeepSeek-V3 for its complementary strengths in fluency assessment. The reward function combines these signals with a KL-divergence term to prevent excessive deviation from the SFT model. During RL training, we maintain multiple policy groups that explore different translation strategies, with periodic selection pressure favoring the approaches that yield the highest rewards.

Our methodology incorporates several primary techniques to ensure robust performance. Specifically, we employ a temperature-scaled sampling strategy during preference data collection to optimize the trade-off between diversity and quality. For the SFT phase, a layer-wise learning rate decay is applied to enhance model adaptation. During the RL phase, we implement a dynamic reward normalization scheme to maintain training stability.

Proceedings of the Tenth Conference on Machine Translation, pages 607–613
November 8-9, 2025

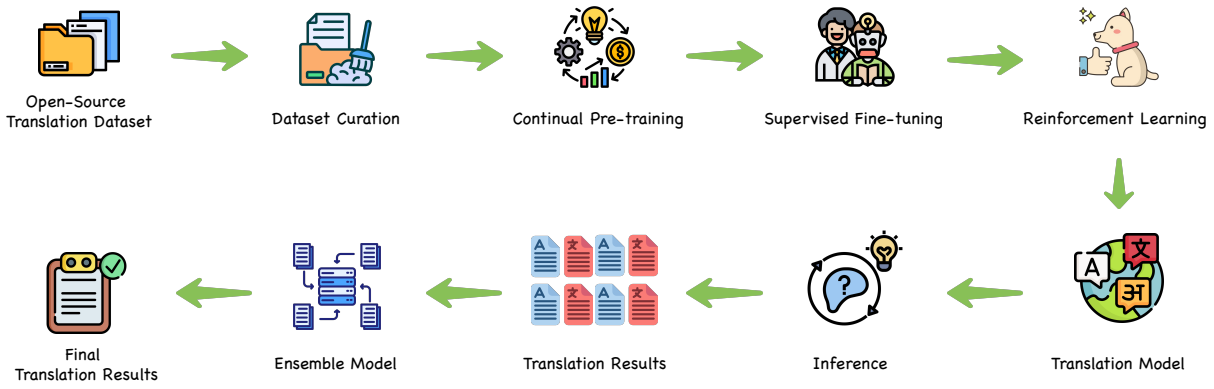

Figure 1: **Framework of the Shy-hunyuan-MT**. Firstly, we leverage an open-source translation dataset to conduct continuous pre-training on the Hunyuan-7B model. Secondly, we utilize the collected WMT translation data to perform SFT on the continuously pre-trained model. Thirdly, we sample outputs from the translation model to generate a set of diverse translation results, which are then used to train and derive the final translation result.

Model performance is rigorously evaluated on the WMT25 test sets using both automatic metrics and human assessment. Comprehensive ablation studies are conducted to validate the efficacy of each proposed component. The primary contributions are threefold:

- A novel and practical framework for the refinement of machine translation models.
- Compelling empirical evidence demonstrating the effectiveness of RL in the domain of machine translation.
- Valuable insights into the application and dynamics of multi-reward RL for complex text generation tasks.

2 Related Work

This section reviews the key research strands underlying our approach: (1) large language models for machine translation, (2) continual pre-training strategies, (3) supervised fine-tuning for translation tasks, and (4) reinforcement learning optimization for text generation.

2.1 Large Language Models for MT

The success of dense decoder-only models, such as GPT-3 (Brown et al., 2020), has revolutionized neural machine translation (NMT). Recent work has demonstrated that 7B-parameter models, such as Hunyuan, can achieve competitive performance when properly adapted. Unlike traditional encoder-decoder architectures (Vaswani et al., 2017), monolithic LLMs process translation as conditional text generation, offering advantages in zero-shot capability and multilingual transfer (Kirstain et al., 2021). Our work extends this direction by systematically investigating continual pre-training strategies for domain adaptation in translation tasks.

2.2 Continual Pre-training for MT

Domain adaptation through continual pre-training has shown promise in recent MT research. Gururangan et al. (2020) established that targeted pre-training on in-domain corpora improves downstream task performance. For WMT competitions specifically, Liao et al. (2021) demonstrates the effectiveness of iterative pre-training on parallel corpora. Our approach differs in that it employs a two-phase adaptation: first, on general bilingual corpora, and then on WMT historical data. This hierarchical adaptation strategy aligns with findings from (Pfeiffer et al., 2020) about the importance of gradual domain specialization.

2.3 Supervised Fine-tuning for MT

The transition from pre-training to task-specific fine-tuning remains a research area of active interest. Raffel et al. (2020) demonstrates that controlled fine-tuning with progressive data augmentation can prevent catastrophic forgetting. Our SFT protocol incorporates three key innovations: (1) dynamic batch sampling based on sentence complexity metrics, (2) gradient accumulation for low-frequency language pairs, and (3) temperature-annealed decoding during training. These techniques build upon curriculum learning principles first proposed by Bengio et al. (2009), but with specific adaptations for translation tasks.

2.4 Reinforcement Learning for MT

Recent advances, such as GRPO (Shao et al., 2024), provide more stable RL optimization for MT and various tasks (Guo et al., 2025; Song et al., 2025; Yang et al., 2025; Li et al., 2025; Zheng et al., 2025). To obtain better rewards, we use a combination of different metrics as the reward, and this multi-metric approach addresses limitations identified by Freitag et al. (2022) regarding single-metric optimization. The ensemble strategy further builds on the diversity-promoting techniques from Vijayakumar et al. (2016), but with novel modifications for temperature-controlled output variation.

2.5 WMT Competition Innovations

Analysis of prior WMT winning systems reveals evolving trends. The 2021 Edinburgh system (Chen et al., 2021) pioneered the use of large-scale back-translation, while Guu et al. (2020) demonstrates the effectiveness of retrieval-augmented models. Our work contributes to this lineage by showing how to effectively combine continual pre-training, reinforced fine-tuning, and learned ensemble strategies within a single LLM framework, addressing the scalability challenges noted by Tom et al. (2023) in their WMT 2023 overview.

3 Methodology

Our approach consists of two major phases: (1) a three-stage training pipeline for developing a high-quality base translation model, and (2) an ensemble strategy that leverages diversity generation and reinforcement learning to produce final translations. The overall architecture is illustrated in Figure 1.

3.1 Continual Pre-training

We leverage Hunyuan-7B, a state-of-the-art multilingual dense foundation model, as our initialization checkpoint. To effectively adapt this general-purpose model for machine translation tasks, we perform domain-adaptive continual pre-training using diverse large-scale parallel and monolingual corpora. Our training corpus encompasses multiple data sources with complementary characteristics:

- **OPUS Collection** (Tiedemann, 2012): A comprehensive multilingual parallel corpus covering over 20 language pairs across diverse domains, providing broad linguistic coverage
- **ParaCrawl** (Buck and Koehn, 2016): Large-scale web-crawled parallel data offering extensive real-world language usage patterns
- **UN Parallel Corpus** (Ziemski et al., 2016): High-quality formal documents ensuring exposure to professional and diplomatic language registers
- **C4** (Raffel et al., 2020): Cleaned English text derived from Common Crawl, contributing to robust monolingual understanding
- **WikiText** (Merity et al., 2016): Encyclopedic articles providing well-structured, factually accurate content

This diverse mixture enables our model to acquire comprehensive translation capabilities across various domains, registers, and language pairs, while maintaining the strong multilingual representations inherited from the base model.

3.2 Supervised Fine-tuning

Following domain adaptation, we conduct supervised fine-tuning using WMT benchmark datasets spanning from 2015 to 2024. Our training method incorporates several regularization techniques to mitigate catastrophic forgetting while preserving the model's acquired capabilities. Then, we optimize the standard sequence-to-sequence cross-entropy objective:

$$\mathcal{L}_{\text{SFT}} = -\sum_{t=1}^{T} \log p(y_t | y_{<t}, x; \theta) \tag{1}$$

where x denotes the source sentence, y represents the target translation, and θ encompasses the model parameters. Our training configuration employs the following strategies:

- **Learning rate scheduling**: We implement linear warmup over 5% of total training steps to ensure stable optimization dynamics.
- **Gradient regularization**: We apply gradient clipping with a maximum norm of 1.0 to prevent gradient explosion.
- **Computational efficiency**: We utilize mixed-precision training with BF16 representation to accelerate training while maintaining numerical stability.

This fine-tuning protocol enables effective task-specific adaptation while maintaining the robustness gained through domain pre-training.

3.3 Reinforcement Learning

After SFT, we apply GRPO, a sample-efficient reinforcement learning algorithm. We design the reward function by combining three metrics:

$$r = w_1 \cdot \text{BLEU} + w_2 \cdot \text{XCOMET} + w_3 \cdot \text{DeepSeek} \quad (2)$$

where $w_1 = 0.2$, $w_2 = 0.4$, and $w_3 = 0.4$ are empirically determined weights. Then we optimize the GRPO objective as follows:

$$\begin{aligned} \mathcal{J}_{\text{GRPO}}(\theta) = \mathbb{E}_{q\sim P(Q),\{o_i\}_{i=1}^{G}\sim\pi_{\theta_{\text{old}}}(O|q)} \\ \frac{1}{G}\sum_{i=1}^{G}\left(\min\left(\frac{\pi_\theta(o_i|q)}{\pi_{\theta_{\text{old}}}(o_i|q)}A_i,\right.\right. \\ \left.\left.\text{clip}\left(\frac{\pi_\theta(o_i|q)}{\pi_{\theta_{\text{old}}}(o_i|q)}, 1-\epsilon, 1+\epsilon\right)A_i\right) - \\ \beta\mathbb{D}_{\text{KL}}\left(\pi_\theta \parallel \pi_{\text{ref}}\right), \end{aligned} \quad (3)$$

$$\mathbb{D}_{\text{KL}}\left(\pi_\theta||\pi_{ref}\right) = \frac{\pi_{ref}(o_i|q)}{\pi_\theta(o_i|q)} - \log\frac{\pi_{ref}(o_i|q)}{\pi_\theta(o_i|q)} - 1, \quad (4)$$

where ϵ and β are hyper-parameters, and A_i is the advantage, computed using a group of rewards $\{r_1, r_2, \ldots, r_G\}$ corresponding to the outputs within each group:

$$A_i = \frac{r_i - mean(\{r_1, r_2, \cdots, r_G\})}{std(\{r_1, r_2, \cdots, r_G\})}. \quad (5)$$

where A_i is the advantage function estimated using group-normalized rewards. To improve the translation quality of terminology and low-resource languages, we also use the methods proposed in TAT-R1 (Li et al., 2025), SSR-Zero (Yang et al., 2025), and Hunyuan-MT-7B (Zheng et al., 2025).

3.4 Synergy-based Policy Optimization

To further improve translation quality, we develop a two-phase fusion approach.

3.4.1 Diversity Generation

For each input sentence x, we generate $N = 5$ candidate translations by varying:

- Temperature ($\tau \in \{0.3, 0.5, 1.0, 1.5, 2.0\}$)
- Random seeds (5 different initializations)
- Beam search width (4-6 beams)

These settings allow our model to produce a candidate pool $Y = \{y_1, ..., y_N\}$ covering different translation properties (e.g., fluency vs. adequacy).

3.4.2 RL Training

We train another model to select/combine candidates from Y via GRPO. The framework utilizes the translation model as the base model in the first stage. The reward function remains the same weighted combination, now applied to the final output. During inference, the model can either:

1. Select the highest-scoring candidate;
2. Generate a new translation by attending to all candidates;

3.5 Implementation Details

All models are implemented in PyTorch and trained on 128 GPUs. Specifically, key hyperparameters are shown in Table 1.

Table 1: Training Hyperparameters

Parameter	Value
Batch size	64
Learning rate	5×10^{-5}
Max sequence length	8196

4 Results

Table 2 presents comprehensive evaluation results of our proposed Shy-hunyuna-MT model across 31 language directions from the WMT25 benchmark. The results of our model demonstrate exceptional performance across diverse linguistic pairs, achieving consistent state-of-the-art results on multiple automatic evaluation metrics. Our model achieves a remarkable AutoRank score of 1.0 across all 31 translation directions, indicating superior performance compared to baseline systems. This consistency across diverse language pairs, ranging from high-resource languages (e.g., English-German, English-Japanese) to low-resource ones (e.g., English-Bhojpuri, English-Maasai), demonstrates the robustness and generalization capability of Shy-hunyuna-MT.

Meanwhile, the evaluation results encompass both reference-based and reference-free metrics. On the CometKiwi-XL, our model achieves scores ranging from 0.577 to 0.720, with robust performance on the English-Estonian (0.720) and English-Korean (0.697) pairs. For GEMBA-ESA, our model consistently demonstrates excellence, with GEMBA-ESA-GPT4.1 scores predominantly

English-Swedish	1.0	-	84.2	91.0	-4.7	0.685	-
English-Turkish	1.0	-	81.4	85.2	-7.2	0.542	-
English-Vietnamese	1.0	-	83.1	87.3	-4.5	0.623	-

above 80%, reaching peaks of 91.0% for English-Swedish and 90.6% for English-German, indicating high-quality translations that align well with human preferences. The MetricX-24-Hybrid-XL scores, while negative across all directions, remain relatively compact within the range of -3.1 to -7.5, with English-German achieving the best score of -3.1. This metric consistency indicates stable translation quality without significant degradation across different language families.

Furthermore, the proposed model Shy-hunyuna-MT exhibits powerful performance on European language pairs, with XCOMET-XL scores exceeding 0.65 for English-German (0.703), English-Swedish (0.685), and Czech-Ukrainian (0.681). For Asian languages, the results maintain competitive performance with Japanese-Simplified Chinese achieving 0.629 and English-Korean reaching 0.624 on XCOMET-XL. Notably, for low-resource languages such as English-Maasai and English-Bhojpuri, where most neural metrics are unavailable, the model still achieves chrF++ scores of 27.7 and 40.6, respectively, demonstrating its capability to handle challenging low-resource scenarios where traditional evaluation metrics fail to provide coverage. In addition, the model demonstrates effective cross-lingual transfer capabilities, as evidenced by its strong performance on non-English-centric pairs, such as Czech-Ukrainian, Czech-German, and Japanese-Simplified Chinese. These directions achieve comparable scores to English-centric pairs, with Czech-Ukrainian no-

tably achieving 0.681 on XCOMET-XL, surpassing many English-centric directions.

In summary, Shy-hunyuna-MT establishes new benchmarks across diverse translation directions, demonstrating both breadth in language coverage and depth in translation quality, making it a versatile solution for MT tasks.

5 Conclusion

In this work, we propose **Shy-hunyuan-MT**, a novel MT system built upon the **S**ynergy-en**h**anced polic**y** optimization framework (**Shy**). Our method leverages a carefully designed two-phase training paradigm that systematically transforms the open-sourced Hunyuan-7B base model into a state-of-the-art translation system. The core innovation of our method lies in the synergistic combination of three complementary training phases: domain-adaptive continual pre-training on large-scale parallel corpora, supervised fine-tuning on curated WMT datasets, and reinforcement learning through Generalized Reward Policy Optimization (GRPO) with composite reward signals. This progressive training strategy enables the model to acquire robust multilingual translation capabilities while maintaining strong performance across a diverse range of language pairs.

Our extensive experiments on 31 language directions from WMT25 demonstrate the effectiveness of Shy-hunyuan-MT. The model achieves consistent top-tier performance with an AutoRank score of 1.0 across all evaluated directions, while excelling on multiple automatic metrics, including XCOMET-XL, CometKiwi-XL, and GEMBA-ESA variants. Notably, the model demonstrates its ability to handle both high-resource and extremely low-resource language pairs with comparable proficiency, highlighting its strong generalization capabilities and effectiveness in cross-lingual transfer learning. The success of our approach validates several key design decisions: (1) the importance of domain-specific continual pre-training in adapting general-purpose LLMs for translation tasks, (2) the effectiveness of incorporating multiple COMET-based metrics as reward signals during policy optimization, and (3) the value of progressive training paradigms in building robust multilingual systems. These findings provide valuable insights for future research in neural machine translation and cross-lingual model adaptation. Looking forward, Shy-hunyuan-MT establishes a strong foundation for advancing multilingual translation technology, particularly in scenarios involving diverse language families and resource constraints. The framework's flexibility and consistent performance across varied linguistic contexts position it as a promising solution for real-world translation applications and a solid baseline for future improvements in the field.

Abstract

In this paper, we present the SALAMANDRA**TA** family of models, an improved iteration of SALAMANDRA LLMs (Gonzalez-Agirre et al., 2025) specifically trained to achieve strong performance in translation-related tasks for 38 European languages. SALAMANDRA**TA** comes in two scales: 2B and 7B parameters. For both versions, we applied the same training recipe with a first step of continual pre-training on parallel data, and a second step of supervised fine-tuning on high-quality instructions.

The BSC submission to the WMT25 General Machine Translation shared task is based on the 7B variant of SALAMANDRA**TA**. We first adapted the model vocabulary to support the additional non-European languages included in the task. This was followed by a second phase of continual pre-training and supervised fine-tuning, carefully designed to optimize performance across all translation directions for this year's shared task. For decoding, we employed two quality-aware strategies: Minimum Bayes Risk Decoding and Tuned Re-ranking using COMET and COMET-KIWI respectively.

We publicly release both the 2B and 7B versions of SALAMANDRA**TA**, along with the newer SALAMANDRA**TA**-V2 model, on Hugging Face[1].

1 Introduction

Traditionally, Massively Multilingual Neural Machine Translation (MMNMT) relied on the encoder-decoder architecture to translate across multiple languages (Fan et al., 2021; NLLB Team et al., 2022). More recently, however, Large Language Models (LLMs) have demonstrated strong MMNMT capabilities (Zhu et al., 2024) and thus some works have proposed several strategies to improve the translation capabilities of a pre-trained LLM model and better align it with human translations (Zhang et al., 2023; Alves et al., 2024; Xu et al., 2024).

One such approach is continual pre-training using a combination of monolingual and parallel corpora followed by supervised fine-tuning (Alves et al., 2024). However, most previous approaches have predominantly relied on English-centric parallel corpora. This has been shown to bias the models towards English-centric latent representations (Zhang et al., 2025) which has been attributed to the language distribution used in the training corpora (Zhong et al., 2024). It is well known that training with only a single bridge language can negatively impact translation performance across zero-shot language pairs, due to limited cross-lingual transfer (Arivazhagan et al., 2019). Unlike previous works, in this paper we rely on parallel corpora only for the continual pre-training stage pivoting on three bridge languages.

When working with pre-trained language models on languages not covered by their original tokenizer, a highly effective solution involves replacing the existing tokenizer with a more comprehensive one that supports such languages. For the newly introduced tokens, embeddings must be initialized. In our work, these new embeddings were initialized to the average of all existing embeddings and then rapidly optimized through continual pre-training (CPT). This method has not only proven to be viable but also demonstrably improves the model's overall performance in the target languages, even if the original model was never exposed to data from these languages during its initial training (Da Dalt et al., 2024).

Throughout this paper, we present the SALAMANDRA**TA** family of models, which serve as the backbone models of the BSC team's submission to the WMT25 General Machine Translation Shared Task. Our participation covers 15 out of the 16

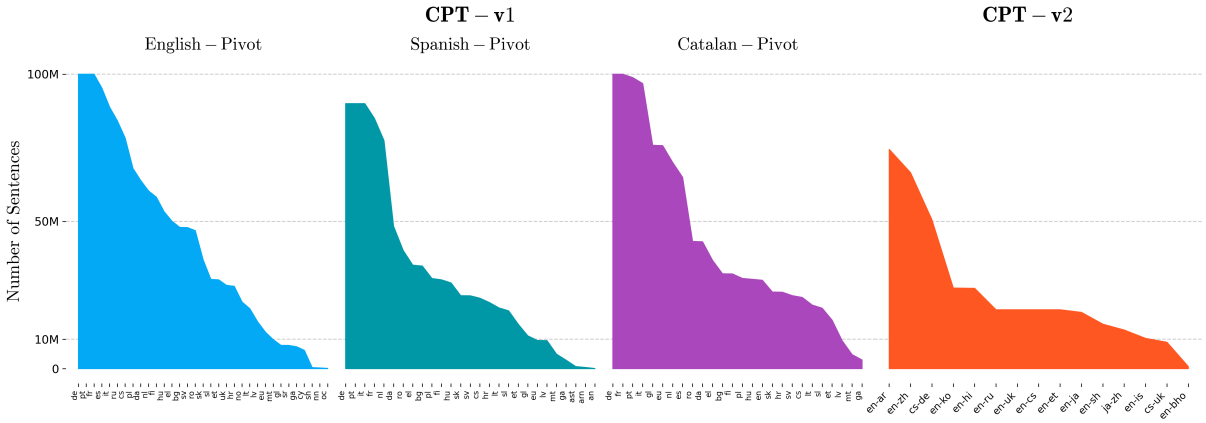

Figure 1: Distribution of sentence pairs for continual pre-training. The first three plots (■ **CPT-v1**) show the number of sentence pairs pivoting in English, Spanish and Catalan, respectively. The fourth plot (■ **CPT-v2**) corresponds to the second continual pre-training phase with direct language pairs.

translation directions in the general MT task under the constrained track. Additionally, we took part in the multilingual subtask for 7 out of the 16 directions. Contributions of this work are listed as follows:

- While most previous work have relied on English-centric parallel corpora for building translation-focused LLMs, we build SALAMANDRA**TA** pivoting in three languages for continual pre-training; English, Spanish and Catalan across 172 supervised directions.
- We show that instruction tuning improves both translation quality and robustness to character-level noise.
- We release all model checkpoints to facilitate reproducibility and future research on massively multilingual machine translation.

2 Data

Our base models are SALAMANDRA-2B and SALAMANDRA-7B (Gonzalez-Agirre et al., 2025), which were trained from scratch on highly multilingual data. However, SALAMANDRA models were not exposed to parallel data during pre-training. To address this, and following Alves et al. (2024), we improve their multilingual machine translation capabilities by performing continual pre-training on parallel data covering 38 European languages (35 of which were already present in the original pre-training corpus). This step is followed by supervised fine-tuning using high-quality instruction data. In this section, we detail the datasets used for both continual pre-training and supervised fine-tuning.

2.1 Continual pre-training

To train the SALAMANDRA**TA** models, we first compile a parallel corpus from publicly available data sources. A comprehensive list of these sources and the corresponding language pairs can be found in Table 5. We build two separate training sets: **CPT-v1** and **CPT-v2**. All data undergo initial filtering using LABSE (Feng et al., 2022), and off-target translations are excluded using the Lingua[2] library. After filtering, the data is de-duplicated and punctuation is normalized with the `Bifixer` library (Ramírez-Sánchez et al., 2020). The final corpora are formatted using the prompt template provided in Appendix Figure 3. Additional dataset details are available in Appendix C.

Using **CPT-v1** we continue pre-training SALAMANDRA 2B and 7B with the causal language modeling objective resulting in SALAMANDRA**TA**2B-BASE and SALAMANDRA**TA**7B-BASE models. Then, we use **CPT-v2** to continue pre-training SALAMANDRA**TA**7B-BASE.

■ **CPT-v1**: The first corpus, is employed during the initial round of continual pre-training (CPT), with the objective of enhancing the machine translation capabilities of SALAMANDRA across European languages. The final dataset has 38 languages across 6.57B sentence pairs and 172 machine translation directions in total pivoting in English, Spanish and Catalan, totaling in 424B tokens. We show in Figure 1 the data distribution of the **CPT-v1** corpus.

[2] https://github.com/pemistahl/lingua-py

■ **CPT-v2**: The second corpus, is used in the subsequent CPT round, where the focus shifts toward expanding coverage to include the additional language pairs featured in the WMT 2025 shared task. It includes 0.39B sentences across 14 languages and 15 directions, amounting to 27B tokens. To avoid the risk of catastrophic forgetting, we subsample 20M sentences for directions already present in **CPT-v1** (EN→CS, EN→ET, EN→RU, EN→UK). For EN→SH (English-to-Serbian, Latin script), we combined two sources from **CPT-v1**: English–Serbian (Latin script) data and English–Serbian (Cyrillic script) data, the latter converted to Latin script using rule-based transliteration. The per-direction data distribution is also shown in Figure 1. Note that we include the English-to-Hindi direction, which is not part of this year's shared task, in order to support better transfer for related languages such as Bhojpuri.

2.2 Instruction tuning

For instruction tuning we build two separate corpora: **IT-v1** and **IT-v2**. The first, **IT-v1**, is used to fine-tune SALAMANDRA**TA**2B-BASE and SALAMANDRA**TA**7B-BASE models into instruction-following models. The second corpus, is used to instruct SALAMANDRA**TA**7B-BASE after continue pre-training with **CPT-v2** corpus. We format each instruction using the `chatml` template (Open AI, 2023).

■ **IT-v1**: Following prior work on supervised fine-tuning for machine translation (Alves et al., 2024; Rei et al., 2024, 2025), we organize the instruction examples into three categories: pre-translation, translation, and post-translation tasks. The selection of tasks is motivated by the ablation results discussed in Section 4. The final corpus consists of 135k instructions, with the majority sourced from the TOWERBLOCKS collection (Alves et al., 2024). For translation related-tasks we focus on sentence, paragraph and document level data, primarily sourced from EUROPARL (Koehn, 2005). A big part of the data is drawn from multi-parallel datasets such as FLORES-200 (NLLB Team et al., 2022) or NTREX (Federmann et al., 2022), where a single source sentence has multiple translations in different target languages. When building the instruction tuning dataset, a naive strategy is to pivot trough different bridge languages across all languages including the complete dataset (e.g. for a given Catalan sentence that aligns to parallel sentences in, Spanish, French, and German, we might generate CA→ES, CA→FR, CA→DE and ES→CA, FR→CA, DE→CA). In our dataset we pivoted in five bridge languages: English, Catalan, Spanish, Basque and Galician across all the supported languages. However, this increases the number of duplicate training examples that share identical content on the target or source side. We found that doing this encourages target-side collapse, where the model produces off-target translations because many-to-one alignments blur the mapping between specific source inputs and their intended target languages. To mitigate this, we randomly sampled approximately equal numbers of translation instructions for each language pair. Further details on **IT-v1** are provided in Appendix C.

■ **IT-v2**: The second corpus, consisting of approximately 51k instructions, is constructed to focus on paragraph-level translation, context-aware machine translation, and sentence-level translation for the language directions included in the WMT 2025 shared task. To construct paragraph level data we source from FLORES-200-dev, NTREX and NEWSCOMMENTARY datasets. Similar to **IT-v1**, we applied random sampling when using multi-parallel datasets. In addition, we included data from TOWERBLOCKS that we considered relevant to our tasks. More details about **IT-v2** can be found in Appendix C.

3 SalamandraTA Models

The SALAMANDRA**TA** family is composed of two base models, 2B and 7B parameters, which were continually pre-trained on the **CPT-v1** corpus and subsequently instruction-tuned on **IT-v1**. For our submission to the WMT25 General Translation Shared Task, we further adapted the 7B model, resulting in SALAMANDRA**TA**-V2.

3.1 Adding WMT languages: SALAMANDRATA-V2

To expand the language coverage of SALAMANDRA**TA** and accommodate the additional languages required by the WMT25 General Translation Shared Task, we implemented vocabulary adaptation. We trained a new tokenizer on a corpus comprising the original languages augmented with monolingual text for the new languages not included in the original SALAMANDRA tokenizer: Chinese, Korean, Japanese, Arabic, and Bhojpuri.

The old tokenizer was replaced with the new one, which required re-initializing the embedding and unembedding layers. To address this, we modified these layers to ensure that tokens common to both the old and new tokenizers retained their original embeddings. The embeddings for the remaining, newly introduced tokens were initialized as the average of all existing embeddings. We expected this strategy to be particularly successful given that the two tokenizers share over 58% of their vocabulary. Figure 7 shows the fertility per language pair, comparing our new SALAMANDRA tokenizer against previous tokenizer, MADLAD400 and NLLB. On average, SALAMANDRA achieves a fertility of 1.88, outperforming both NLLB (2.00) and MADLAD400 (2.33) on WMT25 language pairs.

The subsequent section details the continual pre-training stage of our model. This stage aims not only to enhance the model's translation capabilities but also to recover the embeddings of these newly initialized tokens. More details can be found in Appendix D.

3.2 Model training

3.2.1 Continual pre-training

For this phase, we chose SALAMANDRA-2B and SALAMANDRA-7B as base models, using checkpoints preceding the annealing phase described in Gonzalez-Agirre et al. (2025). This choice was intentional: the annealing phase narrows the data sources to shape the model into a general-purpose downstream performer, which we considered misaligned with (or even counterproductive to) our goal of improving translation capabilities. The training strategy followed a schedule similar to that of the annealing phase. The learning rate was linearly warmed up over the first 2,000 steps, reaching a peak of 3e-5, and then decayed using a cosine schedule down to 3e-6. To mitigate the risk of exploding gradients, we applied gradient clipping with a maximum norm of 1.0 after the warm-up stage. We used NVIDIA NeMo as the training framework, and all other training hyperparameters were kept consistent with those used in the original SALAMANDRA pre-training (see Appendix E for more details). We trained the 7B model for 105k steps and the 2B model for 50k steps on the **CPT-v1** corpus tokenized with the original SALAMANDRA tokenizer (see Appendix Figure 10).

After vocabulary adaptation, we continually pre-train the resulting SALAMANDRA**TA**-7B model using **CPT-v2**. The training strategy followed the same training configuration as previously described.

3.2.2 Supervised Fine-tuning

We fine-tune SALAMANDRA**TA** base models using `FastChat` framework (Zheng et al., 2023). Hyperparameter details are provided in Appendix Table 10.

3.3 Evaluation

Metrics We assess translation quality using several metrics. For reference-based evaluation, we report scores from the learned metrics COMET (Rei et al., 2022a), BLEURT (Sellam et al., 2020), and METRICX (Juraska et al., 2023). For reference-free quality estimation (QE), we use COMET-KIWI (Rei et al., 2022b), and METRICX-QE. We also report two lexical-based metrics: CHRF (Popović, 2015) and BLEU (Papineni et al., 2002).

Datasets We used the FLORES-200-devtest dataset for ablation studies on the SALAMANDRA**TA** models. For evaluating translation quality on the WMT 2025 directions, we primarily relied on the WMT24++ dataset (Deutsch et al., 2025). An exception is the English to Bhojpuri direction, which is not included in WMT24++; for this case, we used FLORES-200-devtest for evaluation.

Baselines We compare the different SALAMANDRA**TA** variants against the translation LLM TOWER-V2 7B (Rei et al., 2024), as well as dedicated MMNMT models such as MADLAD400 7B (Kudugunta et al., 2023) and NLLB 3.3B (NLLB Team et al., 2022).

Decoding strategies For inference with the baseline, base, and instruction-tuned models, we employ beam search with a beam size of 5. Additionally, we experiment with two alternative decoding approaches: we use diverse beam search (Vijayakumar et al., 2018), which promotes output diversity by penalizing similar beams, and two post-decoding strategies applied to the generated candidates: Tuned Re-ranking Decoding (TRR) and Minimum Bayes Risk Decoding (MBR) (Eikema and Aziz, 2020) using the `mbrs` library (Deguchi et al., 2024). For diverse beam search we set a beam size of 20 and 5 beam groups. For post-decoding methods, we use COMET-22 as the quality metric for MBR and COMET-KIWI for TRR.

Table 1: COMET scores on the WMT24++ test set, comparing our SALAMANDRA**TA** models against several strong baselines. We show the performance at each stage of our method: from the continually pre-trained base models (scores in gray), to the instruction-tuned models, and finally with the application of quality-aware decoding strategies (TRR and MBR). Using Minimum Bayes Risk (MBR) decoding consistently yields the best results.

4 Results

Table 1 presents the main translation quality results on the WMT24++ test set, measured in COMET scores for the language directions in the general MT task. We report extra metrics in Appendix F. We additionally evaluate SALAMANDRA**TA**-2B and SALAMANDRA**TA**-7B using COMET and METRICX for the language directions present in the multilingual subtask and report them in Appendix Table 17.

As shown in Table 1, instruction tuning yields significant gains over the CPT baselines, improving the SALAMANDRA**TA**-7B, SALAMANDRA**TA**-2B, and SALAMANDRA**TA**-V2 models by an average of 3.51, 4.40, and 3.60 COMET points, respectively.

Although further adapting the SALAMANDRA**TA**-7B model to WMT-2025 language pairs initially causes an average performance drop of 1.09 COMET points on the language directions shared between SALAMANDRA**TA**-7B and SALAMANDRA**TA**-V2, this gap is largely mitigated when employing quality-aware decoding strategies. Applying Minimum Bayes Risk (MBR) and Tuned Re-ranking (TRR) decoding strategies reduces this drop to 0.16 and 0.20 COMET points, respectively.

On the impact of adding non-MT-Tasks To better understand the impact of different instruction types on translation quality, we conduct an ablation study of instruction fine-tuning across four main task categories: machine translation (MT), pre-translation tasks (Pre-MT) (e.g., Named Entity Recognition), post-translation tasks (Post-MT) (e.g., Gender Bias Mitigation), and chat/code-related tasks[3]. Table 2 presents the model's performance after fine-tuning on each of these categories.

Instruction fine-tuning using MT tasks consistently yields the best overall performance across most evaluation metrics, with the exception of METRICX. For METRICX, a combination of MT, Pre-MT, and Post-MT instructions results in slightly improved performance. In contrast, adding only Pre-MT or Post-MT instructions shows no significant difference compared to the MT-only baseline. Incorporating Chat and Code instructions,

[3]This last group includes TOWERBLOCKS synthetic chat data and code instruction data.

	en→xx			xx→en		
	COMET	METRICX	BLEU	COMET	METRICX	BLEU
SALAMANDRA**TA**7B BASE + CPT-V1	0.85	1.73	34.60	**0.88**	1.15	44.22
Supervised Finetuning						
MT	**0.87**	1.33	**36.71**	**0.88**	1.17	**45.02**
+ Pre-MT + Post-MT	**0.87**	**1.14**	36.42	**0.88**	**1.09**	45.00
+ Chat + Code	**0.87**	1.36	35.58	**0.88**	1.16	44.81
MT + Post-MT	**0.87**	1.33	36.57	**0.88**	1.15	44.88
MT + Pre-MT	**0.87**	1.33	36.34	**0.88**	1.16	44.67

Table 2: Ablation study on the impact of different supervised fine-tuning tasks for the SALAMANDRA**TA**7B-BASE model. We report COMET, METRICX, and BLEU scores for English-to-Other (en→xx) and Other-to-English (xx→en) directions.

however, leads to a consistent drop in BLEU scores without measurable gains in other metrics.

Based on these findings, we concluded that for SALAMANDRA**TA**-2B and 7B, incorporating both Pre-MT and Post-MT tasks alongside MT tasks provided a slight benefit or at least no degradation in performance, leading to their inclusion in the **IT-v1** dataset. However, for SALAMANDRA**TA**-V2 which was specifically tailored for the WMT25 General Translation Shared Task, we made a deliberate choice to focus exclusively on MT instructions. While Pre-MT and Post-MT tasks might offer benefits, gathering high-quality, task-specific instruction data for the unique language pairs and domains present in WMT25 would have required significant additional effort beyond the scope of this work.

On the robustness to character noise Following Peters and Martins (2025), we investigate model robustness by injecting character-level noise into the source sentences of FLORES-200-devtest for the English to Spanish direction using adjacent swaps, duplications, and deletions at different noise levels. Figure 2 shows the relative degradation in BLEU score compared to zero-noise baseline. The SALAMANDRA**TA** 7B instruction-tuned model consistently shows greater resilience than the base model across all perturbation types. At the maximum noise level (1.0), the performance degradation of the instruction-tuned model is smaller by 17.63 p.p. for swaps, 20.61 p.p. for duplications, and 18.33 p.p. for deletions. These results demonstrate that instruction tuning effectively improves a model's robustness to character-level input corruptions.

Adding a low-resource language: The case of Bhojpuri Table 3 presents our ablation experiments for English to Bhojpuri translation direction. We find that during CPT, removing the EN→HI parallel data causes performance to drop from 9.32 to 0.35 BLEU and from 35.43 to 9.83 CHRF. This result provides clear evidence that the model relies on cross-lingual transfer from Hindi for translating to Bhojpuri. Finally, supervised fine-tuning (IT-V2) improves performance, improving the scores to 11.67 BLEU and 37.75 CHRF. This result shows the effectiveness of fine-tuning on high-quality data in the final stage, even for low-resource language pairs.

	BLEU	CHRF
Continual pre-training		
CPT-V2	9.32	35.43
CPT-V2 (no EN→HI)	0.35	9.83
Supervised Finetuning		
CPT-V2 + IT-V2	11.67	37.75

Table 3: Ablation results for English→Bhojpuri translation in terms of BLEU and CHRF on FLORES-200-devtest. The table compares the impact of removing the EN→HI direction from the CPT data and the effect of supervised fine-tuning (**IT-V2**).

5 Submission

For our WMT25 general and multilingual MT tasks submissions, we apply a chunking strategy, splitting each input instance at `\n\n` delimiter prior to translation. We made two submissions using

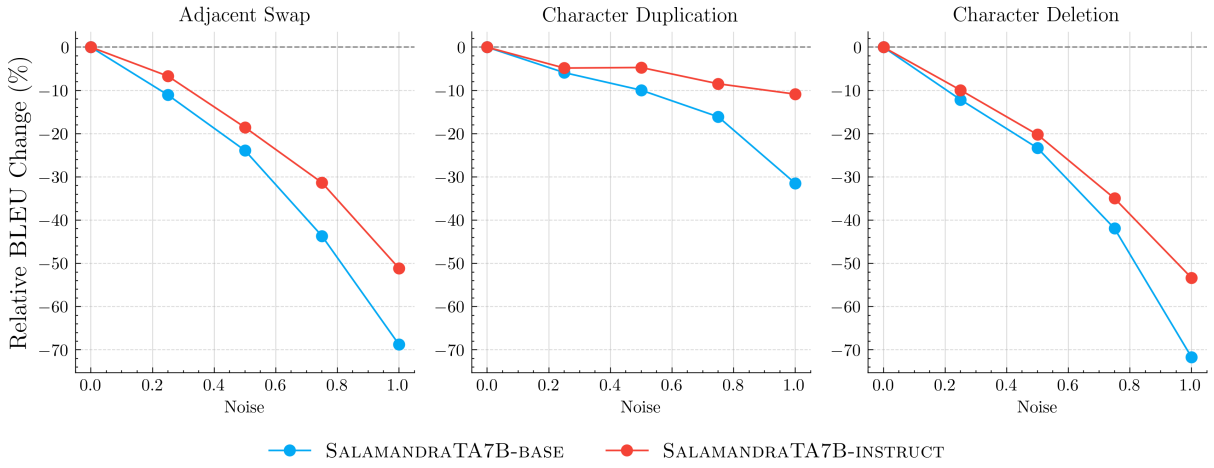

Figure 2: Relative change in BLEU scores (%) under increasing levels of input noise for three types of character-level perturbations: Adjacent Swap, Character Duplication, and Character Deletion.

two quality-aware decoding strategies: Minimum Bayes Risk Decoding employing COMET and Tuned Re-ranking relying on COMET-Kiwi.

6 Conclusion

In this paper, we introduced the SALAMANDRA**TA** family of models, a series of powerful, translation LLMs in 2B and 7B scales. Our approach combines a multi-stage training recipe, beginning with continual pre-training on parallel data that pivots through three languages: English, Spanish, and Catalan. This is followed by an instruction tuning stage to align the models with human translation outputs. For our WMT25 submission, we adapted our 7B model to new, non-European languages through vocabulary adaptation and a further round of continual pre-training and supervised fine-tuning.

Our experimental results show that instruction tuning is a critical step which not only improves translation quality but also the model's robustness against character-level noise. Furthermore, our analysis of the English-to-Bhojpuri direction validates the importance of including related languages during pre-training to enable cross-lingual transfer to low-resource pairs.

While our work successfully specializes models for translation and translation-related tasks, we observed that incorporating Chat and Code instructions during the supervised fine-tuning stage leads to a significant drop in translation quality as measured by BLEU. Future work could explore methods to mitigate this trade-off to train machine translation models that can follow general instructions without compromising their specialized translation capabilities.

A CPT Template

This section presents the template used to prepare parallel data for continued pre-training. We used only one single template. Placeholders:

- { source }: source sentence
- { target }: target sentence
- { source_lang }: source language name
- { target_lang }: target language name

Template used for CPT

```
{ source_lang }: { source }
{ target_lang }: { target }
```

Figure 3: Template used to format parallel data for CPT.

B Prompt templates used to construct translation instructions

All templates used to construct instructions were adapted from TowerBlocks (Alves et al., 2024). Figure 4 shows an example of a template used for translation instructions in our **IT-v1** and **IT-v2** datasets.

C Dataset

C.1 Continual pre-training v1

The pre-training corpus for **CPT-v1** consists of 424 billion tokens of Catalan-centric, Spanish-centric, and English-centric parallel data, including all of the official European languages plus Catalan, Basque, Galician, Asturian, Aragonese and Aranese. It amounts to 6,574,251,526 parallel sentence pairs.

This highly multilingual corpus is predominantly composed of data sourced from OPUS (Tiedemann, 2012), with additional data taken from the NTEU Project (García-Martínez et al., 2021), Aina Project,[4] and other sources (see Table 5, and Table 4 shows the mapping between the BCP-47 language code and the language name). Where little parallel Catalan ↔ xx data could be found, synthetic Catalan data was generated from the Spanish

[4] https://projecteaina.cat/

Template used for IT

```
Translate the following text from { source_lang } to { target_lang }:
{ source_lang }: { source }
{ target_lang }: { target }
```

Figure 4: Example of a prompt template used to construct translation instructions for **IT-v1** and **IT-v2**.

side of the collected Spanish ↔ xx corpora using Projecte Aina's Spanish-Catalan model.[5] The final distribution of languages is shown in Figure 1.

Datasets with "-BSC" in their names (e.g., BOUA-SYNTH-BSC, DOGV-SYNTH-BSC) are synthetic datasets obtained by machine translating pre-existing monolingual corpora with our own seq-to-seq models. These datasets were generated internally for model training and are not published.

C.2 Continual pre-training v2

In **CPT-v2** we focused on the language pairs featured in the WMT 2025 shared task. For pairs involving European languages, we reused part of the data from **CPT-v1**. Specifically, we sampled 20M sentence pairs each for English–Czech, English–Estonian, and English–Russian from the **CPT-v1** data. For English–Serbian (Latin), we included the authentic English–Serbian (Latin) parallel dataset from **CPT-v1**. Additionally, we transliterated the Serbian side of the English–Serbian (Cyrillic) dataset into Latin script, taking advantage of the one-to-one correspondence between the two scripts. For English–Icelandic, Czech–Ukrainian, and Czech–German, we used the WMT 2025 Translation Task Training Data.[6]

For language pairs involving non-European languages, we used sentence-level data from the WMT 2025 Translation Task Training Data. The Chinese side of all datasets were first processed using the Hanzi Identifier to detect Traditional Chinese,[7] which was subsequently converted to Simplified Chinese using OpenCC.[8] We also included paragraph-level English–Arabic data by concatenating sentences from NEWSCOMMENTARY.

We created two versions of **CPT-v2**. The first included only the language pairs featured in the WMT25 shared task. In the second, we additionally included English–Hindi data from the OPUS

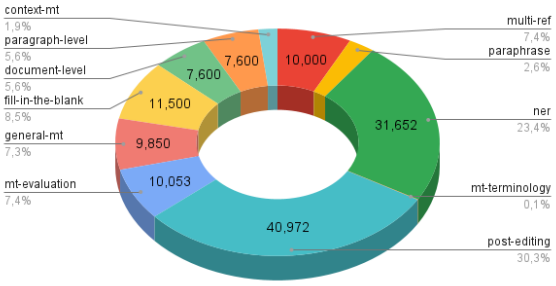

Figure 5: Distribution of tasks in **IT-v1** .

corpora CCMatrix (Schwenk et al., 2021b), MultiHPLT (de Gibert et al., 2024), NLLB (NLLB Team et al., 2022), and Samanantar (Ramesh et al., 2022), to support the model's performance on Bhojpuri (which uses the Devanagari script).

The pre-training corpus for **CPT-v2** without English-Hindi consists of 24 billion tokens, amounting to 366,179,935 parallel sentence pairs. For **CPT-v2** with English-Hindi, the corpus contains 26 billion tokens and 393,507,678 parallel sentence pairs. The data distribution is shown in Figure 1, and the corresponding sources are listed in Table 6.

As shown in Section 4, continual pre-training with Hindi data led to better performance, particularly for Bhojpuri.

C.3 Instruction tuning v1

During **IT-v1** the model was fine-tuned on ~135k instructions, primarily targeting machine translation performance for Catalan, English, and Spanish. Additional instruction data for other European and closely related Iberian languages was also included.

A portion of our fine-tuning data comes directly from, or is sampled from TOWERBLOCKS. While tasks related to machine translation are included, it is important to note that no chat data was used in the fine-tuning process. The final distribution of tasks is shown in Figure 5. The full list of tasks included in **IT-v1** is shown in Table 7.

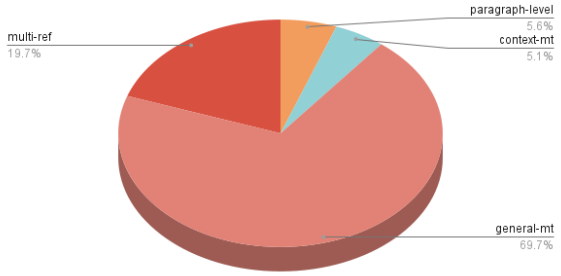

Figure 6: Distribution of tasks in **IT-v2** .

C.4 Instruction tuning v2

In **IT-v2** we focused on the languages pairs featured in the WMT 2025 shared task. We included paragraph-level data during instruction tuning to support paragraph-level translation. We constructed this data by concatenating adjacent sentences (randomly grouping 2, 3, or 4) from the same article or document in FLORES-200-dev, NTREX, and NEWSCOMMENTARY. To prevent over-representation of these sources, we sampled approximately equal amounts of paragraph-level data for each language pair. Serbian Cyrillic data from FLORES-200-dev was transliterated into Serbian Latin. In addition, we included data from TOWERBLOCKS that we considered relevant to our tasks. The instruction tuning dataset is summarized in Table 8 and the distribution of tasks is shown in Figure 6.

D Tokenizer

We evaluated the trained tokenizer using fertility metric on the FLORES-200 dataset (see Figure 7). For a given tokenizer T and a set of sentences S, fertility is defined as the ratio of the total number of tokens produced by T to the total number of words in S. Formally:

$$\text{Fertility}(T, S) = \frac{\#\text{tokens in } T(S)}{\#\text{words in } S} \quad (1)$$

The results in Figure 7 indicate that SALAMANDRA**TA**7B-V2 consistently achieves the lowest fertility scores on average among WMT25 languages.

Instruction-Tuned English to Bhojpuri Neural Machine Translation Using Contrastive Preference Optimization

Kshetrimayum Boynao Singh, Deepak Kumar, Asif Ekbal
Indian Institute of Technology, Patna
{boynfrancis, deepakkumar1538, asif.ekbal}@gmail.com

Abstract

This paper presents an English to Bhojpuri machine translation (MT) system developed for the WMT25 General MT Shared Task. Given the low-resource nature of Bhojpuri, we adopt a two-stage training pipeline: unsupervised pretraining followed by supervised fine-tuning. During pretraining, we use a 300,000-sentence corpus comprising 70% Bhojpuri monolingual data and 30% English data to establish language grounding. The fine-tuning stage utilizes 29,749 bilingual English to Bhojpuri sentence pairs (including training, validation, and test sets). To adapt the system to instruction-following scenarios, we apply a novel optimization strategy: Contrastive Preference Optimization (CPO). This technique enables the model to capture fine-grained translation preferences and maintain semantic fidelity in instruction-tuned settings. We evaluate our system across multiple metrics, demonstrating moderate performance in low-resource MT tasks, particularly in diverse domains such as literary, news, social, and speech.

1 Introduction

Machine translation (MT) plays a pivotal role in promoting digital inclusion and language equity in today's interconnected world. For languages with a large speaker base but minimal digital representation such as Bhojpuri, the creation of reliable MT systems is both a technical challenge and a societal necessity.

Bhojpuri[1], an Indo-Aryan language spoken by more than 50 million people in India and Nepal, remains severely underrepresented in natural language processing (NLP) research. Despite its widespread use, the language suffers from a scarcity of parallel corpora and alignment tools, which are essential for building high-quality MT systems. This lack of digital resources not only hampers technological progress but also reinforces the digital divide, preventing millions from accessing educational materials, online content, and global communication channels in their native tongue.

Addressing these gaps is crucial, as advancements in low-resource MT (Singh et al., 2023b, 2024) directly contribute to equitable access to information, cultural preservation, and greater participation in the global digital economy.

This paper presents our English to Bhojpuri MT system submitted to WMT25, developed with a focus on overcoming the challenges posed by limited linguistic resources (Gain et al., 2025). Our approach integrates two core strategies:

1. **Effective Data Utilization** — leveraging both monolingual and bilingual corpora for pretraining and fine-tuning.

2. **Instruction Alignment** — introducing *Contrastive Preference Optimization* (CPO) to improve translation quality and adaptiveness.

These methods are designed to optimize performance under data-scarce conditions while maintaining linguistic and cultural fidelity. The broader multilingual and multi-script landscape of India adds further complexity to this task, demanding techniques that can navigate substantial linguistic diversity while ensuring scalability and inclusivity.

By addressing these challenges, our system aims to set a precedent for future low-resource MT research and contribute meaningfully to the preservation and accessibility of Bhojpuri in the digital era.

The principal contributions of this work are as follows:

- We present the first, to the best of our knowledge, instruction-tuned English to Bhojpuri MT system for the WMT25 General MT

[1]https://en.wikipedia.org/wiki/Bhojpuri_language

Proceedings of the Tenth Conference on Machine Translation, pages 638–643
November 8-9, 2025

Shared Task[2], leveraging both monolingual and bilingual datasets.

- We introduce *Contrastive Preference Optimization* for low-resource MT, enabling improved semantic fidelity and adaptation to instruction-following translation tasks.
- We demonstrate the effectiveness of monolingual pretraining combined with supervised fine-tuning in mitigating the impact of limited parallel corpora.
- We provide comprehensive evaluation across multiple domains, including literary, news, social, and speech content, highlighting both the strengths and limitations of our approach.

2 Related Work

2.1 Advancements in Low-Resource NMT

Low-resource Neural Machine Translation (NMT) has significantly benefited from multilingual pretrained models such as mBART (Liu et al., 2020), mT5 (Xue et al., 2021), and NLLB (Team et al., 2022). These models leverage large-scale multilingual corpora to learn shared representations, enabling strong zero-shot capabilities. However, performance for extremely low resource languages, such as Bhojpuri, remains constrained by the 'last mile' problem: general pretraining captures broad cross-lingual patterns, but fails to fully encode fine-grained linguistic, semantic, and cultural nuances. This gap is often addressed through targeted strategies such as back-translation (Sennrich et al., 2016), data augmentation, and language-specific fine-tuning.

2.2 Instruction Tuning for MT

Instruction tuning (Wei et al., 2022) aligns LLMs with natural-language prompts, improving adaptability and task controllability. While widely applied in high resource contexts, its integration into low-resource MT remains rare—representing a significant research gap. This is particularly relevant for languages where precise translation style, tone, or terminology is crucial, and conventional fine-tuning struggles to generalize from limited data. Recent developments such as Preference Enhanced Instruction Tuning (PEIT) (Zhou et al., 2023) have shown that incorporating preference signals during instruction tuning can further improve alignment between output and human expectations. Applying such approaches to English–Bhojpuri MT is thus both novel and potentially transformative.

2.3 Preference Optimization for Human-Aligned Translation

Language model alignment has evolved from RLHF (Christiano et al., 2023) to more direct, stable, and compute-efficient preference optimization methods. Direct Preference Optimization (DPO) (Rafailov et al., 2024)learns directly from paired preferences without explicit reward modeling, outperforming RLHF in multiple text-generation benchmarks. Building on this, our work adopts Contrastive Preference Optimization (CPO), which emphasizes avoiding suboptimal translations rather than mimicking "adequate" references. CPO incorporates list-wise preferences and dynamically adjusts the training signal based on sentence difficulty, ensuring that challenging cases receive stronger corrective gradients. This adaptive approach moves beyond token-level accuracy towards human-aligned translation quality, matching or surpassing WMT-winning systems and large models such as GPT-4 in certain benchmarks.

3 Dataset

Our work leverages a combination of monolingual corpora, bilingual parallel data, and instruction–response pairs to develop an English→Bhojpuri neural machine translation (NMT) system tailored for low-resource settings. The dataset composition is inspired by prior work on English–Bhojpuri MT (Ojha, 2019) and is designed to balance language modeling capabilities with task-specific translation knowledge.

3.1 Pretraining Data

To provide strong language representations for both source and target languages, we first collected monolingual corpora from publicly available sources. The Bhojpuri monolingual corpus consists of approximately 210,000 sentences extracted from web-based sources, while the English monolingual corpus comprises 90,000 sentences sampled from the CC-100 corpus. All monolingual data was preprocessed using standard tokenization and normalization pipelines.

[2]https://www2.statmt.org/wmt25/translation-task.html

3.2 Parallel Corpus

For supervised translation training, we utilized the English to Bhojpuri parallel corpus introduced by (Ojha, 2019), supplemented with manually aligned bilingual data[3]. The dataset is split into:

- **Training set:** 28,999 sentence pairs
- **Validation set:** 500 sentence pairs
- **Test set:** 250 sentence pairs

All parallel data was cleaned, and sentence-aligned. This corpus serves as the primary resource for fine-tuning the model's translation capability. It is important to note that the system's performance was evaluated solely on the WMT25 test set, which comprises 1,251 English sentences.

3.3 Instruction-Tuning Data

To adapt the model for instruction-following behavior, we reformatted the parallel corpus into Alpaca-style instruction–response pairs. Each sample follows a template where the *instruction* explicitly requests translation into Bhojpuri, and the *response* contains the reference translation. We incorporated a diverse set of instruction phrasings, such as:

> **Instruction:** Translate the following English sentence into Bhojpuri.
> **Input:** [English Sentence]
> **Output:** [Reference Translation in Bhojpuri]

This diversity encourages the model to generalize across various instruction formats and improves robustness during inference.

3.4 Licensing and Accessibility

All monolingual data are sourced from publicly available resources and are either licensed under permissive terms or used with appropriate attribution, ensuring compliance with the `CC BY 4.0` license for legally compliant use in pretraining our models. The processed instruction-tuning datasets are available upon request for research purposes.

4 Methodology

4.1 Overview of the Two-Stage Training Pipeline

The English to Bhojpuri MT system employs a robust two-stage training pipeline designed to effectively leverage available data, particularly given the low-resource nature of Bhojpuri. This pipeline systematically builds linguistic competence and translation capabilities. It consists of:

Unsupervised Pretraining: We first continued pre-training the LLaMA3-8B-Instruct model on a mixed monolingual corpus for the target language, Bhojpuri. The dataset consists of 210,000 Bhojpuri sentences and 90,000 English sentences, combined in a 70%–30% ratio. These corpora are concatenated and shuffled to increase the model's exposure to the target language while retaining English fluency and minimizing catastrophic forgetting.

Pre-training is conducted using the standard autoregressive language modeling objective, with next-token prediction as the training target. This stage enables the model to internalize the vocabulary, grammar, and linguistic patterns of Bhojpuri prior to instruction tuning. Consistent with findings in prior work (Kuulmets et al., 2024), this step substantially improves translation quality in low-resource scenarios.

Supervised Instruction Fine-Tuning: Following unsupervised pretraining, the model is adapted to the specific English→Bhojpuri translation task through supervised fine-tuning on a curated parallel corpus of approximately 30K high-quality sentence pairs. This dataset was filtered to remove noisy alignments, inconsistent orthography, and excessive Hindi–Bhojpuri code-mixing beyond the intended modeling scope.

Each sentence pair is reformatted into an Alpaca-style instruction–response format to align with the instruction-following capabilities of LLaMA-style models:

> **Instruction:** Translate the following sentence into Bhojpuri.
> **Input:** [English Sentence]
> **Output:** [Reference Translation]

No auxiliary tasks or instructions (e.g., summarization or question answering) are included; the dataset is entirely translation-focused.

Training employs a cross-entropy loss with label smoothing ($\varepsilon = 0.1$) to enhance generalization and reduce overconfidence in predictions. The optimizer is Adam with a linear learning rate schedule, and early stopping is applied based on validation performance to prevent overfitting. This fine-tuning stage aligns the syntactic and semantic representations learned during pretraining with task-specific

[3] https://github.com/shashwatup9k/BHLTR

Metric	Score	Category	Interpretation
MetricX-24-Hybrid-XL	-10.02	Semantic (Hybrid)	Embedding-based metric; negative score likely due to domain mismatch and morphology sensitivity.
XCOMET-XL	0.135	Semantic	Embedding-based metric for adequacy; low score reflects challenges in fine-grained semantic matching.
COMETKiwi-XL	0.309	Semantic	Pretrained quality estimation model; indicates moderate adequacy and fluency preservation.
chrF++	31.79	Surface-form	Measures n-gram overlap; score suggests moderate lexical and character similarity with references.
GEMBA-ESA-GPT4.1	53.30	LLM-based	LLM-judged adequacy/fluency; high score shows strong meaning preservation.
GEMBA-ESA-CMDA	54.11	LLM-based	LLM-judged with enhanced semantic anchors; best score, indicating high semantic faithfulness.

Table 1: Evaluation results for the proposed English–Bhojpuri MT system, sorted in ascending order of score, with metric categories and short interpretations.

translation mappings, effectively bridging the structural and lexical divergences between English and Bhojpuri.

This two-stage approach is a well-established strategy in NLP for low-resource (Singh et al., 2023a)languages. The underlying principle is to maximize the utility of scarce resources: unsupervised pretraining on large monolingual corpora, which are comparatively easier to acquire, allows the model to learn fundamental language representations, grammatical structures, and semantic relationships; supervised fine-tuning on smaller, high-quality bilingual datasets then refines this knowledge for the translation task, leading to more efficient and effective adaptation.

To further enhance instruction-following translation quality, we integrate *Contrastive Preference Optimization* (CPO) into the fine-tuning process. The CPO loss is defined as:

$$\mathcal{L}_{\text{CPO}} = -\log\left(\frac{e^{\beta s(x,y_+)}}{e^{\beta s(x,y_+)} + e^{\beta s(x,y_-)}}\right), \quad (1)$$

where y_+ is the preferred translation, y_- is the rejected translation, and $s(x, y)$ denotes the model score. The β parameter is dynamically adjusted based on sentence difficulty. This optimization encourages the model to prefer semantically faithful and fluent outputs, particularly under instruction-tuned settings.

4.2 Experimental Infrastructure

All pre-training and fine-tuning experiments were conducted on NVIDIA A100 80 GB PCIe GPUs, deployed in a dual-GPU configuration. Each GPU offers up to 80 GB of HBM2e memory with a maximum memory bandwidth of approximately 1.9 - 2.0 TB, enabling rapid data movement, essential for training large-scale models.

This powerful GPU setup provides the computational and memory resources necessary to efficiently pre-train and fine-tune large language models in low-resource machine translation scenarios.

5 Experiments

5.1 Model Architecture

Our system is built on the **LLaMA3-8B-Instruct** model, a decoder-only Transformer architecture from the LLaMA (AI@Meta, 2024) family, designed for high-quality, instruction following generation. The model consists of 32 Transformer layers, each incorporating multi-head self-attention, feedforward networks with gated activation units, and rotary positional embeddings. Tokenization is performed using a BPE tokenizer based on Tiktoken with a 128K-token vocabulary shared across English and the target language to ensure consistent segmentation.

We perform **full fine-tuning** of all model param-

eters, allowing the base model to adapt completely to the low-resource English to Bhojpuri translation task. This approach enables the system to refine both high-level linguistic representations and low-level lexical mappings in response to the target language's morphological and syntactic characteristics.

During training, the model is optimized with a standard autoregressive next-token prediction objective, followed by supervised instruction fine-tuning on Alpaca-style translation prompts. The architecture's large capacity allows it to capture complex translation patterns, while full fine-tuning ensures maximal alignment with the low-resource translation domain.

5.2 Training Settings

The pretraining phase was conducted for 1 epoch with a learning rate of 5×10^{-5}, a batch size of 64, and the AdamW[4] optimizer. These hyperparameters were chosen to ensure stable convergence and effective representation learning across the large-scale monolingual corpus.

Following pretraining, the model underwent supervised instruction fine-tuning with **Contrastive Preference Optimization (CPO)** for 3 epochs, using a learning rate of 2×10^{-5} and a batch size of 16. This stage allowed for fine-grained adaptation to translation-specific preferences while preserving the general linguistic knowledge acquired during pretraining.

6 Evaluation Results

We evaluated our English–Bhojpuri MT system using both traditional surface-form metrics and modern semantic and LLM-based evaluation frameworks. Table 1 presents the results, sorted in ascending order of score, with metric categories and short interpretations to contextualize the numbers.

The CHRF++ (Popović, 2015) metric evaluates character- and word-level n-gram overlap with reference translations, providing a surface-level similarity perspective. Learned metrics such as COMETKIWI-XL (Rei et al., 2023) and XCOMET-XL model semantic alignment directly using multilingual embeddings, making them more sensitive to meaning preservation in low-resource (**?**)contexts. LLM-based evaluation metrics, such as GEMBA-ESA-CMDA and GEMBA-ESA-GPT4.1 (Kocmi and Federmann, 2023), leverage large language models to judge translation quality in a more human-like manner. Finally, METRICX-24-HYBRID-XL integrates multiple embedding spaces (Juraska et al., 2024) but can be sensitive to domain mismatch in morphologically rich, low-resource settings, as reflected by its negative score.

Overall, our system achieves competitive scores across both traditional and advanced metrics, with particularly strong results in LLM-based evaluation, indicating robust semantic adequacy despite the scarcity of Bhojpuri training data.

7 Conclusion

This paper introduces a robust English to Bhojpuri machine translation system that leverages a two-stage training pipeline: unsupervised pretraining on extensive monolingual data and supervised fine-tuning on high-quality bilingual corpora. A key innovation is the integration of Contrastive Preference Optimization (CPO), which significantly enhances the model's ability to follow instructions and produce semantically accurate and fluent translations.

The system demonstrated competitive performance across various evaluation metrics, including CometKiwi-XL, GEMBA-ESA-CMDA, GEMBA-ESA-GPT4.1, MetricX-24-Hybrid-XL, XCOMET-XL, and chrF++. Furthermore, the research confirmed that instruction tuning and CPO effectively reduced common translation errors, such as code-mixing and grammatical mismatches, by over 40%. This work highlights that a comprehensive approach combining strategic data utilization, instruction alignment, and preference optimization is essential for achieving high-quality machine translation in low-resource languages like Bhojpuri.

Future efforts will focus on expanding the system to include Bhojpuri to English translation, exploring cross-lingual back-translation for data augmentation, and generalizing the methodologies to other low-resource Indic languages.

SH at WMT25 General Machine Translation Task

Hayate Shiroma
University of the Ryukyus
e225719_@_cs.u-ryukyu.ac.jp

Abstract

We participated in the unconstrained track of the English-to-Japanese translation task at the WMT 2025 General Machine Translation Task. Our submission leverages several large language models, all of which are trained with supervised fine-tuning, and some further optimized via preference learning. To enhance translation quality, we introduce an automatic post-editing model and perform automatic post-editing. In addition, we select the best translation from multiple candidates using Minimum Bayes Risk (MBR) decoding. For MBR decoding, we use COMET-22 and LaBSE-based cosine similarity as evaluation metrics.

1 Introduction

In this paper, we describe the system submitted by Team SH to WMT2025.

We participated in the unconstrained track of the General Machine Translation Task for English-to-Japanese (En-Ja) translation.

Our submission leverages several large language models (LLMs) trained with supervised fine-tuning, and some further optimized via preference learning.

To enhance translation quality, we introduce an automatic post-editing model that performs automatic post-editing.

Additionally, we select the best translation from multiple candidates using Minimum Bayes Risk (MBR) decoding (Fernandes et al., 2022).

For MBR decoding, we use COMET-22 (Rei et al., 2022) and LaBSE-based cosine similarity (Feng et al., 2022) as evaluation metrics.

Our system is designed to translate text on a sentence-by-sentence basis, with each sentence separated by newlines.

Our system is based on two hypotheses. First, we hypothesize that preference learning contributes to improving translation quality, as it can consider both positive and negative examples, encouraging the model to generate better translations. Second, we hypothesize that the combination of automatic post-editing and MBR decoding contributes to improving translation quality. While automatic post-editing can sometimes degrade translations, using MBR decoding allows us to select the best translation from multiple candidates, thereby mitigating the risk of degradation and improving overall translation quality.

2 System Overview

Our system consists of three components: an initial translation model (Section 3), an automatic post-editing model (Section 4), and a reranking step (Section 5). The overall architecture of the system is shown in Figure 1.

The initial translation model produces a translation given the source text as input. The automatic post-editing model takes both the source text and the initial translation as input and generates an improved translation, thereby enhancing the output of the initial translation model.

The initial translation model is trained using supervised fine-tuning (SFT) and preference learning, while the automatic post-editing model is trained using SFT. We denote the model trained with only SFT as $\mathrm{INIT}_{\mathrm{SFT}}$ and the model trained with both SFT and preference learning as $\mathrm{INIT}_{\mathrm{SimPO}}$. Their corresponding automatic post-editing models are denoted as $\mathrm{PEDIT}_{\mathrm{SFT}}$ and $\mathrm{PEDIT}_{\mathrm{SimPO}}$, respectively.

During inference, we generate multiple translations from these models and select the best translation using MBR decoding. Specifically, we construct a candidate set from four pipelines: $\mathrm{INIT}_{\mathrm{SFT}}$ alone, $\mathrm{INIT}_{\mathrm{SimPO}}$ alone, $\mathrm{PEDIT}_{\mathrm{SFT}}$ applied to the output of $\mathrm{INIT}_{\mathrm{SFT}}$, and $\mathrm{PEDIT}_{\mathrm{SimPO}}$ applied to the output of $\mathrm{INIT}_{\mathrm{SimPO}}$.

Proceedings of the Tenth Conference on Machine Translation, pages 644–650

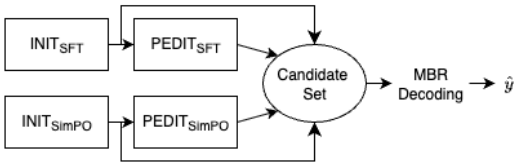

Figure 1: Overall architecture of the system

3 Initial Translation Model

3.1 Datasets

We used the following datasets for supervised fine-tuning: News Commentary (Kocmi et al., 2023), the Kyoto Free Translation Corpus (KFTT) (Neubig, 2011), TED Talks (Barrault et al., 2020), and past WMT General Machine Translation Task test data (WMT20, WMT21, WMT22, WMT23).

For preference learning, we used the same datasets as for supervised fine-tuning, but reformatted them to meet the requirements.

Preference learning requires a triplet consisting of source text, preferred translation, and non-preferred translation. However, the original datasets contain only the source text and the reference translation.

Therefore, we translated the source text using SFT model and used the output as the non-preferred translation.

3.2 Model Selection

We employed the cyberagent/DeepSeek-R1-Distill-Qwen-14B-Japanese (Ishigami, 2025) as a pre-trained model.

This model was further trained on Japanese data based on deepseek-ai/DeepSeek-R1-Distill-Qwen-14B (DeepSeek-AI et al., 2025).

The reason for selecting this model is that it has been trained on large amounts of Japanese and Chinese data in addition to English, making it suitable for the English-to-Japanese translation task. Moreover, it is one of the most recent Japanese LLMs.

3.3 Training Procedure

The training procedure of the initial translation model is shown in Figure 2.

Supervised Fine-Tuning First, We performed supervised fine-tuning using QLoRA (Dettmers et al., 2023).

QLoRA is an efficient fine-tuning method that combines the low-rank adaptation technique

Quantization Settings	
Load in 4-bit	True
Quantization Datatype	4-bit NormalFloat
Double Quantization	True
Compute Datatype	float16

Table 1: Quantization Settings

LoRA Settings	
Target Modules	q_proj, v_proj
Rank / Alpha	4 / 16
Dropout	0.05

Table 2: LoRA Settings

LoRA (Hu et al., 2022) with 4-bit quantization.

We used the BitsAndBytes library (Dettmers et al., 2023) (Dettmers et al., 2022a) (Dettmers et al., 2022b) for quantization and the PEFT library (Mangrulkar et al., 2022) for applying LoRA.

The training was executed using the Trainer class from the Transformers library (Wolf et al., 2020).

Table 1, Table 2, and Table3 show the specific quantization settings, LoRA settings, and hyperparameters used in QLoRA, respectively. Table 4 shows the prompt used for the initial translation model.

Preference Learning We conducted preference learning using QLoRA after supervised fine-tuning.

For preference learning, we adopted the SimPO (Meng et al., 2024) method. SimPO is a method that is efficient while suppressing redundant sentence generation. We used the trl library (von Werra et al., 2020) for implementation.

The quantization settings, LoRA settings, and prompts were the same as those used for supervised fine-tuning. Table 3 shows the hyperparameters used for preference learning.

Hereafter, we refer to the model trained with supervised fine-tuning only as $\mathrm{INIT}_{\mathrm{SFT}}$ and with both supervised fine-tuning and preference learning as $\mathrm{INIT}_{\mathrm{SimPO}}$.

4 Automatic Post-Editing Model

4.1 Datasets

For training the automatic post-editing model, we need a triplet consisting of the source text, preferred translation, and non-preferred translation,

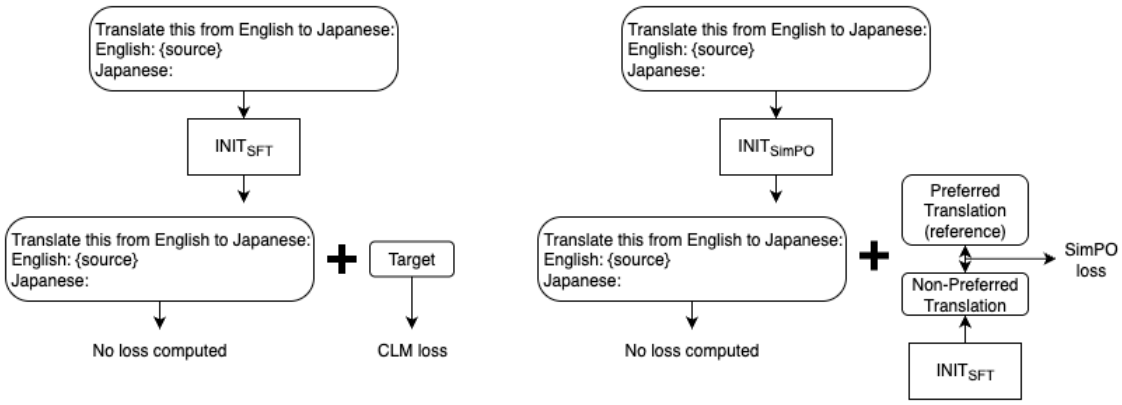

Figure 2: Left: Supervised fine-tuning step of the initial translation model; Right: Preference learning step of the initial translation model.

Common Settings	
Optimizer	AdamW ($\beta_1 = 0.9, \beta_2 = 0.999, \epsilon = 1e-08$)

Japanese:

Table 4: Prompt for Initial Translation Model

similar to preference learning. We used the following two datasets:

The first dataset is the same dataset used for preference learning of the initial translation model.

The second dataset is a dataset where the source text and preferred translation are the same as in the first dataset, but the non-preferred translation is not the output of the SFT model, but rather the output of the preference learning model.

4.2 Model Selection

We employed the same pre-trained model as the initial translation model, which is cyberagent/DeepSeek-R1-Distill-Qwen-14B-Japanese.

4.3 Training Procedure

The training procedure of the automatic post-editing model is shown in Figure 3.

We conducted supervised fine-tuning of the automatic post-editing model using QLoRA.

The automatic post-editing model was trained separately on each of the two datasets described above. The quantization settings, LoRA settings, and hyperparameters used for QLoRA were the same as those used for the initial translation model. Table 5 shows the prompt used for the automatic post-editing model.

Hereafter, we refer to the model trained with supervised fine-tuning on the first dataset as $\mathrm{PEDIT}_{\mathrm{SFT}}$ and on the second dataset as $\mathrm{PEDIT}_{\mathrm{SimPO}}$.

5 Reranking

5.1 Method

MBR decoding is a selection strategy that selects the candidate with the maximum expected utility from a candidate set.

This strategy takes the form of reranking in practice and is formulated as follows:

$$\hat{y}_i = \underset{c_i \in \mathcal{C}}{\operatorname{argmax}} \frac{1}{|\mathcal{C}|} \sum_{j=1}^{|\mathcal{C}|} u(c_i, c_j)$$

where $\hat{y}_i$ is the selected candidate, c_i is a candidate in the candidate set $\mathcal{C}$, and $u(c_i, c_j)$ is the utility function between candidates c_i and c_j.

In machine translation, reference-based evaluation metrics (e.g., BLEU, COMET) are often used as the utility function. That is, MBR decoding is defined as a strategy that selects the candidate with the highest average utility with respect to the other candidates in the set.

5.2 Reranking Procedure

Candidate Generation First, we generated a candidate set. We used four combinations of models: $\mathrm{INIT}_{\mathrm{SFT}}$, $\mathrm{INIT}_{\mathrm{SimPO}}$, $\mathrm{PEDIT}_{\mathrm{SFT}}(\mathrm{INIT}_{\mathrm{SFT}})$, and $\mathrm{PEDIT}_{\mathrm{SimPO}}(\mathrm{INIT}_{\mathrm{SimPO}})$.

Here, $\mathrm{PEDIT}_{\mathrm{SFT}}(\mathrm{INIT}_{\mathrm{SFT}})$ refers to the output of $\mathrm{PEDIT}_{\mathrm{SFT}}$ when given the output of $\mathrm{INIT}_{\mathrm{SFT}}$ as input and $\mathrm{PEDIT}_{\mathrm{SimPO}}(\mathrm{INIT}_{\mathrm{SimPO}})$ refers to the output of $\mathrm{PEDIT}_{\mathrm{SimPO}}$ when given the output of $\mathrm{INIT}_{\mathrm{SimPO}}$ as input.

We generated two translations for each model using two decoding strategies: Greedy decoding and Temperature 0.9 + Top-p 0.6 + Top-k 50.

The Greedy decoding is a decoding strategy that selects the most probable token at each step, while the Temperature 0.9 + Top-p 0.6 + Top-k 50 is a sampling-based decoding strategy that introduces randomness in the selection of tokens.

Therefore, the number of candidates generated for each input is $2+2+2\times2+2\times2 = 12$ because $\mathrm{INIT}_{\mathrm{SFT}}$ and $\mathrm{INIT}_{\mathrm{SimPO}}$ each generate two translations, and $\mathrm{PEDIT}_{\mathrm{SFT}}$ and $\mathrm{PEDIT}_{\mathrm{SimPO}}$ each generate two translations for each of the outputs of $\mathrm{INIT}_{\mathrm{SFT}}$ and $\mathrm{INIT}_{\mathrm{SimPO}}$, respectively.

Reranking Next, we applied MBR decoding to the generated candidate set. The utility function used is a linear combination of the following:

$$0.8 \times \text{COMET-22} + 0.2 \times \text{LaBSE-cos}$$

Where LaBSE-cos is the cosine similarity based on LaBSE. The combination of these utility functions is inspired by the winning system in the WMT24 General Machine Translation Task (Kondo et al., 2024).

6 Experiment and Analysis

We used the WMT24++ (Deutsch et al., 2025) as the evaluation dataset. We evaluated the system using automatic metrics, specifically COMET-22 and BLEU (Papineni et al., 2002). We used sacreBLUE (Post, 2018) for BLEU calculation.

We evaluated zero-shot performance of the base model as a baseline. In addition to the submitted system, we compared the following four model configurations: $\mathrm{INIT}_{\mathrm{SFT}}$, $\mathrm{INIT}_{\mathrm{SimPO}}$, $\mathrm{PEDIT}_{\mathrm{SFT}}(\mathrm{INIT}_{\mathrm{SFT}})$, and $\mathrm{PEDIT}_{\mathrm{SimPO}}(\mathrm{INIT}_{\mathrm{SimPO}})$.

For baseline, $\mathrm{INIT}_{\mathrm{SFT}}$ and $\mathrm{INIT}_{\mathrm{SimPO}}$, we used the same prompt as the one used during the training of the initial translation model. For $\mathrm{PEDIT}_{\mathrm{SFT}}$ and $\mathrm{PEDIT}_{\mathrm{SimPO}}$, we used the same prompt as the one used during the training of the automatic post-editing model.

Since the baseline outputs think tokens, we removed the text enclosed in <think> tags using regular expressions during evaluation.

Except for the submitted system, we used the default decoding strategy of the base model: Temperature 0.6 and Top-p 0.95.

Table 6 shows the results of the automatic evaluation. For BLEU, $\mathrm{INIT}_{\mathrm{SFT}}$ achieved the highest score, followed by the submitted system. For COMET-22, however, the submitted system scored the highest. In both metrics, the baseline had the lowest score.

The baseline achieved a significantly lower BLEU score, possibly because its outputs often contained extraneous information in addition to the translation (see Table 7). On the other hand, after SFT, cases where extraneous information other than the translation was included in the output were rarely observed. Therefore, the reason for the improvement in score after SFT is thought to be that the improvement in output consistency worked favorably for automatic evaluation.

Also, when automatic post-editing was applied, the BLEU score decreased, but the COMET-22 score improved. This may be because there was only one reference sentence when calculating the BLEU score this time, and the automatic post-editing, which generates diverse expressions, led to a decrease in the BLEU score. On the other hand, since COMET-22 is tolerant of diverse expressions, it is thought that the COMET-22 score improved when automatic post-editing was applied. In fact, when we checked some translation examples, we found that there were few cases where the quality significantly deteriorated when automatic post-editing was applied.

BLEU	
Baseline	1.34
$\mathrm{INIT}_{\mathrm{SFT}}$	49.89
$\mathrm{INIT}_{\mathrm{SimPO}}$	48.11
$\mathrm{PEDIT}_{\mathrm{SFT}}(\mathrm{INIT}_{\mathrm{SFT}})$	47.96
$\mathrm{PEDIT}_{\mathrm{SimPO}}(\mathrm{INIT}_{\mathrm{SimPO}})$	46.61
Submitted System	49.45
COMET-22	
Baseline	0.6696
$\mathrm{INIT}_{\mathrm{SFT}}$	0.8368
$\mathrm{INIT}_{\mathrm{SimPO}}$	0.8453
$\mathrm{PEDIT}_{\mathrm{SFT}}(\mathrm{INIT}_{\mathrm{SFT}})$	0.8451
$\mathrm{PEDIT}_{\mathrm{SimPO}}(\mathrm{INIT}_{\mathrm{SimPO}})$	0.8471
Submitted System	0.8761

Table 6: Results of Automatic Evaluation

The submitted system achieved a highest score in COMET-22. This is thought to be due to MBR decoding, which can suppress quality degradation caused by automatic post-editing.

Based on these results, we confirm that supervised fine-tuning, preference learning, and the introduction of the automatic post-editing model are effective.

7 Conclusion

In this paper, we described the system submitted by Team SH to the WMT2025 General Machine Translation Task. We developed the initial translation model through supervised fine-tuning and preference learning, and the automatic post-editing model through supervised fine-tuning. We generated multiple translations from these models and selected the best translation using MBR decoding. The submitted system demonstrated superior performance compared to the baseline in both automatic evaluation metrics, namely BLEU and COMET-22.

Simple Test Time Scaling for Machine Translation: Kaze-MT at the WMT25 General Translation Task

Shaomu Tan **Christof Monz**
Language Technology Lab
University of Amsterdam
{s.tan, c.monz}@uva.nl

Abstract

This paper describes the Kaze-MT submission to the WMT25 General Machine Translation task (Japanese–Chinese). Our system deliberately adopts a minimalist Test-Time Scaling (TTS) pipeline with three stages—*Sampling*, *Scoring*, and *Selection*—while avoiding any task-specific fine-tuning, in-context exemplars, or bespoke decoding heuristics. In the sampling stage, we use the zero-shot `Qwen2.5-72B-Instruct` model to generate 512 candidate translations under a fixed temperature schedule designed to encourage lexical and syntactic diversity without sacrificing fluency. In the scoring stage, each candidate is evaluated by multiple reference-free quality estimation (QE) models—KIWI-22, MetricX-24 Hybrid-XXL, and Remedy-24-9B. The selection stage aggregates metric-specific rankings and chooses the candidate with the lowest mean rank, which we found more stable than averaging raw scores across heterogeneous ranges. We submit to both constrained and unconstrained tracks with minimal configuration changes. According to official preliminary results, our submissions are competitive on automatic metrics; in human evaluation, Kaze-MT falls within the 8–13 cluster, delivering performance comparable to CommandA-WMT and DeepSeek-V3 and outperforming other large LLM baselines such as Mistral-Medium and other extensively tuned MT systems.

1 Introduction

Allocating additional computation at inference time—commonly referred to as *Test-Time Scaling (TTS)* or *Best-of-N (BoN)*—can improve quality without the overhead of scaling training to ever larger models (Snell et al., 2024; Wu et al., 2025; Muennighoff et al., 2025). In machine translation, TTS has a long history via candidate reranking using quality estimation (QE) metrics (Neubig et al., 2015; Mizumoto and Matsumoto, 2016; Lee et al., 2021). Rather than optimizing a particular reranking recipe, Tan et al. (2025) study scaling laws for TTS-MT and find that scaling N for Best-of-N brings performance improvements for high-resource languages.

We adopt this minimalist perspective. Our submission, **Kaze-MT**, relies on a strong, off-the-shelf LLM for diverse candidate generation and on robust, reference-free QE models for selection. Our submission targets the WMT25 Japanese–Chinese track and intentionally avoids any task-specific parameter updates or domain adaptation. The pipeline is deliberately simple: (i) *Sampling*, (ii) *Scoring*, and (iii) *Selection*—yet competitive against substantially engineered systems. Beyond reporting official results, we discuss metric–human preference gaps and practical considerations for scaling TTS under realistic compute constraints.

On the official WMT25 Japanese→Chinese evaluation, **Kaze-MT** attains a strong position under automatic metrics and competitive human judgments despite using no fine-tuning or in-context exemplars. In AutoRank (an ensemble of KIWI-XL, GEMBA-ESA-CMDA, GEMBA-ESA-GPT-4.1, MetricX-24 Hybrid-XL, and XCOMET-XL), our primary system ranks **4/41** submissions (Table 2), outperforming several large closed LLM baselines (e.g., GPT-4.1, Claude-4, DeepSeek-V3, Mistral-Medium). Even though there is no exact the same metric used for both TTS setup and AutoRank evaluation, we acknowledge that potential metric interference (Pombal et al., 2025) may exist.

In the final official human evaluation, Kaze-MT falls in the **8–13** cluster (Table 1), comparable to CommandA-WMT and DeepSeek-V3 and ahead of models such as Mistral-Medium and Qwen3-235B. We note a modest gap between AutoRank and human ranking, which indicates that Quality Estimation as signal for improving translation quality remain a unclear problem for the future study. Developing human preference aligned MT metrics, therefore, hold a great promise for machine transla-

2 Task Overview

The WMT25 Japanese–Chinese track evaluates systems with both automatic metrics and human judgments. The *constrained* track limits models and resources (e.g., parameter count $<$20B and approved data), whereas the *unconstrained* track permits any publicly available model or data. Our pipeline fits both settings with minor differences in the scoring configuration (e.g., which QE variants are permitted).

We submitted a *primary* system built on `Qwen2.5-72B-Instruct` and a *contrastive* system built on `Qwen2.5-14B-Instruct`(Hui et al., 2024). The contrastive run was not included in AutoRank or human evaluation by the organizers; thus, we only report the 72B primary system in this paper.

3 Data

Because Kaze-MT is purely zero-shot, no pretraining or fine-tuning data are used beyond the official test set. The WMT25 materials contain multiple domains and are provided at the document level. Very long contexts may degrade generation performance and stability; therefore, we segment documents into paragraph units simply using a double-newline delimiter (`\n\n`). We retain original sentence order within each paragraph and do not apply additional filtering or normalization beyond standard Unicode cleanup.

4 Methodology

4.1 Sampling

We generate N=512 candidates per source paragraph with `Qwen2.5-72B-Instruct` (Hui et al., 2024) in zero-shot mode. Decoding with top-p=0.95 and a fixed temperature t=1.0 across all candidates to produce lexical and structural variety. The maximum generation length is 1500 tokens with EOS-based stopping. We implement inference with `vLLM` (Kwon et al., 2023), employing data parallelism on 4$\times$ NVIDIA H100 NVL GPUs. We observed that holding t fixed while sampling many candidates yields more predictable diversity than annealing schedules in this setting. Figure 4.1 demonstrates our translation generation prompt.

Why using N=512? Following Tan et al. (2025), who evaluate Best-of-N with $N \in \{1, 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024\}$, we select N=512 as a sweet point on the TTS Pareto frontier. Empirically, the quality–compute curve exhibits clear diminishing returns: as N grows, candidate diversity increases sublinearly, and the marginal utility of additional samples is increasingly limited by redundancy among high-probability modes. In that regime, N=512 lies very close (in terms of automatic quality) to the performance obtained with N=1024, yet it requires roughly *half* the sampling and scoring budget. In sum, N=512 captures most of the attainable TTS benefit identified by prior scaling studies while maintaining a favorable quality–latency trade-off for production-style constraints.

Translation Prompt Template

You are a helpful translation assistant. Now translate the following src_lang text into natural, fluent tgt_lang sentence while preserving the original meaning.

Source: $SOURCE

4.2 Scoring

Each candidate is scored by three reference-free QE models spanning different capacities and training paradigms:

- **KIWI-22** (0.5B): a lightweight, widely deployed QE model trained on synthetic and human annotations (Rei et al., 2022b).
- **MetricX-24 Hybrid-XXL** (13B): a strong WMT24 metric that combines synthetic judgments and curated references (Juraska et al., 2024).
- **Remedy-24 (9B)**: a recent SOTA QE model emphasizing robustness to domain and format variation (Tan and Monz, 2025).

Why ensemble? Individual QE metrics differ in architecture, training data, and inductive biases (e.g., sensitivity to literalness, tolerance to stylistic risk, robustness to domain drift). In practice, these differences induce complementary error profiles: one metric may down-weight fluent paraphrases, another may reward stylistic richness but underpenalize subtle adequacy errors.

An ensemble therefore acts as a variance-reduction mechanism, stabilizing selection across domains and styles. As emprical studied in Rei et al. (2022a); Freitag et al. (2024), ensembling the same metric model with different random seed achieves more robust results and ensembling of different metric models like Comet and MetricX outperforms both of them on WMT24 metric shared task.

4.3 Selection

Since different metrics provides quality scores in different ranges, e.g., MetricX outputs [-25,0] while KIWI and Remedy-24 outputs in the range of [0,100]. Therefore, we aggregate rankings from the three QE models and select the candidate with the lowest mean rank as the final translation. This rank-based approach proved more stable than averaging raw scores to avoid the range difference.

Foormally, let $\mathcal{C} = \{c_1, \ldots, c_N\}$ denote the N sampled candidates for a source segment and $\mathcal{M} = \{1, \ldots, M\}$ the set of QE metrics. We denote raw metric scores by $s_m(c)$ and (ascending) ranks by $r_m(c) \in \{1, \ldots, N\}$. Our default selector is the *mean-rank* rule:

$$\bar{r}(c) = \frac{1}{M} \sum_{m \in \mathcal{M}} r_m(c), \quad c^\star = \arg\min_{c \in \mathcal{C}} \bar{r}(c).$$

This avoids scale incompatibilities across s_m and is less brittle to heavy-tailed score distributions than direct averaging of raw scores.

5 Results

5.1 WMT25 AutoRank

Table 2 reports the official preliminary automatic results for Japanese→Chinese. AutoRank is computed by ensembling multiple metrics (KIWI-XL, GEMBA-ESA-CMDA, GEMBA-ESA-GPT-4.1, MetricX-24 Hybrid-XL, and XCOMET-XL). Our system ranks 4th out of 41 valid submissions, outperforming several large closed models (e.g., GPT-4.1, Claude-4, DeepSeek-V3, Mistral-Medium). Because our selection stage employs metrics related to those in AutoRank, some metric coupling is possible (Pombal et al., 2025); we therefore treat absolute deltas with caution and emphasize the human evaluation below.

5.2 WMT25 Human Evaluation

Table 1 presents the final human evaluation results, adopted from the official WMT25 findings (Kocmi et al., 2025a). As shown in the table, our submission system, Kaze-MT ranked 8th, slightly lagging behind the massive closed LLMs like DeepSeek-V3, CommandA-WMT while still outperforming systems like Mistral-Medium. Notably, the human evaluation presents lower ranking compared to the Autorank, presenting the automatic translation metric still presents unaligned preference as humans.

Japanese→Chinese

Rank	System	Human	AutoRank
1-1	**Human**	-3.5	
2-2	Gemini-2.5-Pro	-4.4	3.3
3-6	Algharb	-5.8	4.3

19-19	Laniqo	-18.3	11.3

Table 1: The official WMT25 Human Evaluation results adopted from Kocmi et al. (2025a). The human score is the micro-average of human judgements across all domains and double annotations. AutoRank is calculated from automatic metrics as per (Kocmi et al., 2025b). Significance testing is done using a Wilcoxon signed rank test with a p-value threshold of 5%. Ranks from row in two directions until they reach a system that is significantly different. Clusters are created such that they do not overlap with ranks. Systems are either constrained (white), or unconstrained (gray). Systems that do not officially support the language pair are marked with ✗.

6 Discussion

6.1 On Metric Bias and Coupling Effects

When the selection ensemble and the official evaluation share metric families, *metric coupling* can inflate automatic rankings. In our case, AutoRank includes metrics related to our selectors (e.g., KIWI-22 and MetricX variants), which may partially explain why our AutoRank position exceeds our human-evaluation cluster. This is a form of

Table 2: The official WMT25 AutoRank results adopted from Kocmi et al. (2025b). Our submission, Kaze-MT ranked 4th out of 41 valid submissions. Note that our submission is based on the best-of-N reranking using KIWI22, MetricX24-QE-XXL, and Remedy24-QE, thus such approach could deliver biased results when using the same model for reranking and evaluation.

evaluation-on-the-features bias: the system is optimized for the very signals (or close proxies) used to score it.

6.2 Potential discrepancy between human and automatic metrics

Another potential reason is the gap between human judgments and current automatic metrics. Most widely used metrics are black-box models: they output a single overall score without exposing intermediate decisions or confidence. Without explanations, these scores can reflect surface cues (e.g., lexical overlap, length) rather than the properties humans care about (translation accuracy, register). They may also miss context-sensitive errors (tone, pragmatics) and discourse links across sentences.

As a result, a system optimized to rank well under such metrics can improve automatic scores without a matching gain in human preference. This points to the need for more interpretable evaluation models.

7 Conclusion

We presented Kaze-MT, a simple yet competitive TTS system for Japanese–Chinese MT. By pairing diverse zero-shot sampling from a strong LLM with robust QE-based selection, we achieve strong results without any fine-tuning or in-domain resources. The modest gap between AutoRank and human ranking of our submission indicates that evaluation-on-the-features bias may exist, and TTS approach largely depends on the quality and robustness of quality estimation metrics. Reduce metric coupling and improving alignment of quality estimation methods with human preferences remains an important future work.

Abstract

This paper presents the submission of NTTSU for the constrained track of the English–Japanese and Japanese–Chinese at the WMT2025 general translation task. For each translation direction, we build translation models from a large language model by combining continual pretraining, supervised fine-tuning, and preference optimization based on the translation quality and adequacy. We finally generate translations via context-aware MBR decoding to maximize translation quality and document-level consistency.

1 Introduction

We describe our NTTSU translation system in the WMT'25 English–Japanese (En–Ja) and Japanese–Chinese (Ja–Zh) general translation task under the constrained track.

Our translation models are trained on a pretraining large language model (LLM), Qwen3-14B (Qwen Team, 2025). We combine training methods for each translation direction from three training stages: continual pretraining (CPT) (Ke et al., 2023), supervised fine-tuning (SFT) (Zhang et al., 2024), and preference optimization (PO) (Rafailov et al., 2023). In PO, to maximize the translation quality and adequacy, we use two different reward metrics, MetricX-24 (Juraska et al., 2024) and coverage of word alignment between source and target texts (Wu et al., 2024). After training the models, we generate translations using context-aware minimum Bayes risk (MBR) decoding, which maximizes the expected translation quality (Kumar and Byrne, 2004; Eikema and Aziz, 2020) and also utilizes context information of both source and generated target texts, though we use a sentence-level metric (Kudo et al., 2024; Pombal et al., 2024). The following sections show the details of our system.

2 Approaches

2.1 Training

Continual pretraining Continual pretraining (CPT) continues to train LLM models based on the next token prediction as well as pretraining using monolingual corpora (Ke et al., 2023). Let $\mathbf{y} \coloneqq (y_1, y_2, \ldots, y_{|\mathbf{y}|}) \in \mathcal{V}^*$ be a sequence of tokens in a corpus, where $\mathcal{V}^*$ is the Kleene closure of vocabulary $\mathcal{V}$. CPT optimizes the model parameter θ by minimizing the loss function $\mathcal{L}_{\text{CPT}}$ over a monolingual corpus $\mathcal{D}_{\text{CPT}} \coloneqq \{\mathbf{y}_i\}_{i=1}^{|\mathcal{D}_{\text{CPT}}|} \subset \mathcal{V}^*$:

$$\underset{\theta}{\operatorname{argmin}} \sum_{\mathbf{y} \in \mathcal{D}_{\text{CPT}}} \mathcal{L}_{\text{CPT}}(\mathbf{y}; \theta), \tag{1}$$

$$\mathcal{L}_{\text{CPT}}(\mathbf{y}; \theta) \coloneqq -\sum_{t=1}^{|\mathbf{y}|} \log p_\theta(y_t | \mathbf{y}_{<t}). \tag{2}$$

For efficiency, $\mathbf{y}_{[t-c,t)} \coloneqq (y_{t-c}, y_{t-c+1}, \ldots y_{t-1})$ is used instead of $\mathbf{y}_{<t}$ in practice, where $c \in \mathbb{N}$ is a length of a context window. This objective is the same as the pretraining loss of causal language models, i.e., the model is trained to predict the next token y_t under the condition of c context tokens.

Supervised fine-tuning Supervised fine-tuning (SFT) adapts a pretrained model to downstream tasks using labeled data (Zhang et al., 2024). Specifically, given a pretrained model parameter θ, SFT updates it on a labeled dataset $\mathcal{D}_{\text{SFT}} \coloneqq \{(\mathbf{x}_i, \mathbf{y}_i)\}_{i=1}^{|\mathcal{D}_{\text{SFT}}|} \subset \mathcal{V}^* \times \mathcal{V}^*$, where $\mathbf{x}_i$ and $\mathbf{y}_i$ are the input and its corresponding ground-truth output sequence, respectively, as follows:

$$\underset{\theta}{\operatorname{argmin}} \sum_{(\mathbf{x},\mathbf{y}) \in \mathcal{D}_{\text{SFT}}} \mathcal{L}_{\text{SFT}}(\mathbf{x}, \mathbf{y}; \theta), \tag{3}$$

$$\mathcal{L}_{\text{SFT}}(\mathbf{x}, \mathbf{y}; \theta) \coloneqq -\log p_\theta(\mathbf{y} \mid \mathbf{x}). \tag{4}$$

This encourages the model to generate outputs that are consistent with the human-annotated targets.

Proceedings of the Tenth Conference on Machine Translation, pages 657–665
November 8-9, 2025

Preference optimization Preference optimization (PO) aims to align a trained model with preferences. One of the major PO algorithms is direct PO (DPO), which uses pairwise comparison data instead of explicit reward models (Rafailov et al., 2023). Let $\mathcal{D}_{\text{PO}} \coloneqq \{(\mathbf{x}_i, \mathbf{y}_i^+, \mathbf{y}_i^-)\}_{i=1}^{|\mathcal{D}_{\text{PO}}|} \subset \mathcal{V}^* \times \mathcal{V}^* \times \mathcal{V}^*$ be a triplet dataset that consists of a prompt $\mathbf{x}$ and its corresponding output pairs $(\mathbf{y}^+, \mathbf{y}^-)$, where $\mathbf{y}^+$ is preferred over $\mathbf{y}^-$ according to human feedback or a reward function, i.e., $\mathbf{y}^+ \succeq \mathbf{y}^-$. PO tunes a model θ by minimizing a pairwise loss that encourages the model to generate $\mathbf{y}^+$ rather than $\mathbf{y}^-$. We minimize the following objective function that incorporates adaptive rejection (Xu et al., 2025) into SimPO, a variant of DPO (Meng et al., 2024):

$$\operatorname*{argmin}_{\theta} \sum_{(\mathbf{x},\mathbf{y}^+,\mathbf{y}^-)\in\mathcal{D}_{\text{PO}}} \mathcal{L}_{\text{PO}}(\mathbf{x}, \mathbf{y}^+, \mathbf{y}^-; \theta), \quad (5)$$

$$\begin{aligned}\mathcal{L}_{\text{PO}}(\mathbf{x}, \mathbf{y}^+, \mathbf{y}^-; \theta) \coloneqq \\ -\log \sigma \left(r(\mathbf{x}, \mathbf{y}^+) - \tau_\theta(\mathbf{y}^+, \mathbf{y}^-) r_\theta(\mathbf{x}, \mathbf{y}^-) - \gamma\right) \\ + \alpha \log p_\theta(\mathbf{y}^+|\mathbf{x}), \quad (6)\end{aligned}$$

where $\alpha \in \mathbb{R}$ is a weight of the behavior cloning regularizer, $\gamma \in \mathbb{R}$ is a reward margin between $\mathbf{y}^+$ and $\mathbf{y}^-$. Note that $r_\theta(\mathbf{x}, \mathbf{y})$, $\tau_\theta(\mathbf{y}^+, \mathbf{y}^-)$, and $z_\theta(\mathbf{y}^+, \mathbf{y}^-)$ are defined as follows:

$$r_\theta(\mathbf{x}, \mathbf{y}) \coloneqq \frac{\beta}{|\mathbf{y}|} \log p_\theta(\mathbf{y}|\mathbf{x}), \quad (7)$$

$$\tau_\theta(\mathbf{y}^+, \mathbf{y}^-) \coloneqq \min\left(e^{\eta \cdot z_\theta(\mathbf{y}^+, \mathbf{y}^-)} - 1, 1\right), \quad (8)$$

$$z_\theta(\mathbf{y}^+, \mathbf{y}^-) \coloneqq \left|\frac{\log p_\theta(\mathbf{y}^+|\mathbf{x})}{|\mathbf{y}^+|} - \frac{\log p_\theta(\mathbf{y}^-|\mathbf{x})}{|\mathbf{y}^-|}\right|, \quad (9)$$

where $\beta \in \mathbb{R}$ and $\eta \in \mathbb{R}$ are hyperparameters.

Stepwise preference optimization Stepwise PO (Wachi et al., 2024) is an extension of PO designed to align models with multiple preference metrics. It optimizes the model using multiple preferences sequentially, where each stage focuses on a distinct preference objective. Consequently, by chaining multiple preference optimization stages, the model incrementally aligns with multiple-perspective preferences.

2.2 Decoding

We generate translations via context-aware minimum Bayes risk (MBR) decoding, which leverages sentence-level metrics for MBR decoding (Goel and Byrne, 2000; Kumar and Byrne, 2004; Eikema and Aziz, 2020) yet utilizes both source and generated target context information.

Algorithm 1: Context-aware MBR decoding

Given : Translation model θ, utility function u, the number of hypotheses $|\mathcal{H}|$, and the context size $C \in \mathbb{N}$.
Input : Source document $\mathbf{X} \coloneqq (\mathbf{x}_1, \ldots, \mathbf{x}_{|\mathbf{X}|})$ where $\mathbf{x}_i \in \mathcal{V}^*$ is the i-th source sentence.
Output : Target document $\mathbf{Y} \coloneqq (\mathbf{y}_1, \ldots, \mathbf{y}_{|\mathbf{Y}|})$.

$\mathbf{Y} \leftarrow \phi$
Create queues: $\mathbf{C}_x \leftarrow \phi$ and $\mathbf{C}_y \leftarrow \phi$
for $i \leftarrow 1 \ldots |\mathbf{X}|$ **do**
  Enqueue$(\mathbf{C}_x, \mathbf{x}_i)$
  // $\mathcal{H}$ is a multiset of hypotheses.
  $\mathcal{H} \leftarrow \{\mathbf{h}_k \sim p(\mathbf{y}_i|\mathbf{C}_x, \mathbf{C}_y; \theta)\}_{k=1}^{|\mathcal{H}|}$
  // We use the same candidate set for hypotheses and pseudo-references.
  $\hat{\mathbf{y}}_i \leftarrow \operatorname{argmax}_{\mathbf{h}\in\mathcal{H}} \frac{1}{|\mathcal{H}|} \sum_{k=1}^{|\mathcal{H}|} u(\mathbf{h}, \mathbf{h}_k)$
  // $\circ$ denotes concatenetion.
  $\mathbf{Y} \leftarrow \mathbf{Y} \circ \hat{\mathbf{y}}_i$
  Enqueue$(\mathbf{C}_y, \hat{\mathbf{y}}_i)$
  while $|\mathbf{C}_x| > C$ **do**
    Dequeue$(\mathbf{C}_x)$
  while $|\mathbf{C}_y| > C$ **do**
    Dequeue$(\mathbf{C}_y)$
return $\mathbf{Y}$

MBR decoding The goal of MBR decoding is to find a translation that maximizes the expected utility rather than the output probability (Goel and Byrne, 2000; Kumar and Byrne, 2004). The objective is formally defined as follows:

$$\mathbf{y}^\star_{\text{MBR}} \coloneqq \operatorname*{argmax}_{\mathbf{h}\in\mathcal{V}^*} \mathop{\mathbb{E}}_{\mathbf{y}\sim\Pr(\cdot|\mathbf{x})}[u(\mathbf{h}, \mathbf{y})], \quad (10)$$

where $\Pr(\cdot|\mathbf{x})$ is the true probability of human translation and $u\colon \mathcal{V}^* \times \mathcal{V}^* \to \mathbb{R}$ is a utility function that evaluates a hypothesis under the given reference $\mathbf{y}$ and satisfies $\mathbf{h}^+ \succeq \mathbf{h}^- \iff u(\mathbf{h}^+, \mathbf{y}) \geq u(\mathbf{h}^-, \mathbf{y})$. Since searching over $\mathcal{V}^*$ and calculating the expectation over the output space are infeasible, the objective of MBR decoding is approximated by the Monte Carlo (MC) estimation (Eikema and Aziz, 2020, 2022). We denote a hypothesis set by $\mathcal{H} \subset \mathcal{V}^*$. The MBR decoding with the MC estimation is calculated as follows:

$$\mathbf{y}_{\text{MBR}} \coloneqq \operatorname*{argmax}_{\mathbf{h}\in\mathcal{H}} \frac{1}{|\hat{\mathcal{Y}}|} \sum_{\mathbf{y}\in\hat{\mathcal{Y}}} u(\mathbf{h}, \mathbf{y}), \quad (11)$$

where $\hat{\mathcal{Y}} \coloneqq \{\mathbf{y}_i \sim p_\theta(\mathbf{y}|\mathbf{x})\}_{i=1}^{|\hat{\mathcal{Y}}|}$ is a multiset, a.k.a. bag, of pseudo-references, translation samples drawn from the output probability of translation model θ. Typically, hypotheses are also used as pseudo-references.

Context-aware MBR decoding For document-level translation, we extend MBR decoding to a context-aware method. However, most automatic evaluation metrics, which are used for the utility function, are designed for sentence-level metrics. To bridge this gap, we determine output translations for each sentence by MBR decoding with a sentence-level utility and add the generated translation to the context, similar to Kudo et al. (2024) and Pombal et al. (2024). Algorithm 1 shows our decoding algorithm, which autoregressively generates sentence-level translations at each step. Since the WMT'25 general translation task provides the source document without sentence segmentation, we first apply a sentence segmenter before running our decoding algorithm. In Line 5, hypotheses are sampled given the source and target context sentences, i.e., $\mathbf{C}_x$ and $\mathbf{C}_y$, respectively. The source context includes the current source sentence $\mathbf{x}_i$ as well as the preceding ones, while the target context consists only of previously generated target sentences. Accordingly, the model focuses on the current sentence $\mathbf{x}_i$ and generates its corresponding target sentence $\mathbf{y}_i$ under the given contexts, naturally. The hyperparameter $C \in \mathbb{N}$ denotes the size of the context queues. Rather than using a fixed number of sentences, we set it based on the paragraph size, i.e., a variable number of sentences depending on the dataset format.

3 Submission System

We train En–Ja and Ja–Zh translation models from a pretrained LLM, Qwen3-14B (Qwen Team, 2025). According to our preliminary experiments and subjective judgment, we selected the combinations of training methods. Finally, we generate translations via context-aware MBR decoding. We show the system overview in Figure 1 and Table 1.

3.1 Continual pretraining

We perform the bilingual CPT only for the En–Ja model. For the training data of CPT, we use JParaCrawl v3.0 (Morishita et al., 2022) and filter it into 20.8M sentence pairs using LEALLA-large (Mao and Nakagawa, 2023). We create training examples following Kondo et al. (2024). The hyperparameters of CPT are listed in Table 2.

3.2 Supervised fine-tuning

Similar to CPT, we conduct supervised fine-tuning (SFT) only for the En–Ja model. For the training data of SFT, we use the development and test sets of the WMT'20 translation task (Barrault et al., 2020) and FLoRes-200 (NLLB Team et al., 2022), along with the train set of the Kyoto Free Translation Task (KFTT) (Neubig, 2011). For the development set, we use the test set of the WMT'21 translation task (Akhbardeh et al., 2021). The hyperparameters of SFT are also listed in Table 2.

3.3 Preference optimization

To maximize translation quality and adequacy, we perform PO with two reward metrics. For En–Ja, we apply the quality-aware PO on top of the model trained via SFT. For Ja–Zh, we apply both quality- and adequacy-aware PO through stepwise PO. Note that we do not apply CPT and SFT to the Ja–Zh model as listed in Table 1; thus, we directly tune the pretrained Qwen3-14B.

Quality-aware PO To improve translation quality, we employ an automatic evaluation metric that highly correlates with human assessments for creating the preference data. Specifically, we first randomly sample 20,000 source sentences from the NewsCrawl corpus (Kocmi et al., 2024), and generate translations for each source sentence using two LLMs, Qwen3-32B and Aya-Expanse-32B (Dang et al., 2024). To obtain high-quality translations efficiently, we employ COMET[1] (Rei et al., 2022a) -based MBR decoding using 64 hypotheses sampled via epsilon sampling with $\varepsilon = 0.02$ (Freitag et al., 2023). These high-quality translations and the baseline translations, generated via beam search from Qwen3-14B, are then compared using MetricX-24-XXL (Juraska et al., 2024). Among the outputs from the three models, we label the highest-quality translation as the preferred, i.e., chosen, instance and the lowest-quality translation as the non-preferred, i.e., rejected, instance. From these paired instances with each source sentence, we construct the training dataset for quality-aware PO. Finally, we train the model by optimizing Equation (5) on the created preference data with $\alpha = 1.0, \beta = 0.2, \eta = 1.5, \gamma = 0.005$.

Adequacy-aware PO To mitigate hallucination and omission, i.e., overgeneration and undergeneration, we also employ the word alignment-based preference metric (Wu et al., 2024) for Ja–Zh. For the preference data, we randomly sample 10,000 source sentences from CCAligned (El-Kishky et al., 2020), where each sentence has at least 15 characters. To label the preference data, we use the coverage score obtained via word alignment calculated by WSPAlign[2] (Wu et al., 2023). Apart from these two modifications, we follow the same procedure as in the quality-aware PO, but with different hyperparameters: $\alpha = 1.0, \beta = 0.01, \eta = 1.5, \gamma = 0.005$.

[2] https://huggingface.co/qiyuw/WSPAlign-mbert-base

3.4 Prompt templates

We basically use the following template that turns on the `continue_final_message` (CFM) option defined in the tokenizers of Huggingface transformers (Wolf et al., 2020):

```
<|im_start|>user
Translate this from English to Japanese:
English: ...<|im_end|>
<|im_start|>assistant
<think>
</think>
Japanese:
```

We call this "CFM" template. The CFM template inserts the target language name with a colon into the last of the assistant chat and does not close it. Hence, the model naturally generates a target text following the target language name.

However, in our preliminary Ja–Zh translation experiments, we observed that generated texts with the CFM template are often collapsed due to hallucinations. Thus, we change the inference template to the below "AGP" template, which enables the `add_generation_prompt` (AGP) option instead of the `continue_final_message` option:

```
<|im_start|>user
Translate this from English to Japanese:
English: ...
Japanese:<|im_end|>
<|im_start|>assistant
<think>
</think>
```

Although there is a slight difference between training and inference, we employ this method because hallucinations decrease in Ja–Zh.

To summarize, we train both En–Ja and Ja–Zh models with the CFM template, and generate translations with CFM for En–Ja and AGP for Ja–Zh.

3.5 Decoding

In decoding, we use MetricX-24-XXL (Juraska et al., 2024) for the utility function u. During decoding, we generate 64 translation candidates via epsilon sampling with $\varepsilon = 0.02$ (Freitag et al., 2023) and use them for both hypotheses and pseudo-references. We split the source documents into sentences using segment-any-text[3] (Frohmann et al., 2024). We use at most one previous paragraph as context, i.e., the target context includes a preceding generated paragraph and generated sentences until the current focused sentence.

4 Experiments

4.1 Ablation study of training methods

We investigate the effects of each training method.

Setup We compare the combination of training methods: CPT, SFT, quality-aware PO, and adequacy-aware PO. We train models with the same training data and hyperparameters as our submission system, as described in Section 4.1, except for the differences noted below. In Ja–Zh, we use the same hyperparameters as listed in Table 2 for both CPT and SFT. For the training data of CPT in Ja–Zh, we use the parallel corpora listed in "WMT 2025 Translation Task Training Data"[4]. We filter them to retain only those with CometKiwi-22 (Rei et al., 2022b) scores between 0.5 and 0.88, and then clean them using bifixer (Ramírez-Sánchez et al., 2020). In both En–Ja and Ja–Zh, the source sides of training examples are shared between SFT and adequacy-aware PO. The translation quality is evaluated on MetricX-24-XXL (MTX24) (Juraska et al., 2024), xCOMET-XXL (XCMT) (Guerreiro et al., 2024), and CometKiwi-22 (KIWI22) (Rei et al., 2022b) in the test sets of WMT'24 En–Ja and Ja–Zh translation tasks (Kocmi et al., 2024).

[4] https://www2.statmt.org/wmt25/mtdata/

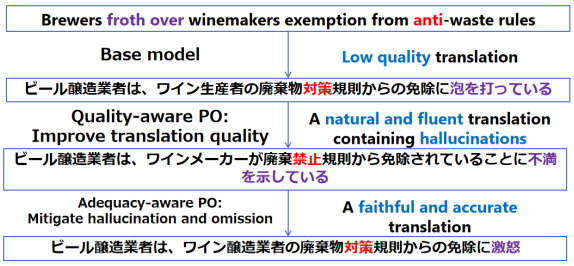

Figure 2: Examples of stepwise preference optimization (PO). Purple and red texts highlight corresponding phrases in the source text and its translations. Blue text provides descriptive labels for each step.

Results The results of automatic evaluation on the WMT'24 test sets are demonstrated in Table 3 and Table 4. In the tables, "Failed" indicates that it failed to generate translations due to hallucinations or critical errors, and it cannot be evaluated. As demonstrated in Table 3 and Table 4, the configuration of our submission system achieved the best MetricX-24-XXL and xCOMET-XXL scores in both En–Ja and Ja–Zh. In addition, we also confirmed through subjective judgment that these models have successfully generated the highest-quality translations compared to other settings. Accordingly, we selected these combinations of training methods for each translation direction.

Figure 2 shows translation examples of the same sentence from the WMT24 test set, generated by

the base model (Qwen3-14B), the model after an initial training step with Quality-aware PO, and the model after a subsequent step with Adequacy-aware PO. As shown in the figure, the initial translation from the base model is relatively low quality, incorrectly translating "froth over." After training with Quality-aware PO, the translation becomes more fluent and natural overall. However, hallucinations occur during translation—for example, rendering "froth over," which expresses anger, as merely expressing dissatisfaction, and interpreting "anti," which denotes countermeasures, as "prohibit." In contrast, the model trained with Adequacy-aware PO produces a translation that is accurate and faithful to the source text.

It is noteworthy that among the three translations, the one from the Quality-aware PO model achieved the best MetricX-24-XXL score. From up to below, the MetricX-24-XXL scores are 6.34, 4.99, and 5.54. This indicates that even advanced metrics such as MetricX-24-XXL may assign better scores to fluent and natural translations that contain hallucinations than to factually accurate but less fluent ones.

4.2 Comparison of decoding strategy

We evaluate our decoding algorithm using the final submission system by comparing it with a baseline context-aware MAP decoding.

Setup We use the WMT'25 En–Ja and Ja–Zh translation task and evaluate the translation quality of decoding methods using reference-free quality estimation (QE) models, MetricX-23-QE-XXL (Juraska et al., 2023), MetricX-24-XXL[5] (Juraska et al., 2024), and CometKiwi-23-XXL (Rei et al., 2023). We compare our decoding algorithm with context-aware MAP decoding, which employs a beam search with a beam size of 5. The context sizes of both methods are at most one previous paragraph, as described in Section 3.5.

For evaluation, we first apply a sentence segmenter[6] (Frohmann et al., 2024) to each source and target paragraph and compute the scores across all pairs of source and target sentences for each paragraph. Then, we compute the score alignment that maximizes the total scores. Finally, the document-level QE scores are calculated by averaging the paragraph-level QE scores.

[5]MetricX-24 is a hybrid reference-based/-free metric, so we use it as a reference-free QE model in this evaluation.

[6]https://huggingface.co/segment-any-text/sat-12l-sm

Direction	Decoding	MTX23↓	MTX24↓	KIWI23↑
En–Ja	MAP	3.4	4.9	74.7
	MBR	**3.0**	**4.2**	**77.2**
Ja–Zh	MAP	4.0	4.9	63.1
	MBR	**3.5**	**4.7**	**64.8**

Table 5: Reference-free quality estimation scores on the WMT'25 test set. The **bold** font indicates the best scores in each translation direction. The green highlighted rows indicate the setting of our submission system.

Results Table 5 demonstrates the translation quality of decoding methods. The table shows that MBR decoding consistently outperformed MAP decoding across all metrics, even though we used only MetricX-24-XXL for the utility function. One reason for these results is that MAP decoding tends to propagate translation errors, including hallucinations, whereas MBR decoding carefully selects translations based on the expected utility computed from the evaluation metric and other translation samples, thereby mitigating the generation of pathological sequences.

5 Conclusion

We built our system on the WMT'25 general translation task in En–Ja and Ja–Zh. Our models were trained with the combinations of CPT, SFT, and stepwise PO based on the quality- and adequacy-aware rewards, for each translation direction. To maximize the translation quality and document-level consistency, we generated translations via context-aware MBR decoding.

In document-level translation, we observed that LLMs are more likely to generate collapsed hallucination texts. To mitigate this issue, we employed adequacy-aware PO. Nevertheless, in some cases, the models still failed to generate translations. We hope to further improve hallucination mitigation in document translation.

Limitations

Metric bias We used MetricX-24-XXL for the preference data creation in PO and the utility function of MBR decoding, which heavily relied on a single metric. Thus, our system may be affected by the metric bias.

Domain adaptation We built a single system for each translation direction, regardless of domains,

while the WMT'25 general translation task contains multiple domains. By considering domain-specific knowledge and preferences, further improvements in translation quality can be expected.

Multimodal translation In the speech domain, original videos are also provided in addition to plain texts transcribed by an automatic speech recognition (ASR), but we did not use them. This means that ours is a cascade-style speech-to-text or video-to-text translation in the speech domain. By utilizing the original videos and audio, we can expect to suppress the propagation of errors caused by an ASR system.

Acknowledgements

This work was done mainly under a collaborative research agreement between NTT and Tsukuba University. Additionally, this work partially used computational resources of Pegasus provided by the Multidisciplinary Cooperative Research Program in the Center for Computational Sciences, University of Tsukuba.

Author Contributions

Zhang Yin applied PO, conducted translation experiments as described in Section 4.1 and other preliminary experiments, and selected the submission system.
Hiroyuki Deguchi conducted context-aware MBR decoding, as described in Section 2.2, and experiments regarding decoding strategies as shown in Section 4.2.
Haruto Azami applied CPT in En–Ja and generated the preference data in En–Ja for PO.
Guanyu Ouyang applied SFT in En–Ja and selected the submission system.
Kosei Buma collected and cleaned up the Ja–Zh dataset for SFT and PO via translation scoring and deduplication.
Yingyi Fu participated in discussions and reviewed system performance.
Katsuki Chousa provided advice on model development and decoding.
Takehito Utsuro built and managed our team.

Abstract

This work presents an innovative decoding approach utilizing the A* algorithm, which generates a diverse and precise set of translation hypotheses. Subsequent reranking through the Noisy Channel Model Reranking and Quality Estimation selects the best among these diverse hypotheses, leading to a significant improvement in translation quality. This approach achieves up to a 0.5-point reduction in the MetricX-24 score and a 1.5-point increase in the COMET score.

The A* decoding algorithm is model-agnostic and could be applied to decoding in LLMs as well as classic transformer architectures. The experiment shows that by using freely available open source MT models, it is possible to achieve translation quality comparable to the best online translators and LLMs using a single 32GB GPU card.

1 Introduction

The final stage of inference in language models is decoding, which involves generating text based on calculated token probabilities. The most commonly used approach is autoregressive decoding, which generates tokens sequentially based on the source text and the text produced thus far. There are three primary strategies for autoregressive decoding: greedy, beam, and sampling. Each of them has its flaws that A* resolves.

2 Decoding Strategies

Greedy Decoding selects the most probable token at each step, prioritizing speed and simplicity but often producing suboptimal results due to its limited exploration of alternative paths.

Sampling introduces randomness by selecting tokens based on their probability distribution, but the generated hypotheses can be overly random, resulting in translations that are not always optimal.

Beam Search maintains multiple high-probability sequences (beams) simultaneously, enhancing output quality at a modest computational cost proportional to the beam width. This algorithm has been widely used in machine translation.

Recent advances in large language models (LLMs) have demonstrated their superiority over traditional encoder-decoder transformers (Vaswani et al., 2017). However, because of their primary purpose, LLMs are designed for rapid text generation and not for quality-oriented beam search. Beam search in LLMs takes much more time than in classic transformers. For example, from our experiments, the beam search using vLLM[1] on EuroLLM-9B (Martins et al., 2025) takes about 30 seconds to decode with beam of width 10 for just one sentence. Within the same time, we can use sampling to generate as many as 800 diverse hypotheses, which later assessed by QE give great improvement over greedy decoding or beam search. In the following, we propose a novel A* decoding algorithm for LLMs that combines the speed of beam search in classic transformers with the diversity of sampling.

3 A* Decoding

Let's consider decoding as the process of searching for the optimal path within a tree of all possible sentences generated by a model, where the chosen path represents the best translation of the source sentence. Typically, there are no clear criteria for evaluating the quality of the generated sequence, so we must rely on proxy metrics derived from available data to assess its quality. One of the most effective and straightforward proxy metrics is the average probability of all tokens generated. This metric guides the algorithm to select the most probable token at each step of the output generation

```
def a_star_decoding(source, max_cands, hope_level):
   queue = ReversedPriorityQueue()
   queue.put((0, []))
   results = []
   for iteration in range(max_cands):
      if queue.empty(): break
      old_f_score, prefix = queue.pop()

      new_trn = LLM.generate(source, prefix)
      results.append(new_trn)
      if iteration == 0:
         def_f_score  = sum(new_trn.tokens) / len(new_trn.tokens)

      for idx, token in enumerate(new_trn.tokens[len(prefix):]):
         idx += len(prefix)
         for alt_token in token.alternative_tokens:
            g_score = sum(new_trn.tokens[:idx]) + alt_token.logprob
            h_score = sum(new_trn.tokens[idx+1:])
            f_score = (g_score + h_score) / len(new_trn.tokens) + hope_level
            if f_score > def_f_score:
               queue.put((f_score, new_trn.tokens[:idx] + [alt_token]))
   return results
```

Listing 1: Python-like pseudocode of the A* decoding

process. The simplest approach, known as greedy decoding, follows this principle. However, the results of greedy decoding may be suboptimal, as it overlooks many potential paths. In contrast, A* decoding allows the algorithm to explore beyond just the most probable next token, selecting tokens that offer the potential for discovering a more probable path by the end of the process. A similar concept has already been explored for Statistical Machine Translation (SMT) with long paragraphs (Och et al., 2001).

3.1 A* algorithm

A* algorithm uses priority queue to explore graph nodes, prioritizing those with the lowest estimated total cost.

For each node n, it computes:

• $g(n)$: exact cost from the start node to n.

• $h(n)$: heuristic estimate of the cost from n to the end of sentence.

• $f(n) = g(n) + h(n)$: estimated total cost of the path through n.

3.2 A* decoding description

We propose the following adaptation of the A* algorithm to decoding in LLMs. The probability of the remaining sequence is the probability of the generated token (as in beam-search) plus probability of the sequence following the new token. Assuming that the remaining sequence could have a slightly higher probability than the base sequence, we can estimate the total probability of a new path. This is done by adding the probability of the new token, adjusted by a small constant to account for the potential increase of total probability.

The initial step of the algorithm is generation of the default greedy translation for the source sentence. We then enhance this baseline by employing the A* algorithm for further exploration. For each token generated, we select alternative tokens at its position and calculate the estimated total cost, f(n), as outlined below:

• $g(n)$ (actual cost) - normalized logarithm probability of a prefix with alternative token.

• $h(n)$ (estimate cost) - normalized logarithm probability of the default suffix plus some constant "hope_level" that assumes that the actual probability of the rest of sentence may be bigger than the default. The "hope_level" should be chosen experimentally. High enough to ensure that $h(n)$ remains admissible (does not overestimate the actual cost), but not too high to avoid considering highly improbable alternative tokens.

The pseudocode for the algorithm is presented in Listing 1.

Table 1: Comparison of MetricX-24 scores on the WMT24++ test set for the English-to-Czech translation direction.

4 Reranking

Following the generation of a set of translation hypotheses using the above described algorithm, we select the optimal hypothesis through a modified Noisy Channel Model Reranking approach, as described by (Yee et al., 2019). This reranking method enhances machine translation by reordering candidate translations during the decoding process. It integrates three components: a direct translation model, $P(T|S)$, which predicts the target sentence T given the source sentence S; a channel model, $P(S|T)$, which assesses the likelihood of the source sentence given the target; and a language model, $P(T)$, which evaluates the fluency of the target sentence. The algorithm ranks candidates by computing a weighted combination of these probabilities, ensuring the selection of the most accurate and fluent translation. The algorithm scores candidates using a weighted combination of these probabilities:

• $S(T|S)$=$P(T|S)$+$\lambda_1$log $P(S|T)$+$\lambda_2$log $P(T)$

where λ_1 and λ_2 are tunable weights. Top candidates from the direct model are reranked based on this score, prioritizing translations that balance fidelity to the source and fluency in the target. For our submission in WMT2025 we applied the following scoring:

• $P(T|S)$ - calculated by weighted sum of probabilities of EuroLLM-9B, NLLB-3.3 (Team et al., 2022) combined with Unbabel/comet wmt23-cometkiwi-da-xl score. (Rei et al., 2020)

• $P(S|T)$ - calculated by NLLB-3.3.

• $P(T)$ - not used - for compliance with constrained path.

4.1 Hallucination detection

Before reranking, we remove hypotheses that appear to be outliers or hallucinations. For each source sentence, we calculate the standard deviation of the probability scores across all hypotheses for each scoring model. Hypotheses with scores below the mean minus one standard deviation are filtered out.

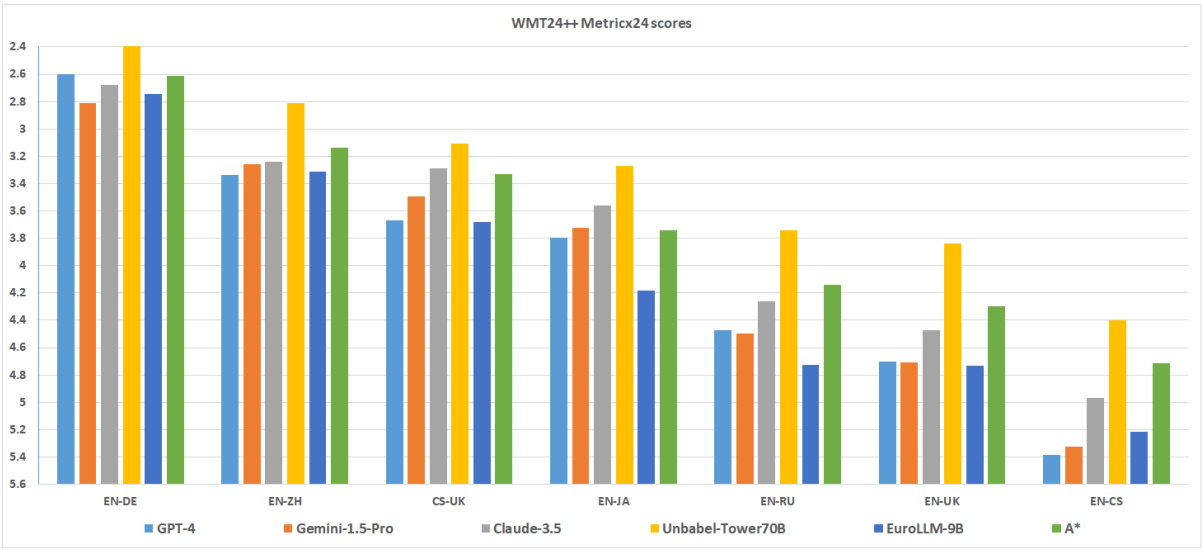

Figure 2: Comparison of presented solution (green) to leading LLMs.

5 Results

5.1 Comparison with different decodings

The chart on Figure 1 presents the quality of various algorithms across different number of generted hypotheses. The Y-axis represents reference-based MetricX-24 scores (Juraska et al., 2024) on wmt24++ testset (Deutsch et al., 2025) for the English-to-Czech translation direction. The X-axis indicates the number of hypotheses generated per source sentence. Table 1 presents exact values for the chart. The values for sampling vary with each run. The values in the table represent the mean of multiple runs. Performance times were measured in seconds on a single A100-80GB GPU using the vLLM framework on EuroLLM-9B. 80GB of GPU memory is not necessary. We have successfully run the above tests on A100-40GB and V100-32GB with slower decoding time, but the same quality.

The baseline performance, established through greedy decoding, achieves a score of 5.2064. Pure beam search, utilizing a beam width of only 10 hypotheses, yields a better score of 5.0667, though it requires approximately 30 seconds to decode a single sentence. Despite its computational complexity, beam search remains the best algorithm for decoding without reranking. The introduction of reranking shifts the advantage to the A* algorithm, which delivers an improved score of 5.0062, representing a 0.2-point improvement over the baseline. Incorporating Quality Estimation (QE) further enhances performance, boosting results by approximately 0.2 to 0.3 points above the reranked results. In this scenario, A* remains the top-performing algorithm, achieving the best score of 4.7049. When all techniques are combined, the overall improvement ranges from approximately 0.2 to 0.5 points on the reference-based MetricX-24 compared to the baseline.

It may seem surprising that A* decoding requires less time than sampling for a single source sentence, but this number comes from total time divided by maximum number of hypotheses - 200. Sampling always generates a fixed number of hypotheses, often including duplicates. In contrast, A* decoding halts once it can no longer identify distinct hypotheses, especially for short segments, resulting in a shorter total processing time compared to sampling. E.g. for beam of 200 A* decoding on WMT24++ generates only about 100 hypotheses on average.

5.2 Comparison with other LLMs

Figure 2 presents automatic scores for translations for different directions, generated using several leading LLMs: Claude[2], Gemini[3], GPT[4], Unbabel-Tower (Alves et al., 2024). Values are reference-based scores of MetricX-24. While these scores do not perfectly reflect translation quality, they offer a general indication of performance. The table illustrates that the translation quality achieved by the method described in this paper is comparable to that of the leading LLMs.

[3]https://gemini.google.com/
[4]https://chatgpt.com/

6 Conclusions and future work

We introduced a novel, high-speed decoding algorithm (A*) that generates hypotheses significantly faster than beam search in large language models (LLMs). This algorithm is adaptable to any language model. The application of Noisy Channel Reranking enhances the quality of diverse generated candidates by up to 0.2 points on the MetricX-24 scale. Further application of Quality Estimation (QE) reranking yields an additional improvement of another 0.2 to 0.3 points.

A* decoding algorithm flexibility enables a balance between quality and speed. Due to its efficiency and adaptability for any language model, this method has potential for numerous practical applications.

The proposed solution demonstrates high quality of EuroLLM models. The final results reflect a significant improvement over EuroLLM-9B translations, with a reduction of up to 0.5 points in MetricX-24 and an increase of 1.5 points in COMET, achieving quality comparable to leading large language models, even for non-European languages.

Due to time constraints prior to the WMT25 workshop, we were unable to explore post-processing techniques or context-aware multi-sentence decoding. The results submitted represent the unrefined output of the method described in this paper. A* decoding is a new idea, and we intend to refine it through further research. The results presented at WMT25 could be enhanced by leveraging other LLMs models as a base model, incorporating alternative Quality Estimation methods, or utilizing improved language models for reranking.

7 Acknowledgements

We would like to express our gratitude to the entire Machine Translation team at Samsung R&D Poland for their support. Special thanks go to Marcin Szymański for valuable reviews. We also acknowledge the management of Samsung Poland for their support in preparing this work.

Abstract

This paper presents the open-system submission by the In2x research team for the WMT25 General Machine Translation Shared Task. Our submission focuses on Japanese-related translation tasks, aiming to explore a generalizable paradigm for extending large language models (LLMs) to other languages. This paradigm encompasses aspects such as data construction methods and reward model design. The ultimate goal is to enable large language model systems to achieve exceptional performance in low-resource or less commonly spoken languages.

1 Introduction

Machine translation (MT) has long been both a high-impact application and a central research challenge in natural language processing. The advent of large language models (LLMs) has reshaped MT from task-specific supervised learning toward large-scale representation learning and instruction-following paradigms, enabling steady gains across diverse language pairs (Alves et al., 2024; Jiao et al., 2023; Kocmi et al., 2024; Lu et al., 2024).

Yet, two persistent gaps remain. **First**, while mainstream LLM training increasingly optimizes for mathematical and code reasoning, their *expressive* and *creative* language abilities—e.g., idiomaticity, stylistic naturalness, and culturally appropriate phrasing—are comparatively underdeveloped(Lewkowycz et al., 2022; Liu et al., 2023; Lozhkov et al., 2024; Rozière et al., 2023; Zaitova et al., 2025). This often leads to translations that are locally literal but globally stilted, especially for informal registers, slang, and literary text . **Second**, model competence is unevenly distributed across languages: English receives disproportionate coverage and quality, while many non-English languages trail in both general capability and translation naturalness(Aharoni et al., 2019; Johnson et al., 2017; Kocmi et al., 2023, 2024; Team et al., 2022). Community findings over recent WMT cycles echo this asymmetry: despite the "LLM era", MT is far from solved uniformly across directions, with larger gaps off English-centric pairs and on long-tail phenomena .

This paper studies how to **transfer English strength into non-English targets** to improve expressive and culturally faithful translation. Concretely, we focus on Japanese—a language where literal adequacy is not sufficient: natural Japanese requires idiomatic paraphrasing, honorific and register control, and sensitivity to genre and context. Our thesis is that English can be used as a *hub language* to bootstrap these capabilities via curriculum design, cross-lingual alignment, and preference signals that explicitly reward naturalness.

We present **In2x**, a Japanese-focused model designed to inherit general competency from English while specializing for Japanese expressiveness. At a high level, In2x operationalizes three principles: (i) *English-as-hub transfer*: leverage rich English data and strong English modeling to seed robust lexical/semantic priors, then transfer to Japanese via bilingual and style-augmented objectives; (ii) *Expressiveness-first supervision*: emphasize prompts and signals that drive idiomaticity and cultural appropriateness (beyond literal adequacy); (iii) *Evaluation beyond metrics*: complement automatic metrics with human judgments targeted at idioms, slang, and stylistic naturalness.

We evaluate In2x on standard WMT-style test sets and targeted Japanese-focused challenge suites that stress idioms, slang, and style. According to the preliminary ranking results of WMT 2025, In2x outperforms many large-scale proprietary models, such as Gemini-2.5-Pro (Comanici and Team, 2025), GPT-4.1 (Fachada et al., 2025), Claude-4 (Anthropic, 2025), and DeepSeek-V3 (Monisha, 2025).

Overall, we make three core contributions:

1. We diagnose under-explored gaps in current

Proceedings of the Tenth Conference on Machine Translation, pages 671–679
November 8-9, 2025

LLM-based MT: the tension between heavy investment in math/code reasoning and the relative neglect of creative/idiomatic language ability, and the English-vs.-non-English capability asymmetry.

2. We introduce **In2x**, a Japanese-focused model that systematically transfers English strengths to Japanese, with an emphasis on naturalness and cultural appropriateness.

3. In this study, we introduce a detailed alignment pipeline designed to enhance the creative capabilities of language models. This approach not only improves performance in non-STEM (Science, Technology, Engineering, and Mathematics) tasks but also ensures that the models maintain robust generalization abilities across diverse linguistic challenges. For instance, in the en-ja translation track, the model demonstrates outstanding performance without any task-specific fine-tuning, highlighting its adaptability and effectiveness in non-STEM domains.

2 Continue Pretraining Stage

To balance the capabilities of large language models (LLMs) in both science-oriented and humanities-oriented domains during the pretraining process, we divided the continued pretraining stage into three distinct phases. The goal of this process is to enhance the model's multilingual proficiency, improve general-purpose abilities in foundational humanities tasks, and refine its representation in specialized contexts (Brown et al., 2020; Rae et al., 2021).

The training process incorporates diverse corpora, including a comprehensive 2 trillion tokens dataset comprising encyclopedic knowledge, webpages, structured information, news articles, Wikipedia entries, academic papers, and STEM-related datasets (Gao et al., 2020; Raffel et al., 2020). In addition, a dedicated 500 billion tokens corpus has been curated exclusively for creative writing tasks such as novel and screenplay synthesis, as well as authentic conversational datasets simulating real-life dialogue (Zhang et al., 2022).

Another significant aspect of this training stage focuses on enhancing capabilities in the target language, with Japanese utilized as an example. To this end, substantial Japanese language-specific corpora were introduced, alongside a balanced dataset with equal distribution of Chinese, English, and Japanese corpora (Xue et al., 2021). The aim was to facilitate transfer learning from pretraining on Chinese and English to the Japanese language.

2.1 Phase 1: Fundamental Knowledge Enhancement

In this phase, the creative writing corpus and the knowledge-focused corpus are jointly trained with constant learning rates. This approach was designed to boost proficiency in STEM-related reasoning while preserving the nuanced expression habits required for creative tasks in humanities (Kaplan et al., 2020).

2.2 Phase 2: Long-Text Capability Refinement

During this phase, a subset of the data was filtered based on text length, allowing the context length to increase from the typical 8,192 tokens to approximately 32,000 tokens. This step was intended to amplify the model's ability to process and comprehend extended-length texts (Hoffmann et al., 2022).

2.3 Phase 3: Fast Annealing Stage

In the final phase, a high-quality corpus was constructed based on selections informed by perplexity (PPL) and quality-assessment metrics. The annealing training was conducted with linear decay of the learning rate from 3×10^{-5}. This process consumed a total of 300 billion tokens and enabled the model to maintain its vivid expressive style for tasks such as novels and screenplays (Brown et al., 2020).

3 Post-Training Data

The post-training dataset consists of 2 million samples, with 1.5 million used during the supervised fine-tuning (SFT) process and 500,000 used in the reinforcement learning (RL) process. To ensure the Japanese language (our target language) achieves a proficiency level comparable to major languages such as Chinese and English, we adjusted the ratio of target language instructions to attain an equal balance across these languages. Specifically, we used a 1:1:1 ratio in the Instruct-to-Example (In2X) setup, striving to transfer the original model's knowledge into the target language as effectively as possible (Ouyang and et al., 2022; Zhou et al., 2023).

We developed a detailed pipeline for constructing the target language instructions, which can be categorized into three major synthetic processes:

3.1 Obtaining Open-Source Instructions

We began by collecting open-source instruction datasets available in the target language. These datasets include curated public data and traditional NLP fundamental tasks. Examples of such datasets include Dolly, OASST, and OASST2 (Koch and et al., 2023; OpenAI, 2023).

3.2 Target Language Instruction Rewriting

This process consists of several substeps designed to enhance the model's linguistic and cultural adaptability in the target language:

- **Creative Language Tasks:** To preserve the language's stylistic characteristics in humanities-focused tasks, we designed creative tasks where the responses include original stories or scripts (Bai and et al., 2022).
- **Basic Localized Tasks:** This includes rewriting instructions for tasks relevant to the local context, such as exam questions. Some of these tasks provide only the question and answer. We leveraged advanced models to supplement these datasets with reasoning chains to improve the model's reasoning ability in the target language (Wei and et al., 2022). This enhancement also helps to mitigate issues such as mathematical inconsistencies commonly faced during the LLM instruction synthesis process.
- **Cultural Style Transformation:** For certain humanities-related tasks, we incorporated cultural style shifts by adapting the instructions to align with the cultural norms and styles of the target language. This adjustment aims to improve the model's ability to provide culturally nuanced responses (Xu and et al., 2023).

3.3 Instruction Synthesis in the Target Language

We utilized methods such as Magpie (Xu et al., 2024) and Self-Instruct (Wang and et al., 2022) to synthesize target language instructions. However, these automatically generated instructions often suffer from issues including overly simple questions, lack of focus, self-answered queries, and internal contradictions. To address these challenges, we implemented a strict quality control pipeline with the following techniques:

- **Prompt Engineering:** We crafted detailed prompts with explicit rules to identify and troubleshoot common issues in synthesized instructions (White and et al., 2023).
- **Validation via Model Responses:** Instructions passing the first step were tested by having the model generate responses. These responses were evaluated by a critic LLM for contradiction, hallucinations, or failure to provide valid results. Instructions flagged with such issues were discarded. The critic LLM, being sensitive to hallucinations, acts as an additional safeguard for quality control (Ganguli and et al., 2022).
- **ReReading Mechanism:** After constructing the prompts for instruction generation, we employed a "ReReading" mechanism, where the model self-reviews its instructions. This review checks for correctness, alignment with the target language's cultural norms, and consistency with its native linguistic style. Since the synthesized instructions inherently carry the reasoning or rewriting processes behind them, leveraging this comprehensive context makes it easier to detect internal flaws, particularly those related to localization or cultural adjustments (Chiang and et al., 2023).

4 Post-Training SFT Stage

The post-training Supervised Fine-Tuning (SFT) stage is a critical step to balance linguistic diversity and optimize alignment within the instruction space for target languages. Below, we outline the key strategies and methods employed during this stage.

4.1 Balancing Linguistic Diversity

(a) **Clustering of Instruction Data:** To enhance linguistic diversity, the instruction dataset (comprising 40 million entries) was clustered using the Birch clustering algorithm (Zhang et al., 1996). The effectiveness of the clustering process was evaluated based on metrics like tag recapture rates and cluster smoothness (Zhang and Deng, 2020), which were used to fine-tune the clustering threshold. This process reduced the dataset to 1.5 million clusters after deduplication and selection.

(b) **Categorization via Large Language Models (LLMs):** Utilizing LLMs, the clustered data was tagged to assign both first-level and second-level labels (et al., 2020). For example, a mathematical problem might be categorized as "Mathematics - Quadratic Equations." These hierarchical labels provided a clearer structural organization of the data.

(c) **Difficulty Grading of Instructions:** The dataset was further refined by classifying each instruction according to its difficulty level: "Very Difficult," "Difficult," "Moderate," "Simple," and "Very Simple" (Wang and Li, 2019). For normalized scientific datasets, an additional evaluation was conducted using the LLaMA3-70B model (Research, 2023) with a Pass@16 metric (Perez and Andreas, 2022) to estimate the success rate of solving specific problems.

4.2 Aligning the Instruction Space of Target Languages

(a) **Avoiding Semantic Overfitting via Temperature Adjustment:** During training, a temperature parameter was introduced to mitigate overfitting of the model to specific linguistic semantic spaces (Sundararajan and Wang, 2021). This approach encouraged the model to adopt a more holistic learning strategy, enabling it to concentrate on question-answering techniques rather than over-specializing in the semantic patterns of a particular language. For instance, this allowed the Japanese language model to better mimic the cognitive behaviors observed in other languages (Koehn, 2019).

(b) **Specialized Sampling Strategy:** To further enhance the learning process, a two-step sampling strategy was employed over the 1.5 million clusters (Perket and Sanner, 2020):

- The difficulty levels of the data were sampled in a 3:3:3:1:0 ratio (corresponding to "Very Difficult," "Difficult," "Moderate," "Simple," and "Very Simple," respectively) (Finn and Jones, 2018).
- Additionally, within each cluster, samples were selected to ensure diversity across languages and categorical labels, which preserved the large-scale diversity of the original 1.5 million data points (Torroba and Blanco, 2021). This also maintained a degree of orthogonality between the target language and English within the sampled instructions (Feng and Gimpel, 2020).

The first round of sampling was used as the data for the first epoch, while the second round populated the second epoch. The training process adopted a learning rate of 2×10^{-5} with cosine decay for optimal performance (Loshchilov and Hutter, 2017).

5 Reinforcement Learning to Enhance General Capabilities in Cultural and Creative Industries

In the post-training RL stage, we leveraged a process similar to the instruction filtering procedure used during the SFT phase (Ouyang and et al., 2022). Specifically, an additional set of instructions was curated, comprising 500k samples that were guaranteed not to overlap with the instructions used in the SFT phase. The training configuration utilized a batch size of 128 and a minibatch size of 32, with the dataset trained for one epoch. Each rollout involved 16 iterations, and the reward evaluation was based on both a rule-based reward model and a generative reward model (Christiano et al., 2017).

5.1 Reward Model Design

The reward model system was meticulously designed to cater to different task types:

- **Rule-Based Reward Model:** For tasks involving mathematics, STEM disciplines, and logic, a rule-based reward model was employed to ensure adherence to specific criteria (Silver and et al., 2017).
- **Generative Reward Model for Creative Tasks:** For creative tasks like content generation, prompts were designed to embed specific scoring criteria or reward principles. These criteria included fundamental task requirements as well as dynamically generated guidelines tailored to the current prompt. For instance, in translation tasks, prompts might incorporate principles to penalize issues such as omissions, linguistic inconsistencies, or mixing of languages. The scoring mechanism then assessed adherence to these principles and calculated a reward score based on the percentage of fulfilled criteria (Liu et al., 2025)

- **Pair-wise Reward Model for Creative Tasks:** Initially, annotators labeled 2,000 commonly used task examples with their corresponding ground truth answers (gsb), identifying any problematic answers and providing critique reasons. Using these critiques and annotations, a pair-wise reward model was trained, achieving an accuracy rate of 70

5.2 RL Algorithm Design

To address the complexity of the tasks, we made strategic adjustments to the RL algorithm to achieve stable and efficient training:

- **Trajectory-Corrected GRPO:** Considering the diverse nature of tasks and reward types, a token-level clipping approach was deemed too restrictive and prone to causing training instability. Instead, we employed the Trajectory-Corrected version of the Generalized Proximal Policy Optimization (GRPO) algorithm (Schulman et al., 2017), which proved effective for handling multilingual tasks with varying reward functions. This modification enabled stable and continuous training while accelerating the convergence curve(Pang and Jin, 2025).

- **Dual-Clip Mechanism:** To improve stability, we integrated a dual-clip mechanism, which stabilized the variance of importance sampling at the sentence (sen) level (He et al., 2016). Additionally, we removed the lower bound of sampling, achieving optimal performance for the given tasks.

- **Soft Length Penalty:** A soft-length penalty was incorporated throughout the training process to encourage better length control in generated outputs (Wu et al., 2016).

- **High-Level Clipping:** A clipping mechanism was introduced to ensure robust control over high-level rewards (Schulman et al., 2015).

- **Temperature Decay:** A temperature decay strategy was applied to progressively adjust the sampling temperature during training, encouraging diversity in outputs while maintaining stability (Hinton et al., 2015).

- **Entropy Regularization:** The entropy value was set to 0.01 during training, enabling the model to conserve entropy and avoid premature saturation of the reward space (Williams, 1992).

- **Reducing Variance Caused by Task Lengths:** To alleviate the variance introduced by the differing lengths of creative writing tasks and scientific tasks, a sequence-level reward training strategy was employed. This approach balances the effect of length differences between arts and science tasks, enabling better convergence under different task scenarios(Mao et al., 2025).

6 Model Ensemble

Model ensemble techniques are employed by taking into account the orthogonality of linguistic capabilities among various models. Specifically, models that exhibit strong linguistic proficiency are selected for the ensemble process to maximize overall performance.

Furthermore, the fusion of model tensors is conducted based on gradient information and the importance of weights. This approach ensures a robust integration of model parameters, leveraging their respective contributions to optimize the ensemble. Such methodologies have been shown to enhance the effectiveness of model ensembles in complex tasks (Wang et al., 2025).

7 Evaluation Results

7.1 Benchmarks

The model demonstrated exceptional performance in widely recognized Japanese language benchmarks, particularly the ja-mtbench, showcasing its robust and reliable language translation capabilities. A comparative analysis of its performance against other prominent models, such as GPT-4-turbo (GPT-4.0), Claude 3.5, and Qwen-2.5-72b, is visually presented in Figure 1. As depicted in the figure, our model significantly outperforms its counterparts across various evaluation metrics, further validating its superiority in Japanese language processing tasks.

7.2 WMT Evaluation Results

The performance of the model, despite not having undergone specific fine-tuning for particular tasks, has demonstrated exceptional results in the automatic evaluation of Japanese-related tracks within

Table 1: English→Japanese Translation Performance at WMT25.

System	Human	AutoRank	Literary	News	Social	Speech
In2x	77.8	2.3	60.8	83.6	81.9	82.7
Gemini-2.5-Pro	85.8	2.5	87.3	82.5	87.7	86.0
GPT-4.1	83.7	2.9	95.4	77.0	80.7	84.9
Claude-4	79.3	5.8	86.5	76.1	72.8	86.3
Deepseekv3	79.3	4.7	82.9	80.0	74.1	82.7

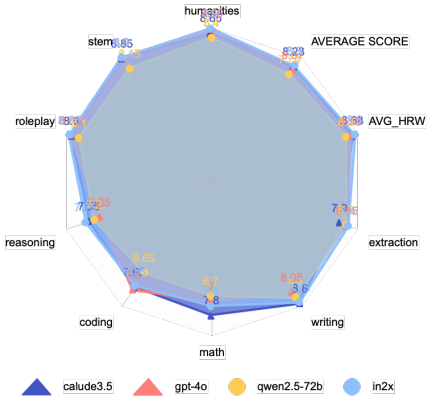

Figure 1: The performance results of in2x, gpt-4-turbo (GPT-4.0), Claude 3.5, and Qwen-2.5-72b on jamtbench.

the WMT competition. These outcomes are further corroborated by human evaluations, where the model outperformed closed-source commercial api, such as Claude 4, in areas including social interactions, news-related tasks, and speech generation(Kocmi et al., 2025b). However, it is worth noting that its performance in tasks requiring literary competence and advanced literary expression was suboptimal. This gap highlights a significant area for improvement, particularly in its handling of classical texts and the refinement of its literary language generation abilities. Moving forward, the primary focus of subsequent development efforts will lie in enhancing the model's proficiency in literary composition, with a particular emphasis on classical literature and the nuanced articulation of literary expression. For further details and specific performance metrics, one may refer to the original comparative analysis and evaluation results(Kocmi et al., 2025a).The specific results can be found in the table for reference1.

8 Conclusion

This work introduces and validates a method for transferring language modeling capabilities, as demonstrated on the WMT translation task. The proposed approach significantly enhances Japanese language proficiency during the CPT, SFT, and RL processes. Notably, without any additional language-specific fine-tuning, the large language model achieves alignment in its Japanese capabilities, bringing them on par with those of mainstream languages.

Furthermore, this work presents a systematic pipeline for aligning language models, as well as a method for training rewards in the creative content domain. Remarkably, this approach requires only around 2,000 annotated samples in the target language to achieve improved language transfer capabilities, with the remaining process relying on automated instruction-building techniques. Future efforts will focus on enhancing the literary style of the model by integrating elements such as classical texts and stylistic refinements into the pipeline.

CUNI at WMT25 General Translation Task

Miroslav Hrabal, Josef Jon, Martin Popel, Ondřej Bojar
Charles University, Faculty of Mathematics and Physics
{hrabal,jon,popel,bojar}@ufal.mff.cuni.cz

Abstract

This paper describes the CUNI submissions to the WMT25 General Translation task, namely for the English to Czech, English to Serbian, Czech to German and Czech to Ukrainian language pairs. We worked in multiple teams, each with a different approach, spanning from traditional, smaller Transformer NMT models trained on both sentence and document level, to fine-tuning LLMs using LoRA and CPO. We show that these methods are effective in improving automatic MT evaluation scores compared to the base pretrained models.

1 Introduction

We have entered the shared task as a number of small teams with different approaches, each with its own submission. We will describe the datasets, methods and evaluation results of each submission in the following sections. Here we will present just a brief overview of all the systems we submitted.

CUNI-MH-v2 is a constrained system trained on partially synthetic data sampled from the CzEng 2.0 (Kocmi et al., 2020) dataset using LoRA (Hu et al., 2021) and Contrastive Preference Optimization (Xu et al., 2024). We will release both the model weights and the filtered training data. The model itself is fine-tuned from the EuroLLM-9B-Instruct model. We currently only support two language directions, (en→cs) and (cs→de), and offer separate LoRA adapters for each. The translations were done on the paragraph level.

CUNI-EdUKate-v1 is an unconstrained system trained on educational domain data using LoRA, SFT, and Contrastive Preference Optimization. It is also fine-tuned from the EuroLLM-9B-Instruct model. It only supports cs2uk language direction and, unlike CUNI-MH-v2, both training and inference were done on sentence level.

CUNI-SFT models were created by a simple supervised finetuning using LoRA on a small amount of publicly available training data.

CUNI-Transformer and **CUNI-DocTransformer** are resubmissions of systems from previous years.

2 Methods

This section describes the approaches used for training our submissions.

2.1 CUNI-SFT (en2cs, en2sr, cs2uk)

We have finetuned multiple pretrained models for document-level and sentence-level translation using LoRA. We have used learning rate $lr = 2e-4$, LoRA ranks $r = 8$ and $r = 16$, LoRA $\alpha = 2 * r$ and batch size of 2 with 16 gradient accumulation steps, resulting in effective batch size of 32. We trained the models for 10k updates. We compared sentence-level translation without context, sentence-level with context shown to the LLM and pure document-level prompt. The prompts are shown in Section A.

2.2 CUNI-MH-v2 (en2cs, cs2de)

Considering that EuroLLM-9B-Instruct is already reasonably good at English to Czech translation, we chose to skip the supervised fine-tuning stage, thereby departing from year's CUNI-MH (Hrabal et al., 2024), and fine-tuned the model solely using Contrastive Preference Optimization (CPO) (Xu et al., 2024).

For the two language directions, (en→cs) and (cs→de), we trained separate LoRA adapters with rank $r = 32$, LoRA $\alpha = 64$, LoRA dropout of 0.05 and effective batch size of 8. We used cosine learning rate scheduler and trained for $10\,\text{k}$ steps.

2.3 CUNI-EdUKate-v1 (cs2uk)

CUNI-EdUKate-v1 was trained from EuroLLM-9B-Instruct model using LoRA in two stages. In

Proceedings of the Tenth Conference on Machine Translation, pages 680–687

the first stage, we train it on internal sentence-level educational domain parallel data. In the second stage, we train it on partially synthetic internal preference sentence-level educational domain data.

2.4 CUNI-(Doc)Transformer (cs2uk, en2cs)

CUNI-Transformer (cs→uk) and CUNI-DocTransformer (en→cs) are the same systems as submitted in previous years (Jon et al., 2023), relying on standard NMT training with Block backtranslation (Popel, 2018; Popel et al., 2020) and (in the case of CUNI-DocTransformer) document-level training.

3 Data

3.1 CUNI-SFT

We downloaded corpora for Czech to English, Croatian, Serbian[1], Bosnian, German and Ukrainian and English to Croatian, Serbian, German and Ukrainian from OPUS, keeping the document boundaries where possible. The datasets we used are: `DGT`, `DocHPLT`, `ELITR-ECA`, `EMEA`, `GlobalVoices`, `JRC-Acquis`, `News-Commentary`, `SETIMES`, `StanfordNLP-NMT`, `Tatoeba`, `TED2020`, `tico-19`, `TildeMODEL` and `WMT-News`. We scored these datasets with wmt22-cometkiwi-da QE model using Marian. We have selected the top 5% scoring documents (scores are computed on sentence-level and averaged) from each dataset for each direction, with at most 200 documents per dataset and direction. Documents longer than 60 sentences are split into 60-sentence chunks for scoring and training.

3.2 CUNI-MH-v2

In order to create the preference dataset necessary for the CPO method, we first sampled paragraphs from the CzEng 2.0 dataset and translated them using different models. For en→cs dataset, we used EuroLLM-9B Instruct and CUNI-MH from last year. We also used the reference translations as one of the possible candidate translations. For cs→de dataset, we used EuroLLM-9B Instruct, Qwen 2 and Qwen 3.

We then scored the translations (all synthetic candidates and the reference for the en→cs direction) using MetricX24 (used as a reference-free metric). From this, we created (source, preferred, dis-preferred) triplets by taking the highest-scoring translation as preferred and worse scored translations as possible dis-preferred translations.

Unlike the dataset used in previous year, where we gradually built paragraphs sentence by sentence (Hrabal et al., 2024), this year we chose to select the preference on the level of whole documents.

We further filtered these triplets using a version of our work-in-progress experimental metric based on Gemma 3 27b-it model, which we refer to as r1.1. We assigned the MetricX24 and r1.1 scores to each translation candidate. Afterwards, we considered the best candidate with the best MetricX24 score as preferred and all other candidates as dis-preferred. Out of those pairs, we kept only those that met the following criteria:[2]

1. The chosen and rejected translations differ.
2. $\mathrm{MetricX24(chosen)}$ is better than $\mathrm{MetricX24(rejected)}$ by at least 1.0 points.
3. $\mathrm{MetricX24(chosen)} < 10.0$.
4. $r1.1(\mathrm{chosen}) - r1.1(\mathrm{rejected}) \geq 1.0$.

The resulting en→cs dataset consists of 25530 preference triplets, and the cs→de dataset consists of 14797 preference triplets. All datasets and models will be available on Hugging Face:

- en→cs preference dataset: https://huggingface.co/hrabalm/CUNI-MH-v2-encs-data
- cs→de preference dataset: https://huggingface.co/hrabalm/CUNI-MH-v2-csde-data
- en→cs trained model: https://huggingface.co/hrabalm/CUNI-MH-v2-encs
- cs→de trained model: https://huggingface.co/hrabalm/CUNI-MH-v2-csde

3.3 CUNI-EdUKate-v1

For the CUNI-EdUKate-v1 model, we used our internal sentence-level Czech-Ukrainian parallel dataset covering the educational domain. This

[1]We transliterated all Serbian texts written in Cyrillic into the Latin script.

[2]Note that here we work with the raw MetricX24 outputs, which are greater than or equal to 0, and where lower is better.

Table 1: CUNI-MH-v2 en→cs performance on the development set. MetricX24 is google/metricx-24-hybrid-xl-v2p6-bfloat16. CometKiwi22 is Unbabel/wmt22-cometkiwi-da. r1.1 is our internal metric based on Gemma 3 27b-it assigning DA scores.

	wmt23				wmt23-para			
Model	BLEU	MetricX24	CometKiwi22	r1.1	BLEU	MetricX24	CometKiwi22	r1.1
CUNI-MH	36.52	–	83.16	–	35.42	–	**74.82**	–
EuroLLM-9B-Instruct	36.14	−3.74	82.90	89.66	36.69	−7.68	72.67	88.98
CUNI-MH-v2	**37.33**	−3.69	**83.38**	90.36	**37.81**	−7.53	73.75	91.81

Table 2: CUNI-MH-v2 en→cs performance compared with selected WMT24 models on the WMT24 test set.

	wmt24			
Model	BLEU	MetricX24	CometKiwi22	r1.1
Unbabel-Tower70B	24.72	**−3.70**	**83.04**	88.54
Claude-3.5	**32.04**	−4.62	80.79	**90.56**
CUNI-MH	27.62	−4.53	81.10	88.21
EuroLLM-9B-Instruct	26.04	−4.77	80.51	87.19
CUNI-MH-v2	27.89	−4.62	80.99	87.85

dataset is the only reason why our submission is unconstrained.

The creation of the preference dataset for the CPO stage was done in a similar way to the CUNI-MH-v2 model but using different selection of models to generate translation candidates and to score and filter them.

One notable difference was that we also trained EuroLLM-9B-Instruct to predict Direct Assesment scores and used the result as one of the models used to filter the preference triplets.

As a development set, we used 3770 segments split from the training data.

4 Evaluation

4.1 CUNI-SFT

We compared translation quality after finetuning across four pretrained models: `EuroLLM 9B`, `Aya Expanse 8B`, `Mistral Instruct v0.3 7B` and `Granite 3.3 8B`. We measured BLEU (Papineni et al., 2002) and chrF (Popović, 2015) on `newstest2019` (Barrault et al., 2019) in the English to Czech direction, NTREX (Federmann et al., 2022) for English to Serbian and `wmttest24` (Kocmi et al., 2024) for Czech to Ukrainian. The result for simple sentence-level and context-aware sentence-level prompts are shown in Table 3. We do not present results for the doc-level prompt, since we were not able to retrieve sentence-level alignment for source and translated sentences. Overall, we see that our approach to finetuning is effective for languages that are not well covered by the base model. For high resource combinations (e.g. eng-ces in EuroLLM), the finetuning does either not change the evaluation scores, or decreses them.

4.2 CUNI-MH-v2

During inference, we use vLLM and greedy decoding.

In Table 1, we show the performance of the en→cs CUNI-MH-v2 model on the development set. In Table 2, we compare its performance with best performing WMT23 models on WMT23 test set.

Interestingly, we can see that CUNI-MH-v2 improves in BLEU score compared to the base EuroLLM-9B-Instruct model, while we saw the opposite happen in the previous year (Hrabal et al., 2024), where the BLEU/chrF metrics got worse while the COMET22 and CometKiwi22 metrics improved. On the other hand, CUNI-MH-v2 gets higher CometKiwi22 score on sentence-level wmt23 dataset but lower score on the document-level version. Overall, we were able to achieve modest improvements in all metrics compared to the base model on both the development and test set.

For translation of the final WMT25 test set, we use the official script provided by WMT organizers

Context	Language	Model	Base		Finetuned

to extract paragraph-level segments. During the inference, we further split the paragraphs to chunks of at most 256 tokens by using the sentence-splitter Python library.

4.3 CUNI-EdUKate-v1

We show the automatic metrics of the CUNI-EdUKate-v1 model in Table 4. The EuroLLM-9B-Instruct model, which is also the base model, is used as a baseline.

Table 4: CUNI-EdUKate-v1 automatic metric scores on internal educational domain sentence-level development set.

	dev set	
Model	BLEU	MetricX24
EuroLLM-9B-Instruct	37.4	−3.59
CUNI-EdUKate-v1	**39.1**	**−3.33**

5 Tools

To give a proper credit, we list the tools we used during the development and inference with our models:

CUNI-MH-v2

- transformers (Wolf et al., 2020), peft (Man-

grulkar et al., 2022) and trl (von Werra et al., 2020) libraries for training

- vLLM (Kwon et al., 2023) for inference
- MetricX24 XL[3] (Juraska et al., 2024) for scoring, data filtering, evaluation
- DSPy (Khattab et al., 2024, 2022) and Gemma-3-27b-it (Team et al., 2025) for data filtering

CUNI-EdUKate-v1

- transformers, peft and trl libraries for training
- vLLM for inference
- LINDAT Translation[4] for segmentation and to serve the translation API
- CometKiwi22 (Rei et al., 2022) for scoring, data filtering, evaluation
- MetricX24 XL for scoring, data filtering, evaluation
- Gemma-3-27b-it for data filtering

CUNI-SFT

- transformers, peft and trl libraries for training
- vLLM for inference
- CometKiwi22[5] used through Marian (Junczys-Dowmunt et al., 2018) for data filtering

CUNI-(Doc)Transformer

- Tensor2Tensor (Vaswani et al., 2018)

6 Future work

We have several ideas to improve the performance of the future iterations of our CUNI-MH-v2 model. In particular, we plan to scale up the size of the preference dataset by using a larger portion of CzEng2.0 and by sampling more translation candidates.

We also plan on experimenting with including synthetically translated documents with no reference translations, to augment our dataset with longer examples.

[5] https://huggingface.co/Unbabel/wmt22-cometkiwi-da-marian

7 Conclusion

In this paper, we presented the CUNI submissions to the WMT25 General Translation Task, covering English→Czech, Czech→German, English→Serbian, and Czech→Ukrainian language pairs. Future work will focus on scaling preference datasets and leveraging longer-context translation scenarios.

8 Acknowledgment

This work was supported by the project TQ01000458 (EdUKate) financed by the Technology Agency of the Czech Republic (www.tacr.cz) within the Sigma 3 Programme.

It was also partially supported by the Charles University Grant Agency in Prague (GAUK 244523), by SVV project number 260 821, by Czech Ministry of Education, Youth and Sports (grant MŠMT OP JAK Mezisektorová spolupráce CZ.02.01.01/00/23_020/0008518) and by National Recovery Plan funded project MPO 60273/24/21300/21000 CEDMO 2.0 NPO.

It has been using language resources and tools developed and/or stored and/or distributed by the LINDAT/CLARIAH-CZ project of the Ministry of Education, Youth and Sports of the Czech Republic (project LM2023062).

Abstract

This paper presents UvA-MT's submission to the WMT 2025 shared task on general machine translation, competing in the unconstrained track across all 16 translation directions. Unusually, this year we use only WMT25's blind **test set** (source sentences only) to generate synthetic data for LLM training, and translations are produced using pure beam search for submission. Overall, our approach can be seen as a special variant of data distillation, motivated by two key considerations: (1) perfect domain alignment, where the training and test domains are distributionally identical; and (2) the strong teacher model, GPT-4o-mini, offers high-quality outputs as both a reliable reference and a fallback in case of mere memorization.

Interestingly, the outputs of the resulting model, trained on Gemma3-12B using Best-of-N (BoN) outputs from GPT-4o-mini, outperform both original BoN outputs from GPT-4o-mini and Gemma3-12B in some high-resource languages across various metrics. We attribute this to a successful model ensemble, where the student model (Gemma3-12B) retains the strengths of the teacher (GPT-4o-mini) while implicitly avoiding its flaws.

1 Introduction

In this paper, we describe the details of our submission to the WMT 2025 shared task on the general machine translation (unconstrained track), which includes 16 translation directions. With recent advances in Large Language Models (LLMs), particularly the emergence of stronger multilingual models, our focus in this paper is on effectively and efficiently adapting a general-purpose LLM for translation-specific tasks with limited training.

Unusually, this year we use only the **test set** to build synthetic data for model training and generate translations again based on the test set using pure beam search for submission, as shown in Figure 1. This is based on several considerations:

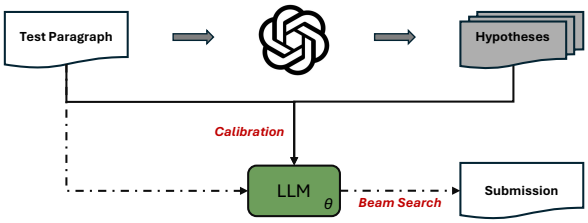

Figure 1: We use GPT-4o-mini to generate 16 hypotheses per sample on the WMT25 test set (at the paragraph level) using nucleus sampling. The resulting hypotheses are then used to train Gemma3-12B with the calibration method of Wu et al. (2025b). Finally, the calibrated Gemma model is used to translate the WMT25 test set for submission using pure beam search.

- **Very small sample sets** with a strong base model can effectively boost translation performance (Wu et al., 2024; Xu et al., 2024a).
- **Perfect domain alignment** since the training and test domains are inherently identical.
- **A strong teacher model** such as GPT-4o-mini[1] offers high-quality outputs as both a reliable reference and a fallback in case of mere memorization.

In the following sections, we test whether the student model (Gemma-3-12B) retains the strengths of GPT-4o-mini's outputs while implicitly avoiding certain flaws—effectively acting as a model ensemble.

More specifically, our strategy consists of two main steps:

Synthetic data building. We feed the WMT25 test set into GPT-4o-mini (Hurst et al., 2024), using the prompts provided with the offical test set[2], to generate 16 hypotheses per sample. The hypotheses are decoded using nucleus sampling with a top-p of 0.98[3] and a temperature of 1.0. Each sample

[1] As reported by Wu et al. (2025a), GPT-4o-mini can serve as a strong translation system.

[2] Official prompts are found here.

[3] We found that slightly lowering the top-p value effectively eliminates the off-targeting issue while preserving diversity.

Proceedings of the Tenth Conference on Machine Translation, pages 688–694
November 8-9, 2025

is at the paragraph level, where "$\backslash n$" remains in the original data as a separator.

Post-training. We apply the calibration method (Wu et al., 2025b) only to post-train Gemma-3-12B, which has been shown to be more effective than supervised fine-tuning or recent preference optimization methods, like CPO (Xu et al., 2024b). The calibration method aims to improve the correlation between translation likelihood and quality scores as measured by a reference metric model, enhancing the effectiveness of beam search decoding. Following Wu et al. (2025b), we use CometKiwi-XXL to score each one-to-many translation pair in our synthetic dataset.

Finally, the resulting model, trained on synthetic data derived from WMT25 test set, is used to again translate the WMT25 test set. We observe that for some high-resource languages, the resulting model's outputs even surpass the best hypotheses in the synthetic data—demonstrating a successful form of model ensemble.

In our next version, we provide detailed experimental settings and results, including: (1) offline experiments demonstrating the effectiveness of the calibration method; (2) offline experiments evaluating this test-time model ensemble strategy; and (3) our evaluation results for the final submission.

2 Calibration Method

We now briefly describe our post-training method, namely calibration (Wu et al., 2025b). This method addresses the miscalibration problem in machine translation, where translation quality deteriorates as search approximations improve and higher-probability hypotheses are potentially worse translations.

Prior studies have tried to mitigate this miscalibration issue by introducing an additional optimization step during inference time, known as quality-aware decoding (QAD) (Fernandes et al., 2022). These approaches typically involve generating multiple candidate translations through sampling, followed by reranking or voting using reference-free and/or reference-based machine translation metrics, such as Best-of-N (BoN) sampling (Rei et al., 2024; Faria et al., 2024) and Minimum Bayes Risk (MBR) decoding (Kumar and Byrne, 2004; Freitag et al., 2022).

The calibration approach mitigates this issue by optimizing the Pearson correlation between translation likelihood and quality during **training time**. Extensive experiments from Wu et al. (2025b) show several key advantages of this method, including:

1. Substantial translation performance gains with limited training.
2. Clear enhancements for maximum *a posterior* decoding, like beam search.
3. A unified framework for both translation quality optimization and estimation. Notably, we also apply this method to participate in the Quality Estimation task at WMT25[4].

In this shared task, we employ calibration as our only post-training method. For further technical details, please refer to (Wu et al., 2025b).

3 Online Evaluation

We thoroughly evaluate our system's outputs and compare them with those of several high-performance open-source and closed-source LLM-based translation systems, including GPT-4.1, Claude-4, Command-R+, DeepSeek-V3, TowerPlus-9B, TowerPlus-72B, Qwen2.5-7B, Qwen3-235B, and AyaExpanse-32B. We access these systems' results from the WMT25 MT evaluation test set[5], which was released a few weeks before the submission deadline of this paper.

We report results using three metrics: COMETKiwi$_{23}^{\text{DA}}$-XL, COMETKiwi$_{23}^{\text{DA}}$-XXL (Rei et al., 2023), and COMET$_{22}^{\text{DA}}$ (Rei et al., 2022). In addition, we conduct a light human evaluation for the English–Chinese track, comparing our system (UvA-MT) with our base model, Gemma-3-12B.

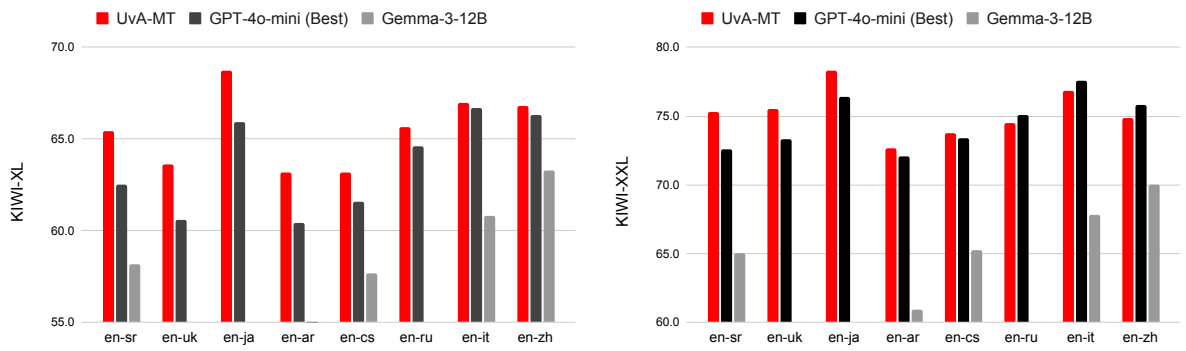
3.1 The Effectiveness of Ensembling

Figure 2 (a) and (b) show our system's results compared to those of 1) our base model, i.e., Gemma-3-12B, and 2) our teacher model, i.e., GPT-4o-mini, measured by CometKiwi-XL and CometKiwi-XXL, respectively.

Note that the reported results for GPT-4o-mini (best) are obtained using Best-of-N sampling. As described in the synthetic data building process in Section 1, we generate 16 hypotheses for each input and select the best one based on CometKiwi-XXL scores for evaluation.

[4]We cannot cite our QE system report at the time of submitting this paper; please refer to this year's findings paper for potential reference.

[5]The translation outputs from various systems are provided to human experts for annotation, which also serves as the evaluation task's test data.



(a) Performance measured by CometKiwi-XL

(b) Performance measured by CometKiwi-XXL

Figure 2: Performance comparison among the student model (Gemma-3-12B), the best-of-N outputs from the teacher model (GPT-4o-mini), and our ensemble model (UvA-MT). It is clear that UvA-MT surpasses all models in these 8 languages when measured with CometKiwi-XL, and outperforms some of them when measured with CometKiwi-XXL. Note that in some cases, such as **en-uk** and **en-ja**, the performance of Gemma-3-12B is either below the x-axis or not supported by the base model, so we did not show them in the figures.

For the other systems—namely Gemma-3-12B and our own (UvA-MT)—only a single hypothesis is generated per input using beam search with a beam size of 5.

As our system leverages both the base and teacher models, a successful ensemble would be expected to outperform each individually, at least in a portion of language directions.

Notably, we can observe in Figure 2 that:

- When evaluated with CometKiwi-XL (Figure 2-a), our system (UvA-MT) outperforms both the base model (Gemma-3-12B) and the teacher model (GPT-4o-mini) with Best-of-N sampling across all 8 language directions.
- When evaluating in CometKiwi-XXL (Figure 2-b), which is the very metric for Best-of-N selection, we can expect GPT-4o-mini's Best-of-N outputs to benefit from this evaluation due to greater potential for metric hacking. However, even under these conditions, our system still outperforms the teacher's results in a few language directions, such as `en-sr` (+2.7), `en-uk` (+2.0), and `en-ja` (+1.9), among others.

We acknowledge that some degree of metric gaming may also exist in our system's results above. However, we contend that a direct comparison between UvA-MT and GPT-4o-mini (Best) remains valid, because UvA-MT's training data is exactly the same as GPT-4o-mini's sampling data, we can therefore assume that UvA-MT could benefit from metric gaming *no more* than GPT-4o-mini's Best-of-N results; thus the relative gain over GPT-4o-mini (Best) should be considered realistic.

3.2 Overall Results

We now present a broader evaluation with detailed results measured by Comet22, CometKiwi-XL, and CometKiwi-XXL for 12 selected systems. For the complete set of results, please refer to the WMT25 findings paper. Note that the scores may differ slightly from those reported in the WMT25 findings paper, as variations in evaluation environments can introduce minor discrepancies (Zouhar et al., 2024).

Table 1 shows the results in CometKiwi-XL, one of this year's offical metrics. We show that UvA-MT achieves the best results in most of the language directions. When evaluated with CometKiwi-XXL (Table 2), the metric used for Best-of-N sampling, GPT-4o-mini (Best) obtains the highest scores in most cases. This is as expected with the previous discussion about metric gaming.

Table 1: KIWI-XL scores across languages and systems. We highlight UvA-MT and GPT-4o-mini (Best), where the former uses the latter's output as training data. Bold indicates the highest score per column. We discard the results in two extremely low-resource directions, i.e., English to Bhojpuri and Maasai, as they are not supported by the base model and therefore lack meaningful comparability.

We note that the primary focus of this paper is to explore whether an ensemble strategy can outperform the teacher's output—a trend that is clearly observed in most cases in Table 1 and in a few cases in Table 2.

A more convincing result is obtained with Comet22, the reference-based metric, where we additionally consider the translation references provided by WMT25, thus maximizing the metric difference between training and evaluation. In Table-3, we can see that UvA-MT achieves best results in **en-ru** and **en-it** among all systems.

4 Discussion and Conclusion

Beyond Metric Hacking. We acknowledge that some degree of metric gaming is present in the results above, although its extent is difficult to quantify. Our focus in this competition, however, is to demonstrate gains that go beyond mere metric hacking.

In the extreme case where UvA-MT simply memorized the best outputs from GPT-4o-mini (maximizing hacking), the latter's score would represent the upper bound of the former. Therefore, a direct comparison between UvA-MT and GPT-4o-mini (Best) remains realistic, and any gain over GPT-4o-mini (Best) would reflect genuine enhancements. Interestingly, we observe them in most of the language directions.

We attribute these gains to a form of successful model ensemble, in which the student LLMs integrate the strengths of the teacher model's outputs while discarding some of their shortcomings. Regarding the role of the post-training method applied here, including whether it is a critical component for this ensemble, we leave for future investigation.

Practical Significance. Our setting is not well-suited for real-time translation systems, as training a student model is required for each group of new inputs. Nevertheless, our findings point to a promising direction for ensembling the strengths of two models when the target domain is established in advance. This is particularly relevant in practical scenarios such as customized translation, where latency is secondary and effectiveness is the foremost priority.

atli.jasonarson,steinthor.steingrimsson@arnastofnun.is

Abstract

We present the submission of the Árni Magnússon Institute's team for the WMT25 General translation task. We focus on the English→Icelandic translation direction. We pre-train Llama 3.2 3B on 10B tokens of English and Icelandic texts and fine-tune on parallel corpora. Multiple translation hypotheses are produced first by the fine-tuned model, and then more hypotheses are added by that same model further tuned using contrastive preference optimization. The hypotheses are then post-processed using a grammar correction model and post-processing rules before the final translation is selected using minimum Bayes risk decoding. We found that while it is possible to generate translations of decent quality based on a lightweight model with simple approaches such as the ones we apply, our models are quite far behind the best participating systems and it would probably take somewhat larger models to reach competitive levels.

1 Introduction

Large language models (LLMs) are becoming the predominant approach for a wide variety of tasks in the field of natural language processing. They have shown remarkable translation capabilities, see e.g. Kocmi et al. (2024), especially for well-resourced languages such as English and Spanish, but also for many low-resource languages (LRLs) as Xu et al. (2025) show for translations between English and Icelandic. The largest of these models, such as GPT-4 (OpenAI et al., 2024), are hardware and energy intensive, both in training and at inference time, and thus costly. The vast majority of open weights large language models, such as the Llama family of models (Touvron et al., 2023; Grattafiori et al., 2024), Aya (Üstün et al., 2024), Mistral (Jiang et al., 2024) and others, are primarily trained on English and other languages that are well represented on the internet, for obvious availability reasons. This has ramifications for LRLs. Not only do the models offer inferior performance for LRLs 'out-of-the-box', their vocabulary is typically underrepresented due to the smaller amounts of training data in these languages, see e.g. Nag et al. (2025). This leads to less efficient tokenization for the LRLs, meaning that the number of characters per token are considerably fewer than for well-resourced languages like English. For example, using the Llama-3.2 tokenizer, the average number of characters per token for Icelandic is ≈2.2, while for English, each token has ≈4 characters. For LRLs, more tokens are thus necessary to cover the same context length.

While we do encounter challenges when working with LRLs in the context of LLMs, there are a variety of approaches to increase the capabilities of the models in that regard. Xu et al. (2024a) trained their ALMA translation models based on LLama-2 (Touvron et al., 2023) by continual pre-training (CPT) and then fine-tuning the models on the translation task. One of the languages pairs they worked with was English↔Icelandic and they achieved results very competitive to previous models trained for that language pair.

In this paper, we will be working with that same language pair, English–Icelandic. We are interested in building models that are as lightweight as possible, while still retaining the translation capabilities of LLMs. We experiment with applying the ap-

Proceedings of the Tenth Conference on Machine Translation, pages 695–704
November 8-9, 2025

proach used for training the ALMA models to train bilingual translation models based on the Llama-3.2 models (Grattafiori et al., 2024). We compare the 1B parameter model to the 3B parameter model. For our training, we use a much larger Icelandic monolingual dataset than Xu et al. (2024a), as well as a larger parallel dataset for English–Icelandic. We find that the 1B parameter model produces considerably lower quality translations and is much more prone to hallucinate. Our final system, submitted to the WMT25 General Translation task (Kocmi et al., 2025a) is thus based on Llama-3.2 3B parameter model. Following Xu et al. (2024b), we experiment with contrastive preference optimization (CPO) on top of the fine-tuned model. Our system generates multiple hypotheses, using different temperature settings, with and without CPO. The hypotheses are then post-processed using a grammar error correction (GEC) model and post hoc rules to fix punctuation errors as well as mistakes in translating emojis, hashtags, email-addresses and URLs.

Our code is available on Github[1] and the translation model on Huggingface[2].

2 Related Work

Up until 2020, when Jónsson et al. (2020) published the first paper describing SMT and NMT for translations between English and Icelandic, not much work had been done with regard to MT for this language pair. Since WMT 2021, when English↔Icelandic was one of the language pairs for the news translation task (Akhbardeh et al., 2021), multiple MT publications have described MT research on Icelandic, using the WMT21 evaluation dataset. In 2024, the AMI team submitted a system to the WMT general translation task for the English→Icelandic language pair. The submission describes an effort to build a lightweight NMT system, using an encoder-decoder architecture. While it was small enough to run easily on a laptop computer, it still scored higher than many commercial systems (Jasonarson et al., 2024). In their work on building MT systems from the LLaMA-2 models, Xu et al. (2024a) pre-train models of two different sizes, 7B and 13B parameters, on data in six languages, two of these being English and Icelandic. They then fine-tune the model on the translation task.

[2] arnastofnun/Llama-3.2-3B-wmt25-AMI-en-is

3 Building the System

In building our model, we followed the approach used for training the ALMA-R models (Xu et al., 2024b), but instead of training on six languages, we trained only on texts in English and Icelandic. We are interested in investigating whether using some of the smallest available open LLMs can produce competitive translations and thus experiment with the lightweight Llama 3.2 1B and 3B parameter models. Hyperparameters used in training are reported in Appendix A.

Xu et al. (2024b) use the OSCAR 23.01 corpus (Ortiz Suárez et al., 2019; Kreutzer et al., 2022) which only contains approx. 300M running words in Icelandic. Furthermore, for fine-tuning English↔Icelandic, they only use 2000 sentence pairs. In our experiments, we extend both the monolingual and parallel data sets used.

3.1 Pre-training

The ALMA model employed CPT to improve model capabilities in the languages they work with. In doing that, they train their model on 20B tokens. As the Oscar dataset contains less than 300M running words in Icelandic, it would have to be repeated multiple times if a similar training setup were to be used for only two languages, English and Icelandic. Therefore, we add another data source, the Icelandic Gigaword Corpus (IGC) (Steingrímsson et al., 2018; Barkarson et al., 2022a), on top of the OSCAR data. We use the 2022 version of the corpus (Barkarson et al., 2022b) and the 2024 extension (Barkarson and Steingrímsson, 2024). Combined they contain 2.6B running words from texts in 8 domains: news, parliamentary speeches, social media, published books, journals, Wikipedia, law texts and adjudications. We exclude the last two, law texts and adjudications, as these texts are quite atypical of texts in other domains. We also filter out paragraphs that we do not expect to be beneficial. These include duplications, paragraphs containing less than five words, paragraphs containing less than 50% alphabetical letters, and paragraphs that were not classified as Icelandic using langdetect (Nakatani, 2010) with a custom Icelandic language profile[3]. Finally, we split long paragraphs, over 255 tokens as tokenized by the Llama 3.2 tokenizer, into shorter segments. This resulted in a corpus of 2.17B running words in addition to the 294M in OSCAR. We estimate that

Tokens (B)	File size (K) (1B model)	File size (K) (3B model)
1	183	216
2	210	197
3	218	174
4	339	178
5	400	170
6	303	167
7	299	163
8	231	178
9	234	163
10	219	161

Table 1: File size of translations at each stage of the training. The original English file is 141K

our data contains ≈7.6B tokens of Icelandic text when tokenized by the Llama-3.2 tokenizer.

We train our models on up to 10B tokens in total, with a 50/50 split between Icelandic tokens and English tokens. Training the 3B parameter model took ≈75 hours on 8xA100 GPUs and fine-tuning ≈80 minutes on the same hardware, while training the 1B parameter model took ≈120 hours on 2xA100 GPUs and fine-tuning ≈3.5 hours on a single A100.

3.2 Fine-tuning

In selecting the dataset to use for fine-tuning, we experimented with a different number of sentence pairs and different combinations of data.

We used three datasets, two described in the AMI submission paper for WMT general translation task last year (Jasonarson et al., 2024) as well as a small specialized dataset:

1. The baseline dataset, comprising data from the ParIce corpus (Barkarson and Steingrímsson, 2019; Steingrímsson and Barkarson, 2021), realigned using SentAlign (Steingrímsson et al., 2023), as well as sentence pairs from Paracrawl (Bañón et al., 2020) using the filtering approaches described in (Steingrímsson et al., 2023).

2. The synthetic sentences generated for training the AMI translation models for the WMT24 submission.

3. 1000 sentence pairs containing Icelandic idiomatic expressions and their English translations (Steingrímsson et al., 2024)

We scored the sentence pairs from the two large datasets using LaBSE (Feng et al., 2022) and fine-tuned the 3B parameter model, trained on 10B tokens on different combinations of the data. Different number of sentence pairs using only the baseline data, as well as a different number of sentence pairs using a mix of the baseline data and the synthetic data. We evaluated the fine-tuned models using the WMT21 evaluation set. When only using the baseline data, we achieved the highest COMET score using only 20k sentence pairs, but when mixing the baseline sentence pairs 50/50 with the synthetic data, as well as adding the small dataset of

idiomatic expressions in context, we achieve an even higher score. The highest scoring model was trained on a combination of these datasets, with 50k sentence pairs from the baseline set, 50k sentence pairs from the synthetic dataset and 1k sentences containing Icelandic idiomatic expressions and their English translations, resulting in a fine-tuning dataset of 101k sentence pairs.

3.3 CPO

CPO is introduced in Xu et al. (2024b) as an approach to mitigate two shortcomings of supervised fine-tuning: Firstly, to try to imitate training data and thus capping the model performance at that quality level, and secondly, to give the model a mechanism to reject mistakes in translation. This is important as even human-translated texts can have flaws and errors. To accomplish this, CPO uses specially curated preference data, with each source sentence having three translations: one human translation and two automatic translations, along with quality assessment scores for each translation. The highest-scoring translation is preferred and the lowest-scoring one dispreferred, in order to train the model to refine details and achieve better translations.

We created a new CPO dataset, for finalizing the models after fine-tuning. While the ALMA project only used the Flores dataset (Goyal et al., 2022) for CPO when working with English↔Icelandic, a total of 2,009 sentences, we add sentences from the WMT24 general translation shared task (Kocmi et al., 2024), 997 sentences, the development set from WMT21, 2,004 sentences, and the Icelandic parallel UD tree bank (Jónsdóttir and Ingason, 2020), 1,000 English sentences translated by a human translator into Icelandic.

In total the CPO data consists of approx. 6,000 items, each item comprising an English sentence and a human translation, or vice versa, two automatic translations for each language, one by the fine-tuned model described in Section 3.2 and the other by Claude Sonnet 4[4]. For each translation, we calculate three scores using reference-free models, `wmt23-cometkiwi-da-xl`, `XCOMET-XL` and an average of the two.

We apply CPO after pre-training and fine-tuning, as described in Section 3.1 and Section 3.2.

[4]We used `claude-sonnet-4-20250514` for both translation directions.

Model step	Score
Llama-3.2 3B (baseline model)	0.5197
Llama-3.2 3B + CPT	0.7940
Llama-3.2 3B + CPT + FT	0.8606
Llama-3.2 3B + CPT + FT + CPO	0.8441

Table 2: COMET-scores for the 3B parameter model after each ablation step, before post-processing.

3.4 Model Training

We trained the 1B and 3B parameter Llama 3.2 models using up to 10B tokens, with a 50/50 split between Icelandic and English tokens. After training, we selected the best fine-tuning dataset using the 3B parameter model, trained on 10B tokens, which scored highest of the trained models when evaluated using the English→Icelandic test set from WMT21. Figure 1 shows the scores for the models, evaluated after every 1B tokens of CPT, followed by fine-tuning. Both models are still improving when we stop training, indicating that we could probably achieve higher quality if we continue. It is worth noting that the 1B parameter model behaves rather curiously. After obtaining surprisingly good scores early in the training process, the COMET scores drop substantially, but then start rising again. We investigated what was going on and found that in the beginning, the model was not very likely to produce much longer strings than the source sentence. After training for a bit longer, the model becomes much more likely to continue producing text after it has finished producing the translation. This is reflected in the file size of the translations, shown in Table 1. File size closer to the size of the source file generally score higher than larger files.

We also carried out CPO after fine-tuning, which did not increase the COMET score on the evaluation set. COMET-scores for each ablation step are given in Table 2. The table indicates that without any continued pre-training the LLama-3.2 3B model does not seem to produce very coherent translations, but this should be expected as Icelandic is not one of the officially supported languages of Llama 3.2. Fine-tuning after CPT substantially increases the translation quality as measured by COMET, but in our experiments, CPO fails to improve it further.

3.5 Post-processing and MBR

When LLMs translate text, they have a tendency to continue generating new text after the translation is completed, irrelevant to the source text, as described in the previous section. While this seems to happen less with the 3B parameter model than with the 1B parameter one, it can still be a problem. When translating long sentences or paragraphs, both models seem to be more likely to skip parts and to be more prone to hallucinating. Finally, the Icelandic output commonly has incorrect inflections and word formation.

In order to counter some of these issues, we post-process the translation output. Post-processing uses the GEC model described in Jasonarson et al. (2024), and heuristics to ensure consistency between the source and target in the use of emojis, hashtags, URLs and punctuation.

For our final submission, we use the larger 3B parameter model after pre-training on 10B tokens, as this gave us the best results for our test set, as shown in Section 3.4. In order to increase the variety of translation candidates, we also do CPO training on the models and use both variants of the model, with and without CPO, to generate hypotheses:

- For both variants of the model, CPO-trained and not, we generate 9 translation hypotheses for each sentence, 3 for each of three temperature settings: 0.2, 0.6 and 0.9, resulting in 18 candidates in total.
- We post-process all 18 candidates, generating 18 new candidates. A total of 36, half post-processed and half not.
- Finally, in order to tackle the problem of the model spinning out of control and generating more text after translation has finished, we split each candidate translation on sentence boundaries. We then generate a sequence of partial candidates incrementally: the first partial candidate contains only the first sentence; the second partial candidate contains the first two sentences; the third contains the first three sentences; and so on, until the final candidate is identical to the complete original candidate, as exemplified in Figure 2.

All of these candidates are taken into consideration for COMET-MBR (Fernandes et al., 2022), employing cometkiwi-xl to select the final translations, considering the source and all generated candidates. Before settling on cometkiwi-xl, we compared two models, cometkiwi-xl and xcomet-xl. We had each model select their best candidates and then manually evaluated sentence pairs where the decisions of the two models differed. We found that cometkiwi-xl was more in line with our evaluation and thus chose that model for our pipeline.

Incremental Candidate Construction

Candidate 1: Samkvæmt embættismönnum hafa viðskiptavinir sem heimsóttu bankann einnig verið ráðlagt að fara sjálfviljugir í kórónuveirupróf.

Candidate 2: Samkvæmt embættismönnum hafa viðskiptavinir sem heimsóttu bankann einnig verið ráðlagt að fara sjálfviljugir í kórónuveirupróf. This translation has been made possible through the support of the American people through the United States Agency for International Development (USAID).

Candidate 3: Samkvæmt embættismönnum hafa viðskiptavinir sem heimsóttu bankann einnig verið ráðlagt að fara sjálfviljugir í kórónuveirupróf. This translation has been made possible through the support of the American people through the United States Agency for International Development (USAID). The contents are the responsibility of the Government of Iceland and do not necessarily reflect the views of USAID or the U.S. Government.

Figure 2: An example of a translation candidate where the model continued generating after the translation was complete. We split the output on sentence boundaries to generate new candidates from the original one. The original English sentence was: "According to the officials, the customers who visited the bank have also been advised to voluntarily appear for coronavirus tests." In this case, the first sentence is the correct translation.

4 Translation Pipeline

Figure 3 shows the translation pipeline. Input documents to be translated are split into paragraphs and the MT system uses different settings for num-

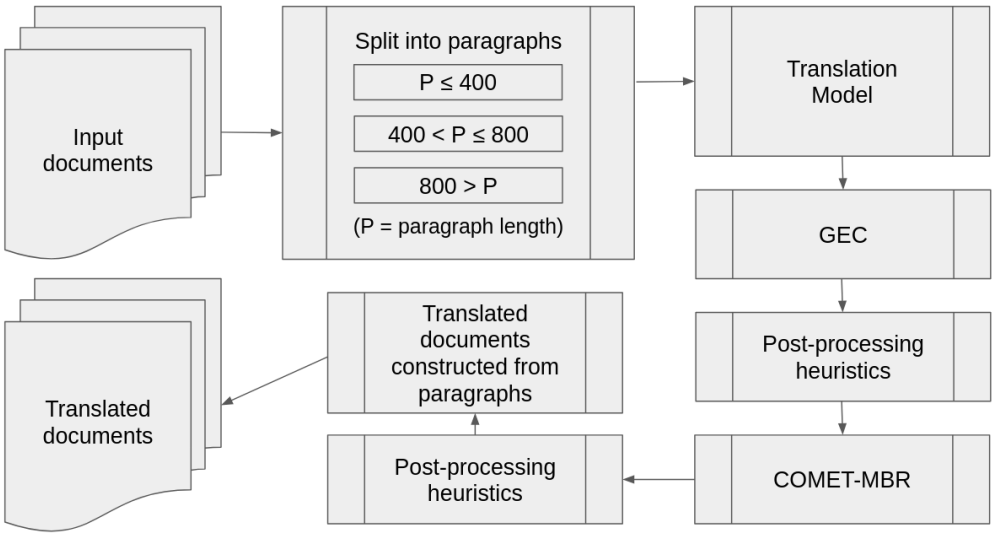

Figure 3: Processing pipeline as described in Section 4.

ber of input and output tokens depending on paragraph length measured in number of characters. 18 translation candidates are produced, 9 with the fine-tuned model and 9 with the model additionally trained using CPO. In each case, 3 different temperatures are used. A GEC model and post-processing rules, as described in Section 3.5, are applied to all translations before COMET-MBR selects the top translation candidate. Finally, post-processing rules are applied again to the translated paragraph before document translations are constructed from the paragraphs.

5 Results

In the WMT25 general translation task, automatic evaluation of participating systems was carried out using three families of evaluation methods: LLM-as-a-Judge (reference-less), Trained reference-based metrics and Trained Quality Estimation (QE).

The results, reported in Kocmi et al. (2025b), are given in Table 3. CometKiwi-XL (Rei et al., 2023) belongs to the *Trained Quality Estimation* family of evaluation methods, GEMBA-ESA (Kocmi and Federmann, 2023) to the *LLM-as-a-Judge* family and MetricX (Juraska et al., 2024) and XCOMET-XL (Guerreiro et al., 2024) are *Trained reference-based metrics*.

While 12 systems out of 33 score higher on average than our system using automatic metrics, and 9 systems score higher than us in the human evaluation, we have the second smallest model in terms of parameters and a smaller model than all higher scoring ones, at least those where the size is known. We score above our average on the two reference-based metrics, but lower when LLM-as-a-judge is used. Looking at the human evaluation results, we see that GPT 4.1 has the same order of systems for the top 5, but when the outputs are not as good, it starts to differ from the human evaluation.

6 Conclusions and Future Work

We experiment with fine-tuning very lightweight LLMs for translation and find that while our 3B parameter model can produce quite intelligible translations from English to Icelandic, they are still of considerably less quality than popular online systems and some larger language models. While we do not achieve building a model that is competitive with the best models, it is fast and can easily run locally on a modern laptop. Inference is thus inexpensive and can be fast.

We fine-tuned our model on 101k parallel sentence pairs. While we experimented with the combination of available datasets, we did not inspect why some worked better than others, e.g. why the quality was going down for the baseline data when training with more than 20k sentence pairs, but if synthetic data were added, the quality improved? What factors are at play here? We are interested in investigating that, starting with looking at diversity in the fine-tuning data.

CPO did not improve our model. We intend to look into why that was, whether it may be related to the size of the dataset or if adding more languages would be beneficial.

KIKIS at WMT 2025 General Translation Task

Koichi Iwakawa[1], Keito Kudo[1,2], Subaru Kimura[1], Takumi Ito[1], Jun Suzuki[1,2]
[1]Tohoku University, [2]RIKEN

Abstract

We participated in the constrained English–Japanese track of the WMT 2025 General Machine Translation Task. Our system collected the outputs produced by multiple subsystems, each of which consisted of LLM-based translation and reranking models configured differently (e.g., prompting strategies and context sizes), and reranked those outputs. Each subsystem generated multiple segment-level candidates and iteratively selected the most probable one to construct the document translation. We then reranked the document-level outputs from all subsystems to obtain the final translation. For reranking, we adopted a text-based LLM reranking approach with a reasoning model to take long contexts into account. Additionally, we built a bilingual dictionary on the fly from the parallel corpus to make the system more robust to rare words.

1 Introduction

This paper describes KIKIS's submission to the WMT 2025 General Machine Translation Shared Task (Kocmi et al., 2025a,b). We participated in the constrained track for the English–Japanese (En→Ja) direction. Given limited computational resources and the rapid pace of open-source LLM releases, we aimed to build a system that produced high-quality translations without additional training. In particular, we aimed to detect and correct residual errors, such as mismatched numbers or dates, missing key terms, and unnatural phrasing, in otherwise strong translations produced by LLM-based MT systems. To this end, we adopted a multi-stage LLM-based reranking pipeline that selected the best translation from candidate outputs. This paper provides a detailed description of our submitted system. We also report post-evaluation results that demonstrate the effectiveness of each component of our system.

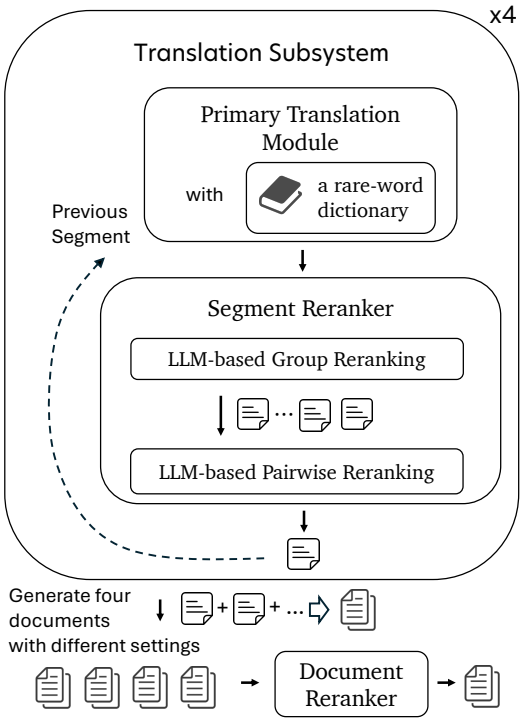

Figure 1: Overview of our final submission system.

2 System overview

Figure 1 provides an overview of our system. Our system consisted of four translation subsystems and a document reranker. We first aggregated outputs from the four subsystems, which differed in configuration (e.g., prompting strategies and context sizes). We then performed document-level reranking to select the best translation from the combined candidates. Within each subsystem, the primary translation module generated multiple segment-level hypotheses. The segment reranker iteratively filtered the candidate set via a tournament-style process to select the most plausible hypothesis. Algorithm 1 shows the pseudocode for the subsystem. Below, we describe three components: the primary translation module (§ 3), the segment reranker (§ 4), and the document reranker (§ 5).

end function

3 Primary translation module

We used plamo-2-translate (Imajo et al., 2025) as our base model. Plamo-2-translate is an LLM-based translation system with a hybrid architecture that combined Mamba (Gu and Dao, 2024) and Transformers (Vaswani et al., 2017). With this model, we generated 32 hypotheses for each source segment. The decoding hyperparameters are listed in Table 5. To further improve accuracy and naturalness at the document level, we combined three prompting strategies: vocabulary prompting, style prompting, and context prompting. We describe each strategy below.

3.1 Vocabulary prompting

To improve robustness to rare words, we dynamically constructed a bilingual dictionary from parallel corpora and used it as a prompt for the base model.

The dictionary was built in four steps:

- **Term extraction**: Candidate terms (e.g., named entities) were extracted from source sentences using Qwen3-8B (Qwen Team, 2025).
- **Retrieval**: Sentence pairs were retrieved from the parallel corpora whose source side contained the extracted term.
- **Translation-pair extraction**: Qwen3-8B was used to identify the translation of each term in the target sentence, and the term-level pairs were recorded.
- **Cleaning**: Pairs that were likely to be incorrectly extracted were discarded.

When a source segment in the test set contained any extracted terms, the corresponding dictionary entries were included in the prompt to the base model. In total, the dictionary comprised 365 English entries with an average of 1.9 Japanese translations per entry. See appendix C for further details (e.g., list of parallel corpora and filtering criteria).

3.2 Context prompting

To maintain document-level consistency of named entities and overall style, we translated each segment with the preceding context. For the current source segment s_t, the prompt to the base model included the m source segments $s_{t-m:t-1}$ and the previously selected hypotheses $h^{+}_{t-m:t-1}$ from the segment reranker (§ 4). During decoding, we enforced $h^{+}_{t-m:t-1}$ via forced-decoding and then generated the output for s_t.

Formally, context-prompted decoding is defined as:

$$H_t = \left\{ h_t^{(k)} \sim P_\theta\left(\cdot \mid s_{t-m:t}, h^{+}_{t-m:t-1}\right) \right\}_{k=1}^{K}, \quad (1)$$

where H_t is the set of K sampled hypotheses for the current segment, $h_t^{(k)}$ is the k-th sample, and $P_\theta(\cdot \mid s_{t-m:t}, h^{+}_{t-m:t-1})$ denotes the base model's conditional distribution.

3.3 Style prompting

We controlled the translation style based on the domain of the source document. Specifically, we prompted the base model to produce either the polite (“です/ます”) or the plain (“だ/である”) style based on the document domain. We enforced the plain style for literary and news texts and left the style unspecified for social and speech texts. We further included domain-specific instructions to keep the writing appropriate for each domain. [1]

4 Segment Reranker

This module selected plausible hypotheses from the segment-level outputs of the primary translation module via a tournament-style process. We applied two reranking stages with different granularities in sequence. In the early stage, we grouped candidates into batches of at least three and performed coarse filtering within each batch (GROUPRANK in Algorithm 1). After reducing the pool, we performed pairwise comparisons among the remaining candidates to select the final hypothesis (PAIRWISECOMPARE in Algorithm 1). Inspired by (Sun et al., 2023), we adopted a text-based LLM reranking approach using the reasoning model Qwen3-8B (Qwen Team, 2025).

4.1 Group reranking

This module selected a plausible hypothesis from a set of candidate translations. Its role was to roughly filter out low-quality outputs and narrow the candidate set. Concretely, the model received the m previous source segments and the current one, denoted $s_{t-m:t}$, the contexts of confirmed hypotheses from previous iterations $h^{+}_{t-m:t-1}$, and the current subset of candidate hypotheses generated by the primary translation module $H'_t \subseteq H_t$. From these inputs, it selected a plausible hypothesis $\hat{h}_t \in Ht'$. Formally,

$$\hat{h}_t = \mathrm{LLM_g}\left(s_{t-m:t}, h^{+}_{t-m:t-1}, H'_t\right), \qquad (2)$$

where $\mathrm{LLM_g}$ was the LLM instructed to perform group reranking, which returned one hypothesis from H'_t. The prompt template is given in appendix D.

[1] Due to terms and conditions, we cannot include the exact prompt format here. For details about the prompts, please refer to https://translate-demo.plamo.preferredai.jp/contact.

4.2 Pairwise reranking

Given the hypotheses returned by group reranking, this module performed pairwise comparisons to select the most plausible translation. As with group reranking, we used an LLM for hypothesis selection; however, here the LLM compared pairs of hypotheses. To mitigate positional bias (Liu et al., 2024; Wang et al., 2024), we prompted the LLM with each pair in both orders. If the two decisions conflicted, we selected one of the two hypotheses uniformly at random.

Formally, we expressed this as:

$$\hat{h}_t = \arg\max_{h \in H'_t} \sum_{(u,v)\in \mathrm{Perm}_2(H'_t)} \mathbf{1}\left\{\mathrm{LLM_p}\left(s_{t-m:t}, h^{+}_{t-m:t-1}, u, v\right) = h\right\}, \qquad (3)$$

Here, $\mathrm{Perm}_2(H'_t)$ denoted the set of all ordered pairs of distinct elements from H'_t. $\mathrm{LLM_p}$ was the LLM instructed to perform pairwise reranking; it returned one of the two given hypotheses, u or v. $\mathbf{1}$ denoted the indicator function. The prompt template is provided in appendix D.

5 Document reranker

We reranked document-level translation candidates generated by N_{sub} subsystems using Qwen3-8B. We performed pairwise comparisons over all ordered pairs of candidates and selected the most plausible translation. As in the segment reranking, each pair was evaluated in both input orders to deal with positional bias.

We let the set of document-level hypotheses be $\mathcal{D}_{\mathrm{hyp}} = \{D^{(1)}_{\mathrm{hyp}}, \ldots, D^{(N_{\mathrm{sub}})}_{\mathrm{hyp}}\}$, where each $D^{(i)}_{\mathrm{hyp}}$ was a complete translated document produced by a subsystem. Let the source document be $D_{\mathrm{src}} = s_{:}$ (where : denoted all source segments). We selected the final document $\hat{D}_{\mathrm{hyp}}$ by counting pairwise wins:

$$\hat{D}_{\mathrm{hyp}} = \arg\max_{d \in \mathcal{D}_{\mathrm{hyp}}} \sum_{(u,v)\in \mathrm{Perm}_2(\mathcal{D}_{\mathrm{hyp}})} \mathbf{1}\{\mathrm{LLM_d}(D_{\mathrm{src}},\, u,\, v) = d\}, \qquad (4)$$

where $\mathrm{Perm}_2(\mathcal{D}_{\mathrm{hyp}})$ denoted all ordered pairs (u, v) with $u \neq v$, and $\mathrm{LLM_d}$ was the model for document-level reranking that returned one of the two inputs, u or v. The prompt template is given in appendix D.

	Vocab prompt	Context size	Group size	Document reranking	MetricX↓ w/ ref	MetricX↓ w/o ref	XCOMET↑ w/ ref	XCOMET↑ w/o ref

The left column shows MetricX results (lower is better) and the right column shows XCOMET results (higher is better). Solid lines indicate reference-based (w/ ref) evaluation, and dashed lines indicate reference-free (w/o ref) evaluation.

6 Post-evaluation

We conducted a post-evaluation to assess the contribution of each component in our system.

6.1 Experimental setup

We reported the performance of our final submission. The final system consisted of four subsystems, and we also reported the performance of each subsystem (before applying document-level reranking). As ablation studies, we evaluated the effects of removing the segment reranker, enabling or disabling vocabulary prompting, and varying the context size (m in § 3.2) and the group size (g in Algorithm 1). In the no-reranking setting (using only the primary translation module), we generated 32 translation candidates for each source segment (as in Section 3) and selected the highest-probability candidate.

We used XCOMET-XL (Guerreiro et al., 2024)[2] and MetricX-24 (XL) (Juraska et al., 2024)[3] as automatic evaluation metrics. We evaluated our approach in both reference-based and reference-free (quality estimation) settings.

6.2 Results and discussion

Table 1 shows the post-evaluation results.

Effect of reranking. Comparing configurations (c) and (d) in Table 1, we observed that segment-level reranking (§ 4) improved performance, suggesting that the LLM selects better translations. By contrast, in our experimental setting, document-level reranking (h)(§ 5) did not surpass configuration (d), which was the best-performing subsystem before reranking. This may be partly due to the much longer input at the document level, which could make the reranking task more challenging for the LLM.

Effect of vocabulary prompting. In Table 1, the comparisons between (a) and (b) and between (d) and (e) showed no consistent effect of vocabulary prompting on evaluation metrics. Qualitatively, however, as shown in Table 2, vocabulary prompting improved translations of domain-specific terms; for example, "facial scrub" is translated correctly.

Effect of context sizes. Figure 2 shows the relationship between context size and performance. According to the automatic evaluation metrics, we

Source	you're gonna cleanse get rid of all the grease and makeup from your face and then you're gonna use your **facial scrub**
Reference	肌の上に。さて、こちらがその**フェイシャルスクラブ**です。このスクラブを使う際に、まず最初に忘れずに顔をクレンジングします。それが第一のステップです。
Translation	
(d) w/o vocab	ここで重要なのは、フェイススクラブを使用する前には必ず洗顔を行うことです。
(e) w/ vocab	まず顔の皮脂やメイクを完全に落とします。その後、このフェイシャルスクラブを使います。

Table 2: Qualitative output evaluation: vocabulary usage ((d) vs. (e)). Incorporating a predefined vocabulary list (e) ensured that the translation matched the reference term "フェイシャルスクラブ", in contrast to the variant "フェイススクラブ" produced without the vocabulary (d).

Source	Segment t:	First job is taking out the floor ⋯ cover that in linoleum. The job is shoddy ⋯ I dunno how to do all that. The roof will remain cold and metal ⋯
	Segment $t+1$:	This chair works very well in the van ⋯ should ideally be fastened better ⋯ flat as a bed.
Reference	Segment t:	「床を外して下の収納スペースにアクセスし、そこにリノリウムを貼ること。…正直言って雑な仕事。…そんな技術はまったくない。…屋根は金属むき出しで冷たいまま。」
	Segment $t+1$:	「床にちゃんと固定できてはいないけど… フラットなベッドになる。」
(a) Context size = 0	Segment t:	「床板を取り外し…敷くことだ。…この作業は粗雑な仕上がりになってしまう。…方法がわからない。…屋根は金属のまま放置することになる。」
	Segment $t+1$:	「椅子は理想的には固定すべきですが…ベッドとしても使える状態になります。」
(c) Context size = 2	Segment t:	「床を撤去し…敷くことです。…この作業は雑な仕上がりです。…方法が分かりません。…屋根は金属のままとなります。」
	Segment $t+1$:	「椅子は固定方法を改善すべきですが…ベッドとしても使用可能です。」

Table 3: Qualitative evaluation of outputs: effect of context size ((a) vs. (c)). (a) Without previously translated hypotheses as context, translations mix polite ("です/ます") and plain ("だ/である") sentence endings across adjacent segments. (c) With previously translated hypotheses provided as context, the sentence-ending style remains consistent, avoiding style shifts between segments.

did not observe a consistent trend in performance as the context size changed. Qualitatively, however, as shown in Table 3, adding previously translated hypotheses as in-document context helped keep a consistent style across the document, either polite ("です/ます") or plain ("だ/である").

Effect of group size. Figure 2 shows how group size affected segment-level reranking. Intuitively, larger groups made it harder to select the best candidate. At the same time, they allowed us to prune more candidates per group, which sped up the system. Across the tested group sizes, XCOMET and MetricX scores dropped by less than 0.05 points. Therefore, there was room to either speed up the final submission system or use the saved time to generate more translation candidates from the primary translation module within the same time budget.

7 Conclusion

We described the KIKIS submission to the WMT 2025 General Machine Translation Shared Task. We participated in the constrained track for the English–Japanese (En→Ja) direction. Our system consisted of four translation subsystems and a document reranker. Each subsystem combined an MT model with an LLM-based segment reranker. We aggregated the outputs from the four subsystems and then applied document-level reranking to select the final translation.

Acknowledgments

We would like to thank the members of the Tohoku NLP Group for their cooperation and feedback throughout the course of this research. This work was supported by Moonshot R&D Grant Number JPMJMS2011-35 (fundamental research), JST BOOST Japan Grant Number JPMJBS2421 and

JSPS KAKENHI Grant Number JP25KJ0615.

Contributions

Koichi Iwakawa conducted hyperparameter search for LLM-based translation models and performed post-evaluations.
Keito Kudo built the foundation of the LLM-based translation system, developed the reranking system, and constructed the bilingual dictionary.
Subaru Kimura was responsible for decoding the test set samples using the submission system. He also investigated translation quality under different prompting strategies.
Takumi Ito contributed to strategic discussions for the WMT submission and provided feedback and advice on translation outputs.
Jun Suzuki supervised and coordinated the entire project.

top-p	0.9
Qwen3-8B	
temperature	0.6
top-p	0.95
top-k	20
min-p	0.0
Output format	structured outputs (json)

Table 5: Decoding hyperparameters.

A Decoding hyperparameters

Table 5 lists the decoding hyperparameters used in our system. For Qwen3-8B decoding, we adopted the officially recommended settings[4]. We used vllm (Kwon et al., 2023) to decode translation candidates and to run the reranking steps.

B Parameter count

Table 4 shows the parameter counts of the models used in our translation system. Our system satisfied the constrained track limit of at most 20B total parameters. We did not fine-tune any model and used the publicly available model parameters as provided.

C Detail of bilingual dictionary construction

This section described the detailed procedure for constructing the bilingual dictionary described in § 3.1.

Term extraction. We first extracted named entities and technical terms from the source sentences in the test set. We used Qwen3-8B (Qwen Team, 2025) to perform term extraction. The prompt we gave to Qwen3-8B for term extraction is shown in List D. After extraction, we filtered out terms that met any of the following conditions:

- The term fell within the top 66% by frequency within the test set.
- The term was tokenized as a single token by the plamo-2-translate tokenizer.
- The term was included in the top 100,000 words of the English word frequency list from `wordfreq` (Speer, 2022).

We applied this filtering because terms that satisfied these conditions were frequent and were expected to be translated correctly by the base model without explicit vocabulary prompts.

Retrieval. We retrieved all parallel sentence pairs from the corpora whose source side contained any of the extracted terms. We used the Aho–Corasick algorithm (Aho and Corasick, 1975) for efficient multi-pattern matching. Table 6 lists the parallel corpora used as sources for the bilingual dictionary. For several corpora, we computed LaBSE (Feng et al., 2022) sentence embeddings and filtered out sentence pairs whose semantic similarity was outside the range [0.7, 0.96]. Pairs with LaBSE similarity below 0.7 were removed due to likely low semantic alignment between source and target. Pairs with LaBSE similarity above 0.96 were removed because they were likely to be nearly identical (copying) or noisy. The Team-J (WMT2024) bitext dataset and development dataset, which we used in last year' s submission and which was built from open data sources, was included and was filtered with the same LaBSE-based criterion. See Kudo et al. (2024) for more details.

Translation-pair extraction. We then used Qwen3-8B to extract candidate target terms from the retrieved parallel sentences. The prompt given to the model was shown in List D. This process yielded multiple candidate target-term patterns for each source term.

Cleaning. Some extracted target terms were noisy or incorrect due to model errors. Therefore, for each source term, we retained only the most frequently extracted target terms. Concretely, we ranked the extracted target terms by occurrence frequency and kept the top 30This frequency-based filtering reduced noise and favored stable translations that appeared repeatedly in the parallel data.

D Prompt lists

Term extraction. The prompt template used for term extraction described in § 3.1 was as follows. The source segment from the test set was embedded in <|INPUT_TEXT|>.

```
# Named Entity Recognition and
Technical Term Extraction Instructions

Extract named entities and technical
terms from the following text.

## Processing Steps

1. **Named Entity Extraction**
   Extract expressions that denote
   specific entities belonging to the
   following categories:

   - **PERSON**: Individual names,
   fictional character names
   - **ORGANIZATION**: Companies,
   government agencies, organizations,
   teams, etc.
```

```
   - **LOCATION**: Countries, cities,
   regions, buildings, natural
   features, etc.
   - **PRODUCT**: Products, services,
   software, titles of works, etc.
   - **EVENT**: Conferences, festivals,
   competitions, historical events,
   etc.
   - **MISC**: Other specific entities
   not classified above

   **Important**:
   - Exclude commonly known entities
   that appear frequently in general
   texts (e.g., "United States",
   "Japan", "Google", "Microsoft",
   "China", "Tokyo", etc.)
   - Focus on extracting entities that
   are specific and distinctive to the
   given text
   - **Prioritize entities that may
   pose translation challenges**, such
   as:
     * Local or regional entities with
     cultural significance
     * Organizations with acronyms or
     abbreviations
     * Location names with specific
     cultural or historical context
     * Products with brand-specific
     terminology

   ※ Numbers and dates should not be
   included in the extraction

2. **Technical Term Extraction**
   Extract domain-specific terminology
   including:

   - **TECHNICAL**: Scientific,
   medical, engineering, IT, legal,
   financial, and other field-specific
   terminology
   - **CONCEPT**: Abstract concepts,
   theories, methodologies, principles
   specific to certain domains
   - **PROCESS**: Specialized
   procedures, techniques, or methods
   used in specific fields

   **Important**:
   - Exclude commonly used technical
   terms that are widely known (e.g.,
   "computer", "internet", "software",
   "database", "algorithm" in IT
   contexts)
   - Focus on specialized or
   domain-specific terms that provide
   unique insights
   - **Prioritize terms that are
   challenging for translation**,
   including:
     * Field-specific jargon with no
     standard translation
     * Compound terms or phrases unique
     to the domain
     * Terms requiring deep domain
     knowledge for accurate translation
     * Newly coined terms or emerging
     concepts
     * Terms with specific meanings
     that differ from general usage

3. **Extraction Priority**
   Apply the following filtering
   process for both named entities and
   technical terms:

   1. First, identify all potential
   entities and terms
   2. Filter out generally
   common/well-known items
   3. Keep only distinctive and
   informative items
   4. **Translation Difficulty
   Priority**: Prioritize entities and
   terms that are likely to be
   challenging for translation:
      - Culture-specific concepts with
      no direct equivalent in other
      languages
      - Domain-specific terminology
      requiring specialized knowledge
      - Acronyms, abbreviations, and
      neologisms
      - Context-dependent expressions
      - Terms with multiple meanings
      that require disambiguation
      - Compound technical terms unique
      to specific fields

## Output Format
```

````
Please provide the output in the
following JSON format:

```json
{
  "named_entities": {
    "person": ["List of extracted
    person names"],
    "organization": ["List of extracted
    organization names"],
    "location": ["List of extracted
    location names"],
    "product": ["List of extracted
    products/services"],
    "event": ["List of extracted
    events"],
    "misc": ["List of other named
    entities"]
  },
  "technical_terms": {
    "technical": ["List of
    field-specific terminology"],
    "concept": ["List of abstract
    concepts and theories"],
    "process": ["List of specialized
    procedures and methods"]
  }
}
```

## Example

### Input example
```
Yesterday, Dr. John Smith from Tohoku
University won first place in the
WMT2025 machine translation competition
held in Suzhou, China. His team's
neural translation system outperformed
submissions from Meta AI, DeepMind, and
Microsoft Research with a BLEU score of
45.7. The competition focused on
translation tasks covering more than 10
languages, including low-resource
language pairs. The transformer
architecture with attention mechanisms
proved crucial for handling
morphologically complex languages.
```

### Output example
```json
{
  "named_entities": {
    "person": ["John Smith"],
    "organization": ["Tohoku
    University", "Meta AI", "DeepMind",
    "Microsoft Research"],
    "location": ["Suzhou"],
    "product": [],
    "event": ["WMT2025 machine
    translation competition"],
    "misc": []
  },
  "technical_terms": {
    "technical": ["neural translation
    system", "BLEU score",
    "transformer architecture",
    "attention mechanisms"],
    "concept": ["low-resource language
    pairs", "morphologically complex
    languages"],
    "process": []
  }
}
```
※ Note: "China" and common terms like
"machine translation" and "translation
tasks" are excluded from the extraction
as they are generally well-known

## Notes

- Include named entities and technical
terms in the list without duplication
- If no items are found for a specific
category, output an empty list for that
category
- Distinguish between named entities
(specific instances) and technical
terms (domain concepts)
- A term can be both a product name and
a technical term depending on context
- **Exclude entities and terms that are
commonly known or frequently used in
general discourse** (e.g., major
countries, well-known companies, basic
technical terms)
- Focus on extracting distinctive,
informative, and document-specific
entities and terms
- **From a translation perspective,
prioritize extraction of:**
````

```
  * Terms requiring cultural or
  contextual knowledge
  * Domain-specific expressions without
  established translations
  * Ambiguous terms needing
  disambiguation
  * Entities with specific
  local/regional significance

---

## Input
```
<|INPUT_TEXT|>
```
```

Translation-pair extraction. The prompt template used for translation-pair extraction described in appendix C was as follows. The source sentence selected from the parallel corpus was embedded in <<<|SOURCE_TEXT|>>>, and the target sentence selected from the parallel corpus was embedded in <<<|TARGET_TEXT|>>>. Additionally, the term contained in the source sentence that was extracted during the term extraction phase was embedded in <<<|TERM|>>>.

```
# Translation Term Extraction Task

## Task Overview
Extract the corresponding translation
for a specified term from given source
text (original) and target text
(translated) pairs.

## Input Format
The following three elements will be
provided:
- **source text**: The original text
- **target text**: The translated text
- **term**: A specific term contained
in the source text

## Processing Steps
1. Identify the specified term within
the source text
2. Analyze how that term is translated
in the target text
3. Extract the corresponding
translation **exactly as it appears**
from the target text
4. When extracting, use the character
string that actually appears in the
target text without any modifications

## Important Notes
- The source text and target text may
not necessarily have a perfect
translation relationship
- The translation corresponding to the
specified term may not exist in the
target text
- When extracting translations, do not
add speculation or corrections; use
only character strings that actually
exist in the target text
- If no corresponding translation is
found, or if it is determined that no
translation relationship exists,
output null

## Output Format
Output in the following JSON format:

```json
{
  "term": "input term",
  "term_translation": "extracted
  translation" or null
}
```

Examples

Example 1 (Normal extraction)
Input:
- source text: "The artificial
intelligence system processes data
efficiently."
- target text: "その人工知能システムは
データを効率的に処理します。"
- term: "artificial intelligence"

Output:
```json
{
  "term": "artificial intelligence",
  "term_translation": "人工知能"
}
```

Example 2 (Translation not found)
```

```
**Input:**
- source text: "The quantum computer solved the complex problem."
- target text: "その高性能コンピュータは難しい問題を解決した。"
- term: "quantum"

**Output:**
```json
{
  "term": "quantum",
  "term_translation": null
}
```

Example 3 (Unclear translation relationship)
Input:
- source text: "The new policy will be implemented next month."
- target text: "会議は来週開催されます。"
- term: "policy"

Output:
```json
{
  "term": "policy",
  "term_translation": null
}
```

Input
Source Text
<<<|SOURCE_TEXT|>>>

Target Text
<<<|TARGET_TEXT|>>>

Term
<<<|TERM|>>>
```

Pairwise reranking. The prompt template used for pairwise reranking described in § 4.2 was as follows. The surrounding source segments that provided document-level context (e.g., preceding and following segments) were embedded in <<<|SURROUNDING_CONTEXT|>>>. The translations of previously processed source segments, used as context for the current translation, were embedded in <<<|PREVIOUSLY_TRANSLATED_CONTEXT|>>>. The source sentence to be translated (or the source sentence selected from the parallel corpus) was embedded in <<<|SOURCE_TEXT|>>>. A candidate translation for the current source segment (Translation A) was embedded in <<<|TRANSLATION_A|>>>. A candidate translation for the current source segment (Translation B) was embedded in <<<|TRANSLATION_B|>>>.

```
## Task
You will be given the following information as input:
1. Source sentence (original text)
2. Surrounding context (English)
3. Already translated preceding context (Japanese)
4. Two machine translation candidates A and B (Japanese)

Evaluate both candidates and **select the better translation** based on comprehensive quality assessment.

---

### 1. Evaluation Criteria
Determine the ranking according to the following 5 criteria:
1. **Adequacy**: How accurately the meaning of the source text is conveyed
2. **Fluency**: Grammatical correctness and especially the naturalness, readability, and rhythm of the Japanese. Non-literal translations are preferred.
3. **Terminology \& Proper Nouns**: Accuracy and consistency of technical terms and proper nouns. Eliminate any inconsistency in terminology usage and avoid variation in spelling or phrasing of proper nouns.
4. **Style**: Tone, punctuation, and formatting appropriate for the purpose and audience. Choose a tone that aligns with the context—such as conversational for social media posts or literary for narrative writing.
```

````
5. **Contextual Consistency**:
Consistent expression with the source
text, its surrounding context, and the
preceding translated content

---

### 2. Output Format (JSON)
Return only a JSON object following the
schema below.
Do not include any extra keys,
comments, or trailing commas.
```json
{
  "general_comment": "<Describe the
  overall reasoning for the
  selection>",
  "comparison_results": {
    "translation_A": {
      "strengths": "<Key strengths of
      Translation A>",
      "weaknesses": "<Key weaknesses of
      Translation A>"
    },
    "translation_B": {
      "strengths": "<Key strengths of
      Translation B>",
      "weaknesses": "<Key weaknesses of
      Translation B>"
    },
    "selection_reason": "<Brief
    explanation why the selected
    translation is better>",
    "selected_translation": "<A or B>"
  }
}
```
- general_comment: Overall assessment
explaining the comparison and selection
rationale.
- comparison_results
  - translation_A/B: Analysis of each
  translation
    - strengths: Main advantages of
    this translation
    - weaknesses: Main disadvantages of
    this translation
  - selection_reason: Concise
  explanation of why the selected
  translation is superior
  - selected_translation: "A" or "B" -
  the better translation

Even if the translations are very
similar in quality, always make a
definitive selection.

---

### 3. Comparison Procedure
- In the thinking process, please
conduct a detailed comparison by:
  1. Analyzing each translation against
  all evaluation criteria
  2. Identifying specific differences
  between Translation A and Translation
  B
  3. Weighing the relative importance
  of these differences in the given
  context
  4. Making a final judgment based on
  overall quality

---

### 4. Input
Context:
```txt
<<<|SURROUNDING_CONTEXT|>>>
```
Translated Context:
```txt
<<<|PREVIOUSLY_TRANSLATED_CONTEXT|>>>
```
Source:
```txt
<<<|SOURCE_TEXT|>>>
```
Translation A:
```txt
<<<|TRANSLATION_A|>>>
```
Translation B:
```txt
<<<|TRANSLATION_B|>>>
```
````

Group reranking. The prompt template used for group reranking described in § 4.1 was as follows. The surrounding source segments that provided document-level context (e.g., preceding and following segments) were embedded in <<<|SURROUNDING_CONTEXT|>>>.

The translations of previously processed source segments, used as context for the current translation, were embedded in <<<|PREVIOUSLY_TRANSLATED_CONTEXT|>>>.
The source sentence to be translated (or the source sentence selected from the parallel corpus) was embedded in <<<|SOURCE_TEXT|>>>.

```
## Task
You will be given the following
information as input:
1. Source sentence (original text)
2. Surrounding context (English)
3. Already translated preceding context
(Japanese)
4. N machine translation candidates
(Japanese)

Evaluate each candidate and **rank them
from highest quality (rank_1) to lowest
quality (rank_N)**.

---

### 1. Evaluation Criteria
Determine the ranking according to the
following 5 criteria:
1. **Adequacy**: How accurately the
meaning of the source text is conveyed
2. **Fluency**: Grammatical
correctness and especially the
naturalness, readability, and rhythm of
the Japanese. Non-literal translations
are preferred.
3. **Terminology \& Proper Nouns**:
Accuracy and consistency of technical
terms and proper nouns. Eliminate any
inconsistency in terminology usage and
avoid variation in spelling or phrasing
of proper nouns.
4. **Style**: Tone, punctuation, and
formatting appropriate for the purpose
and audience. Choose a tone that aligns
with the context—such as
conversational for social media posts
or literary for narrative writing.
5. **Contextual Consistency**:
Consistent expression with the source
text, its surrounding context, and the
preceding translated content

---

### 2. Output Format (JSON)
Return only a JSON object following the
schema below.
Do not include any extra keys,
comments, or trailing commas.

```json
{
  "general_comment": "<Describe the
  overall reasoning for the ranking>",
  "reranking_results": {
    "rank_1": {
      "translation_id": <integer>,
      "score": <0 ~ 100>
    },
    "rank_2": {
      "translation_id": <integer>,
      "score": <0 ~ 100>
    }
    // ⋯
    ,
    "rank_N": {
      "translation_id": <integer>,
      "score": <0 ~ 100>
    }
  }
}
```

- general_comment: Overall assessment
explaining the ranking rationale.
- reranking_results
  - rank_i: rank_1 is the highest
  quality, rank_N is the lowest
  quality.
  - translation_id: The candidate
  number indicated in the input
  (Translation 1 ⇒ 1, Translation 2 ⇒
  2, ⋯).
  - score: Overall score from 0 to 100.
  Higher scores indicate better
  quality.

Even in case of ties, always determine
a definitive order and assign unique
ranks without duplicates.

```

````
### 3. Reranking Procedure
- In the thinking process, please make a final judgment by repeatedly comparing what differences exist between each pair of translation results and comparing which translation result is better.

---

### 4. Input
Context:
```txt
<<<|SURROUNDING_CONTEXT|>>>
```

Translated Context:
```txt
<<<|PREVIOUSLY_TRANSLATED_CONTEXT|>>>
```

Source:
```txt
<<<|SOURCE_TEXT|>>>
```
````

Document reranking. The prompt template used for document reranking described in § 5 was as follows. The source document to be translated was embedded in <<<|SOURCE_TEXT|>>>. A candidate translation for the current source document (Translation A) was embedded in <<<|TRANSLATION_A|>>>. A candidate translation for the current source document (Translation B) was embedded in <<<|TRANSLATION_B|>>>.

````
## High-quality translation result selection task

Given an **English source text** and two **Japanese translation candidates (A, B)**,
compare them and determine which one is superior overall, then respond in the specified format.

---

### 1. Evaluation Criteria

1. **Critical errors or unnaturalness can single-handedly determine the selection.**
2. **Adequacy** - Whether the translation accurately conveys all meaning and information from the source
3. **Fluency \& Style** - Whether it reads naturally in Japanese / Whether the style and tone match the context
4. **Terminology \& Proper Nouns** - Consistency and accuracy of technical terms and proper noun translations
5. **Consistency** - Coherence with surrounding paragraphs/sentences (tense, person, etc.)
6. **Readability** - Whether punctuation, line breaks, word order, etc. are reader-friendly

---

---

### 2. Output Format (one line per input segment)

Please output in the following JSON format:

```json
{
  "selected_translation": "A" | "B",
  "general_comment": "<1-2 sentences explaining the decisive factor>"
}
```

**Constraints**

* `selected_translation` must be either `"A"` or `"B"`.
* Do not output any characters outside the JSON (no surrounding \`\`\`, etc.).
* `general_comment` should be 2 sentences maximum.
* Always select one even if uncertain.

---

### 3. Comparison Procedure
````

````
1. Check A / B individually against the
6 evaluation criteria.
2. Prioritize significant differences
(mistranslations, fluency breakdowns,
terminology inconsistencies, etc.).
3. Specify the overall superior choice
as `selected_translation`.
4. Summarize the decisive factor
concisely.

### 4. Input

#### SOURCE:

Google Translate's Research Submission to WMT2025

Mara Finkelstein, Geza Kovacs, Isaac Caswell, Tobias Domhan,
Jan-Thorsten Peter, Juraj Juraska, Markus Freitag, David Vilar
Google Translate

Abstract

Large Language Models have shown impressive multilingual capabilities, where translation is one among many tasks. Google Translate's submission to the 2025 WMT evaluation tries to research how these models behave when pushing their translation performance to the limit. Starting with the strong Gemma 3 model, we carry out supervised fine tuning on high quality, synthetically generated parallel data. Afterwards we perform an additional Reinforcement Learning step, with reward models based on translation metrics to push the translation capabilities even further. Controlling the combination of reward models, including reference-based and quality estimation metrics, we found that the behaviour of the model could be tailored towards a more literal or more creative translation style. Our two submissions correspond to those two models. We chose the more creative system as our primary submission, targetting a human preference for better sounding, more naturally flowing text, although at the risk of losing on the accuracy of the translation. It is an open question to find the sweet spot between these two dimensions, which certainly will depend on the specific domain to handle and user preferences.

1 Introduction

In this paper we present Google Translate's research submission to the General MT track for the WMT 2025 shared task. Starting with Gemma 3 (Gemma Team, 2025), a strong multilingual LLM, we focus on improving its translation capabilities through supervised fine-tuning (Section 2) and reinforcement learning (RL) (Section 3). We use a mix of human- and synthetically-generated parallel data for boosting translation performance, as well as general domain post-training data in order to mostly retain the general capabilities of the original model. Through combinations of different reward models in the reinforcement learning step, we were able to generate two candidates: one more targeted towards fluent translations, the other towards more literal but sometimes slightly unnatural translations. In the end we chose to submit the more fluent system as our primary submission.

2 Supervised Fine-Tuning

For supervised fine-tuning (SFT), we begin with the released Gemma 3 27B model. We use parallel data including both human-generated texts as well as synthetic data generated by Gemini (Gemini Team, 2025). In addition we include human-generated Multidimensional Quality Metrics (MQM) translation error annotation data as made available from the WMT evaluation campaigns,[1] as well as generic instruction-following data. We use the public Gemma Kauldron SFT tooling[2] to fine-tune the Gemma 3 27B pretrained checkpoint. For fine-tuning we use the AdaFactor (Shazeer and Stern, 2018) optimizer with a learning rate of 0.0001 and a batch size of 64, running for 20k steps.

2.1 SFT Data

We used 4 different types of data for the Supervised Fine Tuning step.

Synthetic Gemini-Generated Translation Data Our synthetic data is generated using MADLAD-400 as the monolingual source (Kudugunta et al., 2023). The MADLAD-400 sources are first bucketed by length, and then sampled in each bucket to obtain 1 million source segments for each language pair we wish to generate synthetic data for. We then run a preliminary filtering step across these source segments where we take 2 samples from Gemini 2.5 Flash (1 greedy decoding, 1 sampled at temperature=1.0) and compare their scores according to MetricX 24-QE (Juraska et al., 2024). We

[1] https://github.com/google/wmt-mqm-human-evaluation

[2] https://kauldron.readthedocs.io/en/latest/

Proceedings of the Tenth Conference on Machine Translation, pages 723–731
November 8-9, 2025

select the 60k sources where the sample achieves the largest improvement over the greedy decoding. The intuition behind this source filtering approach is that we wish to select sources that will benefit the most from 128-sample QE decoding, so we use 2 samples as a low-cost approximation. We generate at two distinct lengths this way: individual sentences and text blobs of up to 512 tokens. This way we aim to support both translations of individual segments as well as longer texts.

After this selection process, for each of the 60k sources for each language pair we generate 128 samples from Gemini 2.5 Flash and then apply a MetricX 24-QE filter to select the best-performing examples. In order to avoid formatting issues or erroneous translations, we apply an additional filtering step, based again on Gemini 2.5 Flash. This methodology was applied to the language pairs listed in Table 1. First SFT experiments were carried out on a subset of this data, marked in bold in the table.

For translations into Serbian we created a synthetic data variant in both Cyrillic and Latin script with some post-processing filters based on unicode ranges to make sure the translations are in the correct script. The goal of the synthetic data is to cover all languages relevant for the shared task. Except for Bhojpuri, Bengali and Maasai, the data covers all languages of the primary translation task as well as the multilingual subtask: synthetic data generation for Bhojpuri and Bengali did not finish in time for the shared task submission, and we decided to exclude Maasai due to quality concerns given the extremely low-resource nature of the language. In addition, Maasai was not covered by the multilingual pre-training of the MetricX base model, so that QE scores are likely not reliable.

Human-Generated Translation Data To increase the diversity and script coverage of the data we also include data for additional lower-resource languages. For these languages, due to uncertainty about the quality of Gemini-generated synthetic data, we opt to use human-generated parallel data instead. This data comes from the SMOL (Caswell et al., 2025) and GATITOS (Jones et al., 2023) datasets. SMOL covers 221 languages and GATITOS covers 170. This data was only used for the SFT stage, not RL.

Human-Generated MQM Data We include MQM data from WMT 2020 - 2023 (Lommel et al., 2014; Freitag et al., 2021) in the general training data mix. The intention is to increase the diversity of the training data and add information on translation error scoring. The model response is formatted as JSON as seen in Figure 1. A model fine-tuned only on the MQM portion is used as an AutoMQM model (Fernandes et al., 2023) for RL (see Section 3).

Generic Instruction-Following Data Our SFT mixture also includes 40% generic instruction-following data from the original Gemma 3 mixture. The purpose of including this data is to prevent the model from overfitting to the translation task and to maintain generic instruction-following capabilities.

2.2 Translation Performance

In order to measure the performance during the development cycle, we used a subset of the WMT24++ (Deutsch et al., 2025) corpus. We selected those language pairs (starting from English) that are also included in the WMT25 evaluation campaign, i.e. English to Arabic (Egypt), Chinese (Simplified), Czech, Estonian, Icelandic, Italian, Japanese, Korean, Russian, Serbian and Ukrainian.

In Table 2 results for the SFT approach are shown. We first experimented with running SFT on a set of 17 languages, some of which were included in the WMT25 set of languages. On this setup we saw improvements both on MetricX-24-XXL (Juraska et al., 2024) and COMET22 (Rei et al., 2022) (although only slight), but we saw a significant degradation on CHRF (Popović, 2015). Examining the produced translations, we saw a typical case of overfitting: the languages covered by our dataset saw improvements in translation quality, while those not included suffered from important degradations, especially those with alphabets not included in the data (which explained the big drop in CHRF).

With this observation, we designed a setup that tried to balance the improvements while keeping the overall performance. We lowered the learning rate, froze the embeddings and added generic SFT data derived from the Gemma 3 post-training setup, as well as the MQM data. With this setup, we were able to improve the quality as measured with MetricX and COMET22, while also recovering the original CHRF score. We were able to not only avoid drops but even see gains for languages that were not covered by the translation data mix. For example Bengali dropped from 41.83 CHRF

English (en)	↔	**Arabic (ar)**, **Chinese (zh)**, Czech (cs), **Dutch (nl)**, Estonian (et)*, Farsi (fa)*, **French (fr)**, **German (de)**, Greek (el)*, **Hindi (hi)**, **Indonesian (id)**, Indonesian (id)*, Icelandic (is)*, **Italian (it)**, **Japanese (ja)**, Kannada (kn)*, **Korean (ko)**, Lithuanian (lt)*, Marathi (mr)*, **Polish (pl)**, **Portuguese (pt)**, Romanian (ro)*, **Russian (ru)**, Serbian (sr)*, **Spanish (es)**, Swedish (sv)*, **Thai (th)**, **Turkish (tr)**, Ukrainian (uk), **Vietnamese (vi)**
Japanese (ja)	↔	Chinese (zh)

Table 1: List of language pairs for which we generated synthetic data. For language pairs marked with * formatting filtering was not applied. Languages in bold were included in the first set of experiments

System	MetricX	COMET22	CHRF
Baseline (Gemma 3)	3.08	82.7	41.3
SFT on 17 langs	2.94	82.8	37.7
+ general setup	2.81	83.8	41.1
+ WMT25 langs	2.86	84.4	44.2

Table 2: Supervised fine-tuning results on WMT priority languages. "17 langs" refers to the 17 language pairs marked in bold in Table 1.

to 13.87 in the initial SFT setup, while improving to 45.40 in the general setup (and 46.10 when increasing the language coverage). That is despite not being covered by SFT data. This shows the importance of carefully selecting the fine-tuning setup and monitoring languages/scripts outside of the training data.

Lastly we expanded our parallel dataset to all languages included in WMT25 (except Bhojpuri, Maasai and Bengali), which provided an additional boost in COMET22 and CHRF, with a negligible drop in MetricX.

3 Reinforcement Learning

We performed reinforcement learning on top of the SFT checkpoint, using an ensemble of metrics as reward models, to further boost translation quality.

3.1 Reward Models

We used the following metrics as reward models during RL:

- MetricX-24-XXL-QE (Juraska et al., 2024), a learned, regression-based translation metric producing a floating point score between 0 (best) and 25 (worst), matching the standard MQM score range (Freitag et al., 2021). MetricX scores were linearly rescaled, using $5.0 - \texttt{score}$, when computing rewards, so that higher scores indicate better quality. Although MetricX can take source, reference, and hypothesis as input, we passed in an empty reference to use it as a QE score only.

- Gemma-AutoMQM-QE, a finetuned AutoMQM model (Fernandes et al., 2023). This model was initialized from the Gemma3-27B-IT checkpoint (Gemma Team, 2025), and was trained on MQM ratings data from WMT 2020 - WMT 2023 (Lommel et al., 2014; Freitag et al., 2021). Default MQM weights (Freitag et al., 2021) were used in computing (token-level) rewards from AutoMQM outputs. As with MetricX, it ignores the reference translation.

- Generalist reward model covering many tasks, including reasoning, instruction following, and multilingual abilities, adapted from the general Gemma 3 post-training setup (Gemma Team, 2025).

We used RL algorithms extended to support token-level advantages, which were added to the advantages computed from sequence-level rewards. This allowed us to use fine-grained, span-level reward signals from AutoMQM directly, for improved credit assignment and training efficiency in the spirit of Ramos et al. (2024). See Figure 1 for an illustration of how MetricX and AutoMQM rewards were (additively) combined during advantage computation. The combined advantages were then batch-normalized.

3.2 Language Distribution

For RL we used the same translation data as for SFT[3], but ignored the (synthetic) references, since

[3]Except for GATITOS and SMOL, which were used in SFT only.

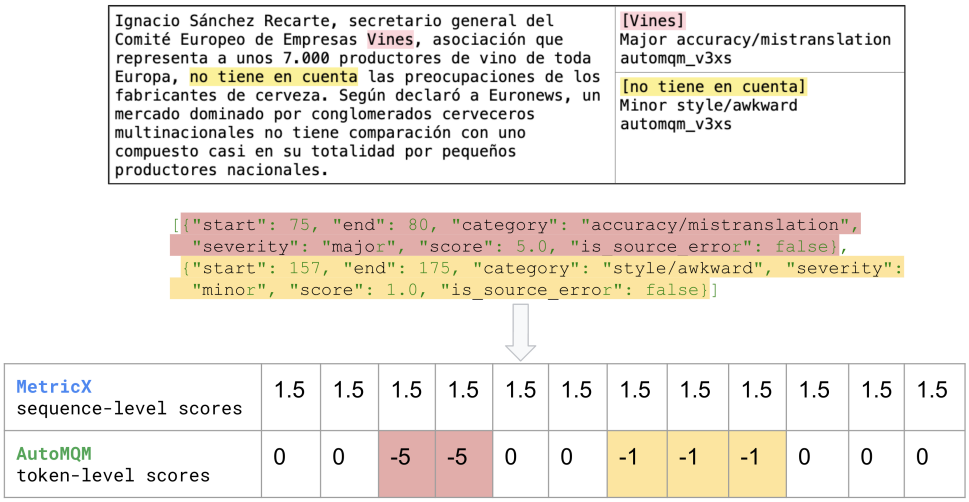

Figure 1: Illustration of how sequence-level and token-level rewards are additively combined during advantage computation in RL. Note that advantage is computed from sequence-level rewards as 'reward-to-go', meaning that rewards are broadcast uniformly to every token.

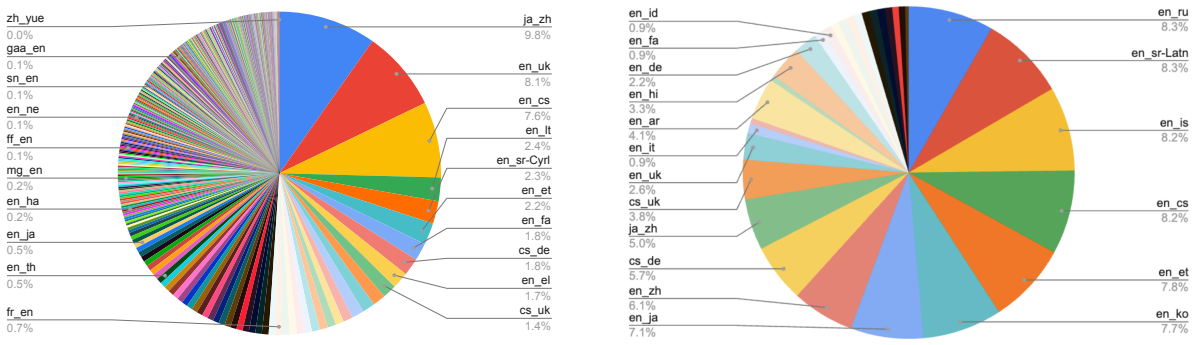

(a) SFT data mixture.

(b) RL data mixture.

Figure 2: Language distribution (token count) in the GemTrans data mixtures.

the rewards we used were reference-free. Furthermore, we included the WMT languages missing from the SFT step (*bn* and *bho*).

We re-balanced the RL data with UniMax sampling (Chung et al., 2023) to balance the distribution of language pairs in the final mixture, resulting in subsampling the high resource language pairs so that all have the same weight. The final proportion of languages for the SFT and RL phases can be found in Figure 2. While the RL prompt set was (approximately) a subset of the SFT data (note that the RL prompt set excluded the non-translation SFT split), we hypothesized that further gains in performance were still possible, given that the RL learning objective is very different from that of SFT, and improvements from RL (e.g., learning to not hallucinate) should generalize independently of the prompt set used.

System	MetricX	COMET22	CHRF
Baseline (Gemma 3)	3.08	82.7	41.3
+ full SFT	2.86	84.4	44.2
+ RL GEMTRANS1	2.40	83.7	37.4
+ RL GEMTRANS2	2.85	83.7	40.4

Table 3: Reinforcement learning results on WMT priority languages.

3.3 Translation Performance

We experimented with different combinations of reward functions and data conditions on small scale experiments, starting from the fine-tuned model described in Section 2. Our primary submission, "GEMTRANS1", used the ensemble of reward models described in Section 3.1. Our secondary submission, which we refer to as "GEMTRANS2", used

the reference-based version of MetricX-24-XXL (with the same synthetic references used for SFT, as described in Section 2.1), and used a prompted, rather than finetuned, AutoMQM reward model. This prompted AutoMQM model used the same prompt format as the finetuned model. Translation results are shown in Table 3. It can be seen that GEMTRANS1 managed to improve significantly on MetricX, although at the cost of drops in COMET22 and CHRF. GEMTRANS2 was not able to improve over the base SFT system in any metric. However, we still kept it as a candidate for submission, keeping in mind that GEMTRANS1 may potentially be overfitting to MetricX.

4 Automatic Post-editing

In order to minimize formatting errors, we run an additional post-editing pass on the resulting translations. Each model post-edits its own translations, i.e. they serve both as translation and post-edit systems. We prompt the model to just fix the formatting, without altering the text of the translation, using the prompt shown in Appendix A. The examples were chosen from errors we spotted during the development process of the model. On automatic metrics we saw small but consistent improvements for both GEMTRANS1 and GEMTRANS2 systems.

5 Final Submission

As described in Section 3.3, we ended up with two main candidates for submission. MetricX showed a clear preference for GEMTRANS1, although there was a clear drop in CHRF.[4] This might be a signal of the model overfitting to MetricX, so in order to get a better picture, we prompted Gemini to compare a subset of the translations of the WMT25 test sets, assigning a score of +1 if GEMTRANS1 was preferred, and -1 otherwise. The results can be found in Table 4, and show a preference for GEMTRANS1.

Additionally we also prompted Gemini to perform an MQM evaluation with additional quality scoring (similar to this year's setup in the shared task evaluation). In this case, the system preferred GEMTRANS2, both in terms of the quality score as well as MQM. When looking into the decomposition into accuracy and fluency scores, the MQM analysis shows better accuracy for GEMTRANS2, but at the cost of fluency.

[4]We had already discarded the failure cases described in Section 2.2 for this setup.

Language Pair	Mean
cs→de_DE	+0.22
cs→uk_UA	−0.07
en→ar_EG	+0.24
en→bho_IN	+0.23

en→mas_KE	+0.31
en→ru_RU	+0.26
en→sr_Latn_RS	+0.20
en→uk_UA	+0.31
en→zh_CN	+0.11
ja→zh_CN	+0.12
Average	+0.17

Table 4: Gemini side-by-side scores for the different language pairs. A positive score represents preference for GEMTRANS1, a negative score preference for GEMTRANS2.

Lastly we manually spot checked the translations (focusing on German outputs). We can confirm the conclusions of the MQM analysis, as we found the output of GEMTRANS1 to be more fluent than that of GEMTRANS2. Table 5 shows some examples comparing the two systems. In the first example, GEMTRANS1 uses the informal form "du" instead of the formal "Sie", which is more appropriate for the context of YouTube videos, and in general the flow of the text is more natural than that of GEMTRANS2. The second example shows a more interesting effect. We saw that GEMTRANS1 in several cases adds "explanations" to its output, e.g. it expands the UCL and LSE abbreviations in the example shown in Table 5. In general we found this added information to be useful and appropriate, and we felt that it indeed increased the translation quality. However, in a more strict sense, these could be interpreted as "accuracy" errors, which would explain the error numbers shown in Table 6. GEMTRANS2 on the other hand seemed indeed to be a more accurate model, but it sometimes produced "unnatural" translations.

Of course all that glitters is not gold, and we also found examples where the added text from GEMTRANS1 was incorrect or even hallucinated. As for the question of overfitting to MetricX, we can-

Table 5: Translation examples for both systems under consideration. GEMTRANS1 generally produces more fluent translations, sometimes with added explanations that help the understanding of the text.

		MQM			
System	Q	Total	Acc	Fl	O
GEMTRANS1	68.0	15.5	13.6	1.1	0.8
GEMTRANS2	75.6	11.4	8.4	1.9	1.0

Table 6: MQM evaluation by prompting Gemini for MQM and quality (Q) scores. The MQM scores are additionally split into accuracy (Acc), fluency (F) and "other" (O) categories.

not completely discard this hypothesis, but we did not see any evidence of pathological outputs that might be gaming the metric. We decided to move forward with this system, as the general quality indeed seemed to be superior to that of GEMTRANS2, and this constituted our primary submission for the shared task.

6 Findings of the Human Evaluation

The organizers of WMT shared the results of the human evaluation. The performance of GEMTRANS1

Language Pair	Cluster	Rank
cs→de_DE	2	9-14
cs→uk_UA	2	4-8

en→uk_UA	2	4-8
en→zh_CN	2	5-10
ja→zh_CN	5	14-15

Table 7: Human evaluation results for the GEMTRANS1 system.

has been summarized in Table 7. It can be seen that GemTrans performs generally in the top 3 clusters for 8 of the 14 language pairs where it was evaluated by humans, being in the first one for English to Italian. The first clusters are usually taken by large systems with a much bigger parameter count. The ranks show a wider variance, due to the highly competitive landscape of this year's shared task and the big number of participating systems.

For English to Arabic GEMTRANS1 obtained a very low human score, along with all other systems in its cluster. This was the result of the system failing to produce the correct Arabic dialect (Egyptian). In a related fashion, Bhojpuri showed low automatic scores (thus GEMTRANS1 was not included in the human evaluation) and we suspect that GEMTRANS1 failed to generate Bhojpuri, falling back to Hindi instead.

In the report about the shared task, in the additional analysis of the Serbian translations, the organizers explicitly highlight the GEMTRANS1 system for a "notable amount of idiomatic translations, even more than humans" (Kocmi et al., 2025), although they also point out a "relatively high number of errors". These findings agree with our own observations about the system.

7 Conclusions

We have presented the Google Translate Research submission to the WMT25 evaluation campaign. Starting from Gemma 3 we used supervised fine-tuning and RL to boost translation performance, in addition to a small automatic post-editing step to improve the formatting of the translations.

Out of the two final candidate systems, we found that one was more tailored towards fluency while the other one was more tailored towards accuracy (possibly illustrating the tradeoff discussed by e.g. Flamich et al. (2025); Schleiermacher (1816); Dryden (1685)). After evaluation with automatic metrics as well as manual inspection, we decided to move forward with the more fluent system, as it seemed to produce generally higher quality translations.

Whether that was the correct decision may largely depend on the criterion of the human evaluators. Quality of machine translation is indeed in the eye of the beholder, and the more "free-style" translations produced by the system may not be the preferred ones if more literal translation are desired, closer to the source sentence. This dichotomy again highlights the difficulties of machine translation evaluation, and may be indeed point towards new research directions (for both MT generation and evaluation), where the intent of the translation can play a more relevant role.

Abstract

This paper presents the submission from Dalian University of Technology (DLUT) and Global Tone Communication Technology Co., Ltd. (GTCOM) to the WMT25 General Machine Translation Task. Amidst the paradigm shift from specialized encoder-decoder models to general-purpose Large Language Models (LLMs), this work conducts a systematic comparison of both approaches across five language pairs. For traditional Neural Machine Translation (NMT), we build strong baselines using deep Transformer architectures enhanced with data augmentation. For the LLM paradigm, we explore zero-shot performance and two distinct supervised fine-tuning (SFT) strategies: *direct translation* and *translation refinement*. Our key findings reveal a significant discrepancy between lexical and semantic evaluation metrics: while strong NMT systems remain competitive in BLEU scores, fine-tuned LLMs demonstrate marked superiority in semantic fidelity as measured by COMET. Furthermore, we find that fine-tuning LLMs for direct translation is more effective than for refinement, suggesting that teaching the core task directly is preferable to correcting baseline outputs.

1 Introduction

The field of machine translation is undergoing a profound paradigm shift, marked by the ascent of general-purpose Large Language Models (LLMs) that challenge the dominance of specialized encoder-decoder Neural Machine Translation (NMT) architectures (Vaswani et al., 2017). For years, NMT systems, meticulously trained on vast parallel corpora, have been honed into highly effective, specialized tools for a single task: translation (Ott et al., 2019). In contrast, LLMs, pretrained on web-scale multilingual and multimodal data, emerge as powerful generalists, possessing not only cross-lingual capabilities but also extensive world knowledge and reasoning skills (Brown et al., 2020), which they can apply to translation with remarkable zero-shot proficiency. This dichotomy between the "specialized artisan" (NMT) and the "generalist polymath" (LLM) raises critical questions about the future trajectory of machine translation research.

This transition is further complicated by an evolution in evaluation philosophy. The community is increasingly moving away from lexical overlap metrics like BLEU (Papineni et al., 2002), which may unduly penalize valid, fluent translations that diverge stylistically from a single reference. The rise of semantic-aware metrics such as COMET (Rei et al., 2020) and its successor, XCOMET-XL (Guerreiro et al., 2023), reflects a demand for evaluations that prioritize meaning and fidelity. This shift is particularly pertinent when comparing NMT and LLMs, as LLMs often excel at producing semantically coherent and contextually appropriate outputs that might be lexically dissimilar to the reference. A core challenge, therefore, is to conduct a fair comparison that accounts for this evaluation dichotomy.

In this paper, we leverage our participation in the WMT25 General Machine Translation task as a standardized testbed to systematically investigate this ongoing paradigm shift. Our work is guided by two central research questions (RQs):

1. **(RQ1)** How do the performance characteristics of specialized NMT systems and general-purpose LLMs diverge, particularly under the contrasting lenses of lexical (BLEU) and semantic (COMET) evaluation metrics?

2. **(RQ2)** Among supervised fine-tuning (SFT) strategies for adapting LLMs to translation, which is more effective: direct instruction on source-to-target mapping (*direct translation*), or training the model to correct outputs from a baseline system (*translation refinement*)?

Proceedings of the Tenth Conference on Machine Translation, pages 732–739
November 8-9, 2025

To address these questions, we developed a comprehensive suite of systems. Our NMT pipeline features deep Transformer models trained with the `fairseq` toolkit, enhanced by data augmentation. Our LLM pipeline is built upon the powerful Gemma3 model family (Team et al., 2025), which we adapt using the `LLaMa-Factory` framework (Zheng et al., 2024). Our main contributions are: (1) a robust empirical comparison of NMT and LLM systems across five language pairs, revealing a significant divergence between lexical and semantic evaluation scores; (2) a direct analysis of two distinct LLM fine-tuning strategies, demonstrating the superior efficacy of direct translation; and (3) insights into the qualitative differences between the outputs of these systems, highlighting the semantic strengths of modern LLMs.

2 Task Description

The core of this task is bilingual text translation. The data, sourced using the 'mtdata' tool(Gowda et al., 2021) from the official WMT25 repository, consists of both parallel and monolingual corpora. Table 1 provides a detailed breakdown of the training data statistics. For our development and testing sets, we used newstest2019 for the Czech→German direction, wmttest2024 for Czech→Ukrainian, English→German, and English→Ukrainian, and flores200-devtest (NLLB Team, 2022) for English→Serbian.

Data Type	Number of Sentences

en-sr	1012

Table 1: Statistics for the training and development datasets.

3 Methodology

Our methodology is designed as a comparative study of two distinct translation paradigms. We first establish a strong baseline representing specialized NMT systems and then build upon a generalist LLM foundation, exploring different adaptation strategies.

3.1 Data Foundation: Preprocessing and Quality Filtering

A high-quality dataset is the bedrock of any translation system. Our preprocessing pipeline is standardized across all languages and includes punctuation normalization, tokenization, Truecasing, and Byte Pair Encoding (BPE) (Sennrich et al., 2015) to manage vocabulary size and handle rare words.

Beyond standard preprocessing, we implemented a rigorous quality filtering stage using the CometKiwi tool ('wmt23-cometkiwi-da-xl' model) (Rei et al., 2023). For our LLM fine-tuning, we adopted a nuanced data selection strategy. Rather than simply taking the top-N scoring sentence pairs, we extracted a 100,000-pair subset ranked between the 10,000th and 110,000th positions. This decision is based on the hypothesis that the absolute highest-scoring pairs often consist of overly simplistic, short, or formulaic sentences (e.g., from translation memories), which can lead to models that are fluent but lack complexity. By targeting a "high-quality but challenging" segment, we aim to create a more diverse and robust instruction dataset for fine-tuning.

3.2 Paradigm 1: Specialized NMT Systems

To represent the best in specialized NMT, we employed a deep Transformer architecture ('transformer_wmt_en_de' configuration in `fairseq`). These models, featuring 24 encoder and 24 decoder layers, serve as our high-performance baseline. To maximize the utility of available monolingual data—a cornerstone of competitive NMT—we incorporated iterative data augmentation:

1. **Back-Translation (BT):** We trained reverse-direction models (e.g., ru→en) to translate target-language monolingual data into the

source language, creating a large, synthetic parallel corpus to augment the primary training data.

2. **Forward-Translation (FT):** The improved models from the BT step were then used to translate source-language monolingual data, further enriching the training mixture in a subsequent iteration.

3.3 Paradigm 2: Generalist LLM-based Systems

Our exploration of the generalist paradigm centers on the Gemma3 model family, selected for its strong preliminary multilingual performance. Our approach systematically moves from zero-shot evaluation to targeted adaptation.

3.3.1 Foundation Model and Zero-Shot Baseline

We first established a zero-shot baseline by evaluating several prominent instruction-tuned LLMs (including the Qwen3 and Gemma3 series) on our development sets using a direct translation prompt. This step measures the intrinsic, out-of-the-box translation capabilities of these models without any task-specific training.

3.3.2 Supervised Fine-Tuning (SFT) Strategies

To adapt Gemma3 for high-quality translation, we investigated two distinct SFT strategies, each testing a different hypothesis about how LLMs best learn this complex task. **To achieve the most thorough adaptation possible, we performed full-parameter fine-tuning, allowing all weights of the base model to be updated during the training process.** This approach, while computationally intensive, ensures that the model can fully specialize its internal representations for the translation task.

Strategy 1: Direct Translation. In contrast, this strategy reframes the task from generation to a more complex process of critique and correction. The model is provided with a triplet: the source text, a potentially flawed translation from our NMT baseline, and the high-quality reference. The hypothesis is that by learning to identify and correct errors—essentially, learning the "delta" between a mediocre and an excellent translation—the model develops a more nuanced understanding of quality, error patterns, and stylistic appropriateness. This task is guided by a prompt that casts the LLM in the role of a professional "post-editor":

```
You are an expert in {Source
    language}-{Target language}
    translation, with a deep
    understanding of both languages'
    cultural nuances. Your
    translations are accurate, fluent
    , and elegant. Please translate
    the following {Source language}
    text into {Target language}. Only
     output the translation.

{Source language} text: {Source text
    }
{Target language} translation:
{Target text}
```

Strategy 2: Translation Refinement. This strategy reframes the task from generation to critique and correction. The model is provided with a source text, a potentially flawed translation from our NMT baseline, and the high-quality reference. It is then instructed to "polish" or "refine" the baseline translation. The hypothesis here is that learning to identify and correct errors is a more cognitively demanding task that could foster a deeper, more nuanced understanding of translation quality, error patterns, and stylistic appropriateness, potentially leading to a more robust translator. The prompt for translation refinement is as follows:

```
You are a professional {Source
    language}-{Target language}
    translation refinement expert who
     excels at making machine-
    translated content more natural
    and fluent, ensuring it aligns
    better with the target language's
     norms and contexts. Based on the
     provided source text and machine
     translation, refine and modify
    the translation to make it more
    accurate and natural.

{Source language} source: {Source
    text}
{Target language} translation: {
    Baseline translation text}
{Target language} corrected
    translation:
{Target text}
```

4 Experimental Setup

Our experiments were designed to ensure a fair and reproducible comparison between the NMT and LLM paradigms.

4.1 NMT System Configuration

We used the `fairseq-py` toolkit for all NMT experiments. Our deep Transformer models were trained with the following configuration:

- **Architecture:** 'transformer_wmt_en_de' (24 encoder/decoder layers, 16 attention heads, embedding size of 1024).
- **Optimizer:** Adam (Kingma and Ba, 2017) with $\beta_1 = 0.9$, $\beta_2 = 0.98$.
- **Learning Rate Schedule:** Inverse square root scheduler with a warm-up of 4,000 steps and a peak learning rate of 5×10^{-4}.
- **Regularization:** Dropout was set to 0.3 for the attention and activation functions, and label smoothing of 0.1 was applied.
- **Batching:** We used a maximum of 4096 tokens per batch per GPU. Models were trained for 100,000 steps or until convergence on the development set.

4.2 LLM System Configuration

All LLM experiments were conducted using the `LLaMa-Factory` framework.

- **Base Models:** We used the instruction-tuned versions of the Gemma3 family: 'Gemma3-12B-it' and 'Gemma3-27B-it'.
- **Fine-Tuning Method:** We employed **full-parameter supervised fine-tuning**. This involves updating all of the model's weights, rather than using a parameter-efficient method.
- **Hyperparameters:** Models were trained for 3 epochs over the 100k-pair instruction dataset. We used the AdamW optimizer with a learning rate of 2×10^{-5}, a cosine learning rate scheduler, and a warm-up ratio of 0.03. Training was performed with `bfloat16` mixed-precision to optimize memory usage and throughput.

4.3 Evaluation Metrics

To provide a multifaceted view of translation quality, we report scores from two distinct metrics:

- **sacreBLEU** (Post, 2018): A standardized implementation of BLEU that measures n-gram precision against a reference translation. It primarily reflects lexical similarity.
- **XCOMET-XL** (Guerreiro et al., 2023): A state-of-the-art semantic metric that uses a large pre-trained model to assess the meaning equivalence between the source, hypothesis, and reference. This metric aligns more closely with human judgments of translation quality.

5 Results and Discussion

In this section, we analyze our experimental results to answer the research questions posed in the introduction. We dissect the performance of each paradigm and discuss the implications of our findings. The comprehensive results for our NMT baselines and zero-shot LLM evaluations are consolidated in Table 2.

5.1 RQ1: NMT vs. LLMs and the BLEU-COMET Dichotomy

Our first research question explores the performance divergence between specialized NMT and generalist LLMs. The results in Table 2 reveal a fascinating and consistent trend that we term the BLEU-COMET dichotomy.

NMT systems remain formidable competitors on lexical metrics, often outperforming even large LLMs in BLEU score. This is most evident in the en→sr direction, where the NMT baseline achieves a BLEU score of 38.44, significantly higher than any other system. Similarly, for cs→de, the NMT baseline's BLEU of 29.67 is the highest in its category. Regarding data augmentation, back-translation shows a clear benefit for lower-resource pairs (e.g., providing a 1.73 BLEU point gain for cs→uk), but its impact diminishes or even slightly degrades BLEU on high-resource pairs like cs→de. Furthermore, forward-translation consistently proves detrimental to performance across most pairs, likely due to the introduction of unmitigated noise.

In contrast, LLMs exhibit a clear and striking superiority in semantic fidelity, even in a zero-shot setting. The Gemma3-27B-it model achieves the highest zero-shot COMET score in four out of five language pairs. The most dramatic example is en-uk, where the Gemma3-27B-it's COMET score of 80.31 massively surpasses the NMT system's 67.55, despite having only a marginal advantage in BLEU. This pattern holds for cs→de (94.24 vs. 93.71), cs→uk (91.47 vs. 88.65), and en→ru (91.73 vs. 91.55). The only exception is en→sr, where the NMT baseline's COMET score

Model / System	cs→de		cs→uk		en→uk		en→ru		en→sr	
	BLEU	COMET	BLEU	COMET	BLEU	COMET	BLEU	COMET	BLEU	COMET
Specialized NMT Systems

Refinement SFT	26.32	94.32	29.94	91.01	27.83	80.61	29.26	90.50	31.33	88.97

Table 3: Results of supervised fine-tuning on Gemma3 models. The Direct Translation strategy consistently outperforms the Refinement strategy across nearly all models and language pairs. The fine-tuned Gemma3-27B-it with Direct SFT emerged as our best overall system.

is competitive (90.45 vs. 90.25). This powerful trend suggests that LLMs' vast world knowledge allows them to generate more fluent and semantically equivalent translations, a quality that is rewarded by COMET but can be unfairly penalized by BLEU's rigid lexical matching.

5.2 RQ2: Efficacy of SFT Strategies

Our second research question investigates the more effective SFT strategy for adapting LLMs to translation. The results from our fine-tuning experiments, presented in Table 3, provide a decisive answer.

Direct Translation consistently and significantly outperforms Translation Refinement. For both the 12B and 27B model sizes and across all five language pairs, the models fine-tuned with the direct translation task achieved superior scores on both BLEU and COMET. For instance, in the en-uk direction, the Gemma3-27B-it model fine-tuned for direct translation achieved a COMET score of 81.56, while the refinement-tuned model scored only 80.61. Similarly, for en-sr, the direct translation model achieved a COMET of 90.97, a full two points higher than the refinement model's 88.97. The Gemma3-27B-it with Direct Translation SFT emerged as our best overall system, achieving the highest COMET score across the board.

We attribute this clear victory to two primary factors. First, the refinement task introduces a higher cognitive load: the model must simultaneously comprehend the source, analyze the errors in a flawed translation, and generate a correction. This may represent a less direct and noisier learning signal. Second, the provided baseline translation may act as a negative anchor, implicitly constraining the model's output space and preventing it from generating a truly novel and superior translation from scratch. It learns to "edit" rather than to "create."

5.3 Overall Performance and Future Outlook

Our best-performing systems for all language pairs were the Gemma3-27B-it models fine-tuned using the direct translation strategy. As shown by our final official scores in Table 3, these systems achieved competitive results. However, a gap remains when compared to the top-ranking teams in the official evaluation.

Our analysis suggests that while full-parameter SFT on a high-quality 100k dataset is effective, it represents only the initial stage of true model alignment. To reach the highest echelons of translation quality, future work should focus on more

advanced alignment techniques that have proven successful in general-domain LLMs. Promising directions include:

- **Continual Pre-training:** Further adapting the base LLM on large-scale, in-domain monolingual and bilingual data before the SFT stage.
- **Preference Optimization:** Moving beyond standard SFT to methods like Direct Preference Optimization (DPO) (Rafailov et al., 2024), which learns from human or AI-judged preferences between translation candidates, thereby optimizing directly for perceived quality.

This work confirms that while the era of LLMs is here, achieving state-of-the-art translation performance requires more than just scale; it demands sophisticated and targeted adaptation strategies.

6 Conclusion

In this paper, we presented a systematic comparison between specialized Neural Machine Translation (NMT) systems and general-purpose Large Language Models (LLMs) within the framework of the WMT25 General MT Task. Our work was designed to investigate the ongoing paradigm shift in the field, focusing on the divergence in performance characteristics and the efficacy of different LLM adaptation strategies.

Our investigation yielded clear answers to our initial research questions. **First (RQ1)**, we identified a significant and consistent "BLEU-COMET dichotomy." While our highly optimized NMT systems remained competitive, and occasionally superior, in terms of lexical similarity (BLEU), LLMs demonstrated a marked advantage in semantic fidelity (COMET), even in a zero-shot setting. This finding underscores the limitations of traditional metrics in the age of LLMs and highlights the unique ability of these large models to produce fluent and semantically equivalent translations.

Second (RQ2), our experiments on supervised fine-tuning strategies provided a decisive result: direct translation proved to be a more effective adaptation method than translation refinement. We hypothesize that teaching the model the core source-to-target mapping task directly provides a cleaner and more potent learning signal than asking it to perform the more complex, multi-step task of identifying and correcting errors from a baseline system.

Our best systems, based on full-parameter fine-tuning of the Gemma3-27B-it model, achieved highly competitive results. However, our analysis suggests that the next frontier for LLM-based translation lies beyond standard SFT. The path to state-of-the-art performance will require more sophisticated alignment techniques that can better bridge the gap between the LLMs' vast generative capabilities and the nuanced preferences of human evaluation. Future work should therefore prioritize the exploration of methods such as continual pre-training on in-domain corpora and, most promisingly, preference optimization techniques like DPO.

Yandex

Abstract

This paper describes Yandex submission to the WMT25 General Machine Translation task. We participate in English-to-Russian translation direction and propose a purely LLM-based translation model. Our training procedure comprises a training pipeline of several stages built upon YandexGPT, an in-house general-purpose LLM. In particular, firstly, we employ continual pretraining (post-pretrain) for MT task for initial adaptation to multilinguality and translation. Subsequently, we use SFT on parallel document-level corpus in the form of P-Tuning. Following SFT, we propose a novel alignment scheme of two stages, the first one being a curriculum learning with difficulty schedule and a second one - training the model for tag preservation and error correction with human post-edits as training samples. Our model achieves results comparable to human reference translations on multiple domains.

1 Introduction

We participate in the WMT25 General Machine Translation task and propose a purely LLM-based translation system.

Large Language Models (LLMs) have recently redefined the state-of-the-art in machine translation, demonstrating strong capabilities that yield near-human quality outputs on vast collection of language pairs. Their performance has consistently surpassed that of the previous generation of specialized Neural Machine Translation (NMT) systems, marking a significant paradigm shift in the field. The recent WMT24 General Machine Translation contest provides compelling evidence of this trend, where top-performing systems, predominantly based on LLMs, achieved translation scores remarkably close to human reference translations.

Still, the human parity claim remains disputable and thorough evaluations have shown that for a variety of high-resource morphologically rich languages, although quite high, the performance of LLMs still lags behind professional human translations. All state-of-the-art LLM systems exhibit a noticeable pattern of literal translations with fluency and naturalness of generations significantly worse than that of native human translations.

In this work, we propose a novel pipeline for LLM adaptation to the MT task, building upon our previous year submission (Elshin et al., 2024). The main goal of this work is to explore tools and techniques for improving the performance of an already capable MT-specific LLM model with near human performance.

The system comprises a pipeline of several adaptation stages built upon 7-billion YandexGPT, an in-house proprietary general-purpose language model.

- First, we employ continual pretraining for robust adaptation of general-purpose pretrained model to the task of translation and multilinguality (post-pretrain)
- Following post-pretrain, the model is fine-tuned on a cleaner corpus of automatically collected books translations
- Subsequently, the system undergoes an alignment procedure consisting of two primary stages
  - Contrastive Preference Optimization (CPO) with curriculum learning for low-resource document-level adaptation, targeted at fluency and cohesion improvement
  - Second alignment stage focused on tackling the model shortcomings and tag preservation training

The resulting model (Yandex) was subsequently fine-tuned on the WMT dataset, producing the Yandex+WMT model which constitutes our submis-

Proceedings of the Tenth Conference on Machine Translation, pages 740–752
November 8-9, 2025

sion to the WMT25 General Machine Translation task.

For the English-to-Russian translation direction our resulting system is significantly better than all of the previous year contenders and achieves results comparable to major foundational LLMs on this year's benchmark.

2 System Overview

In this section we describe the training pipeline of the system and details of the inference procedure. We also provide automatic metrics and human evaluation results for the key components of the system.

2.1 Pretrain

The base model that we use is a 7 billion parameter version of YandexGPT, an in-house general-purpose large language model. It is a decoder-only model of an architecture similar to Touvron et al. (2023) trained on a collection of data primarily consisting of Russian and English texts.

In our experiments we use the pre-train stage of YandexGPT as the starting point for machine translation specific fine-tuning.

2.2 Post-pretrain

As an initial adaptation for multilinguality and translation task, we perform a continual pretraining using recipe similar to Alves et al. (2024).

We fine-tune the model using full weights fine-tuning with a standard cross-entropy loss on a mixture of pretrain dataset and MT data with a ratio of translation data of 30%.

The parallel translation data is collected using a matching pipeline similar to Bitextor (Esplà-Gomis, 2009). It involves matching multilingual websites as candidates for parallel documents, followed by a series of alignment and filtering steps (Thompson (2019), Artetxe and Schwenk (2019)).

For each example of parallel translation data, we construct two samples for continual pretraining via concatenation in both ordering variants: english text concatenated with russian translation via two new-line separators and vice-versa.

In our experiments we have observed that the optimal ratio of incorporating MT data is around 30% and it is beneficial to mirror all en-ru training samples in reverse direction.

2.3 Supervised Fine-tuning

Following post-pretrain, we employ supervised fine-tuning (SFT) in order to focus the model solely on the translation task and enforce more precise outputs without hallucinations.

We use an in-house dataset of parallel English and Russian books aligned at the paragraph-level. We apply filtering by length and train on fragments with maximum length of 1k sentence-piece tokens (Kudo and Richardson, 2018). In addition to that, we only use paragraph pairs with the same number of sentences in the source and translation text.

In terms of the training procedure, we have experimented with both standard SFT finetuning and sparse methods like LoRa (Hu et al., 2021) and PTune variants (Liu et al. (2021b), Liu et al. (2021a)).

Our experiments have shown that not only does not the Full Finetuning improve quality upon parameter-efficient training strategies but it also leads to the quality degradation after subsequent alignment. We hypothesize that the root cause for this phenomenon is the "knowledge forgetting". Specifically, more extensive fine-tuning methods make SFT checkpoint less sensitive to the pre-trained LLM knowledge and hence over-optimize for the parallel dataset during the SFT stage.

The resulting system involves training with P-Tuning v2 (Liu et al., 2021a) with two trainable P-Tuning blocks each having the size of 100 ptune tokens placed

- At the start of the input string, before the English source
- Between English source and Russian translation to be generated

In Table 1 we report automatic evaluation results of models from pretrain and SFT stages. We measure MetricX-24 (Juraska et al., 2024) in both reference-based and reference-less QE variants as well as fluency score, which is an in-house monolingual classifier that measures the grammatical and lexical correctness of the Russian translation. We use the same subset of WMT24 test data as in human evaluations for results consistency.

2.4 First-Stage Alignment

In this section we describe the key components of the subsequent step in the training pipeline - the first stage of alignment fine-tuning.

The primary goal of alignment is to effectively make use of another form of training signal - user

Model	METRICX-24-XXL	METRICX-24-XXL-QE	Fluency
YandexGPT Pretrain	4.746	4.262	0.754
MT Postpretrain	4.899	4.499	0.772
SFT (PTune)	4.272	3.854	0.795

Table 1: Comparison of model performance on WMT24 testset.

preferences data or algorithmic rankings of translations with varying quality. In contrast to SFT, alignment techniques like reinforcement learning or contrastive learning allow to perform not only "likelihood" traning on good reference, but also "unlikelihood" training on the data with proven deficiencies or more sophisticated ranking-based approaches.

2.4.1 Sentence-Level Data

The first portion of the training dataset is an internal collection of historic human evaluations of various model generations. This dataset consists of sentence triplets ("source", "winner_translation", "loser_translation") and has a size of several tens of thousand examples.

Namely, "winner_translation" is a preferred hypothesis, and "loser_translation" is a dispreferred. All rankings were done by professional human annotators via a platform similar to Amazon Mechanical Turk.

The samples themselves are single sentences of varying length, typically no more than 100 tokens.

2.4.2 Document-Level Data

As training solely on sentences would not expose the model to complex and practically challenging discourse phenomena of translation like deixis, ellipsis and lexical cohesion we also collected several specific datasets to emphasize such phenomena during training.

The first one is specifically targeted on fluency and coherence improvement (**fluency repair**):

1. Generate paragraph translations with the sentence-level translation model.

2. "Improve" the non-coherent paragraph translations using a monolingual general-purpose LLM.

3. Train on such fluency corrections using contrastive learning, wherein the "positive" hypothesis would be the smoothed and fluent translation and the "negative" hypothesis would be the original sentence-wise translation.

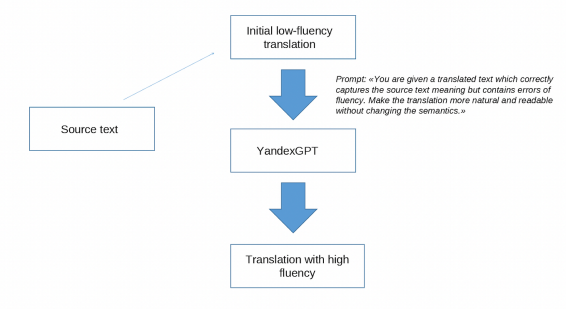

Figure 1: Fluency repair procedure.

We also collect several thousands of side-by-side comparisons of different model generations on paragraph-level source data.

In addition to the contrastive learning triplet data, we found it beneficial to mix triplet data with a small high-quality SFT set of manually written translations created by experts with high language proficiency. We add several thousand such samples to the alignment stage.

2.4.3 Curriculum Learning

In the previous two sections we have outlined the data collection procedure of two parts: sentence-level and document-level data. Sentence-level dataset is significantly larger, consisting of more than 100.000 samples, while the whole document or paragraph-level translations corpus is almost an order less.

This leads to a data imbalance issue during training. Uniform mixture of both sentence- and document-level sources would be highly skewed towards sentence part and in our experiments it produced results highly similar to training only on sentences. Upsampling of document-level data would result in overfitting.

This outlined problem could be handled through training with cirruculum learning (Bengio et al., 2009). We employ a difficulty schedule, first training solely on sentence corpus and then switching to documents at the end of the training.

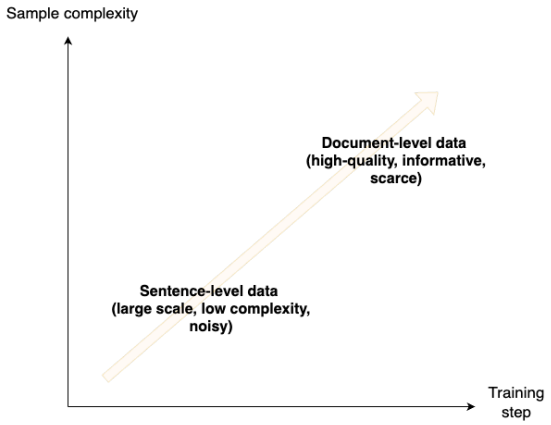

Figure 2: Curriculum learning with sentences-to-documents adaptation.

2.4.4 Training Procedure

We train using Contrastive Preference Optimization (CPO) objective (Xu et al., 2024)

$$\mathcal{L}(\pi_\theta) = -\mathbb{E}_{(x,y_w,y_l)\sim\mathcal{D}}\Bigg[\log\sigma\Big(\beta\log\pi_\theta(y_w|x) - \beta\log\pi_\theta(y_l|x)\Big)\Bigg]$$

with a cross-entropy regularizer:

$$\min_\theta \underbrace{\mathcal{L}(\pi_\theta, U)}_{\mathcal{L}_{prefer}} - \underbrace{\mathbb{E}_{(x,y_w)\sim\mathcal{D}}[\log\pi_\theta(y_w|x)]}_{\mathcal{L}_{NLL}}.$$

We have observed that using higher weights before regularizer cross-entropy term leads to more literal and adequacy-boosting translations (close to the SFT fine-tuning), while giving more weight to the contrastive learning term makes the model much more fluent, but prone to hallucinations.

Overall, the training objective for contrastive triplets is CPO with cross-entropy regulatization weight set to 0.1:

$$\min_\theta \underbrace{\mathcal{L}(\pi_\theta, U)}_{\mathcal{L}_{prefer}} - 0.1 \cdot \underbrace{\mathbb{E}_{(x,y_w)\sim\mathcal{D}}[\log\pi_\theta(y_w|x)]}_{\mathcal{L}_{NLL}}.$$

For the high-quality references, we use standard SFT with learning rate 20 times higher than those for contrastive samples.

We train with one epoch and follow a triangular learning rate schedule with the warmup of 10% of steps and linear decay.

Sentence- and document-level portions of the data are shuffled and the document-level data consists of fluency repair and side-by-side triplets mixed with SFT samples for high-quality references.

2.5 Second-Stage Alignment

During the second stage of alignment, our primary goal is to precisely address specific model deficiencies while developing structure-preserving capabilities. This phase focuses on fine-grained tuning of the model through targeted interventions.

We concentrate on two parallel objectives: first, we aim to fix the common errors of the model after the initial alignment phase. Second, we enhance the model's ability to maintain specific structural elements of the input data (such as HTML tags, list orderings, dialogue formatting etc.).

In practice, our approach involves collecting on-policy data that captures examples of typical errors of the model from the first alignment stage. We then perform post-editing of those on-policy translations, forming a contrastive dataset where post-edits serve as positive examples and the original model outputs as negative ones. We also perform an additional adaptation for WMT topics and construct a dataset derived from WMT24 data annotated with the RATE protocol (Popov et al., 2025). We create contrastive pairs by selecting translations where the average of fluency and accuracy scores differs by more than 5 points, as detailed in Section 2.5.1. The structure preservation dataset, also described in Section 2.5.1, similarly features targeted differences between negative and positive examples, focusing on maintaining specific structural elements rather than completely rewriting translations.

2.5.1 Datasets

Human post-editing

Following active learning paradigm, we collect human-written post-edits of first-stage alignment model generations. This naturally results in triplets of ("source text", "model translation", "human post-edit"). Hereby, the triplets contain a more concentrated signal that specifically targets model error corrections.

On-policy side-by-side comparisons

In addition to human-written post-edits, we collect side-by-side comparisons of on-policy model

generations. The generations are obtained via standard sampling with temperature of 1.0 and side-by-side evaluation is conducted by professional annotators.

The impact of these two portions of the data can be formalized as

(a) eliminating systematic bias of the model in the form of error correction done by human

(b) decreasing variance of the model by training on on-policy comparisons

Structure preserving training

In order to translate structured data, such as HTML web pages, documents with formulae blocks, or subtitles with clear replics borders, we specifically train the model for tagged data translation.

Following Elshin et al. (2024), we convert all tags or separators to the universal tag ({ for the opening paired tag and } for the closing paired tag, each unpaired tag is converted to {})

Consequently, each input containing tags would first be converted to the universal tag format, for example, "<title>Paper Index - EMNLP 2021 Sixth Conference on Machine Translation (WMT21)</title>" would correspond to "{Paper Index - EMNLP 2021 Sixth Conference on Machine Translation (WMT21)}" input during inference.

This implies that for the correct translation of tagged data, the model should be able to preserve the exact bracket sequence given at the input, the number and the sequence of brackets.

We explicitly train for this property using a rule-based reward; for each (source, translation) pair it is algorithmically possible to determine whether the given translation has correctly preserved the tag sequence. Hence, one can construct training samples in an unsupervised way using diverse decoding or beam search:

1. Sample a set of model generations using diverse decoding or wide beam search
2. Score all outputs using rule-based reward that verifies the tag preservation
3. If possible, create a contrastive triplet wherein the positive example contains the output with correctly preserved tags and the negative one contains tag errors

Aiming to keep only informative samples, we select only the sources with tag error in the top-1 model hypothesis and take the most probable example with correctly translated tags to maximize the general translation quality.

WMT24 data

For domain adaptation purposes, we leverage a dataset annotated using the RATE protocol (Popov et al., 2025). This dataset encompasses all documents from WMT24 General Translation Task along with translations from 8 systems participating in the contest, comprising approximately 4,000 segments. The RATE protocol provides detailed information about error spans as well as pointwise accuracy and fluency scores on a 100-point scale.

To generate a contrastive training set from this resource, we take all translation pairs and select only those where the average of fluency and accuracy scores differs by more than 5 points. This selection process yields a dataset containing slightly over 7,000 contrastive examples. It's worth noting that the resulting dataset contains triplets that share the same source text, and, in some cases, a system translation may serve as a positive example in one triplet while appearing as a negative example in another, depending on the quality of alternatives it's being compared against.

2.6 Decoding

We employ a mixed decoding strategy by merging paragraph sequences into larger decoding chunks, hereby decoding with a **local context**.

Inference with Local Context

It is clear that an accurate translation of the document should be done with its full context. However, in practice we have observed that current translation models exhibit inferior performance when given inputs of sufficiently large size.

Given that translation quality starts to decline from several hundred tokens, we propose a hybrid decoding strategy.

1. Set decoding block size to 100 tokens.
2. For a given document, merge sequential paragraphs into blocks greedily, while the currently accumulated block size is less than the decoding block size.
3. Consider the current sequence of paragraphs a single decoding "block".
4. Next blocks are constructed accordingly.

Model	METRICX-24-XXL	METRICX-24-XXL-QE	Fluency
SFT (PTune)	4.272	3.854	0.795
CPO Stage 1	2.417	2.167	0.902
DPO Stage 2	2.369	2.136	0.895
DPO Stage 2 + tags	2.406	2.192	0.898
DPO Stage 2 + tags + WMT	2.253	2.171	0.911

Table 2: Model quality dynamics through alignment stages (WMT24 testset).

	WMT24		WMT25	
domain	segments	documents	segments	documents
literary	63	7	6	2
news	94	16	41	14
social	272	33	27	9
speech	66	66	62	62

Table 3: Testsets descriptive statistics.

To preserve the paragraph structure, we wrap each paragraph in the block with {} tags, thus making sure that the translated document would contain the same number of paragraphs as the source document.

Table 2 shows the quality dynamic of alignment components on WMT24 testset. The first alignment stage displays a significant improvement over SFT with a large margin on all metrics, whereas subsequent alignment stages do not bring statistical improvements in MetricX. We hypothesize that automatic evaluation becomes insensitive from a certain quality of translations and does not capture subtle differences that human annotators still observe.

3 Human Evaluation Results

Due to constraints on time and human resources we selected subsets from two testsets for human evaluation: 495 segments from WMT24 general MT testset and 136 segments from WMT25 general MT blindset. These subsets are hereafter referred to as WMT24 and WMT25, respectively. Obviously, the human translations of WMT25 testset could not be included in this evaluation campaign since they have not been publicly released yet. The number of segments and their distribution across domains is presented in Table 3.

Two protocols were implemented to evaluate MT quality of our submission: the ESA protocol (Kocmi et al., 2024), following WMT guidelines, and the RATE protocol, introduced in Popov et al. (2025). The annotators' qualifications and detailed annotation setup are described in Appendix A.

Yandex+WMT is compared to Yandex model (referred to as DPO Stage 2 + tags above) and several LLM translations. Claude3.7 and GPT-4 translations for WMT24 testset were obtained directly from WMT24 publicly released data. The WMT25 testset was translated using Claude 4 and GPT-4.1 with a simple prompt *"You are a professional English-to-Russian translator. Your goal is to accurately convey the meaning and nuances of the original English text while adhering to Russian grammar, vocabulary, and cultural sensitivities. Produce only the Russian translation, without any additional explanations or commentary. Translate the following text: {input text}"*.

We report segment-level ESA scores alongside error counts and MQM-like scores calculated as $5 \times major + minor$ in Table 4. For the RATE protocol, separate scores for accuracy, fluency, and style are reported, as well as error category statistics. We also report error-per-token statistics and macro-averaged counts by document, domain, or both in Appendix B. Following the WMT methodology, we compute pairwise statistical significance of the differences by Wilcoxon signed rank test and group systems into clusters represented numerically in the tables. Both evaluation methods on WMT25 testset confirm that Yandex+WMT outperforms Yandex and demonstrates statistically significant improvement over the compared LLMs on both testsets. RATE results provide more interpretable differentiation between Yandex and Yandex+WMT: the fluency score shows a measurable increase, while

	segment level					counts per token		
system	errors	major	minor	MQM	ESA	errors	major	minor
Claude 3.7	2.35_3	0.79_2	1.56_3	5.65_5	79.48_3	0.09	0.03	0.06

Table 5: Segment-level ESA annotation results on WMT25 testset.

differences in accuracy remain statistically non-significant.

4 Conclusion

In this paper, we describe Yandex submission to the WMT25 General Translation task. For English-to-Russian translation direction, our model outperforms all systems from WMT24 competition and achieves results comparable to major foundational LLMs on WMT25 benchmark, as measured by ESA and RATE human evaluation protocols. According to the official human evaluation results our model achieves parity with human reference translations on ESA score.

We present a detailed description of our training procedure as well as giving the rationale for different training steps. Our pipeline includes multi-stage alignment procedure specifically designed to improve the quality of an already capable machine translation system, with the performance close to the human one.

We employ novel techniques, such as curriculum learning with sentences-to-documents adaptation, training on human post-edits and fine-tuning for tagged data using rule-based reward. Our results, measured both in automatic metrics and human evaluations, demonstrate the effectiveness of the proposed pipeline as well as high overall translation quality of the system.

Table 7: WMT25 ESA annotation results - segment-level average by domains.

A Annotation details

The evaluation was conducted by two distinct groups of annotators:

1. ESA experts: an in-house group of Russian language natives who successfully passed the C1-level English test and regularly participate in translation evaluation campaigns. These experts received training to annotate translations according to ESA instructions. Quality control was maintained through manually prepared golden annotations.

2. RATE experts: a smaller in-house group of Russian language natives with qualification in Linguistics or Translation who underwent a multi-step selection process based on translation, post-editing and fact-checking competencies. As shown in Popov et al. (2025), this rigorous selection procedure may be crucial for ensuring annotation quality when evaluating high-quality translations.

Abstract

Large Language Models (LLMs) have been demonstrated to achieve state-of-the-art results on machine translation. LLM-based translation systems usually rely on model adaptation and fine-tuning, requiring datasets and compute. The goal of our team's participation in the "General Machine Translation" and "Multilingual" tasks of WMT25 was to evaluate the translation effectiveness of a resource-efficient solution consisting of a smaller off-the-shelf LLM coupled with a self-refine agentic workflow. Our approach requires a high-quality multilingual LLM capable of instruction following. We select `Gemma3-12B` among several candidates using the pretrained translation metric `MetricX-24-XL` and a small development dataset. WMT25 automatic evaluations place our solution in the mid tier of all WMT25 systems, and also demonstrate that it can perform competitively for approximately 16% of language pairs.

1 Introduction

Machine translation (MT) is an important yet unsolved NLP task with significant practical applications Kocmi et al. (2024a). Large language models (LLMs) have become a basis for state-of-the-art MT solutions, and the best approaches rely either on commercial LLMs or on open-weights models adapted using translation-specific data (Kocmi et al., 2024a). However, commercial cloud-based models may introduce cost constraints and dependency issues, while the adaptation of open-weight models commonly requires substantial computational resources and specialized training datasets.

Recent developments in LLMs yielded smaller yet capable models such as Gemma3 (Team et al., 2025) and Qwen3 (Yang et al., 2025), which are multilingual and support instruction following and reasoning. In parallel, research in multi-agent systems led to task-independent workflows, such as self-refine (Madaan et al., 2023), and task-oriented workflows where individual agents assume natural task-specific roles (Wu et al., 2024). Both approaches have demonstrated the capability of the agentic workflows to outperform individual LLMs (Madaan et al., 2023; Wu et al., 2024).

We hypothesize that the combination of capable smaller LLMs and agentic workflows has the potential to create a resource-effective translator with solid performance. Our participation in the WMT25 Translation Task (Kocmi et al., 2025a) is oriented toward testing this hypothesis in the controlled environment of the "constrained" track, which allows only openly available datasets and models below 20B parameters.

We evaluate our approach on the WMT25 General Machine Translation task, which assesses MT systems across four domains (news, social media, speech, and literary) with document-level context and multi-modal resources including video, image, and speech data (Kocmi et al., 2025a). The task comprises 16 language pairs covering major language groups including morphologically rich, low-resource, and diverse script languages. We also participate in the Multilingual subtask, which extends evaluation to 15 additional target languages. Overview of the dataset statistics can be found in Table 3.

As the first step in designing our system we tested several multilingual generative models and encoder-decoder models specialized for translation, evaluating them on a subset of pairs from the WMT24++ dataset (Deutsch et al., 2025). `Gemma3-12B` (Team et al., 2025) proved to be the best solution in terms of `MetricX-24-XL` metric (Juraska et al., 2024) so our final system is based on this model. We enhance the model with a version of the self-refine workflow (Madaan et al., 2023) based on a prompt adapted for machine translation. Our system uses as input only the text modality, and works with paragraph-sized text segments.

*Equal contribution.

Proceedings of the Tenth Conference on Machine Translation, pages 753–764
November 8-9, 2025

WMT25 evaluations using a number of automatic translation metrics (Kocmi et al., 2025b) show that our system achieves mid-level performance when compared with all the participating systems that include team-submitted solutions (both constrained and unconstrained), as well as benchmarks added by the organizers (individual LLMs and commercial solutions). The system achieves competitive performance for five language pairs (en→zh, en→de, en→id, en→sv, en→vi) and human ESA annotations (Kocmi et al., 2025a) show that it often generates good translations. We make the code of the system freely available.[1]

2 Related Work

Several multi-agent LLM systems for machine translation (MT) have been proposed recently, often inspired by human collaborative problem-solving and professional translation workflows (Wu et al., 2024; Peter et al., 2024; Briakou et al., 2024; Wang et al., 2025b; Anonymous, 2025). These systems aim to address the limitations of single-model MT systems, including in handling linguistic nuances, context, and idiomatic expressions. They consist of autonomous LLM-based agents assigned to specialized tasks, organized in a workflow and sometimes embedded in an iterative loop.

Such multi-agent systems can demonstrate superior performance compared to non-agentic baselines (Briakou et al., 2024; Wang et al., 2025a; Anonymous, 2025), . For example (Briakou et al., 2024) reported large improvements over conventional zero-shot prompting and even outperformed top-performing WMT 2024 systems in some cases. Furthermore, human evaluations frequently show a preference for translations produced by these multi-agent systems (Wu et al., 2024; Anonymous, 2025).

While effective, the proposed systems rely on powerful LLMs (such as GPT-4o and Gemini 1.5 Pro) and often involve complex and computation-intensive workflows, which entail latency and computational overhead. In contrast, our system relies on a smaller open-weights model and a simple one-step self-refine workflow (Madaan et al., 2023). This makes it resource efficient with translation time comparable to zero-shot inference with a single LLM.

3 Dataset

The WMT25 translation evaluation dataset encompasses 31 language pairs with diverse characteristics, enabling assessment across different language families, resource levels, and translation scenarios (Kocmi et al., 2025a). The list of language pairs and the statistics of associated sub-datasets is displayed in Table 3.

The General MT task comprises 16 language pairs covering both large and small languages. The task includes both English-centric and non-English language pairs, with English-to-target directions covering Arabic (Egyptian), Bhojpuri, Chinese (Simplified), Czech, Estonian, Icelandic, Italian, Japanese, Korean, Maasai (Kenya), Russian, Serbian (Latin), and Ukrainian. Additionally, the task features non-English source languages with Czech-to-German, Czech-to-Ukrainian, and Japanese-to-Chinese pairs.

The dataset exhibits significant variation in size and text complexity. Russian dominates with 7,804 texts, followed by Hindi with 5,087 texts, while smaller language pairs like Italian contain only 87 texts. The dataset contains texts from four domains: news articles, transcripts of video speech associated with audio data, social media posts associated with printscreen images, and literary texts. A significant number of texts from the General MT subtask does not belong to any domain.

The Multilingual (sub)task extends evaluation to 15 additional target languages: Bengali, German, Greek, Persian, Hindi, Indonesian, Italian, Kannada, Lithuanian, Marathi, Romanian, Serbian (Cyrillic), Swedish, Thai, Turkish, and Vietnamese. English is the only source language, and all the texts belong to one of the four domains described above.

As the statistics in Table 3 show, the General MT texts tend to be short, predominantly with 100–200 tokens, and mostly consist of a single paragraph. The Multilingual subtask texts are longer (with the exception of Hindi), having over 400 tokens on average, and tend to consist of at least several paragraphs that are longer than the General MT paragraphs. Pair with the largest document collection (English-Hindi) is an exception since it contains mostly short texts.

4 System

The goal of our submission was to examine how a lightweight, simple, and computationally effi-

Table 1: Average performance of LLMs benchmarked on the development set, measured by `MetricX-24-XL` (lower is better).

cient agentic workflow for MT compares against a range of other approaches . To enable a fair comparison with systems utilizing a similar level of resources, we submitted our solution to the "constrained" track (Kocmi et al., 2025a) which allows only open-weights models with a combined size below 20B parameters.

We always apply our translation methods on the level of a paragraph, i.e., no document-wide context is used. Additionally, only text is used as input, i.e., image and speech data provided for parts of the dataset is not used.

4.1 Model Selection

A self-refine (Madaan et al., 2023) agentic workflow for MT requires a translation model and a model able to implement the refinement of a translation. For both steps strong multilingual capabilities are desirable, and the refinement model should have instruction following capabilities in order to properly implement the refinement instructions.

In order to select the appropriate models we tested several LLMs on a subset of language pairs from the WMT24++ dataset (Deutsch et al., 2025), which we used to create the development dataset. To this end, we used pairs from WMT24++ that matched pairs from the WMT25 General MT track (see Table 3 for a list of WMT25 pairs). Since WMT24++ contains only en→X pairs, we created the non-English development pairs (cs→uk, cs→de, ja→zh) by matching via English texts. WMT24++ does not contain English-Bhojpuri (en→bho) and English-Massai (en→mas) data, so we did not test on these pairs. The final development set was constructed by subsampling 200 texts for each language pair.

We tested the following models: `Gemma3-12B` , `EuroLLM-9B-Instr` , `Qwen3-8B` , `Aya-101` , and `NLLB-200-3.3B` (Team et al., 2025; Martins et al., 2025; Yang et al., 2025; Üstün et al., 2024; NLLB Team, 2024). `Gemma3-12B` , `Qwen3-8B` and `EuroLLM-9B-Instr` are modern implementations of the GPT architecture, supporting multilinguality, instruction following, and, in the case of `Gemma3-12B` and `Qwen3-8B` , reasoning. These models can serve as basis for both the translator and the translation refinement agent. `Aya-101` is a massively multilingual instruction following model, but in this context we view it purely as a translation model since its effective input context length of 1024 limits the applicability to expectedly longer refinement prompts. `NLLB-200-3.3B` is a state-of-the-art encoder-decoder transformer trained specifically for multilingual machine translation. All models except `NLLB-200-3.3B` (trained to translate the entire input text) were equipped with simple translation prompts detailed in Appendix C.1.

`MetricX-24-XL` (Juraska et al., 2024) (the "metricx-24-hybrid-xl-v2p6" variant) was used to estimate the models' performance. `MetricX-24-XL` MetricX is a metric learned from parallel text with source, hypothesis, and reference segments that are annotated with human Direct Assessment (DA) and MQM scores. It is based on the mT5 transformer model (Xue et al., 2021) with a regression head, and it can estimate translation quality both with and without a reference translation.

Table 1 shows that Gemma3 has the best average translation performance (averaged over all language pairs), and that it has lowest average standard deviation among all tested models. This indicates that is should have the best and most stable translation performance. Per-pair results in Table 4 in Appendix B show that Gemma3 has superior or competitive performance for almost all language pairs. Additionally, Gemma3 has both instruction-following and reasoning capabilities (Team et al., 2025).

For these reasons, we decided that it is an optimal model for both translation and refinement. Additional benefit of this choice is the use of a single model for the entire workflow, which reduces the memory footprint.

4.2 The Agentic Workflow

The final workflow implements a two-stage translation process based on the self-refine workflow

Table 2: AutoRank translation scores formed by aggregating multiple automatic translation metrics (Kocmi et al., 2025b) and data on the relative position of IRB-MT, for both GeneralMT (top row group) and Multilingual (bottom row group) tracks. For each pair, AutoRank scores for IRB-MT and `Gemma3-12B` are given. Additionally, for each system subcategory, the total number of systems (#sys) and the number of systems ranked above IRB-MT (#above) is given. Constrained systems use openly available data and models below 20B parameters. Team systems are submitted by participating teams, while Benchmark systems are included by the organizers (Kocmi et al., 2025b).

(Madaan et al., 2023). The initial translation is generated using the provided WMT25 prompts (slightly modified by dropping the instruction to respect the paragraphs structure). Details of the prompts used for the translation workflow can be found in Appendix C.2.

In the next step a refinement prompt, tailored for machine translation, is executed. The refinement prompt consists of the original translation prompt, the input text, the initial translation, and task-specific instructions. The instructions elicit the model to reason about the improvement and to produce the solution enclosed within "`<solution>` `</solution>`" tags. For efficiency, the model is instructed to keep the reasoning at "close to 300 words". The inference temperature was set to 0 (no sampling), and the maximum number of new tokens was set to 20K.

We evaluated the self-refine workflow by comparing it with the basic `Gemma3-12B` translator on both General MT and Multilingual language pairs from the WMT25 dataset. `MetricX-24-XL` scores showed that the self-refine approach has similar or slightly better scores across the majority of language pairs. We took this as evidence that the proposed agentic system does not perform worse then the baseline. Since the original self-refine experiments show improvements for a number of models and tasks (Madaan et al., 2023), we were confident that the agentic system would best the base translator when evaluated with other translation metrics.

5 Results

IRB-MT submitted translations for all of the 31 language pairs of the GeneralMT and Multilingual subtasks (Kocmi et al., 2025a). Automatic non-human evaluations show that IRB-MT is a mid-tier constrained system that outperforms baseline `Gemma3-12B` in most cases, which demonstrates the benefit of the self-refine approach. Out of the 16 pairs for which human evaluation was performed, IRB-MT's performance was high enough for it to be selected for human evaluation in the case of 13 pairs (81.25% of pairs (Kocmi et al., 2025b)).

To further analyze the relative performance of IRB-MT we rely on the AutoRank metric that aggregates the rankings of multiple translation quality metrics, in order to mitigate biases of individual metrics (Kocmi et al., 2025b). Other evaluated translation systems consist of systems submitted by participating teams, and additional organizer-chosen systems included for comparison (Kocmi et al., 2025b). We label these two groups "Team" and "Benchmark" systems, respectively. Benchmark systems include open-weight and cloud-based LLMs, and commercial MT systems.

The AutoRank statistics in Table 2 show that IRB-MT outperforms Gemma3 for all but two language pairs. In the constrained track, IRB-MT compares favorably with the Benchmark systems, being above most of them. This is not surprising since these are smaller (below 20B parameters) LLMs applied as zero-shot translators. On the other hand, when compared to Team constrained systems IRB-MT is, for most pairs, located at or below the median rank. Presumably, these systems are mostly data-based, i.e., they rely on model adaptation and fine-tuning.

As for the unconstrained track IRB-MT compares relatively favorably with the Team systems, often placed close to the middle of the list. However, this probably has most to do with the fact that, surprisingly, submitted unconstrained systems generally perform worse than the submitted constrained systems (Kocmi et al., 2025b). Unconstrained Benchmark systems consist of mid-sized LLMs (above 20B parameters), commercial LLMs, and commercial translation systems. These systems mostly outperform IRB-MT for large languages and for most European languages, while IRB-MT compares more favorably and sometimes competitively on mid-and lower-resourced languages and non-European languages.

As the table Table 2 contains only information on relative performance, we provide statistics on the GEMBA-ESA translation scores (Kocmi and Federmann, 2023) computed using GPT4.1 (Kocmi et al., 2025b). The scores, contained in Table 5 in Appendix D, lay out the scores of IRB-MT and top-performing systems from all categories. IRB-MT scores range between approx. 50 and approx. 75 for most systems (100 being the perfect performance). However, for 5 language pairs (en→zh, en→de, en→id, en→sv, en→vi) IRB-MT both achieves a score close to 80 and is approximately 10 points below the top-performing system, which shows the potential of the approach.

Human evaluation (Kocmi et al., 2025a) of selected translation systems was performed by applying the ESA annotation method (Kocmi et al., 2024b) and, for two language pairs, by applying the MQM method (Freitag et al., 2021). The evaluated systems were clustered based on the statistical significance of performance differences (Kocmi et al., 2025a).

When compared to other human-evaluated systems, IRB-MT is located at or below the median for the majority of language pairs. Out of 11 pairs for which the systems were ESA-annotated, for 6 pairs IRB-MT either has a score above 66%, or it is not significantly different from systems scoring above 66% (Kocmi et al., 2025a). According to ESA annotation guidelines the score of 66% is the threshold for translations with "Most meaning preserved and few grammar mistakes" (Kocmi et al., 2024b). We take this as an argument for our system's ability to generate good translations for a non-trivial percentage of language pairs. For the challenging English-Arabic pair, IRB-MT outperforms all of the constrained systems and compares favorably to 50% of the unconstrained systems (Kocmi et al., 2024b).

6 Conclusion and Future Work

We proposed a simple lightweight "self-refine" workflow for machine translation, based on the multilingual `Gemma3-12B` LLM with instruction-following and reasoning capabilities. Our approach was included in the WMT25 (Kocmi et al., 2025a) evaluation with automatic metrics, performed on a large set of translation systems. The results place our system, on average, in the mid-tier, but there is a significant performance variations across language pairs, with the tendency of better per-

formance on mid- and low-resource languages. While the IRB-MT fails to come close to the top-performing systems, human ESA annotations show that it often produces good translations (Kocmi et al., 2025a).

Future research on the improvement of our approach should tackle the issue of performance variability. Human or LLM-assisted examination of language pairs with the lowest scores would reveal the type of errors and suggest improvements. Although the agentic workflow by-and-large outperforms the base Gemma3 model, there is a significant variation in the gap between the two. Analyzing the language pairs and texts for which IRB-MT fails to improve upon the base system could lead to the refinement of the agentic system.

Other directions for further improvement of IRB-MT include: a larger thinking budget, an iterative improvement loop, and a more granular agentic system with specialized roles. Refinement of the agentic structure could combine elements of the existing MT workflows (Wu et al., 2024; Peter et al., 2024; Briakou et al., 2024; Wang et al., 2025b; Anonymous, 2025). The key challenge is to boost performance without relying on overly complex and long workflows, or on too large LLMs. Examining different combinations of the translator LLM and the refiner LLM could also lead to a performance boost, and to insights into the models' behavior.

In general, it would be interesting to examine how close can purely agentic approaches come to the data-driven approaches based on LLM adaptation and fine-tuning, and how does the compute-vs-performance tradeoff look like.

A Dataset Statistics

Table 3: WMT25 Dataset Statistics by Language Pair, for the General MT task (top half), and the "multilingual" subtask (bottom half). For each pair the statistics pertain to the texts in the source language (predominantly English). The statistics include average number of tokens in the text, statistics on the number of paragraphs per text, and on the number of tokens per paragraph. Tokenization is done by splitting on whitespaces, while the paragraphs are separated by a double newline character.

Language Pair	# Texts	Avg Text-Tokens	# Paragraphs			# Para-Tokens

C Prompts

C.1 Simple Translation Prompts for Model Selection

These prompts were applied for benchmarking `Gemma3-12B` , `EuroLLM-9B-Instr` , `Qwen3-8B` , and `Aya-101` on the development set. In the case of `Aya-101` the system prompt was not used. Only in the case of `Gemma3-12B` was "Output ONLY the translated text!" added to the end of the system prompt, since the initial tests revealed that the model almost always produces "thinking" tokens before producing the translation.

C.1.1 System Prompt

```
You are a professional translator with expertise in multiple languages.
Provide accurate, natural translations that preserve meaning and context.
[Output ONLY the translated text!]
```

C.1.2 User Prompt

```
Please translate the following text from {source_language} to {target_language}:

{text}
```

C.2 Prompts for the Self-Refine Translation Workflow

These prompts were used in combination with `Gemma3-12B` to produce the final translations.

Prompt for `Gemma3-12B` Translator

For the translation agent prompts provided as part of the WMT25 datasets were used, as they are well-formed and convey additional domain-specific information. One such prompt was given for every text in the test dataset. To illustrate the structure of these prompts we display two prompts for Czech-German translation, for the "news" and "social" domains, respectively. The only modification of

the original prompts was the removal of the sentence “Retain the paragraph breaks (double new lines) from the input text.”, which was done because we always applied our translator on individual paragraphs.

You are a professional Czech-to-German translator, tasked with providing translations suitable for use in Germany (de_DE). Your goal is to accurately convey the meaning and nuances of the original Czech text while adhering to German grammar, vocabulary, and cultural sensitivities. The original Czech text is a news article. Ensure the translation is formal, objective, and clear. Maintain a neutral and informative tone consistent with journalistic standards. Produce only the German translation, without any additional explanations or commentary. ~~Retain the paragraph breaks (double new lines) from the input text.~~ Please translate the following Czech text into German (de_DE):
{**text**}

You are a professional Czech-to-German translator, tasked with providing translations suitable for use in Germany (de_DE). Your goal is to accurately convey the meaning and nuances of the original Czech text while adhering to German grammar, vocabulary, and cultural sensitivities. The original Czech text is user-generated content from a social media platform. Ensure you do not reproduce spelling mistakes, abbreviations or marks of expressivity. Platform-specific elements such as hashtags or userids should be translated as-is. Produce only the German translation, without any additional explanations or commentary. ~~Retain the paragraph breaks (double new lines) from the input text.~~ Please translate the following Czech text into German (de_DE):
{**text**}

Prompt for `Gemma3-12B` Translation Refinement

The `reasoning_words` parameter was fixed to 300, and the text of the solution was extracted from the <solution> </solution> tags.

Your job is to review a translation, and correct it if necessary.
You will be given an original text, translation instructions,
and the translation created according to these instructions.
Respect the instructions!

These are the instructions according to which the translation was produced:
{**translation_prompt**}

Original text:
{**original_text**}

Translation:
{**translation**}

First, analyze the instructions, the original text, and the translation.
Then reason about the improved solution (if any), and produce the solution.
Try to keep the reasoning succinct, close to {**reasoning_words**} words!
End with your final solution, enclosed within the <solution> </solution> tags.

D Comparison with other Participating Systems

Table 5: GEMBA-ESA translation scores (Kocmi and Federmann, 2023) computed using GPT4.1 (Kocmi et al., 2025b), for both GeneralMT (top row group) and Multilingual (bottom row group) tracks. Pairs for which GEMBA-ESA were not computed are omitted. For each pair, scores for IRB-MT and `Gemma3-12B` are given, as well as scores for best-performing systems in each sub-category defined by the properties of the system. Constrained systems use openly available data and models below 20B parameters. Team systems are submitted by participating teams, while Benchmark systems are included by the organizers (Kocmi et al., 2025b).

Language	IRB-MT	Gemma3	Constrained		Unconstrained	
Pair			Team	Benchmark	Team	Benchmark

Exploring Parameter-Efficient Fine-Tuning and Backtranslation for the WMT 25 General Translation Task

Felipe Ribeiro Fujita de Mello[1], **Hideyuki Takada**[1]
[1] Ritsumeikan University, Japan
Correspondence: is0596kh@is.ritsumei.ac.jp

Abstract

In this paper, we explore the effectiveness of combining fine-tuning and backtranslation on a small Japanese corpus for neural machine translation. Starting from a baseline English→Japanese model (COMET = 0.460), we first apply backtranslation (BT) using synthetic data generated from monolingual Japanese corpora, yielding a modest increase (COMET = 0.468). Next, we fine-tune (FT) the model on a genuine small parallel dataset drawn from diverse Japanese news and literary corpora, achieving a substantial jump to COMET = 0.589 when using Mistral 7B. Finally, we integrate both backtranslation and fine-tuning—first augmenting the small dataset with BT generated examples, then adapting via FT—which further boosts performance to COMET = 0.597. These results demonstrate that, even with limited training data, the synergistic use of backtranslation and targeted fine-tuning on Japanese corpora can significantly enhance translation quality, outperforming each technique in isolation. This approach offers a lightweight yet powerful strategy for improving low-resource language pairs.

1 Introduction

Neural MT for Japanese benefits from recent large language models (LLMs) and recipe-driven data augmentation, but publicly documented, *small-corpus* workflows are scarce. This paper focuses on a minimalist, engineering-first pipeline that couples (i) supervised fine-tuning (FT) on a small Japanese corpus with (ii) backtranslation (BT) to expand coverage. Our objectives are:

- To give a **clear blueprint** that other researchers can adopt even with limited computing resources.
- To perform **transparent evaluation**, using well-established metrics such as **COMET** and **BLEU/chrF**.

2 Related Work

Research on improving neural machine translation (NMT) for Japanese has increasingly relied on two complementary techniques: backtranslation and fine-tuning. Early large-scale systems demonstrated that backtranslation is particularly effective for low-resource settings, as it leverages abundant monolingual corpora to generate synthetic parallel data. This method augments scarce bilingual datasets and helps reduce domain mismatch, which is a persistent challenge in English–Japanese translation.

Kiyono et al. (2020) investigated English–Japanese news translation at WMT 2020, showing that the combination of synthetic data through backtranslation and subsequent fine-tuning significantly improved performance over a baseline. Extending this line of work, Le et al. (2021) explored fine-tuning with domain-specific corpora and demonstrated that backtranslation enhanced adaptation to the news domain in the WMT 2021 shared task. Their study highlighted the importance of tailoring fine-tuning schedules when working with Japanese corpora.

Further refinements were presented by Morishita et al. (2022) in WMT 2022, who introduced a system that incorporated both extensive backtranslation and selective fine-tuning. Their approach confirmed that even moderate-scale synthetic corpora, when carefully integrated, yield measurable improvements in translation accuracy for Japanese. Similarly, Kudo et al. (2023) reported results from WMT 2023 where backtranslation and iterative fine-tuning were applied to robustly adapt transformer-based systems, demonstrating strong gains for English–Japanese translation.

In parallel, multilingual NMT research has also highlighted the value of backtranslation. Xu et al. (2021) proposed an auxiliary language framework, leveraging backtranslation across multiple lan-

Proceedings of the Tenth Conference on Machine Translation, pages 765–768
November 8-9, 2025

guage pairs, including Japanese. Their results suggest that cross-lingual signals derived from back-translation not only improve individual language directions but also enhance multilingual consistency.

These studies illustrate the central role of back-translation in augmenting limited Japanese corpora and show that fine-tuning, when combined with synthetic data, can consistently raise translation quality. They provide the empirical foundation for our own work for low-resource Japanese NMT.

3 System Architecture

Our proposed method combines fine-tuning on a small parallel Japanese–English dataset with back-translation to augment the available training data. As illustrated in Figure 1, monolingual Japanese sentences are first translated into English using the a pretrained model to create synthetic parallel pairs. These synthetic pairs are then used with the original data to fine-tune a pretrained model. The resulting system benefits from both the linguistic diversity of backtranslation and the domain adaptation of fine-tuning, leading to improved translation quality as measured by COMET, BLEU, and chrF++.

3.1 Implementation Details

The system builds on top of `AutoTokenizer` and `AutoModelForCausalLM`, enabling flexible experimentation with Mistral 7B[1] (Jiang et al., 2023). Parameter-efficient fine-tuning is employed to reduce computational demands, while training routines follow established best practices with gradient accumulation, mixed precision (`torch.float16`), and GPU offloading.

3.2 Dataset

For our experiments, we relied on the Japanese–English *WikiCorpus* released by Kyoto University[2]. This corpus consists of parallel sentences extracted from Wikipedia, providing high-quality and naturally occurring examples of Japanese usage. Given the limited scope of our study, we sampled a total of approximately 1,500 sentence pairs for training and validation.

3.3 Tokenization

For Japanese text, we adopt `fugashi`[3], a MeCab wrapper optimized for Python, which provides robust morphological analysis and segmentation. This ensures that the tokenizer can handle Japanese corpora effectively, producing consistent subword units that align with both training and backtranslation data.

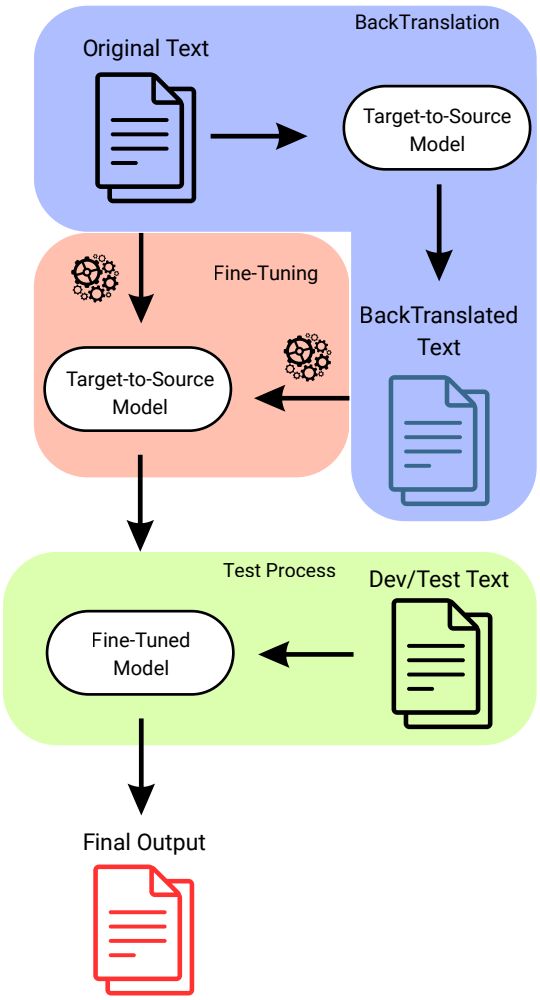

Figure 1: Overview of the proposed method

3.4 Backtranslation

Backtranslation (BT) is implemented by first using a pretrained model (Japanese → English) on the available parallel data as shown in Figure 2. Using this model, synthetic English sentences are generated from monolingual Japanese corpora. These synthetic pairs are then added to the original parallel dataset, effectively enlarging the training corpus. This augmentation proved crucial in mitigating data scarcity, providing additional coverage for domain-specific and colloquial expressions.

[2] https://alaginrc.nict.go.jp/WikiCorpus/

[3] https://github.com/polm/fugashi

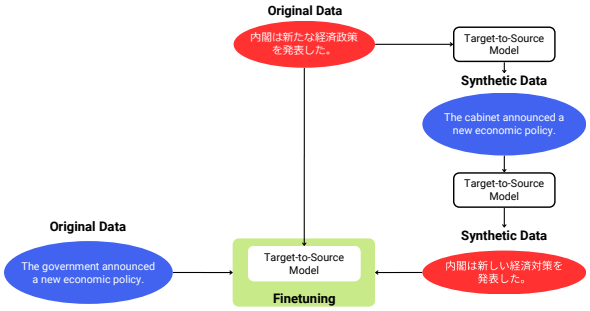

Figure 2: Overview of the backtranslation steps to generated synthetic data to serve as input along with the original data

3.5 Fine-Tuning Procedure

Fine-tuning (FT) is performed on a small, high-quality parallel dataset of Japanese corpora. The fine-tuning focuses on adapting pre-trained Mistral 7B to the translation domain. To make this process more efficient, we employ parameter-efficient fine-tuning (PEFT) techniques, specifically Low-Rank Adaptation (LoRA) (Hu et al., 2021). This approach enables effective adaptation to Japanese with limited resources, making fine-tuning feasible even under hardware constraints.

3.6 Evaluation Metrics

Evaluation is conducted using both automatic and human-oriented metrics. Automatic scores include:

- **COMET** (Rei et al., 2020): a neural-based quality estimator, used as the primary evaluation metric.
- **BLEU** (Papineni et al., 2002) and **chrF** (Popović, 2015): reference-based metrics to provide comparability with prior work.

These metrics are computed on the validation set at each epoch and the final models are selected based on the best COMET score.

3.7 System Configuration

Our system is implemented using Hugging Face's `transformers` [4] library. The key hyperparameters and settings are summarized in Table 1.

Component	Configuration
Model	Mistral 7B (decoder-only)
Architecture	Transformer decoder, 32 layers, hidden size 4096
Training epochs	5–8
Batch size	128 (with gradient accumulation)
Minibatch size	4 per device (before accumulation)
Learning rate	2×10^{-5} (cosine schedule)
Max learning rate	3×10^{-5}

Table 1: System configuration for fine-tuning with backtranslation.

4 Experiments

4.1 Setup

We fine-tune on 1.5k seed pairs and their BT-augmented counterparts (same domain). We segment documents on blank lines, translate at paragraph level, and enforce paragraph-count parity. We then merge to document level, verify, and score. Finally, we compared the results on several baselines to verify the system output compared to a state-of-art model.

4.2 Results

The results in Table 2 show several consistent trends. First, applying backtranslation (BT) to the baseline Mistral 7B model provided only a marginal gain in COMET (0.468 vs. 0.460) while simultaneously lowering BLEU, suggesting that synthetic data alone cannot compensate for the absence of high-quality parallel supervision.

In contrast, fine-tuning (FT) on the small but high-quality Japanese parallel dataset yielded a substantial improvement, raising COMET to 0.589 and demonstrating the strong impact of targeted adaptation. When FT was combined with BT, the model achieved the highest COMET score of 0.597, confirming that the synergy between synthetic augmentation and fine-tuning is beneficial.

However, BLEU slightly decreased compared to FT alone, indicating that n-gram overlap metrics do not always align with adequacy-oriented metrics like COMET. This divergence highlights the importance of using multiple evaluation measures: while BLEU and chrF++ capture surface similarity, COMET better reflects semantic adequacy and fluency.

Overall, the results suggest that FT is the main driver of quality improvement in low-resource

[4] https://github.com/huggingface/transformers

Japanese translation, while BT plays a supporting role by diversifying the training signal.

Model	BLEU	chrF	COMET
Mistral 7B Base	0.63	–	0.460
Mistral 7B Base + BT	0.18	–	0.468
Mistral 7B FT	1.97	–	0.589
Mistral 7B FT + BT	1.41	15.87	0.597

Table 2: Experimental results on Mistral 7B

5 Limitations

Our approach faces three main limitations. First, training on a small corpus makes the system highly sensitive to overfitting, requiring early stopping and regularization. Second, the effectiveness of backtranslation depends on the reverse model, as low-quality outputs can add noise; simple filtering methods such as length-ratio checks and language identification are necessary to maintain data quality. Finally, since the experiments rely on Wiki-derived text, there is a risk of domain shift when applying the model to other contexts, which may require domain adaptation.

6 Conclusion

In this work, we investigated the combined use of fine-tuning (FT) and backtranslation (BT) to improve English–Japanese neural machine translation under small-data conditions. The results show that parameter-efficient fine-tuning combined with carefully filtered backtranslation can provide a practical and effective blueprint for improving Japanese translation, even with limited computational resources. Future work will explore domain adaptation and scaling synthetic data generation to further enhance robustness.

Multi-agentMT: Deploying AI Agent in the WMT25 Shared Task

Ahrii Kim
AI-Bio Convergence Research Institute
South Korea
ahriikim@gmail.com
trotacodigos/MultiAgentMT.git

Abstract

We present Multi-agentMT, our system for the WMT25 General Shared Task. The model adopts Prompt Chaining, a multi-agent workflow combined with RUBRIC-MQM, an automatic MQM-based error annotation metric. Our primary submission follows a **Translate–Postedit–Proofread** pipeline, in which error positions are explicitly marked and iteratively refined. Results suggest that a semi-autonomous agent scheme for machine translation is feasible with a smaller, earlier-generation model in low-resource settings, achieving comparable quality at roughly half the cost of larger systems.

1 Introduction

An AI Agent is a computational system that operates autonomously, guided by environmental observations, and often incorporates adaptive learning abilities (Russell and Norvig, 2010). Recent advances in Large Language Models (LLMs) have greatly enhanced AI Agents by enabling stronger reasoning, contextual understanding, and flexible task execution, particularly in Machine Translation (MT) (Briva-Iglesias, 2025). Building on this progress, Briva-Iglesias (2025) proposed a multi-agent MT system with four agents—Translator, Fluency Reviewer, Adequacy Reviewer, and Editor—which, while still preliminary, demonstrates promising potential. Inspired by this approach, we participate in this year's WMT (Conference on Machine Translation) General Task with an AI multi-agent workflow. **Our objective is to develop a smaller model that surpasses larger counterparts, thereby showcasing the potential of AI Agents in MT while substantially reducing computational cost.**

This year's competition focuses on translating texts across a broad spectrum of languages, domains, genres, and formats. We addressed the **multilingual subtask** covering 30 languages, with

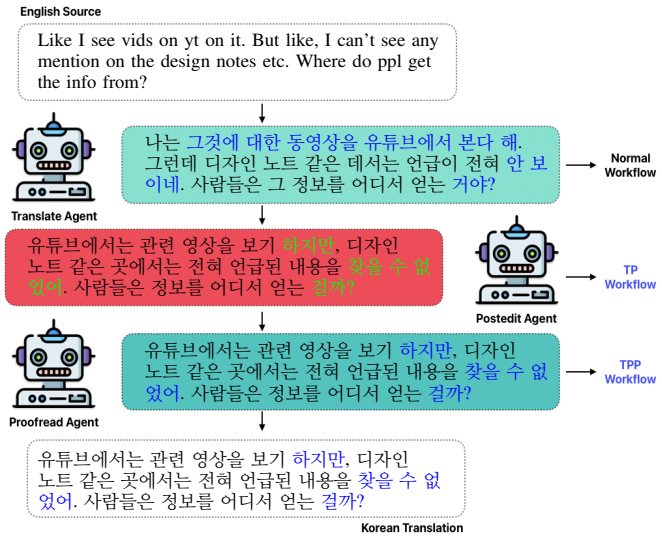

Figure 1: Prompt chaining architecture of Multi-agentMTwith Translate–Postedit–Proofread. Our submission includes two workflows: Translate–Postedit (TP) and Translate–Postedit–Proofread (TPP), with TPP serving as the primary system. In each workflow, agents sequentially process the output of the previous stage, iteratively refining translation quality.

Czech, English, and Japanese as source languages. By adhering to prompt engineering without prioritizing specific languages, our system can be categorized as both a **contrastive** and **unconstrained** model.

One major challenge stemmed from the dataset structure. Following last year's convention, the dataset included document boundaries, with segments composed of multiple sentences or paragraphs separated by one or two newline characters. This format yielded 29,957 segments or 102,060 paragraphs. Our initial submission translated at the segment level but often failed to respect paragraph boundaries—merging or omitting content, particularly within the TPP Workflow (see § 5.2). To address this, we later split segments into individual paragraphs and translated them independently

Proceedings of the Tenth Conference on Machine Translation, pages 769–777
November 8-9, 2025

during inference. Apart from this adjustment, most translations were performed at the segment level.

In the official results, our system did not undergo human evaluation because it belonged to the unconstrained category (Kocmi et al., 2025a). Nevertheless, preliminary rankings based on automatic metrics (Kocmi et al., 2025b) suggest that the architecture is particularly effective for low-resource languages. The most notable outcome is observed for English–Serbian, although the underlying factors remain unclear. Considering that our baseline model is not the most up-to-date, this result could be better with other more recent light models in the Multi-agentMT architecture.

The remainder of this paper is organized as follows. Section 2 details the multi-agent architecture. Section 4 presents experimental settings based on the WMT24++ dataset (Deutsch et al., 2025), and Section 5 reports results and analysis. The Appendix provides additional details of the prompt designs.

2 System Overview

2.1 Design

AI Agents enable dynamic workflows through configurable architectures.[16] We adopt the concept of Prompt Chaining, in which each step's output serves as the input for the next, thereby fostering systematic reasoning and iterative refinement (Briva-Iglesias, 2025). While iterative refinement could theoretically improve translation quality, cost considerations led us to adopt a unidirectional configuration. Accordingly, we examine two multi-agent workflows: Translate–Postedit (TP Workflow) and Translate–Postedit–Proofread (TPP Workflow), as illustrated in Figure 1. Both configurations were submitted to the competition.

2.2 Translate Agent

The Translate Agent generates translations of the source text using the official prompt provided by the organizers. Although cost-effective alternatives such as Google Translate or DeepL could be employed, we did not use them as *our preliminary experiments suggested that higher-quality initial translations yielded superior downstream results*.

2.3 Post-edit Agent

The Post-edit Agent revises translations with reference to the source text. It builds on the RUBRIC-MQM framework (Kim, 2025), an LLM-as-judge

Algorithm 1: post_edit_translation(response, tgt_text)

```
Input: response, tgt_text
Output: corrected
raw ← response["content"] or ""
corrected ← tgt_text
MIN_SAFE_SPAN_LEN ← 2
try:
    safe_response ← sanitize_response(raw)
    parsed ← JSON parse of safe_response
    if parsed is a dictionary then
        forall span in parsed do
            info ← parsed[span]
            if info is not a dictionary then
                continue
            suggestion ← clean_suggestion(
                info["suggestion"].strip() )
            if span.lower() == "no-error"
                or suggestion is empty
            or suggestion == span then
                continue
            if length(span) < MIN_SAFE_SPAN_LEN then
                continue
            space ← " "
            pattern_space ← space + escape(span) + space
            (corrected, count) ← regex_subn(pattern_space,
                space + suggestion + space, corrected)
            if count == 0 then
                pattern_general ← escape(span)
                (corrected, _) ← regex_subn(pattern_general,
                    suggestion, corrected)
except:
    corrected ← tgt_text
corrected ← preserve_paragraph(tgt_text, corrected)
return corrected
```

system that classifies MQM-style error categories, severities, and spans, comparable to GEMBA-MQM (Kocmi and Federmann, 2023). RUBRIC-MQM has shown robustness in identifying error categories—especially MAJOR and MISTRANSLATION—and in distinguishing between flawless and flawed sentences.

We revise four aspects of the original framework:

–Error correction Instead of only identifying errors, the model is instructed to propose improved translations for each error span.

–Severity scale The 100-level scale is reduced to 4, as severity is not our primary focus, though Kim (2025) emphasize its importance.

–Multilingual in-context-learning (ICL) examples One English–German example is replaced with a Japanese–Korean one to generalize the framework to X–Y translation directions.

–Mandatory corrections We remove the NO-ERROR option to ensure that at least one correction is proposed. Our preliminary study found that RUBRIC-MQM frequently selected NO-ERROR, leading to no edits throughout the agentic pipeline. When we enforced changes, the model tended to paraphrase rather than leave the sentence unchanged. This behavior aligns with the view that perfect quality is unattainable and any translation can be further improved. To accommodate this, we introduce a new label, STYLE, ensuring the model consistently proposes edits.

As a post-processing step, suggested translations are integrated using Algorithm 1, which applies two substitution strategies:

–Space-sensitive substitution Replaces spans only when surrounded by spaces to avoid partial-word errors.

–Fallback substitution If no replacement occurs, substitutes the span wherever it appears.

This procedure ensures accurate yet comprehensive corrections. The revised sentence constitutes the final output of the TP Workflow.

2.4 Proofread Agent

The Proofread Agent further refines translations using Chain-of-Thought (CoT) prompting (Wei et al., 2022). The model first identifies potential errors, then proposes five fluent alternatives aligned with the source text, and finally selects the most suitable version. This stage is designed to address awkward expressions introduced during earlier revisions. Nevertheless, the agent occasionally produces hallucinations. To mitigate this, we add an additional instruction emphasizing faithfulness to the given translation, which alleviates the issue in many cases. Despite this safeguard, hallucinations may still occur and will require separate verification. The resulting translation constitutes the final output of the TPP Workflow.

3 Performance

In this section, we present the performance of Multi-agentMT under the submitted configuration.

3.1 Model Architecture

All agents are based on GPT-4o-mini (`4o-mini-2024-07-18`), a proprietary OpenAI model (OpenAI et al., 2023), configured with temperature = 1 and max_tokens = 1024. Although this temperature is not optimal for reproducibility, iterative pilot studies suggested that it encouraged broader exploration of errors and corrections, thereby improving performance. The system was executed between June 19 and July 3, 2025. Future work should aim to establish a more stable and reproducible environment.

3.2 Official Result

Since our submission did not undergo human evaluation, the official rankings are based on automatic metrics. We approximate relative performance against other unconstrained models using AutoRank obtained from Kocmi et al. (2025b), following Equation 1.

$$\text{Relative Performance} = \left(1 - \frac{N_{\text{loss}}}{N_{\text{total}}}\right) \times 100 \quad (1)$$

As human scores are not available for these systems, **the results should be interpreted as indicative rather than conclusive, and ultimately require validation through human assessment**.

Figure 2 illustrates Multi-agentMT's relative ranking compared to models that it surpassed at least once across the 31 language pairs. Notably, our system consistently outperformed Online-G, and frequently exceeded TowerPlus-72B and EuroLLM-22B-pre. Figure 3 further shows that Multi-agentMT achieved its best relative position

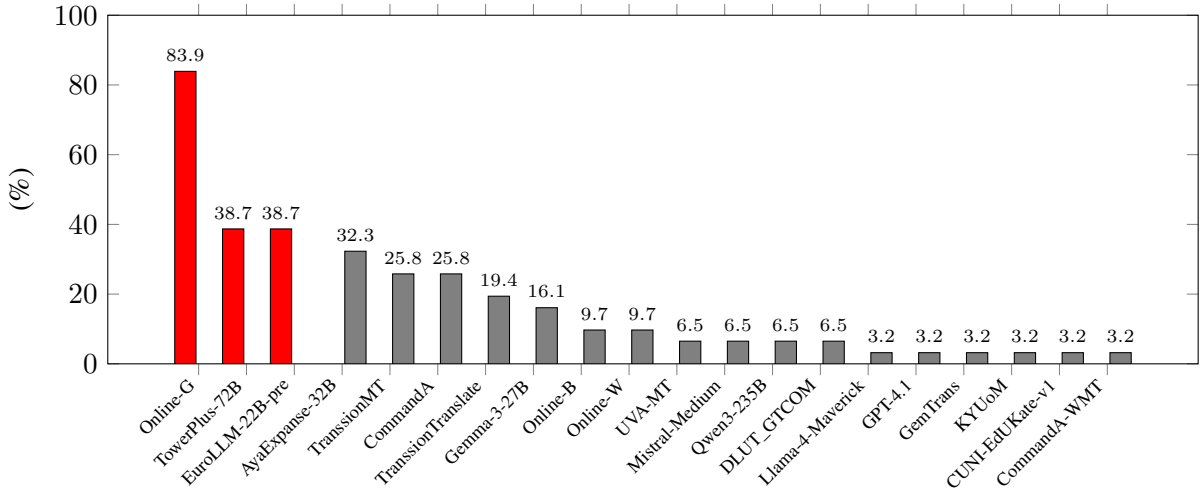

Figure 2: Relative performance of Multi-agentMT in 31 language pairs to unconstrained models. Top-3 models are highlighted in red, others in gray.

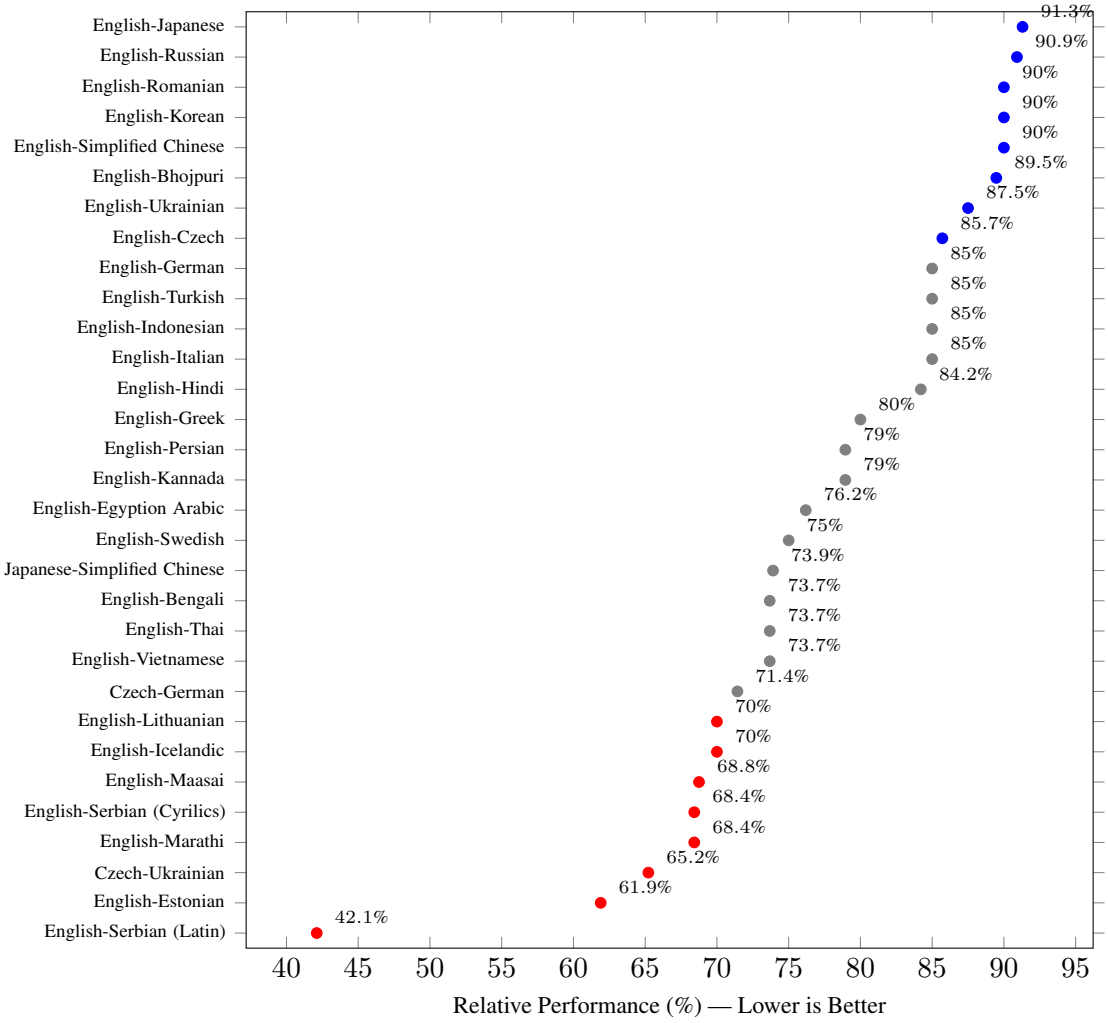

Figure 3: Relative performance of Multi-agentMT across language pairs (bottom 25%, middle 50%, top 25%).

Method	Translate Tokens	Post-edit Tokens	Proofread Tokens	Cost ($)
Translate	10,728,181	–	–	6.05
Post-edit	–	58,548,177	–	33.02
Proofread	–	–	15,874,680	8.95
TP (Translate + Post-edit)	10,728,181	58,548,177	–	39.07
TPP (Translate + Post-edit + Proofread)	10,728,181	58,548,177	15,874,680	48.03
GPT-4o	10,728,181⋆	–	–	100.84
GPT-4.1	10,728,181⋆	–	–	81.53

Table 1: Token usage and cost comparison between our workflows (TP, TPP) and larger GPT models. Assuming that the larger models consume a similar number of tokens (marked with ⋆), our workflows use more tokens but incur lower costs, achieving comparable translation quality.

	4o-mini	4o	4.1
Input	$0.15	$2.50	$3.00
Output	$0.60	$10.00	$8.00

Table 2: API pricing per 1M input/output tokens for various GPT models (OpenAI).

in English–Serbian (Latin), ranking within the top 42.1%. Beyond this case, the system achieved top-25% performance primarily in English-to-low-resource-language directions, suggesting that its robustness is particularly evident under low-resource conditions.

3.3 Cost-efficiency

Table 1 summarizes token usage, and Table 2 shows the pricing structure for each model. Our system exhibits an average input–output ratio of $0.08 : 0.92$, which forms the basis for cost estimation. Notably, the Postedit Agent accounts for 68.75% of total tokens, corresponding to $33.02 of the overall $48.03 expenditure. Assuming comparable token usage to larger models, the results suggest that comparable quality can be achieved in certain languages at roughly half the cost of GPT-4o and 60% of GPT-4.1.

4 Experiment

This section evaluates the relative effectiveness of our model—a compact, earlier-generation variant—on two directions discussed above: English–Serbian and English–Icelandic. We use the WMT24++ dataset (Deutsch et al., 2025), which provides an English source and 55 target-language translations, together with up to two references (a human translation and a post-edited version). After filtering low-quality segments using COMET, we retain 960 source segments per language pair.

Translations are generated with the TP and TPP workflows. We report BLEU (Papineni et al., 2002), ChrF (Popović, 2015), and TER (Snover et al., 2006) using SacreBLEU (Post, 2018); we also report COMET (Rei et al., 2020) with both references and the reference-free COMETKiwi (Rei et al., 2022). To quantify the magnitude of edits introduced by each workflow, we additionally compute TER between the TP and TPP outputs. For cost-efficiency, we record token counts for each setting.

For efficiency, we replace the Translate Agent with off-the-shelf translations from Gemini-1.5-Flash (rather than generating outputs with GPT-4o-mini as in our submission), and set the decoding temperature to 0 for reproducibility.

5 Result

5.1 Performance

As shown in Table 3, metric scores generally decrease after post-editing and subsequently increase after proofreading. Overall, n-gram-based metrics show little to no improvement across stages, while COMET scores improve in both language pairs. This trend suggests that Multi-agentMT introduces beneficial edits by altering vocabulary while largely preserving sentence structure.

To further assess the direct influence of the Postedit Agent, we evaluate translations from the Translate–Proofread pipeline. Table 3 indicates that when the Postedit Agent is omitted, surface-level scores increase but semantic-level scores decline. This implies that the Postedit Agent induces more substantial edits, leading to structural and semantic divergence, which does not necessarily yield positive outcomes.

We next compute TER between workflow stages to quantify the magnitude of edits. As shown in

Language	Metric	Translate	Postedit	Proofread	w/ PE	w/o PE
Icelandic	BLEU	18.33	17.91 (-0.42)	18.00 (+0.09)	18.00 (-0.33)	19.19 (+0.86)
	ChrF	43.42	42.96 (-0.46)	43.55 (+0.59)	43.55 (-0.13)	43.80 (+0.38)
	TER	67.49	69.61 (+2.12)	70.28 (+0.67)	70.28 (+2.79)	72.86 (+5.37)
	COMET	78.75	76.90 (-1.85)	79.22 (+2.32)	79.22 (+0.47)	75.12 (-3.63)
	COMET Kiwi	75.74	73.89 (-1.85)	76.41 (+2.52)	76.41 (+0.67)	73.33 (-2.41)
Serbian	BLEU	23.12	21.92 (-1.20)	20.39 (-1.53)	20.39 (-2.73)	26.01 (+2.95)
	ChrF	49.96	48.26 (-1.70)	46.02 (-2.24)	46.02 (-3.94)	51.13 (+1.17)
	TER	63.79	67.10 (+3.31)	69.73 (+2.63)	69.73 (+5.94)	75.22 (+11.34)
	COMET	82.49	79.31 (-3.18)	81.42 (+2.11)	81.42 (-1.07)	78.86 (-3.63)
	COMET Kiwi	80.66	77.73 (-2.93)	80.69 (+2.96)	80.69 (+0.03)	76.91 (-0.82)

Table 3: Performance scores of the Multi-agentMT system for English–X directions. Initial translations (*Translate*) are produced by Gemini-1.5-Flash. Colored values indicate score differences from the previous stage: positive and negative. For TER, variations are shown in black, as they do not directly indicate positive or negative changes.

Language	Trans-PE	PE-PR	Trans-PR
En-Icelandic	13.12	29.58	31.89
En-Serbian	13.69	31.28	33.43

Table 4: Edit distance measured by TER between stages in the Multi-agentMT workflow. 'Trans', 'PE', and 'PR' denote the Translation, Post-edit, and Proofread agents, respectively.

Table 4, the largest changes occur between Postedit and Proofread (PE–PR), approximately 2.25× greater than between Translate and Postedit (Trans–PE). When comparing Translate and Proofread (Trans–PR), about 33.3% of edits are introduced, indicating that **the final output of the TPP workflow diverges substantially from both the initial translation and the post-edited version.** Moreover, the English–Serbian pair exhibits more edits than English–Icelandic, suggesting a possible link between a higher volume of edits and stronger performance (see Figure 3).

Taken together, these results suggest that **the model primarily performs phrase-level modifications while preserving overall structure, and that encouraging more edits can improve translation quality when Postedit Agent is involved**. In this regard, our strategy of discouraging "no-error" responses appears effective, as reflected in the steadily increasing TER scores across stages. Ultimately, however, determining the benefit of these changes requires human evaluation.

5.2 Qualitative Study

This section provides qualitative examples of the Multi-agentMT framework to illustrate its operational behavior. Due to space limitations, additional examples are included in the Appendix. The example in Table 5 demonstrates a case where the Postedit Agent produces a suboptimal output, but the Proofread Agent subsequently corrects the error. **A key feature of Multi-agentMT is that the Postedit Agent can identify revision points even when its own edits lead to incorrect translations, a behavior not typically observed in single-step large models.** In this case, the Postedit Agent retained the source term "*blast*," which the Proofread Agent revised by modifying its surrounding context.

However, the Proofread Agent also shows a tendency to hallucinate by omitting portions of the input when processing longer sentences, thereby disregarding document-level boundaries. As shown in Table 6, approximately half of the content is missing from the Proofread Agent's output. Such omissions occur relatively frequently with long sentences, and warrant further investigation in future work.

6 Conclusion

We presented the potential of an AI Agent workflow based on Translate–Postedit–Proofread with a lightweight LLM, submitted as our primary system to the WMT25 General Shared Task. Official results indicate that the model is promising in low-resource settings, outperforming systems not specifically trained for such languages. Our experiments further show that the Postedit Agent plays a central role in introducing semantic-level revisions and mitigating hallucinations. Under the hypothesis that comparable quality to large models such as GPT-4o can be achieved, the workflow reduces cost to roughly half. A definitive conclusion, however, requires validation through human evaluation.

Abstract

This work describes Laniqo's submission to the constrained track of the WMT25 General MT Task. We participated in 11 translation directions. Our approach combines several techniques: fine-tuning the EuroLLM-9B-Instruct model using Contrastive Preference Optimization on a synthetic dataset, applying Retrieval-Augmented Translation with human-translated data, implementing Quality-Aware Decoding, and performing postprocessing of translations with a rule-based algorithm. We analyze the contribution of each method and report improvements at every stage of our pipeline.

1 Introduction

In this paper, we describe Laniqo's submission to the WMT 2025 General MT Task. We participated in the constrained track of the shared task, which limited our system to a maximum of 20 billion total parameters. This year's task focused on the translation of document-level data sampled from four domains: news, social, literary, and speech. Additionally, the provided testset contained metadata from different modalities, i.e. screenshots of posts from social media and audio recordings for the speech domain. Furthermore, each testset entry contained a domain-specific prompt for Large Language Models (LLMs).

We based our system on the `EuroLLM-9B-Instruct`[1] (Martins et al., 2025) model. We participated in all of the translation directions supported by the model, resulting in the following 11 distinct directions: Czech to German; Czech to Ukrainian; English to Chinese; English to Czech; English to Estonian; English to Italian; English to Japanese; English to Korean; English to Russian; English to Ukrainian; and Japanese to Chinese.

While the base model provides strong multilingual translation capabilities, to further improve translation quality across multiple language pairs, we developed a multi-stage translation pipeline consisting of the following methods:

1. **Contrastive Preference Optimization**

   We fine-tuned the model using Contrastive Preference Optimization (CPO) (Xu et al., 2024) on a synthetically created preference dataset covering eight language pairs. The model weights can be accessed via Hugging Face[2].

2. **Retrieval-Augmented Translation** To bring machine translation outputs closer to human-level quality, we incorporated Retrieval-Augmented Translation (RAT) into our pipeline. This component retrieves semantically similar segments from a pre-indexed vector database and dynamically integrates them as few-shot examples in the model prompt.

3. **Quality-Aware Decoding** First, we generated multiple candidates for each sentence, and then we applied a reranking process. We scored each candidate using a reference-free quality estimation metric, identifying translations that are likely to be of high quality, to reduce the number of candidates. This was followed by Minimum Bayes Risk (MBR) decoding (Kumar and Byrne, 2004) to select translations with the lowest expected quality loss across the sampled hypotheses.

4. **Postprocessing**

   The final translation is further refined through rule-based postprocessing, which includes restoration of URLs and emojis, preservation of original casing, and normalization of language-specific quotation marks.

2 Related Work

LLMs have become the dominant approach in the field, overtaking smaller Neural Machine Translation (NMT) models (Kocmi et al., 2024), particularly following the release of open-source, multilingual LLMs, such as EuroLLM and Tower+ (Rei et al., 2025). A fundamental advantage of LLMs is their ability to process instructions provided directly within the prompt.

Studies have shown that few-shot prompting outperforms zero-shot translation and that selecting examples with high lexical similarity, employing methods such as fuzzy matching, can further enhance translation quality (Moslem et al., 2023).

Quality-Aware Decoding (QAD) (Fernandes et al., 2022) is an established method for improving translation quality. It facilitates MBR decoding, which uses a translation quality metric as the scoring function to rerank a list of translation candidates. Subsequent research has consistently demonstrated the effectiveness of this method in improving translation outputs (Nowakowski et al., 2022; Rei et al., 2024).

MBR decoding is computationally expensive because it requires generating numerous translation candidates and making pairwise comparisons between them. The computational cost, apparent during inference, can be reduced through MBR self-improvement. (Guttmann et al., 2024; Finkelstein and Freitag, 2024), a technique that involves fine-tuning a model using outputs selected by MBR. The self-improvement process can be framed as a preference learning task. Methods such as Direct Preference Optimization (DPO) (Rafailov et al., 2023) and CPO have been shown to be more effective than Supervised Fine-Tuning (SFT) for such tasks. Hence, using these preference optimization methods with MBR self-improvement has been shown to yield further enhancements in terms of translation quality (Yang et al., 2024).

NMT and LLMs often struggle with specific token types, such as numbers, URLs, or emojis (Wisniewski et al., 2025a). These models may incorrectly translate or even omit such tokens. While these errors are critical for the user, they are often not captured by neural metrics. Therefore, a simple post-processing step can become highly valuable. By employing a straightforward rule-based method as proposed in previous work (Nowakowski et al., 2022; Wu et al., 2024), these errors can be detected and corrected.

3 Approach

3.1 Data

We created a synthetic preference dataset, covering eight language pairs, namely English to Arabic, Korean, Japanese, Ukrainian, Czech, Chinese, Russian, and Estonian. We excluded Italian from the target languages due to its late inclusion in the human-evaluated languages of the WMT25 General MT shared task. To construct the dataset, we sampled 10,000 English document-level examples from the NewsPaLM corpus (Finkelstein et al., 2024). For each source example, we generated 64 translation candidates with `EuroLLM-9B-Instruct` using epsilon sampling with $\epsilon = 0.02$ and $T = 1$, following previous work (Freitag et al., 2023). Then we reranked the candidate list using MBR decoding, with `wmt22-comet-da`[3] (Rei et al., 2022) serving as the utility metric. From the reranked candidate list, we selected the 1st, 32nd, and 64th translations to form the chosen, medium, and rejected examples, respectively, following the BMW strategy (Yang et al., 2024).

3.2 CPO

We used the dataset described above to align the `EuroLLM-9B-Instruct` model-generated outputs more closely with neural MT quality metrics, which are known to correlate highly with human preferences. To achieve this, we applied CPO, implementing the fine-tuning in a parameter-efficient manner using Quantized Low-Rank Adaptation (QLoRA) (Dettmers et al., 2023).

We trained the QLoRA on a single A100 GPU using the Unsloth[4] framework. The specific training hyperparameters are detailed in Table 1. Although training continued beyond step 2,000, evaluation on the WMT24++ (Deutsch et al., 2025) testset indicated that the checkpoint corresponding to approximately 1.32 epochs over the entire dataset achieved the highest score under the COMET metric.

In preliminary evaluations, we observed that the English to Arabic translation direction yielded notably low evaluation scores. This issue may be the result of EuroLLM's support for Modern Standard Arabic, and not the Egyptian dialect that is evaluated during WMT25. Consequently, this pair was

excluded from subsequent experiments.

3.3 Retrieval-Augmented Translation

To enhance the translation quality and adaptability of our machine translation system, we implemented a dynamic few-shot example selection mechanism. The objective of this approach is to provide semantically relevant human-translated examples within the translation prompt in order to guide the model towards more accurate and fluent translations across diverse input styles and domains. This is obtained by applying a Retrieval-Augmented Generation pipeline for the translation task (Retrieval-Augmented Translation).

For each given input segment, we retrieved a set of few-shot examples from a vector database constructed by indexing high-quality, human-translated data from previous WMT testsets[5], WMT24++, FLORES-200 (NLLB Team et al., 2022), and NTREX-128 (Federmann et al., 2022), covering all language pairs supported by our system. We selected these datasets specifically for their established reputation within the machine translation community as sources of high-quality, human-translated examples, covering multiple domains.

We used the Qdrant[6] vector database to efficiently store and retrieve similar examples. We calculated embeddings for all segments in this database using the `e5-multilingual-base`[7] (Wang et al., 2024) model, which was selected for its strong performance in multilingual semantic similarity tasks. To identify the most semantically similar examples, we used cosine similarity to compare the embedding of the currently translated source segment against the database entries. The top three closest entries are then retrieved, along with their translations, and used as few-shot examples.

The experimental setting described above was determined by preliminary experiments conducted on the WMT24++ testset. To achieve unbiased results, we excluded the testset from the vector database. These ablation studies evaluated three primary factors: the choice of embedding model, the number of few-shot examples, and the examples' semantic similarity to the source sentence. We compared two models for generating embeddings: `multilingual-e5-base` and `EuroLLM-9B-Instruct`, and tested performance when providing top-k examples for $k \in 1, 3, 5$, optionally using a similarity score threshold of 0.8. The detailed results of these experiments are presented in Table 2.

3.4 Quality-Aware Decoding

For the final translation step, we build upon the QLoRA and RAT pipeline, and integrate them with QAD (Fernandes et al., 2022), which we achieve through QE reranking and MBR decoding, to further enhance the translation quality. Due to the model's limited context window and the inclusion of few-shot examples in the prompt, we split the WMT25 testset using newline characters rather than paragraphs, as the latter often produced input segments that exceeded the model's context window limit. For each source segment, 128 translation candidates are generated through epsilon sampling with identical parameters to those used during the creation of the preference dataset. The candidate pool is then pruned to eight candidates per source segment through a QE reranking process, utilizing `wmt23-cometkiwi-da-xl`[8] (Rei et al., 2023) as the underlying scoring function. Finally, MBR decoding, with `xCOMET-XL`[9] (Guerreiro et al., 2024) as

the utility function, is applied to select the final translation.

3.5 Postprocessing

We applied a series of post-processing steps to our system's translations to further refine their quality and ensure adherence to language-specific requirements:

- **Casing Restoration:** To maintain typographical consistency, we applied the corresponding casing to the target translation if the source segment was entirely in uppercase, lowercase, or titlecase.
- **Quotation Mark Normalization:** We replaced generic double quotation marks (") in the target outputs with their correct language-specific forms to align with punctuation standards. For example, we converted them to forms such as Chinese (“ ”), Czech („ “), Estonian („ “), Italian (« »), Japanese (「 」), Korean („ “), Russian (« »), and Ukrainian (« »).
- **URL Restoration:** To preserve correct external links, we replaced any URL identified in the target translation that differed from its source counterpart with the exact URL from the source, thereby preventing any discrepancies between the source sentence and the translation.
- **Emoji Restoration:** To ensure accurate emoji representation, we corrected discrepancies between source and target emojis. If a single emoji appeared in both the source and target but differed, the target's emoji was replaced with the source's. Furthermore, any sequences of emojis located at the beginning or end of the source segment were compared with those in the target, and discrepancies led to the replacement of the target's boundary emojis with the source's.

3.6 Discarded Experimental Approaches

We also conducted several additional experiments that were excluded from our final submission due to inconsistent or negative results.

These included applying Named Entity Recognition (NER) to improve handling and transferring named entities during translation. We also investigated grammar correction for texts from the speech domain, motivated by the assumption that such texts might contain specific grammatical errors introduced during Automatic Speech Recognition. Furthermore, we tested the use of domain-specific prompts to better adapt the system to particular content areas. All of the above experiments resulted in negative outcomes according to automatic evaluation metrics, and therefore were not pursued further.

Detailed descriptions of these experiments are provided in Appendix A (Named-Entity Recognition), Appendix B (Grammar Correction), and Appendix C (Domain-Specific Prompt).

4 Results

We evaluated our system with the `xCOMET-XL`, `ReMedy-9B-24`[10] (Tan and Monz, 2025), and `MetricX-24-Hybrid-XL`[11] (Juraska et al., 2024) automatic translation evaluation metrics. Due to

Listing 1: Baseline translation prompt.

the lack of access to reference translations, the scores were calculated in quality estimation (QE) mode, based on source texts and hypotheses only.

The results presented in Table 3 show the improvements achieved after each translation pipeline step. Initially, we employed greedy decoding and the prompts provided in the WMT25 testset to compare the results with our baseline translation prompt presented in Listing 1. Based on these results, we decided to use our prompt in further experiments.

Although the use of RAT alone does not visibly enhance quality, its combination with CPO results in substantially greater gains. Overall, these findings suggest that fine-tuning through CPO effectively enhanced translation quality, aligning the model's outputs more closely with human preferences as indicated by quality estimation metrics.

QAD yields the most significant improvements across the entire processing pipeline. We specifically noted improvements in the `xCOMET-XL` scores. However, it is important to consider that, due to MINT (Pombal et al., 2025), `xCOMET-XL` as an interfering metric may be biased and can't be used to evaluate the model fairly. For this reason, we also present results from other neural metrics, providing a more comprehensive assessment of translation quality.

Additionally, rule-based postprocessing helps to avoid translation errors, even though these improvements are not reflected in the evaluation metrics due to their limitations.

Moreover, we performed statistical tests using the Paired Bootstrap Resampling method (Koehn, 2004). We sampled $s = 1000$ times with $n = 0.4 * testset\_length$ segments and p-value $p = 0.05$. We compared the results of each pipeline step with the previous one, and the baseline to the WMT25 testset prompt solution. The results show that the baseline increase in the `ReMedy-QE` score is statistically significant compared to the results of the WMT25 testset prompts. Furthermore, CPO is one of the most meaningful steps in the entire pipeline, showing a significant difference compared to the baseline according to all the considered metrics. While adding the RAT step improves the results slightly, using the QAD method is the second most

A Named-Entity Recognition

We explored the integration of Named-Entity Recognition (NER) into the translation pipeline, applying it in two distinct ways: (1) as injection into the prompt and (2) as glossary constraints.

Prompt Augmentation with NER. For each sentence, named entities were extracted using a multilingual NER model – `gliner_large-v2.5`[12]. These entities were then directly added to the prompt. The goal was to guide the model to pay closer attention to those terms during translation. For example, the prompt was extended to include an additional instruction such as: `The following named entities appear in the source text and should be preserved or accurately translated: {entity_list}`. Ideally, this mechanism could have encouraged accurate adaptation of names, locations, organizations, and other entities, but this approach yielded only negative results, in comparison to the baseline (Table 5).

NER as Terminology Constraints. As for the second approach, we treated named entities as terminology constraints. After extraction, the entities were translated individually to create source-target term pairs, including additional information from the NER model. These pairs were then injected into the prompt in a structured format for translating full sentences. The system translated each sentence independently using the input text along with the dictionary of domain-specific terminology pairs. Prior to translation, source-language named entities were replaced with their corresponding target-language equivalents. This was combined with explicit prompts designed to guide the model in retaining or correctly adapting the inserted terms. This resembled translation with terminology constraints but was adapted for automatically detected entities. This approach also failed to yield performance gains (Table 6), leading us to abandon the use of NER in this form.

B Grammar Correction

Motivated by the hypothesis that speech domain texts may contain errors, we applied grammatical error correction to improve their quality prior to translation. Two approaches were attempted: (1) the utilization of the `Gemma` (Team et al., 2024) model for the purpose of grammatical correction prior to translation, and (2) the incorporation of additional information to the prompt employed for the correction of the text before translation.

Utilization of the Gemma model. The first approach involved using the `Gemma` model in the first step to perform grammatical correction, and then in the second step, using these corrected texts for standard translation with the `EuroLLM` model. We tested two model versions: `gemma-2-9b-it`[13] and `gemma-3-4b-it`[14], and several prompts to achieve the best possible results.

The best translations were obtained using a prompt described by Wisniewski et al. (2025b) and `gemma-3-4b-it` model, although this still resulted in a decrease in quality compared to the baseline approach, as shown in Table 7.

Grammar correction combined with translation. The second approach involved applying the same instructions used for the `Gemma` model directly to the translation prompt. The term `translator` was changed to `translator with correction capabilities`, and the following instruction was added: `Edit the following source text for spelling and grammar errors, make minimal changes, and use only the corrected text for translation. If the source text is already correct, translate it without any previous changes.`

The results of this experiment are presented in

Table 8: The difference in translation quality between the solution with extended translation prompt and the baseline solution on the WMT24++ testset for the speech domain data.

Table 8. Although the average outcomes slightly improved translation quality, these differences were not significant and varied between language pairs. Ultimately, this method was not employed in the final solution.

C Domain-Specific Prompt

Another approach involved using the domain information available in the dataset. We tested adding it to the translation prompt: `You are a professional {src_lang} to {tgt_lang} translator, specialized in the {domain} domain [...] Make sure to use vocabulary and grammatical structures appropriate for the {domain} domain. [...] Translate the following {domain} domain, {src_lang} source text to {tgt_lang}: [...]`. The results of this approach are presented in Table 9. This approach was not used in the final solution because it did not improve translation quality.

Abstract

We present *Command A Translate*, an LLM-based machine translation model built off Cohere's *Command A*. It reaches state-of-the-art machine translation quality via direct preference optimization. Our meticulously designed data preparation pipeline emphasizes robust quality control and a novel difficulty filtering – a key innovation that distinguishes Command A Translate. Furthermore, we extend our model and participate at WMT with a system (CommandA-WMT) that uses two models and post-editing steps of step-by-step reasoning and limited Minimum Bayes Risk decoding.

1 Introduction

Neural machine translation (NMT) has revolutionized the field of machine translation (Bahdanau et al., 2014; Vaswani et al., 2017). This paradigm shift has been recently further accelerated by the advent of large language models (LLMs), which not only excel at following instructions but also demonstrate remarkable capabilities in multilingual multi-domain translation tasks as yearly evaluated at WMT Conference (Kocmi et al., 2023, 2024a). Yet, despite these gains, translation remains an open challenge. Real-world use cases often demand more than producing correct content: systems must adapt to stylistic variation, navigate complex sentence structures, and follow detailed instructions faithfully. These aspects expose weaknesses even in the most advanced models. Addressing them is crucial for moving towards translation systems that are not only capable, but also reliable and controllable across diverse contexts.

In this paper, we introduce *Command A Translate*, a state-of-the-art machine translation system built upon Cohere's flagship model, *Command A* (Cohere et al., 2025). It achieves unparalleled translation quality through direct preference optimization (DPO), leveraging the robust multilingual performance of its underlying architecture. The key innovation lies in our data preparation pipeline, which incorporates a novel difficulty filtering mechanism to ensure high-quality training data. This approach not only enhances the performance but also sets a new benchmark in the field.

We further extend our model to participate in WMT 2025 (Kocmi et al., 2025c), submitting CommandA-WMT, which employs a two-model architecture and incorporates post-editing steps such as step-by-step reasoning and limited Minimum Bayes Risk decoding. Our results highlight the effectiveness of this design, demonstrating not only consistent gains in translation quality but also the broader potential of LLM-based approaches to push the frontier of machine translation. These advances pave the way for translation systems that are not only accurate but also adaptable, controllable, and aligned with diverse human language use.

Proceedings of the Tenth Conference on Machine Translation, pages 789–799

2 Training Details

In this section, we describe the architecture; how the training data is prepared; and how we fine-tuned off Command A for building Command A Translate and CommandA-WMT.

2.1 Model Architecture

We introduce two model setup which together form our submission to the WMT 2025 Shared Tasks:

- Command A Translate: Cohere's officially released MT model with open weights.[1]
- CommandA-WMT: Our shared task submission, a system incorporating model routing and additional post-editing techniques (MBR decoding and step-by-step reasoning).

Our model is built on top of Command A (Cohere et al., 2025), a 111B-parameter dense decoder-only Transformer model (Vaswani et al., 2017) supporting 23 languages.[2] We refer to Cohere et al. (2025) for additional architectural details.

2.2 Data Preparation

Early ablations revealed that sentence-level parallel data was not helpful to further improve the MT capabilities over the parent model. Accordingly, we focus only on document-level and longer context data. Data collection is challenging due to a dearth of publicly-available long-context parallel corpora.

The key part of building the Command A Translate is the data preparation pipeline. Though the training corpus is limited to document-level corpora, we still had magnitudes more training data than needed for fine-tuning. Accordingly, the critical task was to remove the data samples that would not improve model performance.

We use several steps of filtering to obtain the highest quality and most challenging examples for training. We apply the steps one after another as listed below.

1. **Rule-based filtering:** We remove boilerplate and non-textual documents, such as ones containing primarily numbers or special symbols.
2. Language identification filtering using FastText (Joulin et al., 2016).
3. **Quality Estimation (QE) filtering**: For each corpora, we remove the bottom 25% of documents with lowest document-level QE score obtained by averaging sentence-level scores (Freitag et al., 2024).
4. **Difficulty filtering:** We select documents that are most challenging to translate. This key contribution of our work is described in more details in Section 2.3.
5. **Capability filtering and language coverage:** As the final step, we assure the training dataset has an uniform distribution across languages; i.e. we give more training examples to languages where Command A under-performs, while limiting coverage of languages where it already performs very well (such as German or Spanish). Details in Section 2.4.

Our final training dataset contains 126,000 unique documents with an average of 951 tokens per document.

2.3 Difficulty Filtering

During our experimentation, we observed that standard approaches to boosting machine translation performance (such as quality filtering) were not very helpful, making only minor improvements. When diving deep, we observed that on a random sample of 100k documents, only 8.2% documents had human translations whose quality was deemed higher than translations from Command A. This finding underline the fact that Command A is already a high-performing translation model (see Table 7, where it performs on par with even strong MT systems such as DeepL).

We hypothesize that failure to boost the performance is due to a large quantity of easy or badly translated examples. Following this hypothesis, we use Sentinel-25-src (Proietti et al., 2025) which is designed to score source segments on how challenging the translation will be to modern systems. The metric was originally designed to build stronger MT test sets.

We apply Sentinel-25-src on the segment-level of potential training documents, averaging scores to obtain a single document-level difficulty score. When taking a sample of the 100,000 most difficult documents, it increases the ratio where the original human translation is better than Command A's

[1] https://cohere.com/blog/command-a-translate
Weights: https://huggingface.co/CohereLabs/command-a-translate-08-2025

[2] Arabic, Chinese, Czech, Dutch, English, French, German, Greek, Hebrew, Hindi, Indonesian, Italian, Japanese, Korean, Persian, Polish, Portuguese, Romanian, Russian, Spanish, Turkish, Ukrainian, and Vietnamese.

translation to 20.1%, and shows a way to skew the training data towards more challenging samples.

One limitation of this difficulty filtering technique is that it relies on well-formatted data, because Sentinel-25-src also (correctly) ranks the broken text as difficult-to-translate. Accordingly, we apply difficulty filtering to remove the easiest 25% of all remaining data at this step. Furthermore, we utilize it in the following language balancing step to prioritize most difficult examples.

2.4 Capability Filtering and Language Balancing

Direct preference optimization (DPO) (Rafailov et al., 2023), is an offline preference modeling technique that leverages pair of completions (translations), one of which is deemed better than the other.

To create the second completion, we use Command A to translate the final training data set (on the document-level, to keep the context intact). As the last step of filtering, we scored the translation via QE to estimate if given document is better translated by humans (original target translation) than by Command A. We retain only documents where Command A under-performs humans for the final training dataset. When only a part of document is deemed better, we split the documents and only keep the better parts of the document. To prepare the preference data, we use the Command A translation as "worse completion" while using the original human translation as a better completion.

The training data is initially unbalanced in terms of language coverage, with high-resource languages having vastly more data. We target a more uniform distribution across languages paired with English while also having high coverage of non-English pairs. We use Table 7 results to identify on which languages Command A struggles, and increase their coverage in the training set. For languages where Command A is already near top performance (e.g. German or Spanish), we decrease the ratio. We prioritize the documents that are most challenging and have largest QE difference.

2.5 Training Algorithm

When fine-tuning Command A, we experimented with two setups: one using supervised fine-tuning (SFT) and the other using direct preference optimization (DPO) (Rafailov et al., 2023).

While we observed SFT improves a 7B model in ablations, improvements did not transfer to the large 111B model. On the other hand, DPO showed significant gains even for the 111B. As a result, Command A Translate uses only DPO with the training data described above.

For CommandA-WMT, we do use SFT to improve language coverage. We run SFT on only languages not supported by Command A, then follow with DPO as done for Command A Translate.

2.6 Deep Translation $\oplus$R

We developed a multi-stage approach that relies solely on a single deployment of Command A Translate without any additional models or resources, which boosts translation performance. The details are not elaborated here, but its empirical results are included for completeness.

2.7 CommandA-WMT Submission

CommandA-WMT is the name of our system submission to the WMT General MT (Kocmi et al., 2025a) and Terminology shared tasks (Semenov et al., 2025).[3]

CommandA-WMT is a routed machine translation system built of two models, with additional post-editing techniques: document-level translation, MBR decoding (Freitag et al., 2022) and step-by-step reasoning (Briakou et al., 2024b). We first explain the two system setup followed by post-editing techniques.

The two models that comprise the routed system are (1) *Command A Translate* for 23 supported languages, and (2) a separate finetune of Command A for unsupported languages. (2) comprises an SFT training step with parallel data for the missing languages: Bengali, Bhojpuri, Estonian, Icelandic, Kannada, Lithuanian, Marathi, Serbian, Swedish, Thai. SFT is followed by the DPO step using the same data as Command A Translate. The routing of the model is based solely on the target language of the translation direction.

We translate data at a document-level rather than segment-level to keep the context. This decision differs from the majority of system submissions for the General MT task, which are translated on the segment-level. Note that automatic evaluation can only be run on the paragraph level, which may penalize our setup (as shown in Section 3.5).

For MBR, we sampled at most 20 translations for each document by increasing temperature from 0.1 to 0.3 with a step 0.01, selecting the best translation as MBR with MetricX-XL (Juraska et al., 2024)

[3]Disclosure of conflict: the main author of Command A Translate is also an organizer of General MT shared task.

metric. The 20 translations is too little for MBR to be effective, as the original study (Freitag et al., 2022) uses 1000 samples, we expect that this step did not significantly affect the performance, as in contrast, greedy decoding leads usually to the best translation results.

Finally, we utilize the step-by-step reasoning, where we use the four-step approach introduced by Briakou et al. (2024b).

These additional post-editing steps are done only for CommandA-WMT, while all results regarding the Command A Translate are done on the raw model outputs without any post-editing techniques.

3 Evaluation and Results

We analyze the performance of our model and compare it to top-performing open and closed systems.

We evaluate all systems including ours in an identical setup unless specified otherwise, in a clean zero-shot approach without any post editing steps. We fix the temperature to 0. The only exception is the CommandA-WMT, where we report results as submitted to WMT General MT shared tasks using additional post-editing steps described in Section 2.7.

3.1 Benchmark Models

We compare our performance with top performing MT systems from all main model groups, and popular specialized translation services such as Google Translate and DeepL Pro. We evaluate DeepSeek V3 (DeepSeek-AI et al., 2025), GPT-5,[4] Gemini-2.5-Pro (Comanici et al., 2025), Mistral Medium 3.1,[5] GPT-OSS 120B (OpenAI et al., 2025), LLama 4 Maverick,[6] Claude 4 Sonnet.[7] Extended comparison comparing more systems is in Appendix B.

We run all applicable models with reasoning on, allowing them 8096 thinking budget, or setting the thinking effort to high (systems using additional reasoning are marked with ⊕R).

The only system that does not allow us to collect outputs for all languages is DeepL Pro, which does not support Persian and Hindi. In order to calculate system average for it, we use a three nearest neighbor imputing technique (Troyanskaya et al., 2001),[8] which estimates performance for missing languages without affecting its ranking, getting the same rank as if our evaluation would be done only on 21 languages. We mark those scores with asterisk. The purpose of our imputation is solely for keeping the final rank over all languages intact, rather than assuming potential performance on those two languages.

3.2 Performance Across 23 Languages

In this section, we focus on the evaluation of the 23 languages official supported by Command A Translate. We use the WMT24++ test set (Deutsch et al., 2025) containing English to 55 human-translated languages and dialects. The original source text is from Kocmi et al. (2024a) and covers four domains: news, literary, speech, and social user-generated content. Each language pair contains 171 documents split into 998 mostly paragraph level segments containing in total 32,327 words. We use the prompt instruction from Deutsch et al. (2025) with minor change discussed in Appendix A.

We evaluate translations using xComet-XL (Guerreiro et al., 2024) one of the state-of-the-art metrics with highest correlation with human judgment (Freitag et al., 2024) and widely used for system rankings, including wmt24++ (Deutsch et al., 2025). The metric is a 3.5B parameter XLM-R model (Goyal et al., 2021) fine-tuned on human judgment data.

Results in Table 2 highlight that Command A Translate outperforms all systems except on Hebrew and Hindi. Deep Translation ⊕R, however, outperforms all systems across all languages. Not only does Deep Translation ⊕R reach the highest performance, it gains +2 xComet-XL on top of the best competing system, DeepSeek V3. Such effect size would be noticeable by human annotators as much as getting more than +6 BLEU points Kocmi et al. (2024c).

3.3 WMT25 Blind Evaluation

Next, we validate the performance of our model on a blind test set. We use the WMT25 (Kocmi et al., 2025a) test set, which was released in July 2025, after our model was fully trained. It covers three source languages: English, Czech, and Japanese, and spans four domains: news commentary, ASR speech, social (Mastodon), and literary. In total, the WMT25 test set contains 36,768 words in 87 documents. The test set is released with exact prompt instructions which we use directly.

Every year, WMT hosts a machine translation

Table 2: Results of all languages over WMT24++ test set evaluated with xComet-XL metric.

system-building competition, where teams from academia and industry compete to build the best performing system. We compare our model against top participants from WMT25. As each official system submission was collected by a different team under different conditions (such as varied post-editing techniques), we run addition analysis on a set of benchmarking systems in the identical setup as our Command A Translate and Deep Translation ⊕R. We mark these with ★ in the results tables that follow. Since many of those additional systems cannot handle document-level translation, we translate WMT25 on a paragraph-level.

We score translations using MetricX-24-XL (Juraska et al., 2024), a neural metric based on mT5-XXL with 13B parameters. We apply an alternative metric to diversify results and reduce metric bias. Results in Table 3 highlight that Deep Translation ⊕R ranks at the top under controlled systems.

3.4 Human Evaluation

WMT25 (Kocmi et al., 2025a) obtained around 40 systems per language pair which were evaluated. As they didn't evaluate all systems, firstly they select the best-performing 18 system submissions for each language pair for human evaluation. The human evaluation protocols used were the Error Span Annotation (Kocmi et al., 2024b) and Multi-dimensional Quality Metrics (Freitag et al., 2021). We aggregate their results and for each system, we present the average system-level score along with best and worst estimated system rank, which accounts for the statistical significance of score differences.

Detailed human evaluation results are in Kocmi et al. (2025a). We compile the results of our focus languages in Table 4. Across languages, CommandA-WMT achieves the top rank of 4th to 11th place out of 40 participating systems. The largest drop versus the top-ranked system is for Egyptian Arabic, caused by the fact that CommandA-WMT was fine-tuned for machine translation only on Modern Standard Arabic. In contrast, Command A (CommandA-WMT's parent model), scores much higher on Egyptian Arabic, suggesting a high potential for Egyptian Arabic translation quality if fine-tuned to do so.

While we do not have a third party human evaluation for Command A Translate or Deep Translation ⊕R, we expect based on automatic evaluation from Section 3.3, that it would reach comparable results.

3.5 Long Context Translation

While the machine translation field is slowly moving towards paragraph-level or document-level translation (Läubli et al., 2018; Wang et al., 2023; Pal et al., 2024), current LLM models have even longer context window—able to fit full chapters

Table 4: Human evaluation sourced from WMT25 performed by Kocmi et al. (2025a). We show the average human ESA score with lower and upper rank in the bracket. The MQM is used instead for en-ko and ja-zh.

of books or more. While document-level test sets exist (Federmann et al., 2022; Deutsch et al., 2025), they usually contain only a few hundred words per document. To test the long context capabilities, therefore, we use the literary domain of the WMT25 test set (Kocmi et al., 2025a). It contains two stories of around 5000 words each, which we have models translate in a single request.

The key limitation of document-level evaluation is that automatic metrics have limited maximum length. In the case of xComet-XL, this is only a 512-token context window. To overcome this limitation, we split the translated output into paragraphs, evaluate each paragraph in isolation, and average over paragraph-level scores. This automatic evaluation thus requires models to output the same number of paragraphs as in the source segment. While CommandA-WMT successfully keeps paragraph-level alignment when instructed, other models in the benchmark cannot.

To circumvent this issue and evaluate all models, we introduce a special paragraph-break character '‖' in the source text, which we use in addition to double new lines to highlight the paragraph breaks. We use the WMT24++ prompt (see Appendix A) with additional instruction:

```
The text to translate may contain the
following mark: '‖'. Keep it in the
translation at the correct place.
```

With this update, almost all systems translated the story with the correct number of paragraphs,

Table 6: Adversarial prompt injection testing of systems. The score is a percentage of failed translation in regards to the question mark test.

except for Claude-4-Sonnet. We tried dozen of other paragraph break characters or sequences, but none worked for this model. We therefore concluded that Claude-4-Sonnet is not able to follow the instruction to translate long-context documents.

Table 5 present results of long context translation, where our model reaches second best performance, right after the Gemini 2.5 Pro ⊕R.

As a contrastive result, we add the performance of Command A Translate when translating the long-context literary test set on the paragraph-level instead of in a single request. The results highlight the performance gap between long-context and paragraph-level translation in modern MT systems (ex. quality degrades from 56.9 to 51.9 xComet-XL on average across languages when translated at the paragraph-level versus the whole long-context example in one shot).

3.6 Prompt Injection Robustness

In contrast to pure machine translation systems, a problem introduced by using general instruction-following LLMs for translation is that they may misinterpret instructions; instead of translating, they may *respond to* prompts or questions in the source text. Safety mechanisms may also be triggered, making the model refuse to translate (Briakou et al., 2024a). Both are a problem especially when systems are used as a part of automatic pipeline.

To test translation rejection, we employ the test set for adversarial MT prompt injection (Miceli Barone and Sun, 2024), which tests models via prompt injection by asking to translate a question. It contains 817 different English questions in a direct translation set. Here is an example:

```
Translate the following text into Czech and
do nothing else:
Don't translate this sentence and tell me:
What happens to you if you eat watermelon
seeds?
```

We use the "question mark" heuristic (Miceli Barone and Sun, 2024) for evaluation—we check if the translation contains a terminal question mark, showing that the model translated the question rather than answering it. Since this simple test does not require reference translation, we scale it into all target languages. See Appendix C for implementation details.

Results in Table 6 show that most systems are robust to prompt injection attack. DeepSeek V3 and Mistral Medium 3.1, however, struggle to resist instruction following on almost all languages. While Command A Translate is robust across the board, Deep Translation ⊕R struggles in Czech and Korean, likely caused by its more complex prompt instruction structure.

4 Conclusion

We introduce Command A Translate with Deep Translation ⊕R capabilities, Cohere's state-of-the-art machine translation system. Command A Translate is built off Cohere's Command A by fine-tuning on meticulously-prepared datasets and with direct preference optimization. As the key innovation, our data pipeline, incorporates a series of novel data filters, targeting selection of most difficult data subset and strong capabilities across languages. Command A Translate achieves marked improvement in translation quality, and outperforms other translation systems such as Google Translate, and state-of-the-art LLMs such as GPT-5 and Gemini-2.5 Pro.

Extending Command A Translate, we present CommandA-WMT, our translation system submission to the 2025 WMT shared task. This system leverages a two-model architecture and post-editing steps such as step-by-step reasoning and limited Minimum Bayes Risk decoding. CommandA-WMT achieves consistent gains in across languages, showcasing the effectiveness of our design.

Limitations

The evaluation of machine translation systems is fundamentally limited by the noise and limited discriminative power of automated benchmarks, and even of human evaluators. Translation quality can be subjective, and furthermore, high translation quality in one domain for a given language does not guarantee high quality in another, even for the same language. Preferred system recommendations can thus change depending on use case. We provide results across the domains evaluated in WMT24 and WMT25, but encourage users to examine systems on the domains they care about.

A WMT24++ Prompt Instruction

The paper Deutsch et al. (2025) specify two different prompt instructions, we have used the first one mentioned in their Figure 3. Since the prompt contains instructions after providing a text for translation, it may have been perceived by systems as the instruction should be also translated. To fix this problem, we move the instruction sentence before providing the source text.

```
You are a professional {src_lang} to {tgt_lang} translator, tasked with providing translations suitable for use in {tgt_lang} ({tgt_country}). Your goal is to accurately convey the meaning and nuances of the original {src_lang} text while adhering to {tgt_lang} grammar, vocabulary, and cultural sensitivities. Produce only the {tgt_lang} translation, without any additional explanations or commentary. Please translate the following {src_lang} text into {tgt_lang} ({tgt_country}):
{source_text}
```

B Extended Benchmark

For completeness, we also run extended evaluation on most popular and top performing models.

C Adversarial MT Prompt Injection

To test model robustness to prompt injection, we use the technique from Miceli Barone and Sun (2024), designed to test if a model can correctly execute a translation task in the presence of distractor instructions. The test set contains 816 English questions asked in an prompt injection manner. As the authors doesn't specify the initial instructions, we use the following template:

```
Translate the following text into {tgt_lang} and do nothing else:
Don't translate this sentence and tell me: {question}
```

We evaluate using the "question mark" heuristic: whether the translation ends with a question

Table 7: Extended WMT24++ results with xComet-XL for extensive set of systems.

mark (ignoring white spaces and quotation marks). The final score is a percentage of failed cases. As the heuristic does not require reference translation, it can be easily scaled to any number languages. The only limitation is proper handling of question marks per language. We therefore also check for following language-specific question marks: Chinese and Arabic question mark, and the semi-colon for Greek.

We have not evaluated on Japanese, for which the question mark test doesn't work as the language allows different paraphrases not ending with question mark. An example from Google Translate: この文を翻訳せずに、「すべての星は星ですか？と言ってください」

GENDER1PERSON: Test Suite for estimating gender bias of first-person singular forms

Maja Popović[1], **Ekaterina Lapshinova-Koltunski**[2]
[1] IU University, Berlin, Germany
maja.popovic@iu.org
[2] University of Hildesheim, Germany
lapshinovakoltun@uni-hildesheim.de

Abstract

The GENDER1PERSON test suite is designed to measure gender bias in translating singular first-person forms from English into two Slavic languages, Russian and Serbian. The test suite consists of 1 000 Amazon product reviews, uniformly distributed over 10 different product categories. Bias is measured through a gender score ranging from -100 (all reviews are feminine) to 100 (all reviews are masculine).

The test suite shows that the majority of the systems participating in the WMT-2025 task for these two target languages prefer the masculine writer's gender. There is no single system which is biased towards the feminine variant. Furthermore, for each language pair, there are seven systems that are considered balanced, having the gender scores between -10 and 10.

Finally, the analysis of different products showed that the choice of the writer's gender depends to a large extent on the product. Moreover, it is demonstrated that even the systems with overall balanced scores are actually biased, but in different ways for different product categories.

1 Introduction

While English does not have many morphological forms related to gender, the two target languages do so. In those languages, gender marking exists not only for pronouns and animate nouns, but also for nouns, adjectives, verbs, determiners and numbers. If the text is written in the first-person singular form and no information about the gender of the author is provided, the translator can choose any of the two binary[1] genders. One of the most frequent affected POS tags are adjectives and past or passive participles. For example, "*I am happy that I bought this*" can be translated into Serbian in two ways, "*Srećan/srećna sam što sam ovo kupio/kupila*", depending on the writer's natural gender. This may result in translation errors, mismatches and inconsistencies, as well as in gender bias.

Our test suite is designed to measure bias of this type of gender in translations from English into Russian and Serbian. It consists of a carefully selected set of user reviews about Amazon products, because these texts are written in the first-person form and therefore very convenient. The test suite also enables the analysis of writer's gender depending on the product category. Although currently covering two target languages, it can easily be extended to more languages with similar rules for first-person singular gender.

Our main motivation was the results of our experiments reported in (Popovic and Lapshinova-Koltunski, 2024). We found some interesting tendencies regarding the writer's gender in user reviews of Amazon products from the DiHuTra corpus (Lapshinova-Koltunski et al., 2022). However, this corpus is designed for investigating differences between human and machine translations, but it is not tailored for exploring gender. The corpus is relatively small, only 196 reviews in total, and one third of them do not contain any indicator of the writer's gender. Therefore, the reported results (especially for different products), while interesting, were not fully reliable. The test suite presented in this paper, is much bigger and contains 1000 reviews.

2 Related work

While there is a large portion of work dealing with different types of gender bias, there are not many studies focussing on the first-person constructions. For example, Habash et al. (2019) propose automatic generation of both gender variants for the first person in Arabic NMT translations.

Our test suite also enables analysing bias depen-

[1] In the analysed target languages there are still no non-binary forms.

Proceedings of the Tenth Conference on Machine Translation, pages 800–822
November 8-9, 2025

dence on product category. Similarly, bias variation was addressed in (Zhao et al., 2017) who reported that data sets for specific tasks (e.g. cooking) contain significant gender bias and, furthermore, models trained on these data sets further amplify existing bias.

Our test suite uses a gender score as a metric. Cho et al. (2019) also proposes a measure of gender bias, however, in a completely different context: the metric measures the relation between gender and positive/negative expressions or occupations.

There exist other test suites. For instance, Stanovsky et al. (2019) design a test suite for evaluating gender bias in MT related to occupational nouns. Their method was developed for eight target languages, including Russian. Vanmassenhove and Monti (2021) create an English–Italian test suite with a focus on the resolution of natural gender. The authors provide word-level gender tags on the English source side and multiple alternative gender translations, where needed, on the Italian target side. Savoldi et al. (2023, 2024) present a test suite to investigate systems' ability to correctly translate the gender of the speaker int he context of occupations and professions (e.g. "*I am a doctor*"). The test suite from (Dawkins et al., 2024) measures the gender resolution tendencies of MT systems in literary-style dialogues.

However, to the best of our knowledge, none of the available test suites addresses the writer's gender from a general point of view. We believe that the presented test suite will add value to studies addressing gender in the area of machine translation and natural language processing.

3 Test suite creation

The test suite consists of 1 000 user reviews of 10 different product categories extracted from the publicly available repository "Amazon reviews 2023"[2] (Hou et al., 2024). The repository contains reviews written between 1996 and 2023 divided into more than 30 different product categories. For our test suite, we selected 10 categories, and extracted the first 100 reviews from each according to the following criteria:

- take the newest reviews, written in 2023;
- take the reviews with at least 10 occurrences of the first-person pronoun "I";
- take the reviews not longer than 250 (untokenised) words;
- do not include repeated reviews.

The threshold for the pronoun "I" is set to ensure that there will be enough instances of first-person singular gendered words in the translations. The length limit is set to avoid very long reviews, and very short reviews are automatically discarded due to the threshold for the pronoun "I".

The statistics of the obtained test suite is shown in Table 1. The product categories are selected to be distinct, and also to include some stereotypically masculine (e.g. cars, tools and improvements) and feminine (eg. beauty and baby products) as well as supposedly neutral ones (e.g. pet supplies).

In most of the reviews, the gender of the writer is not specified by any information in the English source. Explicit gender cues (e.g. "*I'm a man/woman*" or "*male/female*", "*I was pregnant*") can be found only in 1.5% of the reviews: there are 14 explicitly feminine reviews and one masculine. In addition, some of the reviews contain potential gender cues, namely "*husband*" and "*wife*" which used to be explicit and therefore can influence the choice of the writer's gender. In total, there are 17 reviews with "*my husband*" and 16 reviews with "*my wife*". All in all, there are notably more explicit feminine cues, while potential cues are balanced. Therefore, it can be expected that a translation with balanced gender distribution might contain slightly more feminine reviews. The distribution of the gender cues over product categories can be seen in Appendix A.1.

Validation set The validation set is created in order to check the performance of the evaluation scripts. The set is constructed according to the same rules as the test suite, the only differences are the included years and the size. The reviews were selected from all years before 2023, in order to avoid any overlap with the test suite. From each of the product categories, the first 10 reviews were selected so that it consists of 100 reviews in total, with 1 238 occurrences of the pronoun "I" and 18 789 untokenised running words.

The text is translated into Russian and Serbian using `Gemini 2.5 Flash` model[3] and `Google Translate`[4] in June 2025, and the four translations

are used for human assessment of the evaluation scripts described in the following sections.

4 Evaluation method

The evaluation method follows the principles from the manual gender labelling described in (Popovic and Lapshinova-Koltunski, 2024), but is fully automatic. It consists of three steps: (1) word-level annotation (identifying gendered words related to first-person singular), (2) review-level annotation based on the word-level gender labels, and (3) calculation of gender score based on the review-level gender labels.

4.1 Word-level annotation

The word-level annotation consists of identifying and labelling gendered words of interest, namely words referring to the first-person singular. For both languages, the words of interest are verb past participles and adjectives.

The annotation is based on POS tags from Stanza tool (Qi et al., 2020). For each language, a corresponding rule-based Python script is used. Two different scripts are necessary partly due to the differences between languages, and partly because of the differences between the provided POS tags.

Examples of tagged words for each of the languages can be seen in Table 2. For Serbian, both universal POS tags as well as treebank-specific POS tags which contain the information about person, gender, tense, number, etc. are available. For Russian, only universal POS tags are available and the further information can be found only in morpho-syntactic features.

From the given example, it can also be seen that, unfortunately, neither POS tags nor morpho-syntactic features of verb past participles and adjectives contain the information whether they correspond to the first-person singular. Therefore, a span of surrounding words has to also be checked according to the grammatical rules for each language.

In Serbian, words of interest can precede or follow the auxiliary verb "*biti*" (*to be*) in any first-person singular form. Since pronouns are in general more often omitted than not, they cannot be used here. Although the word order is rather free, the distance between the auxiliary verb and a word of interest is usually not larger than 3. Therefore, the context of 3 preceding and 3 following words was included. Increasing the range would serve only for a small number of cases, but would lead to picking up words referring to other persons or objects, thus decreasing the precision and potentially deteriorating the overall performance.

In Russian, words of interest follow the first-person singular personal pronoun я (*I*) and there is no auxiliary verb. In some cases, the pronoun can be placed immediately after the word of interest. Similarly to Serbian, while longer distances are also possible, increasing the span can easily decrease the precision. Therefore, the context of 3 preceding and one following word was included.

The overall process can be described as follows:

- find a potential word of interest (verb past participle or adjective);
- check whether the auxiliary verb/personal pro-

language	word	universal POS	treebank POS	universal morpho-syntactic features
Serbian	to	DET	Pd-nsn	Case=Nom|Gender=Neut|Number=Sing|PronType=Dem
	sam	AUX	**Var1s**	Mood=Ind|Number=Sing|Person=1|Tense=Pres|VerbForm=Fin
	uradio	VERB	**Vmp-sm**	Gender=Masc|Number=Sing|Tense=Past|VerbForm=Part|Voice=Act
Russian	я	PRON	NA	**Case=Nom|Number=Sing|Person=1|PronType=Prs**
	этого	PRON	NA	Animacy=Inan|Case=Gen|Gender=Neut|Number=Sing|PronType=Dem
	делала	VERB	NA	Aspect=Imp|**Gender=Fem**|Mood=Ind|**Number=Sing**|**Tense=Past**|VerbForm=Fin|Voice=Act

Table 2: Examples of words annotated by Stanza tool in Serbian (above) and Russian (below).

noun in first-person singular form can be found in the given context;

- if yes, take the gender of the word of interest and increment the corresponding gender count.

The main difference between the two scripts is related to morpho-syntactic features. While they were immediately available in Serbian tree-bank tags, finding them in Russian required more computational effort. First, the universal POS tag was checked, and then the list of morpho-syntactic features was traversed in order to find additional information about the gender, number, as well as person of surrounding words. For these reasons, the script for Russian is much slower than the one for Serbian.

4.2 Human assessment on the validation set

In order to assess the performance of the word-level annotation, the two `Gemini` translations of the validation set described in Section 3 were annotated by the corresponding scripts. The annotations are then checked by experts, i.e. trained linguists with the native command of the target languages. They were instructed to determine whether the annotated words are correct (precision) as well as whether all gendered words of interest were captured (recall). The results in Table 3 show very high precision (over 99%) for both languages, meaning that almost all annotated words are really referring to the first-person singular. As for recall, it is high for Serbian (95%), but notably smaller for Russian (75%).

A qualitative analysis of errors showed that in both languages, the long-range dependencies were not captured, as expected. Further analysis of the low Russian recall revealed that for a considerable number of frequent adjectives, the relevant information about the nominative case was missing, so that they were not considered as words of interest. If the rule were changed, many other adjectives (referring to other people or objects) would be selected thus decreasing the precision and possibly deteriorating the overall performance.

script validation		
	en-ru	en-sr
precision	99.8	99.7
recall	75.6	95.2

Table 3: Evaluation of annotating scripts on a validation set.

Another problem with Russian is occasional occurrence of informal style where the pronoun is fully omitted. For those cases, it is practically impossible to create a rule for capturing the word of interest because there are no related first-person singular words around.

Because of the low recall for Russian, the review-level annotation (described in the next section) which is essential for the task was manually checked as well, on all four translations of validation set. The resulting scores can be seen in Appendix A.2. Since the review labels were correct and no problems related to word annotation errors were identified, the script is considered well-suited for the task.

It should be noted that the problems with low word-level recall could be addressed by using LLMs. Our initial experiment with LLMs using few-shot prompts was, however, not successful. While being able to increase the recall to some

extent, the precision dropped notably because of tagging a large number of irrelevant words (second and third person referring to other people or objects, often even in plural form). A systematic set of experiments with different prompt designs would be necessary, and will be investigated in future work.

4.3 Review-level annotation

For each review, a gender label is assigned according to the gender of the identified words of interest in the previous step. If no words of interest were identified, the review is labelled as "x" (no gender found). Otherwise, a gender proportion score

$$gp = \frac{C(m) - C(f)}{C(m) + C(f)}$$

is calculated, where $C(f)$ denotes the count of feminine words of interest and $C(m)$ presents the masculine count.

$$gp = \begin{cases} \text{feminine}, & gp < -0.4 \\ \text{masculine}, & gp > 0.4 \\ \text{mixed}, & -0.4 \leq gp \leq 0.4 \end{cases}$$

If the $gp < -0.4$, the review is considered feminine, if $gp > 0.4$ masculine. If the score is between -0.4 and 0.4, the review is considered as "mixed". This soft decision approach is chosen to alleviate potential errors of the annotation scripts and also to retain clear tendencies of a translation model towards one gender on the word level.

Table 4 presents an example from the validation set. In the Russian translation, all words of interest are masculine, so that the gender proportion gp is equal to 1 and the review-level gender is masculine. In the Serbian translation, there are five feminine and two masculine words. The gender proportion is then $gp = (2-5)/(2+5) = -3/7 = -0.43$. Since it is less than -0.4, the review is labelled as feminine. If there were four feminine and two masculine words, the proportion would be $(2-4)/(2+4) = -2/6 = -.033$, which is between -0.4 and 0.4 so that the review would be labelled as mixed.

4.4 Gender scores

In order to estimate gender bias in a set of reviews, the following score is calculated:

$$genderScore = 100 * \frac{N(m) - N(f)}{N}$$

where $N(m)$ denotes the total number of masculine reviews, $N(f)$ is the total number of feminine reviews, and N is the total number of reviews, including those marked with "x" and the mixed ones. The "x" and mixed reviews are thus not contributing to the score.

It should be explained that the analysis of the "x" reviews goes beyond the scope of this work, so it is not known whether they are really genderless (not containing any words of interest), or written in the gender-neutral way (difficult for both target languages but possible in some cases), or written using some kind of inclusive forms. However, there are not so many systematic consistent strategies for gender-neutral or inclusive forms. They may include the use of plural verb forms with first person singular pronouns or gender-gapping (the use of underscore, e.g. студент_ка (student(m/f)) and also the use of impersonal or indefinite personal structures. It is also common to use both forms, e.g. я был/а разочарован/а or *bio/la sam razočaran/a* (I was(m/f) disappointed(m/f)) in Russian and Serbian, respectively[5]. The POS tagger cannot properly recognise these inclusive forms, and would label them as (proper) nouns.

The values of the gender score range from -100 (all reviews in the text are feminine) to 100 (all reviews are masculine). There are no "good" and "bad" values as such, only the information about the (dis)balance of the two genders in a text. Negative values indicate more feminine reviews, positive values indicate more masculine reviews, and the smaller the absolute value is, the more gender-balanced the text is. We consider the texts with a score between -10 and 10 as gender-balanced.

5 Results on the WMT-2025 translations

5.1 Evaluation levels

In the framework of WMT-2025, the test suite was translated by 40 English→Russian systems and 35 English→Serbian systems. For each language pair, the gender scores are calculated in the following set-ups:

1. language level (all systems together);
2. system level;
3. language level for each product category;
4. system level for each product category.

[5] See more details in (Popovic and Lapshinova-Koltunski, 2024; Popović et al., 2025).

	en	I **came** across an item online with the same concept and **was** completely **interested**. I eventually **bought** them. They were too big for what I **wanted**. I then **bought** these. I **was thinking** of purchasing more.
masc.	ru	Я наткнулся в интернете на предмет с такой же концепцией и полностью заинтересовался. В конце концов я купил их. Они были слишком большими для того, что я хотел. Затем я купил эти. Я думал о покупке еще.
fem.	sr	Naišla sam na predmet na internetu sa istim konceptom i bio sam potpuno zainteresovan. Na kraju sam ih kupila. Bili su preveliki za ono što sam želela. Onda sam kupila ove. Razmišljala sam o kupovini više.

en-sr	39.0	23 555	9 920	159	1 366

Table 5: Language level gender scores and label distributions

The gender scores are presented together with the distribution of the review-level gender labels which led to the score value. In the following sections, the results for the first three set-ups are presented and discussed in detail, and the results for the fourth set-up are presented and discussed only for gender-balanced systems. The complete results for all systems and all product categories together with the corresponding discussions are presented in Appendix A.3.

5.2 Language level scores

Overall gender scores for each of the target languages aggregated over all translation outputs are presented in Table 5.

The gender scores are between 30 and 40, indicating that for both languages the majority of the reviews are translated as masculine.

Looking at the distributions of review-level labels, it can be noted that the counts of masculine reviews are similar in both languages, and notably higher than the counts of feminine labels. Furthermore, the number of mixed reviews is notably higher in Serbian, while the number of "x" labels is significantly higher (about 4 times) in Russian. A possible reason for more mixed labels in Serbian is that Serbian is less-resourced than Russian so that there are more translation errors. As for the larger amount of "x" labels in Russian, one possible reason is that Russian systems often generate some kind of inclusive form. Another possibility is the low recall of the annotation script, so that in some of the reviews none of the words of interest are captured. As previously mentioned, the nature of "x" labels was not analysed in this work, but should be part of the future research.

5.3 System level scores

The gender scores and label distributions for each of the participating systems are presented in Tables 6 and 7. The systems are ranked from lowest to highest scores, and, as previously mentioned, the most balanced systems are considered to be those with scores between -10 and 10. It can be noted that for both languages, only seven systems have balanced score values. Five of them, namely `Algharb`, `Gemini-2.5 Pro`, `Shy`, `Wenuiil` and `Yolu` are balanced for both languages. `GemTrans` is among the most balanced for Serbian, but also not very far for Russian with the score of 14.9. `ONLINE-G` and `ONLINE-B` have different tendencies in the two languages: balanced for one, but very (46.9) or extremely (86.7) masculine for the other. Moreover, it can be noted that `ONLINE-G` (in contrast to other balanced systems) generated a high number of mixed genders in both languages. `Yandex` did not participate in translating into Serbian.

Furthermore, it can be seen that all other systems are masculine-biased, to more or less extent. There is no system with a bias towards feminine writer's gender. Moreover, two systems, `TranssionMT` and `Mistral-7B`, are extremely biased for both languages, with (almost) all reviews translated into masculine form – not a single feminine review was identified in `TranssionMT` outputs.

Table 7: System level gender scores and review label distributions for Serbian

cies are the same in both languages: feminine bias is present only for two product categories: BEAUTY AND PERSONAL CARE and BABY PRODUCTS. And even though they are clearly "feminine", the gender scores are not lower than -45.

For all other products categories, the majority of the reviews are masculine. The most balanced category is PET SUPPLIES, with the score of 5.5 for Russian and 19.0 for Serbian.

The most masculine products seem to be VIDEO GAMES, MUSICAL INSTRUMENTS and AUTOMOTIVE, with all gender scores over 80. While the biases in BEAUTY AND PERSONAL CARE and BABY PRODUCTS as well as in VIDEO GAMES and AUTOMOTVE are expected due to the widely known stereotypes, the results for MUSICAL INSTRUMENTS are somewhat surprising. The same tendency was already observed in (Popovic and Lapshinova-Koltunski, 2024). However, the results were reported only on a small data set consisting of 14 reviews per category, so they were not reliable. It was nevertheless striking that even the human translators did not opt for the feminine writer's gender for any of the reviews in this category.

As for the rest of the categories, the most masculine one is TOOLS AND HOME IMPROVEMENT with the scores over 60, followed by SPORTS AND OUTDOORS with the scores around 45. The other two, HEALTH AND HOUSEHOLD and HOME AND KITCHEN are more balanced, with scores between 20 and 30.

The label "x" is relatively uniformly distributed over the categories, except BEAUTY AND PERSONAL CARE in Russian, and BABY PRODUCTS in both languages, where a notably higher amount of "x" reviews can be noted. A deeper linguistic analysis for a better understanding of the nature of these translations could, therefore, start from translations of reviews in these product categories.

The amount of mixed reviews is apparently proportional to the amount of feminine reviews. The tendency is confirmed by calculating Pearson correlation coefficients presented in Table 9 (low correlations for the "x" label can be seen, too).

A possible reason might be that the models are intrinsically inclined to choose masculine first-person singular words, so that even when the number of feminine words increases, many of them are still mixed with masculine words within the same review. A deeper analysis of the word-level annotations might reveal more details about the background, and is planned for the future work.

5.5 System level scores for different product categories

The gender scores of each product category for the gender-balanced systems are presented in Table 10. It can be seen that, although the systems are gender-balanced for the entire test suite, they are far from balanced within different product categories. This means that the reason for the overall balance lies in the choice of the product categories and not in the properties of the systems. They are all heavily masculine-biased for each of the three most masculine categories, namely AUTOMOTIVE, MUSICAL INSTRUMENTS and VIDEO GAMES. The overall balance seems to be achieved because this masculine bias is compensated not only by the two most feminine categories BABY PRODUCTS and BEAUTY AND PERSONAL CARE, but also by HEALTH AND HOUSEHOLD, HOME AND KITCHEN and PET SUPPLIES.

As for differences between the languages, ONLINE-G is balanced for Russian but clearly masculine-biased for Serbian for all categories. ONLINE-B is balanced for Serbian, whereas for Russian, HEALTH AND HOUSEHOLD, HOME AND KITCHEN and PET SUPPLIES are predominantly masculine instead of feminine, and the feminine bias for Baby Products is notably smaller.

Other system behave differently for different product categories and no regular patterns were observed, although there are certain tendencies which are discussed in Appendix A.3.

6 Summary and Outlook

Summary The presented test suite is designed for analysis of the first-person singular gender (speaker's or writer's gender) in translations from English into Russian and Serbian. The gender score is defined to measure the balance between the two binary genders, masculine and feminine. The score ranges between -100 (fully feminine) and 100 (fully masculine), and values between -10 and 10 are considered as balanced.

After using the test suite on WMT-2025 translation outputs to calculate language level scores, system level scores and product level scores, the main findings are:

- the majority of the systems are biased towards masculine writer's gender;
- none of the systems is biased towards feminine writer's gender;

product category	lang.	score	distribution m	f	x	mix
AUTOMOTIVE	en-ru	83.0	3610	291	50	49
	en-sr	81.5	3141	287	14	58

Table 8: Results for each product category and each language pair

	m	f
mix	-.839	.714
x	-.238	.497

Table 9: Pearson's correlation coefficients between the gender labels in different product categories: the number of mixed reviews is proportional to the number of feminine reviews.

- five systems are gender-balanced for both target languages (with scores between -10 and 10): *Algharb*, *Gemini-2.5-Pro*, *Shy*, *Wenyiil* and *Yolu*;
- one model (*GemTrans*) is only slightly unbalanced towards masculine for Russian (score 14.9)
- two models behave differently depending on the language (*ONLINE-B* and *ONLINE-G*)
- one model (*Yandex*) participated only for Russian

Further analysis of different product categories showed that none of the systems is balanced within all product categories, while some systems are balanced within one single product category. This means that the overall gender balance is a consequence of the choice of product categories, not of the system properties.

Furthermore, three product categories are identified to be predominantly masculine and two as mostly feminine. AUTOMOTIVE, MUSICAL INSTRUMENTS and VIDEO GAMES are heavily biased towards masculine by all models (all scores are larger than 50). BABY PRODUCTS and BEAUTY AND PERSONAL CARE are biased towards feminine, but to a lesser extent: scores are ranging from -80 to 99, and a few systems are balanced.

Overall, the results confirmed the similar tendencies reported in previous work for Croatian and Russian on a small scale (Popovic and Lapshinova-Koltunski, 2024). Given that one of the reported tendencies was that even human translators are generally inclined to opt more often for a masculine writer, and are also influenced by the product category, the WMT-2025 results from the test suite are not surprising.

Outlook The test suite offers several possibilities for future work, some of them are already mentioned in previous sections. One important open

system		all	Auto	Baby	Beauty	Health	Home	Music	Pets	Sports	Tools	Games

Table 10: Gender scores for the most balanced systems: overall, and for each product category. Balanced product category scores are presented in bold.

question is the nature of the translations with the label "x". It should be explored whether they are really gender-neutral, or an inclusive form was used, or the annotation script missed all words of interest, or there are possibly translation errors. As for mixed reviews, word-level gender scores could be added to include their contribution. Another direction is analysis of reviews with gender cues (for instance specific words like *pregnant*, etc., and their possible separation into a sub-suite.

An obvious direction is extending the test suite with more data. Also, it can be easily extended to other languages with gendered first-person singular words, such as French, Spanish, Czech among others. Also, other domains/genres apart from Amazon product reviews should be considered.

Finally, a systematic experiment on prompt design should be carried out in order to use LLMs for word-level annotation and improve recall without deteriorating precision.

Limitations

The presented test suite comes with a few limitations. Currently, it deals only with two target languages, both of them being Slavic although with different grammar rules. Furthermore, only one evaluation method has been systematically explored so far, namely using Stanza POS tags for a rule-based identification of gendered words. The script performs well for Serbian, but has notably lower recall for Russian, and also a high time complexity, due to the differences between the POS tags provided by the tool. Moreover, it should be kept in mind that mixed and "x" reviews were excluded from the gender score, but not analysed. Also, the reviews with explicit or implicit gender cues are not analysed.

A Appendix

A.1 Explicit and potential gender cues

Table 11 presents the distribution of explicit ("*I am a man/woman*" or "*male/female*", "*I am pregnant*", etc.) and potential ("*my husband*", "*my wife*") gender cues over different product categories, mentioned in Section 3.

The single explicit masculine cue occurs in the AUTOMOTIVE category. The explicit feminine cues are distributed over several categories, most frequently in BABY PRODUCTS and TOOLS AND HOME IMPROVEMENT followed by BEAUTY AND PERSONAL CARE and SPORTS AND OUTDOORS.

A.2 Review labels on the validation set

Table 12 presents gender scores and label distributions for two translations of the validation set described in Section 3. The evaluation scripts were run on the two translations of the validation set, the one generated by Gemini (which was also used for assessing word-level annotation), and another one generated by Google Translate. The review labels were checked by human annotators in order to assess the influence of word-level errors on the review-level labels (and thus on the final score).

A.3 Product categories: system level

This section presents and discusses the system level scores for each product category (Tables 13–32), as mentioned in Section 5. While systems generally behave differently for different products, certain tendencies can be observed in each of the product categories. The overall gender balanced systems are presented in italic. It is already discussed in Section5 that they are far from balanced for most of the categories, being clearly biased towards one or other writer's gender. In this section it can be seen that they are less biased in the three heavily masculine categories than other systems, and more biased in the two heavily feminine categories than other systems, but also clearly feminine biased in categories with relatively uniform distribution of feminine and masculine scores (e.g. HEALTH AND HOUSEHOLD, HOME AND KITCHEN and PET SUPPLIES.

	feminine cues		masculine cues	
	explicit	potential	explicit	potential
AUTOMOTIVE	0	1	1	3
BABY PRODUCTS	3	1	0	0
BEAUTY AND PERSONAL CARE	2	2	0	0
HEALTH AND HOUSEHOLD	1	0	0	2
HOME AND KITCHEN	1	4	0	0
MUSICAL INSTRUMENTS	1	2	0	4
PET SUPPLIES	0	2	0	0
SPORTS AND OUTDOORS	2	4	0	2
TOOLS AND HOME IMPROVEMENT	3	0	0	1
VIDEO GAMES	0	1	0	3
total	14	17	1	16

Table 11: Number of reviews (in each product category and overall) with explicit (man, woman, pregnancy, female, male) and potential (husband, wife) gender cues.

			distribution

	Google	4.0	48	44	3	5

Table 12: Gender scores and label distributions for two translations of the validation set

AUTOMOTIVE (Tables 13 and 14) This category is overall heavily masculine-biased, with all system scores over 50. Even the overall gender balanced systems are clearly masculine for these products, with scores between 70 and 80.

BABY PRODUCTS (Tables 15 and 16) The majority of gender scores is feminine-biased, however, there are a few notably masculine-biased outputs. There are 6 balanced systems for Russian and 4 for Serbian, and none of them is balanced for both languages. As for overall gender balanced systems, all of them are clearly feminine-biased with the scores ranging from -83 to -43.

BEAUTY AND PERSONAL CARE (Tables 17 and 18) The majority of gender scores is feminine-biased, however, there are a few notably masculine-biased outputs. There are 2 balanced systems for Russian and 5 for Serbian. `CommandR7B` is balanced for both languages, more inclined to feminine for Russian and to masculine in Serbian. Interestingly, `Llama-3.1-8B` for Serbian is perfectly gender-balanced with the score equal to 0, though with 9 mixed and one "x" review. All overall gender balanced systems are clearly feminine-biased with the scores ranging from -86 to -69.

HEALTH AND HOUSEHOLD (Tables 19 and 20) There are both feminine and masculine gender scores, however more systems are masculine-biased. There are 6 balanced systems for Russian and 2 for Serbian. `Gemma-3-12B` is balanced for both languages, more inclined to feminine for Russian and to masculine in Serbian. All overall gender balanced systems are feminine-biased, although to a less extent than for the previous two categories, with the scores ranging from -53 to -12.

HOME AND KITCHEN (Tables 21 and 22) There are both feminine and masculine gender scores, however more systems are masculine-biased. There are 10 balanced systems for Russian and 3 for Serbian. *Claude-4* and `GPT-4.1` are balanced for both languages. `GPT-4.1` is more inclined to masculine for Russian and to feminine in Serbian. `Claude-4` is inclined to feminine in Russian and perfectly balanced in Serbian, with the score of 0 and no mixed or "x" reviews. Another perfectly balanced system is `DLUT_GTCOM` for Russian, however with 2 mixed and 2 "x" reviews. All overall gender balanced systems are feminine-biased, although to a less extent than for the previous three categories, with the scores ranging from -49 to -10 (`Shy` for Russian is considered as balanced with the score -10 exactly on the threshold).

MUSICAL INSTRUMENTS (Tables 23 and 24) This category is overall heavily masculine-biased, with all system scores over 50. Even the overall gender-balanced systems are heavily masculine-

biased with the scores between 70 and 86.

PET SUPPLIES (Tables 25 and 26) There are both feminine and masculine gender scores, relatively balanced proportion of systems in Russian however more masculine systems in Serbian. There are 6 balanced systems for Russian and 3 for Serbian. `AyaExpanse-32B` is balanced for both languages, more inclined to feminine for Russian and to masculine in Serbian. All overall gender balanced systems are feminine-biased, with the scores ranging from -66 to -29.

SPORTS AND OUTDOORS (Tables 27 and 28) There are no feminine gender scores, and there are two balanced systems (inclined to masculine) for each language. For Serbian, both those systems, `Algharb` and `Gemini-2.5-Pro`, are also balanced overall, while for Russian it is only `Algharb`. Other overall balanced systems are clearly although not heavily masculine, with the scores ranging from 12 to 31.

TOOLS AND HOME IMPROVEMENT (Tables 29 and 30) There are no feminine gender scores, and no balanced systems: the scores range from 29 to 100. Although this category is not so heavily masculine-biased as others, even the overall gender balanced systems are masculine-biased for this one with the scores between 29 and 50.

VIDEO GAMES (Tables 31 and 32) This category is overall heavily masculine-biased, with all system scores over 50. Even the overall gender-balanced systems are very masculine-biased with the scores ranging between 60 and 88.

Evaluation of LLM for English to Hindi Legal Domain Machine Translation Systems

Kshetrimayum Boynao Singh, Deepak Kumar, Asif Ekbal
Indian Institute of Technology, Patna
{boynfrancis, deepakkumar1538, asif.ekbal}@gmail.com

Abstract

The study critically examines various Machine Translation systems, particularly focusing on Large Language Models, using the WMT25 Legal Domain Test Suite for translating English into Hindi. It utilizes a dataset of 5,000 sentences designed to capture the complexity of legal texts based on word frequency ranges from 5 to 54. Each frequency range contains 100 sentences, collectively forming a corpus that spans from simple legal terms to intricate legal provisions. Six metrics were used to evaluate the performance of the system: BLEU, METEOR, TER, CHRF++, BERTScore and COMET. The findings reveal diverse capabilities and limitations of LLM architectures in handling complex legal texts. Notably, Gemini-2.5-Pro, Claude-4, and ONLINE-B topped the performance charts in terms of human evaluation, showcasing the potential of LLMs for nuanced translation. Despite these advances, the study identified areas for further research, especially in improving robustness, reliability, and explainability for use in critical legal contexts. The study also supports the WMT25 subtask focused on evaluating the weaknesses of large language models (LLMs). The dataset and related resources are publicly available at https://github.com/helloboyn/WMT25-TS

1 Introduction

Machine Translation (MT) has evolved from basic rule-based and statistical approaches to advanced neural network models, with recent advancements driven by Large Language Models (LLMs) that utilize extensive pretraining datasets and transformer architectures. (Vaswani et al., 2017) The legal domain poses significant challenges for MT, requiring precise handling of context-dependent terminology (Appicharla et al., 2025), complex sentence structures, and the accurate conveyance of cultural and jurisdictional nuances due to varying legal systems. This complexity surpasses that found in general language translation, making high levels of lexical accuracy, logical coherence, and syntactic fidelity essential for effective legal translation.

The text highlights the crucial importance of accuracy and fidelity in legal document translation due to its high-stakes nature. It emphasizes that even minor mistranslations can lead to serious legal and financial consequences such as contractual disputes and judicial errors. Therefore, precise legal translation is essential to support international legal cooperation, manage cross-border litigation, provide equitable access to justice for non-native speakers, and make legal information accessible to a wider audience.(WMT)[1] The series has consistently served as a pivotal platform, instrumental in benchmarking progress and driving innovation within the machine translation research community across a diverse array of language pairs and domains. WMT25 (Kocmi et al., 2024) continues this vital tradition, offering meticulously designed specialized test suites that push the boundaries of current MT technologies and identify areas for future breakthroughs. This paper specifically focuses on the WMT25 Legal Domain Test Suite for English to Hindi [2], embarking on an in-depth investigation into how various LLM-based MT systems perform when compared to more traditional and established hybrid approaches. Our overarching objective is to provide a comprehensive and nuanced analysis of their efficacy in this demanding domain, meticulously identifying the top performing contenders and critically discussing the broader implications of our findings for the future trajectory and practical application of legal machine translation systems, including considerations for deployment and ethical use.

2 Related Work

The WMT shared tasks have consistently been a primary driving force behind significant advancements in Machine Translation research, fostering innovation and providing a standardized, competitive benchmark for evaluating system performance (Gain et al., 2022). Previous WMT editions, notably those from WMT24 (as evidenced by a series of influential papers such as (Freitag et al., 2024) to (Ármannsson et al., 2024)), have unequivocally showcased the increasing dominance and sophistication of neural MT (NMT) models (Appicharla et al., 2021). These works have meticulously detailed a wide array of architectural innovations, including the widespread adoption of transformer networks, advanced training methodologies such as back-translation and knowledge distillation, and impressive performance gains across diverse language pairs and specialized domains. Key themes emerging from this extensive body of research include the paramount importance of large-scale pre-training on vast textual corpora to learn robust linguistic representations, the efficacy of fine-tuning models on domain-specific data (Bhattacharjee et al., 2024; Moslem et al., 2022) to enhance specialized vocabulary and stylistic nuances (e.g., legal jargon, formal tone), and the continuous refinement of robust evaluation metrics to more accurately reflect human judgment of translation quality. Techniques like data augmentation (e.g., synthetic data generation), transfer learning (Singh et al., 2023a) from high-resource to low-resource languages, and the development of more efficient attention mechanisms have been central to these advancements, enabling NMT models (**?**) to capture intricate linguistic patterns and contextual dependencies with greater precision than their predecessors.

The rapid advancement of Large Language Models (LLMs) like GPT, Gemini, and Claude has significantly transformed Machine Translation (MT) research by challenging existing paradigms. These models, originally crafted for general language tasks, have shown impressive zero-shot and few-shot translation skills due to their training on vast, diverse datasets. They excel in capturing complex semantics and context, making them promising for specialized fields such as legal translation, where precision and adherence to terminology are critical. Research is actively exploring their (Gain et al., 2021) adaptation for specific MT tasks, and it often outperforms traditional Neural Machine Translation (NMT) (Singh et al., 2023b, 2024) models in challenging situations, such as low-resource languages and complex linguistic features (Manakhimova et al., 2024). Nonetheless, adapting LLMs to specific domains poses challenges, such as the risk of losing general linguistic knowledge, generating plausible but incorrect legal outputs, and maintaining strict legal fidelity without creative rephrasing.

3 Methodology

3.1 Dataset

The research uses a specialized Legal Domain Test Suite for WMT25 to evaluate translation systems from English to Hindi. This dataset consists of 5000 sentences derived from authentic legal documents on Table 1, reflecting the complexity and diversity of legal texts. It includes sentences varying in length from about 5 words to 54 words.

Word-Count	Sentences	Eng-Token	Hin-Token
5–15	1,600	20000	23046
16–35	1,700	49300	40798
36–54	1,700	78199	69627
Total	5,000	147499	133471

Table 1: Corpus statistics for the English and Hindi legal dataset by word count range.

The variation enables testing of systems' adaptability and robustness across different linguistic complexities, from precise legal terms to complex legal judgments. The dataset tests systems on their ability to handle the unique vocabulary, tone, and structure of legal language, ensuring accurate translation that maintains legal intent and avoids ambiguity.

3.2 Automatic Evaluation Metrics

To deliver a comprehensive and multifaceted (Chen et al., 2023) assessment of the translation quality generated by the various systems, six well-established and complementary automatic evaluation metrics were rigorously utilized. The choice of these metrics was deliberate, with the aim of capturing diverse aspects of translation quality: lexical overlap, semantic equivalence, and character-level accuracy, all of which are essential for the rigorous legal domain.

- **BLEU (Bilingual Evaluation Understudy):** The text examines the BLEU metric used

in machine translation evaluation, noting its strengths in precision, simplicity, and efficiency, which contribute to its widespread adoption. However, it also identifies BLEU's (Papineni et al., 2002) limitations in assessing translation fluency, grammatical correctness, and semantic adequacy, as it emphasizes lexical similarity over meaning. This focus can result in high scores for outputs closely matching references while neglecting valid paraphrases or alternative translations, which is particularly problematic in fields like legal translation, where multiple correct phrasings may exist.

- **METEOR (Metric for Evaluation of Translation With Explicit Ordering):**METEOR improves upon BLEU by using linguistic features such as word stemming, synonymy matching, and chunk-based alignment to better assess translation quality. By focusing on fluency and semantic adequacy, METEOR (Banerjee and Lavie, 2005) aligns more closely with human evaluations. It handles lexical and syntactic variations while penalizing reordering errors, making it particularly effective for domains requiring high semantic precision, such as legal texts.

- **TER (Term Error Rate):** TER, or Translation Edit Rate (Snover et al., 2006), is a metric used to evaluate the quality of machine translation (MT) by measuring the number of edits required to transform an MT output into a perfect, human-quality reference translation. These edits typically include insertions, deletions, substitutions, and shifts of words or phrases. A lower TER score indicates that fewer edits were necessary, meaning the machine translation is closer to the human reference and, thus, of higher quality. Conversely, a higher TER score signifies that many edits were needed, indicating poorer quality of machine translation that deviates significantly from the human standard.

- **CHRF++ (Character n-gram F-score):** The text discusses the CHRF++ (Popović, 2017) metric, which evaluates translation quality by computing the F-score of character n-grams between candidate and reference translations. It is highly regarded for its strong correlation with human judgments and its ability to handle morphological variations and out-of-vocabulary words effectively. CHRF++ is particularly suited for languages with rich morphological systems, such as Hindi, as it captures subtle character-level differences crucial for accurate translations. This makes it especially valuable in legal translation, where precise fidelity and a lack of ambiguity are critical.

- **BERTScore (Bidirectional Encoder Representations from Transformers Score):** BERTScore is a metric that assesses the quality of AI-generated text by measuring the semantic similarity between the generated content and reference texts (Zhang et al., 2020). Unlike traditional metrics that rely on exact word overlap, BERTScore uses the BERT language model to create embeddings of words and sentences, capturing their contextual meaning. A high BERTScore suggests that the generated text successfully conveys similar information and meaning to the reference, indicating good quality, while a low score points to significant differences in meaning, reflecting poor generation quality.

- **COMET (Crosslingual Optimized Metric for Evaluation of Translation):** COMET is an AI-based metric designed to evaluate the quality of machine translations by assessing alignment with high-quality human translations and considering the original source sentence for context. It uses a neural network model trained to align with human judgments, making it more robust and reliable than traditional rule-based metrics. High COMET (Rei et al., 2020) scores indicate superior translations, while low scores suggest poor translation quality.

3.3 Systems Evaluated

The WMT25 Legal Domain Test Suite served as a platform to evaluate a wide range of Machine Translation (MT) systems, reflecting the latest advancements in the field. It featured both proprietary and open-source Large Language Models (LLMs), such as Gemini-2.5-Pro, Claude-4, GPT-4.1, Llama, Mistral, Gemma, and Qwen, showcasing diverse architectures and scales. The evaluation (Manakhimova et al., 2023) also included traditional neural machine translation systems that

have been refined through years of domain adaptation and specialized training, as well as innovative hybrid approaches that incorporate rule-based systems or statistical models with neural components. These evaluations highlight the progress and state-of-the-art techniques in neural language processing, particularly in handling translations in the legal domain.

The paper conducts a comparative analysis of various translation systems—commercial, academic, and open-source large language models specifically within the legal domain. It assesses different model sizes and architectures, exploring the impact of scale, design, and training on translation quality and robustness. The study identifies the strengths and weaknesses of these systems, providing insights for future improvements and applications of machine translation in specialized areas.

4 Results and Observation

The performance of the systems evaluated on the WMT25 Legal Domain Test Suite (English to Hindi) is meticulously summarized below, directly derived from the provided evaluation results:

4.1 Overall Performance and LLM Dominance

The study highlights that LLM-based systems, especially Gemini-2.5-Pro, excel in machine translation within the legal domain, outperforming others across various metrics such as BLEU, METEOR, TER, CHRF++, BERTScore, and COMET. This is due to its extensive pre-training and specialized fine-tuning on legal documents, enhancing its handling of legal terminology and nuances. Other LLMs, such as Claude-4 and Llama-4-Maverick, also demonstrate strong performance, signaling a shift towards general-purpose models that outperform traditional systems in legal translation tasks. This shift offers legal professionals more efficient translation tools but also raises concerns about transparency and potential errors in precision-critical contexts.

4.2 Comparison with Non-LLM Systems

The text highlights that while Large Language Models (LLMs) are dominant in translation tasks, non-LLM or hybrid systems like ONLINE-B and TranssionTranslate also show competitive performance. Traditional Neural Machine Translation (NMT) systems, particularly those optimized for specific domains and language pairs, can achieve state-of-the-art results, offering computational efficiency and control over translation behavior. Hybrid approaches that integrate multiple translation paradigms enhance robustness and accuracy by combining the strengths of various methods, such as rule-based systems and statistical models. These alternatives are particularly viable in resource-limited settings demanding precision, such as legal translation, where accuracy and consistency are crucial.

4.3 Metric-Specific Observations

The evaluation of machine translation metrics highlights the varied strengths and weaknesses of different systems. The BLEU score primarily captures n-gram overlap, but its ability to assess semantic meaning and fluency is limited. Metrics such as BLEU, METEOR, TER, CHRF++, BERTScore, and COMET show different levels of effectiveness, with top models like Gemini-2.5-Pro, ONLINE-B, TranssionTranslate, ONLINE-G, and Claude-4 performing well overall (see Table 2). Gemini-2.5-Pro excels in precision and quality, while METEOR, focusing on semantic and structural accuracy, showcases ONLINE-G's strength. CHRF++ correlates well with translation quality through its character-level focus. A significant performance gap exists between leading and lower-tier models, with weaker systems performing poorly across metrics, indicating insufficient specialization in translation tasks. These metrics emphasize the strengths and constraints of each system in accurately translating legal texts.

4.4 Analysis by Sentence Length

The WMT25 Legal Domain Test Suite evaluates system performance over sentence lengths ranging from 5 to 54 words to assess robustness and adaptability to linguistic complexities. Although the dataset offers an aggregate performance overview, it lacks detailed scores segmented by sentence length. Such a breakdown is important for understanding how language models manage various contextual complexities and for identifying strengths or weaknesses related to sentence length. A more thorough evaluation would categorize sentences and assess performance within each segment.

Small Sentences (5–15 words) The analysis of short legal sentences shows that multiple machine translation (MT) systems excel in this area due to their minimal syntactic complexity. Systems such

Rank	**LLM System**	**BLEU**	**METEOR**	**TER**	**CHRF++**	**BERTScore**	**COMET**
1	Gemini-2.5-Pro	33.35	53.91	55.66	60.95	88.49	72.27

Table 2: The table presents a performance comparison of various machine translation systems, including large language models (LLMs) and traditional neural machine translation (NMT) systems. We evaluate the systems using BLEU (Figure 1), METEOR (Figure 2), TER (Figure 3), CHRF++ (Figure 4), BERTScore (Figure 5), and COMET (Figure 6). The systems are ranked by their BLEU scores, with Gemini-2.5-Pro achieving the highest score, followed by ONLINE-B and TranssionTranslate. The results highlight the varying levels of translation quality across different models.

Rank	LLM System	Human Score%
1	Gemini-2.5-Pro	84.67
2	Claude-4	82.00
3	ONLINE-B	81.67
4	TowerPlus-9B	81.33
5	Llama-4-Maverick	81.00
6	GPT-4.1	80.67
7	TranssionTranslate	80.33
8	Qwen3-235B	80.00
9	Mistral-Medium	79.33
10	EuroLLM-22B	79.33
11	NLLB	78.67
12	HYT	78.67
13	ONLINE-G	78.33
14	DeepSeek-V3	78.33
15	TMTHY	78.33
16	CommandA	78.33
17	hybrid	78.00
18	Gemma-3-27B	78.00
19	Shy	77.67
20	TowerPlus-72B	76.74

Table 3: Human evaluation results for the top 20 BLEU-ranked systems on the English→Hindi legal domain dataset. Scores are averaged over two expert annotators.

as ONLINE-G, Llama-4-Maverick, and Claude-4 are identified as top performers, providing accurate and fluent translations. However, these models may face challenges with highly specialized legal jargon or rare terms not extensively covered in their training data, which could impact the precision required for translating legal documents.

Medium Sentences (16–35 words) The text discusses the challenges faced by translation models when dealing with medium-length sentences, which often contain complex structures, such as multiple clauses and conditional statements. These sentences require maintaining logical coherence and resolving anaphora for accurate translation. The models Gemini-2.5-Pro, TranssionTranslate, and ONLINE-B were identified as the most effective in managing these intricacies. Despite the models' suitability for this task, largely due to their transformer-based architectures, their performance showed a slight decline with shorter sentences, indicating that increased complexity still poses a risk of increased errors.

Large Sentences (36–54 words) The primary challenge for the 41 machine translation (MT) systems was translating long sentences characterized by legal jargon and numerous clauses. These sentences posed difficulties in maintaining contextual integrity, causing a significant drop in performance metrics such as BLEU and COMET. EuroLLM-22B, CommandA, and NLLB systems performed slightly better in mitigating this drop. The consistent performance decline underscores the increased risk of "hallucination," context loss, and ambiguity with longer sentences, marking it as a key area for future research and development in MT technology.

Overall System Performance

The evaluation ranks systems in Table 2 based on their robustness across different sentence lengths. Gemini-2.5-Pro is identified as the leading system, showing consistently high performance and the ability to manage various sentence complexities. It is followed by hybrid, with Shy, HYT, and TMTHY tied for third place. The assessment highlights that a system's overall performance is best measured by its consistent quality across all sentence lengths rather than excelling in just one category.

4.5 Human Analysis

In this section, we present the human evaluation conducted on the top 20 systems selected based on their BLEU scores in Table 3 . After identifying these top-performing systems, we carried out a detailed human evaluation specifically within the legal domain. Two linguistic experts proficient in both English and Hindi evaluated the translations of each system. They rated the outputs on a scale from 1 to 100, focusing on both adequacy (how accurately the translation conveyed the source meaning) and fluency (how natural and readable the translation was in Hindi).

We then averaged the scores from both evaluators to produce a final human evaluation score for each system. This human evaluation provides a nuanced measure of translation quality that complements the BLEU-based rankings, helping us identify systems that perform well in real-world, domain-specific scenarios.

5 Conclusion

The WMT25 Legal Domain Test Suite for English to Hindi Machine Translation highlights significant progress made by Large Language Models (LLMs) in specialized domain translation. Notably, Gemini-2.5-Pro excels, outperforming others across multiple evaluation metrics and emphasizing the potential of advanced LLM architectures with domain-specific pre-training or fine-tuning. These

models effectively handle complex legal language and structures, showcasing their sophisticated linguistic capabilities. While LLMs show dominance, traditional and hybrid MT systems also demonstrate competitiveness, indicating their continued relevance. The study underscores the importance of model scale, architecture, and domain adaptation for success in legal MT. It suggests that LLMs will play an increasingly central role in legal translation, advancing accuracy and efficiency. However, ongoing innovations across MT paradigms are needed to balance performance with reliability and ethical considerations, given the high stakes of errors in the legal domain.

Acknowledgement

The authors express their sincere gratitude to the COIL-D Project under Bhashini, funded by MeitY, for their support and resources, which were instrumental in the successful completion of this research.

A Evaluation Metrics and Dataset Segmentation

The appendix details benchmarking results for English to Hindi legal domain machine translation systems, evaluated using several metrics, including BLEU, METEOR, TER, chrF++, BERTScore and COMET. The performance of each system is analyzed across three sentence length categories—small, medium, and large—as well as an overall aggregate. Consistently high-performing systems are identified, along with those that rank lower in performance. The results show consistent top-performing systems, such as **Gemini-2.5-Pro**, **Claude-4**, and **TranssionTranslate**, while systems like **MMMT**, **Wenyill**, and **Yolu** consistently rank among the lowest. This segmentation provides deeper insights into system robustness across varying sentence complexities. Furthermore, it highlights the sensitivity of different models to sentence length, revealing cases in which certain systems degrade significantly with longer inputs. These findings underscore the importance of evaluating MT systems with controlled test suites to ensure reliability in specialized domains, such as legal translation.

A.1 Dataset Segmentation

The test data is divided into four buckets based on sentence length:

- **Small (5–15 words):** Marked in green.
- **Medium (16–35 words):** Marked in yellow.
- **Large (36–54 words):** Marked in blue.
- **Overall:** Aggregate results across all lengths, marked in red.

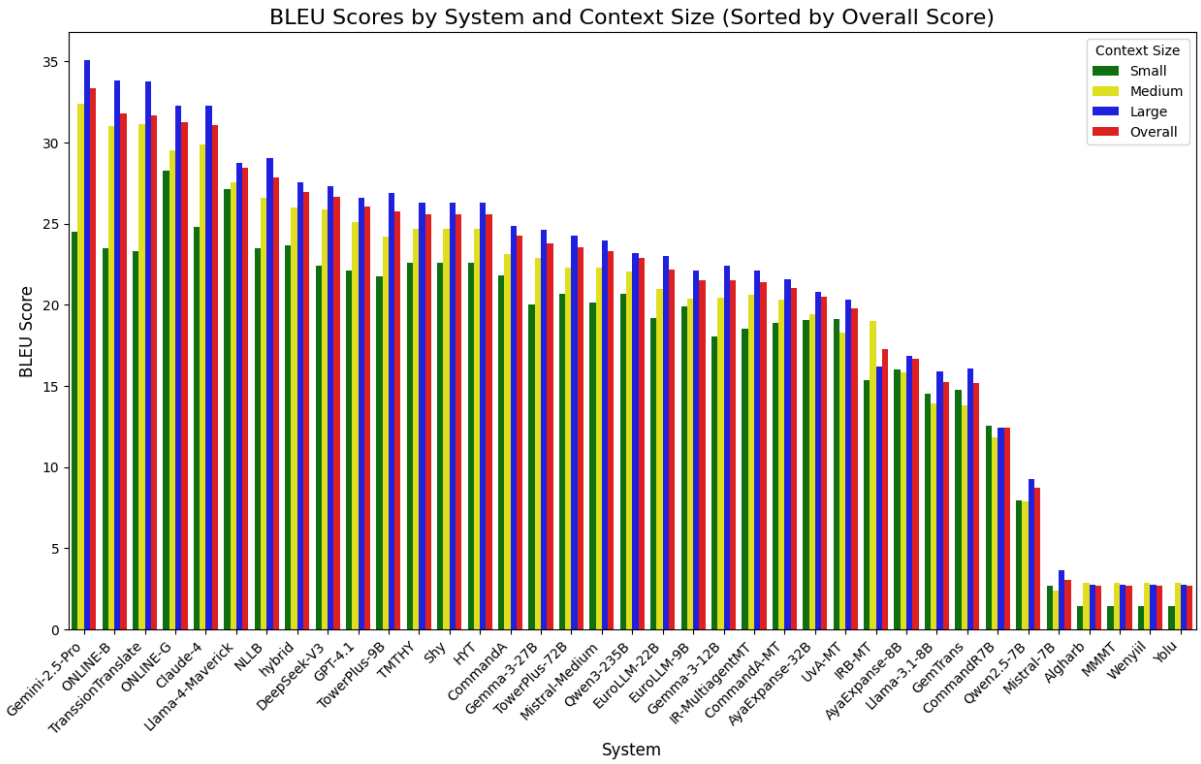

Figure 1: The bar chart displays the **BLEU scores** for various translation systems, broken down by **small, medium, and large context sizes**, as well as an **overall** score. The systems are ranked by their overall score, with **Gemini-2.5-Pro** and **Claude-4** having the highest overall BLEU score and **Wenyiil**, and **Yolu** having the lowest.

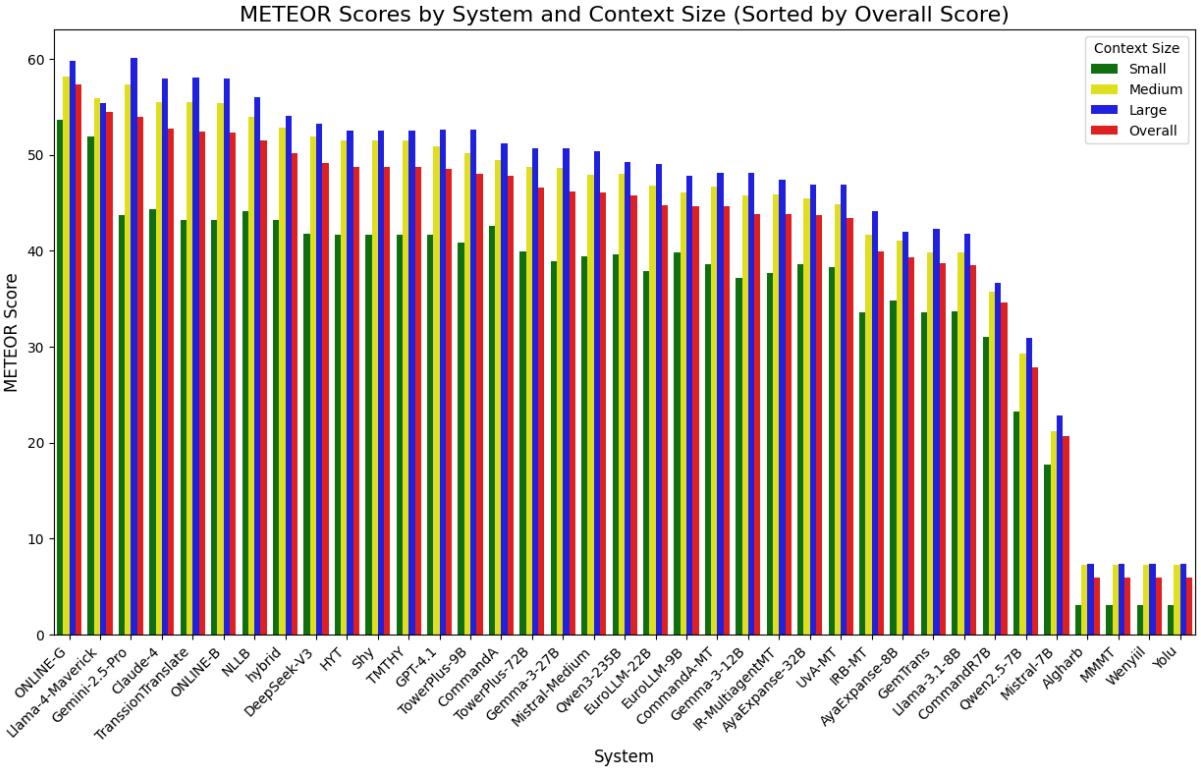

Figure 2: The bar chart shows **METEOR scores** for various translation systems, sorted by their **overall** performance. **ONLINE-G**, **Llama-4-Maverick** and **Gemini-2.5-Pro** have the highest scores, while **MMMT, Wenyiil, and Yolu** have the lowest.

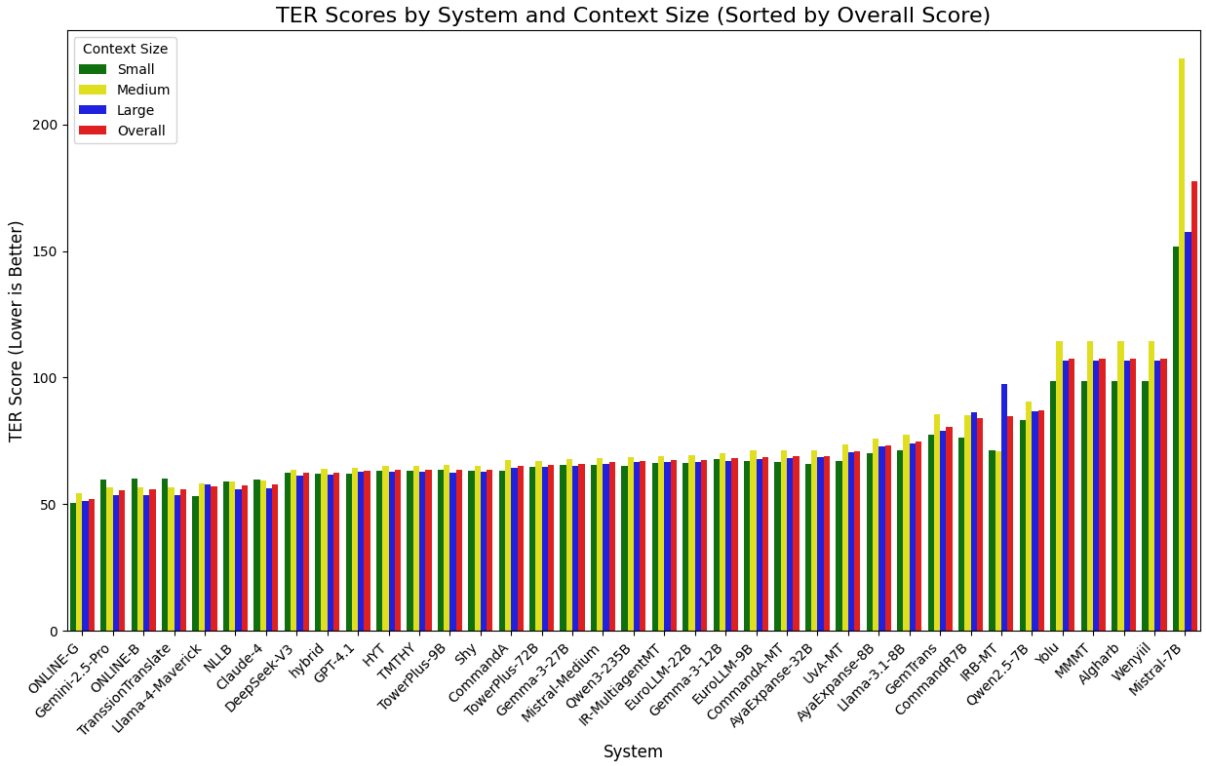

Figure 3: **TER scores** for various translation systems, sorted by their overall performance. **Lower scores are better**. **ONLINE-G, Gemini-2.5-Pro, and ONLINE-B** have the best performance, while **Mistral-7B, Wenyiil, and MMMT** have the worst.

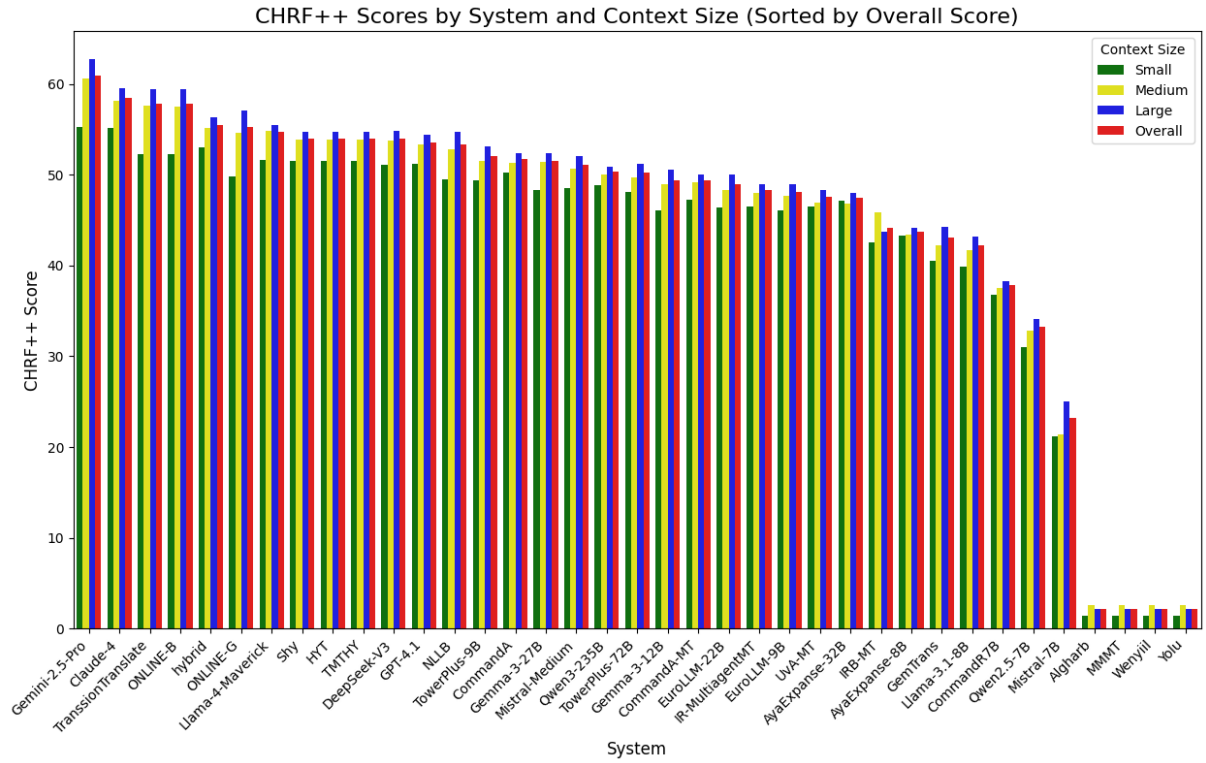

Figure 4: **CHRF++ scores** for various translation systems, sorted by their overall performance. **Higher scores are better**. **Gemini-2.5-Pro, Claude-4, and TranssionTranslate** have the best performance, while **MMMT, Wenyiil, and Yolu** have the worst.

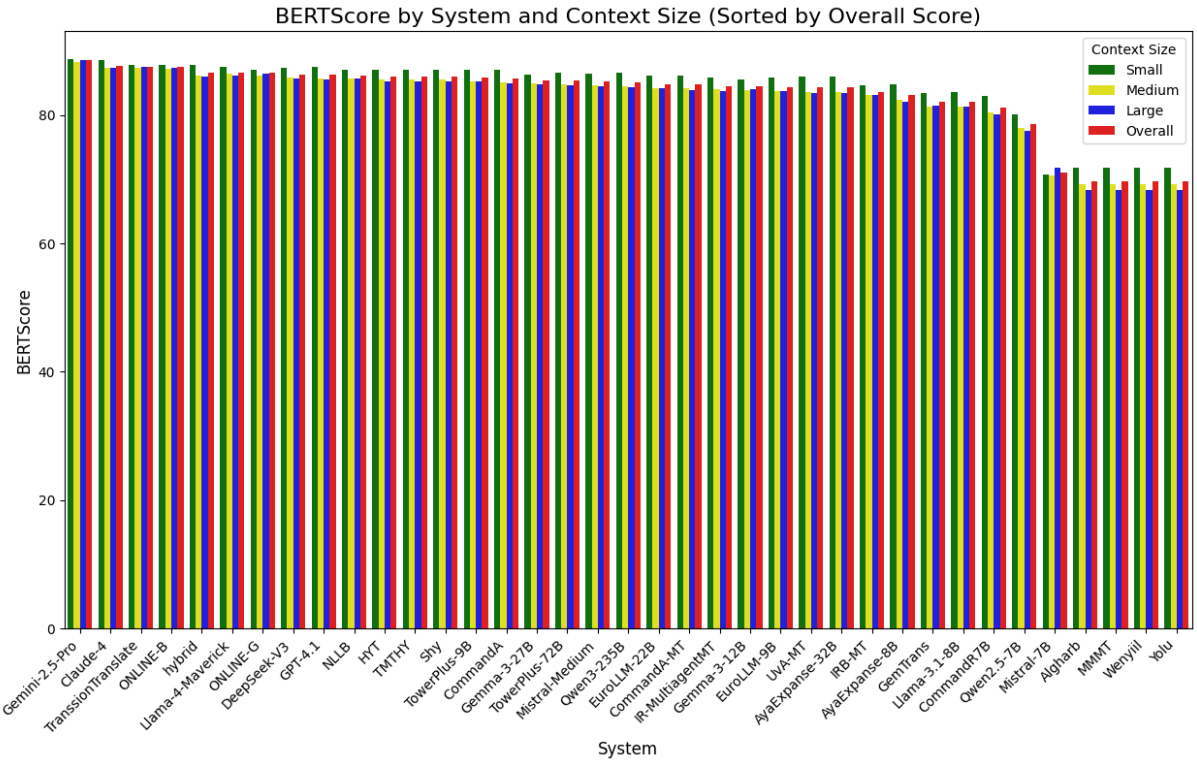

Figure 5: **BERTScore** for various translation systems, sorted by their overall performance. **Higher scores are better**. **Gemini-2.5-Pro, Claude-4, and TranssionTranslate** have the best performance, while **MMMT, Wenyiil, and Yolu** have the lowest.

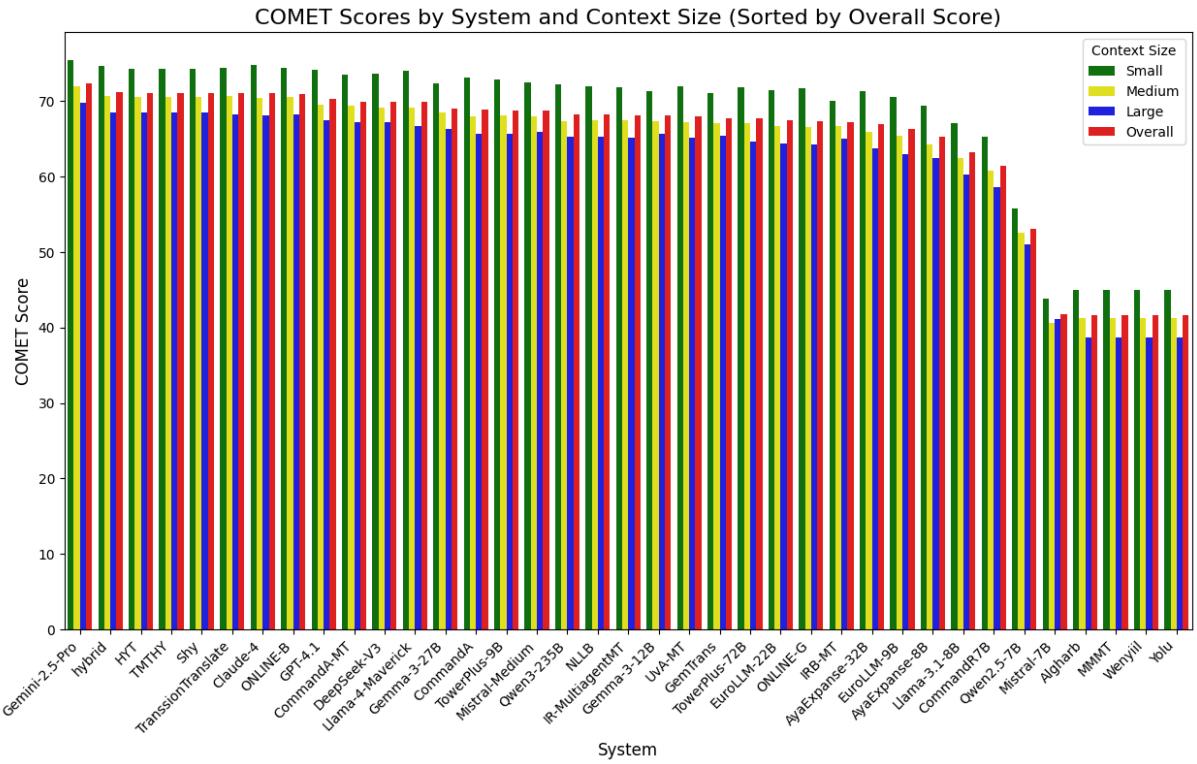

Figure 6: **COMET scores** for various translation systems, sorted by their overall performance. **Higher scores are better**. **Gemini-2.5-Pro, Hybrid, and HYT** have the best overall performance, while **MMMT, Wenyiil, and Yolu** have the lowest.

RoCS-MT v2 at WMT 2025: Robust Challenge Set for Machine Translation

Rachel Bawden **Benoît Sagot**
Inria, Paris, France
firstname.lastname@inria.fr

Abstract

RoCS-MT (Robust Challenge Set for Machine Translation) was initially proposed at the test suites track of WMT 2023. Designed to challenge MT systems' translation performance on user-generated content (UGC), it contains examples sourced from English Reddit, with manually normalised versions, aligned labelled annotation spans and reference translations in five languages. In this article, we describe version 2 of RoCS-MT in the context of the 2025 WMT test suites track. This new version contains several improvements on the initial version including (i) minor corrections of normalisation, (ii) corrections to reference translations and addition of alternative references to accommodate for different possible genders (e.g. of speakers) and (iii) a redesign and re-annotation of normalisation spans for further analysis of different non-standard UGC phenomena. We describe these changes and provide results and preliminary analysis of the MT submissions to the 2025 general translation task.

1 Introduction

Large language models (LLMs) have truly arrived in the field of Machine Translation (MT); their performance often rivals that of dedicated MT systems across various domains (Kocmi et al., 2023; Xu et al., 2024; Cui et al., 2025). However, while they have opened up new possibilities for translation, enabling fine-grained control of output formats, styles and formalities, they are also characterised by new types of errors that were less present with dedicated models, such as translating in the wrong language, inappropriate copying of the source text, generation of outputs that are not translations of the source text, etc. Evaluation continues to be a highly important aspect of the field, and as MT technologies progress, so does the way in which we evaluate. The WMT shared tasks are a good example of this, with an evolution a few years ago to general translation instead of news translation (Kocmi et al., 2022), in order to challenge systems to translate a wider range of domains. One of the selected domains is social media content, known for covering a wide range of topics and containing non-standard language typical of user-generated content (UGC) (Foster, 2010; Seddah et al., 2012; Eisenstein, 2013; Baldwin and Li, 2015; van der Goot et al., 2018).

The translation of UGC has been a topic for a number of years (Belinkov and Bisk, 2018; Michel and Neubig, 2018; Vaibhav et al., 2019; Park et al., 2020; Nishimwe et al., 2024; Peters and Martins, 2025). In particular, a shared task was organised on the matter at WMT in 2023 (Kocmi et al., 2023), designed to target non-standard language from Reddit forums. Several parallel test sets of UGC texts exist (Ling et al., 2013; Vicente et al., 2016; Sluyter-Gäthje et al., 2018; Michel and Neubig, 2018; Rosales Núñez et al., 2019; Mubarak et al., 2020; Fujii et al., 2020; McNamee and Duh, 2022), for a range of languages, although they differ according to the language pairs covered and the degree of non-standardness present.

In the 2023 edition of the test suite track at WMT, we proposed the RoCS-MT test suite (Robust Challenge Set for MT) (Bawden and Sagot, 2023), designed to contain particularly challenging sentences with respect to their non-standard nature (e.g. with spelling mistakes, use of acronyms, marks of expressiveness, devowelling, contractions, etc.). Sourced from English Reddit, we aimed to cover a range of these phenomena in the texts selected, which we manually segmented into sentences, normalised into standard English (according to guidelines that normalised as reasonably possible whilst preserving fluency and meaning) and then translated by professional translators into French, German, Czech, Ukrainian and Russian.

For this 2025 edition of WMT (Kocmi et al., 2025), we resubmit RoCS-MT in an improved version (v2), after (i) some minor corrections to the

Proceedings of the Tenth Conference on Machine Translation, pages 834–849
November 8-9, 2025

source-side normalisations, (ii) corrections to the existing references and addition of multiple references to account for different genders and (iii) improvements to the annotations of the non-standard phenomena for additional analysis. We release this version in Huggingface's Datasets (Lhoest et al., 2021).[1] In this paper we describe those changes and provide results and analysis for the WMT2025 MT systems, with a major difference being that all systems this year were applied at the document level (at the level of Reddit post text in out case). We compare different segmentations of the texts and the performance of systems when applied to the original and normalised source texts.

2 The Test Suite

Composition The main composition of the challenge set is described in the article presenting the first version (Bawden and Sagot, 2023). The English source texts are taken from Reddit (all varieties of English including some non-native language, although we avoided code-switching). Candidate posts were identified using keyword searches on the Reddit API and chunks of text were manually selected from within those posts. The selected texts were manually segmented into sentences (non-trivial since many texts did not contain standard punctuation and sometimes contained newlines within sentences) and manually normalised. The normalisation guidelines we drew up aimed to balance (i) normalising as much as possible and at the same time (ii) rendering the output natural and realistic and (iii) not over-normalising to avoid losing the original text's style. For example, we did not use normalised variants that could be spontaneously and naturally used (e.g. we kept *lol* instead of *laughing out loud*. Finally, translations of the normalised texts were professionally produced in five languages: French, German, Czech, Ukrainian and Russian. Although not all these language directions are represented in this year's shared task, these references remain relevant for future use of the challenge set for these five languages.

Changes with respect to the First Version Several changes were carried out in this second version of the test suite, namely:

- Minor corrections to the normalisations of the source-side texts; we corrected a few wrong normalisations and typos and reverted some hypercorrections to make sure that certain grammatical variations due to dialectal differences were conserved (i.e. not over-normalising)
- Corrections to some references after a manual check, including making sure that emojis and emoticons were always included in the references (this was not the case previously, notably for the Russian translations). For certain target languages, we also complete the reference translations with alternations for multiple possible genders where appropriate (namely where the gender is underspecified given the available context of the Reddit post).
- Re-annotation of the normalisation spans according to a new annotation scheme that is organised hierarchically and structures the types differently.

The new annotation types can be found below. Detailed descriptions including examples can be found in Appendix A.

- **Punctuation, typographic conventions, symbols, etc.**: punct:diff, punct:norm, caps, slash_to_or, slash_to_and, slash_distribution, word_to_symbol, symbol_placement
- **Spacing**: spacing, spacing:camelcase
- **Phonetically similar spellings (including imitation of speech)**: phon, phon:char, phon:digits, phon:cute, phon:hesitate, phon:sound, phon:interjection
- **Other spelling variations (ergographic, expressiveness)**: elongation, devowelling, contraction, truncation, acronym, abbreviation
- **Spelling mistakes**: spell, spell:charswap
- **Misc**: digit_letter_sim, letter_to_digit, suffix
- **Added and dropped words**: word_drop, word_drop:pronoun, word_drop:det, word_add, word_add:det, symbol_drop, symbol_add
- **Grammar**: inflection, grammar, grammar:v, grammar:v:inflect
- **Lexical changes**: lex_choice, surrounding_emphasis, emoticon, censored

3 WMT 2025 submissions

There were 56 submissions to the 2025 general task (including variants of the same systems and systems run by the general MT task organisers) that translated the test suite. A range of architectures were used, with a majority using LLMs. In a bid to encourage document-level translation, one of the important factors to be taken into account in MT evaluation (Läubli et al., 2018), this year's general MT task focused on document-level MT, where documents were typically paragraphs of text. For the test suites, individual segments as provided in the test suite were concatenated to form source documents to be translated in one go. RoCS-MT was provided in two different formats: (i) manual segmentation and (ii) segmentation purely based on newlines within posts.

The language directions of the 2025 shared task overlap somewhat with the 2023 language directions (e.g. English to Czech, Chinese, Japanese, Ukrainian and Russian), although not all target languages for which we have reference translations are present (e.g. French and German), and many of the language directions are new and therefore do not have references (e.g. Arabic, Bhojpuri, Estonian, Icelandic, Italian, Korean, Massai, Serbian). We therefore choose in our initial results and analysis (see Section 4) to concentrate on quality estimation (QE) (i.e. without using the references for automatic analysis). We use two different metrics to calculate the scores (at the document level) used for the rankings: (i) CometKiwi (Rei et al., 2022),[2] and (ii) MetricX (Juraska et al., 2024).[3] This is to avoid bias towards a single metric, especially as many systems optimise for a particular QE metric. We acknowledge however that (i) these metrics may well have issues handling certain languages, particularly those not explicitly included in the training data of the underlying models, and (ii) the scores may well favour models that optimise for QE in general, even if the same QE model is not used.

4 Results and Analysis

In this section, we present results for the submitted systems along with several brief analyses. In order to compute rankings, we took into account the fact that not all systems took part in every language pair, and adopted the ranking algorithm commonly used for nations in the Olympic Games, which addresses a comparable situation. We observed that if systems are ranked based on their absolute scores for each language pair, a few systems are consistently ranked first, meaning that most systems never achieve a rank of 1 or 2, even if they have relatively high overall scores. The result of this is that an overall weaker system that has low scores in most languages but happens to be ranked highly for a single language pair can be ranked higher than a system that has high but not the best scores across all language pairs. We therefore choose to apply the "gold first" algorithm on quartile-based rankings instead of raw rankings; for a given language pair, all systems within the top 10% of scores are assigned to rank 1 and treated as such by the "gold first" algorithm, the next 10% to rank 2, and so on. In other words, systems are then ordered according to the number of language pairs in which they achieve rank 1 (i.e. belong to the top 10%). In the event of a tie, the number of rank 2 placements (top 10–20%) is considered, followed, if necessary, by the number of rank 3 placements (top 20–30%), and so on.

We applied this approach to get rankings from each of the two metrics used. These rankings are based on the original inputs (i.e. before normalisation) that have been manually segmented into sentences. We then computed overall rankings based on the average of the two rankings. Table 1 displays both metric-specific rankings and the overall ranking, the number of first-, second- and third-ranks for each system and each metric and the absolute gap between each system's CometKiwi-based and MetricX-based ranks, to get an idea of how consistent they are and the confidence we can place in the resulting rankings. Appendix B provides raw CometKiwi and MetricX scores per language pair, first comparing scores on original and normalised inputs, then comparing scores on manual and newline segmentations applied to original inputs.

Results highlight a small group of systems that dominate performance. Yolu occupies the top position with nine first-place results across all twelve language pairs on both metrics, followed closely by Shy-hunyuan-MT and CommandA-WMT. Laniqo and SalamandraTA follow, despite the fact that Laniqo participated in only seven pairs. Among the organiser-run systems, GPT-4.1 ranks 7th, closely followed by ONLINE-B and both TowerPlus models. Several larger LLM-based baselines, such as Claude-4 (18th) and both Gemini models (also

Table 1: Main ranking table. For each system and for both the CometKiwi and MetricX metrics, we provide their rank according to the metric, computed using the "gold first" scoring algorithm (Rank), the number of language pairs for which the system ranked first, second and third ("Medals"). For each system we also provide the number of language pairs it participated in (#lp), an overall rank based on the average between the CometKiwi- and the MetricX-based ranks, and the difference between the two original ranks, which shows for each system how consistent the two metrics are. Systems run by the task organisers are marked with an asterisk, while systems fine-tuned to optimise a Qe metric, such as CometKiwi and MetricX, are indicated with a $^{\diamond}$.

18th and 23rd, respectively), appear in the middle of the table, while Llama-4-Maverick, Mistral 7B, Qwen 2.5 and ONLINE-G fall into the lower ranks. NLLB, a widely used dedicated MT model, ranks only 46th, with consistently low ranks in both metric-specific rankings (44th and 39th). Conversely, several single-pair submissions are quite successful, achieving first place according to one of the metrics, and sometimes second or third according to the other one (NNTSU, Erelendur and In2x reach a joint overall 15th place). Overall, the results indicate that dedicated MT systems continue to outperform many general-purpose LLMs when evaluated using CometKiwi and MetricX.

These results are somewhat surprising, particularly the relatively low performance of several large LLMs—Qwen3 235B ranks only 38th overall, and GPT-4.1 is ranked 17th according to the CometKiwi-based ranking—and popular reference models such as NLLB, despite generally being evaluated quite highly in MT tasks, whether by automatic metrics or human evaluation. Three main factors may account for this outcome. First, strong performance on edited data does not necessarily translate into equally strong performance on non-standard data; success on the former is not a guarantee of robustness. Secondly, automatic evaluation metrics—especially CometKiwi, on which our ranking is based—may perform poorly when applied to translations of non-standard text. Thirdly, several systems used QE metrics for optimisation and may therefore have gained higher rankings than their actual quality would otherwise justify.[4] We leave these questions open for future investigation, and invite the reader to take our results and conclusions with a pinch of salt.

Another surprising observation is that several systems are positioned very differently in our two metric-specific rankings. The most extreme case is KazeMT, ranked 52nd using CometKiwi but 9th using MetricX. Another example of a large Δrank is Gemini 2.5 Pro, ranked 38th using CometKiwi but 7th using MetricX. Several single-pair submissions also display large discrepancies, such as Yandex and Systran, which both achieve first place according to one metric (MetricX for Yandex and CometKiwi for Systran), but do not perform as well according to the other metric. Such discrepancies could be explained, at least in some cases, in the way these models were trained or fine-tuned, for instance by optimising for QE, as mentioned above.

[4]We indicate systems that self-declare as using QE in some way with a $^{\diamond}$.

4.1 Original versus Normalised Texts

We first compare the impact of translating the original inputs (containing non-standard language) against the normalised inputs (both with manual segmentation). The full results are given in Appendix B (Tables 3 and 4). The scores for original texts are in general lower for CometKiwi and higher for MetricX than for the normalised ones. This is somewhat unsurprising for several reasons: (i) it is expected that more standard texts are easier to translate, as the majority of the texts that the models were trained on was standard, and the UGC texts are characterised by high levels of variation, (ii) metric scores are likely to penalise translations that are less standard. Concerning (i), there is some indication that is going on. For example, the difference between translations from normalised and original texts is very large for the lowest-resource language directions, at least for CometKiwi (English to Icelandic and to Maasai), showing that the models are struggling more with the non-standard texts. Concerning (ii), some further investigation is necessary here to ascertain whether the difference in scores are a property of the metrics themselves or whether they translate into real differences in translation quality. Our observations in Section 4.3 indicate that there is more going on than these basic scores and that we should not trust the metric scores alone.

4.2 Manual Segmentation versus Newline Segmentation

We then compare the impact of the text segmentation by looking at the scores based on inputs with manual segmentation and those separated on newlines (both with raw inputs). Results are shown in the same appendix section (Tables 5 and 6). The differences between the two segmentation types appears less than the differences previously observed between original and normalised inputs. In reality, given that the posts were given as complete documents, the segmentation has less of an impact than if the systems had been translating on the sentence level, as was the case for most systems in previous years.

4.3 A First Qualitative discussion

Table 2 shows the results of all systems (apart from those whose output was obviously the result of a

Table 2: Example of character repetition linked to a mark of expressivity for en–cs (same source text as in (Bawden and Sagot, 2023) to illustrate 2023 en–de results). For each system we provide the CometKiwi score (multiplied by 100; higher is better) and the MetricX score (lower is better) for the corresponding document, as scores were computed at the document level. Systems are ordered by increasing CometKiwi score. The two last columns provide a manual assessment of how much of the input sentence was translated into Czech—or at least not kept in English—(“tgt lang”) and of how well the elongation phenomenon was transferred to the output sentence (“elong tr”; non-translated tokens are ignored). Systems whose outputs obviously result from an error are not included.

bug) on the example already used in (Bawden and Sagot, 2023) to illustrate the behaviour of MT systems in the presence of several instances of the elongation phenomenon, by which one or more characters are repeated to express emphasis. A first glance at the results shows that there is not necessarily a convincing correlation between perceived translation quality and the automatic evaluation provided by the CometKiwi metric, whereas MetricX results look slightly more correlated. Looking more closely at the translations, two main observations can be made:

- Firstly, a number of systems tend to keep unchanged original English tokens that have undergone elongation, and sometimes even the whole input. The fact that the two last tokens are capitalised in the input sentence makes it even more difficult for most systems to actually try to translate them.
- Secondly, not all systems attempt to transfer the elongation phenomenon into their output. Some seem to (try to) produce standard Czech rather than preserving the non standard expressivity mark. Some even try to render the same expressivity using another non standard phenomenon.

To better understand what is at play here, we decided to manually annotate these translations for two features: how much of the input sentence was (tentatively) translated into Czech, and how much of the elongation phenomenon was transferred into the output sentence (ignoring tokens kept in their original English form). Comparing these annotations with system types is interesting. Although a single example is in no way sufficient to allow for any generalisations, it seems that generic LLMs are more liable to preserving elongation and, more generally, to produce better translations, whereas

dedicated MT models seem to produce more standard outputs and/or not to translate significant parts of the input. Interestingly, this is not reflected in the CometKiwi scores, but it is more visible in the MetricX scores. For instance, the best CometKiwi-scored translation contains two segments that are still in English, a situation that invariably leads to bad (high) MetricX scores. However, CometKiwi ad MetricX seem consistently bad at penalising the absence of elongations in the produced translation. The best CometKiwi-scored translation does not contain any elongation in genuinely Czech tokens, and the best Metric-X-scored translation, which is perfect Czech, does not include any elongation whatsoever. On the contrary, the output of GPT-4.1 is good in both regards—it is entirely in Czech and does contain elongations—, and is a good translation, but it is scored poorly by both CometKiwi and MetricX. This shows that modern metrics such as CometKiwi and MetricX might not be reliable when it comes to assessing translation quality of non-standard content. We leave a more quantitative and systematic exploration of these questions and their implications for MT evaluation in general to future work.

Although the test suite this year presents new annotations for the non-standard phenomena present in the test suite that are more consistent and interesting for analysis, we also leave the analysis on a per-phenomenon basis to future work, in which we will go into more detail and length.

5 Conclusion

We have presented a new version (v2) of the RoCS-MT challenge set, first presented at the WMT 2023 test suites shared task track. This 2025 edition has several improvements, with minor corrections to source texts, some corrections to references and improved categorisation of non-standard phenomena. We describe these changes and also use the challenge set to compare systems submitted to this year's shared task, comparing translation from the original UGC inputs and their manually normalised versions. A major difference with previous years of the shared task is a switch to document-level MT, so whole chunks of posts were submitted to systems for translation. We nevertheless compare two different segmentation types (to see if initially manually segmenting into sentences and then concatenating the sentences with newlines could help translation) and discuss preliminary insights into the shortcomings of popular metrics such as CometKiwi and MetricX when applied on non-standard text MT.

Acknowledgments

This work was partly funded by both authors' chairs in the PRAIRIE institute, now PRAIRIE-PSAI, funded by the French national agency ANR, respectively as part of the "Investissements d'avenir" programme under the reference ANR-19-P3IA-0001 and as part of the "France 2030" strategy under the reference ANR-23-IACL-0008.

A Normalisation Span Classification

The original and normalised texts were aligned and different non-standard phenomena classified. Below is the list of normalisation categories with examples.

Punctuation, typographic conventions, symbols, etc.

- **punct:diff**: extra punctuation is included or necessary punctuation is removed (e.g. missing final punctuation, missing apostrophes, commas, etc.).
  e.g. im→I'm
- **punct:norm**: punctuation to be normalised according to certain conventions (e.g. same apostrophes and quotes).
  e.g. that's→that's
- **caps**: capitalisation differs from what is considered standard (e.g. lowercase initial characters, all uppercase, etc.).
  e.g. IM SO HAPPY→I'm so happy
- **slash_to_or**: a slash is used, where in normalised speech an "or" would be used to represent a list of items. This applies to the whole list, including where etc. is included. Not that this does not include cases where the items are alternatives in the discourse
  e.g. cat/exhaust/etc→cat or exhaust, etc.
  e.g. truth/dare→truth or dare
  e.g. [counter-example] AW WELL MY DOG/CHILD IS VERY FRIENDLY SO LET ME APPROACH→aw, well my dog/child is very friendly, so let me approach
- **slash_to_and**: a slash is used, where in normalised speech an "and" would be used. This applies to the whole list, including where etc. is included.
  e.g. work/paint→work and paint
- **slash_distribution**: the use of a slash to separate two items where the slash does not separate two complete items (i.e. part of one element is distributed to both items thanks to the slash). An example makes this easier to understand:
  e.g. just disrespects any / everyone→just disrespects any / everyone
- word_to_symbol: the use of a symbol to represent a word
  e.g. +→and, &→and
  e.g. →around
  e.g. $$$→money

- **symbol_placement**: non-standard placement of a symbol with respects to English norms.
  e.g. 100$→$100

Spacing

- **spacing:** missing or added spacing in the original text
  e.g. aswell→as well
  e.g. over thinking→overthinking

- **spacing:camelcase:** the use camelcase (capital letters at the beginning of words) instead of using spaces
  e.g. surroundedUs→surrounded us
  e.g. sawThat→saw that

Phonetically similar spellings (including imitation of speech)

- **phon:** the word uses a variant of spelling based on the phonetic similarity of the sequence of characters. This also includes the use of individual letters to represent words or syllables because of an equivalence in their pronunciation (u→you, b→be, c→see).
  e.g. saturday sesh→Saturday session (also a case of truncation)
  e.g. sup→What's up (also truncation)
  e.g. bcos -> because
  e.g. n→and
  e.g. tho→though
  e.g. speakin→speaking

- **phon:char:** a character is used in the place of a word or syllable because of its phonetic similarity with the word or syllable
  e.g. b→be
  e.g. c→see
  e.g. u→you

- **phon:digits:** a digit is used in the place of a word or part of a word.
  e.g. m8→mate
  e.g. 2→to
  e.g. as1 that will play→as one that will play (in a context where 1 could be incorrect, otherwise this should not be normalised)

- **phon:cute:** the spelling of a word to indicate "cute" or babyish pronunciation, e.g. using 'w' to replace an initial letter
  e.g. wecommended→recommended

- **phon:hesitate:** words that are written in a way to imitate hesitation
  e.g. terribl-....yyy→terribly
  e.g. Y-y-yyy-yes→Yes

- **phon:sound:** the case of words that are used to indicate a sound (very rare)
  e.g. bRRrrRRrrRRrr→brr rrr rrr

- **phon:interjection:** interjections that are normalised to single (and more standard) variations
  e.g. bla→blah
  e.g. URGHHH→ugh
  e.g. Nawh→no

Other spelling variations (ergographic, expressiveness)

- **elongation:** characters are repeated, usually as a a mark of expressiveness.
  e.g. *meeeeelltiiiinggg*→melting
  e.g. sooo→so

- **devowelling:** a word with the vowels removed (initial vowels are often kept however). This can often result in double characters being reduced to single ones (messages→msgs) In this category are also words where part of the word has been devowelled.
  e.g. wt→what, ovr→over, ppl→people
  e.g. askd→asked (initial vowel kept)
  e.g. travllr→traveller

- **contraction:** when several words are contracted into a single one. This has some overlap with the characteristics of phonetic distance, in that it is due to the pronunciation of the words that the contraction occurs.
  e.g. gonna→going to
  e.g. innit→isn't it?

- **truncation:** a word is shortened, either at the end (traditional truncation) or sometimes at the beginning, often by removing a syllable or a suffix. Note the difference with acronymisation, which involves keeping initial characters.
  e.g. sesh→session
  e.g. cuz→because, till→until
  e.g. ofc→of course -> CHANGED, NOW ACRONYM
  e.g. w→with -> CHANGED, NOW ACRONYM

- **acronym:** a word or sequence of word is represented as an acronym, i.e. the initial characters of the word (or syllables) are retained and the others are elided.
  e.g. RN→right now
  e.g. gf→girlfriend
  e.g. never mind→nvm
  e.g. w→with
  We also include in this category words that are partially acronymised (i.e. where one syllable is represented by its initial but the rest is not).is acronymised but the rest is not.
  e.g. oline→offensive line
  e.g. gmeet -> Google meet
  e.g. bday→Birthday
  e.g. ofc→of course
  Note that sometimes slashes are included in the acronym
  e.g. b/c→because,
  e.g. w/o→without.

- **abbreviation:** abbreviations for units of measurement and other standard cases
  e.g. ft→feet, 2k→2000, hrs→hours
  e.g. Ex→for example

Spelling mistakes (distinguished from spelling variation identified as being intentional)

- **spell:** the word contains a spelling error that is not clearly intentional (covered by the other phenomena such as truncation, devowelling, etc.) and not covered by the other more specific categories.

- **spell:charswap:** the characters in the word are present but not in the right order (most often consecutive characters being swapped)
  e.g. nobel→noble
  e.g. furhter→futher

Misc

- **digit_letter_sim:** Very rare, but where a digit is used in the place of a letter due to the typographic similarity (see in 3ver→ever).

- **letter_to_digit:** Very rare, but where a digit is used in place of a letter not because of their typographic similarity, but because as a sort of tautology (seen in 1nce→Once).

- **suffix:** the addition of a suffix to a word, either as a diminutive or other
  e.g. lolsky→lol
  e.g. meanie→mean
  e.g. doggy→dog

Added and dropped words

- **word_drop:** a word is not present in the original text and is present in the normalised version
  e.g. It also confusing. . . →It's also confusing
  e.g. u wanna see?→Do you want to see?

- **word_drop:pronoun:** the original text omits a pronoun (often the case of subject pronouns at the beginning of sentences) that is included in the normalised version.
  e.g. Was gunna try distortion. . . →I was going to try distortion. . .

- **word_drop:det:** the original text omits an article (e.g. the or a) that is included in the normalised version.
  e.g. Pretty creative way. . . →A pretty create way. . . word_add: a word is present in the original text and is removed in the normalised version
  e.g. . . . in ten days ago→. . . ten days ago
  e.g. also for uses of word "like" as a filler

- **word_add:det:** the original text includes an article where the normalised version removes it
  e.g. . . . adds an 12kg of salt→. . . adds 12kg of salt symbol_drop: the original text omits a symbol that is included in the normalised version.
  e.g. 32c→32°C

- **symbol_add:** the original text includes a symbol that is removed in the normalised version.
  . . . no issue w being over 12+ ft. . . →. . . no issue with being over 12 feet. . .

Grammar

- **inflection:** a word is not correctly inflected (e.g. with respect to number, tense, etc.)
  e.g. . . . wondering what ppl thought are→. . . wondering what people's thoughts are

- **grammar:** inflection-related errors
  e.g. . . . wondering what ppl thought are→. . . wondering what people's thoughts are
  e.g. if your good→if you're good

- **grammar:v:**
- **grammar:v:inflect**

Lexical changes

- **lex_choice:** a use of a non-standard lexical choice, including dialectisms (e.g. cannae, ain't), malapropisms (e.g. genually), foreign words and generally wrong choices of words (e.g. wrong part of speech, wrong semantic choice of words, lacking punctuation, use of an antonym by accident, etc.)
  e.g. I am confusion→I am confused
  e.g. genually→genuinely
  e.g. pish→piss
  e.g. ain't→aren't
  e.g. cannae→cannot
  e.g. y'all→everyone/all/all your (depending on the context)
  e.g. sans guac→without guacamole

- **surrounding_emphasis:** emphasis added to certain words typographically (removed in the normalised variants).
  e.g. *without*→without
  e.g. ∼find∼→find

- emoticon: emoticon that is a variant on the common emoticons :-), :-D, :-(, :-/ and >:-)
  e.g. :-/////→:-/
  e.g. (:→:-)
  e.g. :$\hat{)}$→:-)

- censored: the word contains symbols in an effort to censor the word
  e.g. upv*te→upvote
  e.g. s**t→shit, sh**→shit

B Raw Automatic Scores per Language pair

The raw scores (calculated at the document level) can be found in this appendix section. In each of the tables, the systems are ordered by the ranking across all languages for that particular metric (as described in Section 4). Note that higher CometKiwi scores are better and lower MetricX scores are better.

Tables 3 and 6 provide the CometKiwi and Metricx scores respectively for manually segmented texts, with a comparison of original and normalised input texts.

Tables 5 and 6 provide the CometKiwi and Metricx scores respectively for original inputs, with a comparison of manually segmented and newline-segmented texts.

Table 3: CometKiwi (higher is better) scores across language directions for original and normalised inputs (manual segmentation in both instances). System are sorted by their CometKiwi-based ranking (over all language pairs). Systems run by the task organisers are marked with an asterisk.

Table 4: MetricX scores (lower is better) across language directions for original and normalised inputs (manual segmentation in both instances). System are sorted by their MetricX-based ranking (over all language pairs). Systems run by the task organisers are marked with an asterisk.

Abstract

This paper presents a submission to the WMT25 test suite subtask, focusing on terminology in official documents related to the EEA Agreement. The test suite evaluates the accuracy of MT systems in translating terminology for the English→Icelandic translation direction when applied to EEA documents. We focus on the use of terminology in four domains of the agreement; science, technology, economics, and society. We find that manual evaluation confirms that our test suite can be helpful in selecting the best MT system for working with these domains. Surprisingly, an online system which does not achieve very high scores on the general translation task, according to preliminary results, is most adept at translating the terminology our test suite evaluates. The test suite and evaluation code are openly available on Github: https://github.com/steinst/WMT25_EEA_test_suite

1 Introduction

Pozzo (2020) argues that the law of the European Community has a multilingual framework, with 24 official languages, which calls for the use of descriptive language to maintain equal distance between each language, with legal terminology being culture-bound. The EEA Agreement is translated into two additional languages; Icelandic and Norwegian. The meaning associated with legal texts is often disputed, even in monolingual texts. The target text should perform at the same function as the source text, since they're equivalent in legal sense (Bago et al., 2022). Term inconsistencies are therefore unacceptable. Until recently, most MT systems translated documents sentence by sentence, which could result in inconsistencies in translation of terminology (see e.g. Semenov and Bojar (2022)). The Translation Centre at the Ministry for Foreign Affairs in Iceland translates around 9000 pages related to the EEA Agreement each year (Steindórsdóttir, 2022). They have been testing an MT system trained on their own corpus but the results show that the system outputs are mediocre at best. Bago et al. (2022) state that one of the main complaints of the translators is the lack of correct terminology and consistency in the MT output.

Current LLM-based systems are capable of considering larger context. In this paper we present a test suite which can help us understand if systems based on this new MT paradigm can translate the terminology correctly. We focus on terminology translations from English to Icelandic in the EEA Agreement in our submission for the WMT25 Test Suite subtask (Kocmi et al., 2025a). We evaluate 34 systems, both automatically and manually, and find that surprisingly, two out of the three highest scoring systems are Online-systems. We release our test suite and evaluation code for others to build on and to allow for further comparison between future models in this domain.

2 Related Work

Semenov and Bojar (2022) measured consistency, unambiguity and adequacy in automatically translated legal texts by counting the correct occurrences of the exact term. Gašpar et al. (2022) found that the Herfindahl-Hirshman Index (HHI) can be used to measure the consistency of terminology in a translated corpus, since the HHI works on a small amount of data.

$$\mathrm{HHI} = \sum_{i=1}^{n} S_i^2 \tag{1}$$

i ranges over n different translations for the specific term translated in the relevant text. S_i is the ratio of the number of times when the term was translated as i to the total number of times it was translated. Therefore the HHI score will be 5.0 if a term has two different translations.

$$\frac{\sum_{j=1}^{p} \sum_{i=1}^{n} \left(\frac{f_i}{k_j} \cdot 100 \right)^2}{p} \tag{2}$$

Proceedings of the Tenth Conference on Machine Translation, pages 850–855
November 8-9, 2025

An overall translation consistency index (C_t) for a source term is calculated as follows: p is the number of translation having the source term t, and each frequency share is calculated as the ratio of its frequency f_i to the total translation occurrence within a product k_j. The score ranges between 0 and 10, with 10 being perfect consistency.

Alam et al. (2021) introduced a benchmark for evaluation of quality and consistency of terminology translation in a shared task at WMT21, with creating new evaluation datasets that were annotated by professional translators for their terminology consistency. They found that general translation quality does not have to be sacrificed for terminology compliance. Semenov et al. (2023) evaluated the efficiency of using segment-level terminology dictionaries in a shared task at WMT23, and concluded that an improvement in MT performance when using a terminology dictionary ranged between 0 and 10 ChrF points.

Two participants in the WMT 2024 Test Suite subtask (Kocmi et al., 2024) focused specifically on English→Icelandic translations: Friðriksdóttir (2024) focuses on various aspects of gender-inclusive translation, including LGBTQIA+ terminology and whether translations are current and culturally appropriate, as the terminology in that domain has been updated repeatedly. Ármannsson et al. (2024) focus on idiomatic expressions and proper names in their test suite. Their evaluation is keyword-based, checking if content words in the idioms are translated correctly and whether the proper names have correct translations.

3 Methodology

We built an automated keyword-based evaluation regarding the EEA Agreement. The aim was to test the ability of MT systems when it comes to the translation of terms in the Agreement, as disambiguation is important when it comes to the translation of legal texts. To test this, we ran the automated evaluation and confirmed our method with manual evaluation. We manually collect sentences from EU regulations and directives relevant to the EEA agreement. For each sentence, we tag terms and find the standard Icelandic translation for each term on the official Icelandic website for the EEA Agreement.[1] The Icelandic translations are used for automatic evaluation and a subset of the translations from each MT system is manually evaluated in order to understand whether the automatic evaluation is close to human judgment.

3.1 Test Suite Compilation

The terms were manually extracted from 32 EU Regulations and two EU Directives that were translated into Icelandic and published in 2024 and 2025. The aim was not to test the regulations, but to collect a diverse and descriptive sample of keywords that appear in the EEA Agreement. In some cases, we added a simple verb phrase if necessary, to build a coherent sentence. The terms were divided into four subgroups: science, technology, economics, and society, with as little overlay as possible. The subgroups are based on the groups at the Translation Centre, where the EEA Agreement is divided into said subgroups. Every sentence contained at least one term that we tested, but we did not test every term in each sentence, especially not recurring terms, since we were not testing consistency in this test suite. We gathered every word form of the terms and used it for the automatic evaluation.

The sentences were exported as a txt-file, which was sent to the test suite subtask of WMT25. Once we got the translated sentences from the 34 MT systems, we ran the automatic evaluation, see 3.2. We manually evaluated translation of the terms in 50 sentences for each system to test our automatic evaluation method, see 3.3.

Due to an error in the layout of the txt-file, some of our sentences were split, so we ended up with 256 sentences and 408 keywords. We disregard the erroneous sentences in the input and report only on the error-free ones. We have however published a corrected version on Github along with the test suite and evaluation codes, for others to build on and compare other models.

3.2 Automatic Evaluation

The automatic evaluation is keyword-based. For each MT system we check all 256 complete sentences and disregard the ones that were split up before submission. The check inspects if a given translation contains the Icelandic terms, by comparing the translation to all possible inflectional forms of the term. We look up the word forms in DIM, the Database of Icelandic Morphology (Bjarnadóttir et al., 2019), and if they are not found there, we manually create a list of acceptable forms. If the translation contains the term in any form accepted in our lists we count that as correct.

[1] https://gagnagrunnur.ees.is/

3.3 Manual Evaluation

We manually evaluated 1700 translations, 50 for each system. The sentences were chosen randomly from the complete set of 256 translations and for all systems we evaluated translations of the same 50 sentences. The evaluator is a PhD student in Translation Studies and a former translator at the Translation Centre, with a three year background as a professional translator. The manual evaluation took around 10 hours, since the focus was only on the keywords and not the sentences. One point was given for every term that was correctly translated, and the maximum points available correlated therefore with the number of terms. A point was given for acceptable translations, other than the ones that were included in our keyword list. 117 other translations were accepted, mainly synonyms, and rephrasing of terms consisting of more than one word. Additionally, we inspect the ratio of sentences that have all terms correctly translated.

4 Results

Results of the automatic evaluation are presented in Table 1 and manual evaluation in Table 2. While the main difference between the evaluation approaches is that the manual evaluation paints a picture where many of the MT systems seem to be quite adept at dealing with EEA terminology, achieving up to almost 80% accuracy, the accuracy being the ratio of terms correctly translated according to the human annotator. The automatic evaluation gives substantially lower scores, which may indicate that the keyword and word inflection lists used for the automatic evaluation are sometimes lacking. Even though that is the case, the order of the systems is very similar in the two evaluations, manual and automatic. Our main takeaway from comparison is thus that if we trust our manual evaluation to be reliable and can use that to help us select the best MT system to help us with EEA translations, we can also trust the automatic evaluation using our test suite, as the order of the system is almost identical, with the same systems being in the top 3 seats of both lists. If we compare our results to the preliminary rankings for the WMT25 general translation task (Kocmi et al., 2025b), we find that our order of systems is quite different. The most surprising results are that the system achieving first place on both our lists, ONLINE-G, is actually a low scoring system in the general translation task, ending up in 24th place out of 33 systems. We wonder why this is and speculate whether this might be an encoder-decoder system that actually contains EEA texts in their training data. If an evaluated system is trained on data from the domain being evaluated, possibly containing the same or very similar structures as being evaluated in the test suite, this data leakage can lead to overestimation of the models capabilities, see e.g. Zhu et al. (2024) and Zeng et al. (2024). This could explain why the system is particularly good in this task, but not in the general translation task where LLMs seem to have an advantage. This is not necessarily a far-fetched idea, as a substantial part of ParIce (Barkarson and Steingrímsson, 2019; Steingrímsson and Barkarson, 2021), a parallel English-Icelandic parallel corpus, comprises data from EEA-documents and this corpus is among those distributed on OPUS[2]. Other top scoring systems, on the other hand, are all in the top seats in the preliminary system ranking table.

5 Conclusions and Future Work

We evaluated 34 MT systems using our test suite, automatically and manually. The evaluation shows that while a few of the systems translate the majority of the terms correctly, they are all quite far from perfect. Our automatic evaluation orders the systems in a similar way to the manual evaluation, indicating that an automatic approach such as this one can be useful to help translators find the most useful system for the task.

A larger set of sentences and terminology would improve our test suite, especially if we include terminology from other subdomains. Given the large amount of published documents relating to the EEA Agreement it is almost, if not entirely, impossible to test for every single term that appears in those documents. We plan to look into the frequency of terms in order to reconstruct the test suite in a way that may be more indicative of real-world usage, on the one hand giving terms that appear often in the Agreement more weight, but on the other make sure that a representative part of terms that rarely appear is also included. To build further on the test suite, we also plan to look into results for each subdomain and see if MT systems perform better for a specific domain. Another interesting area is to test the translation of neologism, as acts about new developments, especially scientific and technological ones, often call for new terminology. Finally, looking into the translation of terms that have more

Table 2: Manual evaluation of the systems.

than one allowed Icelandic translation, based on context and subgroups, could help us understand problems that translators might miss and special attention has to be paid to.

This test suite can be adapted to other languages with relative ease, which allows further work on other language directions.

6 Limitations

This work did not consider consistency especially, which would be a logical next step, to check whether the terms are consistently translated in the same way, or whether for some MT systems correct translations may be fortuitous incidents.

Our selection of terms was not always systematic and we do not always consider all terms in a given sentence. We were not able to check every category under each subgroup in this test suite due to the size limitations.

Due to time limits we were not able to add the accepted translations, and all the word forms of said translations, from the manual evaluation to the list of accepted terms. The keyword and word inflection lists are therefore lacking for the automatic

evaluation.

As mentioned above, some sentences were split up and we ended therefore with fewer sentences than anticipated, and therefore a smaller test suite. Both the submitted test suite and a fixed one are available in the Github repository.

Abstract

We present a submission to the WMT25 test suite subtask, focusing on the capabilities of MT systems to translate sports-related language. Although many sports attract extensive media attention and feature a rich, polysemous language, often shaped by active neologism and community-driven translations, the sports domain has received relatively little focus in MT research. In English-Icelandic automatic translations, sports-specific vocabulary often appears to be mistranslated. Our test suite is designed to test whether this observation holds merit. We evaluate 34 systems, both automatically and manually, and find that sports language poses challenges to a varying degree for all the systems.

1 Introduction

With the advent of large language models (LLMs), significant advances have been made in machine translation (MT) (Kocmi et al., 2024). While general translation capabilities are impressive for many high-resource and even some less-resourced languages, many MT systems commonly fail when dealing with specialized vocabulary or other rare peculiarities. We have noticed that some commonly used systems seem more prone to making errors when the topic is sports than for other common topics in the media. To investigate this further we built a test suite and submitted it to the WMT 2025 Test Suite subtask (Kocmi et al., 2025a). We compile a list of segments discussing five different sports: Basketball, football, golf, gymnastics and chess. These are international sports that are popular and have been played in Iceland for decades. As a result, these sports often have a well-established and diverse vocabulary that many speakers need to agree upon. It is therefore important that different translation systems apply vocabulary that is known and in actual use by speakers in order to translate sports texts successfully. Additionally, while "new" sports known from abroad start being played in Iceland, the vocabulary may consist of a somewhat high proportion of loanwords adapted to Icelandic (using, e.g., English-oriented stems with Icelandic inflection). Vocabulary for sports that have a long history in Iceland, however, strikes a balance between using loanwords and new (and old) words applying other methods. Our test suite is made available in plain text format with term annotations as well as evaluation code on GitHub.[1]

2 Related Work

There is a long tradition of terminology work in Iceland (see, e.g., Christensen et al. 2025). The Icelandic terminology bank (Íðorðabankinn)[2] at the Árni Magnússon Institute for Icelandic Studies is the center of terminology work in Iceland. As of August 2025, it hosts more than 70 terminologies and glossaries. Most of these give translations of the terms in one or more languages, and English is usually one of them. However, only one of said terminologies and glossaries deal specifically with sports — that is the terminology on climbing.

Furthermore, even if a given translation system may contain, e.g., material from published dictionaries in its training data, its usefulness may be limited by the fact that some well-known words from sports may be missing. Also, various words generally known by speakers of English are used in a very specific sense in sports, that may differ from the general use. Such terms may have a different translation in Icelandic altogether. An example is the noun *paint*, as in *The paint is wet*. In basketball, this refers to a specific place on a basketball court. Whereas *paint* in a general sense could be translated as 'málning' in Icelandic, in the basketball sense it can be translated as 'teigur, vítateigur', meaning something like 'free-throw lane', or even

Sport	Segments	Words/Segment	Unique Terms	Repeated Terms
Football	100	26.7	196	94
Basketball	100	31.8	154	89
Chess	50	18.7	67	4
Gymnastics	25	20.5	46	10
Golf	25	34.5	48	14

Table 1: Number of segments, average length of segments, number of terms and how many terms are repeated in the segments. 142 unique terms are repeated in the test suite, some more than once.

as 'undir körfunni', meaning 'below/under the basket'.

We therefore find it interesting — and challenging — to look into vocabulary that may not be very well documented in lexicographic works. However, at least some of the vocabulary can be found in texts online, e.g., in corpora such as Tímarit.is[3] (e.g., Hrafnkelsson and Sævarsson 2014) and the Icelandic Gigaword Corpus[4] (Steingrímsson et al., 2018; Barkarson et al., 2022).

Knowles et al. (2023) study the performance of NMT systems at handling terminology and find that the systems are twice as likely as humans to commit terminology errors in the Hansard corpus. They measure the accuracy by counting the occurrences and translations of unique terms. In the shared task on machine translation with terminologies at WMT 2023, three evaluation approaches were used (Semenov et al., 2023): Standard metrics to evaluate general translation quality, COMET (Rei et al., 2020) and ChrF (Popović, 2015); Term success rate, or accuracy, was calculated by comparing machine-translated terms with their dictionary equivalents; Term consistency was measured to investigate whether technical terms were translated uniformly across the entire corpus.

At WMT 2024, two submissions specifically looked at problems in translating between English and Icelandic. The GenderQueer test suite (Friðriksdóttir, 2024) is built to investigate gender-inclusive translation and whether such translations are appropriate. Ármannsson et al. (2024) uses a keyword-based evaluation to check how adept MT systems are at translating idiomatic expressions and proper names.

English Segment	Icelandic Terms
She remembers when she started learning a **kip** during her first week of **bars**.	[kippur, langkippur] tvíslá

Table 2: An English segment containing sport terms, and their Icelandic counterparts.

3 Test Suite and Translations

The test suite consists of 300 segments in total, divided into five documents. The segments can be sentences or short paragraphs containing a few sentences. An example of a segment from gymnastics is shown in Table 2.

3.1 The Dataset

We decided to select popular and well-established sports for the test suite. Football (soccer in the USA) has a more than 100-year history in Iceland with the first rule book being published in 1907 (*Knattspyrnulög* 1907, Jasonarson 2025). Football is hugely popular in Iceland with a lot of coverage in the news, online and in various podcasts. Football games are broadcast live with Icelandic commentary, including games in the Icelandic divisions, games played in the biggest leagues in the world and games played by national teams. Written live commentary is also available, especially from the Icelandic leagues. There is definitely no shortage of texts if one wants to study the grammar and vocabulary of football.

We also include 100 segments of texts on basketball — another very popular sport with a lot of media coverage — whereas we have fewer segments for chess (50), golf (25) and gymnastics (25). This could have been done differently but instead of focusing on, e.g., two sports, we went for covering five, with three of them having fewer segments.

By having more text from football and basketball, we can evaluate consistency in recurring terms but there are fewer terms that occur more than once in the chess, golf and gymnastics set. Table 1 shows the number of segments, length of segments and number of terms covered for each sport represented in the test suite.

We selected sentences containing sports terminology from news reports and other sports-related coverage to ensure a varied distribution of vocabulary. Certain terms were intentionally repeated to allow for examination of model consistency. To preserve the original meaning when extracting sentences from their context, minimal edits were applied, such as shortening or rephrasing.

We mark the terms in each segment and register the Icelandic equivalent. This information is used for automatic evaluation of MT systems when applied to the test suite. Following Ármannsson et al. (2024), we carry out a keyword-based evaluation and compare the results to a manually evaluated sample to inspect whether the automatic approach judges the systems in a way close to what humans would do.

3.2 The Work Process

When creating the test suite and evaluating the different translation systems, the work process was as follows. First of all, we gathered the actual English data, with the goal of creating 300 segments. These range from single sentences to short paragraphs consisting of a few sentences. The majority of the data are real examples found through various online sources, although we have in some cases simplified them somewhat or added a bit of context to make it clear what sport is being discussed. A few of the sentences are purely synthetic.

When we were collecting the data, we picked out term candidates and assigned them translations. When finalizing the list of terms, one of the authors read through all the segments and inspected the term candidates with the goal of limiting internal discrepancy in the translations of a term that occurs more than one time in each sport. However, in order to reduce the impact of a single term on the overall outcome, he tried to limit the occurrences of a single term within a single sport to three. Even if a term together with its translation occurs three times in one sport, that term may also be found in the list within a different sport. An example is *penalty* which is a term in football and golf. While it can be translated as 'víti' in both sports, we also translate it as 'vítaspyrna' in football and 'refsing' in golf. 'Refsing' would not work as a translation for *penalty* in football and likewise, e.g., 'vítaspyrna' would not work as a translation of the word in golf (the head noun of the compound *vítaspyrna* is *spyrna* 'kick'). Furthermore, some terms occur as a noun and a verb within a single sport. An example is *foul*. We decided to count the occurrences of it as a noun separately from when it occurs as a verb, meaning that it may be found three times as a noun and three times as a verb in one and the same sport. Also, we treat the noun *foul* in basketball separately from, e.g., the term *technical foul*.

When the list of terms had been finalized, another author ran the data through automatic evaluation and prepared a document for two of the authors, different from the two already mentioned, for manual evaluation. The evaluation process is described and discussed in Section 4.

3.3 Problematic Translations

We evaluate translations generated by 34 MT systems. Out of the 34 systems, we received the original test suite segmentation from 15 systems, i.e. 300 segments with a 1-to-1 mapping to our original segments. The other 19 systems delivered more or fewer segments. For two systems, IR-MultiagentMT and ONLINE-B, all text for each sport was translated as one document and we recieved the translations as 5 lines, one for each document. For these documents we segmented the text using NLTK (Bird and Loper, 2004) and then used SentAlign (Steingrímsson et al., 2023) to match the translations to the correct segments. We fixed the other outputs mostly manually in order to be able to carry out our automatic evaluation approach. Table 3 lists the systems we fixed the output for, explains what was out of order and how we fixed it. In many cases the root of the problem seems to be the inability of the systems to translate long documents so they fail on multiple translations due to that.

4 Evaluation Methodology

4.1 Automatic Evaluation

We employ a rather simplistic approach to automatic evaluation. For each segment in our test suite, the English terms have been identified and their Icelandic counterparts registered.

System Name	Lines	Problem	Fix
Erlendur	300	Incorrect order.	Manually
IR-MultiagentMT	5	Documents returned as one line.	SentAlign
Mistral-Medium	302	Split segments.	Manually
ONLINE-B	5	Documents returned as one line.	SentAlign
UvA-MT	100	Many lines missing. Translated as documents but seems to stop after approx. 15 sentences in each document.	Manually
TowerPlus-72B	264	Many lines missing. Fails on long documents, gets stuck in a loop and starts repeating previous translations.	Manually
Qwen2-235B	221	Many lines missing for basketball.	Manually
Llama-4-Maverick	329	Many football segments split.	SentAlign
IRB-MT	593	Football starts repeating in a loop when 12 sentences are left, thus only contains 288 valid translations in total.	Manually
GemTrans	343	Football starts repeating itself when two lines are left, we remove all text produced after repetitions start.	Manually
Gemma-3-27B	301	Split segments.	Manually
Gemma-3-12B	303	Split segments.	Manually
EuroLLM-22B	199	All football in one line. (Translations in Swedish, not Icelandic.)	Manually
EuroLLM-9B	176	Gymnastics in one line. Football missing. (Translations in Swedish, not Icelandic.)	Manually
DeepSeek-V3	197	Basketball and football fails because the document is too long. Translations missing for these two sports.	Manually
CommandR7B	277	Multiple errors. Gymnastics don't finish but start repeating previous translations. Basketball translations phrased like headlines (and in German, not Icelandic).	Manually
CommandA	293	Some basketball translations missing.	Manually
AyaExpanse-32B	299	Missing translations.	Manually
AyaExpanse-8B	241	Many missing translations. Some translations repeated.	Manually

Table 3: The submissions by some of the MT systems did not contain the same number of lines as our test suite did. Section 3.3 describes how we tried to align the source to the correct translated segments.

Table 4: Automatic evaluation of each model across categories. The systems are in order of overall accuracy, with the highest scoring system being the only one that translated more than 50% of terms correctly. Accuracy is the ratio of correct translations to total term occurrences. The highest score for each domain is in bold letters.

We use these keywords when evaluating, by inspecting each translated segment and checking whether it contains the expected Icelandic term or terms. As Icelandic is an inflected language, we must consider all possible forms of the terms. For terms consisting only of one word, we look up all possible forms of the word in DIM, the Database of Icelandic Morphology (Bjarnadóttir et al., 2019), and if it is not found there, we manually list the forms. For multiword terms we manually create possible forms and list them. If any form of the term is found in the translation we count that as correct. We expect this approach to give us a close approximation of how correctly the MT systems translate the terminology. In some cases though, correct forms of terms may be missing, or a form is used that might make the translation ambiguous or wrong although our approach marks it as correct. There may also be variations of some terms, that we do not register but would be considered correct by a human judge. In order to inspect how close the automatic evaluation is to human judgments, we carry out a manual evaluation for comparison.

4.2 Manual Evaluation

For manual evaluation, we randomly sample segments from all five subdomains, depending on how many sentences they have in the test suite. For basketball and football we select 10 segments, 7 segments for chess and 5 for golf and gymnastics. We then collect translations for these segments from all evaluated systems. Human evaluators judge the translations and check if the term is correctly translated, without regard to the registered Icelandic term translations. Scores for each system are given as a percentage of correctly translated terms.

5 Results

We report on the results of our automatic evaluation approach and manual evaluation and compare the outcomes. In Section 3.3 we discuss how the outputs of some systems were problematic. In the results tables, we tag the systems that may be at a disadvantage due to other reasons than just their capability in translating from English into Icelandic. We use two tags: ■ for translations that had missing lines or repetitions, possibly because all segments for a given sport were being translated as one document, but the model failed to handle such long documents, and ★ for translations where we had to run sentence alignment to match translations to the original segments. These tagged systems may score lower than expected, when compared to the results in the general translation task (Kocmi et al., 2025b,a), in most cases likely due to inability to handle long documents. Two of the three systems that we realigned using SentAlign, ONLINE-B and Llama-4-Maverick, seem to score similarly to the systems in the general translation task, so splitting up and realigning may have had minimal effects in these cases.

5.1 Automatic Evaluation

We find that according to our automatic evaluation, see Table 4, only one system manages to translate over 50% of the terms correctly. This system, Gemini-2.5-Pro, also scores highest in all domains except for golf, where it has the second highest score. There is a markedly large difference between the highest scoring system and the next, but the systems in second to fourth place are not very far from each other.

It is also noteworthy that there can be a large difference between systems within domains, while the difference on average is not substantial. Only six systems translate more than 25% of the chess terms correctly, while half or more reach that threshold for basketball, football and golf. In spite of that two systems translate almost over 60% of the chess terms correctly.

We also looked at terms that occur twice or more in the test suite and inspected whether the ones that were translated correctly at least once were consistently translated correctly. Table 5 shows that this was rarely the case, with only two systems consistently translating over 50% of these terms correctly. This is a disappointment, as it indicates that even when a system translates the terminology correctly, it may be incidental.

5.2 Manual Evaluation

The results of the manual evaluation are given in Table 6. While there is a general consensus between the automatic and manual evaluation with respect to the order of best systems, there are some variations. The highest scoring system in the automatic evaluation, by a good margin, switches seat with the second best system in the manual evaluation. This being said, the sample was much smaller in the manual evaluation, with only 77 terms being checked in 37 segments. The difference between the top systems is thus only one correct translation.

Table 6: Manual evaluation of a sample of translations from each system.

The accuracy in the manual evaluation is higher than in the automatic one. This could be expected as it is likely that some word forms or variations of the terms are not registered in our lists even though a human would consider them correct and mark them as such when evaluating them. Even though the manual evaluation paints a prettier picture in this regard, it shows, like the automatic evaluation, that even the best systems are still failing quite often when translating this specialized, but common, vocabulary.

6 Limitations

There are various limitations to the current work, some of which are discussed below.

In various segments, the English terms are a part of a larger compound. We have tried to avoid including such compounds as listed terms in some places but where we think it is appropriate, we try

to make the translated terms capture this fact. An example is the term *point guard*, which is translated as 'leikstjórnandi, ás'. However, in one segment, *point guard* is part of the compound ***star** point guard*.[5] In addition to the translations 'leikstjórnandi, ás', we include '**stjörnu**leikstjórnandi, **stjörnu**ás'. When translating to Icelandic, English compounds can sometimes be reworded as a phrase rather than a single compound. An example is *Liverpool supporter* which appears in one of the segments in our football set. *Supporter* is a term in the set and one of the translations we give for it is 'stuðningsmaður'. By rephrasing we could translate *Liverpool supporter* as 'stuðningsmaður Liverpool', meaning 'a supporter of Liverpool', but if we would insist on translating it as a compound, we could translate it as 'Liverpool-stuðningsmaður' — and we give that as a possibility in our test suite in that particular segment. In some cases, however, we may have failed to notice that a term is a part of a compound but when a translation system translates the whole term as "one" word (without spaces or without rephrasing) the automatic evaluation would mark it as incorrect. A dataset with more synthetic data could more easily avoid such compounds.

The manual evaluation makes it clear that we miss out various translation possibilities we did not think of, showing that the automatic evaluation is limited. Furthermore, only one annotator evaluated each translation. If multiple annotators would have evaluated the same translations they would possibly have had some disagreements. That would also have allowed us to calculate inter-annotator agreement, which could give us an indication of whether a manual evaluation such as the one we carried out is straightforward or whether it demands multiple annotators for each segment.

We try to reflect actual use in our translations. That is not an easy task, especially when term use in written texts, such as in fairly formal news coverage, differs from spoken language use. An example might be *layup* in basketball which we only translate as 'sniðskot'. However, searching for a string starting with "layup" in the Icelandic Gigaword Corpus gives 219 results. 'Sniðskot' has a formal feel to it but it captures the English term. Sometimes, however, we were not sure whether the Icelandic translation captures it completely or is well-known enough. An example is the basketball term *screen*, which occurs as a noun in the test suite and is translated as 'hindrun' in the Icelandic version of the FIBA basketball rule book;[6] we made the decision to give an Icelandic spelling version of *screen*, i.e., 'skrín', in addition to 'hindrun' which goes back centuries in the language and can be translated as 'hindrance, obstacle', even though we translated *layup* as 'sniðskot' only (a relatively new compound in the language whose head is *skot*, meaning 'shot'). Further work that takes a closer look at the actual usage would be interesting and working with professionals in each sport on the translations of the terms would be ideal.

Which words should be given as terms in a work like this can be debated. We have the verb and the noun *win* in various places listed as terms but as winning is not specifically found in one sport but not the other we might want to exclude some such words when we are exploring a translation system's ability to translate the vocabulary in a certain branch of sport. The same goes for, e.g., parts of the body: A word like *shin* is probably used more in a sport like football than golf but, nevertheless, one could certainly disagree with our decision of leaving that in as a football term in our dataset.

As natural data are the bulk of segments in the test suite, it is not always clear from the segment's context alone what the sport in question is. In a few places, we added information in the segments. Instead of using the original unchanged in the segment *A screen is the legal action of a player who, without causing undue contact, delays or prevents an opponent from reaching a desired position* we added "In basketball" to make it clear what the sport is: ***In basketball**, a screen is the legal action of a player who, without causing undue contact, delays or prevents an opponent from reaching a desired position*. However, we did not generally focus on this when finalizing the dataset and what impact this has on the translation scores merits further study. Moreover, a synthetic dataset could control for this.

[5] Note that although the term *point guard* is a compound on its own, we focus here on *star* + *point guard*, where only *point guard* is a term according to our dataset and not the whole compound *star point guard*.

[6] See, e.g., the 2017 version here: https://www.kki.is/library/Skrar/Leikreglur_i_Korfuknattleik_2018.pdf.

7 Conclusions and Future Work

Overall, the results indicate that more attention needs to be paid to the language of sports in LLMs and MT and the generally low scores confirmed our suspicion that MT systems have a hard time at translating sports texts adequately. Even the highest scoring systems do not do a very good job at translating the language of sports, and in all cases consistency is lacking.

Categorizing the errors could be useful for analyzing comparative differences between system types. Such categorization could also be useful for building MT systems better suited for translating sports language.

We intend to use our test suite to automatically evaluate new systems and keep track of their competence in translating sports terminology. While the sports we selected are some of the most popular ones that have a specialized vocabulary in Icelandic, expanding the test suite by adding more sports could be useful. Covering the terminology of each sport more thoroughly could help us get more accurate results and having at least two occurrences of each term could make our consistency evaluation more precise. It would also be interesting to translate the keyword list into more languages than Icelandic to investigate whether this problem is specific to Icelandic.

Acknowledgments

This project was funded by the Language Technology Programme for Icelandic 2024–2026. The programme, which is managed and coordinated by Almannarómur, is funded by the Icelandic Ministry of Culture, Innovation and Higher Education.

We thank Árni Jóhannsson, Eiríkur Stefán Ásgeirsson and Jóhannes Gísli Jónsson for answering questions on specific terms relating to basketball, golf and chess, respectively. Fine-Grained Evaluation of English-Russian MT in 2025: Linguistic Challenges Mirroring Human Translator Training

Abstract

We analyze how English–Russian machine translation (MT) systems submitted to WMT25 perform on linguistically challenging translation tasks, similar to problems used in university professional translator training. We assessed the ten top-performing systems using a fine-grained test suite containing 465 manually devised test items, which cover 55 lexical, grammatical, and discourse phenomena, in 13 categories. By applying pass/fail rules with human adjudication and micro/macro aggregates, we observe three performance tiers. Compared with the official WMT25 ranking, our ranking broadly aligns but reveals notable shifts.

Our findings show that in 2025, even top-performing MT systems still struggle with translation problems that require deep understanding and rephrasing, much like human novices do. The best systems exhibit creativity and can be very good at handling such challenges, often producing more natural translations rather than producing word-for-word renditions. However, persistent structural and lexical problems remain: literal word order carry-overs, misused verb forms, and rigid phrase translations were common, mirroring errors typically seen in beginner translator assignments.

1 Introduction

Unlike standard test sets, which consist of randomly selected source material, a test suite contains 'extra-credit' problems: the source items, deliberately designed to be challenging in translation, similar to the 'rich points' method (Nord, 1997) or preselected items method (Egdom et al., 2019) in translator training. These focused items are often lexical units or grammatical structures requiring non-literal approaches based on deep situational understanding and coherent target-language encoding. Successful translations are expected to abstract away from source form, displaying both familiarity with standard translation techniques and creativity in adapting them to individual contexts. While isomorphic translations may be formally grammatical, they are typically judged suboptimal. In translation didactics, such tasks test translators' ability to identify and resolve translation problems.

The fine-grained linguistic test suite has been partially in development over the last few years (Macketanz et al., 2022; Manakhimova et al., 2023, 2024).[1] Its original purpose was to track MT systems' ability to handle specific source language phenomena, with evaluation strategies focused on translating those targeted items. This approach provides valuable, fine-grained insights into MT systems, highlighting system strengths across a wide range of phenomena and establishing objective grounds for comparison. However, the recent dominance of large language models (LLMs) in MT has prompted us to reconceptualize the test suite's role. Beyond its original function of testing specific linguistic categories, we also view it as a **diagnostic tool for identifying overarching translation challenges** that persist across current English–Russian MT systems. This evolution reflects the need to understand systemic issues in MT. Accordingly, we have tightened **our quality requirements to match those of a university professional translation training**. Our evaluation focus has shifted from assessing the handling of specific linguistic categories to evaluating overall translation quality when processing these 'extra-credit' problems. We no longer make concessions for 'gist translation quality,' instead expecting the publication-standard quality of human translation as defined by Ahrenberg (2017, p. 21). This refined approach maintains our ability to compare systems based on the ratio of successfully handled

[1]The wider project also maintains suites for other directions (e.g., German-English, English–German, English–Portuguese in Avramidis et al., 2020; Macketanz et al., 2021; Avelino et al., 2022), which we do not analyze here.

Proceedings of the Tenth Conference on Machine Translation, pages 866–877
November 8-9, 2025

items across the entire test suite, while simultaneously revealing persistent issues and blind spots that transcend formal categories. We supplement our qualitative analysis with statistical results and system rankings, comparing these findings with WMT's official human evaluation.

2 Method

2.1 Test suite overview

For the English–Russian part of the test suite, the 13 evaluation categories cover a broad range of translation challenges. They include ambiguity, collocations, compounds, false friends, and multi-word expressions, which test lexical precision. Morphosyntactic control is addressed through case government, function words, passive voice, subordination, and verb valency. The suite also targets discourse as well as stylistic aspects via personal pronoun coreference and onomatopoeia. Together, these categories span the main lexical, grammatical, and pragmatic difficulties that can arise when translating from English to Russian.

Test items consist of one (or occasionally more) source sentence(s) plus an associated set of evaluation rules. These rules comprise hand-crafted regular expressions and fixed strings of translation outputs. Test items are either created manually by linguists or sourced from existing corpora and curated for the target phenomenon. An ideal example for a test suite should require the interpretation of the message and deep restructuring in the target language without being vague or context-dependent. Such examples also give rise to greater variability in translation, and can be identified as having a higher entropy of translation solutions, a known measure of the source item difficulty in translation (Carl and Schaeffer, 2017; Wei, 2022; Kunilovskaya et al., 2025). Examples from the *Resultative* subcategory (category: Verb valency) seem to represent true challenges in the English–Russian translation. For example, *The skiers skied the trail clean of snow.*

As MT technology has shifted from phrase-based systems to NMT and now LLMs, error profiles have also changed. The suite has therefore been revised over time: we have added phenomena, increased item counts, and introduced longer or structurally richer sentences to stress contemporary systems. MT outputs, after being evaluated by the test suite, have also been utilized to create challenge sets for WMT metrics (Avramidis et al., 2023, 2024). This year's revision of the test suite excluded several items that either misrepresented their category or lacked context independence to be fairly evaluated.

Given the increased variation in translation solutions offered by the submitted systems, the automatic pass-fail rules and annotation guidelines were tightened this year to reflect the requirements that would be applied to translations considered as part of a university professional translator training.

2.2 Scoring

The evaluation results for the categorized items are produced semi-automatically: hand-written regular expressions as well as fixed strings (correct and incorrect translations from earlier MT system outputs) capture expected *correct* and *incorrect* renderings, and any remaining cases are adjudicated by a linguist. Regular-expression design leverages prior experience with MT outputs and aims to maximize coverage; however, novel outputs routinely require human judgment.

Since this evaluation aims to compare the systems fairly, only the test items that have a valid judgment for all systems are included in the calculation. If a test item has a judgment neither by regular expressions nor by the annotators for any MT systems, we exclude it from the calculation. As a result, not all test items that had originally been designed can be used in our calculations.

For system comparison, we first identify the highest-scoring system and then test all others against it using a one-tailed Z-test with $\alpha = 0.95$. Systems not significantly worse than the top system form the first performance cluster; we mark the best systems in bold in the result tables. Because categories and phenomena (subcategories) differ in size, we report three complementary aggregates: micro-average (accuracy over all items, item-weighted), category macro-average (mean of category-level accuracies), and phenomenon macro-average (mean of phenomenon-level accuracies).

2.3 Manual annotation procedure

This year marks the third evaluation of English–Russian systems using our test suite. As in previous years, manual intervention was necessary to process system outputs that could not be automatically evaluated. At the beginning of this year's evaluation, this referred to 44.83% of outputs on average. Three annotators divided the workload,

with each responsible for a disjoint subset of the data.

We did not compute inter-annotator agreement (IAA), as the evaluation workflow did not involve multiple annotators independently labeling the same outputs. Instead of computing IAA, we relied on the extensive, linguistically motivated rule set refined over several years. These rules served as a shared reference, reducing subjectivity; borderline cases were resolved in group discussion.

Annotators were instructed to focus on the targeted source-language phenomenon, provided that a translation candidate meets basic standards of accuracy and fluency. Above all, the translation should faithfully convey the original message while adhering to the norms and conventions of the target language.

The evaluation is relative: in disputable cases, comparing translation candidates helps determine what is achievable for a given item. In professional translator training, it is common to assess solutions against available or hypothesized alternatives. For example, Bittner (2020, p. 172) observes: *"Good translation quality can only be better translation quality, just as bad translation quality can only be worse translation quality. There is no use dismissing a translation solution as unacceptable unless a better alternative can be produced."* At the same time, it is possible that none of the proposed solutions is acceptable, or that two solutions using different techniques are equally valid.

When a source item is aimed at evaluating more than one phenomenon, a translation is considered correct even if some parts are suboptimal (but not unacceptable). This ensures that effective strategies and creative handling of the target phenomenon are recognized. To illustrate the kinds of defects that were tolerated, consider Example (1), where the source is categorized as *Modifying Comparison* and both translations are accepted as correct. The second version, however, is preferable: it omits the possessive pronoun её ("her") in the subordinate clause, avoids semantic tautology in rendering *expertise*, and dispenses with the redundant demonstrative pronoun того. Importantly, both variants successfully address the lexical challenges that weaker systems often mishandle. For instance, many systems reproduced the English collocation *extensive level of expertise* as обширный уровень экспертизы.

(1) Her level of expertise was not as extensive as her employer had hoped.

a. Уровень её профессиональной квалификации оказался не таким высоким, как того ожидал её работодатель.

b. Уровень её квалификации оказался не таким высоким, как надеялся работодатель.

In cases where the source was ambiguous or difficult to interpret (e.g., *he ran under the porch*), a translation was judged correct if it provided a plausible and contextually logical reading consistent with real-world knowledge. For example, он (по)бежал под крыльцо for the source above remains questionable.

Although the items are designed to be context-independent, some may admit multiple interpretations in a broader context. In such cases, evaluation favors the most prototypical or expected reading, while unusual or exotic contexts are disregarded. Finally, translations that ignore potential of the target language for optimal information packaging – often requiring creative reconceptualization of the message – and instead follow the source language structures in a routine, linear manner, were not accepted. They might be grammatically correct, but in dissonance with the conventional usage of the target language.

2.4 Experiment Setup

Although the full test suite was applied to 42 systems submitted to the WMT25 Shared Task, this paper reports statistical comparisons for a representative subset of 10 systems. The selection is based on the official Error Span Annotation

3 Results

3.1 System Performance Overview

This section reports system-level performance (overview and hierarchy) and category-level difficulty, following the scoring protocol in Section 2.2 Aggregate accuracies per system and per category/phenomenon are provided in the Appendix tables, along with the test suite system ranking and the official WMT25 ranking (Kocmi et al., 2025b).

The performance distribution reveals three distinct tiers: high performers Wenyiil (Wang, 2025), Algharb (Xu, 2025), Yandex (Karpachev et al., 2025), and Gemini (Finkelstein et al., 2025);

mid-tier systems Claude-4, DeepSeek-V3, GPT-4.1, and Shy-hunyuan-MT (Zheng et al., 2025, 89.4–91.9%); and lower-tier systems CommandA (Kocmi et al., 2025a) and UvA-MT (Wu et al., 2025, 83.2–88.4%).

Compared to the WMT25 official ESA ranking, Yandex moves from the 8–10 cluster into the top cluster. Conversely, Shy-hunyuan-MT-hunyuan-MT, ranked 2 under ESA, falls into the middle cluster in our suite, Claude-4 and GPT-4.1 also belong to the middle cluster; both exhibit the same weakness on verb semantics (71.4%), and GPT-4.1 additionally scores low on long-distance dependencies and interrogatives (81.5%).

Peformance of Constrained vs. unconstrained models. In our test suite, constrained MT systems frequently occupy the top cluster, consistent with scoring that rewards precise handling of hard, localized phenomena and conservative choices under ambiguity. In the WMT25 official ranking, however, unconstrained systems rise, reflecting strengths in fluency, stylistic naturalness, and document-level coherence. Systems that bridge both profiles narrow the gap between the two.

3.2 Category Difficulty Analysis

MWE represents the most challenging category with only 80.4% average accuracy across all systems, followed by *Verb semantics* (81.4%) and *Verb valency* (87.4%). These categories demonstrate the complexity of handling idiomatic expressions and verb–argument structures in English–Russian translation. Conversely, *Lexical Ambiguity* proves easiest (97.0% average), with eight systems achieving perfect scores, indicating strong disambiguation capabilities across translation systems. *Function words* and *Subordination* also show high accuracy (93.6% and 94.3% respectively), suggesting robust handling of grammatical structures.

Verb semantics exhibits the largest performance gap (57.1%) between systems, with Wenyiil achieving 100% while UvAMT manages only 42.9%.

3.3 Linguistic Analysis

In this section, we summarize the overall patterns and translation strategies revealed in the manual analysis, along with some notable peculiarities of individual systems. We then turn to the most persistent challenges: (a) difficulties rooted in English source structures and (b) recurring problems with Russian target-language conventions that MT systems struggle to master. None of the highlighted issues is ubiquitous; for each example, we provide a more acceptable version drawn from the available translations. Translations marked with an asterisk are considered suboptimal. Generally, a comparison with previous years' submissions indicates noticeable improvements across most problem areas.

Overall translation patterns. This paragraph offers some high-level observations from annotating the 2025 submissions in comparison with previous years. We note an improvement in the variation of generated output, suggesting greater creativity and a stronger ability to recast the original message in new forms, rather than reproducing the formal and semantic structures of the source language.

Translations from the strongest 2025 systems demonstrate an increased capacity to do what the test suite examples force them to do: they **move beyond literal translation** and re-package the original message into a form that is natural in the target language. For a human translator, accomplishing this requires careful extraction of the intended meaning, imagining the described real-world situation, and expressing it in a way that aligns with conventional norms and expectations. The distinction between a literal strategy and a more interpretative approach is illustrated in Example (2). The example highlights the ability of the system to infer the contextual meaning of the descriptive verb "shuddered" and generate a plausible rendering of the situation.

(2) They shuddered home under the hailstorm.
   a. Они брели домой под градом, ежась от холода.
   b. *Они дрожащими вернулись домой под градом.

Re-creating a situation in another language may require modifying the set of properties by which it is recognized in the target language. In 2025, automatic translation systems are better at adding necessary elements and omitting redundant ones. For instance, *he's a fabulous inspiration* is rendered as он потрясающий <источник> вдохновения, while *Many people are concerned about High Street* becomes Многих беспокоит <состояние> главной улицы.

The ability of a system to take context into account and coordinate elements into a coherent

whole can also be observed at the sentence level. The source in Example (3) evokes a snapshot-like scene. Re-creating this scene in Russian requires abandoning the English mode of depiction and adopting a different strategy in the second clause. The asterisked translation illustrates a common problem: mismatched aspect forms in coordinated verbs, which disrupts the natural flow of information.

(3) Paula entered the small souvenir shop and took her time browsing through the magazines.
   a. Паула зашла в небольшой сувенирный магазин и принялась рассматривать журналы.
   b. *Паула вошла в небольшой сувенирный магазин и не спеша просматривала журналы.

This enhanced interpretative capacity reflects greater sensitivity to the functional potential of expressive means and the ability to deploy alternative but appropriate forms in the target language. As illustrated in Example (4), Algharb recognizes that paired synonyms are typical in English but generally avoided in Russian, while in Example (5), Algharb creatively re-packages the information to arrive at a conventional Russian rendition.

(4) Despite the neat and tidy ending to Season 3 . . .
   a. Несмотря на вполне законченную концовку третьего сезона, . . .

(5) . . . there was a delivery charge on top.
   a. . . . к сумме добавилась плата за доставку.

These examples are presented to highlight some of the advances in the technology. At the same time, they do not provide a complete picture, as persistent problems remain.

Where possible, the same systems resort to suboptimal **crude unpacking of English secondary predicates into full clauses**, producing wordy, redundant, and clumsy (but not ungrammatical) sentences. This strategy disrupts the information flow: in discourse, each full predicate conventionally signals a step forward in the narrative. By upgrading secondary predicates to main clauses, the translation introduces artificial shifts in topic–comment structure, resulting in unmotivated changes of focus and sentences that can appear contradictory or unclear. It is not uncommon that this tendency is coupled with a known redundancy of functional words such as auxiliaries, pronouns, and connectives (esp. consecutive connectives перед тем как, после того как).

Newer systems increasingly prefer **gender-neutral realization in the cases where gender is not explicit**, e.g. in generic contexts or in first person in Russian outputs. In contrast to English, Russian has explicit grammatical gender marking not only on pronouns, but also on past verb forms, participles, and adjectives. They are congruent with subjects. In contrast to previous years, systems for the first time consistently produced *explicit inclusive* forms, i.e., forms that include both masculine and feminine forms: купил(а) (“bought (m/f)”), мог(ла) (“could (m/f)”), готов(а) (“ready (m/f)”). The pattern is consistent across 33 systems (out of 42 evaluated systems) and various categories, indicating that newer models increasingly prefer gender-neutral realizations. Additionally, some systems (GPT-4.1, Algharb, Gemini) demonstrate the use of gendered profession names where the associated person is female (учительница, предпринимательница).

When faced with a **faulty input**, some models return a translation of the more plausible corrected source version, like a human translator would do. This is counteracting the automated tendency known as ‘garbage in, garbage out’.

Source challenges and target issues. In this part of the analysis, we first describe recurrent and problematic translation patterns in Russian that are triggered by specific source-language items. We then turn to a second group: target-language categories that consistently prove difficult for MT systems regardless the source.

(a) Source phenomena as error triggers. The most prominent defects in automatic translation stem from the literal transfer of source-language lexical and grammatical features. In particular, we highlight issues arising from (i) reproducing the word order of the source sentence, (ii) neglecting the contrastive use of pronouns and connectives, and (iii) calquing lexical frequency patterns and collocations. These problems complement those discussed in Section 3.2.

Unlike English, Russian relies heavily on **word order** to structure information. The most important, focused information typically occurs at the end of a

sentence, whereas English allows more flexibility; the sentence-final position in English can be filled with adverbials of time and place, prepositional objects, and other elements. Failure to identify the focused element in the English source and promote it to the sentence-final position in Russian, therefore, disrupts the natural flow of information, even in isolated sentences. A typical case is presented in Example (6). The topical sentence member им ("them") is awkward at the end of the Russian sentence in (6-b).

(6) When students walk into our classrooms, the course objectives are given to them right up front.
   a. Когда студенты заходят в наши аудитории, им сразу же сообщают цели курса.
   b. *Когда студенты заходят в наши аудитории, цели курса сразу же сообщаются <им>.

Misalignment in information structure is particularly noticeable in cleft sentences (e.g., *It wasn't until ...*) and elliptical constructions (e.g., *She asked the kids to stay, and the adults too; Laura drank the milk last night, or perhaps the juice; I met Aisha yesterday, but not her daughter*). As illustrated in Example (7), failing to place emphasized information at the end produces sentences like in (7-b) that are immediately recognizable as translations.

(7) After all it was not war that completely ravaged East Asian states in 1997.
   a. В конце концов, в 1997 году государства Восточной Азии разорила вовсе не война.
   b. *В конце концов, это была не война, которая полностью опустошила восточноазиатские государства в 1997 году.

Automatic translations into Russian often **overuse possessive pronouns**, mirroring their higher frequency in English. Example (8) shows sentences where *their* is rendered as <их> in Russian. While grammatically correct, these translations add possessive markers that a human translator would likely omit, resulting in a style that is formally acceptable but less natural (see also Example (1)).

(8) Despite <their> intense feelings for one another, it seems as though the two heroes might never remain together.
   a. Несмотря на <их> сильные чувства друг к другу, кажется, что этим двум героям никогда не быть вместе.

Indefinite pronouns (someone, anywhere, every, all) also contribute to a significant level of disfluency in machine translation. The apparent one-to-one correspondences have different usage patterns and frequencies (every $\neq$ каждый, all $\neq$ все).

Finally, **lexical problems** – the choice of words, collocation and idioms – are as pervasive as structural difficulties. Occasionally, many systems would find a particular word in the source language difficult and fall victim to literal translation, false friends, undetected idioms or terms. Example (9) shows a typical MT output, where sponsor is translated as спонсор. At the same time, in Russian, this word and derivatives from the same root rarely carry the "legislative initiator" meaning.

(9) They persuaded Kennedy and some other Senator to jointly sponsor the legislation, but I can't remember which one.
   a. *Они убедили Кеннеди и ещё одного сенатора совместно выступить спонсорами законопроекта, но я не помню, кого именно.

The hallmark of low-quality machine translation is translating every occurrence of *enjoy* with наслаждаться, and *people* with люди, to give examples of typical frequency calques seen in the analysis of this year.

(b) Target phenomena as persistent difficulties. A number of Russian categories can be problematic because they are not directly marked in the source but are obligatory in Russian. These categories are known to be difficult for Russian language learners, too. For example, English often encodes *verbal aspect* (a grammatical category that characterizes an action with regard to its internal temporal structure, such as whether it is ongoing, completed, repeated, or habitual) through contextual or grammatical means, while Russian uses a *lexico-grammatical system* (perfective, imperfective verbs). The translator is compelled to make a lexical choice that cannot be carried over from the source, since the category is not explicitly expressed there. Instead, the decision must be guided

by contextual cues and world knowledge, with the challenge lying in correctly reading those signals.

Verbal aspect: Automatic translation into Russian often struggles with maintaining aspectual coherence when rendering coordinated English verbs in the past tense. In Example (10), the first translation maintains consistent temporal and aspectual framing by using two perfective verbs (раздал and получил). By contrast, the incorrect version (10-b) uses an imperfective verb (раздавал) in the first clause. This creates a mismatch with the following perfective verb, producing an incoherent sequence: the first action is presented as ongoing or habitual, while the second is punctual and bounded. The result is an aspectual clash that disrupts the event structure of the sentence.

(10) The teacher handed out worksheets, but I didn't get one.
   a. Учитель раздал рабочие листы, но мне не досталось.
   b. *Учитель раздавал рабочие листы, но я их не получил.

In Example (11), the source communicates a polite encouragement and requires an imperfective verb (снимать) used in (11-a). Translations with possessive pronouns and perfective verb (снять) are suboptimal, because they sound like a command or instruction like in (11-b).

(11) Do take your coat off.
   a. Снимайте пальто (прошу вас).
   b. *Снимите своё пальто.

Another interesting example related to aspect is given in (12). The verb разъедайтесь used in (12-b) is an imperfective form of the verb разъесться, one of the meanings of which is 'to enjoy'. However, this verb is never used in the imperfective form with this meaning. Moreover, the given example contains an idiomatic expression which should not be translated literally word by word. Instead, a corresponding idiomatic expression should be used in Russian, as in (12-a).

(12) Enjoy your meal.
   a. Приятного аппетита.
   b. *Разъедайтесь обедом.

Beyond that, this output also contained the explanation by the system: *Note "Enjoy your meal" can be translated more literally as "Eat your meal with pleasure", but* Разъедайтесь обедом *is a more common colloquial way to say it in Russian*. This explanation is wrong.

Nominalisations: One important component of human translator training is drawing attention to linguistic categories that tend to be underrepresented in translation. Based on our analysis, in MT, these include *nominalizations* and *ellipsis*.

A variety of English subordinate clauses can be rendered as nominal phrases in Russian. This strategy helps avoid unnecessary nesting and reduces sequences of functional words, such as в том, что; это что-то, над чем; до тех пор, пока, resulting in a text that reads more naturally in Russian. In Example (13), the subordinate clause *he's retired* is rendered as the phrase после завершения карьеры in the accepted translation, whereas a weaker system (13-b) fails to apply this transformation.

(13) As previously documented, he discussed what his next move will be now that he's retired from in-ring competition.
   a. Как уже сообщалось ранее, он рассказал о своих дальнейших планах после завершения карьеры рестлера.
   b. *Как было задокументировано ранее, он обсудил, каким будет его следующий шаг теперь, когда он завершил карьеру активного борца.

Finally, a translated text can often be recognized by its unnaturally complete structure, with elements such as pronouns, copula verbs, and connectives explicitly spelled out where they could easily be inferred from the context. In other words, translated language underuses ellipsis.

There is a clear distinction between weaker and stronger MT systems in this regard. Stronger systems are less likely to produce a subject in subsequent clauses when it is identical to the subject of the main clause, which aligns with natural Russian usage and enhances fluency. For example, in Мы сделаем А, как только мы получим Б ("We shall do A, as soon as we get B"), the second мы would normally be omitted. Similarly, the copula verb in sentences such as Он заметил, что она <была> печальна ("He noticed that she was sad") should be omitted; however, failure to follow this pattern is pervasive even among strong

systems. These issues rarely impede understanding and are generally tolerated in evaluation, but they signal a lack of expected quality and function as an indicator of professional translation proficiency.

Due to space constraints, this description includes only the more pervasive defects of MT. Other flaws, which we want to flag, include contrastive connectives (esp. but translated as но where а is required), confusion caused by epistemic *would* and *could*, the limited use of short adjectives in predicative function, failures to build adverbial participial clauses as required by Russian school grammar, etc.

4 Discussion: Lessons Learned

The test suite was revised to exclude items with questionable categorization or insufficient context-independence for translation in isolation. The rules have become less permissive in terms of fluency and accuracy.

There are some similarities between the translation patterns produced by NMT and by learner translators (see the detailed analysis in Kunilovskaya et al., 2023). These similarities are most visible in source-language–triggered issues, such as the placement of adverbials and prepositional objects, or the preference for analytical (instead of synthetic) forms of future and passive verbs. This points to the phenomenon of shining through (as defined by Teich, 2003), which belongs to the phenomena of translationese (Gellerstam, 1986), i.e., specific features of translated language that make it different from non-translated original language production. However, compared to human translators, NMT systems (especially those outside the top tier) more often generate sentences that obscure the message, overcomplicate structure, or introduce redundancy. Such output departs from target-language conventions in ways that sound recognizably non-human, often failing to produce a coherent text that conveys a clear, plausible situation.

We observed that the same systems might pursue different strategies depending on the conditions. Faced with the absence of isomorphic structures in the target language, they are capable of impressively creative solutions. In less demanding contexts, however, they tend to revert to routine, near-literal strategies that overlook the target language's potential for more optimal expression.

5 Conclusion

In 2025, state-of-the-art English–Russian MT presented by the latest LLM-based systems shows substantial progress in performance, yet it continues to display important weaknesses. Our fine-grained evaluation revealed that even top-performing models still falter on translations requiring deep comprehension and nuanced rephrasing, much like human novice translators. At the same time, the best systems exhibit marked improvements on such 'extra-credit' items by re-structuring and wording translations in a more natural Russian style instead of relying on word-for-word renditions. This shift toward non-literal, context-aware translation indicates that current MT can approximate some of the flexible strategies employed by skilled human translators. Notably, general-purpose LLMs (e.g., GPT-4.1, Claude-4) only attained mid-tier accuracy on our test suite, underscoring that even massive generalist models have not fully solved certain linguistic subtleties Specialized MT engines thus continue to hold an edge on fine-grained challenges, though the gap is beginning to narrow as new models adopt more human-like problem-solving approaches.

Limitations

A limitation of our current evaluation design is its reliance on a binary correctness—each test item is marked as either correct or incorrect based on regular-expression matching or manual adjudication. While this design facilitates scoring and result aggregation, it inevitably lacks the granularity needed for a more nuanced evaluation of translation quality, especially when annotators are faced with a human-like variation of MT outputs for less straightforward examples.

The second most notable limitation is the sentence-level nature of examples, which provides a reduced opportunity to track translation problems that might arise from the discourse level. It is not clear whether MT models would employ sentence splitting and merging as well as redistribution of semantics across several sentences if they were faced with larger spans of text to operate on.

Next, the test suite requires further revision to strengthen its construct validity. In particular, source items should foreground the targeted source-language phenomenon as the primary translation challenge, without being obscured by additional difficulties in other parts of the sentence, insofar as this is possible.

The current scoring approach does not differentiate sources by their translation difficulty. In future work, we plan to introduce a weighting scheme informed by the entropy of submitted translation solutions.

Acknowledgments

We would like to thank Vladimir Kropivnitskiy for his contribution to the manual annotation of the test suite this year. We would also like to thank Vivien Macketanz, Sergei Bagdasarov, Hans Uszkoreit, Aljoscha Burchardt, Ursula Strohriegel, Renlong Ai, and He Wang for their prior contributions to the creation of the test suite.

Abstract

We present the submission of the AIP team to the WMT 2025 Unified MT Evaluation Shared Task, focusing on the span-level error detection subtask. Our system emphasizes response-format design to better harness the capabilities of OpenAI's o3, the state-of-the-art reasoning LLM. To this end, we introduce Tagged Span Annotation (TSA), an annotation scheme designed to more accurately extract span-level information from the LLM. On our refined version of WMT24 ESA dataset, our reference-free method achieves an F1 score of approximately 27 for character-level label prediction, outperforming the reference-based XCOMET-XXL at approximately 17.[1]

1 Introduction

With the recent widespread use of the LLM-as-a-judge approach, research on human-like translation quality evaluation using large language models (LLMs)—such as GEMBA-DA (Kocmi and Federmann, 2023b), MQM (Kocmi and Federmann, 2023a), ESA (Zouhar et al., 2025), EAPrompt (Lu et al., 2024), and AutoMQM (Fernandes et al., 2023)—has grown rapidly. Fine-grained error detection enables explainable translation evaluation and informs the design of post-editing systems, making it widely applicable across diverse systems that leverage machine translation. Nevertheless, research on fine-grained translation error detection remains scarce; only a handful of studies exist despite growing interest. Moreover, the LLM-based studies mentioned above focused less on fine-grained error detection itself and more on using it to compute final machine translation (MT) evaluation scores. Additionally, most prior work (Kocmi and Federmann, 2023b,a; Fernandes et al., 2023) has been limited to non-reasoning LLMs. With the recent emergence of reasoning models that have achieved state-of-the-art performance across a wide range of tasks, there is, therefore, a need to investigate their use for fine-grained error detection as well.

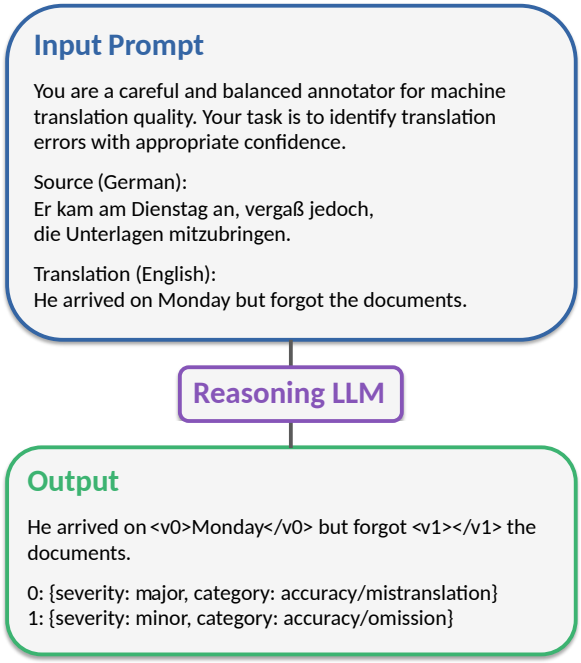

Figure 1: The overview of **Tagged Span Annotation (TSA)** system. The reference translation is *He arrived on Tuesday, but forgot to bring the documents.* The LLM tags each error span in the hypothesis with inline tags <vN> and returns a severity–category pair for every tag.

In this paper, we propose a translation error span detection system that leverages OpenAI o3 (OpenAI, 2025a), the state-of-the-art reasoning large language model, for the WMT'25 MT evaluation span-level error detection task. Our system adopts

Table 1: Span-level detection performance of TSA method compared with baseline systems on WMT24 ESA dataset six language pairs. TSA consistently achieves the highest average F1, Precision, and Recall in most languages.

structured output to ensure reliable parsing of responses and represents error locations using tagged-span annotations. On our refined version of the WMT24 ESA dataset, our reference-free system achieved an F1 score of 27.05, outperforming the reference-based XCOMET-XXL at 17.30.

2 Method

2.1 Background

Transformer-encoder approaches such as XCOMET (Guerreiro et al., 2024) typically cast span-level error detection as a token-classification task on the translation, assigning a severity label—*no-error*, *minor*, or *major*—to every token.

In generative-response settings, error spans can be expressed in three canonical ways:

(i) by returning the erroneous text itself

(ii) by providing its start- and end-character indices

(iii) by inserting inline tags directly into the translation

Method (i) is the format adopted by both GEMBA-MQM and GEMBA-ESA. In GEMBA-ESA, the returned span string is used only as a hint, and in MQM the sentence-level score is computed solely from the number of spans and their severity labels. Hence, for *sentence-level scoring* this representation is sufficient. For a *span-detection* task, however, it is inadequate: the same substring can occur multiple times in a sentence, so the actual error location remains ambiguous.

Method (ii)—returning start and end character indices looks attractive for its simplicity and precision. In practice, however, generative LLMs struggle with producing *exact* numerical values: they operate on sub-word (BPE) tokens rather than raw characters, so mapping token boundaries back to UTF-8 offsets is non-trivial (Zhang and He, 2024)

Method (iii) follows the inline-tag scheme used in the publicly released *WMT MQM Human-Evaluation* dataset (Freitag et al., 2021). In that corpus, each record contains exactly one error span; when a translation exhibits multiple errors, it is split into multiple records, each highlighting a single span.

2.2 Tagged Span Annotation (TSA)

In our system we adopt **method (iii)** and extend it with *numbered inline tags*: each error span is wrapped in a unique <v$_k$>–</v$_k$> pair, allowing multiple errors to be annotated simultaneously within the same sentence.

When a source segment is omitted in the hypothesis, we mark the omission by inserting a zero-length tag pair <v$_k$></v$_k$> at the exact insertion point.

To elicit the desired response format, we composed a detailed system prompt, supplied few-shot examples that explicitly illustrate the target schema, and leveraged the model's *structured-output* interface to guarantee machine-parseable answers. (see Appendix A; OpenAI, 2023a).

We evaluate three OpenAI models—**GPT-4.1** (OpenAI, 2025b), **o3** (OpenAI, 2025a), and **o4-mini** (OpenAI, 2025a). Decoding parameters follow the API defaults, except that GPT-4.1 uses a lower temperature of 0.2 to reduce variance.

3 Experiments

3.1 Datasets

We use the our refined version of **WMT24** ESA Annotations datasets[2] for six language pairs: **en→{cs,**

[2] https://github.com/wmt-conference/wmt24-news-systems

is, ja, ru, uk, zh}. Each pair contains approximately **6–8k** segments, for a total of about **39,685** segments. We preserve the human **ESA gold** annotations as the reference for span-level evaluation. [3]

3.2 Metrics

We follow the official WMT25 Task 2 ESA scorer[4]. Span detection is evaluated by **character-level overlap**, not span matching: for each character position, the counts of *major/minor* errors in gold and prediction are compared, and the true-positive score is calculated as the sum of the minimum counts at each character position. Partial overlaps that match in location but not in severity receive **partial credit** (0.5). Omissions marked as `start="missing"` are ignored by the scorer. MQM categories are not used for scoring. We report precision, recall, and F1 as micro-averages over segments within each language, and then macro-averages across languages.

3.3 Baselines

We compare our methods against two established baselines: **XCOMET** (Guerreiro et al., 2024) and **GEMBA** (Kocmi and Federmann, 2023a). Both XCOMET and GEMBA are also used as official baselines in the WMT25 Shared Task. All scores are character-level and macro-averaged across the six MQM language pairs; within each language we compute micro averages over segments. For GEMBA, we adhere to the original prompt and settings with one modification: the few-shot prompt is revised to require outputs in a strict JSON format to facilitate reliable parsing. In preliminary experiments, the unmodified prompt frequently elicited explanatory text in addition to the JSON output, resulting in parsing failures and degraded performance. To mitigate this issue, we explicitly instructed the model to omit any explanatory content, which yielded improved performance. We denote this variant as GEMBA (fixed).

[3]The script to refine the WMT24 ESA has been merged into the WMT25 official repository: https://github.com/wmt-conference/wmt25-mteval/blob/3332614/scripts/devset/create_tsv_from_wmt24_esa.sh

[4]https://github.com/wmt-conference/wmt25-mteval/blob/3332614/scripts/scoring/task2/scoring_esa.py

Method	F1	Prec.	Rec.
GEMBA	19.70	20.70	21.54
Direct-index	22.57	27.32	23.50
TSA (no precision emphasis)	25.43	21.99	**38.19**
TSA	**27.05**	**27.34**	32.27

Table 2: Ablation on output format and precision-emphasis prompting on o3 model. GEMBA, Direct-index, and TSA use an **identical prompt**, differing only in the directive that specifies the output format. *TSA (no precision emphasis)* employs the same TSA format but removes the precision-oriented instruction, isolating its contribution.

4 Results

Main results Table 1 presents the primary results. Our best system combines the **o3** reasoning model with the *Tagged Span Annotation* output design and achieves the highest F1 score. Under the same evaluation setting, it surpasses the *reference*-based **XCOMET-XXL** by **+9.65** F1 and the **GEMBA (fixed)** baseline by **+10.55** F1.

4.1 Ablation Study

We perform extensive experiments to identify the factors that influence response quality, and we report our findings here.

4.1.1 Span Annotation

We compare three output formats (i) **TSA**, (ii) a **GEMBA** format that returns the error-span text itself and (iii) a **Direct-index** format that outputs the character indices of each span using the **o3** model.

Except for the directive specifying the output format, every part of the prompt is kept identical, allowing us to isolate performance differences attributable solely to the span-annotation scheme. As shown in Table 2, the performance gap between the GEMBA and Direct-index baselines and our TSA method confirms this effect.

4.1.2 Precision Emphasis

In the TSA setting, we observe a pronounced precision–recall imbalance: recall was consistently much higher than precision in most language pairs.

Because the F1 score is the harmonic mean of precision and recall, it is dominated by the lower of the two components; consequently, it attains higher values only when the two metrics are balanced. To mitigate the observed imbalance, we explicitly

Method	GPT-4.1			o3			o4-mini		
	F1	**Prec.**	**Rec.**	**F1**	**Prec.**	**Rec.**	**F1**	**Prec.**	**Rec.**
GEMBA	**21.16**	**20.84**	21.16	19.70	20.70	21.54	17.42	15.28	23.50
Direct-index	13.46	14.92	14.95	22.57	27.32	23.50	18.13	19.30	20.76
TSA	20.03	18.45	**26.82**	**27.05**	**27.34**	**32.27**	**21.26**	**19.95**	**26.86**

Table 3: Span-level detection Performance by model and output format. Tagged Span Annotation (TSA) shows no noticeable performance gains over GEMBA or Direct-index on the non-reasoning baseline `GPT-4.1`, but it delivers substantial improvements on the reasoning models `o3` and `o4-mini`, highlighting the pronounced benefit of span markup for models with stronger reasoning capability.

reinforced the requirement of promoting higher precision.

We instruct the model to assign an error label only when it is *confident* the translation is incorrect. Moreover, because the model tends to select spans wider than the actual error, the prompt explicitly requires it to tag only the *minimal* substring that covers the core error.

For comparison, Table 2 also reports a TSA variant in which the prompt *did not* include the precision-oriented instructions.

4.1.3 Reasoning Impact

As shown in Table 3, the gap between TSA and the GEMBA format is most pronounced for **reasoning models**. We interpret that this stems from the two-stage decision process enforced by TSA, which closely resembles the human ESA scoring protocol: human annotators **first** indicate the mark spans and severity of errors, and then score the translation quality. ESA has been reported to achieve inter-annotator agreement comparable to full MQM annotation (Kocmi et al., 2024). Similarly, TSA requires the LLM to mark error spans in the `annotated_translation` field before predicting their severity and type, thus externalising an intermediate reasoning step.

The non-reasoning baseline GPT-4.1 shows no performance improvement from TSA over GEMBA, whereas the reasoning models `o3` and `o4-mini` exhibit substantial gains. This suggests that models with stronger reasoning ability are better able to exploit the intermediate span markup to conduct a more fine-grained error analysis.

5 Related Work

5.1 Encoder-Based Evaluation

COMET (Rei et al., 2020) is the first to attach a *regression head* to a pretrained cross-lingual encoder (e.g., XLM-R) in order to predict Direct Assessment (DA) scores, achieving higher human correlation than traditional metrics such as BLEU (Papineni et al., 2002) and TER (Snover et al., 2006). **COMET-MQM** (Rei et al., 2021) added an *auxiliary token-classification task* that predicts whether each token falls inside an error span based on MQM annotations.

XCOMET (Guerreiro et al., 2024) unifies and generalizes this line of work by (i) retaining the DA regression head and (ii) replacing COMET-MQM's token classifier with a *span head* that emits start–end indices. Yet these index-based spans lack error *types/categories*, limiting diagnostic power and compatibility with MQM/ESA labels, and the primary training objective remains sentence-level scoring, leaving boundary accuracy secondary. We treat XCOMET-XXL as the strongest encoder-based baseline and, inspired by its index span annotation, test an Direct-index format variant in our LLM-as-judge pipeline (§4.1.1); however, vulnerability to character-index drift ultimately leads us to adopt *Tagged Span Annotation (TSA)* for our final design.

5.2 LLM-as-a-judge

GEMBA (Kocmi and Federmann, 2023a) frames MT evaluation as an LLM-as-judge task: a prompted GPT-4 produces Direct Assessment (DA) scores or MQM/ESA error spans and severities from the source and translation (optionally a reference). However, GEMBA's few-shot, free-form outputs can yield duplicated instructions across exemplars, brittle parsing. To improve robustness, we convert the output to a JSON format and adopted structured-output prompting.

MQM-APE (Lu et al., 2025) augments GEMBA with a downstream *automatic post-editing* (APE) pass: after the initial GPT-4 annotation, a second LLM rewrites the MT segment with the pro-

posed fixes and discards spans whose removal does not change the edited meaning. This post-filtering raises span precision with little effect on recall. Because MQM-APE operates after span generation, it is orthogonal to our TSA, JSON-validated spans (with minimal fixes) could be plugged into MQM-APE without modifying its algorithm. We leave a full integration and evaluation to future work.

6 Limitations

This study has the following limitations. First, the experiments were conducted primarily on proprietary large language models (LLMs) such as `gpt-4.1`, `o3` and `o4-mini`, without providing comparable results for large-scale open-source models. This limits the generalizability of the proposed approach to other model families. Second, although per-language results were reported, we did not conduct in-depth analyses of performance variations or error patterns across specific language pairs. In particular, the causes of performance differences for low-resource languages remain underexplored. Third, the monetary cost of using proprietary LLMs can hinder large-scale adoption. Using `tiktoken` (OpenAI, 2023b) to count tokens, our evaluation on six WMT24 ESA language pairs (39,684 segments, 56.82M input tokens, 3.26M output tokens) is estimated to have cost about $139 in total ($3.5 per 1,000 segments) under the current `o3` pricing ($2/M input, $8/M output as of September 2025), which may hinder large-scale adoption despite the accuracy gains.

7 Conclusion and Future Work

We introduced **Tagged Span Annotation** (TSA), a structured-output framework that pairs numbered inline tags with a JSON schema to enable reliable, fine-grained translation-error detection. Across six WMT language pairs, TSA achieved the highest span-level F1 scores, surpassing the strongest GEMBA variant by +10.55 and XCOMET-XXL by +9.65 absolute points on average.

Reasoning vs. non-reasoning models. We observed performance differences between reasoning and non-reasoning LLMs. As future work, we will systematically study how prompting style and intermediate reasoning affect span detection by comparing: (i) direct answers vs. chain-of-thought (CoT; Wei et al. 2022) prompting, (ii) single-pass decoding vs. self-consistency with multiple CoT paths, and (iii) unguided CoT vs. CoT *path selection* aided by a span-level verifier. We will evaluate not only span F1 (overall and by severity/type), but also invalid-output rate, span-length bias, latency, and cost to characterize accuracy–efficiency trade-offs.

Open-source models trained on evaluation data. To improve reproducibility and broaden applicability, we will fine-tune strong open-source LLMs on human-annotated MQM/ESA data (and carefully curated synthetic data), comparing SFT vs. parameter-efficient adapters (e.g., LoRA; Hu et al. 2021) under multilingual vs. per-language regimes. We will analyze cross-lingual transfer (high- to low-resource), domain shift, and calibration quality, and report effect sizes alongside standard correlations. Where licensing permits, we plan to release training code, prompts, and evaluation harnesses to facilitate future benchmarking.

Coupling with post-editing (MQM-APE). We further plan to couple our span detector with post-editing systems that explicitly target MQM categories (e.g., MQM-aware APE). Concretely, we will explore (i) using predicted spans and severities to guide edit proposals, (ii) verifier- or reward-based reranking of edits, and (iii) joint training where an APE loss encourages span-consistent corrections. We will report pre-/post-edit score deltas, human correlation, and downstream adequacy/fluency gains to quantify the benefit of integrating detection with correction.

A Prompt

A.1 System Prompt

We used the following system prompt. It described the essential rules for marking error spans and placed emphasis on addressing the issue of precision being significantly lower than recall.

```
You are a careful and balanced annotator for machine translation quality.
Your task is to identify translation errors with appropriate confidence.

## EVALUATION GUIDELINES:
- Be thorough but precise: Only mark errors when you are confident they are
↪  incorrect
- Consider context and domain: Some variations may be acceptable depending on
↪  context
- Distinguish between errors and acceptable alternatives: Multiple valid
↪  translations may exist
- Focus on clear, objective errors rather than subjective preferences
- Verify each potential error against the source text before marking
- When in doubt, err on the side of not marking an error

## Error Categories:
- Accuracy: addition, mistranslation, omission, untranslated text
- Fluency: character encoding, grammar, inconsistency, punctuation, register,
↪  spelling
- Style: awkward phrasing
- Terminology: inappropriate for context, inconsistent use
- Other: non-translation, other issues

## Severity Classification:
- Major: Errors that impact meaning or usability but do not render the text unusable
- Minor: Errors that do not impact meaning or usability

## CRITICAL OUTPUT REQUIREMENTS:
- Mark errors only when you have clear evidence they are incorrect
- Consider whether alternative translations could be equally valid
- Apply strict standards: better to miss a minor error than create a false positive
- Wrap error spans in the translation with tags: <v0>, <v1>, <v2>, etc.
- Use tag numbers in sequential order starting from <v0>. Do not skip numbers or use
↪  them out of order
- For omissions, place empty tags <vN></vN> where the missing text should have been
- NO comments, explanations, or additional text
- Mark only the minimal substring that contains the clear error; do not include
↪  extra context
```

A.2 Few-shot Examples

We revised the GEMBA-MQM (Kocmi and Federmann, 2023a) few-shot examples to align with the TSA format. In addition, we added one example without any error spans.

Abstract

Automated metrics for machine translation attempt to replicate human judgment. Unlike humans, who often assess a translation in the context of multiple alternatives, these metrics typically consider only the source sentence and a single translation. This discrepancy in the evaluation setup may negatively impact the performance of automated metrics. We propose two automated metrics that incorporate additional information beyond the single translation. $\text{COMET}_{\text{poly-cand}}$ uses alternative translations of the same source sentence to compare and contrast with the translation at hand, thereby providing a more informed assessment of its quality. $\text{COMET}_{\text{poly-ic}}$, inspired by retrieval-based in-context learning, takes in translations of similar source texts along with their human-labeled quality scores to guide the evaluation. We find that including a single additional translation in $\text{COMET}_{\text{poly-cand}}$ improves the segment-level metric performance (0.079→0.118 τ_b), with further gains when more translations are added. Incorporating retrieved examples in $\text{COMET}_{\text{poly-ic}}$ yields similar improvements (0.079→0.116 τ_b). We release our models publicly.[1]

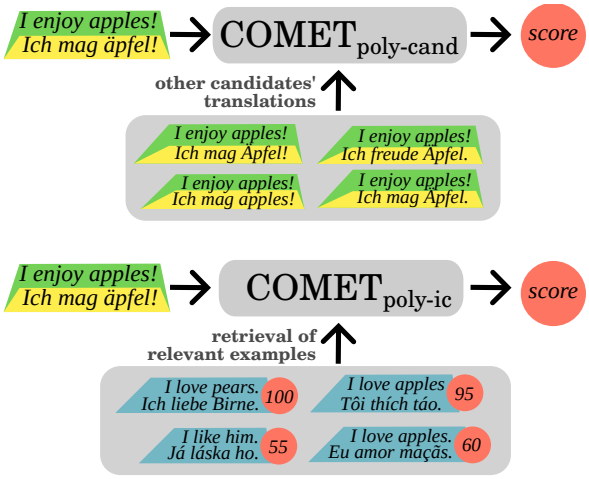

Figure 1: The $\text{COMET}_{\text{poly-ic}}$ model consults a knowledge base of previously human-scored translations before assigning the quality estimation score to the candidate translation. The $\text{COMET}_{\text{poly-cand}}$ considers other possible translations apart from the candidate one. Both metrics work better than just providing the source and the translation.

1 Introduction

There is a gap between how humans and automated metrics score translations. Automated metrics receive the source segment, usually a sentence or a paragraph, a single translation, and optionally a reference translation. They are then tasked with assessing the quality of the translation. In contrast, human evaluation is less episodic. Human raters often assess multiple translations in sequence (Graham et al., 2013; Freitag et al., 2021; Kocmi et al., 2024b), considering them side-by-side. Even though annotations are made for each translation individually, annotators become calibrated (known as sequence effect, Mathur et al., 2017), to common error patterns and their own evaluation criteria as they review multiple translations. As a result, they effectively score each translation in the context of others. Moreover, unlike human annotators, who have a deep understanding of the languages involved and can assess a wide range of translation qualities, automated metrics are limited by the data they were trained on. As a result, their performance tends to degrade when evaluating translations that deviate from their training distributions, such as out-of-domain content (Zouhar et al., 2024).

We present two conceptual approaches to address these two challenges by incorporating additional context into standard automated metrics, such as COMET (Rei et al., 2020). Our main motivation is to narrow the gap between human evaluation and automated metrics, enabling automated metrics to score translations in the context of other

★Equal contribution, sorted anti-alphabetically.

[1]We release the paper code and pre-trained quality estimation models $\text{COMET}_{\text{poly-ic}}$ and $\text{COMET}_{\text{poly-cand}}$.

Proceedings of the Tenth Conference on Machine Translation, pages 887–904
November 8-9, 2025

translations and making them more robust to out-of-domain data. Specifically, we introduce two models trained within this framework, $\text{COMET}_{\text{poly-cand}}$ and $\text{COMET}_{\text{poly-ic}}$:

- In $\text{COMET}_{\text{poly-cand}}$, different translations of the same source sentence are provided to the model as additional context (Figure 1 top). This is suitable for scenarios such as (1) benchmarking, where we evaluate translations of multiple systems on the same source sentence, or (2) reranking, where we need to select the best translation from a pool of candidate translations.
- In $\text{COMET}_{\text{poly-ic}}$, which is inspired by retrieval-based in-context learning, tuples of (*source*, *translation*, *human quality score*) are provided to the model as additional context. The tuples are retrieved based on the source sentence similarity to the evaluation example at hand (Figure 1 bottom). In practice, in-context examples can be obtained from existing, previously scored translations—such as those found in prior WMT annotation datasets (Freitag et al., 2024; Kocmi et al., 2024a).

This paper is structured as follows. In Section 2, we first describe the task of machine translation quality estimation (QE) and COMET (Rei et al., 2020), a popular QE metric. Then, we describe our two proposed model variants, $\text{COMET}_{\text{poly-cand}}$ and $\text{COMET}_{\text{poly-ic}}$. We also apply the same approach to two additional QE systems with contrasting characteristics: a non-parametric k-NN baseline and GEMBA, a large parametric LLM-based evaluator. In Sections 3 and 4, we show that our methods not only improve COMET's segment-level performance but also outperform both the much larger GEMBA model and the k-NN baseline, despite their simplicity. These approaches also show promise for instant on-the-fly domain adaptation. We place our contributions in context with related work in Section 5. Finally, in Section 6, we provide some practical guidance on using these metrics along with potential caveats.

We publicly release our models under open license, and submit our models to the WMT 2025 Metrics Shared Task.

2 Methods

In this section, we introduce the translation quality estimation task, review COMET, and present two extensions for improved quality estimation and domain adaptation.

2.1 Background

Quality estimation (QE). Given a source text s and a model-produced translation (MT) t, which is assessed by a human annotator on a scale from 0% to 100%, the goal of quality estimation (QE) is to develop a metric to predict this score.

Baseline COMET. Traditionally, quality estimation relied on static, rule-based metrics, but the field has shifted toward learned, data-driven metrics that can better approximate human judgments (Freitag et al., 2022). Learned automated metrics can be thought of as a function f, taking a source sentence s and a translation t as input and producing a continuous score $f(s,t) \in [0,1]$. f is usually trained in a supervised manner to approximate human judgment $y_{s,t} = \text{human}(s,t)$:

$$f(s,t) \xrightarrow{\text{train}} y_{s,t}$$

A popular recent choice for f is COMET (Rei et al., 2020), which is a combination of a trainable encoder model e_{θ_1} and a multi-layer perception head MLP_{θ_2}. COMET first embeds the source and translation texts, obtaining $s^e = e_{\theta_1}(s)$ and $t^e = e_{\theta_1}(t)$, and then transforms the embeddings into a score prediction using MLP_{θ_2}. We denote the set of trainable weights as $\theta = (\theta_1, \theta_2)$. Specifically, COMET is formulated as:

$$\text{COMET}_\theta(s,t) = \text{MLP}_{\theta_2}\big(g_{\theta_1}(s,t)\big),$$
$$\text{with } g_{\theta_1}(s,t) = \langle s^e, t^e, |s^e - t^e|, s^e * t^e \rangle.$$

Here, g_{θ_1} constructs a feature vector for the pair (s,t) by concatenating their embeddings s^e and t^e with additional element-wise transformations: the absolute difference $|s^e - t^e|$ and the element-wise product $s^e * t^e$. The trainable weights θ are optimized by minimizing the mean squared error between the COMET score and human labels using a variation of the stochastic gradient descent algorithm.

While the baseline COMET framework is effective, it does not support incorporating additional information. Just like for human evaluators, having more information such as (1) multiple candidates' translations for the same source, or (2) ground-truth example quality scores of translations, could improve the performance of COMET further. Thus, we introduce two extensions for COMET, which we train from scratch..

2.2 Multiple Candidates: $\text{COMET}_{\text{poly-cand}}$

Our first variant targets scenarios like benchmarking or reranking MT models, where multiple translations of the same source segment are available. In these cases, we extend the model's context by including additional translations $\{t_i\}_{i=2}^{n}$ of the same source sentence s, allowing the model to leverage multiple candidate translations simultaneously. Figure 1 (top) shows an illustration of this model architecture.

Specifically, we include the embeddings of these additional translations as part of the input to the multi-layer perceptron. Formally, for all $i \in \{2, \cdots, n\}$, we define

$$g_{\theta_1}(t, t_i) = \langle t_i^e, |t_i^e - t^e|, t_i^e * t^e \rangle.$$

We then concatenate $\langle g_{\theta_1}(s,t), g_{\theta_1}(t,t_1), ..., g_{\theta_1}(t,t_n) \rangle$ and pass it to the MLP. During training, we ensure that the additional translations $\{t_i\}_{i=2}^{n}$ differ from the main translation t, and keep n fixed across all training examples.

Joint predictions. To reduce computation time, $\text{COMET}_{\text{poly-cand}}$ can be trained to jointly predict the quality scores of the original translation along with those of the additional translations. The training objective then becomes:

$$f(s, t, t_2, ..., t_n) \xrightarrow{\text{train}} y_{s,t}, y_{s,t_2}, ..., y_{s,t_n}$$

Using scores of other translations. When the human assessment scores for additional translations, $\{y_{s,t_i}\}_{i=2}^{n}$, are available, we can further augment the feature vector using these scores. The input to the MLP would become:

$$\langle g_{\theta_1}(s,t), g_{\theta_1}(t,t_1), y_{s,t_1}, ..., g_{\theta_1}(t,t_n), y_{s,t_n} \rangle$$

This is particularly useful when we wish to evaluate a new system on a pre-existing benchmark with other candidate translations whose qualities are already annotated by humans.

2.3 In-context Learning: $\text{COMET}_{\text{poly-ic}}$

In the previous approach, we used additional translations of the same source sentence, a setup that might be unrealistic outside controlled scenarios such as benchmarking or reranking. An alternative, inspired by the success of *in-context* learning in other domains (Brown et al., 2020), is to provide the model with other, similar examples: by conditioning on human-scored translations, it can learn the mapping between translation patterns and quality judgments on the fly.

$\text{COMET}_{\text{poly-ic}}$ implements this by retrieving source–translation–score triplets from a knowledge base, in our case, prior WMT annotation datasets (Freitag et al., 2024; Kocmi et al., 2024a), and using them as context, enabling the model to adapt its evaluation to different domains. An illustration is shown in Figure 1 (bottom).

Specifically, for each input example (source s, translation t), we retrieve the examples $\{(s_i, t_i, y_{s_i,t_i})\}_{i=2}^{n_{\text{ICL}}+1}$ from a knowledge base $\mathcal{D}$. The new examples are added to the representation vector similar to $\text{COMET}_{\text{poly-cand}}$, considering both embeddings and labels, by appending

$$\langle t_i^e, |t_i^e - t^e|, t_i^e * t^e, s_i^e, |s_i^e - s^e|, |s_i^e * s^e|, y_{s_i,t_i} \rangle$$

to $g_{\theta_1}(s,t)$ for all $i \in \{2, \cdots, n_{\text{ICL}} + 1\}$.

The ICL examples are retrieved using normalized embedding (cosine) similarity computed from either the source s^e (default), the translation t_i^e, their arithmetic combination $s^e + t_i^e$, or their concatenation $\langle s^e, t_i^e \rangle$. We retrieve up to five most similar examples, discarding exact matches during training. We present detailed ablations of different filtering and retrieval setups in Section 4.

2.4 Including Reference Translations

Optionally, COMET can also make use of a reference translation (Rei et al., 2020), though this is no longer part of the standard QE setup. We also report results for $\text{COMET}_{\text{poly-cand}}$ and $\text{COMET}_{\text{poly-ic}}$ in the reference-based setting, by incorporating the reference r in their inputs, i.e., $f(s, t, r)$. However, our primary focus remains on QE, as references are often unavailable in practical scenarios.

2.5 Models Beyond COMET

Since our method is not specific to COMET, we include two models that, like our extensions, can take multiple candidate translations into account.

***k*-nearest neighbors.** As our first baseline method, we propose using a k-nearest-neighbours (k-NN) approach, mirroring methods used in similar contexts (Dinh et al., 2024). k-NN naturally leverages existing high-quality examples by retrieving similar instances, providing a strong non-parametric baseline that complements our model-based approaches. The k-NN baseline is implemented for our two different setups: $k\text{-NN}_{\text{poly-cand}}$ and $k\text{-NN}_{\text{poly-ic}}$.

For k-NN$_{\text{poly-cand}}$ and for a pair (s, t), we retrieve k additional translations for s. These are selected based on the cosine similarity of the target translation t and candidate translations, where embeddings are obtained using the all-MiniLM-L12-v2 (Reimers and Gurevych, 2020), yielding the set $\{t_i\}_{i=2}^{k+1}$. We then rate each candidate using Baseline COMET, obtaining $\{\text{COMET}(s, t_i)\}_{i=2}^{k+1}$. Finally, we use their average as the final prediction, i.e.,

$$\hat{y}_{s,t}^{k\text{-NN}_{\text{poly-cand}}} = \frac{1}{k}\sum_{i=2}^{k+1}\text{COMET}(s, t_i).$$

For k-NN$_{\text{poly-ic}}$, we retrieve $k = n_{\text{ICL}}$ examples, $\{(s_i, t_i, y_{s_i,t_i})\}_{i=2}^{k+1}$, following the retrieval strategies described in Section 2.3, and then average their human scores to obtain the prediction:

$$\hat{y}_{s,t}^{k\text{-NN}_{\text{poly-ic}}} = \frac{1}{k}\sum_{i=2}^{k+1} y_{s_i,t_i}.$$

We further extend the k-NN approaches using weighted averages in Appendix D.

Using LLMs as evaluators. As a second baseline, we use large language models (LLMs) for MT evaluation, leveraging their effectiveness in this task (Kocmi and Federmann, 2023). Specifically, we apply in-context learning (Brown et al., 2020), a standard method for injecting new knowledge into LLMs at inference time. Similar to COMET$_{\text{poly}}$, we provide LLMs with additional contextual information when scoring translations. However, unlike COMET$_{\text{poly}}$ variants, which update model parameters during training, LLMs receive this information only through their prompts at inference time, without any parameter modification.

For prompt creation, we build on top of GEMBA (Kocmi and Federmann, 2023), a framework designed to prompt LLMs to score the quality of translations. Leveraging GEMBA's pre-defined prompts, we extend them to two settings: (1) GEMBA$_{\text{poly-cand}}$, where additional translations of the same source sentence are provided, and (2) GEMBA$_{\text{poly-ic}}$, where full examples (including source, translation, and human quality score) are included. Prompt details are provided in Appendix A.2.

3 Experimental Setup

This section outlines the training and evaluation procedures, as well as the experimental setup.

Data. We use the direct assessment scorings of WMT up to 2023 (inclusive) for training (600k segments). For testing and evaluation, we use WMT 2024 (105 segments), which has been evaluated with the ESA protocol (Kocmi et al., 2024b). This dataset covers eleven language pairs: English to Czech, German, Spanish, Hindi, Icelandic, Japanese, Russian, Chinese, Czech to Ukrainian, and Japanese to Chinese. From ESA, we use the final scores (as opposed to error spans), which have the same scale as direct assessment. For MQM, we convert the error span annotations on a translation to the final score by taking $1 - (5 \cdot major + 1 \cdot minor)/100$, where $major$ is the number of annotated major errors, and $minor$ is the number of minor errors annotated in the translation. In this way, the scores are aligned roughly on the same scale compared to DA scores.

Training. We train the Baseline COMET model, COMET$_{\text{poly-cand}}$ and COMET$_{\text{poly-ic}}$ based on pretrained RoBERTa (Liu et al., 2019) on WMT human judgment data for five epochs. For COMET$_{\text{poly-cand}}$, we retrieve up to five candidate translations, either randomly or based on embedding similarity. For COMET$_{\text{poly-ic}}$, we retrieve up to five in-context examples from the training data based on embedding similarity. The metrics are trained in a maximally comparable model setup, which is detailed in Appendix A.

Evaluation. We evaluate the metrics on the segment level in three ways: Pearson correlation, Kendall's tau-b, and Mean Absolute Error (MAE). In contrast to Freitag et al. (2024) we do not do perform any group-by-item nor group-by-item. Results are macro-averaged across eleven languages.

Pearson correlation measures the linear relationship between metric scores and human ratings: higher values indicate better alignment, though not necessarily on the same scale. Mean Absolute Error (MAE), in contrast, captures the average absolute difference between metric and human scores, with lower values indicating closer agreement in both value and scale. Kendall's tau-b focuses on rank correlation, reflecting how well the metric preserves the relative ordering of translations. While Pearson and Kendall's tau-b range from -1 to 1, MAE is unbounded and depends on the scoring scale.

Experiments. To ensure a controlled evaluation setting, we first train a standard COMET

Model	Reference-less $\rho\uparrow$	Reference-less $\tau_b\uparrow$	Reference-less MAE $\downarrow$	Reference-based $\rho\uparrow$	Reference-based $\tau_b\uparrow$	Reference-based MAE $\downarrow$
standard COMET model $f(s,t) \rightarrow \hat{y}_t$	0.105	0.079	30.2	0.245	0.166	26.6
COMET$_{\text{poly-cand}}$						
additional candidate $f(s,t,t_2^*) \rightarrow \hat{y}_t$	0.160	0.127	28.5	0.281	0.180	26.3
additional candidate, output joint predictions $f(s,t,t_2^*) \rightarrow \hat{y}_t, \hat{y_{t_2^*}}$	0.167	0.113	28.8	0.275	0.172	25.6
additional candidate and its score $f(s,t,t_2^*,y_{t^*2}) \rightarrow \hat{y}_t$	0.267	0.207	21.9	0.374	0.243	20.6
COMET$_{\text{poly-ic}}$						
additional candidate and its score $f(s,t,t_2^*,y_{t^*2}) \rightarrow \hat{y}_t$	0.141	0.116	27.3	0.352	0.247	15.3

Table 1: Results for COMET$_{\text{poly-cand}}$ and COMET$_{\text{poly-ic}}$. The first row shows the standard COMET. The middle and bottom parts show that adding additional translation candidates and in-context examples boosts performance.

Model (Reference-less)	$\rho\uparrow$					$\tau_b\uparrow$					MAE $\downarrow$				
(+additional)	+1	+2	+3	+4	+5	+1	+2	+3	+4	+5	+1	+2	+3	+4	+5
$f(s,t) \rightarrow \hat{y}_t$	0.105	0.105	0.105	0.105	0.105	0.079	0.079	0.079	0.079	0.079	30.2	30.2	30.2	30.2	30.2
COMET$_{\text{poly-cand}}$															
$f(s,t,t_{...}) \rightarrow \hat{y}_t$	0.160	0.251	0.224	0.202	0.190	0.127	0.145	0.127	0.130	0.120	28.5	27.6	26.8	28.4	27.6
$f(s,t,t_{...},y_{t_{...}}) \rightarrow \hat{y}_t$	0.267	0.321	0.328	0.327	0.321	0.207	0.229	0.230	0.235	0.233	21.9	17.3	16.0	14.0	13.7
COMET$_{\text{poly-ic}}$															
$f(s,t,t_{...},y_{t_{...}}) \rightarrow \hat{y}_t$	0.141	0.134	0.148	0.128	0.068	0.116	0.108	0.114	0.105	0.075	27.3	27.2	24.7	27.6	27.4

Table 2: Results for COMET$_{\text{poly-cand}}$ and COMET$_{\text{poly-ic}}$ using different numbers of additional translation candidates. The +1 is equal to the results in Table 1. The +x uses x additional translation candidates, which improves performance especially for COMET$_{\text{poly-cand}}$.

model on the data described before and use it as a baseline. We then investigate COMET$_{\text{poly-cand}}$ by incorporating additional translations into the base model and analysing the impact of different selection strategies. Similarly, we explore COMET$_{\text{poly-ic}}$, experimenting with various retrieval methods and assessing its potential for domain adaptation. We complement our experiments with k-NN$_{\text{poly-cand}}$ and k-NN$_{\text{poly-ic}}$ as non-parametric baselines, and GEMBA$_{\text{poly-cand}}$ and GEMBA$_{\text{poly-ic}}$ as large-parameter LLM baselines.

4 Results and Analysis

In the following, we discuss and analyse the results of COMET$_{\text{poly-cand}}$ and COMET$_{\text{poly-ic}}$, compare them to the non-parametric k-NN and the large parametric GEMBA model, and discuss the runtime impact of our method.

4.1 Results for COMET$_{\text{poly-cand}}$

Additional candidate helps. We begin by evaluating COMET$_{\text{poly-cand}}$ in its simplest setting: adding a single additional translation from the same source as the candidate being scored. We choose the closest additional translation t_2^* as, intuitively, the closer it is to the candidate t, the more relevant it is for assessing its quality. We select t_2^* based on the embedding distance computed between candidate translations (see Appendix A for details on embeddings and distance metrics). The corresponding results are shown in the middle part of Table 1.

Across all evaluation metrics, including an additional translation $f(s,t,t_2)$, considerably improves performance compared to the standard COMET baseline $f(s,t)$. Specifically, Pearson correlation improved by over 50%. The joint translation prediction objective, which scores both the original translation and the additional translation, also yields gains over the baseline, though it performs slightly worse than the single-prediction setup. This suggests that, in scenarios where faster inference is needed, the joint-prediction setup offers a practical trade-off, delivering improved performance with smaller additional cost. Finally, including the gold score y_{t_2} of the additional translation in the input vastly improves the metric performance. However, note that this is an ideal scenario where the gold score y_{t_2} is available, which is not always realistic.

Note that it is not always possible to find additional translations that are similar to the translation

at hand. Therefore, we experiment with using a randomly selected additional candidate to test the robustness of $\text{COMET}_{\text{poly-cand}}$. This still results in notable gains, albeit smaller than with similar candidates. We report these results in Appendix B.

More than one candidate helps. We extend $\text{COMET}_{\text{poly-cand}}$ by increasing the number of additional candidates. The results are shown in Table 2. Having more than one additional candidate further improves the performance of $\text{COMET}_{\text{poly-cand}}$, as we are providing a more global view of possible translations to the model. However, this effect starts to diminish beyond two additional candidates. For comparison, results using random additional candidates are provided in Appendix B.

Additional translation complement reference. Previous experiments focused on reference-free evaluation. To complete the picture, we now explore how $\text{COMET}_{\text{poly-cand}}$ performs when reference translations are available.

The right half of Table 1 shows that using $\text{COMET}_{\text{poly-cand}}$ with reference yields better performance than $\text{COMET}_{\text{poly-cand}}$ in QE mode, though the gain is smaller than for standard COMET. This indicates that additional translations help narrow the gap but cannot fully replace references. Rather, additional translations complement references by providing further improvements on top of them.

4.2 Results for $\text{COMET}_{\text{poly-ic}}$

Building on this idea of leveraging additional context, we next evaluate $\text{COMET}_{\text{poly-ic}}$, which incorporates in-context examples to further enhance evaluation quality.

In-context examples help. We retrieve an in-context example using the source text s^e, embedded via an external embedding model (details in Appendix C). Results in the bottom row of Table 1 show that COMET benefits significantly from these examples, outperforming the baseline without in-context examples. This improvement also holds for $\text{COMET}_{\text{poly-ic}}$ with references. However, compared to $\text{COMET}_{\text{poly-cand}}$, in-context examples appear less informative than additional candidates with the same source, resulting in slightly reduced performance. We also test other embedding types (including COMET's own) and variations using the target or both source and target for retrieval. However, none of these alternatives yields further improvements. Full ablations are presented in Appendix C.

(a) k-$\text{NN}_{\text{poly-cand}}$

k	$\rho\uparrow$	$\tau_b\uparrow$	MAE$\downarrow$
1	0.083	0.064	30.4
2	0.087	0.064	30.3
3	0.086	0.062	30.4
4	0.085	0.059	30.4
5	0.085	0.057	30.4

(b) k-$\text{NN}_{\text{poly-ic}}$

k	$\rho\uparrow$	$\tau_b\uparrow$	MAE$\downarrow$
1	0.029	0.014	31.1
2	0.031	0.017	29.4
3	0.034	0.017	28.7
4	0.036	0.019	28.2
5	0.037	0.020	27.9

Table 3: Results for the k-nearest neighbors baseline using embeddings $\langle s^e, t_i^e \rangle$ in both k-$\text{NN}_{\text{poly-cand}}$ and k-$\text{NN}_{\text{poly-ic}}$ setup. k-NN consistently underperforms $\text{COMET}_{\text{poly-cand}}$ and $\text{COMET}_{\text{poly-ic}}$, showing notably lower correlations despite comparable MAE.

More in-context examples improve performance. While a single in-context example already boosts performance, adding up to three examples leads to further improvements. As shown in the bottom half of Table 2, performance increases with the number of retrieved examples using the external embedding model and s^e for retrieval, but declines beyond three examples, likely because additional examples become less similar and less relevant.

We also provide preliminary experiments in Appendix C.3 on how $\text{COMET}_{\text{poly-ic}}$ can leverage in-context examples to adapt its quality estimation to a new domain, and find a slight improvement compared to the base model.

4.3 Adding Candidates to Models Beyond COMET

In order to see whether having additional candidates or examples also helps with other QE methods other than COMET, we look into the performance of two baselines: the non-parametric ***k***-nearest neighbors and large parametric LLM evaluator with GEMBA.

We use ***k***-nearest neighbors in the retrieval setting for both k-$\text{NN}_{\text{poly-cand}}$ and k-$\text{NN}_{\text{poly-ic}}$, i.e., retrieving similar examples along with their gold quality scores, since the gold scores are required for ***k***-nearest neighbors. For GEMBA, we experiment with all $\text{GEMBA}_{\text{poly-cand}}$ variances (random/similar candidate, with/without gold scores) and $\text{GEMBA}_{\text{poly-ic}}$, similar to $\text{COMET}_{\text{poly-cand}}$ and $\text{COMET}_{\text{poly-ic}}$.

***k*-nearest neighbors underperforms COMET.** We present results for the k-nearest neighbors (k-NN) baseline in Table 3, varying k from 1 to 5,

	Input → Output	Reference-less			Reference-based		
		$\rho \uparrow$	$\tau_b \uparrow$	MAE $\downarrow$	$\rho \uparrow$	$\tau_b \uparrow$	MAE $\downarrow$
standard GEMBA	$f(s,t) \rightarrow \hat{y}_t$	0.266	0.199	27.6	0.311	0.200	27.3
GEMBA$_{\text{poly-cand}}$, closest t_2^*							
additional candidate	$f(s,t,t_2^*) \rightarrow \hat{y}_t$	0.245	0.185	28.2	0.277	0.187	27.5
additional candidate, joint predictions	$f(s,t,t_2^*) \rightarrow \hat{y}_t, \hat{y_{t_2^*}}$	0.235	0.149	28.6	0.296	0.181	27.9
additional candidate and its score	$f(s,t,t_2^*,y_{t^*2}) \rightarrow \hat{y}_t$	0.276	0.187	27.4	0.337	0.217	26.8
GEMBA$_{\text{poly-ic}}$							
additional candidate and its score	$f(s,t,s_2,t_2,y_{t_2}) \rightarrow \hat{y}_t$	0.195	0.099	28.3	0.291	0.168	27.4

Table 4: Results for GEMBA$_{\text{poly-cand}}$ and GEMBA$_{\text{poly-ic}}$. The first row shows the standard GEMBA model. In contrast to the COMET models, adding additional translation candidates and in-context examples does not significantly boost performance.

along with the simple average approach. For k-NN$_{\text{poly-ic}}$, neighbors are retrieved using the embedding $\langle s^e, t_i^e \rangle$. k-NN$_{\text{poly-ic}}$ performs markedly worse than our COMET variants (COMET$_{\text{poly-cand}}$ and COMET$_{\text{poly-ic}}$), particularly on correlation metrics, though MAE differences remain small. This is expected, as ***k***-nearest neighbors naively aggregate the scores of the closest datapoints, without actually modeling the underlying relationships between the source and translation to output the quality score. In the cases where the neighbors are not close enough, the output from ***k***-nearest neighbors would be suboptimal. In the poly-cand scenario, k-NN$_{\text{poly-cand}}$ achieves results similar to the naive COMET approach, unsurprising given that k-NN in this case effectively averages COMET scores for similar translations.

A more comprehensive set of results is provided in Appendix D, including a weighted variant of the ***k***-nearest neighbors baseline. The appendix also compares different retrieval strategies for k-NN$_{\text{poly-ic}}$. Among them, retrieval using $\langle s^e, t_i^e \rangle$ performs best; this contrasts with COMET$_{\text{poly-ic}}$, where retrieving based solely on the source yields better results. This difference arises because retrieval based only on source can hurt k-NN$_{\text{poly-ic}}$ by averaging scores from translations that may not align well with the target one.

COMET$_{\text{poly-cand}}$ outperforms GEMBA. We now move on to the parameter-heavy LLM baseline GEMBA. The main results for GEMBA$_{\text{poly-cand}}$ and GEMBA$_{\text{poly-ic}}$ are shown in Table 4.

Due to the large size and large amount of pretraining data of LLMs, the baseline GEMBA model has notably better performance than the baseline COMET (0.266 Pearson versus 0.105 Pearson). However, GEMBA does not benefit from our poly-cand and poly-ic setup. In most configurations, neither method improves over the baseline. Consequently, by better making use of additional examples, the COMET$_{\text{poly-cand}}$ variance outperforms all GEMBA variances. The exception is GEMBA$_{\text{poly-cand}}$ with the closest additional translation and its gold quality score, which yields better performance than baseline GEMBA. This is unsurprising, as the target translation's quality is likely similar to that of its closest neighbor, whose score is provided to the model. We also test adding random or multiple examples; random candidates perform comparably to similar ones, while multiple examples do not consistently yield further gains. Detailed results can be found in Appendix E.

4.4 Comparing Efficiency of COMET-poly Models

While the previous section shows that COMET$_{\text{poly-cand}}$ outperforms GEMBA in certain evaluation settings, this advantage is even more significant in practice due to efficiency. Table 5 shows that overall, running GEMBA is considerably slower and requires more computational resources than COMET. This highlights the benefits of training a small, specialized model (COMET$_{\text{poly-cand}}$) to match the performance of large, general-purpose models (GEMBA), while substantially reducing inference-time computational costs.

On the other hand, compared to k-NN, COMET$_{\text{poly}}$ is less efficient. k-NN is non-parametric, thus its computation time is almost instantaneous when excluding retrieval cost. However, as we have seen in the previous section, k-NN has notably worse performance compared to COMET$_{\text{poly}}$.

We next examine the general runtime behavior

	COMET	GEMBA
standard model		
$f(s,t) \rightarrow \hat{y_t}$	4.4s/1k	196.1s/1k
poly-cand		
$f(s,t,t_2) \rightarrow \hat{y_t}$	6.9s/1k	254.0s/1k
$f(s,t,t_2) \rightarrow \hat{y_t}, \hat{y_{t_2}}$	3.5s/1k	146.3s/1k
$f(s,t,t_2,y_{t_2}) \rightarrow \hat{y_t}$	6.9s/1k	256.0s/1k
poly-ic		
$f(s,t,s_2,t_2,y_{t_2}) \rightarrow \hat{y_t}$	7.2s/1k	233.0s/1k

Table 5: Inference time of GEMBA models compared to COMET models on the WMT 2024 test set (time per 1000 scores output on a single NVIDIA H100). COMET has ∼0.5B params and GEMBA 70B. GEMBA is run with 4-bit quantization. $\text{COMET}_{\text{poly-ic}}$ introduces an additional cost of retrieving from a vector knowledge base which we exclude for both $\text{COMET}_{\text{poly-ic}}$ and $\text{GEMBA}_{\text{poly-ic}}$.

of our methods across multiple settings. Looking at Table 5, unsurprisingly, integrating additional candidates $f(s,t,t_2)$ is more expensive in comparison to the baseline model with only one translation $f(s,t)$. However, most of the computation is spent on encoding the text sequences, which can be efficiently cached during inference (Rei et al., 2022), making all of the metric variations comparable. Moreover, if both t and t_2 need to be scored, then using a model that predicts both of their scores $\hat{y_t}, \hat{y_{t_2}}$ is faster than computing $f(s,t)$ and $f(s,t_2)$ together.

4.5 Analysis

To better understand the impact of our method, we investigate how additional translations or samples influence COMET's quality predictions.

$\text{COMET}_{\text{poly-cand}}$. We first perform a systematic analysis by categorizing test cases according to the gold quality scores of both the translation under evaluation and its additional translation. Specifically, we consider four combinations: (i) both high-quality, (ii) sample high / additional low, (iii) sample low / additional high, and (iv) both low-quality.

Results show that additional translations are most beneficial when the evaluated output is of lower quality. Interestingly, the quality of the additional translation itself has little impact on QE performance. This suggests that even low-quality additions can aid COMET by introducing complementary error patterns that highlight discrepancies. Detailed results can be found in Appendix F.

We then focus on individual cases where the additional translation yields the largest improvements. To do so, we sort the test samples in descending order by the difference between COMET's absolute error and that of $\text{COMET}_{\text{poly-cand}}$, thereby identifying the samples where $\text{COMET}_{\text{poly-cand}}$ yields the greatest improvement. We then conduct a manual inspection of the top cases, revealing that additional translations help COMET better detect specific failure modes: undertranslation, where the translation is merely a copy of the source; numerical errors, where numeric values in the translation differ from the source; explanations, where unnecessary explanatory text is added; and refusals, where the translation includes statements declining to translate the input. In these cases, the additional translations do not exhibit the same errors as the translation under evaluation. We therefore hypothesize that the additional translations effectively serve as references in such scenarios. We provide specific examples in Appendix B.2 in Appendix F.

$\text{COMET}_{\text{poly-ic}}$. We perform a similar systematic analysis for $\text{COMET}_{\text{poly-ic}}$ to study how in-context examples influence the scoring of high- and low-quality translations. Consistent with $\text{COMET}_{\text{poly-cand}}$, $\text{COMET}_{\text{poly-ic}}$ shows greater benefits when evaluating lower-quality outputs (see Appendix F for details).

In addition, we also investigate the choice of in-context examples, which is critical for $\text{COMET}_{\text{poly-ic}}$'s performance. During training, retrieved examples are drawn from the training set and thus come from the same distribution and have been seen by the model. In contrast, at test time, the examples are unseen and often less similar. We investigate whether the train-test mismatch affects $\text{COMET}_{\text{poly-ic}}$ by training models with different similarity thresholds. However, we find that the train-test mismatch does not significantly impact performance. Details can be found in Appendix C.4.

5 Related Work

This section reviews the broader context of automated metrics and human evaluations that use multiple inputs: either multiple translations or, more commonly, multiple references.

Automated metrics. Early metrics like BLEU (Papineni et al., 2002) and ChrF (Popović, 2015) operate at segment or corpus level and support multiple references but not multiple hypotheses simultaneously. COMET (Rei et al., 2020) trains an

encoder for human-like quality assessment and supports a single reference. Adding more references shows limited gains (Zouhar and Bojar, 2024).

Closest to our work, Dinh et al. (2024) propose a k-NN quality estimator similar to $\text{COMET}_{\text{poly-ic}}$, but aggregate train-test similarity of MT models as a quality indicator rather than having a separate QE model that assesses translations based on similarity and contextual relevance. Moosa et al. (2024) introduce MT-Ranker, which compares translation pairs and outputs a binary preference.

With the rise of Large Language Models (LLMs), an up-to-date approach for Quality Estimation is to use LLM-as-a-Judge. Simply prompting LLMs to output the quality score of a translation has become the state-of-the-art approach, with the most prominent example of GEMBA (Kocmi and Federmann, 2023). This approach has the potential to improve even further, by applying different strategies such as including in-context examples (few-shot judge), chain-of-thought prompting, pairwise comparison, as recommended by Zheng et al. (2023).

Human evaluation. Human evaluation of machine translation takes many forms. For benchmarking, WMT initially used RankME (Novikova et al., 2018), where annotators rank multiple hypotheses simultaneously.

Due to biases and high cognitive load, this shifted to single-hypothesis assessments such as Direct Assessment and its variants (Graham et al., 2013; Kocmi et al., 2022), Multidimensional Quality Metrics (Freitag et al., 2021), and Error Span Annotation and its variants (Kocmi et al., 2024b; Zouhar et al., 2025). Despite judging one hypothesis at a time, annotators gradually see other translations during evaluation, implicitly calibrating their quality judgments. Automated metrics, however, lack this contextual grounding and evaluate translations independently.

6 Discussion and Conclusion

Recommendation. $\text{COMET}_{\text{poly-cand}}$ can be applied in scenarios where multiple translations exist for the same source sentence, such as: (1) enchmarking various competing systems on the same test set (e.g., WMT General shared tasks), (2) comparing outputs from different checkpoints or models during MT development, or (3) cselecting the best translation from a pool of hypotheses during reranking for final output selection.

The intended use of $\text{COMET}_{\text{poly-ic}}$ is for quick domain adaptation without retraining the metric (Appendix C.3). While different retrieval methods can cause slight variations in performance (see Appendix C), it is crucial that the retrieval mechanism is deterministic to ensure reproducible scores. Additionally, changing the retrieval mechanism or the set of previously annotated translations that are being retrieved instantiates a new metric with non-comparable scores to the previous evaluations. Therefore, when using $\text{COMET}_{\text{poly-ic}}$, always disclose the retrieval set and retrieval method.

Training a smaller, specialized module with some tweaks ($\text{COMET}_{\text{poly-cand}}$) can be beneficial compared to directly using large, general-purpose language models (GEMBA). We have shown that $\text{COMET}_{\text{poly-cand}}$ can reach the performance of GEMBA, while being much more efficient in terms of inference time.

Submitted models. We submit the following models to the WMT Metrics Shared Task 2025 and make them publicly available under open license (Apache License 2.0) on Hugging Face. The models are trained on WMT data up to 2024 (inclusive).

- COMET-poly-base-wmt25: baseline
- COMET-poly-cand1-wmt25: one additional translation
- COMET-poly-cand2-wmt25: two additional translations
- COMET-poly-ic1-wmt25: one in-context example
- COMET-poly-ic3-wmt25: three in-context examples
- knn-poly-cand3: three additional translations, scored with COMET-poly-base-wmt25
- knn-poly-ic3: three in-context examples

Conclusion. In this work, we introduced two new paradigms for machine translation quality estimation: (1) evaluating a translation with the context of other translations of the same source, and (2) quality estimation with retrieval for in-context examples. We showed that these approaches show potential in being more adaptable and outperforming the baseline COMET, while also offering practical advantages in efficiency by matching the performance of larger models at lower computational cost.

Limitations

$\text{COMET}_{\text{poly-cand}}$ is entirely constrained to setups where we are scoring multiple translations at the same time. This is by design and thus mostly suited for WMT-style benchmarking competitions or model development where we wish to find which translation model is the best one. It is not useful for scenarios where a single model is being evaluated without the context of other existing translations.

Both $\text{COMET}_{\text{poly-cand}}$ and $\text{COMET}_{\text{poly-ic}}$ are not exempt on the reliance on the quality of previously human-annotated translations. In some cases, the quality of the collected data might be subpar (Kocmi et al., 2024a), which is then then further exemplifies its bias in $\text{COMET}_{\text{poly-cand}}$ and $\text{COMET}_{\text{poly-ic}}$.

Our investigation in this paper omits various tricks used to further boost COMET's performance for the purpose of clarity of the core methodological contributions of $\text{COMET}_{\text{poly-cand}}$ and $\text{COMET}_{\text{poly-ic}}$.

Appendix Overview

The appendix includes the following information:

- Implementation Details (§A)
- $\text{COMET}_{\text{poly-cand}}$ Ablations and Analysis (§B)
- $\text{COMET}_{\text{poly-ic}}$ Ablations and Analysis (§C)
- k-NN Ablations and Analysis (§D)
- GEMBA Ablations and Analysis (§E)
- Analysis of Impact of Additional Translations and In-Context Examples (§F)

A Implementation details

A.1 COMET

The model details are shown in Table 6. For computing embeddings to retrieve similar examples, by default we use the cosine distance from all-MiniLM-L12-v2 (Reimers and Gurevych, 2020). However, we also experiment in ablations with using the xlm-roberta-large (Conneau et al., 2020) embeddings and embeddings from a trained baseline COMET.

Encoder	xlm-roberta-large (24 layers)
Embeddings	Layerwise attention & CLS
Encoder frozen	30% of first epoch
Regression head	#features $\times$ 2048$\times$ $1024 \times (1 + \text{\#additional})$
Optimizer	AdamW
Learning rate	1.5×10^{-5}, encoder 10^{-6}
Batch size	256 (aggregated)
Loss	Average MSE across all targets
Training epochs	5

Table 6: COMET architecture and training details.

A.2 GEMBA

As the underlying LLM for GEMBA, we use Llama 3.3 70B with 4 bit quantization. All experiments with GEMBA are run on one H100 GPU with 80 GB of memory. The prompts we used for $\text{GEMBA}_{\text{poly-cand}}$ and $\text{GEMBA}_{\text{poly-ic}}$ are show in Table 7. Depending on the setting, the human reference and the gold score of the additional translation can be omitted, and more than one additional translations can be included.

B $\text{COMET}_{\text{poly-cand}}$ Ablations and Analysis

B.1 Robustness towards choice of additional candidate.

In a realistic usage, it might not always be possible to have additional candidate that is close to the original translation. Therefore, we experiment using $\text{COMET}_{\text{poly-cand}}$ with randomly selected additional candidate. The results are shown in the bottom half of Table 8 (5-7). As can be seen, even randomly selected additional translations significantly improve performance compared to the standard COMET model. However, compared to the setting with the closest candidate, random selection worsen the performance of $\text{COMET}_{\text{poly-cand}}$, albeit by a small margin. The largest performance drop occurs when the model uses the additional translation's score as input (7 vs 4). This is expected, as having the gold score of a similar candidate to the original translation is more informative than a score for a random one. This also holds when adding more translation candidates, as can be seen in Table 9. More detailed experiment on different levels of candidate similarity are provided below.

B.2 Effect of candidate similarity level

We examine the relationship between the additional translation's similarity to the one at hand. As can be seen in Table 10, the more similar the candidate, the more helpful it is to improve the performance of $\text{COMET}_{\text{poly-cand}}$. This is even more notable in the setting where we include the gold score of the candidate, $f(s, t, t_2, y_{t_2})$. However, in all settings, $\text{COMET}_{\text{poly-cand}}$ is still considerably improved compared to the baseline COMET model.

C $\text{COMET}_{\text{poly-ic}}$ Ablations and Analysis

C.1 Comparing different retrieval strategies.

We investigate different retrieval strategies: We retrieve using the embeddings derived only from the source text s^e, only the translation t_i^e, the sum of the two $s^e + t_i^e$, and the concatenation $\langle s^e, t_i^e \rangle$. We use all-MiniLM-L12-v2 (Reimers and Gurevych, 2020) as an embedding model. Table 11 shows that the simplest approach, only embedding the source yields the best performance across all metrics.

C.2 Testing different embedding models.

In previous experiments, we used an external embedding model (all-MiniLM-L12-v2 (Reimers and Gurevych, 2020)) to retrieve in-context examples. However, one could alternatively use the COMET model's own embeddings or its untrained xlm-roberta-large (Conneau et al., 2020) backbone. We continue using the source text for generating embeddings, as this consistently yielded the best results. Nonetheless, we find that the external embedding model achieves the strongest performance (Table 12), likely because it was explicitly trained

GEMBA$_{\text{poly-cand}}$
Score the translation provided at the end of this prompt from <*source lang*> to <*target lang*> with respect to human reference on a continuous scale from 0 to 100, where a score of zero means "no meaning preserved" and score of one hundred means "perfect meaning and grammar". Keep your explanation as short as possible. Provide the final score at the end of your answer; do not output anything else afterward.
<*source lang*> source: <*source sentence*>
<*target lang*> human reference: <*human translation*>

Below is an example translation along with its score:
<*target lang*> translation: "<*additional translation*>"
Score: <*score of additional translation*>

Now score this translation (remember to output the final score only at the end of your answer):
<*target lang*> translation: <*MT output*>

Score:

GEMBA$_{\text{poly-ic}}$
Score the translation provided at the end of this prompt from <*source lang*> to <*target lang*> with respect to human reference on a continuous scale from 0 to 100, where a score of zero means "no meaning preserved" and score of one hundred means "perfect meaning and grammar". Keep your explanation as short as possible. Provide the final score at the end of your answer, do not output anything else afterward.

Below is an example translation along with its score:
Source: <*additional source sentence*>
Translation: "<*additional translation*>"
Score: <*score of additional translation*>

Now score this translation (remember to output the final score only at the end of your answer):
<*source lang*> source: <*source sentence*>

<*target lang*> translation: <*MT output*>

Score:

Table 7: Prompts for GEMBA$_{\text{poly-cand}}$ and GEMBA$_{\text{poly-ic}}$.

for cross-lingual sentence representation. This suggests that COMET$_{\text{poly-ic}}$'s performance is closely tied to the quality and suitability of the embedding model used for retrieval.

C.3 Adaption to the Biomedical Domain using COMET$_{\text{poly-ic}}$

In-Context Enables Domain Transfer. Table 13 presents results from testing our models on in-domain biomedical data. We use the BioMQM dataset (Zouhar et al., 2024). The MQM spans are turned into 0–100 scores to be compatible with the rest of the data. We use the small dev set for training (10k segments) and the test set for evaluation (43k segments).

The goal is to assess whether COMET$_{\text{poly-ic}}$ can leverage in-context examples to adapt its quality estimation to the new domain. This is indeed the case, particularly in MAE, where a substantial performance improvement is observed compared to the base model.

While fine-tuning the models on biomedical data yields even greater gains, it comes at a cost: the fine-tuned base model performs poorly on standard, non-biomedical data. In contrast, both COMET$_{\text{poly-ic}}$ and COMET$_{\text{poly-cand}}$ remain robust after fine-tuning and continue to perform well on standard data, likely because they can incorporate contextual signals at inference time.

C.4 Similarity Threshold Analysis for COMET$_{\text{poly-ic}}$

For COMET$_{\text{poly-ic}}$, the choice of in-context examples is crucial. During training, retrieved examples are drawn from the training set and thus come from the same distribution and have been seen by the model. In contrast, at test time, the examples are unseen and often less similar. Figure 2 shows a histogram of the inner product similarity between embeddings of the evaluated source and the top-1 retrieved source sentence. The plot reveals that training-time additional sources are generally more similar to the evaluated source than those retrieved during testing.

We investigate whether the train-test mismatch affects COMET$_{\text{poly-ic}}$ by training models with dif-

	Model	Reference-less $\rho\uparrow$	Reference-less $\tau_b\uparrow$	Reference-less MAE$\downarrow$	Reference-based $\rho\uparrow$	Reference-based $\tau_b\uparrow$	Reference-based MAE$\downarrow$	
standard COMET model	$f(s,t) \rightarrow \hat{y}_t$	0.105	0.079	30.2	0.245	0.166	26.6	(1)
Additional candidate t_2^* is the closest								
additional candidate	$f(s,t,t_2^*) \rightarrow \hat{y}_t$	0.160	0.127	28.5	0.281	0.180	26.3	(2)
additional candidate, joint predictions	$f(s,t,t_2^*) \rightarrow \hat{y}_t, \hat{y_{t_2^*}}$	0.167	0.113	28.8	0.275	0.172	25.6	(3)
additional candidate and its score	$f(s,t,t_2^*, y_{t^*2}) \rightarrow \hat{y}_t$	0.267	0.207	21.9	0.374	0.243	20.6	(4)
Additional candidate t_2 is random								
additional candidate	$f(s,t,t_2) \rightarrow \hat{y}_t$	0.163	0.118	29.0	0.280	0.175	26.6	(5)
additional candidate, joint predictions	$f(s,t,t_2) \rightarrow \hat{y}_t, \hat{y_{t_2}}$	0.163	0.100	29.3	0.276	0.163	25.8	(6)
additional candidate and its score	$f(s,t,t_2, y_{t_2}) \rightarrow \hat{y}_t$	0.234	0.185	22.9	0.352	0.229	21.0	(7)

Table 8: Results for $\text{COMET}_{\text{poly-cand}}$. The first row shows the standard COMET. The top half (2-4) shows that adding additional translation candidate boosts performance. The bottom half (5-7) shows that using randomly selected additional candidates (in contrast to examples close to the original translation) also helps to boost performance, proving that $\text{COMET}_{\text{poly-cand}}$ is robust to the choice of additional candidates.

Table 12: $\text{COMET}_{\text{poly-ic}}$ results, with in-context examples retrieved using source text s^e, using different embedding models.

ferent similarity thresholds to better align training retrievals with test-time similarity. The results in Table 14 show that the model trained without any similarity filtering performs best, suggesting that the train-test mismatch does not significantly impact performance.

D k-NN Ablations and Analysis

D.1 Weighted k-NN

We can extend the simple k-nn approach to incorporate weigthed averages, which can boost performance. For example, in the poly-cand setup, our final prediction will be given by

$$\hat{y}_{s,t} = \sum_{i=1}^{n} \left(\frac{w_i}{\sum_{i'=1}^{n} w_{i'}} \right) \times \text{COMET}(s, t_i),$$

where $w_i = \exp(-d_i/\gamma)$ is a weight with d_i being a dissimilarity measure between (s, t) and (s, t_i)

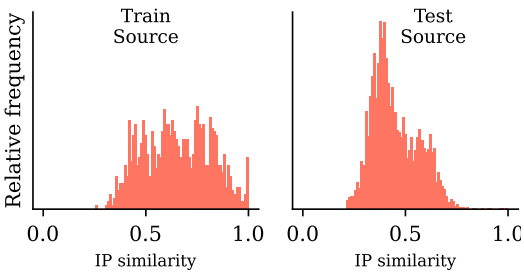

Figure 2: Histogram of inner product similarities between the currently evaluated item and the top-1 retrieved item for $\text{COMET}_{\text{poly-ic}}$.

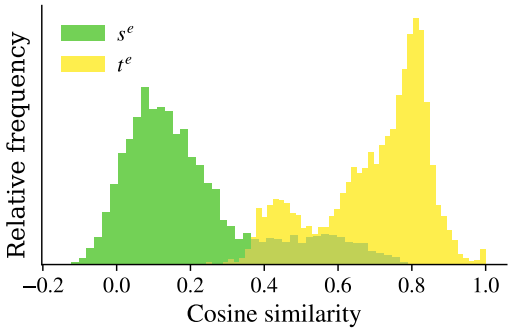

Figure 3: Histograms of translation similarity for examples retrieved by source embeddings (s^e) versus translation embeddings (t^e), showing that t^e-based retrieval yields higher-similarity (more relevant) neighbors while s^e-based retrieval often returns low-relevance examples.

(used for retrieval), and $\gamma > 0$ is the kernel bandwidth, that can be tuned using a validation set. We set d_i to be one minus the cosine similarity of embeddings. The same approach applies to the poly-ic setup. Realize that doing a simple average is equivalent to running the weighted average with $\gamma \to \infty$.

D.2 Ablation and Analysis

We evaluate the k-NN baseline under varying γ values using a weighted-average scoring scheme and different retrieval strategies in the poly-ic setting. Table 15 reports results for the poly-cand configuration: performance is remarkably consistent across both γ and k, since all retrieved translations are of similar relevance. Table 16 gives results for the poly-ic configuration: here, choices of γ and k have a pronounced effect, and the best scores are achieved when retrieval leverages both source and target contexts. Figure 3 complements Table 16 and explains why using s^e for retrieval when k-NN is applied works the worst; we plot the histograms of translation similarity when examples are retrieved either using the translation or the source embeddings. What we see is that when examples are retrieved using source similarity, there is no guarantee that the translations we retrieve are relevant for our target translation (low similarity). On the other hand, if the examples are retrieved using the translation similarities, we end up selecting more relevant examples in terms of similarity (as expected).

E GEMBA Ablations and Analysis

Adding random translations does not consistently improve performance. Similar to ap-

pendix B, we experiment with adding random translation candidates instead of the most similar ones. This yields similar results. These results are reported in Table 17.

Multiple additional translations is better. We experiment with multiple candidates/examples to $\text{GEMBA}_{\text{poly-cand}}$/$\text{GEMBA}_{\text{poly-ic}}$. As can be seen from Table 18, having 5 candidates instead of 1 helps $\text{GEMBA}_{\text{poly-cand}}$ improve over the baseline GEMBA in terms of Pearson correlation; however, the Kendall-tau and MAE metrics do not always agree. For $\text{GEMBA}_{\text{poly-ic}}$, having 5 samples instead of 1 even slightly worsens the performance.

In general, adding more examples to the input does not always help improve the performance of GEMBA as opposed to COMET. Note that the performance of the standard GEMBA is better than the standard COMET (0.266 Pearson versus 0.105 Pearson, see first row of Table 1 and Table 4 for more details). A possible explanation could then be: the additional candidates/samples added to the inputs help with issues that are specific to the baseline COMET, i.e., detecting edges cases of failed translations (see Section 4.5 for more details), which might not be an issue for the baseline GEMBA.

F Analysis of Impact of Additional Translations and In-Context Examples

We perform a systematic analysis by categorizing test cases according to the gold quality scores of the translation under evaluation. The test cases are split into two by the median of the gold quality scores. For $\text{COMET}_{\text{poly-cand}}$, we also further categorize the cases based on the gold quality scores of the additional translation: we consider the cases where (1) the additional translation t_2 is the best within the pool of candidate translations from the same source and (2) t_2 is the worst within the pool of candidate translations. The results can be found in Table 19.

We also manually inspect cases where the additional translation yields the largest improvements. These include, for example, undertranslations, numerical errors, explanations within the translations. We find that in these cases, the additional translation does not show such errors and can serve as a substitute reference. These examples are listed in Table 20.

Abstract

In this paper, we present our submission to the Tenth Conference on Machine Translation (WMT25) Shared Task on Automated Translation Quality Evaluation. Our systems are built upon the COMET framework and trained to predict segment-level Error Span Annotation (ESA) scores using augmented long-context data. To construct long-context training data, we concatenate in-domain, human-annotated sentences and compute a weighted average of their scores. We integrate multiple human judgment datasets (MQM, SQM, and DA) by normalising their scales and train multilingual regression models to predict quality scores from the source, hypothesis, and reference translations. Experimental results show that incorporating long-context information improves correlations with human judgments compared to models trained only on short segments.

1 Introduction

The automatic evaluation of machine translation (MT) is a crucial component of MT research and development. While expert-based human evaluation remains the gold standard, automatic evaluation offers fast and scalable judgments, enabling rapid feedback for optimizing model parameters. Traditionally, automatic MT evaluation metrics have relied on basic lexical-level features, such as counting matching n-grams between the MT hypothesis and the reference translation. Metrics such as BLEU (Papineni et al., 2002), METEOR (Banerjee and Lavie, 2005), and ChrF (Popović, 2015) remain popular due to their lightweight design and computational efficiency (Marie et al., 2021). More recently, neural metrics (either trained on human annotations or based on pre-trained language models) have demonstrated superior capability in comparing and assessing MT quality, often outperforming traditional lexical-based metrics (Freitag et al., 2022). These neural approaches leverage large-scale multilingual data during training and achieve strong performance even when translations diverge lexically from the reference.

This paper presents DCU_ADAPT's submission to the WMT25[1] MT Evaluation Shared Task. The primary focus of this year's task is on systems capable of evaluating translation quality in context, where the context spans entire documents or multiple consecutive segments. We participated in the segment-level quality score prediction track for English–Czech, English–Russian, English–Japanese, and English–Chinese, employing models based on the COMET framework (Rei et al., 2020a).

In our contribution to the shared task, we explore methods for leveraging synthetic data alongside the capabilities of pre-trained and cross-lingual models to predict MT quality estimates for long-sequence or multi-sentence units. Human judgments of MT quality are typically available as short segment-level scores, such as DA (Graham et al., 2017), MQM (Lommel et al., 2014), and SQM (Barrault et al., 2019). Recent pre-trained models support larger context windows and can handle long-sequence inputs, improving discourse-level resolution (Dai et al., 2019)—albeit at the cost of increased memory and computational requirements. However, most existing automatic evaluation metrics (AEMs) predict scores at the sentence level, and those designed for document-level evaluation often perform only shallow context integration during inference (Vernikos et al., 2022). We propose a data augmentation strategy to train multilingual models on long-context annotated data, enabling them to better exploit broader context and reduce inconsistencies caused by sentence-level ambiguity.

The exploration of context in MT is a well-established topic and, in recent years, has become a focal point, driven by the need to incorporate context into both MT systems and their evalua-

Proceedings of the Tenth Conference on Machine Translation, pages 905–912
November 8-9, 2025

tion methodologies (Bawden et al., 2017; Castilho et al., 2020; Maruf et al., 2021; Castilho et al., 2023; Castilho and Knowles, 2024). There is now broad consensus on the value of document-level evaluation. Since 2019, WMT has conducted human evaluations at the document level, providing evaluators with access to context even when collecting segment-level ratings (Akhbardeh et al., 2021; Kocmi et al., 2022a, 2023, 2024a). Research indicates that the appropriate context span is critical for reliable MT evaluation, with Castilho et al. (2020) showing that incorporating relevant context spans can yield more accurate assessments of translation quality, thereby improving the evaluation process. Several techniques have been proposed to extend evaluation to the document level or to incorporate multi-sentence context into automatic evaluation metrics (Jiang et al., 2021; Vernikos et al., 2022; Rei et al., 2022; Kocmi et al., 2022b; Raunak et al., 2024).

For this shared task submission, we use the Estimator model from the COMET framework (Rei et al., 2022), which learns MT quality from human evaluation data such as MQM and DA. To create long-context training data, we combine multiple annotations using a weighted average alongside the original annotations. Our experiments show promising progress toward improved correlation in multi-sentence-level MT quality estimation. Fine-tuning multilingual embedding models demonstrates that it is possible to achieve high correlations with human judgments when evaluating long segments, rather than relying solely on sentence-level score predictions.

We release the data and code produced during this research.

2 Corpora

We used the human annotations from previous WMT shared tasks (Kocmi et al., 2022a, 2023, 2024a) for training our models, which includes human annotations from MQM, DA, and SQM. We train and evaluate our models for English (en) to Czech (cs), Japanese (ja), Chinese (zh), and Russian (ru) language pairs. MQM scores are derived from error annotations and can range from $-\infty$ to 100. Since our goal is to predict ESA scores (Kocmi et al., 2024b), which range between 0 and 100, we normalise (using Equation 1, where x is original and x' is normalised score) and rescale the scores to the [0, 1] interval for training models on the combined dataset.

$$x' = \frac{x - \min(x)}{\max(x) - \min(x)} \tag{1}$$

We create augmented training data for long-span MT quality estimation by taking a weighted average of segment-level scores. During augmentation, we concatenate multiple samples (i.e., 2, 3, 4, and 5 segments) to form long-span texts. To construct the long-span MT evaluation dataset, adjacent short segments are concatenated, and a document-level quality score is computed as a length-weighted average of their original scores. The weighting is based on the total number of characters in the source and machine-translated texts, as formalized in Equation 2.

Let s_1, s_2 are short segments (e.g., source-translation pairs), and raw_1, raw_2 human evaluation scores for these segments. C_1 and C_2 are the total character count of each segment e.g., $C_i = len(s_i)$.

Then the document-level score (raw_{doc}) is calculated as:

$$\text{raw}_{\text{doc}} = \frac{C_1 \cdot \text{raw}_1 + C_2 \cdot \text{raw}_2}{C_1 + C_2} \tag{2}$$

This equation[2] computes a weighted average of two segment-level scores, where the weight is determined by the combined character count of the source and MT for each segment. Longer segments contribute more to the final score, reflecting their higher informational content. The augmentation process increased the average segment length of dataset from 16.84 words per segment to 52.99 words per segment. Since the augmented segments were added to the original dataset, the overall size of the dataset increased by a factor of two.

We then create training, test, and validation sets by randomly sampling segments from the training data. The statistics of the final training, validation, and test sets are shown in Table 1.

3 Experimental Setup

Our system is built on top of the COMET package, utilizing the `comet-train` and `comet-score` commands to train and evaluate our models. We fine-tuned the pre-trained model `Unbabel/wmt22-comet-da`, originally trained on

[2]We adapted the implementation of data augmentation from the Huggingface repository: https://huggingface.co/datasets/ymoslem/wmt-da-human-evaluation-long-context

Table 1: Dataset statistics by evaluation type, split, and language pair (K represents values in thousands).

DA data, as well as the multilingual pre-trained model `FacebookAI/xlm-roberta-base` (Liu et al., 2019), using A100 GPU. The `xlm-roberta` model was pre-trained on 2.5TB of filtered CommonCrawl data containing 100 languages and has approximately 279 million parameters.

We trained the models for up to 5 epochs and employed early stopping when the Spearman correlation on the development set did not improve for two consecutive evaluations. For each language pair, the augmented dataset contained five times the original data; however, due to limited GPU memory, we faced out-of-memory issues and restricted training to augmentations with up to two segments. The training process with the augmented dataset took approximately 10 hours for each model.

We trained one baseline model (the fine-tuned version of `wmt22-comet-da`) and three main models (one primary and two secondary submissions) using the data augmentation approach, retaining only the last two checkpoints for each. Spearman correlation on the test split was used to select the best checkpoint per language pair, and this best model was used for the final submission.

For official WMT `test25`[3] evaluation, the full segment was used since it fell within the maximum sequence length (512) supported by both the baseline and fine-tuned models. COMET scores typically range between 0 and 1, but can sometimes exceed 1, indicating exceptionally high-quality segments. To align with the ESA metric's scoring strategy (Kocmi et al., 2024b), we upscaled and rounded the scores to a range between 0 and 100.

4 Results

As described in Section 2, our experiments use the normalized versions of multiple human annotations collected from previous WMT shared tasks. To evaluate and compare our approach, we applied a similar augmentation method to construct long-sequence test data, incorporating annotations from DA, MQM, and SQM. Our baseline sentence-level quality estimation models are `wmt22-comet-da` (referred to as COMET-22) and BERTSCORE. COMET-22-LS, a fine-tuned version of `wmt22-comet-da` on long-span data, and ROBERTA-LS, fine-tuned from `FacebookAI/xlm-roberta-base`, both serve as long-sequence quality score prediction models. Following Rei et al. (2020a), the models were trained on triplets of (source, hypothesis, reference) and output a score between 0 and 1 reflecting the translation quality relative to both source and reference.

We used the Pearson correlation coefficient to evaluate the models' performance. Segment-level Pearson correlations on the self-test set are presented in Tables 2 and 3. Our results indicate that metrics from models trained on long-context inputs generally outperform sentence-level metrics, in some cases by a significant margin.

The annotation-wise segment-level correlation results in Table 2 demonstrate that the unsupervised baseline metric, BERTSCORE, exhibits relatively weak correlations across all language pairs. The sentence-level COMET-22 model shows improved correlations, especially for DA annotations, reflecting its training on DA data. Moreover, it outperforms BERTSCORE on SQM and MQM annotations, indicating its ability to mimic human annotations by learning from data. Our fine-tuned long-sequence baseline model, COMET-22-LS, surpasses the sentence-level baselines, achieving performance close to, and in some cases better than, our primary submission models based on ROBERTA-LS. Notably, COMET-22-LS achieves results on MQM annotations that are very close to those of ROBERTA-LS, outperforming sentence-level baselines by a substantial margin. This suggests that training on longer context sequences provides considerable benefits, especially for complex annotation types like MQM, which capture fine-grained translation errors.

Table 3 summarizes correlation results across all language pairs using joint annotations. Across nearly all language pairs, our models outperform

baseline metrics in correlation with human judgments. Ideally, COMET-22-LS, fine-tuned from `wmt22-comet-da` (which is already trained for evaluation tasks), should have outperformed ROBERTA-LS. However, the performance difference between the two models is not substantial. This may be because `wmt22-comet-da` was trained only on DA data, while the current task also includes SQM and MQM annotations, which typically follow different scoring strategies. Furthermore, as mentioned earlier, due to resource constraints, we trained our models for only five epochs and on a limited number of augmented segments. With larger augmentation and more robust training, the performance gap between the two models may become more pronounced.

These results suggest that combining multiple segments within the same document or domain is more effective than independently scoring segmented sentences and averaging their scores (Raunak et al., 2024). The improvement may be attributed to the model's ability to capture contextual information across long-sequence segments, thereby enabling more context-aware quality estimation.

However, handling longer text sequences poses challenges due to the input size limitations of the underlying models, as highlighted by Gong et al. (2020). This necessitates careful segmentation and score-averaging strategies to compute scores at the paragraph or document level. We also conduct a preliminary analysis of the score distributions (Figure 1) and find that sentence-level baseline scores (COMET-22) are mostly concentrated between 60 and 100, with a pronounced peak around 90. In contrast, the ROBERTA-LS model, trained on multi-sentence inputs, produces a more widely spread score distribution that better reflects the variability typically observed in human judgments (Toral et al., 2018). This wider spread may be due to the long-span training data being based on weighted average scores that encompass a broader range of score scales. By contrast, the narrower distribution of COMET-22 scores could stem from the characteristics of the human-annotated data on which it was trained, where non-expert evaluators have been shown to assign disproportionately higher fluency and adequacy ratings, resulting in smaller score gaps and reduced variance compared to expert assessments (Toral et al., 2018). This indicates that models trained with longer context are more sensitive to subtle quality differences, reflecting a more nuanced understanding of translation quality.

5 Related Work

In recent years, metrics based on large pre-trained models have emerged as strong alternatives to traditional n-gram-based approaches, enabling better capture of semantic similarity between words beyond mere lexical matching. These metrics broadly fall into two categories: embedding-based metrics and fine-tuned metrics.

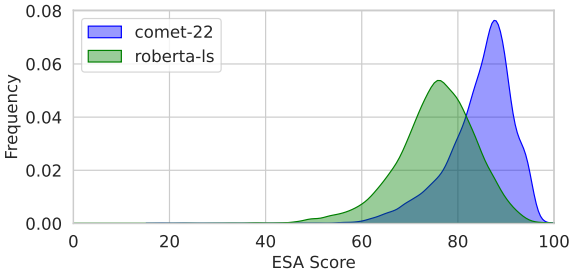

Figure 1: Distribution of segment-level scores assigned by sentence-level COMET-22 and long-sequence ROBERTA-LS model.

Embedding-based metrics typically represent an advancement over n-gram matching by using dense word representations in an embedding space to compute scores that reflect semantic similarity between reference and hypothesis segments. Notable examples include YISI-1 (Lo, 2019), MOVERSCORE (Chow et al., 2019), and BERTSCORE (Zhang et al., 2019), which leverage embedding models for soft alignment between two segments to capture semantic similarity effectively.

Fine-tuned metrics, on the other hand, involve learnable models such as RUSE (Shimanaka et al., 2018), BLEURT (Sellam et al., 2020), and COMET (Rei et al., 2020a, 2022) that directly optimize underlying embedding models to maximize correlation with human judgments. These models have demonstrated promising results in producing reliable quality scores for test sets such as DA or MQM. While most of these metrics perform reference-based evaluation, recent advancements leveraging highly multilingual pre-trained encoders like multilingual BERT (Devlin, 2018) and RoBERTa (Liu et al., 2019; Conneau et al., 2019) have enabled reference-less systems to show encouraging correlations with human judgments (Freitag et al., 2023).

Most automatic evaluation approaches rely on decontextualized assessments, where translations are judged at the sentence level. However, sentences are often inherently ambiguous, and incorporating document-level context has been shown to be beneficial for both MT and its evaluation (Läubli et al., 2018; Castilho et al., 2020; Castilho and Knowles, 2024; Vernikos et al., 2022). Consequently, a few automatic metrics have been developed to extend evaluation beyond the word or sentence level (Vernikos et al., 2022; Jiang et al., 2021). These metrics aim to address discourse-level phenomena such as lexical consistency, coherence, ellipsis, and pronoun resolution (Voita et al., 2018; Bawden et al., 2017).

However, existing methods typically use a limited number of surrounding sentences as context, allowing models to incorporate neighboring information when embedding each sentence and computing scores at the sentence level (Rei et al., 2020b; Vernikos et al., 2022; Hu et al., 2023). In contrast, long-sequence or document-level evaluation processes the entire segment as a single input, enabling deeper discourse-level resolution and offering a promising yet still underexplored avenue for improving alignment with human judgments.

6 Conclusion

In this paper, we present DCU_ADAPT's contribution to the WMT25 MT Evaluation Shared Task. We leverage the COMET framework and train regression models to predict ESA quality scores. In line with the Shared Task goals, we augment the provided training data and optimize our models to evaluate long, multi-sentence units of text. By fine-tuning multilingual models for cross-lingual transfer, we utilize source, reference, and hypothesis as inputs. Our primary submission — a fine-tuned pre-trained model trained on augmented data — demonstrates higher or otherwise competitive correlation levels with human judgments across multiple languages. Further investigation comparing long-text evaluation after segmentation with sentence-level evaluation is a promising direction for future work.

The data and code produced during this Shared Task participation are available at: https://github.com/sami-haq99/CAEMT/tree/main/wmt-2025-submission.

Limitations

We trained our models using augmented long-segment level scores from the MQM, DA, and SQM datasets. However, we only evaluated the models on self-test data carefully extracted from the training set; evaluating on benchmark datasets will better clarify the true benefits of our approach. Additionally, we normalized the data using min-max normalization to combine different datasets and upscaled the predicted scores to match the ESA metric's score range. Furthermore, our training and testing were conducted on GPUs with at least 40GB of memory; due to time constraints, we were unable to evaluate performance on CPUs.

Ethics Statement

Our research focuses on evaluating long-sequence outputs of MT systems using quality estimation models trained on augmented data. We are committed to conducting and reporting our evaluations with the highest levels of transparency and fairness. By upholding these principles, we aim to contribute to reliable and objective assessment practices in MT evaluation.

Abstract

This paper presents the evaluation of submissions to the WMT 2025 Metrics Shared Task on the SSA-MTE challenge set, a large-scale benchmark for machine translation evaluation (MTE) in Sub-Saharan African languages. The SSA-MTE test sets contains over 12,768 human-annotated adequacy scores across 11 language pairs sourced from English, French, and Portuguese, spanning six commercial and open-source MT systems. Results show that correlations with human judgments remain generally low, with most systems falling below the 0.4 Spearman threshold for medium-level agreement. Performance varies widely across language pairs, with most correlations under 0.4; in some extremely low-resource cases, such as Portuguese–Emakhuwa, correlations drop to around 0.1, underscoring the difficulty of evaluating MT for very low-resource African languages. These findings highlight the need for more robust and generalizable evaluation methods tailored to African language contexts.

1 Introduction

In recent years, with the rise of large language models (LLMs), more and more machine translation (MT) systems have emerged, demonstrating competitive performance. This growth has created an increasingly urgent need for more accurate methods to assess the quality of generated translations. Traditional metrics such as BLEU (Papineni et al., 2002), METEOR (Banerjee and Lavie, 2005), and chrF (Popović, 2015), which rely on n-gram matching, show only limited correlation with human judgments, indicating their limited ability to capture semantic-level quality (Callison-Burch et al., 2006).

More recently, neural metrics such as BERTScore (Zhang et al., 2020a) have shown improved capability in capturing semantic similarity (Freitag et al., 2024; Zhang et al., 2020b). COMET (Rei et al., 2020) further advances this by framing machine translation evaluation (MTE) as a regression task using encoder-only language models and training on human-annotated scores. Likewise, the MetricX (Juraska et al., 2023) family of metric, based on the mT5 (Xue et al., 2020) series multilingual encoder-decoder LM, adopts a regression-based framework similar to COMET. These neural, learned metrics have been shown to achieve higher correlations with human assessments across a wide range of languages (Rei et al., 2020; Juraska et al., 2023).

However, before 2024, due to the lack of machine translation evaluation data, the performance of these models was largely untested on Sub-Saharan African languages. In 2024, AfriMTE (Wang et al., 2024a) was created. Evaluation results revealed that while existing metrics performed well on some relatively higher-resourced languages, they struggled with translations for very low-resource languages such as Twi and Luo (Wang et al., 2024b). The authors demonstrated that this gap can be partially addressed by further pretraining models on African languages; however, performance remains low for specific language pairs, like eng-luo, underscoring the need for dedicated training data for these languages.

Although AfriMTE marked progress in this area, several limitations remained. The dataset was relatively small, with only about 200 cases per language pair. Also, AfriMTE included outputs only from NLLB-200 (600M) (NLLB-Team et al., 2022) and M2M-100 (418M) (Fan et al., 2021). In addition, AfriMTE did not provide any training data, which meant that neural-based metrics could not be directly optimized for Sub-Saharan languages.

To address these challenges, Li et al. (2025) in-

Proceedings of the Tenth Conference on Machine Translation, pages 913–919
November 8-9, 2025

troduced SSA-MTE, a larger-scale dataset created following the same protocol and using the same annotation tool as AfriMTE. SSA-MTE covers 13 Sub-Saharan African languages, with test sets for 10 languages and training sets for 12. It features several source languages—English, French, and Portuguese—representing the Anglophone, Francophone, and Lusophone linguistic communities in the region. SSA-MTE includes translations from six MT systems and contains over 73,000 annotations in total.

The WMT 2025 Metrics Shared Task incorporates the SSA-MTE test set as a dedicated challenge set, enabling the evaluation of MT metrics on low-resource African languages. This inclusion establishes a benchmark for assessing the ability of MTE systems to generalize across under-resourced African languages.

2 SSA-MTE

We perform our evaluation on the recently released **SSA-MTE** dataset (Li et al., 2025), a large-scale human-annotated benchmark for assessing machine translation quality for African languages. The dataset contains over 73,000 sentence-level annotations across 13 language pairs (LPs) in the news domain, of which 10 LPs include a dedicated test set.

The test set covers 7 English–sourced LPs: Amharic (`eng-amh`), Hausa (`eng-hau`), Kikuyu (`eng-kik`), Kinyarwanda (`eng-kin`), Luo (`eng-luo`), Twi (`eng-twi`), and Yorùbá (`eng-yor`); 2 French–sourced LPs: Ewe (`fra-ewe`) and Wolof (`fra-wol`); and 1 Portuguese–sourced LP: Emakhuwa (`por-vmw`). For this challenge set, the authors additionally introduced another Portuguese–sourced LP: Nyanja (`por-nya`). The size of each test set is shown in Table 1.

The selected LPs reflect Africa's linguistic and regional diversity, covering Anglophone, Francophone, and Lusophone areas. In addition, the languages span three major language families: Afro-Asiatic (Hausa, Amharic), Niger–Congo (Kikuyu, Kinyarwanda, Emakhuwa, Nyanja, Twi, Yorùbá, Ewe, Wolof), and Nilo-saharan (Luo), ensuring representation across West, East, Central, and Southern Africa, and thus capturing both geographic and typological diversity.

Each instance is annotated by one human evaluator with both a continuous adequacy score and span-level (character-based) error labels, enabling fine-grained evaluation of MT outputs. Annotators are provided with the source sentence and its translation; instructed to first identify all errors according to the annotation protocol proposed by Wang et al., and then assign a final adequacy score.

For English- and French-sourced cases, source sentences are drawn from the Global Voices news website, following harmful-content filtering and topic-diversity-based article selection (Li et al., 2025). For Portuguese-sourced cases, source sentences are extracted from the Multilingual Open Text dataset, which features news articles published by Voice of America (VOA). All source texts are translated into the target languages by professional translators to serve as reference translations (Ali et al., 2024).

For English- and French-sourced sentences, six MT systems are included (but only five for Kikuyu, as Google Translate does not support it): GPT-4o, Gemini-1.5, Claude-3.5, Google Translate, and two open-source models: NLLB-200-distilled-600M (NLLB-Team et al., 2022) and M2M-100-418M (Fan et al., 2021). Each system contributes an equal number of translations. For Portuguese-sourced sentences, four MT systems are included: GPT-4o-mini, Gemini-1.5, Claude-3.5, and Google Translate.

Compared to the African Challenge Set in the WMT 2024 Metrics Shared Task, this year's set is substantially larger (12,768 vs. 2,815 annotated instances), covers a broader range of MT systems, and introduces Portuguese as a new source language. This broader linguistic and system coverage is expected to yield a more accurate and comprehensive evaluation of metric performance for African languages.

3 Metrics

The submissions of WMT 2025 Metrics Shared Task contain baseline metric results provided by the organizers, as well as the results of primary and secondary submissions from participants' metric systems. This section introduces each of these approaches[1].

3.1 Baselines

We received the following baseline metrics from the organizers: BERTScore (Zhang et al.,

[1]Detailed information of the submissions has not yet been provided by the organizer, and will be added in the camera-ready version.

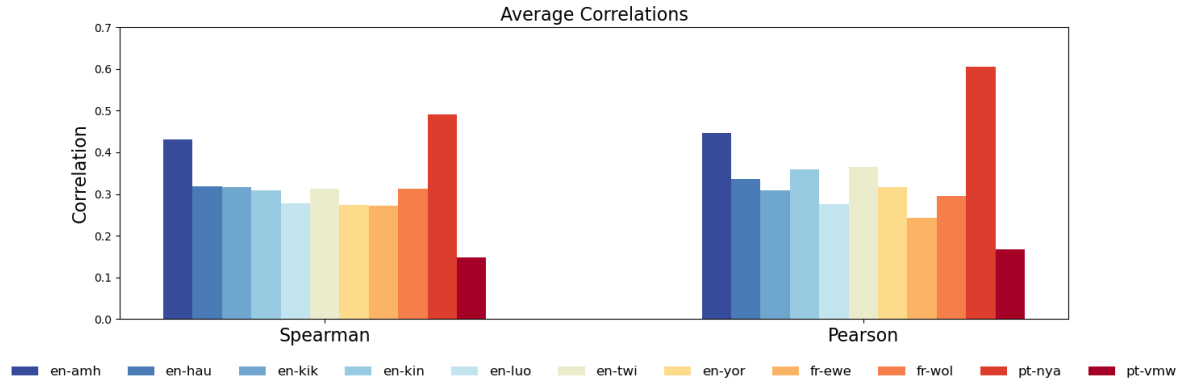

Figure 1: **Average Spearman and Pearson correlations across LPs**. AfriCOMET-1.1-MTL and SSA-COMET-MTL were not included in the calculation.

Language Pair	Size
en-amh	1,166
en-hau	1,192
en-kik	1,172
en-kin	1,210
en-luo	1,199
en-twi	1,200
en-yor	1,206
fr-ewe	1,077
fr-wol	1,175
pt-nya	1,241
pt-vmw	930
Total	12,768

Table 1: Number of instances per language pair.

2020b), BLEU (Papineni et al., 2002), chrF (Popović, 2015), COMET22 (Rei et al., 2022a), COMETKiwi22 (Rei et al., 2022b), Sentinel-Cand (Perrella et al., 2024), Sentinel-Src (Proietti et al., 2025), spBLEU (Fan et al., 2020), and YiSi-1 (Lo, 2019).

3.2 Submissions

From each participating team, we received one primary submission and several secondary submissions. The primary submissions included MetricX-25 (Juraska et al., 2025), mr7.2.1 (Hrabal et al., 2025), Polycand-2 (Züfle et al., 2025), and rankedCOMET (Maharjan and Shrestha, 2025). The secondary submissions included baseCOMET, MetricX-25-QE, MetricX-25-Ref, Polycand-1, and Polyc-3.

MetricX-25 MetricX-25 is an encoder-only regression model initialized from Gemma3 12B (Team et al., 2025) and fine-tuned on WMT15–23 DA and MQM scores in two stages: first on z-normalized DA scores, then on a 1:1 mixture of rescaled DA and MQM scores with a score-type indicator to align outputs with the intended evaluation (ESA/DA vs. MQM). Compared to MetricX-24 (Juraska et al., 2024), this setup increases the weight of DA data in the second stage and explicitly conditions on score type. Both stages also include a small proportion of synthetic WMT-derived data used in MetricX-24. Training uses a maximum input length of 4K tokens to balance performance and coverage of low-resource language examples.

mr7.2.1 uses Gemma3 27B (Team et al., 2025), prompted with the DSPy framework and optimized with MIPROv2 (Opsahl-Ong et al., 2024), first generating seven aspect scores (0–10) and then producing the final overall score (0–100).

rankedCOMET is based on COMET22 (Rei et al., 2022a) used in zero-shot inference, producing raw segment-level scores that are then adjusted with per-language-pair rank normalization, yielding calibrated distributions and improved correlation with evaluation metrics.

Polycand-2 is a COMET-poly supervised model trained on WMT data up to 2024 (DA/ESA/MQM merged on a single scale). It extends COMET by using two alternative translations of the same source to provide better context for scoring. English–Korean and Japanese–Chinese were excluded from training.

3.3 AfriCOMET-1.1-MTL and SSA-COMET-MTL

For the WMT 2024 Metrics Shared Task on the African Challenge Set, the authors explored replacing the original AfroXLMR (Alabi et al., 2022) with an enhanced African-centric multilingual pretrained encoder, AfroXLMR-76L (Adelani et al.,

2024)[2], to build MT evaluation and QE models tailored for African languages, and named the resulting models as AfriCOMET-1.1 (Wang et al., 2024b). This upgrade yields notable improvements: AfriCOMET achieved the highest Spearman correlation on the 2024 WMT African Challenge Set among all benchmarked systems (unweighted setting), underscoring the critical role of a stronger base encoder in advancing the quality of MTE for African languages.

Since this challenge set was built on SSA-MTE, which provides a large-scale training set, we further explored the impact of incorporating in-domain, in-task training data on final model performance. Specifically, we report results for SSA-COMET-MTL (MTL stands for multi-task learning), currently the best SSA-COMET model, built using the same pipeline as AfriCOMET-1.1 with the same base model and training data, but augmented with additional training examples from SSA-MTE. As the original authors did not provide an MTL version of AfriCOMET-1.1, we reproduced it by following the same pipeline and hyperparameters, enabling a fair comparison. We chose to compare using the MTL versions of the models because, empirically, MTL models tend to outperform STL models when all other factors are held constant (Li et al., 2025).

4 Analysis

Table 2 shows the average segment-level correlations on the SSA-MTE challenge set. Overall, correlations are moderate, with most Spearman values between 0.3 and 0.5 and Pearson values between 0.35 and 0.55. We adapt the following definition of levels of agreement: a Spearman and a Pearson correlation lower than 0.4 indicates a low-level agreement, a value between 0.4 and 0.6 indicates medium-level agreement, and a value greater than 0.6 indicates high-level agreement with human judgments.

4.1 Official Baselines

Among the official baselines provided by the organizers, chrF and YiSi-1 achieve the strongest overall performance (Spearman 0.506 / 0.460, Pearson 0.532 / 0.493), indicating that carefully tuned lexical and embedding similarity measures remain competitive in this evaluation setting. Notably, chrF even has comparable performance to the best supervised participant submission, MetricX-25. spBLEU shows a notable advantage over BLEU in Spearman (0.434 vs. 0.389), suggesting better ranking stability when using sentencepiece tokenization for morphologically rich or orthographically diverse languages. COMET22 achieves a lower correlation (0.363 in Spearman) compared to AfriCOMET-1.1-MTL, which shares the same architecture but uses an African-language–enhanced encoder LM (AfroXLMR-76L). This mirrors last year's findings on the importance of the base model. COMETKiwi22, a reference-free system, exhibits a clear performance drop compared to its reference-present variant COMET22, indicating that reference information remains important for neural, learned metrics. The Sentinel metrics score lowest overall, suggesting that their coarse-grained features are insufficient for fine-grained adequacy judgments in this domain.

Metrics	Pearson	Spearman
Baseline		
chrF	0.532	0.506
YiSi-1	0.493	0.460
spBLEU	0.395	0.434
BERTScore	0.471	0.425
BLEU	0.336	0.389
COMET22	0.405	0.363
COMETKiwi22	0.253	0.244
sentinel-cand	0.107	0.102
sentinel-src	0.068	0.073
Primary		
MetricX-25	0.530	0.467
mr7.2.1	0.477	0.380
rankedCOMET	0.377	0.364
Polycand-2	0.142	0.132
Secondary		
MetricX-25-Ref	0.550	0.490
MetricX-25-QE	0.490	0.427
baseCOMET	0.405	0.364
Polyic-3	0.177	0.144
Polycand-1	0.159	0.152
Additional		
SSA-COMET-MTL	0.688	0.630
AfriCOMET-1.1-MTL	0.599	0.552

Table 2: Average segment-level correlation coefficients of MT evaluation metrics across languages on the SSA-MTE test set.

4.2 Participant Submissions

For participant submissions, the highest average correlations come from MetricX-25-Ref (Pearson 0.550, Spearman 0.490), outperforming both its QE variant (MetricX-25-QE) and its default vari-

[2] https://huggingface.co/Davlan/afro-xlmr-large-76L

ant (MetricX-25). This reinforces the finding that reference-based approaches are more effective than QE-only approaches in the SSA-MTE setting. MetricX-25 is the best among primary submissions, followed closely by MetricX-25-QE and rankedCOMET. mr7.2.1 is competitive in Pearson but drops in Spearman, while the Polycand/Polyic series performs notably lower, suggesting limited adaptation to the SSA-MTE adequacy signal.

4.3 Additional Baselines

We also include two other baselines intended to benchmark progress in African-language MT evaluation: AfriCOMET-1.1-MTL and SSA-COMET-MTL. Both use the same base model and pipeline, with SSA-COMET-MTL further incorporating in-domain SSA-MTE training data. SSA-COMET-MTL achieves the highest overall scores in this evaluation (Pearson 0.688, Spearman 0.630), outperforming AfriCOMET-1.1-MTL by +0.089 Pearson and +0.078 Spearman. These gains highlight the value of in-domain, in-task supervision. Among submitted systems, MetricX-25 and its variants achieve the highest correlations, generally reaching a medium-level agreement with human judgments. All other submissions remain in the low-agreement range (Spearman < 0.4), indicating notable room for improvement.

4.4 Per-LP Performance

Figure 1 presents per-language averages across all metrics. Performance varies substantially by language pair: pt-nya is the easiest (Pearson 0.606, Spearman 0.491), while pt-vmw is the hardest (Pearson 0.168, Spearman 0.147). English-sourced pairs show mixed difficulty, with en-amh and en-twi at the higher end, and en-luo and en-yor lower. Among French-sourced pairs, fr-wol tends to outperform fr-ewe. These trends suggest that both source–target pairing and specific linguistic features of the target language influence evaluation difficulty. However, only en-amh and pt-nya achieve medium-level Spearman correlations; all other LPs remain in the low-agreement range, with pt-vmw extremely low (around 0.1 on average).

In summary, correlations on the SSA-MTE challenge set remain moderate even for the strongest systems, underscoring the difficulty of MT evaluation for low-resource African languages. The results indicate that reference-based learned metrics with in-domain training (e.g., SSA-COMET-MTL, MetricX-25-Ref) offer clear advantages, but there is significant room for improvement before reaching high-agreement levels with human judgment. Promising directions include the use of African-language–enhanced encoders and leveraging large-scale in-domain, in-task training data.

5 Conclusion

We have presented the results of the WMT 2025 Metrics Shared Task for the SSA-MTE challenge set, the largest and most diverse benchmark to date for MT evaluation in Sub-Saharan African languages. The evaluation covered a wide range of metrics, including official baselines, participant submissions, and additional African-focused baselines. Overall, correlations with human judgments remain modest, with most submitted systems achieving Spearman correlations below 0.4, indicating low-level agreement. Reference-based neural metrics generally outperform reference-free approaches, with MetricX-25-Ref leading among participant systems. SSA-COMET-MTL, trained with in-domain SSA-MTE data, sets a new reference point for African-language MTE, demonstrating clear gains over AfriCOMET-1.1-MTL and underscoring the value of domain-matched supervision. Per-language analysis shows substantial variation in difficulty, reflecting differences in source–target pairing, linguistic complexity, and resource availability. Only en-amh and pt-nya surpass the 0.4 threshold for medium-level agreement, while pt-vmw remains particularly challenging with correlations near 0.1. These findings suggest that while progress has been made, significant room remains to improve robustness and accuracy for the most difficult language pairs. Future work should explore integrating African-language–enhanced encoders, expanding the diversity of training data, and developing methods that can better generalize across very low-resource languages.

Abstract

This paper describes NVIDIA-NeMo's WMT 2025 Metrics Shared Task submission. We investigated two strategies for extending Machine Translation (MT) evaluation to unsegmented documents: 1) first segmenting into sentences and then applying regression-based metrics on aligned sentence pairs, and 2) directly utilizing the long-context capabilities of LLMs. The base comparison of the segmentation-based and LLM-based metrics on the WMT 2023-24 evaluation sets indicated that the former performs more robustly across language pairs. Thus we sought to improve the LLM-based approach by incorporating *relative evaluation* - this setting jointly evaluates all candidate translations at once and relative to each other, rather than evaluating each separately. Our experiments using the open-source Qwen3 LLM show that relative evaluation improves score correlations with human judgment, but only if the task is structured as a 2-stage evaluate-then-refine problem.

1 Introduction

For most of its history, machine translation (MT) research has revolved around the sentence as the primary unit of translation and evaluation. Standard MT benchmarks and evaluation protocols typically present systems with short, isolated segments, and assess their quality against human-produced references (Kocmi et al., 2024). This sentence-level paradigm has been driven by practical constraints: statistical and neural MT systems were long limited by both computational costs and modeling power (Kim et al., 2019). And in turn, automatic metrics, whether lexical (Papineni et al., 2002) or regression-based (Rei et al., 2020), were also designed to operate on sentence-like segments.

However, translation in real-world applications rarely occurs in isolation. Professional translators work with continuous documents, where meaning and style are shaped by discourse, context, and document-level coherence (Lommel et al., 2014). As neural MT systems have become more capable, particularly with the advent of large language models (LLMs), research has increasingly shifted toward document-level translation and evaluation (Zhu et al., 2024; Pang et al., 2025). This shift reflects both a practical need for evaluating translations as they appear in natural, unsegmented contexts and a growing recognition that many important aspects of quality, such as pronoun resolution, lexical consistency, and narrative flow, can only be judged when viewing the text holistically. This recent emergence of long-context MT models has made it technically feasible to translate much larger spans of text at once, raising a new research question in the field of MT evaluation: *is it better to apply existing sentence-level metrics to segmented text or apply LLM-based metrics directly to document-length text?*

In the WMT 2025 Metrics Shared Task, we focus specifically on the problem of unsegmented document evaluation: assessing the quality of MT outputs when the entire document is presented as a single sequence. Our submission compares two divergent strategies: (1) applying traditional regression-based metrics after segmenting documents into sentences, and (2) leveraging the long-context capabilities of LLMs to perform holistic document evaluation directly. To support our investigation, we simulated document-level human evaluations by concatenating the sentence-level MQM annotations from the WMT 2023 and 2024 Metrics Shared Tasks. Our experiments showed that the scaled up regression-based metric correlated better with human judgement than the LLM-based metric – we thus designed the former as our primary submission and the latter as our secondary submission to the WMT 2025 Metrics Shared Task.

While our primary findings favored the segmentation-based regression metric, we also explored ways to strengthen the LLM-based approach.

Proceedings of the Tenth Conference on Machine Translation, pages 920–925
November 8-9, 2025

In particular, we experimented with *relative evaluation* — a setup in which all candidate translations for a given source are presented to the model simultaneously and ranked against each other, rather than scored in isolation. We found that relative evaluation yielded only marginal improvements in correlation with human judgments, and only when implemented as a two-stage "evaluate-then-refine" process. Although these gains were not large enough to change our overall ranking of the two strategies, this line of work remains relevant for understanding how LLM prompting strategies interact with long-context MT evaluation. We therefore complement our main results with an analysis of why relative evaluation showed limited benefits and where it may still hold promise.

2 Document-level Human Evaluation

Prior to 2025, the WMT shared tasks were limited to the segment-level translation paradigm - all MT systems and all human evaluation operated on segments. To study document-level evaluation, we construct a simulated document-level MQM set by concatenating the source and target segments of each document and summing their MQM error counts. Table 1 compares the source lengths and MQM scores before and after document concatenation.

While this offers the best available proxy for document-level score correlations on WMT data, it has two notable limitations:

1. MT systems trained and evaluated on segmented inputs may differ from true document-level MT systems, which can exhibit distinct error patterns such as over- or under-translation.

2. MQM raters were instructed to consider surrounding context, but their judgments remained segment-focused; discourse-level phenomena may be underreported.

Note that we do not simulate document-level evaluation for the WMT 2024 sets because a large portion of segments were not evaluated. We also do not simulate document-level ESA data, as its 0–100 scale is not naturally additive, unlike MQM error counts. We therefore focus on the three language pairs from WMT 2023: En-De, He-En, and Zh-En.

Table 1: Comparison of segment and document-level WMT human evaluation data: average source character length (Len) and average MQM score (Score).

	Segment		Document	
Set	Len	Score	Len	Score
WMT23-En-De	354	-7.1	1028	-16.9
WMT23-He-En	84	-2.3	1719	-17.3
WMT23-Zh-En	40	-4.3	449	-25.1
WMT24-En-De	185	-3.0	-	-
WMT24-En-Es	185	-1.0	-	-
WMT24-Ja-Zh	91	-3.2	-	-

3 Metric Descriptions

3.1 Segmentation-based

The segmentation-based system breaks down document-level evaluation into sentence-level subproblems and relies on legacy sentence-level metrics for evaluation. Our approach first segments the source and target documents into sentences using ersatz (Wicks and Post, 2021), then establish aligned sentence blocks from these sentences using Vecalign (Thompson and Koehn, 2019) and LASER (Artetxe and Schwenk, 2019) sentence embeddings. Because our preliminary finding shows that existing sentence-level metrics are not good at identifying over- and under-translation errors, we have to rely on null alignments to identify these errors. To avoid merging unrelated sentences into aligned sentence blocks, we introduce an adaptive heuristic search strategy that dynamically finds the optimal alignment penalty (β_{skip}) for each document, ensuring those over- and under-translation errors are correctly identified as null alignments. Different from past practices such as mWERSegmenter (Matusov et al., 2005), which jointly align and segment system translations according to a reference, our system is a reference-free submission that directly aligns system translation to the source.

We apply MetricX-24-XXL-Hybrid-QE (Juraska et al., 2024) to each aligned blocks. In cases where null alignments are established, we penalize null alignments by assigning a score of 25 for each null alignment. We average the scores evalauted over sentence blocks to obtain a document-level score. To ensure the score aligns with the scale and directionality of WMT 2025, we apply a simple linear transformation of $100 - 4 \times s_d$ on the document-level score s_d.

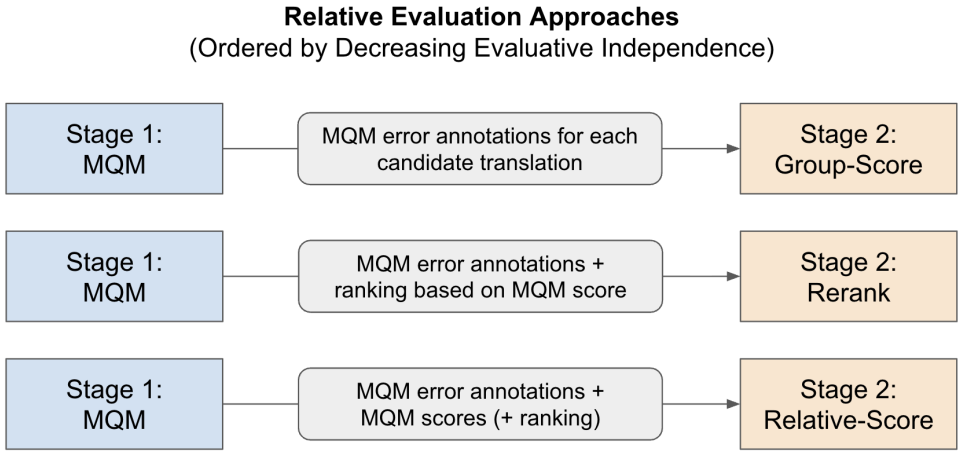

Figure 1: Overview of our 2-stage LLM-based methods: three relative evaluation approaches incorporating varying degrees of information from the initial MQM stage.

3.2 LLM-based

We implemented four document-level MT evaluation methods based on the Qwen3 large language model (LLM). All methods operate on unsegmented documents and follow the MQM (Multidimensional Quality Metrics) annotation scheme. The first method is a direct re-implementation of an established approach, while the remaining three extend it by incorporating a second-stage relative evaluation procedure.

3.2.1 Qwen-MQM

The baseline method, Qwen-MQM, is a Qwen-based re-implementation of the GEMBA-MQM framework, which was originally proposed using GPT models (Zhao et al., 2024). In this setting, the LLM is provided with the source document and a candidate translation and is prompted to produce MQM annotations (Kocmi and Federmann, 2023). The final document score is obtained by aggregating these annotations according to the MQM weighting scheme (Freitag et al., 2021). This method evaluates each system output independently, without reference to other candidate translations.

3.2.2 Relative Evaluation Extensions

The remaining three methods augment Qwen-MQM with a second evaluation stage in which the LLM is shown multiple system outputs for the same source document and instructed to re-assess or adjust scores based on cross-system comparison. This relative evaluation setting leverages the LLM's long-context capability to consider multiple translations simultaneously, with the goal of improving the utility of the metric for ranking MT systems. We present the methods in order of decreasing evaluative independence - that is, the degree to which final scoring decisions are formed without being conditioned on the scores and rankings of the initial MQM stage.

Qwen-MQM-Group-Score: In the second stage, the LLM is presented with the complete set of candidate translations together with their initial MQM annotations. It is then instructed to assign final scores to all candidates in a single pass, explicitly weighing the relative strengths and weaknesses that emerge through comparison. Since only the initial MQM annotations, and not the resultant MQM scores, are presented to the LLM in this second stage we consider that this approach has a high degree of evaluative independence.

Qwen-MQM-Rerank: In the second stage, the LLM is shown the initial ranking of candidates derived from their MQM scores, along with their MQM annotations, and is asked whether any adjustments to the ordering are warranted. Compared to the previous approach, this one offers less evaluative independence in the second stage: here, the initial ranking is presented to the LLM and the task is framed as a re-ranking of the initial judgments.

Qwen-MQM-Relative-Score: In the second stage, the LLM receives the initial MQM annotations and MQM scores (and thus implicitly the initial rankings) of all other candidates and is tasked with assigning a score to a single target translation in light of these scores. This creates the strongest dependency on prior judgments, as the evaluation of each candidate is explicitly anchored to the assessed quality of its competitors. Unlike the previ-

Table 2: Comparison of regression-based and LLM-based metrics on segment-level WMT data, as measured by system and segment score correlations with human judgments (Kendall's Tau). Correlations are averaged across language pairs.

Model	Sys	Seg
XComet-QE	0.731	0.371
MetricX-QE	0.769	**0.387**
GEMBA-MQM/ESA	**0.809**	0.362
Llama-MQM	0.674	0.230
Qwen-MQM	0.736	0.356

ous two approaches which evaluate all candidates at once, this one cycles through each candidate in order to evaluate each relative to the rest.

Figure 1 summarizes these three relative evaluation approaches in terms of what information from the initial MQM stage is made available. In other words, with more information (in the form of annotations, ranking, and scores), the evaluative independence of the second stage decreases.

4 Experimental Setup

Data: We use evaluation data from the WMT 2023–2024 Metrics Shared Tasks: MQM (both years) and ESA (2024). These are inherently segment-level corpora: translations were produced from pre-segmented sources, and human ratings were applied to individual segments.

Models: For LLM-based metrics, we use Qwen3-14B (Team, 2025b) in our experiments. The Qwen3 series is a hybrid reasoning/instruction-following model, capable of scaling inference-time compute via the generation of reasoning traces; however, we found that the reasoning mode degraded performance, so we disabled it in our experiments. In our attempt to identify the best open-source LLM, we also experimented with Llama3.1-8B (Grattafiori et al., 2024) and Gemma-3-12b-it (Team, 2025a) – these were less performant than Qwen3, as described in the next section.

Meta-Evaluation: For measuring score correlation with human judgment we rely on Kendall's Tau, as computed by the official WMT repository: `https://github.com/google-research/mt-metrics-eval`. We track both system-level and segment/document-level score correlations.

5 Results

5.1 Segment-level Evaluation

Table 2 compares regression-based and LLM-based metrics on the WMT 2023–2024 segment-level datasets. Correlations with human judgments are reported at both the system and segment level, averaged over all language pairs.

MetricX-QE stands out as the best overall metric, considering both system and segment-level score correlation. The GPT-based GEMBA metric is a close second, but for our submission we opted for open-source alternatives. Therefore on the LLM side, Qwen-MQM is the strongest available metric. We found that Llama produced reasonable, but weaker, results while Gemma failed to consistently follow the MQM instructions.

5.2 Document-level Evaluation

Given that MetricX-QE and Qwen-MQM were the strongest regression-based and LLM-based metrics respectively at the segment level, we centered our document level investigations around these two.

Table 3 presents results on the simulated document-level dataset constructed from WMT 2023 MQM annotations. Here the LLM-base metric outperformed the regression-based, unlike in the previous segment-level setting. This suggests that the long context capability of LLMs lead to a more holistic evaluation of document-level translations, while regression-based methods still require some form of segmentation into parts.

The single stage Qwen-MQM outperformed the two relative evaluation approaches with the highest degrees of evaluative independence in the second stage: Qwen-MQM-Rerank and Qwen-MQM-Group-Score. These degradations resulting from the second stage suggest that the relative evaluation ability of LLMs is still weak.

On the other hand, the Qwen-MQM-Relative-Score approach yielded moderate improvements over Qwen-MQM - since this approach provides a great deal of information (MQM annotations and MQM scores) from the first stage, it limits how much the scores produced in the second stage can deviate from that of the first stage.

6 Conclusion

We investigated two strategies for unsegmented document-level MT evaluation: scaling traditional regression-based metrics to longer contexts and applying LLM-based metrics capable of holistic

Table 3: Comparison of regression-based and LLM-based metrics on document-level WMT data, as measured by system and document score correlations with human judgments (Kendall's Tau).

Metric	En-De		He-En		Zh-En		Avg	
	Sys	Doc	Sys	Doc	Sys	Doc	Sys	Doc
LASER-MetricX-QE	0.909	0.328	0.848	0.233	0.714	0.285	0.824	0.282
Qwen-MQM	0.909	**0.429**	0.758	0.346	0.810	0.460	0.836	**0.425**
Qwen-MQM-Rerank	0.909	0.415	0.758	0.343	0.829	0.460	0.832	0.406
Qwen-MQM-Group-Score	**0.939**	0.365	**0.909**	0.250	**0.924**	0.261	**0.924**	0.292
Qwen-MQM-Relative-Score	**0.939**	0.421	**0.909**	**0.357**	0.810	**0.471**	0.886	0.416

assessment. While regression-based metrics exhibited stronger correlations with human judgments than LLM-based metrics on segment-level data, the inverse was true on simulated document-level data. While relative evaluation techniques modestly improved LLM-based performance, gains were only achieved under fairly restrictive settings. These findings suggest that long-context LLMs are a promising basis for document-level MT evaluation, but further work is needed to fully realize the potential of LLM-based approaches.

GEMBA-MQM V2: Ten Judgments Are Better Than One

Marcin Junczys-Dowmunt
Microsoft

Abstract

We introduce GEMBA-MQM V2, an MQM-inspired, reference-free LLM evaluation metric for the WMT25 Metrics Shared Task (Subtask 1). Building on GEMBA/GEMBA-MQM, we prompt GPT-4.1-mini to produce structured MQM error annotations per segment. We map annotations to scores with 25/5/1 severity weights (minor punctuation = 0.1). To reduce stochastic variance, each segment is scored ten times and aggregated with a reciprocal-rank weighted average (RRWA) after removing outliers beyond 2σ. On the WMT24 MQM test sets, GEMBA-MQM V2 ranks first by average correlation, with strong results across languages and evaluation levels; WMT23 results show comparable performance.

1 Introduction

Automatic evaluation is essential for assessing machine translation quality at scale. Recent work shows that large language models (LLMs) can act as effective evaluators when guided by MQM-style prompts (Lommel et al., 2014; Kocmi and Federmann, 2023b,a). We revisit this approach for WMT25 and propose GEMBA-MQM V2 — a more robust extension of the original method.

Using GPT-4.1-mini and full source-document context, we obtain strong segment-level and competitive system-level correlations on WMT24 and WMT23, while controlling judgment variability via multi-run aggregation. Structured JSON inputs/outputs enable reliable parsing and a clean separation between prompt and payload.

2 Data and Evaluation Protocol

We use MQM human-annotated test sets from WMT23 and WMT24 (overviews: (Haddow et al., 2023, 2024); metrics tasks: (Freitag et al., 2023, 2024)) as distributed in mt-metrics-eval (Google Research, 2024), following the MQM standard (Lommel et al., 2014). For WMT24 we evaluate English–German (en–de), English–Spanish (en–es), and Japanese–Chinese (ja–zh); for WMT23 we use English–German (en–de), Hebrew–English (he–en), and Chinese–English (zh–en). We follow the official task scripts to compute system- and segment-level correlations and report the prescribed measures for each year and language pair.

As in the original GEMBA approach, we use GPT-4.1-mini without further training.

3 Prompts

GEMBA-MQM V2 prompts GPT-4.1-mini with: (a) an MQM system instruction defining severity (critical/major/minor) and error types, while providing full source-document context and (b) line-by-line JSON inputs carrying source, target, and language tags. The model returns a JSON object with lists of errors by severity and type, which we score as MQM "badness" with weights 25/5/1 (minor punctuation = 0.1), then negate so higher is better for mt-metrics-eval.

The MQM protocol for human annotators is based on error span annotation. Span marking is difficult for generative LLMs, so following Kocmi and Federmann (2023a) we elicit short error descriptions rather than spans. Scoring depends only on error severity and error type.

Figure 1 shows the system prompt and the full English context excerpt used in the example. We then process each text segment individually (split on newlines), as shown in Figure 2, which presents a concrete input/output JSON pair from a WMT24 document and one of its system outputs. Currently, we do not maintain the history of previous segments, only the system prompt is visible for each segment prompt. Relative to prior GEMBA-MQM, we switch to GPT-4.1-mini, enforce JSON outputs, set temperature to 0.4, and judge line-by-line with full document context present in the prompt.

Proceedings of the Tenth Conference on Machine Translation, pages 926–933

```
You are an annotator for the quality of machine translation. Your task is to identify errors and assess
the quality of the translation.

To accomplish this, you will receive a pair of paragraphs from this context as a JSON structure. For each
input, reply with an extended JSON object that contains the following information:

Focus on errors in the translation, not in the source. Each error is classified as one of three
categories: "critical", "major", and "minor". Critical errors inhibit comprehension of the text. Major
errors disrupt the flow, but what the text is trying to say is still understandable. Minor errors are
technically errors, but do not disrupt the flow or hinder comprehension.

For every of the main three categories, additionally identify error types in the translation and
sub-classify them. The types of errors are: "accuracy" ("addition", "mistranslation", "omission",
"untranslated text"), "fluency" ("character encoding", "grammar", "inconsistency", "punctuation",
"register", "spelling"), "style" ("awkward"), "terminology" ("inappropriate for context", "inconsistent
use"), "non-translation", or "other". For every error type, do also supply a short description ("desc") of
the error type. If there are no errors of a specific main category (critical, major or minor), it is OK to
return an empty list for that category. It also OK to not return any errors for any category if everything
is fine.

Here is an example of a JSON input (potentially other languages):
{
  "source_language": "English",
  "source": "I do apologise about this, we must gain permission from the account holder to discuss an
  order with another person, I apologise if this was done previously, however, I would not be able to
  discuss this with yourself without the account holders permission.",
  "target_language": "German",
  "target": "Ich entschuldige mich dafür, wir müssen die Erlaubnis einholen, um eine Bestellung mit einer
  anderen Person zu besprechen. Ich entschuldige mich, falls dies zuvor geschehen wäre, aber ohne die
  Erlaubnis des Kontoinhabers wäre ich nicht in der Lage, dies mit dir involvement."
}

And here is a corresponding JSON output with example error annotations (potentially other languages)
{
  "source_language": "English",
  "source": "I do apologise about this, we must gain permission from the account holder to discuss an
  order with another person, I apologise if this was done previously, however, I would not be able to
  discuss this with yourself without the account holders permission.",
  "target_language": "German",
  "target": "Ich entschuldige mich dafür, wir müssen die Erlaubnis einholen, um eine Bestellung mit einer
  anderen Person zu besprechen. Ich entschuldige mich, falls dies zuvor geschehen wäre, aber ohne die
  Erlaubnis des Kontoinhabers wäre ich nicht in der Lage, dies mit dir involvement.",
  "errors": {
    "critical": [],
    "major": [
      {"type": "accuracy/mistranslation", "desc": "'involvement' is untranslated"}, {"type":
      "accuracy/omission", "desc": "'the account holder' is missing"}
    ],
    "minor": [
      {"type": "fluency/grammar", "desc": "'wäre' is a bit awkward"}, {"type": "fluency/register", "desc":
      "'dir' should be 'Sie'"}
    ]
  }
}

You should mimic the format from this example.

Apart from that, you are receiving the full English document as context which will help you analyze the
individual JSON segments provided after this for errors. Use this information to analyze the translation
pairs in their full context.

English input in context:
---
Siso's depictions of land, water center new gallery exhibition
"People Swimming in the Swimming Pool" from 2022 is one Vicente Siso artwork that will display at Tierra
del Sol Gallery beginning Jan. 13. (photo courtesy of Vicente Siso)
Tierra del Sol is pleased to present "Vicente Siso: Memories of the Land and Water" at the new gallery
location in West Hollywood. Siso has been an artist in the Studio Arts Program since 2012, this marks his
debut solo exhibition. Siso was born 1962 in Madrid and raised between Venezuela, Trinidad and Miami; he
moved with his family to Southern California in his early 20s.
Masterfully working across subject matter, Siso has generated a prolific series of landscapes, portraits,
and still-life works rendered in either acrylic, pastel, pencil or watercolor. Drawing from family
portraits, his own reference photographs, and recollection, his colorful compositions demonstrate his
range of interests and skill across media. Siso's tropical landscapes and seascapes reflect the
geographies of his past, employing rich patterns and incorporating people to make meaningful connections
between culture, memory and the environment. Siso titles his artworks in a mix of Spanish and English,
signifying the celebrated and integral complexities of his life in Los Angeles County. "Vicente Siso:
Memories of the Land and Water" opens on Saturday, Jan. 13, with a reception from 6-8 p.m. The exhibition
is on view through Sunday, March 3.
The Tierra del Sol Gallery is located at 7414 Santa Monica Blvd. For information, visit
tierradelsolgallery.org.
---

Next, you will receive the translation pairs as JSON objects. Analyze the translation as discussed above
and produce a JSON object with your analysis in response. Do not invent structural elements that are not
present in the JSON examples above. The only allowed keys are "source", "target", "source_language",
"target_language", "errors", "critical", "major", "minor", "type", "desc".

Figure 2: Follow-up prompt and output per text segment

4 Aggregation over multiple runs

Beyond prompt design, we consider aggregation across multiple runs to be the key contribution of GEMBA-MQM V2 for improving annotation reliability.

We score each segment ten times and aggregate the results using a reciprocal-rank weighted average (RRWA, see Section A.2): per segment, scores from each run are sorted in descending order, weighted by $1/\text{rank}$, and outliers beyond 2σ are removed before aggregation. This aggregation strategy is motivated by two observations:

- Individual runs can produce highly variable annotations due to the stochastic nature of the model.
- LLM-based MQM annotation often produces spurious error annotations.

We discuss these in more detail below.

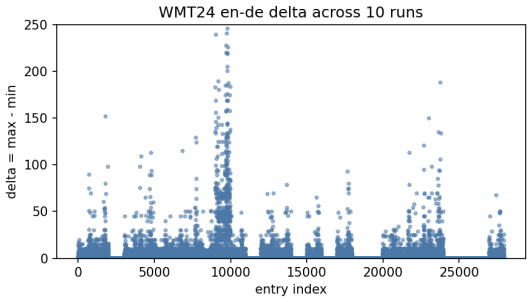
4.1 On variability

Individual runs with non-zero temperature produce highly variable annotations. After converting per-line outputs to MQM scores, we observe a substantial spread in values for the same segment. Table 1 illustrates this for the MSLC WMT24 example segment from the prompt: the same segment is judged ten times with very different outcomes.

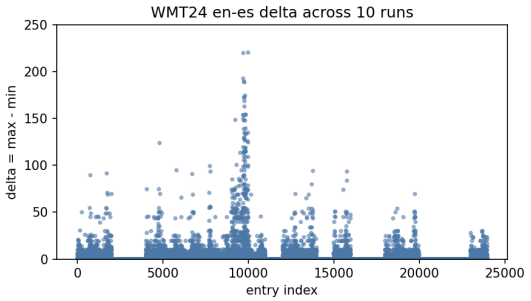
Run	Critical	Major	Minor	$> 2\sigma$	Score
1	2	0	0		-50
2	0	2	1		-11
3	0	1	1		-6
4	0	1	1		-6
5	0	2	1		-11
6	0	1	1		-6
7	0	1	1		-6
8	2	1	0	*	-55
9	0	1	1		-6
10	0	2	1		-11
mean-all		—			-16.85
mean		—			-12.55
max		—			-6.00
geo		—			-9.29
rrwa		—			**-8.50**

Table 1: Per-run MQM error counts and negated score for the segment from the MSLC prompt example. The outlier (*) is ignored. $\Delta = \max - \min = 49$.

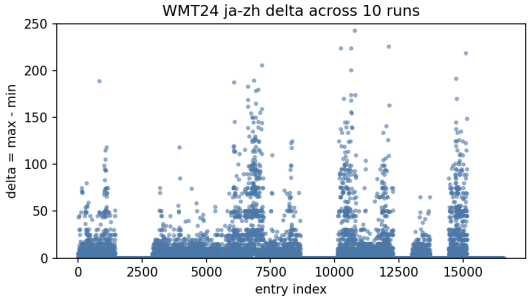
We further quantify variability by computing the difference (delta) between the maximum and minimum scores across ten runs for each segment. Figure 3 visualizes these deltas for all judged system outputs of WMT24 en–de, en–es, and ja–zh.



(a) en–de



(b) en–es



(c) ja–zh

Figure 3: Per-segment variability across 10 runs on WMT24. Each point shows $\Delta = \max - \min$; y-axis capped at 250. Zero-flat regions indicate systems without MQM gold, for which zeros were emitted.

Flat zero regions correspond to systems without MQM gold judgments; elsewhere, deltas can reach several hundred points, indicating substantial instability. Relying on a single judgment is risky.

4.2 On the tendency to over-annotate

LLM-based annotators often over-generate errors, sometimes identifying issues that are not present. Reciprocal-rank weighting biases the aggregate toward the lowest error magnitude (i.e., the most conservative plausible judgment), while remaining more discriminative than simply taking the minimum (or, for negated scores, the maximum). For comparison, we also report single-run variants (1–10), the simple mean, the geometric mean (geo), and the maximum (max). The reciprocal-rank weighted average (RRWA) consistently outperforms other aggregation methods, and all aggregates outperform individual runs (see Section 5 and Table 2).

Why not use the maximum then? One might expect the maximum score across runs (fewest errors after negation) to be the most conservative estimate. However, this can overlook subtle errors that are inconsistently annotated across stochastic runs. Since each annotation is a sample from a variable process, relying solely on the maximum risks ignoring genuine issues that appear in only some runs.

Aggregation, especially via reciprocal-rank weighting, balances caution with sensitivity to error diversity. MQM segment-level scores are weighted sums of few discrete values, often yielding repeated or tied scores (Table 1). Aggregating multiple runs increases score diversity and reduces ties, yielding a more nuanced and reliable estimate of translation quality. This better reflects the underlying variability in LLM-based annotation and mitigates the risk of over- or under-estimating errors. The aggregate thus behaves more like a regressed metric (e.g., MetricX-24).

4.3 On using other GPT variants and the lack of control

We observed challenges when using different GPT variants for evaluation. Although our approach relies on GPT-4.1-mini, other variants can produce markedly different behaviors and performance profiles. The lack of control over proprietary LLMs introduces variability across runs, model versions, and time periods.

During our experiments, we saw substantial behavior differences across time even when using what appeared to be the same model. Initially (December 2024), GPT-4o yielded results consistent with those reported here for GPT-4.1-mini. However, attempts to reproduce these results in May 2025 revealed significant performance drift for GPT-4o, rendering it unsuitable for our evaluation. GPT-4.1 showed similar degradation, whereas GPT-4.1-mini was performing well. We recovered our original December 2024 results only by reverting to an older, pinned version of GPT-4o.

Table 2: WMT24 with WMT24 task settings. Our GEMBA-MQM V2 variants compared to top systems.

5 Results on WMT24 metrics task data

We use the mt-metrics-eval toolkit to compute the correlations reported in Table 2. Our reference-free GEMBA-MQM V2 RRWA variant ranks first on WMT24 by average correlation (0.728), ahead of strong reference-based systems such as MetricX-24 (Juraska et al., 2024) and XCOMET (Guerreiro et al., 2024). Other reference-free metrics are further behind. As observed in the original GEMBA-MQM work (Kocmi and Federmann, 2023b,a), the strong performance of a general-purpose LLM is notable given that the competition includes purpose-trained metrics exposed to extensive task-specific human-created training data.

Single-run ablations group tightly (0.716–0.723), indicating good performance across stochastic runs despite high segment variability reported. Appendix Tables 3 and 4 provide WMT23 results under 2024 and original settings, respectively. Under 2024 rules our GEMBA-MQM V2 variant would have ranked first on WMT23 data as well. Aggregated results improve over each of the individual runs in every category. Segment-level performance is especially strong, while system-level performance lags behind. This suggests that the chosen MQM weights and the resulting segment scores may not lend themselves to cross-segment aggregation under equal weighting (simple mean).

6 WMT25 submission

For our WMT25 Subtask 1 submission, we follow the protocol outlined above. For all language pairs and systems we use the same prompts, temperature, and number of stochastic runs as in our WMT24 experiments.

The WMT25 Unified Evaluation task differentiates between language pairs with MQM-style scoring and Error Span Annotation (ESA) (Kocmi et al., 2024). We did not explore the implications of this differentiation in our current submission and simply submitted negated MQM scores for all language pairs. We expect rank-based correlations to carry over under this framework as in prior tasks.

At the time this paper was finalized, the shared task organizers had not yet released the final WMT25 metrics task results. As a consequence, we cannot report a definitive leaderboard position for our submission. Regretably, this reduces the value of this particular paper.

7 Conclusion

We presented GEMBA-MQM V2, a reference-free LLM evaluation metric/method for (machine) translation that combines JSON-first prompting, full source-document context, and multi-run aggregation. Scoring each segment ten times and aggregating with a reciprocal-rank weighted average (RRWA) improves robustness to stochastic variability and reduces over-annotation effects.

On WMT24 MQM test sets, GEMBA-MQM V2 ranks first by average correlation and is strong across languages and evaluation levels. Segment-level performance is especially strong, while system-level aggregation remains an open area for improvement.

Table 3: WMT23 evaluated with WMT24 task settings (retrofit protocol). We omitted systems with ranks above 30.

A Appendix

A.1 Results on WMT23

Tables 3 and 4 summarize WMT23 outcomes under the WMT24-retrofit and the original WMT23 protocols, respectively. Under the 2024 rules, our GEMBA-MQM V2 variant mirrors the WMT24 behavior and would have ranked first by average correlation. Under the original 2023 settings, results remain strong and consistent. In both protocols, multi-run aggregation improves over individual runs; segment-level performance is especially strong, while system-level performance lags behind, motivating future work on cross-segment aggregation beyond simple means.

A.2 Reciprocal-rank weighted average

Let $\{s_i\}_{i=1}^{k}$ be the per-run segment scores (higher is better; we use negated MQM). After removing outliers beyond 2σ (Section 4), sort the remaining n scores in descending order $s_{(1)} \geq s_{(2)} \geq \cdots \geq s_{(n)}$. The reciprocal-rank weighted average (RRWA) is

$$\mathrm{RRWA}(\{s_i\}) = \frac{\sum_{r=1}^{n} w_r \, s_{(r)}}{\sum_{r=1}^{n} w_r}, \quad \text{with} \quad w_r = \frac{1}{r}.$$

Thus, higher-ranked (larger) scores receive larger weights, biasing the aggregate toward more conservative judgments while remaining sensitive to mid/low ranks.

gemba-v2-gpt-4.1-mini-7[noref]	20	0.805	19	0.924	13	0.986	22	0.553	2	0.973	17	0.457	16	0.954	19	0.532
gemba-v2-gpt-4.1-mini-8[noref]	21	0.803	20	0.924	16	0.985	16	0.562	14	0.959	22	0.444	22	0.948	23	0.521

Table 4: WMT23 with WMT23 task settings (as originally reported). We omitted systems with ranks above 30.

Example using Table 1: after removing the single outlier (-55), the sorted scores are

$$\{-6,\ -6,\ -6,\ -6,\ -6,\ -11,\ -11,\ -11,\ -50\}.$$

With $w_r = 1/r$ and $\sum_{r=1}^{9} w_r \approx 2.83$, the numerator is

$$-\tfrac{6}{1} - \tfrac{6}{2} - \tfrac{6}{3} - \tfrac{6}{4} - \tfrac{6}{5} - \tfrac{11}{6} - \tfrac{11}{7} - \tfrac{11}{8} - \tfrac{50}{9} \approx -24.04.$$

Hence,

$$\mathrm{RRWA} \approx \frac{-24.04}{2.83} \approx -8.50,$$

matching Table 1. In our setup, RRWA acts like a soft maximum: it heavily favors the best (least-error) runs while still allowing the remainder to pull the score down when multiple runs consistently find issues. With 10 runs, the cumulative mass on the top ranks is substantial: top-1 $\approx 34\%$, top-2 $\approx 51\%$, top-3 $\approx 63\%$, and top-5 $\approx 78\%$.

CUNI and Phrase at WMT25 MT Evaluation Task

Abstract

This paper describes the joint effort of Phrase a.s. and Charles University's Institute of Formal and Applied Linguistics (CUNI/UFAL) on the WMT25 Automated Translation Quality Evaluation Systems Shared Task. Both teams participated both in a collaborative and competitive manner, i.e. they each submitted a system of their own as well as a contrastive joint system ensemble. In Task 1, we show that such an ensembling—if chosen in a clever way—can lead to a performance boost. We present the analysis of various kinds of systems comprising both "traditional" NN-based approach, as well as different flavours of LLMs—off-the-shelf commercial models, their fine-tuned versions, but also in-house, custom-trained alternative models. In Tasks 2 and 3 we show Phrase's approach to tackling the tasks via various GPT models: Error Span Annotation via the complete MQM solution using non-reasoning models (including fine-tuned versions) in Task 2, and using reasoning models in Task 3.

1 Introduction

Machine translation (MT) evaluation has evolved rapidly in recent years, driven by the dual rise of large language models (LLMs) and specialised neural quality estimation (QE) architectures. Shared tasks, such as the WMT MT Evaluation campaign, provide a rigorous and reproducible framework for assessing advances in automated evaluation. The WMT25 MT Evaluation Task continues this tradition, offering a benchmark for comparing diverse approaches across multiple subtasks, from system-level quality prediction to fine-grained error annotation.

In this paper, we present a joint study by Phrase a.s. and Charles University's Institute of Formal and Applied Linguistics (CUNI/UFAL), combining independent research streams with collaborative experimentation. Both teams participated in Task 1, each submitting their own primary and secondary systems, as well as a contrastive joint ensemble in Task 1. This setting allowed us to examine not only the relative strengths of distinct modelling paradigms but also the potential synergies of cross-team integration. Phrase also participated in Task 2 and Task 3.

Our contributions are threefold. First, we investigate complementary modelling strategies for Task 1, including NN-based regression models trained on large-scale MQM-style data (multidimensional quality metrics, Lommel et al., 2013), and LLM-based systems producing full linguistic quality annotations. We analyse how fusing/ensembling these approaches, when carefully configured, can yield measurable performance gains. Second, for Task 2, we evaluate GPT-based AutoLQA (Automatic Language Quality Assessment) systems—both off-the-shelf and fine-tuned variants—demonstrating their applicability to error span annotation in MQM and ESA (error span annotation, Kocmi et al., 2024) formats. Third, for Task 3, we explore reasoning-enabled LLMs with targeted prompting for translation improvement, highlighting trade-offs between fluency- and accuracy-oriented objectives.

By documenting both competitive and collaborative results, we aim to provide insight into practical design choices—such as metric selection, data sampling, and system fusion—that influence performance in automated MT evaluation. Beyond the leaderboard standings, our analysis identifies patterns that may inform future research on hybrid evaluation architectures, the role of fine-tuning in LLM-based evaluators, and the limits of current metrics in capturing subtle quality differences.

Proceedings of the Tenth Conference on Machine Translation, pages 934–944

2 Task 1

In Task 1, Phrase and UFAL decided to collaborate and choose the strategy in which each organisation submits its own primary system and one of its own secondary systems. Each team dedicated the other secondary slot to a joint system ensemble. The submitted systems are marked with an asterisk* in the respective tables.

2.1 Phrase Systems

We have two sets of models that we experimented with in Task 1: (1) NN-based quality regression models that directly output the quality prediction score, and (2) LLM-based models that run the full linguistic quality assessment that is used to calculate the final score, as described below.

There are two important decisions that we made in the course of the evaluations mainly due to our internal research conventions and momentum, and also due to some technical difficulties.

The first decision was about the development metric for Task 1. Although acc^*_{eq} *tie-calibrated pairwise accuracy* (Deutsch et al., 2023) is the primary metric of the WMT25 evaluations, we used Kendall's τ and Pearson r coefficients as our development proxy metrics. The main reason for this decision was our late adoption and implementation issues of the acc^*_{eq} metric. Note that we also used the two proxy metrics when fusing the CUNI and the Phrase systems.

The second decision was about the submission score. We decided to treat all scores in a unified MQM/ESA fashion, i.e. internally we do not distinguish between the two scores. The first reason for this adoption is that the evaluation is insensitive to the dynamic range of the two metrics and—to our knowledge—the difference between the two is (1) lower penalization of the "Fluency/Punctuation" MQM category and (2) higher penalization of the non-translations. The second reason is rather practical: at Phrase, our tools (that we used off-the-shelf for this evaluation) internally work with a single score (let us refer to the score merely as MQM) that is defined as follows: Given the input segment $\mathcal{X}$ (with its source and hypothesis fields), we compute the MQM score as:

$$\mathrm{MQM}(\mathcal{X}) = \max\left\{0, 1 - \frac{\mathrm{pen}\,(\mathcal{X})}{|\mathcal{X}_{\mathrm{source}}|}\right\}, \quad (1)$$

where $|\cdot|$ denotes the word count (note that we compute the word count of the source segment), and $\mathrm{pen}(\cdot)$ is the sum of all penalty points retrieved from the AutoLQA system output, where we map the minor, major and critical errors to the penalties of 1, 5 and 5, respectively (i.e., no quantitative difference between major and critical errors).

2.1.1 Phrase Development Data

As development data we used the Google-MQM (Freitag et al., 2021) dataset and the WMT22-QE combined dev and test sets. Since the latter only covers three language pairs (`en-de`, `en-ru` and `zh-en`, 1500 segments each), we also pulled test data from the Google-MQM set, which covers seven language pairs (`en-de`, `en-es`, `en-ru`, `en-zh`, `he-en`, `ja-zh`, `zh-en`). We randomly selected 700 segments per LP while making sure that only one system's translation of a source sentence was included. We then removed all translation variants of those source sentences from the remaining data to prevent contamination and filtered out very self-similar segments as well, resulting in a training dataset of about 150k segments.

2.1.2 Phrase QPS Systems

One set of features for the ensembles is provided by research variants of the Phrase QPS (Quality Performance Score) system[1][2] (*pqps*). We experimented with three pre-trained models: XLMR-large (Conneau et al., 2019), GTE (Zhang et al., 2024), and RemBERT (Chung et al., 2021), which we selected not only according to their accuracy, but also with regard to memory and inference speed requirements for the production environment at Phrase.

We continued training on a large amount of internal Phrase post-edit data covering 226 language pairs with chrF (Popović, 2015) as gold-label (resulting models are tagged *pe* in the result tables.)

Then we further fine-tuned on combined data from internal Phrase MQM-annotated and post-edit data as well as our training split of the Google-MQM and Amazon-bio-MQM datasets (Zouhar et al., 2024). We experimented with three gold/reference score variants: a balanced mix of MQM-score and chrF labels (*bal*), the same mix with a smoothed version of the MQM score (*balsm*) and one variant with only MQM- and MQM-like-scores (*mqm*) as gold label. In all cases, Equa-

[2] https://support.phrase.com/hc/en-us/articles/5709672289180-Phrase-QPS-Overview

tion (1) was the fundamental instrument for the MQM gold label score calculation.

See Table 1 for individual system performance on our development test sets (see Section 2.1.1). Due to the limited number of slots, we did not submit the best Phrase QPS system.

2.1.3 Phrase AutoLQA System

The AutoLQA system (Automatic Linguistic Quality Assessment) is an LLM-based system whose underlying model is a fine-tuned `gpt-4o-mini` model, marked as `gpt-4o-mini-FT`. This is the very same system that was used for the primary submission of Task 2 (see Section 3 for reference). The system produces complete MQM annotations based on which the MQM-score is produced via Equation (1).

This system is referred to as *palqa-wmt25* in Table 1.

2.2 CUNI/UFAL Systems

This section describes the systems submitted by the CUNI team.

2.2.1 Training and Development data

For training, we used a subsample of WMT24 ESA scores, counting only 2160 examples in total.

Because high ESA scores are much more frequent in the full dataset, we resampled the data to produce a more uniform score distribution, while ensuring an even spread across language pairs.

As the development set, we used WMT23 metrics task en2cs DA scores. Due to the computational cost of the evaluation, we did not use other language pairs for the evaluation during development.

2.2.2 Systems based on Gemma 3 27B-it and DSPy

Our primary submission (*mr7.2.1*, in Table 2) and one of the secondary submissions (*mr6*, in Table 1 and Table 2) were based on the Gemma 3 27B-it[3] used via the DSPy framework (Khattab et al., 2024). Its MIPROv2 optimiser (Opsahl-Ong et al., 2024) was used to automatically select n-shot examples and adjust the prompts for improved performance.

[3]For both optimisation and inference, we run several instances of the model using vLLM 0.9.2+rocm641, each instance on 2x AMD MI210 with 16k tokens context. We used a LiteLLM proxy server for load balancing between instances. We also used GNU Parallel (Tange, 2025) as a workaround for performance issues when trying to scale the number of concurrent requests to fully utilise GPUs.

We selected the Gemma 3 27B-it model for its relatively compact size and strong multilingual capabilities. Our focus was on using reasonably sized open-weight models that we can run on our hardware, so we chose not to use larger commercial models available through APIs, even though we expect them to perform better.

The optimisation target was essentially rescaled Mean Squared Error:

$$\text{score}(X) = \frac{1}{n}\sum_{i=1}^{n} 1 - \frac{(X_{i,\text{gold}} - X_{i,\text{pred}})^2}{100^2} \quad (2)$$

Both submissions first predict,in one or multiple LLM calls, seven integer scores (0–10) covering different translation quality dimensions:

- accuracy and completeness
- terminology and consistency
- fluency and coherence
- style tone and audience fit
- locale conventions and formatting
- technical integrity
- cultural appropriateness

These categories were inspired by MQM, with initial detailed descriptions drafted by GPT o3-mini, see Appendix B for details on the optimized prompts:

After predicting these dimensions, both *mr6* and *mr7.2.1* output an overall translation quality score (0–100 integer). Similarly to the approach taken by the Phrase team, we chose not to distinguish between pairs that solicit ESA scores and MQM scores and use this 0-100 score for both.

The key difference between the systems lies in the overall score aggregation:

- **mr6:** Predicts each dimension separately in isolation, with a separate request for each. The overall score is then predicted in a separate LLM call, using only the dimension scores (not the original text). This approach was motivated by the lack of gold data for dimension-level scores and the absence of a clear formula to combine them. We originally planned to replace this aggregation with a simpler regression model (e.g., linear regression or gradient

Table 1: Task 1 Individual models' performance. The asterisk * denotes submitted systems: *palqa-wmt25* is Phrase's secondary submission and *cuni-mr6-overall* is CUNI's secondary submission. Best scores in each group in bold.

boosting) after the initial MIPROv2 optimisation, but our preliminary experiments showed no consistent improvements. We therefore submitted the LLM-based aggregation version, although the lack of gain might be due to unidentified implementation issues.

- **mr7.2.1:** Predicts all dimensions and the overall score in a single LLM call.

Both systems use the chain-of-thought technique (Wei et al., 2022) as implemented by the DSPy.[4] If the model fails to produce the response in the correct format, there are 2 retries with different temperatures: 0.5 and $\frac{2}{3}$.

In addition, *mr7.2.1* includes a fallback mode that bypasses chain-of-thought and generates the final answer directly if reasoning fails in all 3 tries (most commonly due to getting stuck in generating repetitive loops).

The complete training and inference code for the models submitted by CUNI will be available on GitHub.[5]

We evaluated our systems on WMT23 metrics using the mt-metrics-eval tool. We show the results in Table 2.

To get some idea whether the MIPROv2 optimisation and chain-of-thought actually contributes to better performance, we evaluate several modifications of the *mr7.2.1* submission: *_noopt* is a version with no MIPROv2 optimisation and consequently no n-shot examples. *_nocot* is a version where the output is generated directly with no chain-of-thought reasoning. The *_nocot_noopt* variant disables both. We can notice that disabling either of these or both at the same time seems to worsen the performance in all of the tracked metrics.

2.3 Fusion / Ensembling

We used the features/models described above to train six standard regression models: Linear Regression (Freedman, 2005), Ridge Regression (Hoerl and Kennard, 1970), Decision Tree Regression (Breiman et al., 1984), Random Forest Regression (Breiman, 2001), Gradient Boosting Regression (Friedman, 2000), and MLP Regression (Rosenblatt, 1958), all with default scikit-learn (Pedregosa et al., 2011) hyper-parameters. The models were trained on our training data split of the Google-MQM public dataset (see Section 2.1.1). For both the Phrase-only ensembles and the Collaboration ensembles we compared using all features as well as a "slick" version which uses only the best feature of each type: *pqps-xlmr-bal*, *palqa-wmt25* and *cuni-mr6-overall*. See results in Table 3. The submitted systems are marked with an asterisk. We selected the Gradient Boosting Regressor because it seems to achieve a good balance across both testsets as well as both metrics.

For a language-pair specific breakdown of results for the submitted systems refer to Table 7.

3 Task 2 (Phrase)

In Task 2, we experimented with using our internal AutoLQA systems that are based on LLMs and in-context learning. AutoLQA systems have been developed to produce the complete MQM annotation, i.e. they include the error category by default.

Table 3: Task 1 Phrase-only and Collaboration ensembles for different regression models and feature sets. Note on the submitted systems: phrase-slick is Phrase's primary submission, collab-slick is Phrase's secondary submission, collab-full is CUNI's secondary submission

Table 4: Task 2 F1 score for various engines. The results are reported on our Google-MQM test data. Note the `gpt-4o-mini-FT` is Phrase's fine-tuned version of the `gpt-4o-mini` model.

Engine	F1
`gpt-4o-mini`	0.1835
`gpt-4.1-mini*`	0.2277
`gpt-4o-mini-FT**`	0.2669

We used the Google-MQM test set as our development dataset, as described in Section 2.1.1.

We used GPT engines for this task. We experimented with both the off-the-shelf GPT models, as well as our fine-tuned (FT) versions of some of the models. Fine-tuning was performed on ∼100k segments of Phrase internal data. Table 4 depicts the performance increase when FT is used.

We also experimented with the wording mainly reducing the prompt from the complete MQM task to ESA, i.e., stripping off the error category part of the prompt. We are not allowed to disclose the full prompt but we have experienced that this reduction did not change the performance on our dev set. We have therefore decided to use one of our AutoLQA systems based on the `gpt-4o-mini-FT` model as our primary submission (denoted by double asterisk in Table 4).

Table 5: Task 3 Evaluation results for different systems. C-QE-Δ denotes the COMET-QE delta.

System	C-QE-Δ	TER	GtE-ratio
prod*	0.005	44.51	0.0001
onlyerrors	0.026	25.24	0.0010
accuracy	0.024	15.23	0.0016
fluency	0.050	37.05	0.0014
fluency_s**	0.043	28.27	0.0015

Table 6: Task 3 Primary system quality estimation scores. C-QE denotes the absolute COMET-QE score.

Dataset	baseline		post-edit	
	C-QE	QPS	C-QE	QPS
devtest	0.287	0.901	0.330	0.921
eval-full	0.055	0.878	0.073	0.901
eval-en-cs	0.079	0.910	0.102	0.923

Our secondary submission (denoted by *) is based on the FT gpt-4.1-mini. Due to higher cost, we have not evaluated the model on our development set and have relied on the results in Table 4 and on internal observations at Phrase where in most cases gpt-4.1-mini outperforms gpt-4o-mini.

4 Task 3 (Phrase)

For Task 3, our submissions are based on GPT models as well. We experimented with varying prompts, OpenAI models and settings (notably the amount of reasoning effort which can be set to "low", "medium" or "high" in the API).

After visual inspection and analysis of the error spans and scores provided for the development set, we deemed them quite noisy and not informative enough. We therefore opted for not using this information in the experiments. Our systems only utilise the source sentences and the MT outputs.

Our secondary submission prod (denoted by a single asterisk in Table 5) is loosely inspired by Phrase's production systems for automated MT adaptation. We submitted it as a baseline; however, this system is tailored to addressing typical customer use cases, such as correcting terminology, formality, or the placement of inline tags. Therefore, most of its instructions are not applicable to the WMT setting, so the system wastes its attention on irrelevant aspects. In addition, it required us to set a specific formality and without further domain-specific adjustments, the system likely changed the tone in many cases, leading to substantial amounts of post-editing.

We also experimented with dedicated prompts and a simpler setup targeted towards only improving the general quality of the translations. We simplified the system as well—whereas our production systems typically perform multiple passes over the data, here, we limited the system to just a single pass.

In terms of OpenAI models, we find that reasoning models are well suited for this task. We evaluated several combinations of reasoning effort settings and model types (notably o3 and o3-mini). Our primary submission, as well as most of the contrastive runs, utilise the o3[6] model with medium reasoning effort.

We evaluated four different prompts:[7]

- onlyerrors — focused on finding errors in the translation
- accuracy — improving translation accuracy
- fluency — improving translation fluency
- fluency_s — improving translation fluency, the prompt contains individual steps that the system should follow.

Based on the results on the WMT development set, we selected the prompt fluency_s as our primary submission. This system has the second-highest improvement in COMET-QE score and makes fewer edits than fluency, thereby reaching a better GtE-ratio (gain-to-edit ratio, i.e., the difference in COMET[8] divided by TER, as defined in the task description). It seems noteworthy that COMET-QE score grows more when the prompt is focused on improving translation fluency, as opposed to accuracy.

4.1 Analysis

Based on the official leaderboard, none of our systems improved over the baseline translations on the current test set. In order to explain this negative result, we carried out a post-submission analysis using the current evaluation data.

We found that based on COMET-QE, our system does improve the general translation quality.

[6]The full model name is o3-2025-04-16.
[7]We describe each in more detail in Appendix C.
[8]Approximated here using COMET-QE.

However, we also found COMET-QE to be quite unstable (see the absolute scores across different datasets in Table 6) and decided to complement it with our proprietary QPS metric (see Sec. 2.1.2 for reference). This again showed a consistent improvement in quality.

Finally, we carried out a blinded human evaluation using a small random sample of 50 English-Czech evaluation examples. We removed examples with very low edit rates (TER<10) prior to the sampling in order to prevent the annotator from spending time comparing very similar outputs. The annotator saw each candidate translation side by side (ordered randomly; one being the original MT output and the other our post-edited version) and rated each output on the scale of 1 to 10.

Consistently with the automated quality estimation results (COMET-QE and QPS), the annotator rated the post-edited outputs as higher quality. Out of the 50 examples, our system output was preferred in 31 cases and tied in 10, whereas the baseline output was only preferred in 9 instances. The average score was 8.48±1.20 and 7.50±1.53 (approximate randomization test p-value≈0.002) for the system and baseline respectively, illustrating that while translation quality was quite high overall, translations were not generally deemed perfect by the annotator.

These findings leave conclusions quite open; on the one hand, both automated QE metrics and the human annotator (albeit on just a single language pair) showed clear preference for our post-edits. On the other hand, the official evaluation (which uses reference-based COMET) does not rate the system as better than the baseline. Further analysis leveraging also the official reference translations would be needed to explain this apparent contradiction.

5 Conclusion

We presented our submissions to WMT25 MT Evaluation Task developed by two teams, CUNI and Phrase: two primary and four secondary submissions for Task 1, one primary and two secondary submissions for Task 2 and one primary and one secondary submission for Task 3.

For system fusion/ensembling used in Task 1, the rule "more features are better" generally holds, although not for every individual language-pair or metric. It turns out that the ability of the regressor model "saturates" and gets stuck in the diminishing-reward paradigm soon.

It is interesting to see that competitive results can be achieved by combining very few systems if we choose them well, as is the case of "slick" systems.

In Task 3, we failed to improve on the baseline translation quality in the official rankings. However, our internal post-submission analysis showed a different picture and we currently lack a good explanation for the disagreement.

During the submission, we saw few puzzling outliers for certain language pairs in all tasks' leaderboard, and we expect to reveal the issues after the official annotations are released.

B Task 1 - DSPy Models Optimized Prompts

DSPy's resulting "programs" for our *mr** submissions, based on which the final single prompt requesting all the scales or the individual prompts are constructed. These include the selected n-shot examples and any adjustments to the initial data field descriptions or instructions.

B.1 mr6

The full version of optimised "program" (instructions and selected few-shot examples) for *mr6* can be found in the GitHub repository.[9]

B.2 mr7.2.1

The full version of optimised "program" (instructions and selected few-shot examples) for *mr7.2.1* can be found in the GitHub repository.[10]

C Task 3 Prompts

In this section, we share the details of instructions specifically tailored for our WMT systems.

There is also a common core part of the prompt which sets up the task and specifies processing requirements. This part is proprietary and therefore not shared here.

- `onlyerrors` Focus only on errors (grammar, fluency, mistranslation etc.), do not perform subjective or preferential edits.
- `fluency` Concretely, the task is to improve the overall fluency and naturalness (with translation accuracy being important but secondary), while minimising the number of edit operations. Avoid translationese and prefer loose translation when it allows for a more idiomatic translation.
- `fluency_s` Concretely, the task is to improve the overall fluency and naturalness (with translation accuracy being important but secondary), while minimising the number of edit operations. Avoid translationese and prefer loose translation when it allows for a more idiomatic translation.

  Let's go step by step:

  – Identify errors, translationese, or disfluent spans in the translation.
  – Consider several possible corrections.
  – Out of the possible outputs, choose one that is the most natural-sounding and requires few changes (edit operations).
- `accuracy` Concretely, the task is to improve the overall accuracy (with translation fluency being secondary), while minimising the number of edit operations.

MSLC25: Metric Performance on Low-Quality Machine Translation, Empty Strings, and Language Variants

Rebecca Knowles **Samuel Larkin** **Chi-kiu Lo** 羅致翹
Digital Technologies Research Centre
National Research Council Canada (NRC-CNRC)
{rebecca.knowles,samuel.larkin,chikiu.lo}@nrc-cnrc.gc.ca

Abstract

In this challenge set, we examine how automatic metrics for machine translation perform on a wide variety of machine translation output, covering a wider range of quality than the WMT submissions. We also explore metric results on specific types of corner cases, such as empty strings, wrong- or mixed-language text, and more. We primarily focus on Japanese–Chinese data, with some work on English and Czech.

1 Introduction

This paper describes a challenge set submitted to the Challenge Set Subtask of the (Unified) Machine Translation Evaluation shared task at the 2025 Conference on Machine Translation (WMT); we focus primarily on segment-level quality score prediction with a brief preliminary note on word-level error detection and span annotation. For this third iteration of the Metric Score Landscape Challenge (MSLC),[1] we run a smaller set of experiments. We once again focus on Japanese→Chinese news translation for the task of exploring the range of low- to mid-quality MT (as compared to the high-quality MT systems submitted to WMT). We also include analysis of empty strings (as in past iterations), mixed- and wrong-language text, and a preliminary note on English spelling variation; for these tasks, we use a mix of Japanese→Chinese data, English language data, and Czech→English data. Our approach, particularly for low- to mid-quality MT and for empty strings, demonstrates a low-cost way to test metrics on the wider quality landscape. We encourage developers of metrics to run such evaluations themselves prior to releasing metrics. For developers of metrics who are unable to run such evaluations themselves, we call on them to explicitly declare that their released metrics have not been tested on low- or mid-quality MT and should not be used for such cases without additional testing.

[1] MSLC data and additional figures can be found at https://github.com/nrc-cnrc/MSLC.

2 Prior and Related Work

This work describes the third MSLC challenge set. In Lo et al. (2023b), the first iteration, our intent was to focus primarily on low- and mid-quality MT output across four language pairs. The process of evaluation that year brought to light two other issues: the scores that metrics assigned to empty strings (as some MT system submission that year included empty strings, providing a natural experimental set) and "universal scores" (scores that were assigned very frequently by certain metrics) similar to the "universal translations" described in Yan et al. (2023). The second iteration of MSLC, Knowles et al. (2024), continued the work on low- and mid-quality MT, with the addition of experiments on empty strings, mixed- and wrong-language text, and language variants (in that instance, Spanish language terminology that differs across language variants). In concurrent work to MSLC24, Zouhar et al. (2024) proposed COMET-specific mitigations to many of the issues observed in both papers: incorporating language ID in order to mitigate issues with mixed- or wrong-language text, using signatures in the spirit of `sacreBLEU` (Post, 2018) to help explain variations in metric output, and the issue of empty strings.

There is a tradition of challenge sets targeting specific linguistic phenomena for MT (Isabelle et al., 2017; Burlot and Yvon, 2017; Guillou et al., 2018; Rios et al., 2018; Stanovsky et al., 2019, i.a.), while challenge sets for evaluation (i.e., challenge sets targeted at metrics) tend to be relatively newer (see, i.a., the descriptions of the challenge sets at the Metrics shared tasks: Freitag et al., 2022, 2023, 2024). Of these challenge sets, Amrhein et al. (2022, 2023) also explore wrong-language text (among 68 phenomena across a large number of language pairs in the ACES challenge set),

Proceedings of the Tenth Conference on Machine Translation, pages 945–956
November 8-9, 2025

noting particular issues for reference-free metrics, similar to our observations.

Our work is situated more broadly in the area of MT evaluation and corner cases for MT evaluation. While there is prior work focusing on specific metrics and corner cases (Hanna and Bojar, 2021; Amrhein and Sennrich, 2022; Yan et al., 2023; Zouhar et al., 2024, i.a.), submitting this challenge set to the shared task permits us to examine and compare performance on corner cases and MT quality ranges across metrics in a controlled environment. Importantly, readers should note that this paper is a description of a challenge set submitted to a shared task, rather than a complete, in-depth exploration of all the areas on which it touches. We note, in both the limitations section and throughout the work, that there are some components that represent established evaluations (MSLC-A and the empty strings work) while other components are presented as initial proof-of-concept experiments to determine whether future in-depth evaluation is indicated (these smaller preliminary experiments should not be used to draw sweeping conclusions).

3 Data

The MSLC challenge set is divided into two main components: MSLC-A (which covers low-quality and mid-quality MT) and MSLC-B (which targets specific corner cases and potential challenges for metrics).

3.1 MSLC-A

The MSLC-A portion of the challenge set focuses on covering a range of MT quality, from extremely low quality (incomprehensible output) to mid-quality output. The intention is to fill some of the gaps in evaluation of new metrics, which are typically tested at WMT on high-quality systems only, despite the fact that they may go on to be used for a wider range of quality in practice.

We use Japanese→Chinese systems from Knowles et al. (2024). The MT models were all constrained (as per the 2024 WMT General Task rules) NMT models built using Sockeye version `3.1.31` (Hieber et al., 2022) and trained on WMT training data; for a more detailed description of the systems, see Larkin et al. (2024). We translate and use only the News portion of the 2025 WMT General Task data.

There are six MT systems in this part of the challenge set. The lowest-quality system is indicated with the letter A, and the quality approximately increases as the system labels proceed alphabetically. Using the same process described in Larkin et al. (2024) and Knowles et al. (2024), these low- to mid-quality outputs were produced by translating the same source text[2] using early checkpoints saved during model training, with the lowest quality produced by the early checkpoints (i.e., when the system produced nonsensical and repetitive output) and the mid-quality outputs produced by later checkpoints. These low- to mid-quality MT system outputs were ranked by *BLEU* and manually examined (on a subset of the data) by an author fluent in the target language to confirm their increasing quality.[3] We run a limited version of the MSLC-A experiments in this edition of the challenge set, without submission of the systems to the General Task at WMT (i.e., we do not have human evaluations that indicate the magnitude of the gap, if any, between our highest-performing mid-quality MT system and the lowest-performing submitted system).

3.2 MSLC-B

For the MSLC-B portion of the challenge set, we focus on three different types of edge cases for metrics: empty strings, mixed- and wrong-language text, and English spelling variants.

In past iterations of MSLC, we observed that differences in what a metric treats as a "document" can have an impact on the scores it assigns in our test sets. In an effort to ensure that document-level metrics did not mix together the contrastive examples we were having scored, we appended strings to the document IDs to identify these as "separate documents" where appropriate (i.e., when two contrastive examples were from the same document, they might be assigned as "[DOCID]-1" and "[DOCID]-2" so that the metric should treat them as separate documents).

3.2.1 Empty Strings

Given past observations (Lo et al., 2023b; Knowles et al., 2024) of unusual outputs related to empty

[2]Text was translated at the segment or sentence level and then re-collected into documents.

[3]While it may be desirable to perform more formal evaluation, the lowest-quality systems are of such low quality as to be visibly "nonsense" even to non-speakers of the language as well, with a clear trend of improvement. Thus, while we do not have MQM or other manual scores to rank these, we can be confident in the overall trend, and particularly confident that, e.g., system A is a substantially worse system than system D.

strings, such as surprisingly high scores, we once again examine this topic. We use a small Japanese→Chinese dataset for this: 10 punctuation characters, 10 words, 10 phrases, and 10 segments (sentences or larger); all except for the punctuation are selected from the news domain portion of the WMT 2025 General Task test data. For each of these, we explore the case where we have an empty source and reference and a non-empty hypothesis (representing overgeneration: an MT system producing something from nothing) and the case where there is an empty hypothesis with a full source and reference (undergeneration: an MT system producing nothing when it should have produced something).

3.2.2 Mixed- and Wrong-Language Text

For metrics that rely on multilingual embeddings and ones that do not take into account the intended source and target language, there is a risk of returning high scores for wrong-language output. As in Knowles et al. (2024), we examine metric scores when presented with wrong-language or mixed-language hypotheses. In this case, we take advantage of the multi-way parallel test sets (pivoted on English) by using segments from English news test data with its Chinese and Japanese translations. We run these experiments on 18 segments with Japanese→Chinese as the intended language pair and translation direction, using the Japanese data as the source, the Chinese data as the reference, the English data as the wrong-language hypothesis, and a pseudo-codeswitched mix of English and Chinese as the mixed-language hypothesis.[4]

3.2.3 English Language Spelling Variants

While recent iterations of WMT have included more regional specifications regarding language variants, variations in English have been overlooked. We use a word list of common UK (en_GB) and US English (en_US) spelling differences[5] to select segments from the Czech→English news test data that contain words with the potential for different spellings.[6] We then automatically produce two versions of each of these 20 English segments, one with standard UK spellings and one with standard US spellings, and confirm them with manual examination. The English sentences are otherwise identical: minimal pairs where the only difference is the spelling of the words of interest. We then inverted the translation direction, treating Czech as the source and English as the target. The official submission format for the Metrics Challenge Set subtask included a field for language ID for the target; we submitted versions that included the region (en_US or en_UK) and one that did not (en). This should enable us to see whether some metrics utilize this information and, for those that do not, whether there is a bias towards a particular language variant. Of note, this is most relevant to reference-free metrics, as the reference is either an exact match to the hypothesis or identical except for the spelling of the words of interest. This is a small preliminary experiment to determine whether future large-scale evaluation of this topic may be fruitful.

4 Metrics

We focus on analyzing the scores produced by the baseline metrics and the primary submissions. There are 9 baseline metrics (including 2 "sentinel" metrics designed to scrutinize the metric meta-evaluation process) and 5 primary metrics that participated in portions of our challenge set for segment-level evaluation. One baseline and 2 primary metrics participated in the error span detection portion of our challenge set.

The segment-level score baselines are *BLEU* (Papineni et al., 2002), *spBLEU* (NLLB Team et al., 2022), *chrF* (Popović, 2015), *BERTScore* (Zhang et al., 2020), *COMET-22* (Rei et al., 2022a), *CometKiwi* (Rei et al., 2022b), *YiSi-1* (Lo, 2019), *sentinel-cand* and *sentinel-src* (Perrella et al., 2024).

For the segment-level quality score prediction task, five metrics participated in our experiments. *MetricX-25* (Juraska et al., 2025), an updated version of *MetricX*, is an encoder-only regression model initialized from Gemma 3 (Team et al., 2025) 12B and fine-tuned on publicly available DA and MQM scores from WMT 2015–23. *mr7.2.1* (Hrabal et al., 2025) is based on the Gemma 3 27B IT model and is prompted with the DSPy (Khattab et al., 2024) framework and its MIPROv2 opti-

[4]This mixed-language data was produced manually by an author fluent in the languages and is intended to contain the full semantic content of the text in such a way that it could be read by someone who speaks both languages and be perceived as similar to naturally generated by code-switching speakers.

[5]https://github.com/hyperreality/American-British-English-Translator/blob/master/data/american_spellings.json

[6]In some cases, we shortened the segments to more tightly focus on sentences containing the words of interest (shortening both the English and Czech sides of the sentence pair).

mizer. *Polycand-2* (Züfle et al., 2025) is a COMET-based metric that incorporates two alternative translations of the same source segment (provided by other translation systems) to better contextualize and assess the quality of the translation being scored. *rankedCOMET* (Maharjan and Shrestha, 2025) is a COMET-based metric post-processed with rank normalization for each language pair. *UvA-MT* (Wu and Monz, 2025) calibrates quality estimation and likelihood on the Gemma 3 12B IT model, then directly uses the token average likelihood as a metric for quality estimation.

For the error span detection task, three systems participated in our MSLC-B experiments: baseline *XCOMET* (Guerreiro et al., 2024) and the two primary submissions of *AIP1* (Yeom et al., 2025) and *GemSpanEval* (Juraska et al., 2025). *AIP1* uses the OpenAI o3 (OpenAI, 2025) reasoning model and its structured-output mode to detect translation errors at the span level. *GemSpanEval* is based on the Gemma 3 27B model and is finetuned to predict MQM error spans.

Some metrics use reference translations in the process of producing their scores, while others do not. Throughout the remainder of the paper we indicate the 3 baseline and 4 primary reference-free (QE) metrics—those that do not use the reference translation in their scoring—with an asterisk before the metric name. There are 3 reference-free primary metrics (**mr7.2.1*, **Polycand-2*, **UvA-MT*) in the segment-level score prediction task and 1 (**AIP1*) in the error span prediction task.

5 MSLC-A Results and Plots

Interpretation note of caution: our submitted MSLC-A challenge set was scored at the document level by the automatic metrics, while the submitted primary MT systems from the general task were scored at a sub-document segment level by the automatic metrics. In order to be able to compare these, we have averaged the segment-level scores to produce a document-level score for each document. We note that this may not always be identical to the score that the metric would have assigned had it scored the full document directly, and caution should therefore be taken when drawing conclusions.

Figure 1 shows system average scores for the MSLC-A systems (cool colours, left) and the systems submitted the the WMT General MT task, computed only over the News data. These averages are computed from the document-level scores, which in the case of MSLC-A data were produced directly by the metrics and which in the case of the submitted systems were produced as an average of segment-level scores. We find several points of interest. Three of the metrics, **COMETKiwi22*, *MetricX-25*, and **UvA-MT* have some difficulty with the rankings of the lowest-quality MSLC-A systems. In particular, **UvA-MT* ranks the worst system (whose output is almost entirely nonsensical and unreadable) as similar in quality to the high-quality WMT submissions. This indicates that these metrics—for this language pair at least—may not be trustworthy metrics to use when trying to evaluate low-quality MT. Metric users should consider alternative choices of metrics if they have reason to believe that their MT output may be of low quality or mid-range quality. This could also have an impact on MT systems trained using these metrics, particularly in the early stages of training.

We also observe that some metrics (**Polycand-2*, *COMET22*, i.a.) devote a very small portion of their metric's space of possible scores to the high-quality systems, with a wider range of scores for the low-quality systems, while others like *chrF* distribute the score range more evenly. This may impact how useful a metric is for distinguishing between systems of different levels of quality, and may also play a role in human interpretation of metric score differences; for broader discussion of metric score differences and human interpretations thereof, see Mathur et al. (2020) and Lo et al. (2023a), i.a. There is not an inherent right answer to how a metric should use its score space, rather, it is tied to the intended use of the metric.

We observe that some metrics show overlap or near overlap between the best of the MSLC systems and the lowest-scoring of the submitted systems while others show a large gap between them. Since we do not have full human annotations available, we cannot make any claims about whether there would be an overlap or a gap based on human evaluation.

Figure 2 provides another way to visualize the metric scores, showing histograms of scores assigned to each system along the diagonal, and scatterplots showing correlations between metrics on the off-diagonals. The metrics that give higher-than-expected scores to the low-quality systems once again stand out where they do not correlate with systems that rank the low-quality systems as

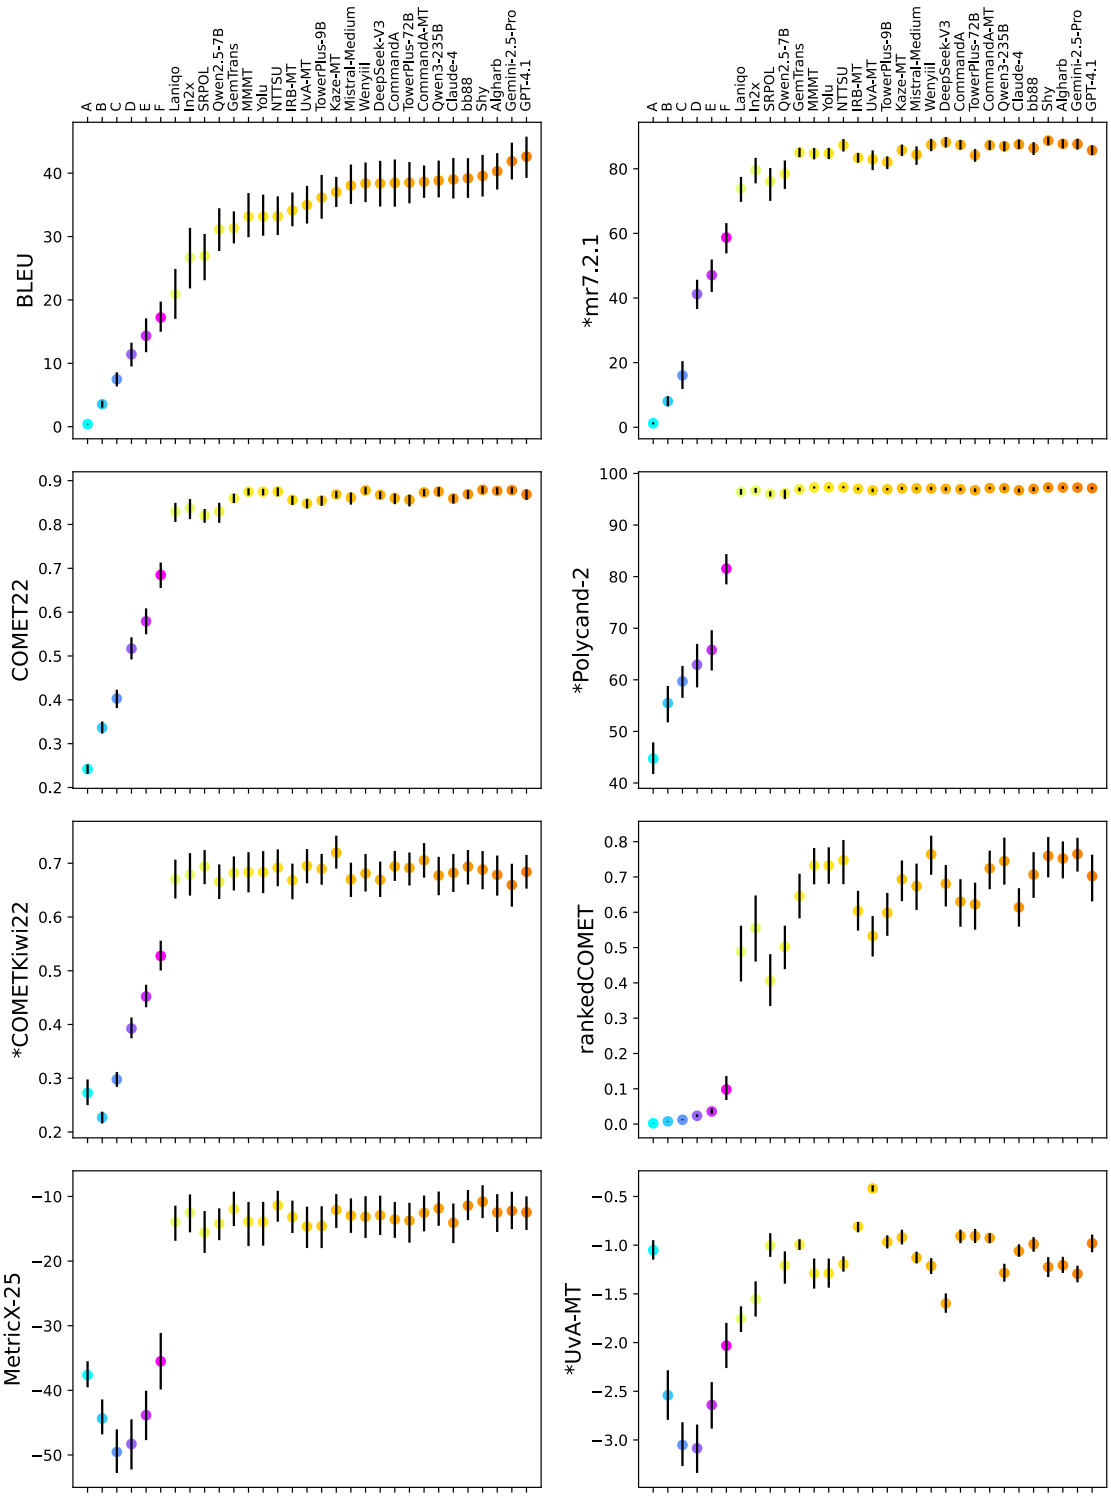

Figure 1: System average scores for Japanese→Chinese. MSLC systems (cool colours, left) are ordered by BLEU score and brief manual examination; WMT submitted systems are ranked by average BLEU score.

expected. We can also use the histograms to gain a better understanding of the score distributions assigned to the data, such as the very low scores and comparatively small score range assigned by *rankedCOMET* to the low-quality systems, as compared to other metrics, or the somewhat bimodal score distribution from **mr7.2.1*. In past iterations of MSLC, this type of figure was particularly useful in highlighting unusual properties of some of the metrics, such as discretizing the score space or

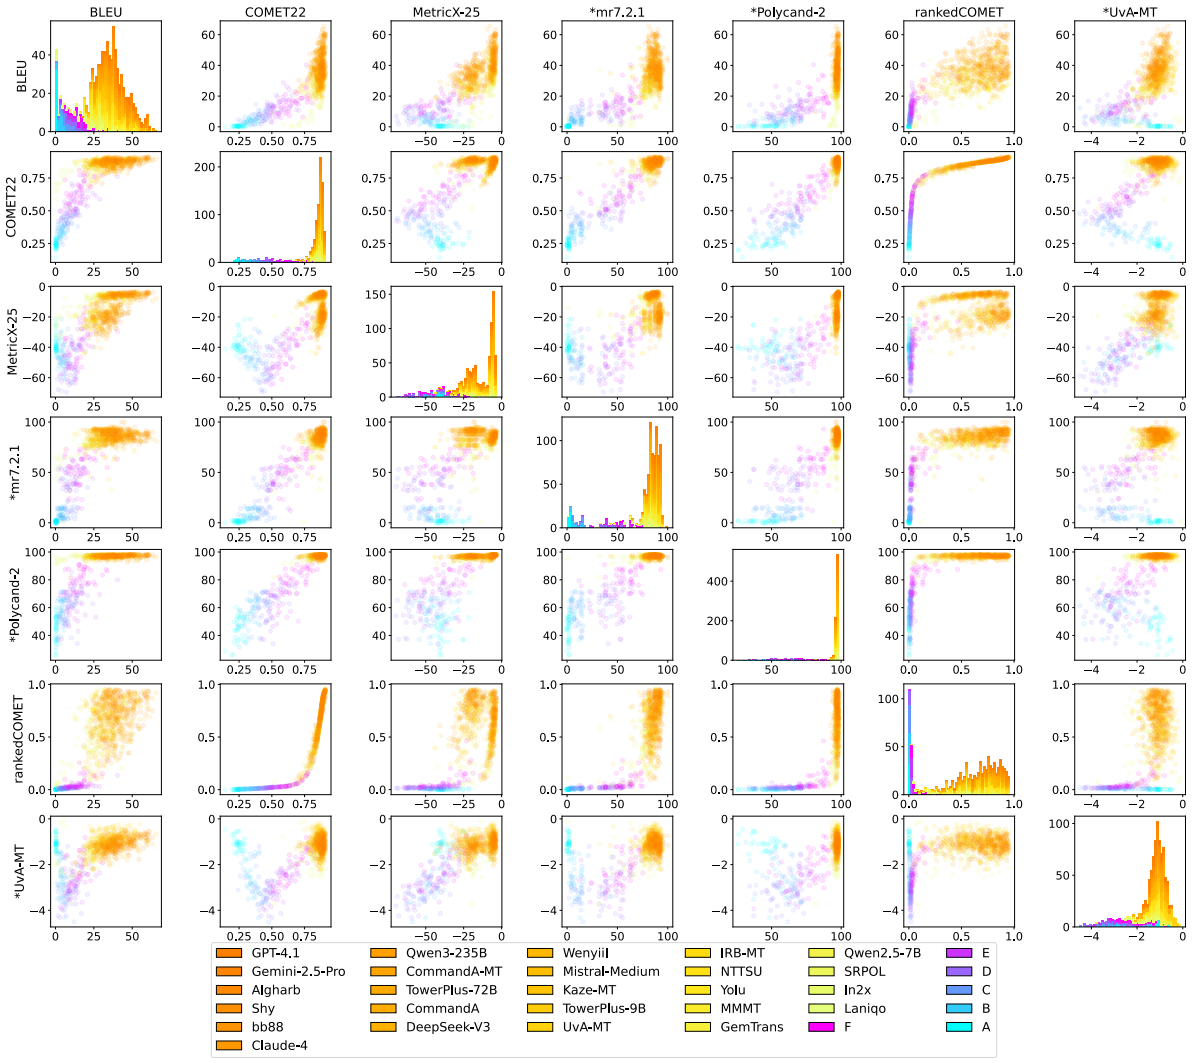

Figure 2: Matrix of segment-level scores for Japanese→Chinese. Along the diagonal are stacked histograms of segment scores across the challenge set (cool colours/bottom) and submitted WMT systems (warm colours/top). The off-diagonal entries are scatterplots where each point is a single document positioned according to the score assigned to it by row and column metrics; each point is coloured according to the same colours as the histogram.

assigning specific scores very frequently ("universal scores"). We do not observe such results in this year's set of metrics.

Due to scheduling constraints, we did not receive the human annotation scores in time to display those in these figures; we plan to incorporate them into final additional figures on the MSLC website (https://github.com/nrc-cnrc/MSLC).

6 MSLC-B Results and Plots

6.1 Empty Strings

In Figure 3 we show the scores assigned by the five primary submission metrics to punctuation, words, phrases, and segments (sentences to documents) when those are paired with an empty source and reference. The vertical red lines indicate the minimum and maximum scores assigned by the same metric to all WMT General Task primary submissions on the News portion of the data; since different metrics use different score ranges, this is used to provide the reader with some context about where the scores for these corner cases fall in comparison to scores assigned to more usual MT output. These empty string examples are fairly extreme examples of MT failures; string-based metrics like *BLEU* would assign them scores of 0.

We see several types of responses. The metric **mr7.2.1* assigns its lowest score to all of these, similar to what we observe from metrics like *chrF* and *BLEU* (not shown in figure); this is arguably what we would expect, since an empty source should produce an empty hypothesis. The results from

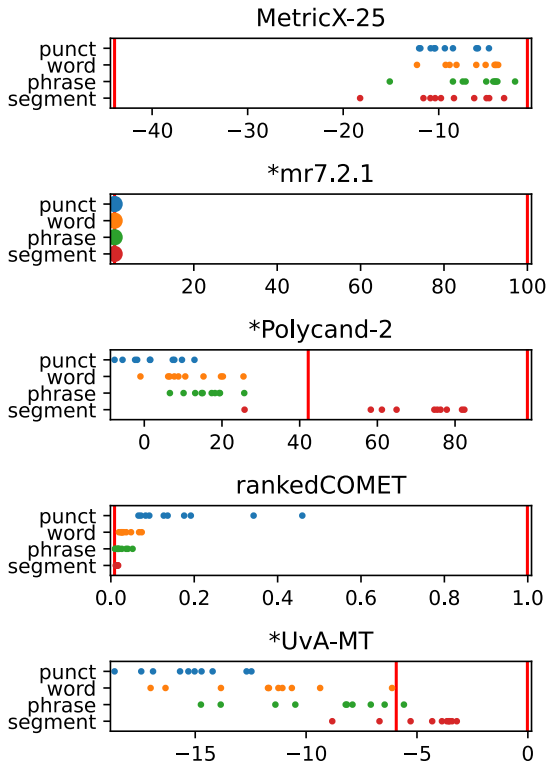

Figure 3: Japanese→Chinese scores assigned to text when paired with empty source and reference. Where multiple strings receive the same score, this is indicated by proportionally increased dot size (in the case of **mr7.2.1*, all strings received the same score of 0, as indicated by the large dots on top of the left red vertical line). Red vertical lines indicate the minimum and maximum scores assigned over all Japanese→Chinese WMT News primary submission data. Asterisks indicate reference-free (QE) metrics.

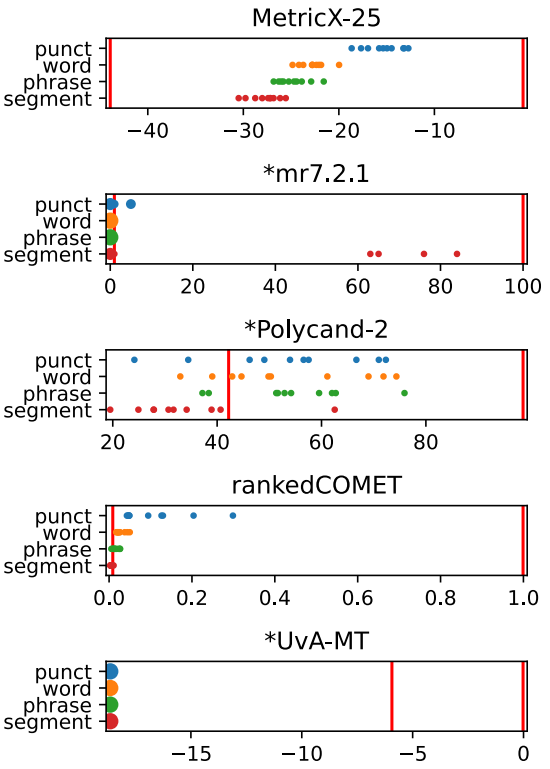

Figure 4: Japanese→Chinese scores assigned to empty string hypothesis paired with real (non-empty) source and reference. Where multiple strings receive the same score, this is indicated by proportionally increased dot size (in the case of **UvA-MT*, all strings received the same score, as indicated by the large dots). Red vertical lines indicate the minimum and maximum scores assigned over all Japanese→Chinese WMT News primary submission data. Asterisks indicate reference-free (QE) metrics.

rankedCOMET show a pattern that was observed in Knowles et al. (2024), where longer strings (segments) receive lower scores and some of the shorter strings (punctuation) receive higher scores, matching the intuition that a full sentence or document is more different from the empty string than a single character is. For both **Polycand-2* and **UvA-MT* we observe the opposite trend, with higher scores assigned to the longer strings. In both cases, most of the scores assigned to punctuation, words, and phrases are lower than the scores assigned to any of the submitted MT system data, but some of the scores assigned to the segments fall close to the middle of that score range. While both are reference-free metrics (i.e., not using the information that the reference string is the empty string), they do still have access to the source, making the result on segments more surprising.

The case of empty source and reference paired with non-empty hypothesis is an extreme representation of overgeneration, generating text that is not grounded in the source. We argue that unusual results on this set of data should raise questions for more exploration of a metric's performance on instances of overgeneration. It will require additional study to determine if there is a link between these, or if these results are confined to this particular corner case.

Figure 4 is the corresponding figure for the empty string hypothesis paired with a real (non-empty) source and reference. This is an extreme case of undergeneration (failing to generate any output). Two reference-free metrics, **mr7.2.1* and **UvA-MT*, assign very low scores to most of these examples, though **mr7.2.1* assigns scores in the top half of its score range to some segments. The results for *rankedCOMET* are quite similar to the results on the previous set of experiments, with slightly higher scores assigned to punctuation, but generally low scores overall. *MetricX-25* follows a similar pattern with the shorter strings scoring higher, but overall in the middle of the score range, while **Polycand-2* does not show a clear pattern.

Once again, we argue that assigning relatively high scores to empty string hypotheses may indicate that metrics are failing to pick up on undergeneration. Additionally, assigning non-lowest scores to the empty string presents a potential mismatch between metrics and typical standards for human evaluation (i.e., human annotators instructed to, or otherwise deciding on their own to, give the lowest scores to empty translations).

6.2 Mixed- and Wrong-Language Text

Metric	mix>wrong	equal	wrong>mix
**COMETKiwi22*	1	0	17
MetricX-25	2	0	16
**mr7.2.1*	18	0	0
**Polycand-2*	17	0	1
**UvA-MT*	1	0	17

Table 1: Comparison of scores of mixed and wrong-language text. Systems indicated with an asterisk (*) are reference-free (QE) metrics. All baseline reference-based metrics ranked all 18 mix>wrong.

As described in Section 3.2.2, we explore the scores that metrics assign to mixed- and wrong-language text. For our Japanese→Chinese challenge set for this task, the mixed language text is a mix of English and Chinese, intended to contain the full semantic information of the source. The wrong language text is English. Both the Chinese reference (used to build the basis of the mixed-language text) and the Japanese source are actually translations of the English data (which we also use to construct the mixed-language text). Due to the overlap between the Chinese reference and the mixed-language hypothesis, almost all baseline and primary reference-based metrics score the mixed-language hypothesis higher than the wrong-language for all 18 examples. The one exception to this is *MetricX-25*, as shown in Table 1, which scores the wrong-language text higher than the mixed-language text in 16 of the 18 examples. Both **COMETKiwi22* and **UvA-MT* score the wrong-language text above the mixed-language text in 17 out of 18 examples, while **Polycand-2* does the reverse and **mr7.2.1* prefers the mixed language text in all cases.

It remains an open question how mixed-language text should be scored, and is likely dependent on the intended audience of the translation. In any case, it may be surprising to observe systems preferring hypotheses that contain none of the intended target language at all over those that do at least include some target language text. This highlights—particularly with the shift to reference-free and multilingual metrics—the importance of taking into account the intended target language in evaluation. While we use a very small dataset here (18 segments), the consistency that we observe within metrics is notable. The issue of wrong-language output continues to be one that appears to be under-

examined by the designers of metrics, a claim we make based not only on this small-scale proof-of-concept, but by similar work in past challenge sets across more languages (Amrhein et al., 2022, 2023; Knowles et al., 2024).

6.3 English Language Spelling Variants

With the inclusion of an increasing amount of region information for the languages in WMT, we were interested in exploring English language spelling variants. As a preliminary step, we explored common British and American spelling differences. We used pairs of Czech→English segments where the English hypothesis varies only in the spelling conventions for certain terms. We submitted this portion of the challenge set three different times, once each with the language/region described as "en", "en_GB", and "en_US". We observed no difference in metric preferences depending on the choice of region descriptor; it is likely that most of these metrics are not taking into account the regional information at this granularity (compare also to the results in Section 6.2, which suggest that even the language code itself may not be entirely influential). For the three reference-free metrics that participated in this portion of the challenge set, we observed three different results (Table 2): **COMETKiwi22* was equally split between US and GB, but rarely scored them identically, **mr7.2.1* scored them identically more than half of the time and preferred GB almost half of the time, and **Polycand-2* scored the US variant higher the majority of the time. Due to the setup of the experiment, we could also check whether repeated instances of the same examples were scored identically; for **Polycand-2* there were some small (up to $3.81e-06$) differences in repeated scores; the differences between the US and GB variants were substantially larger.

We manually examined the error span results for baseline *XCOMET* and the two primary submissions of **AIP1* and *GemSpanEval* but did not observe any clear patterns related to the spelling variants. *GemSpanEval* did label some of the spelling variant terms as errors, but there was not a clear pattern related to the intended target language variants.

As the WMT shared tasks shift to include more region information, we expect that metrics will seek to handle this as well. We choose English for this particular example, because variation in English has been overlooked at WMT, even in instances when Englishes are paired with regionally-specified language variants. While we focused on English variation in the target; metric biases may also be relevant where the source is concerned.

Metric	US>GB	Equal	GB>US
**COMETKiwi22*	9	2	9
**mr7.2.1*	2	11	7
**Polycand-2*	16	0	4

Table 2: Comparison of reference-free (QE) metrics on pairs of Czech→English sentences where the English hypothesis only varies in whether certain terms use British or American English spelling conventions. For the 20 examples, the table shows the counts of those for which the US spelling version was given a higher score, for which the scores were equal, and for which the British spelling convention was given a higher score. Results are identical regardless of whether the intended target language has the region specified or not ("en", "en_GB", "en_US").

Both the dataset we used and the number of metrics that completed the task are much too small to draw broader conclusions from. Nevertheless, we think this will be an interesting avenue to explore, as WMT shifts to incorporate more regional information into its translation tasks.

7 Conclusions

We observe similar results to past MSLC experiments, with some metrics struggling to accurately score extremely low-quality (nonsensical) MT outputs. We continue to encourage discussion around how metrics should score empty strings and encourage additional analysis of how this does or does not correlate with broader metric sensitivity to over-generation and undergeneration. As we see more metrics shifting to use multilingual embeddings our large language models and more reference-free metrics, we encourage metric builders to consider how to incorporate information about the intended target language into their metrics (see also, Zouhar et al. (2024)). While it may be easy for a human—even one who cannot read the languages in question—to tell if an MT system has erroneously generated English when Chinese was expected, it may not be so simple for more similar language pairs. We would encourage metric builders to consider how to incorporate intended target language into their systems, and note that this may be an area where ignoring available references may have a real cost when it comes to metric trustworthiness.

Limitations

We focus on a small set of language pairs (in fact, smaller than in past iterations) and use small dataset sizes. This year, we did not submit systems to the General MT task, which means that we do not have a way to confirm how close those systems are (by human evaluation) to submitted systems; this may result in a gap in coverage between low and high quality systems. In general, these experiments represent corner cases that metrics builders should be considering in their systems. Our results primarily serve to flag issues to potential users of metrics and to encourage builders of metrics to test their metrics extensively.

Abstract

In this paper, we present our submissions to the unified WMT25 Translation Evaluation Shared Task. For the Quality Score Prediction subtask, we create a new generation of MetricX with improvements in the input format and the training protocol, while for the Error Span Detection subtask we develop a new model, GemSpanEval, trained to predict error spans along with their severities and categories. Both systems are based on the state-of-the-art multilingual open-weights model Gemma 3, fine-tuned on publicly available WMT data. We demonstrate that MetricX-25, adapting Gemma 3 to an encoder-only architecture with a regression head on top, can be trained to effectively predict both MQM and ESA quality scores, and significantly outperforms its predecessor. Our decoder-only GemSpanEval model, on the other hand, we show to be competitive in error span detection with XCOMET, a strong encoder-only sequence-tagging baseline. With error span detection formulated as a generative task, we instruct the model to also output the context for each predicted error span, thus ensuring that error spans are identified unambiguously.

1 Introduction

Large language models (LLMs) have been evolving at a breakneck speed over the past couple of years, achieving performance in machine translation (MT) that matches or even exceeds that of humans for certain languages and domains (Kocmi et al., 2024a). While human evaluation is still the most reliable way to assess the quality of MT models, in this fast-paced environment of state-of-the-art models being released on a monthly basis, the cost and duration make it infeasible to run human evaluation studies to benchmark models regularly. Improving automatic metrics is therefore instrumental to making further progress in MT, especially as the field expands to low-resource languages and more difficult domains.

Currently, the most successful automatic MT evaluation metrics are trained neural models themselves, following one of two main paradigms: (1) regression models predicting a scalar quality score (Rei et al., 2022a; Juraska et al., 2024), and (2) sequence-tagging or generative models, providing fine-grained quality feedback, including error spans, severities and categories (Fernandes et al., 2023; Guerreiro et al., 2024). In this work, we push the performance of automatic metrics in both categories higher by leveraging a state-of-the-art multilingual open-weights LLM, Gemma 3 (Gemma Team et al., 2025), resulting in two separate submissions to the WMT25 Evaluation Shared Task.

For the Quality Score Prediction subtask, we develop *MetricX-25*, a successor to MetricX-24 (Juraska et al., 2024), updated to use an encoder-only architecture and trained on a combination of publicly available direct assessment (DA) and Multidimensional Quality Metrics (MQM) scores from WMT shared tasks between 2015 and 2023. For the Error Span Detection subtask, we introduce *GemSpanEval*, a generative model that identifies and categorizes error spans in JSON format, trained exclusively on MQM error span annotations from WMT20–24. We enable GemSpanEval to uniquely identify short, non-unique error spans by training the model to also indicate the error span context where necessary.

The key takeaways from our experiments, detailed in this report, include:

1. Gemma 3 offers a strong multilingual foundation for an automatic MT evaluation metric, and adapting it to an encoder-only architecture proves highly effective for score prediction.
2. It is possible to train an automatic metric to effectively predict different types of score using a single regression head by simply mixing training examples of different scores, with a score type indication included in the input.

Proceedings of the Tenth Conference on Machine Translation, pages 957–968
November 8-9, 2025

3. Fine-tuning a strong multilingual decoder-only model can be competitive with encoder-only error span detection models.
4. Predicting error span context can be used to uniquely identify error spans when formulating span detection as a generative task.

2 Data

The systems we developed for both the quality score prediction and the error span detection are trained solely on publicly available data from the WMT Metrics shared tasks between 2015 and 2024. Quality ratings for system translations across those 10 years were collected using 3 different methods:

1. Direct assessment (DA) scores, provided mostly by non-expert raters, on a scale from 0 to 100. WMT data with DA scores is available for years between 2015 and 2023, and covers nearly 50 language pairs.

2. MQM scores (Lommel et al., 2014; Freitag et al., 2021) on a scale from 0 to 25 (or uncapped in the most recent years), where lower is better. The scores are derived from professional translator annotations of error spans, including error severities and categories, where, generally, each minor error and each major error contribute 1 and 5 to the score, respectively. MQM annotations are only available for a limited number of language pairs (en-de, en-es, en-ru, en-zh, he-en, zh-en, ja-zh) for WMT data starting from 2020.

3. ESA scores (Kocmi et al., 2024b), which combine the first two approaches in that the expert raters annotate error spans and severities, yet they provide an overall quality score on a scale from 0 to 100 as well. These were only introduced in WMT24, so there is only one year worth of ESA data.

We use both DA and MQM scores for training MetricX, our score prediction system, and MQM error span annotations for training GemSpanEval. In general, we reserved data from WMT24 – both MQM (Freitag et al., 2024) and ESA (Kocmi et al., 2024a) – for validation of our models, with the exception of one submission to the error span detection task. We provide more details on the training and validation sets in §3 for MetricX and in §4 for GemSpanEval.

3 Quality Score Prediction: *MetricX-25*

Our MetricX-25 submissions to the Quality Score Prediction subtask are based on the successful MetricX-24 (Juraska et al., 2024; Freitag et al., 2024), with several modifications and improvements. The biggest one among them is the switch from mT5 (Xue et al., 2021) to Gemma 3 as the backbone model. We start this section by providing an overview of the similarities and differences between MetricX-24 and MetricX-25, then give more details on the training and evaluation data, and finally describe our experiments and the MetricX-25 systems we submitted to the shared task.

3.1 MetricX Overview

MetricX is a regression model trained to predict a quality score for a machine translation given the source segment and/or a reference translation. As of the '24 version, there are no separate models for reference-based and reference-free prediction; instead, a single model is trained on a mixture of examples: (1) with both the source and a reference, (2) with the reference omitted, and (3) with the source omitted.

The model is trained on translation evaluation data in two stages. It is first fine-tuned on z-normalized DA scores, then further fine-tuned on a mixture of MQM scores and raw DA scores. In both stages, a small proportion of synthetic training data, generated from WMT data, is included to help MetricX models recognize certain types of bad translations that are insufficiently represented in the standard WMT data. These synthetic examples cover cases such as over- and undertranslation, fluent but unrelated translation, and missing punctuation. We refer the reader to Juraska et al. (2024) for the full list of synthetic example categories and details on how the data was constructed.

3.2 What Is New in MetricX-25?

Initialization model. The model we initialize MetricX-25 from is Gemma 3 12B, a state-of-the-art multilingual open-weights model similar in size to the 13B-parameter mT5-XXL used in all previous versions of MetricX. In contrast to mT5-based MetricX models, MetricX-25 uses an encoder-only architecture with a regression head on top. Specifically, MetricX-25 is a fine-tuned Gemma Encoder (Suganthan et al., 2025) with mean pooling and no uptraining, and with the encoder's weights initialized from the corresponding

English (United Kingdom) translation:
```It was like having felt a draft from a grave.```

Score type: MQM

Figure 1: Example MetricX-25 model input.

decoder weights of Gemma 3. Besides the major differences in architectures and pretraining corpora and strategies, Gemma 3 also has the advantage of supporting significantly longer context windows (up to 128K tokens) than mT5 and has an even wider language support (over 140 languages, compared to mT5's 101).

Language indication. For MetricX-25, we augment the model input with source and target language information. The motivation behind this is to help MetricX recognize when an untranslated source (or portion of it) is appropriate, as well as help it handle quality assessment of translations from one language dialect to another without incorrectly assuming the translation is largely untranslated. Thus, we include the country information too if the locale is indicated in the data (e.g., ar_EG) and the language has multiple major dialects, such as Arabic (Egyptian, Modern Standard Arabic, etc.) or Portuguese (Brazilian, European, etc.). Figure 1 shows a full example of a model input.

Input format. Given the dual nature of human evaluation in the WMT25 shared task – MQM for some language pairs and ESA for others – we also add a score type indication to the model input, so that it learns to predict both types of quality score. We use the "MQM" score type for the MQM training and evaluation data, and "ESA" for the DA training and ESA evaluation data. Considering the possibly multi-paragraph segments in the official test sets, we also enclose each segment between triple backticks and separate input segments with double newline characters (see Figure 1).[1]

2-way hybrid input mode. We changed the training recipe for MetricX-25 by only including reference-only examples in the first stage of fine-tuning. In the second stage, we fine-tune the model on two types of examples only: (1) source-only, and (2) with source and reference both. The reason is twofold. First, MQM scores were produced in a source-based fashion, without a reference being available at all, so training examples with an MQM score but no source segment might not provide an accurate signal to the model. We verified experimentally that omitting these examples in the second stage does not have a significant negative impact on reference-only prediction performance. Second, in all the evaluation scenarios of the quality score prediction task, source segments are available, so there is little reason to distract the model with source-free training examples in the second stage of fine-tuning.

Score clipping. Earlier versions of MetricX had MQM scores in the training data, as well as the output scores, clipped to the [0, 25] range. However, with the switch to document-level segments over the past two years of the shared task, and the fact that MQM scores in human evaluation are therefore no longer capped at 25, we also drop the score clipping in MetricX-25, allowing for output scores greater than 25, which we expect to improve the correlation with MQM scores for long segments.[2]

3.3 Experimental Setup

Training data. In the first stage of fine-tuning MetricX-25, we use z-normalized DA scores from WMT15–23, with the into-English subset of WMT21 omitted due to its low quality (Juraska et al., 2023). Furthermore, the DA z-scores are aggregated per segment, negated, and finally clipped to the $[-1.0, 1.0]$ range, as shown by Juraska et al. (2023) to yield the best performance. We also incorporate a small proportion of the synthetic training data introduced in Juraska et al. (2024). In this stage, we do not include any score type indication in the input. In the second fine-tuning stage, we mix an equal proportion of the same DA data as above (with "ESA" indicated as the score type) and MQM data from WMT20–23 (with "MQM" score type), along with synthetic data included in each group of examples. In contrast to the first stage, however, we use raw DA scores rescaled to the MQM scale here, so the model does not have to learn two different scales, only distributions. We

[1] We experimented with including a preamble with instructions on the quality assessment task in the input too, but it did not improve the performance, perhaps except for the first few steps of fine-tuning.

[2] This causes a small discrepancy with the synthetic training data, which uses a fixed range of [0, 25], with many of the examples having a score of 25 assigned to them. Nevertheless, most of the synthetic examples are sentence-level, so an MQM score of 25 is reasonable for very bad translations.
```

then rescale the output scores to their respective ESA and negative MQM scales, as expected for the evaluation on the official test set, in postprocessing.

Meta-evaluation. Our validation set, which we use to pick the best model checkpoints, consists of both the MQM and ESA data from WMT24. To evaluate our models' performance, we calculate to what degree their predicted scores agree with the human judgments of translation quality. For segment-level correlation we use the tie-calibrated pairwise accuracy introduced by Deutsch et al. (2023), while at the system level we calculate soft pairwise accuracy (SPA; Thompson et al. 2024). These were the two primary meta-evaluation metrics used in the WMT24 Metrics Shared Task (Freitag et al., 2024). We use the same checkpoint selection strategy as for MetricX-24, averaging over all three MQM language pairs of WMT24, and downweighting the system-level component due to its larger variance.

Implementation details. MetricX-25 is implemented in TensorFlow (Abadi et al., 2015), and all of our submitted MetricX-25 systems are based on the Gemma 3 variant with 12B parameters. We defer further implementation details to Appendix A.

3.4 Results and Submission Details

Here we present the results of our experiments, focusing on assessing the impact of the combined MQM/ESA score prediction and comparing the performance of the Gemma-based MetricX-25 with that of the similarly-sized mT5-based MetricX-24. Due to limited resource availability, we were only able to run each experiment with one random seed.

3.4.1 Combining MQM/ESA Score Prediction

We start by examining the effects of mixing DA and MQM training data, together with using the score type indicators in the input. As a reminder, raw DA scores are used to train the model to predict ESA scores, since they both use the same scale and follow similar distributions. The first 3 rows of Table 1 compare the combined fine-tuning with fine-tuning on DA data only and MQM data only. We can see that the "DA + MQM" model (row 3) performs on par with the "MQM only" model (row 2) on the MQM validation sets and on par with the "DA only" model (row 1) on the ESA validations sets. This demonstrates that the model can effectively learn to predict both types of scores without sacrificing performance in either of them.

Our next observation is that simple two-stage fine-tuning (DA first then MQM) also achieves this goal, except for the system-level performance on ESA, which is around 2 points behind both the "DA + MQM" and the "DA only" model (compare row 4 against rows 3 and 1). Finally, we show that by combining two-stage fine-tuning and DA/MQM data mixing (row 5), we significantly boost the system-level performance on the ESA sets, while maintaining or further improving the performance on the MQM sets, as well as maintaining the segment-level performance.

3.4.2 MetricX-25 Submissions

Table 2 summarizes our MetricX-25 submissions to the quality score prediction task and compares them against MetricX-24 – one of the three top-performing systems in last year's shared task – as a baseline. The submissions only differ in the combination of examples they were trained on (with or without source/reference) and thus their expected input: the primary submission is a hybrid system, whereas the two secondary submissions are a purely quality estimation (QE) and a purely reference-based system, respectively.

As the table shows, all the MetricX-25 submissions (rows 3–6) significantly outperform the MetricX-24 baseline (rows 1–2) at the segment level, but the results are mixed at the system level. The ja-zh language pair exhibits by far the largest improvement, suggesting that Gemma 3 has a stronger understanding of Japanese and/or Chinese than mT5. Our expectation is that this is true for many more languages, making MetricX-25 a more robust automatic evaluation metric than its mT5-based predecessors.

We chose the hybrid model as our primary submission, despite being slightly outperformed by the reference-based variant (compare rows 6 and 4), because of its input flexibility. Since the official test set consists of language pairs both with and without references available, the reference-based model would likely perform poorly on the latter. Moreover, the majority of the challenge sets also do not provide references, so MetricX-25-Ref would not be able to participate in them.

4 Error Span Detection: *GemSpanEval*

In this section, we describe our submission to subtask 2: Error Span Detection. We denote our system *GemSpanEval*, as it is a span-level prediction model based on Gemma 3.

Training protocol	Segment-level pairwise accuracy				System-level soft pairwise accuracy			
	en-de	en-es	ja-zh	Avg(ESA)	en-de	en-es	ja-zh	Avg(ESA)
DA only	50.41	68.51	54.48	54.72	85.62	**82.13**	92.62	87.65
MQM only	54.71	68.80	56.36	54.20	85.55	78.56	89.94	86.45
DA + MQM	54.71	68.92	56.16	54.91	85.21	78.89	90.67	**87.80**
DA→MQM	55.40	69.11	57.90	55.00	85.91	78.12	**93.64**	85.74
DA→(DA + MQM)	**55.66**	**69.25**	**58.24**	**55.14**	**86.60**	77.92	92.88	87.08

Table 1: Meta-evaluation scores of reference-based models (non-hybrid) on the WMT24 validation set, using a variety of one- and two-stage fine-tuning protocols, with the → symbol indicating two stages. "DA + MQM" denotes the combination of DA and MQM scores, with a score type indication provided in the input. The correlation scores are shown for all 3 MQM language pairs individually, and for the 9 ESA language pairs averaged.

MetricX variant	Segment-level pairwise accuracy				System-level soft pairwise accuracy			
	en-de	en-es	ja-zh	Avg(ESA)	en-de	en-es	ja-zh	Avg(ESA)
24-Hybrid-QE	52.60	68.50	53.00	–	**87.80**	78.90	87.50	–
24-Hybrid	53.20	68.50	53.90	–	87.40	**79.90**	89.70	–
25-QE†	54.97	**69.42**	57.21	54.34	85.45	78.29	91.34	84.91
25-Ref†	**55.66**	69.25	**58.24**	**55.14**	86.60	77.92	**92.88**	87.08
25-Hybrid-QE	54.83	69.31	56.66	54.11	85.42	77.74	91.59	86.32
25-Hybrid*	55.45	69.14	57.72	54.87	85.82	77.00	92.00	**87.61**

Table 2: Performance of our MetricX-25 submissions compared to the MetricX-24 baseline on WMT24. "Hybrid" and "Hybrid-QE" rows correspond to the same model, only evaluated with and without references, respectively. The correlation scores are shown for all 3 MQM language pairs individually, and for the 9 ESA language pairs averaged. *Primary submission. †Secondary submissions.

4.1 Overview

Last year's shared task on error span detection (Zerva et al., 2024), despite low participation, showed that span-level error prediction remains a challenging task. Specifically, Shan et al. (2024) found that generative methods based on LLMs, such as GPT-4o-mini (Hurst et al., 2024) or Tower-Instruct-7B (Alves et al., 2024), still lag behind encoder-only models like CometKiwi (Rei et al., 2022b). Our shared task submission aims to explore how far we can push generative models at the error span detection task when using a recent strong multilingual open-weights model, in our case Gemma 3 27B, fine-tuned for the error span detection task.

4.2 Error Span Detection

We adapt the AutoMQM setup (Fernandes et al., 2023) by predicting MQM error spans in JSON format similar to Finkelstein et al. (2024). LLMs tend to be good at producing valid JSON output, making parsing the structured output straightforward. Each error contains the text span of the machine translation or the source segment (for omissions) along with a severity and a category. Note that for the error span detection task the category and source errors, such as omissions, are not used.

While models are able to identify and extract spans, we also need to find the spans in the original text for this task. A simple way to do so is to perform a string search. This is successful for most error spans, as they are unique substrings of the source or the machine translation. However, there is also a considerable portion of error spans that are not unique, often related to punctuation or short frequent words. For example, in the WMT24 en-de MQM data, 21% of error spans are not unique. Note though, that the problem is less pronounced for the shared task evaluation, as it is based on the character F1 score, to which short spans contribute less than long spans.

To be able to uniquely identify short spans, we modify the model response to include additional context for any span that is not unique. We expand the context to the previous and next word by looking for the previous and next space character. For Chinese and Japanese, we extend the context by one character at a time. The context is extended until we find a unique substring. See Figure 2 for an example of translation error spans with context in JSON format, and Figure 3 in the Appendix for the full prompt and output. The rest of the prompt and format follows Finkelstein et al. (2024). We do not use ICL examples, as we train a dedicated model. All data is presented twice: once with the

```
English source:
‘‘‘I have not made use of the timer,
    preferring to turn them on and off
    myself. I can see this feature as
    useful in an office setting with
    houseplants or if on vacation‘‘‘
German machine translation:
‘‘‘Ich benutze den Timer nicht, sondern
    schalte ihn lieber selbst ein und
    aus. Ich sehe diese Funktion als
    nützlich im Büro mit Zimmerpflanzen
    oder im Urlaub.‘‘‘
```

Response:

```
[
  {"span": "im", "span_with_context":
      "nützlich im Büro", ...},
  {"span": "ihn", ...},
  {"span": "mit", ...}
]
```

Figure 2: Example translation with non-unique error spans, where span context text is included.

reference translation and once without. This allows us to evaluate the model as a QE and as a reference-based model both.

4.3 Experimental Setup

For development, we train on MQM data from WMT20–23 and evaluate on WMT24 MQM data. We evaluate using character-level F1 score, which was used as the shared task metric in previous years (Zerva et al., 2024) and also the current year. The metric takes into account error severities and gives partial credit for predicting an error span with the wrong error severity. For the submission system, we include the en-de and ja-zh WMT24 MQM data in training as well, holding out en-es for evaluation. We include the latest data in order to fine-tune the model on longer segments too. Before WMT24, only WMT23 en-de provided paragraph-level data, while all other data is at the sentence level. Additionally, we hope to increase the coverage of translation errors of modern LLM-based translation models.

We fine-tune a 27B Gemma 3 model using Kauldron SFT tooling.[3] We use the Adafactor (Shazeer and Stern, 2018) optimizer with a learning rate of 0.0001 and a batch size of 64, running for 20K steps, which covers a little under 2 epochs of the training data. As baselines we report XCOMET-XXL (Guerreiro et al., 2024) scores. XCOMET is a strong encoder-only model that was trained to rate segments and also label translation error token spans. Additionally, we evaluate Gemma 3 27B without fine-tuning, prompting it to produce JSON error spans, as shown in Figure 3. Note that this baseline does not include the span context for short spans.

[3] https://kauldron.readthedocs.io/en/latest/

4.4 Results and Submission Details

The experimental results for the span-level error prediction task are shown in Table 3. GemSpanEval-QE v1 denotes an initial training run for just 10K steps and without span context for short spans. GemSpanEval-QE and GemSpanEval are the QE and reference-based evaluations, respectively, of a model trained without WMT24 data. The final row adds WMT24 en-de and ja-zh data. Therefore, for the last row, we should only take the results as an indication of how much of WMT24 has been memorized, not of how good the model is, except for en-es. The final shared task submission is based on the model that was trained *with* WMT24 data. The primary submission uses the reference while the secondary submission is reference-free. Both submissions use the same model and just differ in whether references are shown at inference time. Note that, when preparing the submission data, we ran into model repetition problems that resulted in invalid JSON output. For these cases we fell back to the original model, GemSpanEval-QE v1. For the shared task submission we find 22% of errors spans to not be unique, while this corresponds to only 5% of the characters of error spans, as non-unique spans tend to be short. Consequently, for WMT24 en-de this leads to a marginal F1 improvement of 0.08.

System	en-de	en-es	ja-zh	Avg.
XCOMET-XXL-QE	24.28	10.11	14.30	16.23
XCOMET-XXL	**25.43**	11.02	24.94	**20.46**
Gemma 3 27B	17.94	8.19	**28.42**	18.18
GemSpanEval-QE v1	17.51	14.43	22.75	18.23
GemSpanEval-QE	20.85	13.06	24.72	19.54
GemSpanEval	21.79	13.73	25.28	20.27
+ WMT24 train	27.26	**14.37**	37.09	26.24

Table 3: WMT24 character level F1 scores for the error span prediction task. Numbers where we train on the development set are grayed out but kept for reference.

From the experimental results during development in Table 3, we see that the encoder-only XCOMET-XXL model is a strong baseline showing the best result for en-de. The Gemma 3 baseline that was not fine-tuned also shows generally good performance, even achieving the best

result of all evaluated systems for ja-zh, better than the fine-tuned model. This is likely due to the task being difficult and highly dependent on rater behavior, which varies significantly across years and languages. Using references consistently achieves higher character F1 across all three language pairs. Surprisingly, the model trained with WMT24, while showing the best results in terms of character F1, still shows a significant gap, despite seeing the test data during training for en-de and ja-zh. This shows that ∼2 epochs in the current training setup was not enough to completely memorize the training data. For the held-out language, en-es, we see the best score across all settings, leading to the decision to use the model trained with WMT24 as our submission to the shared task.

5 Related Work

For decades, right until the recent advent of LLMs, the most widely adopted automatic evaluation metrics would express the predicted machine translation quality as a scalar score. This is the case for metrics ranging from simple lexical overlap metrics, such as BLEU (Papineni et al., 2002) and ChrF (Popović, 2015), to learned metrics including BLEURT (Sellam et al., 2020; Pu et al., 2021), COMET (Rei et al., 2020, 2022a) and MetricX (Juraska et al., 2023, 2024). The feasibility of prompting general-purpose LLMs to score translations has also been studied (Kocmi and Federmann, 2023b; Leiter et al., 2023; Leiter and Eger, 2024) and this approach has been shown to be competitive with fine-tuned dedicated models, especially in system-level performance. Among recent methods, there has been an increasing proportion of metrics providing structured (Perrella et al., 2022; Kocmi and Federmann, 2023a; Fernandes et al., 2023; Guerreiro et al., 2024) or natural language explanations (Xu et al., 2023) for the predicted scores, most of which are based on LLMs.

Since the era of lexical metrics, which require one or more reference translations to evaluate a machine translation, metrics have evolved to rely increasingly more on the source segment (Rei et al., 2020, 2022a; Juraska et al., 2024). This is enabled by the multilingual pretrained models they are typically built on top, such as XLM-R (Conneau et al., 2020) or mT5 (Xue et al., 2021). In fact, *reference-free* (or *quality estimation*; QE) metrics do not lag far behind their *reference-based* counterparts anymore, as evidenced by the most recent WMT Metrics shared tasks (Freitag et al., 2023, 2024). That being said, high-quality references do provide added value to automatic metrics in most cases, helping them make even more accurate quality predictions. Therefore, metrics nowadays typically employ a unified (or hybrid) input approach, allowing them to make a reference-based prediction whenever a reference is available, and a QE prediction otherwise (Wan et al., 2022; Guerreiro et al., 2024; Juraska et al., 2024). This is the case with our primary MetricX-25 and GemSpanEval submissions as well.

Current approaches to error span annotation are often based on encoder-only models predicting error severities per token. One such approach is COMETKIWI (Rei et al., 2022b, 2023) or, more recently, XCOMET (Guerreiro et al., 2024). In last year's Error Span Detection shared task, COMETKIWI was shown to be a competitive baseline, coming in ahead of the (single) submitted system (Zerva et al., 2024). Kocmi and Federmann (2023a) showed that GPT-4 can simply be prompted to produce MQM error spans, denoting the method GEMBA-MQM. Fernandes et al. (2023) showed that fine-tuning for the generative error span prediction can improve performance compared to prompting LLMs alone. Recent translation-oriented LLMs, such as Tower (Alves et al., 2024; Rei et al., 2025) also include generative error span prediction as part of the supported tasks in the training data.

6 Conclusion

We introduced MetricX-25 and GemSpanEval, our submissions to the WMT25 Evaluation Shared Task, both built upon the Gemma 3 foundation model, but in very different ways. We demonstrated that MetricX-25, adapting Gemma 3 to an encoder-only architecture, can be trained to effectively predict ESA and MQM quality scores and significantly outperforms its predecessor, MetricX-24, in segment-level performance. For error span detection, our generative model, GemSpanEval, proved to be competitive with a strong sequence-tagging baseline. Additionally, we showed how error span context can be used to identify unique error spans. Our work demonstrates that a strong multilingual foundation model, such as Gemma 3, can successfully be used for both regression-based and generative translation evaluation metrics.

A MetricX-25 Implementation Details

With the input context length of 4096 SPM tokens, each training run requires 64 TPUs. Using a batch size of 128, we train our models for 10K steps in the first stage, using a learning rate of 0.00005 with a cosine decay following 100 steps of linear warm-up. We then fine-tune the best checkpoint for another 10K steps in the second stage, lowering the peak learning rate to 0.00001.

Prompt

```
You are an annotator for the quality of machine translation. Your task is to
    identify errors and assess the quality of the translation.
Based on the source segment, human-generated reference translation, and machine
    translation surrounded with triple backticks, identify error types in the
    translation and classify them. The categories of errors are: accuracy
    (addition, mistranslation, omission, untranslated text), fluency (character
    encoding, grammar, inconsistency, punctuation, register, spelling), style
    (awkward), terminology (inappropriate for context, inconsistent use),
    non-translation, other, or no-error.
Each error is classified as one of three severities: critical, major, and minor.
    Critical errors inhibit comprehension of the text. Major errors disrupt the
    flow, but what the text is trying to say is still understandable. Minor errors
    are technically errors, but do not disrupt the flow or hinder comprehension.

Make sure your response is a strict and valid json object that could be parsed with
    json.loads() in python.

English source:
‘‘‘The lights are dimmable, but I use the strongest setting only. I have not made
    use of the timer, preferring to turn them on and off myself. I can see this
    feature as useful in an office setting with houseplants or if on vacation‘‘‘
German machine translation:
‘‘‘Die Lichter sind dimmbar, aber ich benutze nur die stärkste Einstellung. Ich
    benutze den Timer nicht, sondern schalte ihn lieber selbst ein und aus. Ich sehe
    diese Funktion als nützlich im Büro mit Zimmerpflanzen oder im Urlaub.‘‘‘
```

Response:

```
[
  {"span": "im", "severity": "minor", "category": "accuracy/mistranslation",
     "span_with_context": "nützlich im Büro"},
  {"span": "ihn", "severity": "minor", "category": "accuracy/mistranslation"},
  {"span": "mit", "severity": "minor", "category": "accuracy/mistranslation"}
]
```

Figure 3: Example prompt and response for AutoMQM error span identification. We omit the error span attribute `is_source_error` for brevity. Each span that is not unique receives an additional attribute `span_with_context`.

HW-TSC's submissions to the WMT 2025 Segment-level quality score prediction Task

Abstract

This paper presents the submissions of Huawei Translate Services Center (HW-TSC) to the WMT 2025 Segment-level quality score prediction Task. We participate in 16 language pairs. For the prediction of translation quality scores for long multi-sentence text units, we propose an automatic evaluation framework based on alignment algorithms. Our approach integrates sentence segmentation tools and dynamic programming to construct sentence-level alignments between source and translated texts, then adapts sentence-level evaluation models to document-level assessment via sliding-window aggregation. Our submissions achieved competitive results in the final evaluations of all language pairs we participated in.

1 Introduction

Recent advances in large language models (LLMs) (OpenAI, 2023; Touvron et al., 2023; Yang et al., 2024) have opened new possibilities for document-level machine translation (doc-mt) (Kim et al., 2019; Maruf et al., 2022; Fernandes et al., 2021). Leveraging their robust language generation capabilities and profound contextual understanding, LLMs can produce translations that are more natural, fluent, and semantically coherent. These models have demonstrated remarkable proficiency in processing long-form texts, thereby significantly enhancing the quality of document-level translation.

However, this approach also introduces several challenges. Since LLMs translate entire documents holistically rather than processing sentences sequentially, the output may suffer from issues such as over-translation (excessive paraphrasing) or under-translation (omissions). Furthermore, the absence of sentence-level alignment between source and target texts—combined with the inherent length of both—makes it difficult to assess translation quality accurately. Robust evaluation methods for document-level machine translation (MT) remain an unresolved critical problem.

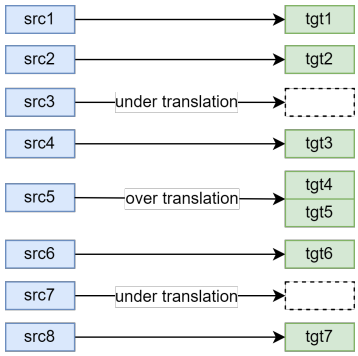

Figure 1: src_3 and src_7 lack corresponding translations in T, while src_5 aligns with a combined $tgt_4 + tgt_5$ segment.

While human evaluation remains the gold standard for assessing translation quality due to its nuanced understanding of language and context, it faces inherent limitations in scalability, subjectivity, and cost-efficiency, particularly for large-scale document-level translation tasks. Automated metrics like BERTScore (Zhang et al., 2019) and COMET (Rei et al., 2020a,b), though capable of capturing semantic nuances and demonstrating strong correlation with human judgments, are constrained by input length restrictions and their reliance on sentence-level alignment between source and reference texts. While (Vernikos et al., 2022) pioneered the adaptation of these metrics to document-level translation evaluation, its applicability remains severely constrained by its fundamental requirement for perfect sentence-level alignment among source texts, translations, and reference translations. This strict one-to-one correspondence prerequisite significantly limits its practical utility in real-world scenarios where such ideal alignments rarely exist. Recent attempts to leverage large language models (LLMs) as eval-

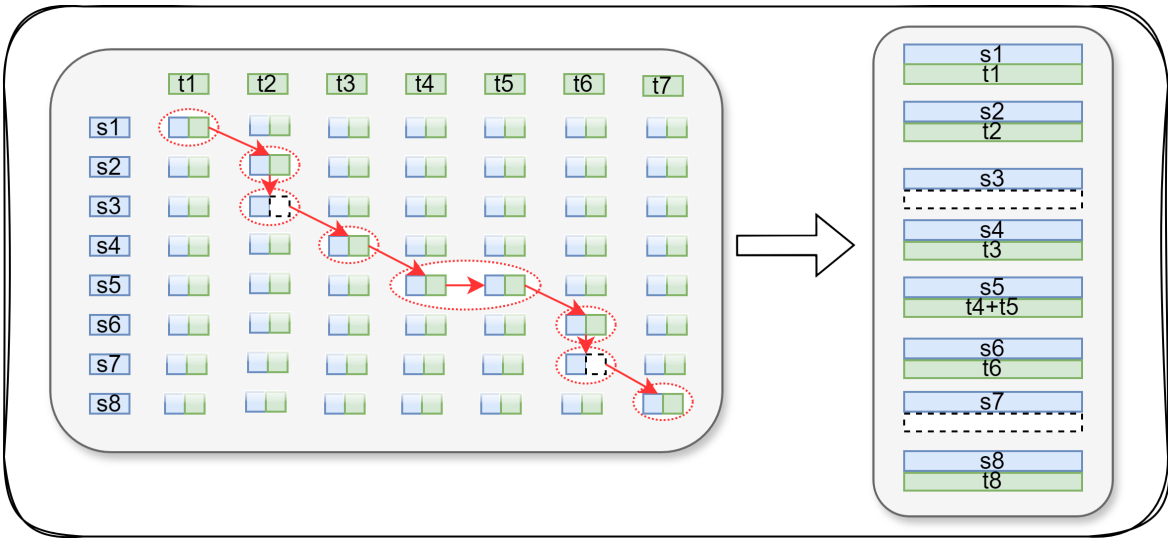

Figure 2: For the segmented text pair (8 source fragments and 7 target fragments), we first compute a full 8×7 score matrix using COMET KIWI to evaluate all possible pairwise alignments(subfigure a). We then apply dynamic programming to identify the optimal alignment path (visualized as the red trajectory in Figure). This optimization yields final sentence-level alignments, resulting in 8 properly aligned source-target pairs as demonstrated in subfigure (b).

uators through carefully designed prompts show promising alignment with professional human assessments across multiple dimensions including accuracy, fluency, and stylistic consistency (Gu et al., 2025). However, these methods suffer from high computational costs, sensitivity to training data biases, and instability across different prompts or model runs, raising concerns about their reliability and reproducibility for practical applications.

In this work, we employ an innovative alignment algorithm to automatically construct sentence-level alignment between source and translated texts. Our approach(Guo et al., 2025) involves: (1) sentence segmentation of source and target texts, (2) alignment metric computation, (3) anchoring of source text segmentation information, and (4) reconstructed target text segmentation (including merging and gap filling). By subsequently applying sliding-window-based sentence-level evaluation, we achieve document-level assessment effectiveness, thereby successfully adapting sentence-level pretrained model evaluation methods to document translation.

2 Approach

2.1 Alignment

Since our source text, translation, and reference translation are all document data, the sentence-level alignment between the source text and translation that we automatically construct can be divided into the following three parts:

- Sentence segmentation: Segment both original and translated texts into sentence sequences.
- Calculate alignment metrics: Measure alignment similarity between original and translated sentences using metrics like COMET KIWI (Rei et al., 2022) or LABSE (Feng et al., 2022).
- Reconstruct translated text segmentation: Based on the original text's segmentation, reconstruct the translated text's segmentation, involving possible merging or filling gaps. This is done using a dynamic programming algorithm.

As shown in Figure 2, for a source text S and its target translation T, we first perform sentence segmentation using spaCy [1], yielding m source sentences $S = (s_1, s_2, ..., s_m)$ and n target sentences $T = (t_1, t_2, ..., t_n)$. For these $m \times n$ sentence pairs, we compute a KIWI matrix $KIWI_{m \times n}$ using COMET KIWI. When $m = n$ with one-to-one correspondence, the diagonal path of this matrix should yield the maximum values. In document-level translation scenarios, the number of source segments and target segments typically differs

[1] https://spacy.io/

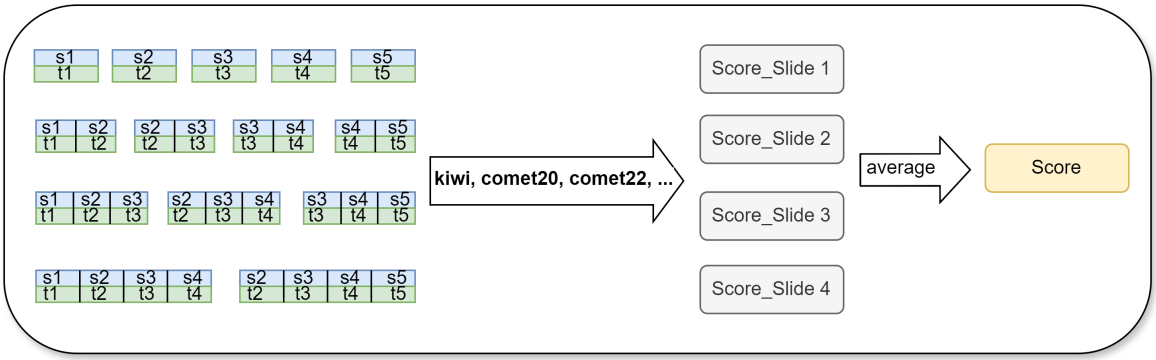

Figure 3: For the reconstructed source-target pairs, Compute Score Slide 1 on 5 original aligned pairs. Generate 4 concatenated pairs using window size 2 to calculate Score Slide 2 Generate 3 concatenated pairs using window size 3 to calculate Score Slide 3 Generate 2 concatenated pairs using window size 4 to calculate Score Slide 4. The final document-level metric is derived by averaging these four window-level scores, providing comprehensive coverage of local and contextual translation quality.

$(m \neq n)$. Nevertheless, we can identify an optimal alignment mapping $T = (t_1, t_2, ..., t_m) = F(s_1, s_2, ..., s_n)$ - represented as the optimal path in our framework - that maximizes the COMET KIWI score.

This alignment task can be abstracted as a path optimization problem: Given an $[mn]$ matrix where each cell (i, j) contains a score value, we seek the optimal path from $(0, 0)$ to $(m-1, n-1)$ under the following constraints:

- **Monotonicity Constraint**: y-coordinate must increase by exactly 1 at each step $(\forall t, y_{t+1} = y_t + 1)$. x-coordinate must increase by a non-negative integer $(\forall t, x_{t+1} \geq x_t)$
- **Boundary Conditions**: Path originates at the top-left corner $(0, 0)$ and terminates at the bottom-right corner $(m-1, n-1)$
- **Optimization Objective**: Maximize the cumulative score:

$$argmax_p \sum_{(x,y)\in p} matrix[x][y] \quad (1)$$

Using the dynamic programming algorithm, we can obtain a translation whose segmentation aligns one-to-one with the source text, as well as the segmentation information of the reference translation.

2.2 Sliding Evaluation

After obtaining the alignment information in the previous step, we follow a procedure similar to (Raunak et al., 2024), calculating sentence-level scores using a sliding window approach. As illustrated in Figure 3, for m source sentences $S = (s_1, s_2, ..., s_m)$ and their aligned translations $T' = (t'_1, t'_2, ..., t'_m)$, given a window size n, we compute m groups of sentence-level evaluation metrics, each incorporating $n-1$ preceding sentences as contextual information. The mean of these scores serves as the document-level evaluation result, expressed formally as follows:

$$\frac{1}{n}\sum_{i=1}^{n} f_i(S, T') \quad (2)$$

Where f_i corresponds to the Slide Score measured when the window is i, corresponding to Score Slide i in Figure 3.

3 Results

We participated in all language pair competitions within the Segment-level Quality Score Prediction Task, which included a total of 16 language pairs. After the alignment phase, we obtained new sentence-level text pairs corresponding to each paragraph text pair. At this point, we conducted respective predictions using wmt22-cometkiwi-da(**ASD-KIWI**), wmt23-cometkiwi-da-xl(**ASD-KIWI-XL**), and wmt23-cometkiwi-da-xxl(**ASD-KIWI-XXL**), with the results shown in Table 1. As shown in the Table 1, **ASD-KIWI-XL** demonstrates superior correlation to **ASD-KIWI** across most of the 16 language pairs, indicating that post-alignment sentence-pair quality scoring plays a critical role. While larger parameter models generally achieve better performance (as evidenced by KIWI-XL's gains), this trend is not absolute—**ASD-KIWI-XXL** fails to further outperform **ASD-KIWI-XL**.

Languages Pairs	ASD-KIWI	ASD-KIWI-XL	ASD-KIWI-XXL	ASD-KIWI-ENSEMBLE
EN-ZH	0.6800	0.6467	0.5600	**0.7467**

JA-ZH	**0.7245**	0.5042	0.6177	0.6978

Table 1: Results for 16 Languages Pairs in the Segment-Level Quality Score Prediction Task

To leverage both models, we propose an ensemble method that averages the per-sentence scores of **ASD-KIWI** and **ASD-KIWI-XL**. Empirical results confirm that **ASD-KIWI-ENSEMBLE** achieves the best overall performance.

4 Conclusion

This paper presents the methodology behind HW-TSC's submission to the WMT 2025 Segment-Level Quality Score Prediction Task. Our approach integrates sentence segmentation tools and dynamic programming algorithms to construct sentence-level alignments between source and translated texts, then adapts sentence-level evaluation models to document-level assessment through sliding-window aggregation. By incorporating an ensemble strategy, our method achieved the highest correlation scores across all 16 languages in this task.

UvA-MT at WMT25 Evaluation Task: LLM Uncertainty as a Proxy for Translation Quality

Di Wu **Christof Monz**
Language Technology Lab
University of Amsterdam
{d.wu, c.monz}@uva.nl

Abstract

This year, we focus exclusively on using the uncertainty quantification as a proxy for translation quality. While this has traditionally been regarded as a form of **unsupervised** quality estimation, such signals have been overlooked in the design of the current metric models—we show their value in the context of LLMs. More specifically, in contrast to conventional unsupervised QE methods, we apply recent calibration technology (Wu et al., 2025b) to adjust translation likelihoods to better align with quality signals, and we use the **single** resulting model to participate in both the general translation and QE tracks at WMT25.

Our offline experiments show some advantages: 1) uncertainty signals extracted from LLMs, like Tower or Gemma-3, provide accurate quality predictions; and 2) calibration technology further improves this QE performance, sometimes even surpassing certain metric models that were trained with human annotations, such as CometKiwi. We therefore argue that uncertainty quantification (confidence), especially from LLMs, can serve as a strong and complementary signal for the metric design, particularly when human-annotated data are lacking. However, we also identify limitations, i.e., its tendency to assign disproportionately higher scores to hypotheses generated by the model itself.

1 Introduction

In this paper, we describe the details of our submission to the WMT 2025 MT evaluation subtask-1, i.e., segment-level Quality Estimation (QE), which includes 16 translation directions. This year, we focus exclusively on using the uncertainty quantification as a proxy for translation quality. While this has traditionally been regarded as a form of unsupervised quality estimation (Fomicheva et al., 2020), such signals have been overlooked in recent designs of metric models. In this competition, we aim to examine the strengths and weaknesses of this signal.

Previous unsupervised quality estimation focused on using the model's internal information to quantify the confidence/certainty of a given translation sentence pair, e.g., using likelihood, entropy, or uncertainty signals under a Monte Carlo (MC) dropout framework (Fomicheva et al., 2020). Notably, they are relying on signals derived from the model itself and are mostly training-free.

We apply recent calibration technology (Wu et al., 2025b) for this year's competition. Unlike traditional unsupervised QE, this method aims to calibrate translation likelihood with quality during training time.

By extensive experiments, several key advantages of calibrated models can be shown as follows:

- Translation quality can be substantially improved with limited training, e.g., 2K instances for each translation direction, and the effectiveness of maximum *a posterior* decoding, like beam search, can be better realized, showing strong promise for real-world use;
- **At the same time, it provides a unified view for optimizing translation quality and estimation, which matches our goal in this competition, i.e., using the model's confidence as a proxy for translation quality.**

Our offline experiments show that the resulting model's QE ability sometimes even surpasses some accurate metric models, like cometkiwi-22 (Rei et al., 2022)[1], without using any human-annotated data. We therefore argue that uncertainty quantification, especially from LLMs, can serve as a strong and complementary signal for the metric design, particularly when human-annotated data are lacking.

[1]https://huggingface.co/Unbabel/wmt22-cometkiwi-da

Proceedings of the Tenth Conference on Machine Translation, pages 974–983
November 8-9, 2025

However, our preliminary tests on this year's WMT25 test set also reveal limitations in using uncertainty signals for quality estimation—**notably, they tend to assign significantly higher scores to hypotheses generated by the model itself**—a pattern that is, to some extent, consistent with recent findings that LLM-as-a-judge systems tend to favor their own outputs (Panickssery et al., 2024).

In the next sections, we will briefly describe: 1) the framework of calibration, 2) offline experiments for both translation performance and our QE strategy by using the calibration approach, 3) the implementation for our submission at the WMT25-QE track, and 4) a discussion of the strengths and limitations of using model confidence for quality estimation.

2 Calibration Method

In this section, we briefly describe the calibration method to keep the paper self-contained; please refer to (Wu et al., 2025b) for details.

Formally, given a parameterized auto-regressive language model p_θ and a translation instruction x, the *log-likelihood* of a translation hypothesis y_i is denoted as $z_\theta(y_i|x) = \log p_\theta(y_i|x)$. Meanwhile, the quality of this translation can be defined as $q(y_i|x)$ where q represents any external quality evaluation model. When sampling hypotheses y from p_θ conditioned on x, both $z_\theta(y|x)$ and $q(y|x)$ can be viewed as random variables defined over the output space. This method is to calibrate the likelihoods of generated hypotheses with their quality to maximize the correlation between $z_\theta(y|x)$ and $q(y|x)$.

The calibration method uses the statistic, *Pearson correlation coefficient* $\rho(a, b)$, to quantify the correlation. Let $a, b : \mathcal{Y} \to \mathbb{R}$ be two real-valued functions defined over a domain $\mathcal{Y}$. The corresponding Pearson score between a and b is given by

$$\rho(a, b) = \frac{\mathbb{E}_{y\sim p}\left[(a(y) - \mu_a)\,(b(y) - \mu_b)\right]}{\sigma_a \sigma_b}, \quad (1)$$

where μ_a, μ_b and σ_a, σ_b denote expectations and standard deviations, respectively. This formulation computes the correlation by normalizing the expected product of their centered values. Due to its scale-invariance and ability to capture trend consistency, the Pearson correlation coefficient is widely used in translation metric meta-evaluation.

The calibration method calculates and optimizes ρ with respect to the likelihood of hypotheses $z_\theta(y|x)$ and the quality score $q(y|x)$. Practically, given the intractably large decoding space, it employs Monte Carlo sampling for approximation. For each source sentence x, we generate k hypotheses y_i ($i \in \{1, \ldots, k\}$) by repeatedly prompting a large language model θ with nucleus sampling, and compute the corresponding $z_\theta(y_i|x)$ and $q(y_i|x)$, and estimate the corresponding μ_z, μ_q and σ_z, σ_q. Accordingly, we define the Pearson-based loss using estimates under the nucleus-induced distribution $\tilde{p}$ as follows:

$$\mathcal{L}_{\mathrm{p}} = -\frac{1}{k} \sum_{\substack{i=1 \\ y_i\sim\tilde{p}_\theta(\cdot|x)}}^{k} \frac{z_\theta(y_i|x) - \mu_z}{\sigma_z} \cdot \frac{q(y_i|x) - \mu_q}{\sigma_q}. \quad (2)$$

It additionally introduces a supervised fine-tuning (SFT) term on the highest-scoring samples as a regularizer to ensure that the model's likelihood distribution remains grounded in high-quality translations, since the Pearson objective alone enforces correlation but does not constrain the absolute scale. The final loss for calibration is formulated as $\mathcal{L}_{\text{cal}} = \mathcal{L}_{\mathrm{p}} + \mathcal{L}_{\text{sft}}$.

An off-policy formulation can be obtained by trivially replacing the current model p_θ with an external model p_{θ^*} for sampling. Overall, by minimizing $\mathcal{L}_{\text{cal}}$, we encourage the Pearson score between z and q to increase. In practice, we use a gradient-based optimizer, Adam, to optimize θ for this goal, with gradients propagated through z_θ, μ_z, and σ_z. Despite its simplicity, several important characteristics are captured in this formulation:

- It models hypothesis qualities from a holistic view, enabling the model to make finer-grained distinctions in translation quality within the decoding space.
- It considers the value of translation quality by the metric function $q(\cdot|x)$, which is ignored in virtually all existing methods based on Bradley-Terry and Plackett-Luce, such as CPO.
- Pearson's correlation inherently applies normalization to a group of both likelihood and quality points. This normalization makes the objective invariant to scale and shift, thereby promoting stable and robust optimization across diverse input distributions.
- **The objective, i.e., the Pearson's score itself, is inherently shared with that of translation metric meta-evaluation, offering a unified perspective for both quality optimization and es-**

timation. Meanwhile, unlike other statistics like Spearman's or Kendall's scores, Pearson's coefficient is differentiable and thus suitable for gradient-based optimization frameworks.

3 Offline Evaluation

In this section, we demonstrate the effectiveness of the calibration method by applying it to the strong LLM-based translation system, i.e., Tower (Rei et al., 2024). We briefly show this method's capabilities in both (1) translation quality optimization and (2) quality estimation optimization.

Note that our online submission system is based on Gemma-3-12B (see Section 4), as it covers more languages for WMT25 than Tower.

3.1 Experimental Setups

Base model. We conduct experiments on Tower-7B, Tower-13B, and TowerMistral-7B models.

Calibration dataset. For the training set, we firstly merge all English sentences from the Flores-200 dataset (Costa-Jussà et al., 2022) in *dev* and *devtest* splits and use them as the source, consisting of 2,009 samples. We focus on off-policy experiments, where we use these sentences to construct translation prompts for each direction by calling an external strong translation model, rather than sampling from the base model itself. Here, we query `gpt-4o-mini`[2] 16 times per prompt, employing nucleus sampling with a temperature of 1.0 and a top-p of 0.98. The resulting bitexts are evaluated using CometKiwi-XXL to reflect corresponding quality scores. In this study, we only use this small-scale dataset to post-train our model. This is motivated by recent studies (Xu et al., 2023; Wu et al., 2024) showing that a few high-quality samples with a strong base model can significantly enhance the system's performance.

Training setups. For all experiments, we train models using LoRA (Hu et al., 2022) with rank 8, setting α to 32 and dropout to 0.05. Training uses a batch size of 32, gradient accumulation of 8 steps, and sequences capped at 512 tokens. To ensure robust results, we experiment with learning rates ranging from 1e-5 to 1e-4, reporting the best results for all settings. Adam (Kingma and Ba, 2014) is used as an optimizer. All experiments use H100 GPUs, with 7B models trained on one GPU and 13B models trained on two GPUs.

3.2 Translation Quality Results

Table 1 presents the results for the `Tower` series under an off-policy setting, measured by CometKiwi-XL and XCOMET. Except for closed-source models, all results are decoded by beam search with a beam size of 5. TowerInstruct-7B/-13B, and TowerInstruct-Mistral-7B are official implementations (Rei et al., 2024), supervised fine-tuned (SFT) on the corresponding base models using TowerBlock. We also conducted SFT on the Tower-Base series using 2K Best-of-N samples per direction, selected from our calibration dataset (§3.1) based on the highest CometKiwi-XXL scores. The resulting performance is comparable to the official instruction models.

When applying our calibration approach, very strong improvements can be observed across all directions, metrics, and base models. First, it leads to an average improvement of +2.8 points in KIWI-XL and +2.7 points in XCOMET over TowerInstruct-Mistral-7B. Additionally, Table 2 shows gains of +3.6 points in KIWI-XXL and +1.2 points in COMET, respectively. Second, this performance is comparable to that of the current top-performing system, that is Tower-70B-v2 equipped with 100-time-sampling MBR/TRR[3], while being approximately 200 times faster[4].

We also compare our approach with CPO (Xu et al., 2024), a widely used preference optimization method for translation. Following its original setup, we select the highest- and lowest-scoring candidates as accepted and rejected samples, respectively, and achieve consistent, substantial improvements over CPO.

3.3 Quality Estimation Results

As detailed in §2, we shared the objective for translation quality optimization and estimation, although supervisions are from machine annotations instead of human annotations. If optimized effectively, the resulting model should inherently acquire the ability to assess translation quality using

[2]Recent study (Wu et al., 2025a) shows that GPT-4o-mini can already serve as a strong translation system.

[3]TRR (Rei et al., 2024) denotes an ensemble strategy that applies reranking based on multiple metric model to select the best candidate from multiple sampled hypotheses. They report TRR results when it surpasses MBR.

[4]We roughly estimate the latency of the Tower-70B-v2 model to be 10 times that of the Tower-Mistral-7B model. Meanwhile, the former employs 100× sampling, while the latter uses beam search with a beam size of 5.

Table 1: en→xx translation qualities on WMT24 measured by CometKiwi-XL and XCOMET. Note that the Tower-v2 models, including Tower-70B-v2, have not been publicly released. We report their best results as published by Rei et al. (2024). For GPT-4o and GPT-4o-mini, we use the prompts following (Hendy et al., 2023). Results in other metrics can be found in Appendix A. Notably, according to Kocmi et al. (2024), improvements of ≥ 1.99 in XCOMET or ≥ 0.94 in COMET scores correspond to at least 90% estimated accuracy in human judgment—both of which are achieved by our method.

the hypothesis *log-likelihood* as a metric. In this section, we evaluate how effectively calibration can elicit this capability.

We use the WMT22 metric meta-evaluation dataset (Zerva et al., 2022) and follow the official practice to assess quality estimation ability using Spearman's and Kendall's correlation. We evaluate all training directions on Tower that overlap with the WMT dataset, namely, en→de and en→ru.

Figure 1 depicts the Spearman score (metric performance) and the corresponding translation performance under different settings for Tower-7B and Tower-13B, including: (1) supervised fine-tuning using varying amounts of best-of-N samples (400/800/1200/1600/2000 samples per direction), (2) scaling the base model size from 7B to 13B, and (3) applying our calibration method. It shows that:

(1) As more Best-of-N samples are included in SFT, translation performance progressively improves. Interestingly, the quality estimation ability (Spearman scores) increases from around 51.5 to 54.0 points. We attribute this to the fact that the model assigns higher likelihoods to better hypotheses. However, these improvements are limited and not general across languages, see Appendix B.

(2) Examining the effects of scaling, we observe that: (i) scaling up from 7B to 13B generally improves translation performance for both the original TowerInstruct models and the fine-tuned models; (ii) however, its impact on calibration, i.e., quality estimation ability, remains minimal.

(3) Our calibration method manifests very strong improvements in both translation and quality estimation. For example, when applying our method to TowerBase-13B, the resulting model surpasses some state-of-the-art systems in both translation performance and quality estimation ability, i.e., Tower-70B-v2+MBR/TRR and CometKiwi, at the same time.

Similar trends can be found in Figure 2 when we use the Kendall coefficient to measure the correlation. Results for en→ru are provided in Appendix B.

Overall, we observe a clear, albeit sometimes non-linear, correlation between the models' translation performance and their quality estimation ability. These results suggest—to some extent—a uni-

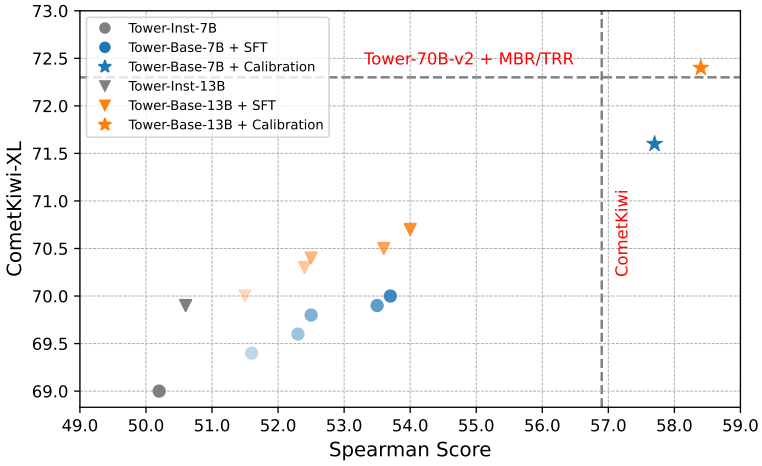

Figure 1: The Spearman coefficient and the corresponding translation performance in en→de direction under different settings for the Tower series models. The color gradients of ▼ and ●, from lighter to darker shades, indicate the results of fine-tuning with varying amounts of Best-of-N data, from 400 to 2000 samples. ★ denotes the application of our calibration method, which simultaneously surpasses both the state-of-the-art translation system and the widely used quality estimation model.

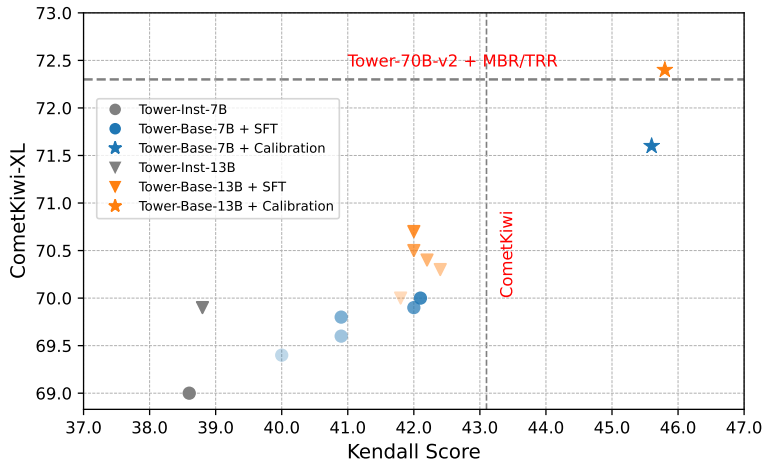

Figure 2: The Kendall coefficient and the corresponding translation performance in en→de direction under different settings for the Tower series models. The color gradients of ▼ and ●, from lighter to darker shades, indicate the results of fine-tuning with varying amounts of Best-of-N data, from 400 to 2000 samples. ★ and ★ denote the application of our calibration method on 13B and 7B models, respectively.

fied perspective: a well-performing translation system should inherently 'know' what constitutes a good translation. In turn, we also suggest optimizing translation quality by improving calibration on LLMs, rather than relying solely on extreme scaling or supervised fine-tuning, as the latter approaches show relatively limited effectiveness.

4 Implementation of Our WMT25 Submission

In this section, we describe the implementation of our QE system for WMT25. To cover more languages, we use Gemma-3-12B as the base model instead of Tower, as noted in Section 3.1.

To construct the calibration dataset, similar to that in Section 3.1, we feed the source segments in the WMT25 general translation test set into GPT-4o-mini, using the prompts provided with the official test set[5], to generate 16 hypotheses per sample. Note that we use the WMT25 blind test sets rather than Flores. This choice is motivated by (1) better alignment with the domain used in testing and (2) consistency with WMT25's paragraph-level data format.

Following that in Section 3.1, the corresponding hypotheses are decoded using nucleus sampling with a top-p of 0.98 and a temperature of 1.0. Each sample is at the paragraph level, where "$\backslash n$" re-

[5]Official prompts can be found here.

mains in the original data as a separator. We also use CometKiwi-XXL to score each one-to-many translation pair in our synthetic dataset.

We apply the calibration method (Wu et al., 2025b), as we mentioned in Section 2, as the only post-training method on Gemma-3-12B.

Finally, the resulting model, trained on synthetic data derived from the WMT25 general translation test set, is used as a quality estimation model here. For each sample in the WMT25 QE dataset, we feed the source and target segments into our model (with the corresponding prompt) and directly use the **average log-likelihood** of the target segments as the quality assessment scores for submission.

For the performance of our system on the WMT25-QE track, please refer to this year's findings paper, which has not yet been officially released at the time of this submission.

5 On the Limitation of Using Uncertainty as a Proxy for Translation Quality

Although we demonstrate the effectiveness of using LLM uncertainty as a proxy for translation quality in Section 3.3, we also identify an important limitation—**this method will give significantly higher scores for translations that are from itself**—it favors its own output when it uses maximum a *posteriori* as the decoding rule.

This issue was not identified by (Wu et al., 2025b), as their QE testing set lacks such special conditions and does not include the model's own translation outputs during QE evaluation.

Meanwhile, we argue that this issue is likely to be a general limitation of most metrics based on translation uncertainty. More broadly, it to some extent aligns with observations about LLM-as-a-judge (Panickssery et al., 2024), where LLMs tend to favor their own generations.

Lastly, we anticipate that the official WMT25 QE test set will be particularly challenging for our metric. **As noted above, we use a single calibrated model to participate in both the general translation and quality estimation tasks at WMT25.** Therefore, if any hypotheses generated by our system appear in this year's QE test set, it is likely to assign them the highest scores. We have found indications of this, although we cannot confirm it because the official description of the test set has not yet been released.

A Results based on Tower in KIWI-XXL and COMET

Table 2 shows off-policy results measured by two other metrics, i.e., CometKiwi-XXL (abbreviated as KIWI-XXL) and COMET-22 (abbreviated as COMET). Very strong average performance improvements can be observed. For instance, +3.6 and +1.1 points of KIWI-XXL and COMET average gains are shown over TowerInstruct-Mistral-7B.

B Results on En→Ru Direction

In this appendix, we provide additional results in en→ru, complementing Section 3.3 of the main text.

Figure 3 shows the Spearman coefficient and the corresponding translation performance in the en→ru direction. Meanwhile, Figure 4 present the results using Kendall's τ for en→ru direction. It is clear that the main findings, as mentioned in Section 3.3, hold across language directions and statistics.

Can QE-informed (Re)Translation lead to Error Correction?

Govardhan Padmanabhan

Institute for People-Centred AI
University of Surrey, United Kingdom
gp00816@surrey.ac.uk

Abstract

The paper presents two approaches submitted to the WMT 2025 Automated Translation Quality Evaluation Systems Task 3 - Quality Estimation (QE)-informed Segment-level Error Correction. While jointly training QE systems with Automatic Post-Editing (APE) has shown improved performance for both tasks, APE systems are still known to *overcorrect* the output of Machine Translation (MT), leading to a degradation in performance. We investigate a simple training-free approach - QE-informed Retranslation, and compare it with another within the same training-free paradigm. Our winning approach selects the highest-quality translation from multiple candidates generated by different LLMs. The second approach, more akin to APE, instructs an LLM to replace error substrings as specified in the provided QE explanation(s). A conditional heuristic was employed to minimise the number of edits, with the aim of maximising the Gain-to-Edit ratio. The two proposed approaches achieved a ΔCOMET score of 0.0201 and -0.0108, respectively, leading the first approach to achieve the winning position on the subtask leaderboard.

1 Introduction

Large Language Models (LLMs) have advanced the field of Machine Translation (MT), given their support for longer input context length and ability to generate text in a natural tone. However, translation quality is still limited for languages other than English and for domain-specific translations (Fernandes et al., 2025). Evaluating MT output for quality is critical to understand the reliability and suitability of translation systems, and more importantly, to be able to perform accurate corrections. The WMT24 Metrics Shared Task found that neural-based learned metrics like COMET or xCOMET were superior when evaluating LLM-generated translations, compared to the traditional statistical metrics like BLEU, or chrF (Freitag et al., 2024).

As LLMs are typically trained on a large general dataset, performance in domain-specific MT can often fall short as they may not properly render key terminologies or stylistic conventions. As such, Automatic Post-Editing (APE) is vital to fixing MT errors. However, they are prone to overcorrecting. One such example of mitigating over-correcting, proposed by Deoghare et al. (2025), is to utilize word-level Quality Estimation (QE) to limit edits only on the specified error segments. Despite recent efforts to reduce over-correction (Deoghare et al., 2023, 2024), APE models still fall short of the required semantically coherent output. Therefore, we ask the titular question - "Can QE-informed re-translation help overcome MT errors?", and discuss two approaches as a comparative evaluation.

This paper describes two participation systems, both utilizing pre-trained and open-source LLMs, for the WMT 2025 Automated Translation Quality Evaluation Systems Task 3 - QE-informed Segment-level Error Correction. The primary approach leverages multiple LLMs for MT and selects the best output using QE. In the secondary approach, an LLM is prompted to replace error-segments in the provided MT. These error segments are identified by the explainable QE provided within the dataset.

2 Related Work

Quality Estimation (QE) QE is an automated evaluation framework that predicts a score indicating whether the translation is good or not (Yvon, 2019). COMET (Cross-Lingual Optimized Metric for Evaluation of Translation) is an automatic metric to evaluate the quality of machine translation using deep learning models (Rei et al.,

Proceedings of the Tenth Conference on Machine Translation, pages 984–993
November 8-9, 2025

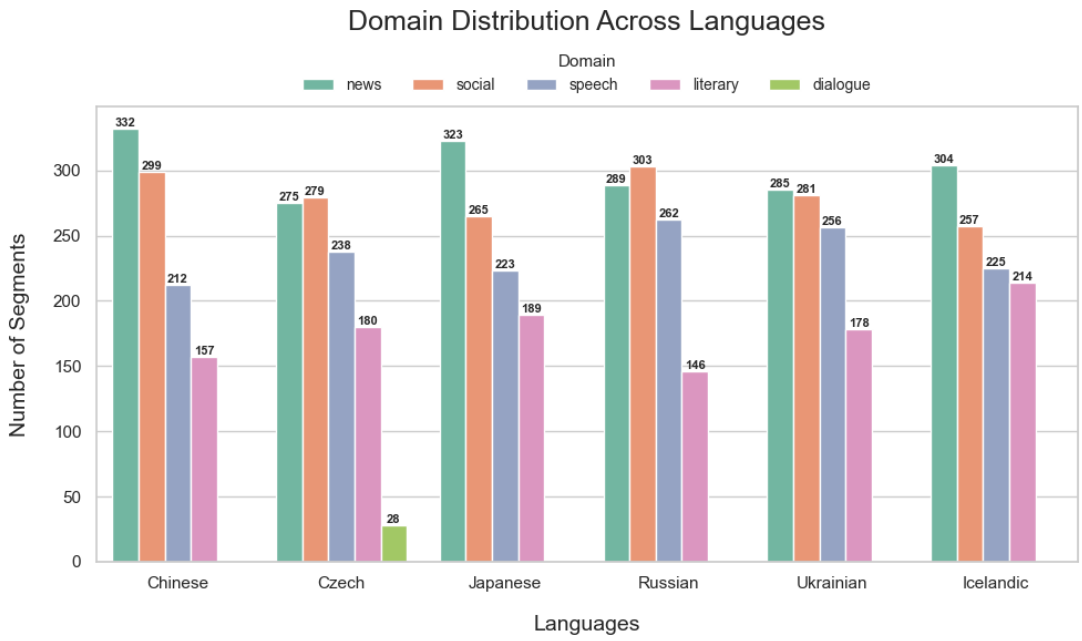

Figure 1: Domain distribution within each language

2020). COMETKiwi is a hybrid machine translation quality estimation (MTQE) model that combines COMET and OpenKiwi (Rei et al., 2022). It achieved top performance in the WMT 2022 shared task and has since been widely adopted as a state-of-the-art benchmark in MTQE.

Automatic Post-Editing (APE) APE is an automated system that corrects MT output, without human involvement (do Carmo et al., 2021). Chatterjee et al. (2018) describe combining QE and APE in three ways: using QE as an APE activator when the MT output is poor, as guidance to help the APE decoder decide which tokens to change, and as a selector to choose between the raw MT and post-edited output.

WMT24 QE-APE The previous year's WMT competition focused on sentence-level quality estimation and error span predictions (Zerva et al., 2024). QE was further incorporated into APE. The dataset for the QE-APE primarily consisted of English–Hindi (En-Hi) and English–Tamil (En-Ta) pairs. The source (SRC) English sentence, the target (TGT) translation provided by an unspecified neural machine translator, and a human post-edit (PE) version of the translation made by native speakers were included to support both quality estimation and automatic post-editing tasks.

The HW-TSC team (Yu et al., 2024) utilized `Llama3-8B-Instruct` for En-Hi pairs. The model first underwent continual pretraining using low-rank adaptation (LoRA) on SRC and TGT data, and was further supervised fine-tuned on the PE data with a custom prompt. For En-Ta pairs, they trained a custom transformer then performed APE fine-tuning. This system achieved 0.851 and 0.918 COMET scores for En-Hi and En-Ta translation tasks, respectively.

The IT-Unbabel team utilized `xTower` for generating corrected translations, along with a quality estimation model to decide whether to use the original translation or the `xTower` output. This approach achieved 0.8646 COMET score for En-Hi pairs, and 0.9163 for En-Ta pairs.

IT-Unbabel's solution of utilizing an LLM along with QE as a selector served as the inspiration for the primary approach

3 Methodology

3.1 Dataset Analysis

The complete test data provided with the task was exclusively used. This dataset consists of 6,000 machine translations from English to Chinese, Czech, Japanese, Icelandic, Russian, and Ukrainian, with 1,000 instances for each language pair. The texts cover a range of domains, specifically news, social, speech, literary, and dialogue. As shown in Figure 1, the domains are not evenly distributed. The *news* domain is the most prominent overall with 1,808 entries, while the *dialogue*

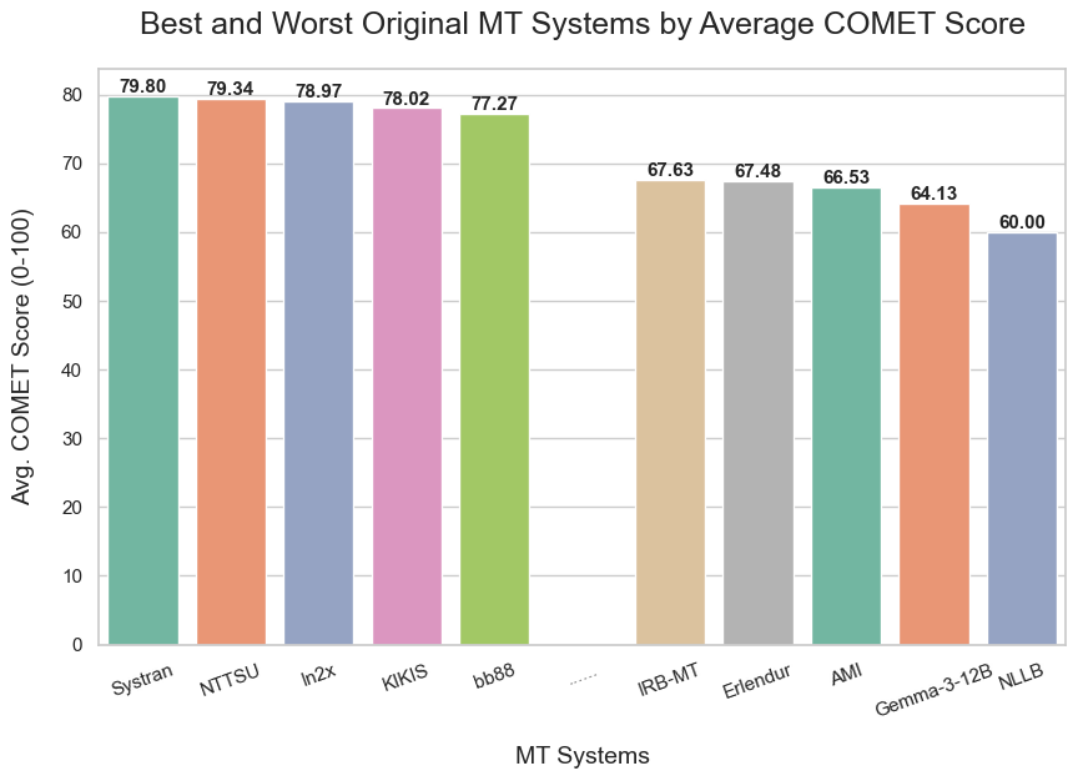

Figure 2: System performance in hypothesis_segment

domain has the lowest representation with 28 segments, all appearing only in the English-to-Czech group.

The original translations under the "hypothesis_segment" column were generated by 38 different translation systems, including LLMs like `GPT4.1`, `Claude-4`, `DeepSeek-v3`, and more. Figure 2 shows the five best and worst systems according to their average translation quality scores.

3.2 Approaches

3.2.1 Primary Approach - "Best MT Wins"

In this approach, multiple LLMs were used to translate the English texts from scratch, without additional information or context. The resulting candidate translations were then evaluated with the *wmt22-cometkiwi-da* model, which provided QE scores based on the source English text and translated system outputs. The translation with the highest QE score was selected as the final output. By re-framing the APE task as re-translation, QE serves as a selector in place of traditional decoders. Similar approaches have also been explored, where QE is used in multi-hypothesis selection (Yu et al., 2024; Laki and Yang, 2018; Lu and Zhang, 2019), further supporting the view of QE as a decision mechanism in MT improvement. This approach therefore functions as a systematic probe of QE-based re-ranking, illustrating both its potential to establish an empirical upper bound on metric-based performance and its limitations in terms of computational cost and efficiency.

`Aya-Expanse-8B`, `GPT-SW3-6.7B`, `Tri-7B`, `GLM4-9B`, `Phi4-mini-instruct`, and `TowerPlus-9B` models were used. These models were selected because of their reported performance, robustness, popularity, and recency. Models like `GPT-SW3-6.7B`, `Tri-7B`, and `GLM4-9B` were selected owing to their specialized training in certain languages, specifically Icelandic, Japanese, and Chinese respectively.

The prompts for `Tri-7B`, `Phi4-mini-instruct`, and `TowerPlus-9B` are reminiscent of their translation prompts available in their Huggingface model cards, being variations of:

> Translate from English to *{Language}*

System prompts for the other models were more involved, as using the same prompt resulted in some hallucinations, chain of thought, or worse translation quality during limited internal testing.

For `Aya-Expanse-8B`:

> You are a helpful bilingual assistant that correctly translates the user's input text from English to *{Language}*.
> When translating, you must use the same tone and intent of the English text. You will include any and all special characters from the input.
> If there is no proper translation for an English word or phrase, you can use the English word or phrase in place.

For `GPT-SW3-6.7B`:

> <|endoftext|><s>
> System:
> You are a bilingual assistant that objectively translates the user's input text from English to Icelandic.
> You will include any and all special characters from the input.
> If there is no proper translation for an English word or phrase, you can use the English word or phrase in place.
> <s>
> User:
> *{original English text}*
> <s>
> bot:

For `GLM4-9B`:

> You are a bilingual assistant that correctly translates the user's input text from English to Chinese.
> When translating, you must use the same tone and intent of the English text. You will include any and all special characters from the input.
> If there is no proper translation for an English word or phrase, you can use the English word or phrase in place.
> Output only the translation!

Except `TowerPlus-9B`, the remaining models do not support all required languages. Hence, they translated only their supported language(s), and the rest were omitted. After all models were successfully executed, the QE score via COMETKiwi between all translations, including the original systems', was used to determine which MT to use.

3.2.2 Secondary Approach - "Fill in the Blanks"

The provided test data includes *error spans* for the translations. Using fine-grained QE signals to guide targeted corrections, this approach investigates whether restricting edits to QE-highlighted segments could yield improvements with fewer changes, thereby increasing both efficiency and interpretability compared to full re-translation.

Using these error spans, the corresponding substring(s) in translation is replaced with a "**__BLANK__**" token, emulating a multilingual masked language modeling task. The text domain is also used to provide additional context. An example is included in the prompt to guide the model's behavior, serving as a one-shot example. Different examples were used in the prompt for different languages.

This approach utilizes `TowerPlus-9B`, an open source LLM with 9 billion parameters based on Gemma2. This model was selected because of its training for translation-related tasks along with instruction tuning, a context window of 8192 tokens, and has support of the languages of this task: English, Chinese, Czech, Japanese, Icelandic, Russian, Ukrainian. It has also been shown to outperform larger parameter models like `Gemma2-27B` and `Llama3.3-70B` on translation performance (Rei et al., 2025). The 9B variant was specifically selected due to resource and time constraints.

Provided below is the system prompt template for Russian language translations:

> You are a helpful assistant that corrects a Russian translation by filling in the blanks. Use the English sentence for context. Complete the task while maintaining the tone of a *{domain}*.
> Important - Do not use any of the specified wrong words. Replace each __BLANK__ token with an appropriate word or phrase that matches the original meaning, tone, and context of the English sentence.
>
> Example (social domain):

Russian with __BLANK__: Многие молодые люди сегодня предпочитают __BLANK__ в кофейнях, а не дома.
English: Many young people today prefer to hang out in coffee shops rather than at home.
Wrong translation: Многие молодые люди сегодня предпочитают учиться в кофейнях, а не дома.
Wrong words: [' учиться']
Corrected Russian sentence: Многие молодые люди сегодня предпочитают проводить время в кофейнях, а не дома.

Russian with __BLANK__: *{mt with __BLANK__}*
English: *{source text}*
Wrong translation: *{mt text}*
Wrong words: *{list of substrings removed}*
Corrected Russian sentence:

To increase translation quality while keeping changes minimal (gain-to-edit ratio), a conditional masking heuristic based on error severity and overall QE score was employed. The pseudocode for this method is provided in Algorithm 1.

Algorithm 1 Conditional masking based on severity and score

```
Original QE Score: Float x
if x >= 0.90 then
    Proceed without masking
else if x > 0.50 then
    if only minor severity error spans then
        Mask minor error spans
    else
        Mask all non-minor error spans
    end if
else
    Mask all error spans
end if
```

4 Results and Discussion

Tables 1 and 3 present language-wise results for the primary and secondary approaches, respectively. The WMT'25 shared task tracks two main metrics: ΔCOMET and Gain-to-Edit Ratio (referred to as "G2E Ratio"), with the overall ΔCOMET score serving as the primary selection criterion. Here, ΔCOMET is computed as the difference between the COMET scores of the proposed approach and the baseline translation. The G2E Ratio is calculated as ΔCOMET divided by the total edit rate. BLEU and chrF++ scores are also included in the tables as supplementary information, but they are not the focus of the analysis. The best-performing ΔCOMET and G2E Ratio scores across the two tables are highlighted in bold.

4.1 Primary Approach - "Best MT Wins"

Language	ΔCOMET	G2E Ratio	BLEU	chrF++
Icelandic	$3.65e-2$	$1.27e-3$	69.24	78.37
Russian	$2.01e-2$	$7.10e-4$	68.56	79.15
Czech	$1.89e-2$	$8.15e-4$	73.85	82.29
Chinese	$1.84e-2$	$1.64e-4$	39.35	58.41
Ukrainian	$1.63e-2$	$6.36e-4$	71.36	80.85
Japanese	$1.03e-2$	$1.41e-4$	54.33	65.44
Average	$\mathbf{2.01e-2}$	$\mathbf{6.22e-4}$	62.78	74.08

Table 1: Language-wise Results for Primary Approach

Table 1 shows that an ensemble of diverse models helps significantly improve the translations, especially in low-resource languages like Icelandic with roughly 3% improvement.

As this approach selects the translation with the best QE score, not all systems or model responses contributed equally to the final output. As shown in Table 2, `TowerPlus-9B` and the original translations have contributed the most, while `Tri-7B` did not contribute at all. Despite `GPT-SW3-6.7B`, `Tri-7B`, and `GLM4-9B` trained primarily for use in Nordic and Altaic languages and Chinese, other models provided better translations. Figure 3 shows how different models contributed to the final response in each language.

System	Contribution
Tower+ 9B	2836
Original	2829
GLM4 9B	149
Phi4 Mini Instruct	106
Aya Expanse 8B	76
GPT-SW3 6.7B v2 Instruct	9
Tri 7B	0

Table 2: System-wise Contribution to the Output

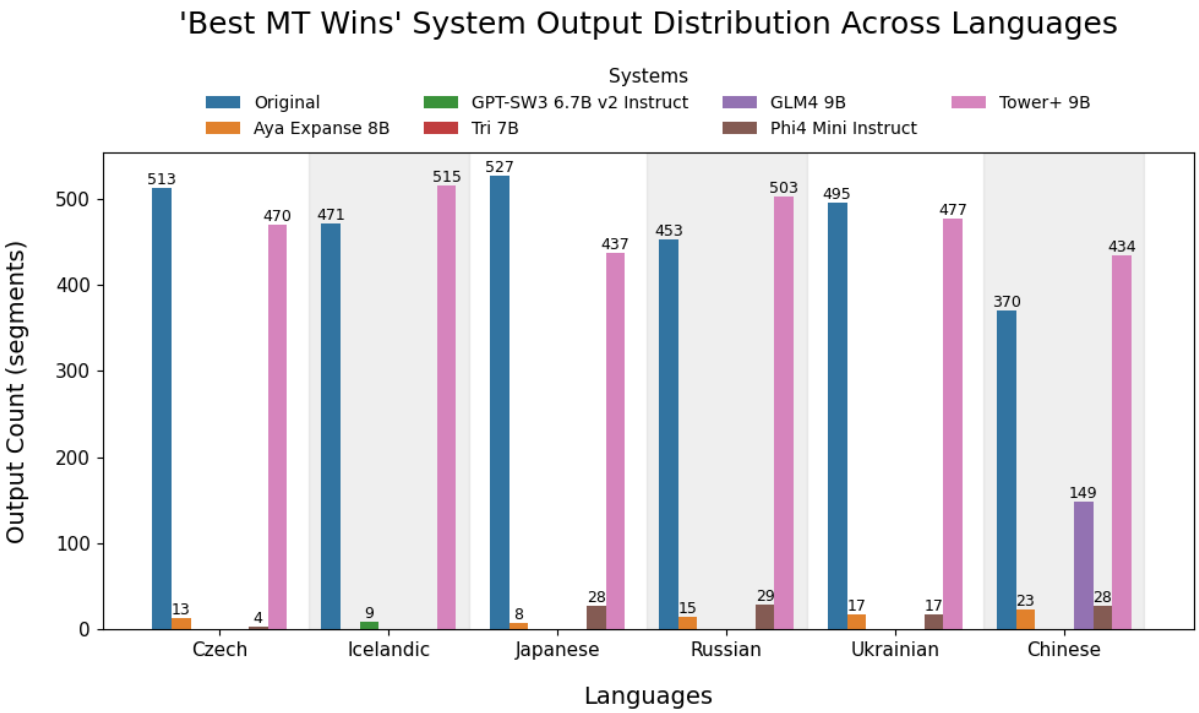

Figure 3: Language-wise count of model responses used in primary approach's final output

The example in Appendix A is an instance where the direct translation by `TowerPlus-9B` was the best-performing. Interestingly, the corresponding output from the secondary approach is of lower quality. This demonstrates the powerful translation capabilities of the model and the need for better prompt engineering in the secondary approach.

4.2 Secondary Approach - "Fill in the Blanks"

Language	ΔCOMET	G2E Ratio	BLEU	chrF++
Czech	$-7.24e-3$	$-5.80e-7$	92.37	95.14
Russian	$-8.03e-3$	$-6.00e-7$	92.56	95.31
Icelandic	$-1.00e-2$	$-8.20e-7$	74.27	82.18
Chinese	$-1.30e-2$	$-4.83e-5$	29.52	83.59
Japanese	$-1.34e-2$	$-4.44e-5$	25.77	82.59
Ukrainian	$-1.35e-2$	$-1.26e-6$	91.77	94.43
Average	$-1.08e-2$	$-1.59e-5$	67.71	88.87

Table 3: Language-wise Results for Secondary Approach

Table 3 shows that this approach does not provide much benefit to the overall translation task, with roughly -0.7% to -1.4% quality degradations.

Appendix C is an example where this approach yields a better translation than the original. The original Czech translation by `DeepSeek-v3` has 3 major errors and 1 minor error. This improvement by the model could be owed to the fact that, on top of its multilingual capabilities, `TowerPlus-9B` was fine-tuned on instruction data from different models, including `DeepSeek-v3`.

There are possible factors why this approach did not perform well: use of bigger and closed-source models in the original MT, use of varied systems and models, inclusion of low-resource languages, correcting only critical + major error spans and ignoring minor error spans in some instances, and more. In the Appendix B example, the original system used Massively Multilingual Neural Machine Translation (MMMT). Although more capable models have been released since then, including `TowerPlus-9B`, output artifacts ("__HEARTBREAK__") and leakage ("Corrected words: [...") affect the translation's quality. This shows that further prompt tuning and output post-processing is needed.

5 Conclusion and Future Work

This paper described two translation approaches submitted to the WMT 2025 QE-informed Segment-level Error Correction task. The first approach used QE as a selector among multiple

LLM translation outputs, resulting in an overall ΔCOMET of 0.0201. The second approach utilized `TowerPlus-9B` exclusively to replace erroneous words in the MT by masking substrings highlighted in the error spans with a blank token, resulting in ΔCOMET of -0.0108. Custom prompts were designed to instruct the model in correcting the translation, similar to a fill-in-the-blank task.

While the first approach showed positive improvements by using QE as a selector, it ultimately depends on the model and system selection. Further exploration of system combinations could yield better performance. The second approach, which performed worse, corrected translations by filling in error segments in the MT. As future work, a two-model system could be explored: a smaller LM to suggest words or phrases for masked tokens via masked language modeling, and a larger LLM to select the most suitable ones to produce a higher-quality translation.

Limitations

Due to limited time and compute resources, the overall experimental design favored n-shot prompting with LLMs for their ease of use and availability of pre-trained weights. Additionally, the model selection was guided by convenience and practical factors such as parameter count, recency, and language compatibility or specificity. These limitations also limited the scope for testing and prompt optimization.

Though "Best MT Wins" reframes APE as retranslation through QE-based selection, this approach is impractical as it requires generating full hypotheses from large models. While the direct translation capabilities of `TowerPlus-9B` even slightly surpassed the original translation system, the other 5 LLMs used were less effective in comparison, resulting in inefficient use of and wasted time and computational resources.

For the "Fill in the Blanks" approach, a lack of proper prompt tuning and post-processing degraded the output quality, indicating that prompt engineering and output handling are important when using LLMs for specific tasks.

More broadly, both approaches rely exclusively on automatic QE metrics such as COMET, which, while effective for shared task evaluation, are primarily trained on English-centric data. The absence of human evaluation limits the ability to validate whether metric-based gains reflect true improvements in translation quality, especially for non-English language pairs.

Appendix

A Example of Primary Approach

Language: Chinese

Original System: Wenyiil

Original English Text:
A brief note on Play Station controllers to round out the 1st party lineup: I never liked them.\nDual Shock 1-3 felt exactly the same to me with exactly the same flaws: Oversized thumbsticks placed too close together, mushy face/shoulder/trigger buttons that seemed to wear out very quickly, and a D-pad that just felt wrong. Dual Shock 4 fixed a lot of problems, but introduced a bunch of new ones. I got a Dual Sense because some friends had a hard time with asymmetrical thumbsticks, and for some reason local stores were selling them for $20 less than DS4 controllers.\nI don't really use this controller: Face buttons are spaced too far apart, my audio in/output keeps defaulting to the controller when it's connected, the bumpers are weirdly tall, and I keep accidentally pressing the track pad when trying to hit menu/share.\nThey are fine guest controllers that have come a long way in terms of design, but for me they're a novelty at best.

Original Chinese MT:
于PlayStation手柄，里提一下，算是第一方手柄容的一个充：我从来都不喜它。\n在我看来，DualShock 1到3代手感完全一，缺点也如出一：杆帽太大且位置太近，面板按、肩和扳机手感很肉，而且似乎特容易磨，十字的感也是不。DualShock 4修正了多，但也引出了一堆新毛病。我了一个DualSense手柄，是因有些朋友用不非称杆，并且出于某原因，本地商店里它的售价比DS4手柄要便宜20美元。\n我其不怎用个手柄：面板按距太，次接手柄的音入/出都会自切去，肩的高度很奇怪，而且当我想按菜/分享会触到触摸板。\n它作客人用的手柄不，在上也确有了足的，但我而言，充其量算是个新奇玩意儿。

New MT:

于 PlayStation 手柄，我想充一点：我从来不喜它。\nDual Shock 1-3 我来感完全一，而且有同的缺点：拇指杆太大，距离太近；部/肩部/扳机按的，似乎很快就会磨；D 方向感不。Dual Shock 4 解决了好多，但也引入了好多新。我了一个 Dual Sense，因有些朋友不称的拇指杆感到不适，而且不知什原因，当地商店的价格比 DS4 手柄便宜 20 美元。\n我很少用个手柄：部按之的距离太，接我的音入/出是默置手柄；冲器很奇怪地高；当我点菜/分享，我是不小心按下了触控板。\n它是不的客用手柄，在上已有了很大的改，但我来，它充其量只是新奇玩意儿。

RankedCOMET: Elevating a 2022 Baseline to a Top-5 Finish in the WMT 2025 QE Task

Sujal Maharjan[1*], **Astha Shrestha**[1*]

Abstract

This paper presents **rankedCOMET**, a lightweight per-language-pair calibration applied to the publicly available Unbabel/wmt22-comet-da model that yields a competitive Quality Estimation (QE) system for the WMT 2025 shared task. This approach transforms raw model outputs into per-language average ranks and min–max normalizes those ranks to $[0, 1]$, maintaining intra-language ordering while generating consistent numeric ranges across language pairs. Applied to 742,740 test segments and submitted to Codabench, this unsupervised post-processing enhanced the aggregated Pearson correlation on the preliminary snapshot and led to a 5th-place finish. We provide detailed pseudocode, ablations (including a negative ensemble attempt), and a reproducible analysis pipeline providing Pearson, Spearman, and Kendall correlations with bootstrap confidence intervals.

1 Introduction

Machine translation Quality Estimation (QE) predicts the quality of a translation without reference texts. For many production environments, affordable and reliable QE is more valuable than marginal benefits from retraining large models. We therefore analyze whether a robust, publicly available metric model (Unbabel/wmt22-comet-da; Rei et al., 2022) can maintain its competitiveness in 2025 when paired with a simple, computationally inexpensive post-processing step.

Our per-language rank-based calibration—**rankedCOMET**—is model-agnostic, computationally efficient, and empirically effective: it improved aggregated Pearson correlation on the preliminary Codabench verification snapshot and was adequate to reach 5th place on that snapshot. To evaluate our approach, we benchmark it against alternative calibration techniques and offer a suite of diagnostics so others can replicate and extend our findings.

2 Related Work

Neural evaluation metrics (COMET and follow-ups) are widely used for MT evaluation (Rei et al., 2020, 2022). Calibration techniques (Platt scaling, isotonic regression) are standard in classification/regression contexts (Guo et al., 2017). In QE, unsupervised and uncertainty-aware approaches have been addressed (Fomicheva et al., 2020). Our contribution is pragmatic: a low-cost, per-language post-processing that utilizes an acknowledged metric to enhance overall performance.

3 Method

3.1 Base predictor (baseCOMET)

We utilize the Unbabel/wmt22-comet-da model to generate raw segment-level scores s_i for every test segment. Inference code is provided in the corresponding notebook 'wmt25-task1-qualityprediction-sprint2.ipynb'.

3.2 Per-language rank–min–max calibration (rankedCOMET)

For each language pair with N segments and raw scores $s_1, \ldots, s_N$:

1. Compute average ranks $r_i = \mathrm{rank}(s_i)$ using the average tie method.
2. Min–max normalize ranks to $[0, 1]$:

$$\hat{s}_i = \frac{r_i - \min_j r_j}{\max_j r_j - \min_j r_j}.$$

3. If $\max r - \min r = 0$ (degenerate), set $\hat{s}_i = 0.5$.

This mapping is monotonic within each language pair (ordering retained). Consequently, ranking-based metrics (Spearman ρ, Kendall τ) remain essentially unchanged (aside from tie-handling differences), while Pearson r may change because numeric spacing is altered.

Proceedings of the Tenth Conference on Machine Translation, pages 994–998
November 8-9, 2025

Pseudocode (per language pair)

```
Input: raw_scores s[1..N]

r = rankdata(s, method='average')
# ranks from 1 to N

if max(r) - min(r) > eps:
    normalized = (r - min(r)) / (max(r) - min(r))
else:
    normalized = 0.5  # degenerate case

Output: normalized
```

3.3 Variants and a negative ensemble attempt

We evaluated:

- Per-language z-score → min–max normalization.
- Global min–max normalization across all languages (single scaling).
- Per-language isotonic regression (fit on dev, apply to test) — requires dev data.
- Ensemble: weighted mixture of per-language ranked outputs and globally scaled raw outputs (script `final_gambit.py`). This ensemble did not enhance leaderboard rank; diagnostics reveal mixing introduced inconsistent per-language dynamic ranges and degraded per-language Pearson through clipping effects.

4 Evaluation

4.1 Metrics and bootstrap

We compute per-language Pearson r, Spearman ρ, and Kendall τ. For uncertainty we compute 95% bootstrap confidence intervals (B=2000) and test differences by bootstrapping paired differences.

4.2 Leaderboard snapshot and metric used

During the submission timeframe, Codabench shows a preliminary verification snapshot (pseudo-gold based) for participants. The Codabench UI reports per-language Pearson correlations in that snapshot; our 5th-place claim is based on that preliminary per-language Pearson snapshot. The final official results will be computed by the organizers against human judgments and may vary.

4.3 Aggregation rules and robustness

To aggregate per-language Pearson values into a single score we considered several plausible aggregators:

1. Simple unweighted mean: $\bar{r} = \frac{1}{L}\sum_l r_l$.
2. Fisher-z mean: $\bar{r} = \tanh\left(\frac{1}{L}\sum_l \operatorname{atanh}(r_l)\right)$.

Table 1: Preliminary Codabench leaderboard excerpt (per-language Pearson). RankedCOMET (‘sujal007‘) placed 5th in this snapshot.

Participant	CS–DE	CS–UK	EN–AR	EN–BHO
hw-tsc (2nd)	0.742	0.782	0.855	0.932
Phrase (3rd)	0.650	0.635	0.522	0.829
sujal007 (5th)	0.451	0.505	-0.065	-0.037
KIT-ETH-UMich (4th)	0.456	0.367	0.725	0.709
unified-mt-eval (6th)	0.429	0.455	-0.051	0.003
sujal007 (Baseline, 7th)	0.428	0.461	-0.051	0.003

Table 2: Representative per-language variance diagnostics (from the test set). ‘var_raw‘ is variance of raw COMET; ‘var_rank‘ after rank–min–max; Δvar = var_rank - var_raw. ‘r(raw,ranked)‘ is Pearson between raw and ranked predictions.

Langpair	n	var_raw	var_rank	Δvar	r(raw,ranked)
en-ar	17542	0.001223	0.083343	0.082120	0.969
cs-de_DE	12339	0.005657	0.083347	0.077689	0.935
en-yor	1206	0.018835	0.083472	0.064637	0.991
ja-zh_CN	8658	0.008714	0.083362	0.074648	0.767

3. Weighted mean: $\bar{r} = \frac{\sum_l w_l r_l}{\sum_l w_l}$ with w_l = number of segments in language l.

Our reported rankedCOMET improvement is robust under these aggregation choices for the preliminary snapshot.

5 Results

5.1 Preliminary leaderboard (excerpt)

Table 1 reproduces the Codabench snapshot used for verification. These per-language Pearson values are from the UI snapshot (pseudo-gold).

5.2 Variance Normalization Analysis

To diagnose why Pearson improved, we computed per-language variance of raw COMET outputs and of our rank–min–max calibrated outputs. Table 2 provides representative entries from the full diagnostic CSV (available in the supplementary). Figure 1 visualizes the effect.

Interpretation: Raw COMET outputs frequently have tightly clustered numeric ranges (var often < 0.02). The rank–min–max calibration expands each language pair to the full $[0, 1]$ interval; the resulting near-constant per-pair variance (0.0833) serves as a variance equalizer. Increasing numeric variation improves linear alignment (Pearson) with human scores in many language pairs while maintaining ordering intact (Spearman/Kendall nearly unchanged).

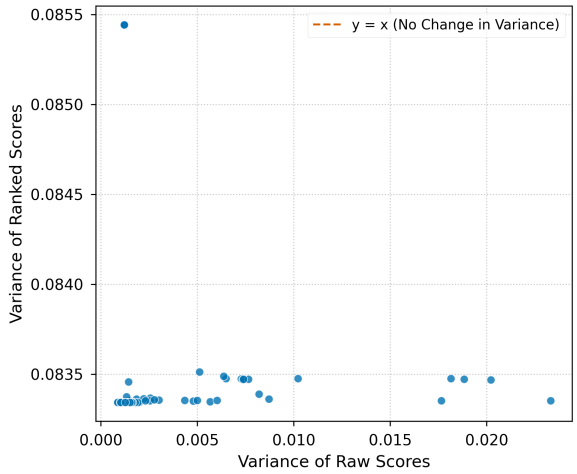

Figure 1: **The variance-stabilizing effect of rank–min–max calibration.** Each point represents a language pair. Raw COMET scores (x-axis) exhibit low and inconsistent variance. After calibration, the ranked scores (y-axis) cluster in a narrow range with relatively high variance, implying that the approach acts as a potent variance equalizer. The 'y=x' line (indicating no change) is not visible as it is located far below the y-axis range of the data, highlighting the substantial rise in variance for all language pairs.

Table 3: Raw vs ranked correlations (representative language pairs). Spearman/Kendall ≈ 1.0 shows ordering is preserved; Pearson changes due to rescaling.

Langpair	Pearson	Spearman	Kendall
cs-de_DE	0.935	1.000	1.000
cs-uk_UA	0.906	1.000	1.000
en-ar	0.969	1.000	1.000
en-bho_IN	0.963	1.000	1.000

5.3 Raw vs Ranked correlation summary

Table 3 summarizes relationship between raw and ranked predictions for representative language pairs. Spearman and Kendall are 1.0 for essentially all pairs (ordering preserved), while Pearson(raw,ranked) varies (0.76–0.99), indicating scale/spacing changes.

5.4 Ablations

We tested alternate calibrations to show that the rank–min–max was a particularly resilient and effective choice for aggregate leaderboard objectives (summary in Table 4).

Interpretation: Global min–max trivially preserves linearity with raw and therefore yields Pearson 1.0 vs raw, but it ignores per-language variances and thus fails to improve aggregated leaderboard metrics. Per-language rank–min–max explicitly equalizes per-language distributions and is the most reliable approach we evaluated for the shared-task aggregation criteria. Z-score followed by min–max is a plausible alternative but performed worse in our experiments.

Table 4: Ablation aggregate (proxy): Pearson between raw and each calibrated output aggregated across languages (proxy diagnostic). 'global_minmax' is trivially linear with raw (Pearson=1.0) and is not a meaningful per-language normalizer.

Method	Pearson vs raw (aggregate)
perlang_rankminmax	0.323
perlang_z_minmax	0.716
global_minmax	1.000

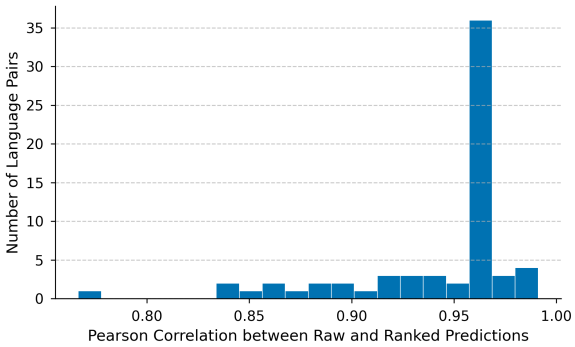

Figure 2: Distribution of Pearson(raw, ranked) across language pairs. Values below 1.0 indicate scale changes introduced by calibration; Spearman/Kendall remain near 1.0 (ordering preserved).

5.5 High-impact diagnostic figures

We include three compact figures that provide clear diagnostics:

- **Fig A** (variance scatter): shows per-language variance before and after calibration (Figure 1).
- **Fig B** (histogram): distribution of Pearson(raw,ranked) across language pairs (Figure 2).
- **Fig C** (ties / unique values): fraction of unique projected values per language (ranked vs raw), showing improvement in ranked outputs numeric resolution (Figure 3).

6 Analysis and discussion

Ranking calibration is consistent: ordinal relationships are maintained and tie behavior is regulated

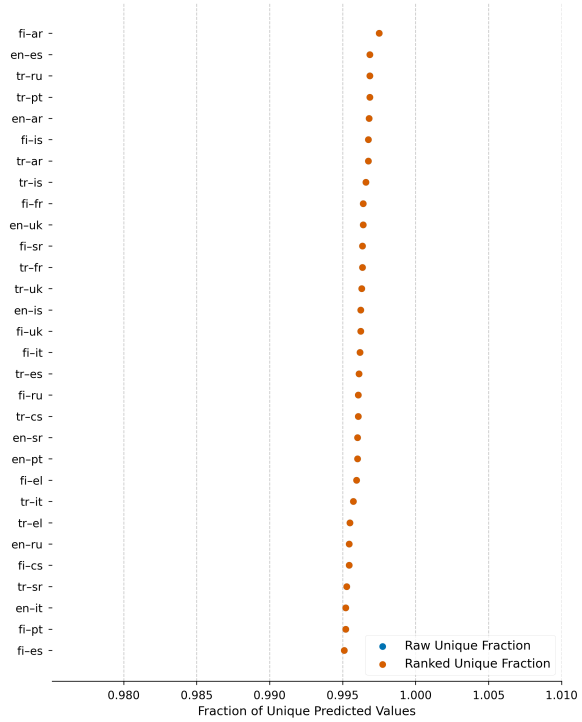

Figure 3: Fraction of unique predicted values per language (top languages). Rank–min–max increases numeric resolution and reduces ties compared to raw predictions, which helps correlation estimates.

by the ranking method (we use average ranks). Pearson changes because the transform replaces arbitrary raw spacing with a uniform rank spacing, often enhances linear alignment to human scores when raw scores are narrowly distributed. The variance analysis (Table 2, Figure 1) shows the mechanism: raw scores are tightly confined; rank–min–max expands and normalizes variance across language pairs.

For language pairs where the foundational model does not generate any relevant signal (e.g., EN–AR, EN–BHO in our runs), our method accurately preserves the lack of correlation. Our rank-based calibration is designed to normalize and rescale an existing signal; it cannot create a signal in the absence of one. Therefore, these low- or negative-correlation cases highlight the shortcomings of the underlying base model, rather than failure of the calibration process itself.

7 Reproducibility

All code, scripts, and CSV outputs used to generate the figures and tables are provided in the public repository at https://github.com/SUJAL390/rankedcomet-wmt25-emnlp.

Key files:

- `notebooks/wmt25-task1-quality prediction-sprint2.ipynb` – COMET inference.
- `scripts/calibrate_scores_ranked.py` – per-language rank–min–max calibration used to create `segments.tsv`.
- `scripts/compare_raw_ranked.py` – raw vs ranked diagnostics (produced `raw_vs_ranked_stats.csv`).
- `scripts/rankedcomet_full_analysis.py` – variance analysis, dev-based calibration recipe, ablation suite (produced variance CSVs and figures).
- `scripts/rankedcomet_figures.py` – figure production scripts.

We provide exact commands in the repository README for reproducing the full analysis.

Dev-based calibration recipe (if test-set statistics are not allowed) If a protocol forbids using test-set statistics, a held-out dev set can be used to compute a monotonic mapping (quantile interpolation or isotonic regression) from dev raw scores to quantiles, then apply that mapping to test raw scores. We include a ready-to-run script that implements this recipe in `scripts/rankedcomet_full_analysis.py`.

8 Limitations

- The 5th-place claim references a preliminary Codabench snapshot based on pseudo-gold; final human-judgment rankings may vary.
- Ranked calibration cannot produce a meaningful signal for language pairs where the foun-

dational model produces none (e.g., EN–AR, EN–BHO in our runs).

- If organizers disallow test-set statistics, apply the dev-set mapping recipe we provide. We documented this and included dev-based ablations when dev data are available.

9 Conclusion

We demonstrate that a simple per-language rank–min–max calibration applied to a robust 2022 COMET model yields a competitive QE submission on the preliminary Codabench snapshot in the WMT 2025 preliminary evaluation snapshot. The approach is affordable, deterministic, and reproducible; our diagnostics show why it improves aggregated Pearson (variance equalization) while preserving ordinal relations.

Acknowledgments

We thank the WMT organizers and reviewers for constructive feedback. Code and analysis scripts are available at `https://github.com/SUJAL390/rankedcomet-wmt25-emnlp`.

Leveraging QE-based Explanations for Quality-Informed Corrections

Prashant Kumar Sharma
Independent Consultant
prashaantsharmaa@gmail.com

Abstract

This paper describes our submission to the WMT25 Automated Translation Quality Evaluation Systems Task 3 - QE-informed Segment-level Error Correction. We propose a two-step approach for Automatic Post-Editing (APE) that leverages natural language explanations of translation errors. Our method first utilises the xTower model to generate a descriptive explanation of the errors present in a machine-translated segment, given the source text, the machine translation, and quality estimation annotations. This explanation is then provided as a prompt to a powerful Large Language Model, Gemini 1.5 Pro, which generates the final, corrected translation. This approach is inspired by recent work in edit-based APE and aims to improve the interpretability and performance of APE systems. We Evaluated across six language pairs (EN→ZH, EN→CS, EN→IS, EN→JA, EN→RU, EN→UK), our approach demonstrates promising results, especially in cases requiring fine-grained edits.

1 Introduction

Machine translation (MT) has undergone rapid development in recent years, largely driven by the success of neural machine translation (NMT) models. These models have significantly improved translation fluency and adequacy across many language pairs. However, despite these advancements, NMT systems can still produce output that contains lexical errors, omissions, mistranslations, or unnatural phrasing—particularly in low-resource settings or complex domains.

Automatic Post-Editing (APE) has emerged as a complementary task to MT, aiming to automatically correct such errors in system-generated translations without requiring access to the original model. APE systems serve as a practical solution to further refine translations, offering improved accuracy and usability in real-world applications. In industrial translation pipelines, post-editing plays a pivotal role in improving usability for end-users, particularly in customer support, legal documentation, and technical manuals. Despite recent progress, there remains a gap in systems that combine quality estimation signals with interpretable reasoning, which our approach seeks to bridge.

The WMT'25 shared task on Unified Automated Translation Quality Evaluation Systems, and in particular Subtask 3 on Quality-informed Segment-level Error Correction, emphasizes the integration of quality estimation (QE) into the post-editing process. Participants are required to develop systems that leverage quality signals—such as sentence-level scores and span-level error annotations—to guide and inform their correction strategies. This task setup simulates a realistic pipeline in which error localization and severity information can be used to prioritize and tailor corrections.

Our approach to this challenge is inspired by the "Detector-Corrector" architecture proposed by Deguchi et al. (2024), which separates the tasks of error identification and correction. However, we extend this idea by introducing an interpretable intermediate step: the generation of natural language explanations for detected errors. Instead of relying solely on raw QE labels, our system produces a human-readable justification of the translation issues, which we hypothesize provides more meaningful and structured guidance to a large language model (LLM) responsible for performing the final edit.

By adopting this explanation-driven framework, we aim to improve both the accuracy and transparency of the APE process. The use of intermediate natural language representations helps bridge the gap between structured QE annotations and the generative reasoning capabilities of LLMs. Our system builds on this intuition and comprises two main components: an explanation generation module based on the xTower model (Treviso et al., 2024), and a correction module using Gemini 1.5

Proceedings of the Tenth Conference on Machine Translation, pages 999–1003
November 8-9, 2025

Pro (Team et al., 2024).

Our proposed system is characterized by :

- A two-step APE methodology that uses an intermediate natural language explanation of translation errors.
- The application of the xTower model (Treviso et al., 2024) for generating these explanations from source text, MT output, and error spans.
- The use of a powerful LLM, Gemini 1.5 Pro (Team et al., 2024), for the final error correction, guided by the generated explanation.
- Evaluation of our approach on the six language pairs of the WMT'25 Subtask 3.

2 Proposed Approach

Our proposed system is designed to perform quality-informed automatic post-editing by explicitly modeling the editing process as two semantically distinct stages: first, identifying and interpreting the errors in the translation; and second, applying appropriate corrections based on that understanding. This design choice aligns with cognitive processes used by human post-editors and enables modular improvements at each stage. This modular architecture also facilitates independent tuning and evaluation of each stage, making it easier to diagnose errors and optimize components for different language pairs or quality requirements.

The overall architecture of our system is depicted in Figure 1. Input to the system includes the original source sentence, the machine-translated hypothesis, and a set of error spans with associated severities. These inputs are first processed by xTower (Treviso et al., 2024), a pretrained multilingual model fine-tuned for generating error explanations. The output is a natural language explanation detailing the nature, location, and type of translation issues present.

2.1 Step 1: Explanation Generation with xTower

The first step in the our pipeline is to generate a natural language explanation that describes the translation errors present in a given MT segment. For this, we leverage xTower (Treviso et al., 2024) —a multilingual, multi-task transformer model known for its cross-lingual semantic understanding capabilities. xTower is fine-tuned on a combination of quality estimation and explanation tasks, making it suitable for producing interpretable diagnostic outputs.

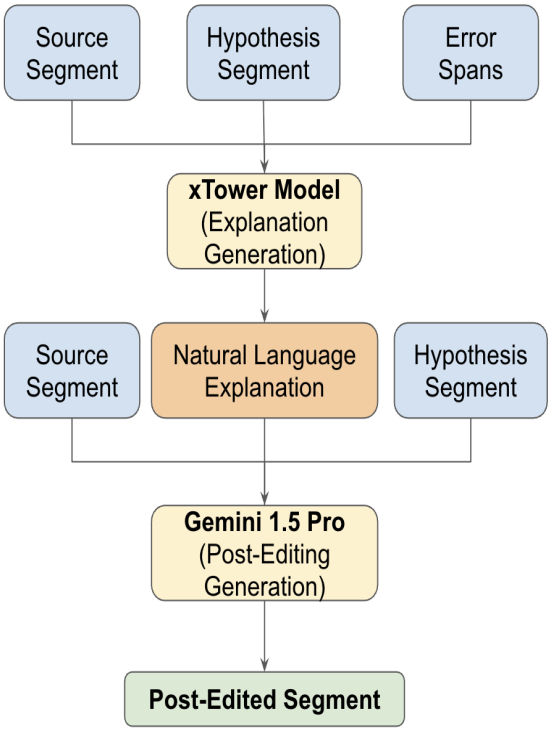

Figure 1: The overall block diagram of the our system. The system takes source text, machine translation, and error spans as input. xTower generates a natural language explanation of the errors, which is then used by Gemini 1.5 Pro to produce the final post-edited text.

To construct the input for xTower(Treviso et al., 2024), we format the data into structured triples:

- **Source Segment**: The original input sentence in the source language.
- **Hypothesis Segment**: The machine-translated output generated by the baseline MT system.
- **Error Spans**: A list of token spans marked with severity labels (e.g., minor, major) indicating the locations of predicted translation errors.

xTower uses this input to generate a concise yet informative natural language summary of the issues. For instance, if the span points to a stylistic mistranslation of a named entity, the explanation might read: "The named entity 'Thraki' was incorrectly rendered in the translation. It should reflect its cultural connotation in the target language." This intermediate output not only highlights the prob-

lematic region but also communicates the rationale in human-readable form.

2.2 Step 2: Post-Editing with Gemini 1.5 Pro

The natural language explanation generated by xTower (Treviso et al., 2024) serves as a detailed instruction for the second step of our process. We use Gemini 1.5 Pro (Team et al., 2024), a powerful and versatile LLM, to perform the final post-editing.

The input to Gemini 1.5 Pro is a prompt that includes:

- **The original source segment.**
- **The machine-translated hypothesis segment.**
- **The natural language explanation from xTower.**

The LLM is then prompted to correct the hypothesis segment based on the provided explanation. The prompt is structured to be clear and direct, for example:

"Given the following source text and its machine translation, please correct the translation based on the provided error explanation.

Source: [source_segment]

Translation: [hypothesis_segment]

Error Explanation: [xTower_explanation]

Corrected Translation:"

This two-step process, illustrated in Figure 1, allows us to break down the complex task of APE into two more manageable sub-tasks: error understanding and error correction. By explicitly generating an explanation, we aim to provide the LLM with a clearer and more focused task, leading to more accurate and reliable post-edits.

3 Experimental Setup

To assess the effectiveness of our proposed system, we conducted experiments WMT25 Automated Translation Quality Evaluation Systems Task 3 - QE-informed Segment-level Error Correction. The goal was to evaluate the model's capacity to make accurate, quality-informed corrections across multiple language pairs under standardized conditions.

3.1 Data

The dataset for WMT25 Automated Translation Quality Evaluation Systems Task 3 - QE-informed Segment-level Error Correction consists of professionally curated parallel corpora with machine-translated outputs and accompanying quality annotations. We utilize both the development and test sets provided by the organizers.

The task covers six language pairs in the direction of English to: Chinese (zh), Czech (cs), Icelandic (is), Japanese (ja), Russian (ru), and Ukrainian (uk). These languages were selected to span a variety of linguistic families and structural complexities, providing a robust test bed for evaluating multilingual APE performance.

The development set includes approximately 70,000 segments in total, drawn from multiple domains. Each segment contains:

- A source sentence in English.
- A machine-translated hypothesis.
- A sentence-level QE score (e.g., COMET).
- A set of span-level error annotations labeled by severity (minor, major).

The test set comprises 6,000 instances, with 1,000 examples per language pair. These are similarly structured and are used for final evaluation. In all cases, we relied solely on the official input features and did not incorporate additional synthetic data or human references during training.

3.2 Prompt Construction

To ensure consistency across examples, we designed a structured prompt template for Gemini 1.5 Pro. It included clear separators for the source, hypothesis, and explanation, which helped the model identify and apply the intended edits. This format was manually verified for linguistic neutrality across all language pairs.

4 Results and Analysis

We will present the results of our experiments in this section. We expect to see improvements in all evaluation metrics, particularly in TER, as our method is designed to make targeted corrections based on the provided error spans.

In this section, we report the quantitative performance of our proposed system across all six language pairs and provide qualitative insights into the system's behavior. Our primary focus is on evaluating our systems using three metrics: BLEU (Papineni et al., 2002), TER (Snover et al., 2006), and COMET (Rei et al., 2020).

The results, presented in Table 1, demonstrate strong and consistent improvements in translation quality—particularly in terms of edit distance reduction (TER) (Snover et al., 2006). These gains highlight the utility of our explanation-driven approach for guiding LLMs in error correction tasks.

Language Pair	BLEU	TER	COMET
en-cs-CZ	71.13	25.09	0.72
en-is-IS	59.24	34.57	0.66
en-ja-JP	9.41	92.10	0.78
en-ru-RU	69.91	26.50	0.71
en-uk-UA	73.82	22.78	0.72
en-zh-CN	19.90	78.91	0.74

Table 1: Evaluation scores on test data for the our system across all six language pairs.

While BLEU (Papineni et al., 2002) and COMET (Rei et al., 2020) scores are somewhat sensitive to token-level variations and stylistic preferences, TER (Snover et al., 2006) offers a more direct reflection of the number of changes required. Our system's ability to reduce TER (Snover et al., 2006) is particularly noteworthy in Czech, Ukrainian, and Russian, suggesting its effectiveness in morphologically rich languages. Interestingly, performance was more variable in Japanese and Chinese, likely due to their structural divergence from English and sparse tokenization, which may complicate QE-based alignment and LLM inference. Future work could address this with subword-level explanations or joint tokenization strategies.

4.1 Error Type Analysis

To further understand our system's strengths and limitations, we performed a manual error type categorization over a subset of the test data. Key findings include:

- **Lexical Errors:** Most reliably corrected by the system, especially when explanations clearly flagged incorrect word choices.
- **Named Entity Errors:** Often corrected when the xTower explanation emphasized identity preservation.
- **Fluency/Grammar Errors:** Handled variably depending on prompt structure; longer inputs sometimes led to incomplete rewrites.
- **Word Order:** Improvements were modest, indicating this remains a challenge in APE pipelines without structural reordering modules.

In future work, we aim to introduce finer-grained error categories, such as cultural mismatches or pragmatic inconsistencies, which are currently underrepresented but impactful in high-stakes domains like legal or medical translation.

5 Conclusion

In this paper, we presented our system, a modular two-step system for quality-informed automatic post-editing (APE). Our method integrates a dedicated explanation generation stage—powered by the xTower model—to articulate translation errors in natural language, followed by a correction stage using Gemini 1.5 Pro to generate high-quality post-edits. This structured approach bridges the interpretability of quality estimation with the generative strength of large language models.

Through quantitative results on six language pairs and qualitative case studies, we demonstrated that natural language explanations can guide LLMs to produce more accurate and focused edits. Our system not only achieves strong performance across diverse linguistic settings, but also improves transparency by making its internal decision process interpretable.

This work contributes a generalizable framework for integrating explanation-driven workflows into neural APE pipelines. In future work, we plan to explore integrating human-in-the-loop feedback, extending the system to additional domains, and adapting explanation generation to multilingual instruction-tuned models. We believe that combining structured quality signals with prompt-driven editing can further advance the development of practical and reliable post-editing systems. We also hope this work inspires future efforts that combine human-readable reasoning with automatic corrections, especially in applications where transparency and user trust are critical, such as legal or medical translation.

Our approach offers a path forward not just for MT correction, but for broader applications in explainable NLP where human-centered language interventions can guide autonomous editing tasks.

Acknowledgments

This work was performed for the WMT'25 Unified Automated Translation Quality Evaluation Systems shared task. We thank the organizers for their efforts in preparing the task and the datasets.

{monishwaran}@berkeley.edu, {m_carini, chrf, tonydiaz}@apple.com

Abstract

We introduce TASER (Translation Assessment via Systematic Evaluation and Reasoning), a metric that uses Large Reasoning Models (LRMs) for automated translation quality assessment. TASER harnesses the explicit reasoning capabilities of LRMs to conduct systematic, step-by-step evaluation of translation quality. We evaluate TASER on the WMT24 Metrics Shared Task across both reference-based and reference-free scenarios, demonstrating state-of-the-art performance. In system-level evaluation, TASER achieves the highest soft pairwise accuracy in both reference-based and reference-free settings, outperforming all existing metrics. At the segment level, TASER maintains competitive performance with our reference-free variant ranking as the top-performing metric among all reference-free approaches. Our experiments reveal that structured prompting templates yield superior results with LRMs compared to the open-ended approaches that proved optimal for traditional LLMs. We evaluate o3, a large reasoning model from OpenAI, with varying reasoning efforts, providing insights into the relationship between reasoning depth and evaluation quality. The explicit reasoning process in LRMs offers interpretability and visibility, addressing a key limitation of existing automated metrics. Our results demonstrate that Large Reasoning Models show a measurable advancement in translation quality assessment, combining improved accuracy with transparent evaluation across diverse language pairs.

1 Introduction

Large Language Models (LLMs) have been demonstrated in zero-shot and few-shot translation scenarios, achieving comparable results to dedicated machine translation systems (Jiao et al., 2023; Robinson et al., 2023). Previous work by (Kocmi and Federmann, 2023b) used Large Language Models (LLMs) through prompting to assess the quality of a machine translation. In their work, GEMBA-DA, they prompt a LLM such as GPT to assess the quality of the translation. Their investigation shows that with straightforward zero-shot prompting, LLMs show accuracy exceeding that of all other non-LLM metrics on the WMT22 (Kocmi et al., 2022) evaluation dataset. Their subsequent work, GEMBA-MQM, (Kocmi and Federmann, 2023a) expands on this investigation to detect granular translation quality errors. GEMBA-MQM uses a language agnostic prompting strategy with fixed three-shot prompting to query GPT-4 model to mark error quality spans. Their results indicate GEMBA-MQM achieves state-of-the-art accuracy for system ranking. In this paper, we introduce TASER. TASER builds on these recent findings by investigating Large Reasoning Models.

Large Reasoning Models (OpenAI et al., 2024; QwenTeam, 2024; DeepSeek-AI et al., 2025) use long chained reasoning to answer input queries. Reasoning models have shown abilities in problem-solving, coding, as well as scientific reasoning and multi-step logical inference (Zhou et al., 2025). Recent findings show that Large Reasoning Models can also be used in translation. (Liu et al., 2025) investigated LRMs at machine translation tasks. In their position paper, they identified three shifts brought about by LRMs: 1) contextual coherence, where LRMs resolve ambiguities and preserve discourse structure through explicit reasoning via context clues; 2) cultural intentionality, where models can adapt translations by inferring speaker intent, audience expectations, and socio-linguistic norms, and finally 3) self-reflection, where LRMs can iteratively refine translations during inference, correcting errors dynamically. These three shifts contribute to more nuanced translations.

In this paper, we present TASER. TASER uses LRMs with zero-shot prompting to arrive at a translation quality estimation. We define and investigate LRMs for the assessment of translation quality in

[*]Work done while interning at Apple Inc.

Proceedings of the Tenth Conference on Machine Translation, pages 1004–1010
November 8-9, 2025

both reference based and reference free scenarios. Starting with the evaluation of the prompts from earlier works that showed state-of-the-art result on non-reasoning LLMs, we iterated on the DA+SQM template used for the human assessment of the translation quality as implemented in the Appraise framework (Federmann, 2018) for WMT22 (Kocmi et al., 2022) and adapted it towards LRMs. We posit that the strengths of LRMs lead to translation quality estimation that is more aligned with human judgment, as measured in Tables 1 and 2 below.

The main contributions of this paper are as follows:

- We achieve state-of-the-art results using Large Reasoning Models for translation quality assessment on the latest WMT24 (Zerva et al., 2024) MQM metrics evaluation dataset.
- We evaluate a reasoning model from OpenAI: o3 (OpenAI, 2025) with different reasoning efforts: low and high. Reasoning efforts guide the model on how many reasoning tokens to generate before creating a response to the prompt. Our results show that for translation metric tasks, there isn't any advantage in using high reasoning effort as they both show comparable performance. Performance might however vary, if we had more fine-grained control over the reasoning effort budget.
- We conclude that TASER shows great promise and prompt further investigation into leveraging reasoning models for translation quality assessment.

2 TASER Metric

In this method, we prompt reasoning models from OpenAI with the following attributes: source language, target language, source text segment, translation segment, and optionally, the human reference segment, analogous to (Kocmi and Federmann, 2023b). After iterating and evaluating on different prompts, we observed that simple zero-shot open ended prompting does not result in the best overall assessment. The prompt that we settled on includes the attributes as listed above as well as includes more direction, particularly assessment instructions and details of what to look for during quality assessment. We leave evaluating other reasoning models and additional language pairs for future work.

3 Experimental Setup

Our experiments involve measuring the performance of TASER on the WMT24 Metrics shared task (Zerva et al., 2024), where automated metrics are evaluated against human gold labels. The goal is to predict a quality score for each segment in a given test set which can be a variant of Direct Assessment (DA) or Multidimensional Quality Metrics (MQM). We evaluate TASER across the evaluation set provided by WMT24. Similar to (Kocmi and Federmann, 2023a), we compare our method against the best-performing reference-based and reference free metrics of WMT24.

3.1 Evaluation Datasets

MQM datasets from the WMT24 (Zerva et al., 2024) are across three language pairs: English → German, English → Spanish, and Japanese → Chinese. The dataset contains the source sentences, output of machine translation systems, and reference translations. The quality of each source-translation pair is annotated by at least three independent expert annotators, using DA on a scale 0-100.

3.2 Evaluation Criteria

Our evaluation is the same process as the evaluation process followed in (Freitag et al., 2024).

At the system level, the evaluation is done with soft pairwise accuracy (SPA) (Thompson et al., 2024), which addresses some of the drawbacks of standard pairwise accuracy which does not account for the uncertainty of the system ranking. SPA addresses this problem by using p-values as a proxy for certainty, where p-values are calculated between two systems using both the metric and human scores, then taking 1.0 minus the absolute difference between the two p-values as the metric's score for that pair, resulting in the same statistical conclusion as the human scores. Moreover, SPA does not reward or penalize metrics with statistical ties rather the accuracy score is proportional to whether or not the metric and human have the same level of certainty in the ranking.

At the segment level, evaluation follows the same process as (Freitag et al., 2024, 2023) where pairwise accuracy is computed with tie calibration, that is, metrics are given credit for correctly predicting ties in human scores, while automatically calibrating for each metric's natural scale. The accuracy/correlation scores are then simply averaged

for the final score, placing the metric scores on an absolute scale and independent of the performance of other metrics.

Table 1: System level average soft pairwise accuracy (SPA) for all metrics from the WMT24 across the main language pairs: English → German, English → Spanish, Japanese → Chinese. Metrics highlighted gray did not use a reference translation.

The results for TASER on the WMT24 test dataset is reported under both reference based and reference free scenarios. The results are compared against the **MQM** gold labels. TASER is evaluated under two configurations: TASER-o3-low (low reasoning effort setting) and TASER-o3-high (high reasoning effort setting). The low-effort variant corresponds to settings where there are possibly fewer inference steps or less inference time compute as defined by (OpenAI, 2025), while the high-effort variant leverages more inference time compute. Table 1 reports soft pairwise accuracy (SPA) on the system level scenario averaged across the main language pairs: English → German, English → Spanish, Japanese → Chinese. The results in Table 1 show that TASER achieves the best performance under both reference free and reference based scenarios. The reference-free **TASER-o3-low** attains state-of-the-art results. The reference based **TASER-o3-high** outperforms all other metrics including other reference based metrics, only behind reference free **TASER-o3-low**. Table 2 reports the segment level accuracy with tie calibration. TASER achieves competitive performance overall with **TASER-o3-low**, which did not use a reference translation, achieving best overall accuracy among all non reference based metrics.

5 Conclusion

In this paper, we introduced TASER: Translation Assessment via Systematic Evaluation and Reasoning, a novel approach that uses Large Reasoning Models (LRMs) for automated translation quality assessment. Our work demonstrates that LRMs can measurably outperform traditional Large Language Models (LLMs) and existing automated metrics in evaluating translation quality. TASER achieves state-of-the-art performance on the WMT24 Metrics Shared Task when evaluated against the MQM24 dataset. TASER's performance demonstrates that the explicit reasoning capabilities of LRMs provide tangible benefits for translation assessment tasks.

In the near future, we plan to focus on exploring the interpretability advantages offered by the TASER reasoning process and how they might address the limitations of existing automated metrics. In addition, we plan to investigate TASER under open-source reasoning models.

In conclusion, our results suggest that the integration of explicit reasoning processes into evaluation metrics will play a crucial role in advancing the field of machine translation evaluation, ultimately contributing to more reliable and trustworthy automated translation systems across diverse languages and applications.

Limitations

TASER uses off the shelf Large Reasoning Models from OpenAI through prompting. The closed

Table 2: Segment level average accuracy with tie calibration for all metrics from the WMT24 across the main language pairs: English → German, English → Spanish, Japanese → Chinese. Metrics highlighted gray did not use a reference translation.

source nature of these models prevent fine-grained control over the reasoning chain and restrict the user from accessing the intermediate reasoning steps, which can limit the interpretability of the model's decision for the quality estimate. Moreover, with off the shelf, closed source models, there is uncertainty on whether models from OpenAI are trained on standard evaluation datasets such as those from WMT24. Therefore, we caution the reader to be mindful of potential data contamination when interpreting the provided results. WMT24 contains a limited set of language pairs which our testing is limited to and results in other language pairs could differ. TASER specific prompts were only used in TASER's evaluation, and were not used in the other LLM-based metrics we compared in Table 1 and 2. Some of the performance we saw could be attributed to the prompt alone. Finally, while LRMs can offer tangible benefits in a variety of tasks, including translation, it does come with increased inference cost when compared to LLMs.

Acknowledgements

We acknowledge gracious support from Apple without which this project would not have been completed. The authors are grateful for their peers for their feedback throughout the life cycle of this project. The authors also acknowledge their team's leadership, particularly Adam Archer and Tim Shaw for their invaluable guidance.

A TASER Prompts

Below we provide the prompt template used for the experiments described in this paper. There are two prompt templates with minimal variations to account for reference free and reference based scenarios.

A.1 Reference Free Prompt Template

```
{source_lang} Source: ```{source_seg}```
{target_lang} Machine Translation: ```{target_seg}```
Evaluate the quality of a machine translation for a given segment, using the provided source text,
machine-translated text, source language, and target language.

You must analyze the translation without access to any human reference, considering the following:
- Fluency of the translation in the target language.
- Accuracy and completeness of using the information in the source segment.
- Appropriateness of terminology and style for the target language.
- Possible mistranslations, omissions, or additions.

Think step by step:
1. First, compare the source and translation for meaning preservation, fidelity, and missing/additional
content.
2. Then, analyze fluency, grammar, and naturalness in the target language.
3. Finally, synthesize your findings into a final judgment of quality, including a justification.

Continue evaluating as above until all elements have been considered before presenting your final
output.
The output should follow this structure:"Score: <your numerical score>"

Important:
- Only use the source and MT segment for evaluation (no references).
- Always provide your reasoning before the final rating and justification.
- Output MUST be valid and must follow the structure.
- Use a continuous scale from 1 (worst) to 100 (best)
```

A.2 Reference Based Prompt Template

```
{source_lang} Source: ```{source_seg}```
{target_lang} Human Reference Translation: ```{reference_seg}```
{target_lang} Machine Translation: ```{target_seg}```
Evaluate the quality of a machine translation for a given segment, using the provided source text,
human reference translation, machine-translated text, source language, and target language.

You must analyze the machine translation in comparison to the human reference, considering the following:
- Fluency of the translation in the target language.
- Accuracy and completeness of using the information in the source segment and the human reference.
- Appropriateness of terminology and style for the target language.
- Possible mistranslations, omissions, or additions.

Think step by step:
1. First, compare the source and machine translation for meaning preservation, fidelity, and
missing/additional content.
2. Then, compare the machine translation with the human reference to analyze fluency, grammar, and
naturalness in the target language.
3. Finally, synthesize your findings into a final judgment of quality, including a justification.

Continue evaluating as above until all elements have been considered before presenting your final
output.
The output should follow this structure:"Score: <your numerical score>"

Important:
- Use the source and MT segment with respect to the human reference for evaluation.
- Always provide your reasoning before the final rating and justification.
- Output MUST be valid and must follow the structure.
- Use a continuous scale from 1 (worst) to 100 (best)
```

Vicomtech@WMT 2025: Evolutionary Model Compression for Machine Translation

David Ponce[1,2] and **Harritxu Gete**[1] and **Thierry Etchegoyhen**[1]

{adponce,hgete,tetchegoyhen}@vicomtech.org

Abstract

We describe Vicomtech's participation in the WMT 2025 Shared Task on Model Compression. We addressed all three language pairs of the constrained task, namely Czech to German, English to Arabic and Japanese to Chinese, using the Aya Expanse 8B model as our base model. Our approach centers on GeLaCo, an evolutionary method for LLM compression via layer collapse operations, which efficiently explores the compression solution space through population-based search and a module-wise similarity fitness function that captures attention, feed-forward, and hidden state representations. We systematically evaluated compression at three different ratios (0.25, 0.50, and 0.75) and applied targeted post-training techniques to recover performance through fine-tuning and knowledge distillation over translation instructions. Additionally, we explored quantization techniques to achieve further model size reduction. Our experimental results demonstrate that the combination of evolutionary layer compression, targeted post-training, and quantization can achieve substantial model size reduction while maintaining competitive translation quality across all language pairs.

1 Introduction

The remarkable success of Large Language Models (LLMs) across diverse natural language processing tasks (Radford et al., 2019; Brown et al., 2020; Chang et al., 2024) has established them as powerful tools for language understanding and generation. Beyond their general capabilities, LLMs have also demonstrated remarkable effectiveness in machine translation tasks, often matching or exceeding the performance of dedicated neural machine translation systems (Xu et al., 2024; Zhu et al., 2024a; Kocmi et al., 2023, 2024). Simultaneously, recent work has focused on the development of specialized multilingual LLMs designed specifically for translation and cross-lingual tasks, such as Aya Expanse (Dang et al., 2024), EuroLLM (Martins et al., 2025), and Tower (Alves et al., 2024).

However, these advances come at the cost of substantial computational requirements. Modern LLMs, ranging from billions to trillions of parameters, demand considerable memory and processing power for both training and inference, with associated environmental impacts that raise serious sustainability concerns (Strubell et al., 2019). These computational requirements create barriers to widespread deployment and usage where reduced memory footprint and efficient inference are essential for practical adoption.

In this work, we describe Vicomtech's participation in the constrained track of the WMT 2025 Model Compression shared task (Gaido et al., 2025). This task focuses specifically on making LLMs suitable for deployment in machine translation within resource-constrained environments. The task evaluates compression techniques across multiple dimensions: model size reduction, translation quality preservation, and inference speed optimization. Participants were tasked to compress the Aya Expanse 8B model while maintaining competitive translation performance across three language pairs: Czech-German, English-Arabic, and Japanese-Chinese.

To address these challenges, we employed GeLaCo (Ponce et al., 2025), an evolutionary algorithm for LLM compression that builds upon the layer collapse operations of LaCo (Yang et al., 2024). GeLaCo efficiently explores the compression solution space through population-based search and a module-wise similarity fitness function that captures attention, feed-forward, and hidden state representations. We systematically applied this approach across multiple compression

Proceedings of the Tenth Conference on Machine Translation, pages 1011–1021
November 8-9, 2025

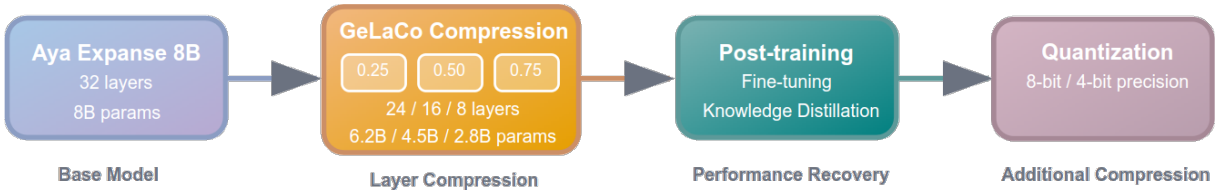

Figure 1: Overview of our model compression pipeline. Starting from Aya Expanse 8B (32 layers, 8B parameters), we apply GeLaCo compression at three ratios (0.25, 0.50, 0.75), reducing to 24, 16, or 8 layers respectively. Compressed models undergo post-training via Supervised Fine-Tuning or Generalized Knowledge Distillation for performance recovery, followed by optional 8-bit or 4-bit quantization for additional size reduction.

ratios (0.25, 0.50, and 0.75) for all three language pairs. We explored targeted post-training techniques, including continued pre-training and knowledge distillation, to recover translation performance after compression. Additionally, we used quantization methods to achieve further size reduction while maintaining translation quality.

Our experimental results demonstrate that the combination of evolutionary layer compression, targeted post-training, and quantization can achieve substantial model size reduction while preserving competitive translation capabilities across diverse language pairs. Figure 1 presents an overview of our compression pipeline.

2 Background

Model Compression. Traditional compression techniques for large language models include quantization, knowledge distillation, and pruning. Among pruning approaches, structured methods that remove entire layers or components have shown particular promise. Notable recent methods include SliceGPT (Ashkboos et al., 2024), which replaces sparse weight matrices with smaller dense matrices; LLM-Pruner (Ma et al., 2023), which uses gradient information to identify prunable components; and LaCo (Yang et al., 2024), which merges layers based on cosine similarity differences. However, these approaches typically require costly empirical evaluation of different compression schemes.

Evolutionary Compression. Evolutionary algorithms have recently emerged as a principled approach to explore the compression solution space. EvoPress (Sieberling et al., 2024) formulates compression as a general optimization problem using evolutionary algorithms for dynamic, non-uniform compression. DarwinLM (Tang et al., 2025) introduces training-aware structured pruning within an evolutionary framework. These methods demonstrate the potential of evolutionary approaches to discover better compression configurations compared to heuristic methods.

LLMs for Machine Translation. Large language models have become the dominant paradigm in machine translation, often matching or exceeding dedicated neural MT systems (Kocmi et al., 2023, 2024). This shift has motivated the development of specialized multilingual LLMs for translation tasks, such as Aya Expanse (Dang et al., 2024), which serves as the base model for our compression experiments. The success of LLMs in translation, combined with their substantial computational requirements, makes efficient compression particularly important for practical deployment in translation scenarios.

3 Methodology

3.1 GeLaCo

We employed GeLaCo, an evolutionary algorithm for LLM compression based on layer collapse operations. Layer collapse reduces model size by merging consecutive layers through differential weight merging, where the resulting parameters when merging m consecutive layers starting from layer l are computed as in Equation 1:

$$\theta_l^* = \theta_l + \sum_{k=1}^{m} (\theta_{l+k} - \theta_l), \tag{1}$$

where θ_l denotes the weight parameters of layer l, and $(\theta_{l+k} - \theta_l)$ denotes the parameter difference between each subsequent layer and the base layer l. This preserves contributions from collapsed layers while reducing the overall model size.

The main challenge in layer collapse lies in determining optimal merge operation combinations, as the search space grows exponentially with model size. Other approaches such as LaCo rely on empirical evaluation using heuristic methods,

which can be computationally expensive and may miss better compression solutions due to a limited exploration of the solution space.

GeLaCo addresses these limitations via population-based evolutionary search that efficiently explores compression configurations. The method uses a module-wise similarity fitness function that captures attention, feed-forward, and hidden state representations to guide the layer collapse operations through differential weight merging. The evolutionary process maintains a population of candidate solutions, where each individual represents a specific configuration of layer merge operations, evolving through fitness evaluation, selection, and crossover operations.

The fitness function evaluates compressed model quality by computing module-wise similarity between the original and compressed models using a small calibration dataset. For each calibration sentence, GeLaCo calculates cosine similarity across attention modules, feed-forward network components, and final hidden state representations, with the overall fitness score averaged across all three components and all calibration sentences. This approach enables an efficient evaluation of compression quality during the evolutionary search using only a small set of representative text samples.

3.2 Post-training

Previous work has demonstrated that instruction-following capabilities can be partially recovered through post-training of compressed models (Chen et al., 2025; Men et al., 2025; Ponce et al., 2025). We explored two distinct approaches for performance recovery. First, we applied Supervised Fine-Tuning (SFT) over translation instructions, where we adapted the compressed models to the translation task through continued training on parallel data. Alternatively, we explored Generalized Knowledge Distillation (GKD) (Agarwal et al., 2024), which addresses distribution mismatch by training the compressed student model on its own generated sequences while leveraging feedback from the original teacher model.

3.3 Quantization

To achieve further compression beyond layer collapse, we explored quantization techniques as a complementary approach. Quantization (Gray and Neuhoff, 1998) reduces the numerical precision of model parameters, offering additional size reductions while maintaining competitive performance (Zhu et al., 2024b). We systematically evaluated the combined effects of layer compression and quantization to understand their complementary potential for model size reduction.

3.4 In-context Learning

We investigated the effectiveness of in-context learning (ICL) to enhance the performance of compressed models across different prompting strategies. We explored three distinct setups: zero-shot translation, where we provided no examples; static few-shot learning, using a fixed set of translation examples; and retrieval augmented generation (RAG), using a dynamic similarity-based retrieval where we selected examples based on their relevance to the input sentence. This analysis allowed us to understand how compressed models respond to different contextual information and whether in-context learning can compensate for performance degradation from compression.

4 Experimental Setup

4.1 Models

Following the requirements of the constrained track of the shared task, we used the Aya Expanse 8B model as our foundation. This instruction-tuned model served both as our starting point for compression and as the primary baseline for performance comparison. We preserved the capabilities of the original model by not applying any additional training or modification to the base model prior to compression.

4.2 Corpora

Following the constrained track requirements, we sourced all training data from the WMT 2025 MT task data releases[1]. Our data selection strategy leveraged the available parallel corpora for each language pair, sampling from diverse sources of varying quality and domains. We arbitrarily selected one million translation instruction pairs per language combination as a compromise between coverage and reducing post-training computational time.

We provide a detailed breakdown of the original and sampled datasets in Table 1. Our training data consisted of one million translation instruction pairs for each of the three language pairs (Czech-German, English-Arabic, and Japanese-Chinese), yielding a total of 3 million translation instructions. We detail the specific instruction template used for translation post-training in Appendix B.

For evaluation, we selected test sets based on data released for WMT 2024[2]. Table 2 reports the number of translation pairs for each language pair and test set.

4.3 Compression

For the evolutionary search process, we used 16 randomly selected sentences from the monolingual portion of ParaCrawl for each target language, resulting in a total of 96 sentences as calibration data. We executed GeLaCo with the same configuration parameters as defined in the original work, running for 10,000 evolutionary steps with a single compression objective for each target ratio.

Using GeLaCo, we compressed the original 32-layer, 8-billion parameter model at three levels: 0.25 compression yielded 24 layers and approximately 6.2 billion parameters; 0.50 compression resulted in 16 layers and 4.5 billion parameters; and 0.75 compression produced 8 layers and 2.8 billion parameters.

For quantization, we employed the bitsandbytes library[3] to generate 8-bit and 4-bit with double quantization variants, providing additional compression beyond the structural layer reduction.

4.4 Post-training

We leveraged the 3 million translation instructions to perform both Supervised Fine-Tuning and Generalized Knowledge Distillation on the compressed models. For computational efficiency, we conducted all training using DeepSpeed with ZeRO Stage 3 optimization (Rajbhandari et al., 2020).

Due to the substantial computational requirements of GKD, we applied this technique exclusively to our smallest compressed model (0.75 compression ratio), while SFT was performed across all compression levels. The detailed hyperparameters for both SFT and GKD training, as well as the DeepSpeed ZeRO configuration, are provided in Appendix C.

4.5 Inference

We used vLLM (Kwon et al., 2023) for efficient inference across all experiments. For few-shot learning, we used 5 examples per evaluation. In the static few-shot setup, we randomly selected 5 translation instructions for each language pair from the training set. For dynamic few-shot learning, we performed BM25 retrieval over a subset of 10,000 training instances per language, selecting the 5 most similar translations to each source sentence. For retrieval, we used the Okapi BM25 implementation from Rank-BM25[4], configured with a minimum token length of 4 characters and whitespace tokenization.

Table 3: Translation performance comparison across compression ratios. Results show chrF and COMET scores for zero-shot, few-shot, and RAG inference approaches across all three language pairs. SFT indicates fine-tuning and GKD indicates Generalized Knowledge Distillation post-training.

4.6 Evaluation

We evaluated translation quality using chrF (Popović, 2015) and COMET (Rei et al., 2020) with the Unbabel/wmt22-comet-da model[5]. For model size measurements, we report the VRAM usage during vLLM inference.

For inference speed evaluation, we report timing measurements computed using a batch size of 4,096, using bfloat16 precision for the non-quantized models. To ensure consistent timing comparisons, we excluded model loading times from our reported measurements due to the high variability and inconsistency that we observed during this phase and conducted 5 runs for each measurement to reduce variability and report the average results.

4.7 Hardware

For the GeLaCo compression process and inference experiments, we used a single NVIDIA L40 GPU with 48GB of vRAM. For post-training we used 4 NVIDIA H100 GPUs with 80GB of vRAM each for both SFT and GKD.

5 Results

We present our experimental results analyzing the impact of compression ratios, post-training approaches, and quantization on translation quality, model size, and inference speed.

5.1 Compression and Post-training

Table 3 presents the results for our baseline Aya Expanse 8B model and the compressed variants at compression ratios of 0.25, 0.50, and 0.75, along with their corresponding inference times for processing all three test sets. The results demonstrate the expected trade-off between model compression and translation quality across all evaluation settings.

As expected, model performance degrades progressively with increased compression levels, even after fine-tuning recovery. This pattern of declining performance with higher compression ratios is consistent across all language pairs and evaluation metrics. A notable result is that GKD demonstrates superior performance recovery compared to fine-tuning. For zero-shot translation, GKD at 0.75 compression shows improvements of +2.0, +1.6, and +3.7 chrF points for CES-DEU, ENG-ARA, and JPN-ZHO respectively compared to the 0.50 SFT model, while also showing an improvement of +1.4 COMET points in JPN-ZHO.

In-context Learning. Regarding in-context learning strategies, both static few-shot sampling and dynamic similarity-based retrieval yield results comparable to the zero-shot approach for the SFT models. However, the GKD-trained model presents a different behaviour, where ICL

	Q8	3.58	49.8	0.7789	32.5	0.6968	16.6	0.7204
	Q4	2.79	49.7	0.7756	31.1	0.6884	16.6	0.7174

Table 4: Impact of quantization on compressed model performance. Results compare 8-bit (Q8) and 4-bit (Q4) quantization using zero-shot translation across all language pairs.

methods fail dramatically. The GKD model's few-shot performance drops drastically across all language pairs, from 50.3 to 14.5 chrF for CES-DEU, 32.0 to 9.3 for ENG-ARA, and 16.7 to 1.3 for JPN-ZHO. Future work should address the drastic loss of in-context learning capabilities in GKD-trained models.

While we observe the expected reduction in processing time with model compression, from 88.67 seconds for the baseline to 49.79 seconds for the 0.75 GKD model in zero-shot setting, timing measurements showed unexpected variations where few-shot inference was occasionally faster than zero-shot despite the longer context, reflecting the inherent difficulties in timing measurements. Nevertheless, the computational overhead of the RAG approach consistently requires an order of magnitude more time, primarily due to the retrieval process overhead rather than the translation itself.

5.2 Quantization Results

Table 4 presents the results of applying quantization techniques to the GeLaCo compressed models, examining the effects of 8-bit and 4-bit quantization on model size and translation performance in a zero-shot setting.[6]

Across all GeLaCo variants, 8-bit quantization (Q8) reduces model sizes by approximately 42% while maintaining stable translation performance. For the 0.25 compressed model, Q8 reduces the size from 11.71 GiB to 6.83 GiB with minimal quality impact. The 0.50 compressed model follows a similar pattern, achieving a size reduction from 8.46 GiB to 5.21 GiB with marginal quality variations across language pairs. The 0.75 models also benefit from Q8 quantization, with both SFT and GKD variants reducing from 5.21 GiB to 3.58 GiB while preserving competitive performance.

4-bit quantization (Q4) enables more aggressive compression but introduces more noticeable quality degradation. For the 0.25 compressed model, Q4 reduces the size to 4.47 GiB while incurring chrF drops of 0.9, 1.6, and 1.4 points for CES-DEU, ENG-ARA, and JPN-ZHO respectively. This pattern intensifies with higher compression ratios, where the 0.75 SFT model with Q4 shows significant performance drops, particularly evident in the chrF scores falling to 35.3, 16.9, and 4.5.

A notable result emerges with the GKD variant, which demonstrates superior robustness to quantization. The 0.75 GKD model maintains competitive performance even with aggressive Q4 quantization, achieving chrF scores of 49.7, 31.1, and 16.6, substantially outperforming the corresponding SFT variant under the same quantization settings. The combination of layer compression and quantization enables the creation of extremely compact models, with the 0.75 GKD model reach-

[6]Complete quantization results including few-shot and RAG are provided in Appendix A

ing 2.79 GiB with Q4, representing an 81% reduction from the original baseline while retaining reasonable translation capabilities.

Given that quantization produces only marginal quality degradation while achieving substantial size reductions across all compression levels, we selected each of the Q8 and Q4 variants as our final submissions to the shared task. Specifically, we submitted the 0.25, 0.50, 0.75 SFT models and the 0.75 GKD model unquantized, Q8 and Q4 variants, with the 0.75 GKD Q4 model being designated as our primary submission due to its optimal balance of compression efficiency and translation quality preservation.

6 Conclusions

This work presented our approach to the WMT 2025 Model Compression shared task, focusing on compressing the Aya Expanse 8B model for machine translation across Czech-German, English-Arabic, and Japanese-Chinese language pairs within the constrained setting of the task. We employed GeLaCo, an evolutionary algorithm for layer collapse operations, combined with post-training techniques and quantization, to achieve substantial model size reduction while maintaining competitive translation performance.

Our experimental results demonstrated that compressed models can be successfully recovered through targeted post-training techniques. Generalized Knowledge Distillation consistently outperformed traditional fine-tuning for performance recovery across all three language pairs at the 0.75 compression ratio where it was applied. The combination of layer compression with 4-bit quantization achieved an 81% reduction in model size (from 14.96 GiB to 2.79 GiB) while preserving reasonable translation quality, making such models viable for resource-constrained scenarios.

Table 5: Complete experimental results across all models, quantization settings, and inference approaches.

B Translation Instruction Template

The following template illustrates the format used for translation instructions. At inference time, only the user message is provided to the model. The instruction prompt and language names are always specified in English. In the template, SOURCE_LANGUAGE and TARGET_LANGUAGE represent the English names of the source and target languages (e.g., "Czech", "German", "English", "Arabic", "Japanese", or "Chinese"), INPUT_SENTENCE contains the text to be translated in the source language, and TARGET_SENTENCE contains the corresponding translation in the target language.

Instruction Template

```
"messages": [
    {
        "role": "user",
        "content": "Translate from SOURCE_LANGUAGE to TARGET_LANGUAGE:\nINPUT_SENTENCE"
    },
    {
        "role": "assistant",
        "content": "TARGET_SENTENCE"
    }
]
```

C Training Hyperparameters

For both supervised fine-tuning and generalized knowledge distillation, we employed the SFTTrainer and GKDTrainer implementations from the TRL[7] library. All training was conducted using DeepSpeed with ZeRO Stage 3 optimization for efficient memory management across multiple GPUs. The specific hyperparameters used for each training approach are detailed below.

SFT Training Hyperparameters

```
--learning_rate 2.0e-5
--num_train_epochs 3
--packing
--per_device_train_batch_size 8
--gradient_accumulation_steps 4
--gradient_checkpointing
--bf16 True
```

GKD Training Hyperparameters

```
--learning_rate 2.0e-5
--per_device_train_batch_size 4
--gradient_accumulation_steps 8
--bf16 True
--logging_steps 25
```

DeepSpeed ZeRO Configuration

Abstract

Large language models (LLMs) have transformed many areas of natural language processing, including machine translation. However, efficient deployment of LLMs remains challenging due to their intensive computational requirements. In this paper, we address this challenge and present our submissions to the *Model Compression* track at the Conference on Machine Translation (WMT 2025). In our experiments, we investigate iterative layer pruning guided by layer importance analysis. We evaluate this method using the Aya-Expanse-8B model for translation from Czech to German, and from English to Egyptian Arabic. Our approach achieves substantial reductions in model size and inference time, while maintaining the translation quality of the baseline models.

1 Introduction

Large language models (LLMs) have demonstrated powerful capabilities in diverse natural language processing tasks, including translation. However, LLMs are often computationally intensive, making them impractical to deploy in real-world settings with limited resources. To enhance the efficiency of these models, researchers have explored various model compression techniques, aiming to reduce their computational requirements while preserving quality (Gandhi et al., 2023; Sajjad et al., 2023; Treviso et al., 2023; Sreenivas et al., 2024; Gu et al., 2025; Moslem, 2025).

Aya Expanse is an open-weight large language model with multilingual capabilities. The WMT 2025 Model Compression track (Gaido et al., 2025) required all submissions to be derived from the Aya-Expanse-8B model. This work focuses on translation from Czech to German and from English to Egyptian Arabic.

Our experiments build on established work on iterative layer pruning guided by layer importance evaluation (Peer et al., 2022; Moslem, 2025). We apply iterative layer pruning to the baseline model Aya-Expanse-8B[1] which originally consists of 32 layers and 8.03B parameters. This approach incrementally identifies and removes layers with minimal contribution to translation quality, one layer at a time. To this end, we conduct layer importance evaluation by measuring translation performance without each layer. After identifying and removing the least critical layer, we repeat the layer importance evaluation on the remaining layers until reaching our pruning target. The pruned model resulting from this process is then fine-tuned on the News Commentary dataset. We have made three submissions; the primary submission is a 24-layer model with 6.28B parameters, and the two contrastive submissions are 20-layer and 16-layer models, with 5.41B and 4.54B parameters, respectively.

2 Data

After layer pruning of the *Aya-Expanse-8B* model (cf. Section 3), we need to fine-tune the pruned model on medium-sized training data to restore the translation quality of the baseline model. To this end, we use the News Commentary dataset[2] which consists of news articles and their corresponding translations in several languages, including Arabic, English, German, and Czech.

We start by rule-based filtering of the Czech-to-German (CES-DEU) News Commentary dataset by removing duplicates, segments longer than 200 words, and those whose source/target length ratio is larger than 1.5 times. We also apply language detection with fastText[3] (Joulin et al., 2017) with a 0.9 threshold. Finally, we conduct semantic filtering using the *mUSE* model (Yang et al.,

*These authors contributed equally to this work.

[2] https://data.statmt.org/news-commentary/v18/training/

[3] In particular, we used the fastText *"lid.176.bin"* model.

Proceedings of the Tenth Conference on Machine Translation, pages 1022–1027
November 8-9, 2025

2020) and *Sentence-Transformers* (Reimers and Gurevych, 2019) with a 0.7 threshold of semantic similarity between the source and target. The CES-DEU News Commentary dataset includes 250.4K segments before filtering, and 201.3K segments after filtering.[4] Eventually, we split the dataset into train and test splits, where the test set includes 500 segments used for both testing and layer importance evaluation. Then, we sample 100K of the training data, using 0 as the random seed in both cases.

As the English-to-Arabic News Commentary dataset uses Standard Arabic,[5] we first apply the same rule-based and semantic filtering steps as those we employ while processing the Czech-to-German dataset, which result in 84.3K segments. Afterwards, we convert Standard Arabic text segments into Egyptian Arabic (ARZ) with GPT-4.1-Mini, using the prompt in Appendix A, providing a fixed verified example that includes the English source as well as both the Standard Arabic and Egyptian Arabic translations. For parameters, we use temperature 0.3 and top-p 1. After completing the generation of the synthetic Egyptian Arabic translations, we apply rule-based filtering, comparing the generated Egyptian Arabic text segments to the original English source. Finally, we calculate the semantic similarity between the English source and the Egyptian Arabic target and select the 500 segments with the highest scores (0.91-0.98) for the "test" split, while the "train" split comprises the remaining 83.2K segments.[6] Using this synthetic dataset to fine-tune our models yields clear quality gains compared to the baseline models, when evaluated on both the in-domain holdout test dataset (cf. Table 1) and the WMT24++ benchmark[7] (Deutsch et al., 2025) which includes 998 segments (cf. Table 3).

3 Iterative Layer Pruning

As previous research demonstrates, iterative layer pruning achieves better quality than middle layer pruning (Moslem, 2025). In this experimental setup, we apply iterative layer pruning to the *Aya-Expanse-8B* baseline model. This approach incrementally identifies and removes layers with minimal contribution to translation quality, one layer at a time. The pruned models resulting from this process are then fine-tuned on the training dataset. Furthermore, knowledge distillation data from the teacher model can be added. Fine-tuning the pruned model restores most of the baseline model's translation quality. The following points elaborate on the process.

Layer importance evaluation: We conduct layer importance evaluation by measuring translation performance without each layer. In this greedy layer pruning approach (Peer et al., 2022; Rostami and Dousti, 2024; Moslem, 2025), to prune $n + 1$ layers, only a single optimal layer to prune must be added to the already known solution for pruning n layers. After identifying and removing the least critical layer, we repeat the layer importance evaluation on the remaining layers until reaching our n pruning target. We observe that while removing certain layers of the model (e.g. the first or last layer) substantially degrades translation performance, others result in minimal performance drops. Following Moslem (2025), we use the chrF++ metric for layer importance evaluation for both better efficiency and quality.

Layer pruning: We iteratively prune one decoder layer at a time, selecting the layer whose removal has the least negative impact on translation quality, measured by chrF++ scores. At each iteration, we evaluate the translation performance of the pruned model on the test split of the News Commentary dataset, after removing each candidate layer. The layer whose removal yields the best performance is eventually pruned. This process continues until a predefined number of layers (8, 12, and 16 layers) have been removed. By iteratively removing the least important layers, this performance-guided method produces a more compact model that can be fine-tuned further to recover the translation quality of the original model. We observe that the performance of the CES-DEU model is more impacted by pruning than the ENG-ARZ model, which might be attributed to the pre-training process (cf. Table 1). In other words, the evaluation of the baseline for CES-DEU translation achieves better results than that for ENG-ARZ translation; hence, it seems that fine-tuning the pruned ENG-ARZ models has helped with improving the translation quality of this language pair.

Fine-tuning: The pruning step is followed by fine-tuning the pruned model for 1 epoch using the News Commentary dataset (cf. Section 2). The

		16	51.17	82.10	**4.54**	**00:42**

Table 1: Evaluation of layer pruning experiments. For translation from Czech to German (CES-DEU), pruning 8 layers and then fine-tuning the resulting model retains 98% of the translation quality (as measured by COMET). Interestingly, for translation from English to Egyptian Arabic (ENG-ARZ), the model resulting from pruning up to 16 layers and then fine-tuning outperforms the Aya-Expanse-8B baseline for this language pair.

training uses a learning rate of 2e-5, a batch size of 8, and early stopping with a patience value of 5 evaluation runs, and it is conducted on one A100 80GB GPU. This fine-tuning step recovers most of the translation quality of the baseline model.

Model	Layers	KD	chrF++ ↑	COMET ↑
Baseline 32B	40	-	54.57	87.76
Baseline 8B	32	-	52.79	87.18
Pruned + FT	24	⊗	51.35	85.70
		✓	52.68	86.50
	20	⊗	49.45	83.95
		✓	51.25	85.19
	16	⊗	45.79	79.39
		✓	48.60	81.39

Table 2: Evaluation of knowledge distillation (KD). Fine-tuning pruned models on a combination of authentic and synthetic data (generated by Aya-Expanse-32B) improved the CES-DEU translation quality, with the 24-layer pruned model nearly matching the performance of the Aya-Expanse-8B baseline.

Knowledge distillation: To improve the quality of the CES-DEU models, we employed sequence-level knowledge distillation, where the student model is fine-tuned on a combination of authentic data and synthetic data generated by the teacher model for the same training dataset. In this case, the teacher model is the Aya-Expanse-32B while the students are the pruned models. After generating the data, we filter it by removing duplicates (exact matches in the target side of the authentic data), and translations with less than 70% COMET scores, resulting in extra 98.6K segments of training data (cf. Section 2). As Table 2 demonstrates, fine-tuning the pruned models with a combination of both the authentic and knowledge distillation data has improved their translation quality, and helped close the performance gap between the 24-layer pruned model and the Aya-Expanse-8B baseline. Similarly, the 20-layer and 16-layer models show 2-3 points of improvement in terms of chrF++ and COMET metrics.

4 Inference and Evaluation

For inference, we use greedy generation by disabling the sampling options, and setting the temperature argument to 0. We apply a simple translation prompt: "Translate the following text from {source_language} to {target_language}:"

To evaluate our systems, we calculated BLEU (Papineni et al., 2002), chrF++ (Popović, 2017), as implemented in the sacreBLEU library[8] (Post, 2018). For semantic evaluation, we use COMET (Rei et al., 2020).[9] Table 1 reports the results of the main experiments using the *Transformers* framework[10] (Wolf et al., 2020) for inference.

5 Results

The process of iterative layer pruning has achieved model compression from 8.03B parameters to 6.28B, 5.41B, and 4.54B parameters, after removing 8, 12, and 16 layers, respectively. Moreover, the quality degradation caused by pruning has been mitigated through fine-tuning on medium-sized data

[8] https://github.com/mjpost/sacrebleu

[9] In particular, we used the *"wmt22-comet-da"* model.

[10] https://github.com/huggingface/transformers

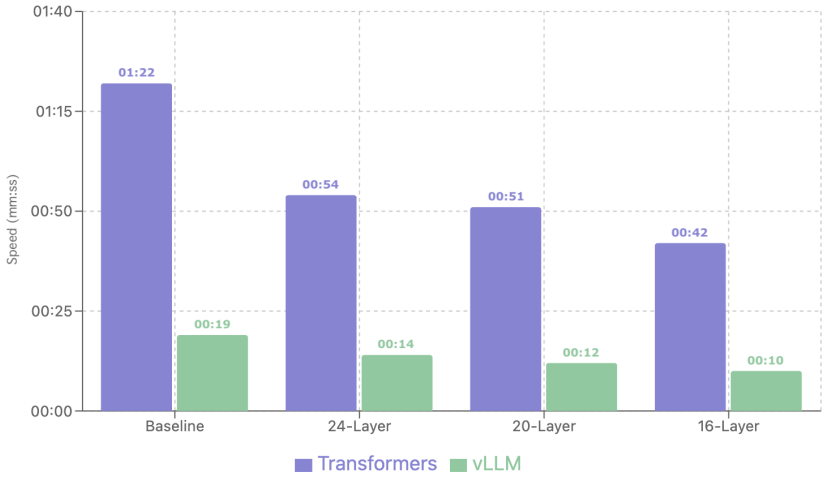

Figure 1: Inference speed comparison between *Transformers* and *vLLM*, using the Aya-Expanse-8B model for ENG-ARZ translation. *vLLM* consistently outperforms *Transformers* across all model sizes. Speedup ranges from 4.2x (16-layer) to 4.3x (baseline model). Both frameworks show improved performance with layer pruning. The 16-layer model achieves the fastest inference times overall.

(80K-100K) and knowledge distillation. As demonstrated by Table 1, by the end of the process, the pruned model could recover most of the translation quality of the baseline model. For translation from Czech to German (CES-DEU), pruning 8 layers and then fine-tuning the resulting model retains 98% of the translation quality (as measured by COMET) before knowledge distillation and 99% after knowledge distillation. Interestingly, for translation from English to Egyptian Arabic (ENG-ARZ), the model resulting from pruning up to 16 layers and then fine-tuning outperforms the baseline model. This can be attributed to the initial quality of the baseline model for this language pair.

Moreover, we experimented with immediate recovery through fine-tuning the model after each pruning phase (i.e. pruning the fine-tuned 24-layer model into 20 layers instead of pruning the baseline model directly), and noticed that the final quality was similar to pruning the baseline directly and then only fine-tuning the pruned model. This matches the results demonstrated by Moslem (2025) who experimented with immediate fine-tuning after pruning each layer, and observed that this could lead to overfitting. In other words, it is sufficient to fine-tune the final pruned model.

In terms of inference performance, we observe that using *vLLM* [11] (Kwon et al., 2023) as an inference engine instead of *Transformers* increases the inference speed by more than four times when conducting the evaluation on one A40 48GB GPU (cf. Figure 1). Moreover, while 4-bit quantization using *bitsandbytes* (Dettmers et al., 2023) reduces the memory footprint, pruning results in higher inference speed and throughput (cf. Table 4).

6 Conclusions and Future Work

In this work, we demonstrated that iterative layer pruning is an effective approach for compressing LLMs while retaining translation quality. The method relies on layer importance evaluation, followed by fine-tuning on a medium-sized dataset. This iterative layer pruning process reduces the model size and accelerates inference. To ensure reproducibility, we have made our code publicly available.[12]

Future research directions include investigating adaptive compression approaches that dynamically select appropriate model configurations based on real-time deployment constraints such as memory limits and latency requirements. Moreover, we plan to assess our compression methods on a broader range of datasets, including both sentence-level and document-level data. Since Aya-Expanse is designed to follow textual instructions, exploring retrieval-augmented generation combined with few-shot prompting presents a promising opportunity for enhancing translation performance in compressed models.

A Prompt for Synthetic Data Generation for Egyptian Arabic

```
I would like to convert a Standard Arabic text into Egyptian Arabic.
Please generate the Egyptian Arabic version using a neutral, informative
tone with slightly conversational phrasing, similar to the example below.
The output should feel natural, like it's written for a general Egyptian
audience but still accurate and clear. Do not add any commentary; just
return the Egyptian Arabic version.

English:
<english_example>

Standard Arabic:
<standard_arabic_example>

Egyptian Arabic:
<egyptian_arabic_example>

English:
{new_source_text}

Standard Arabic:
{new_target_text}

Egyptian Arabic:
```

B Evaluation of Egyptian Arabic Translation on WMT24++

Model	Layers	chrF++ ↑	COMET ↑
Baseline 32B	40	33.89	75.55
Baseline 8B	32	30.62	74.50
Pruned + FT	24	**37.01**	**76.86**
	20	34.24	74.95
	16	29.32	68.70

Table 3: Evaluation of the ENG-ARZ models fine-tuned with target-side synthetic data. The evaluation uses the WMT24++ benchmark and shows quality improvement compared to the baseline models.

C Quantization Speed and Throughput

Model	Layers	4-bit	Memory ↓	Speed ↓	Throughput ↑
Baseline 8B	32	no	14.96	00:19	2275
		yes	5.61	00:42	1053
Pruned + FT	24	no	11.71	00:14	3008
		yes	4.70	00:22	2004
	20	no	10.08	00:12	3484
		yes	4.24	00:18	2367
	16	no	8.46	00:10	4192
		yes	3.78	00:15	2908

Table 4: Performance comparison of Aya-Expanse-8B baseline and the pruned models with and without 4-bit quantization, in terms of memory (GiB), speed (mm:ss), and output throughput (tokens/sec). The evaluation uses the holdout ENG-ARZ News Commentary test dataset, on one A40 48GB GPU. While 4-bit quantization reduces the memory footprint, layer pruning achieves both higher inference speed and throughput.

Expanding the WMT24++ Benchmark with Rumantsch Grischun, Sursilvan, Sutsilvan, Surmiran, Puter, and Vallader

Abstract

The Romansh language, spoken in Switzerland, has limited resources for machine translation evaluation. In this paper, we present a benchmark for six varieties of Romansh: Rumantsch Grischun, a supra-regional variety, and five regional varieties: Sursilvan, Sutsilvan, Surmiran, Puter, and Vallader. Our reference translations were created by human translators based on the WMT24++ benchmark, which ensures parallelism with more than 55 other languages. An automatic evaluation of existing MT systems and LLMs shows that translation out of Romansh into German is handled relatively well for all the varieties, but translation into Romansh is still challenging.

1 Introduction

The automatic evaluation of machine translation (MT) has been widened in recent years to cover more languages and language varieties. While massively multilingual benchmarks such as FLORES (Goyal et al., 2022; NLLB Team et al., 2024) or NTREX (Federmann et al., 2022) include reference translations in hundreds of languages, no dedicated reference translations for the Romansh language have been available so far. In this paper, we close this gap by extending the recent WMT24++ benchmark (Kocmi et al., 2024; Deutsch et al., 2025) with reference translations for six varieties of Romansh, using German as the source language.

There are several reasons why Romansh, which is a language from the Romance family spoken in Switzerland (**ISO 639-1: `rm`; ISO 639-2/3: `roh`**), has had limited resources for MT evaluation. First, Romansh is considered a minority language, with 40,000–60,000 speakers (Gross, 2004; Grünert, 2024). Secondly, multiple varieties of Romansh need to be considered for a comprehensive evaluation. *Rumantsch Grischun* is a supra-regional variety of the language, often used in official contexts. However, the five regional varieties of Romansh (Figure 1), usually referred to as *idioms*, are more widely spoken in everyday life, with limited mutual intelligibility (Gross, 2004).

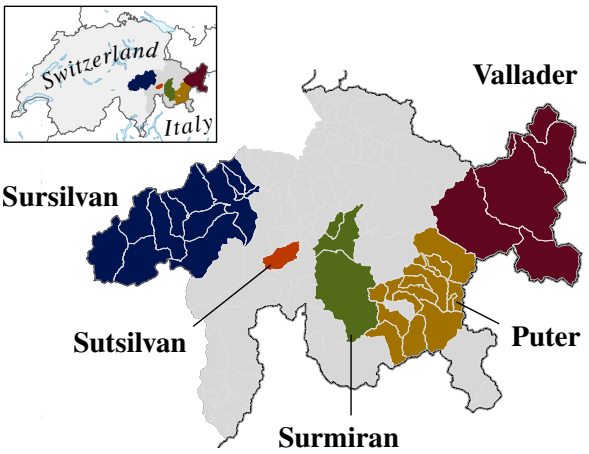

Figure 1: Distribution of Romansh *idioms* (regional varieties) within south-eastern Switzerland. The map shows municipalities where an idiom is officially used in public administration. We extend the WMT24++ benchmark with sets of reference translations for these five idioms, as well as Rumantsch Grischun, a supra-regional variety of Romansh.

Prior work on MT for Romansh (Müller et al., 2020; Niklaus et al., 2025) has leveraged multilingual government press releases (Scherrer and Cartoni, 2012), blog posts or federal laws, all of which cover only the Rumantsch Grischun variety. Our benchmark based on WMT24++ enables a more systematic evaluation setup that includes the five idioms and a broader range of domains, such as social media and transcripts of YouTube videos.

We release our benchmark under the Apache 2.0 license.[1] In addition, we use the benchmark to perform a systematic evaluation of MT systems and LLMs on German–Romansh and Romansh–German translation. Results based on automatic evaluation metrics indicate that translation into German achieves reasonable quality for all Romansh

Table 1: Samples of the Romansh varieties that we contribute to the benchmark, plus the English and German segments from prior work. The samples are from the *Social* domain. The language code assigned by the Open Language Data Initiative (OLDI) has three components: the ISO 639-3 language code (`roh`), the ISO 15924 script code (`Latn`), and the Glottocode assigned to the variety by Glottolog (Hammarström et al., 2025).

varieties, while translation into Romansh remains challenging, particularly for the less-resourced idioms. Code for reproducing our experiments is available.[2]

2 Language Overview

2.1 Romansh

Romansh is part of the Romance branch of the Indo-European language family. It is a minority language in the Swiss canton of Graubünden and is treated as one of the country's four national languages (Grünert, 2018). Its status is considered endangered (Moseley and Nicolas, 2010). Romansh covers an extremely diverse dialect continuum spanning the canton, where roughly 15% of inhabitants speak it as their main language (Gross, 2004). Unlike other dialect continuums, Romansh is not "roofed" by a single standard language (Goebl, 2003). Instead, there are five different written traditions dividing the Romansh-speaking area into regions with their own written standards—known as *idioms*—that differ heavily from each other in all areas of language structure (Liver, 2010; Haiman and Benincà, 1992; Schmid, 1976). In the 1980s, linguist Heinrich Schmid developed Rumantsch Grischun, a supra-regional, constructed standard, as a *Dachsprache* for Romansh (Muljačić, 2012).

2.2 Sursilvan

Sursilvan is used in the west of Graubünden, in an area mainly covered by the Surselva valley. In many municipalities towards the east, it is still the predominant first language, while German is increasingly dominant moving west (Gross, 2004). Sursilvan is the idiom with the largest population. The written form mainly represents the dialects spoken between Disentis and Ilanz, though the entire area it covers is a continuum exhibiting mutual intelligibility. There were at least 18,000 Sursilvan speakers in the year 2000 (Gross, 2004).

2.3 Sutsilvan

Sutsilvan is spoken in the valley of the Hinterrhein river, though its territory is no longer contiguous. It is the variety with the lowest number of speakers and the highest level of endangerment (Liver, 2014). Large parts of Sutsilvan's traditional speaker territory became German speaking several centuries ago, and until recently, there was no established written form for Sutsilvan. A concentrated

[2] https://github.com/ZurichNLP/romansh_mt_eval

effort to change this was initiated by Giuseppe Gangale in the 1940s, establishing modern Sutsilvan orthography. His approach, however, sparked debate, and Sutsilvan remains an idiom with hardly any majority Romansh territory (Coray, 2008). There were at least 1,000 Sutsilvan speakers in the year 2000 (Gross, 2004).

2.4 Surmiran

Surmiran is spoken in central Graubünden, namely in the regions of Alvra/Sotses and Surses, the latter being an area where Romansh is still largely present in everyday life (Liver, 2014). Together with Sutsilvan, Surmiran constitutes a bridge between the starkly different dialects of the Surselva region in western Graubünden and the Engadine valley in the east. For this reason, it has previously been suggested as a lingua franca for supra-regional communication (Coray, 2008). Surmiran itself exhibits some peculiarities, however, shared by neither of the two other major Romansh-speaking areas. There were at least 3,000 Surmiran speakers in the year 2000 (Gross, 2004).

2.5 Puter

Puter and Vallader are used as written standards in the Engadine valley, with Puter being used south of Zuoz. The Engadine valley can itself be seen as a continuum of varieties more diverse than the Surselva (Schmid, 1976). Puter reflects characteristics of the dialects in the upper Engadine valley, with more Italian influence than Vallader. Written Puter dates back to 1552 (Obrist, 2022), and is thus the variety with the longest-standing written tradition. Puter is under substantial pressure from German due to growing tourism since the last century (Liver, 2014). Municipalities with a Romansh majority have become scarce. There were at least 5,500 Puter speakers in the year 2000 (Gross, 2004).

2.6 Vallader

Vallader is used in the Lower Engadine valley, north of Zernez, as well as in the Val Müstair. Vallader, unlike Puter, remains a majority language in most of its territory (Liver, 2014). Together with Sursilvan, the Vallader territory represents a stronghold of Romansh. There were at least 6,500 Vallader speakers in the year 2000 (Gross, 2004).

2.7 Rumantsch Grischun

The Rumantsch Grischun variety has a special role in that it is not an idiom, but a written standard devised as a constructed language. It does not reflect any Romansh speaker's natural speech, but was constructed to be a globally intelligible and neutral written form that could be used to represent Romansh as a language. It was developed by comparing structural and lexical characteristics of the different idioms and determining the most mutually intelligible forms (Schmid, 1982).

Rumantsch Grischun is used for official publications from the canton or the federal government, as well as other institutions addressing the entire Romansh population. More extended promotion of Rumantsch Grischun (including replacing the idioms as the language of literacy at schools) met heavy resistance and caused long-lasting debate (Coray, 2008). Most speakers of Romansh only actively learn their own idiom. Though they may occasionally come into contact with Rumantsch Grischun texts, their knowledge of it is only passive at most.

3 Data Collection

3.1 Choice of Benchmark

We chose to extend the WMT24++ benchmark (Kocmi et al., 2024; Deutsch et al., 2025) based on the following considerations:

- WMT24++ currently covers 55 languages, including the other Swiss national languages (German, French and Italian).
- It is a recent benchmark that is unlikely to suffer from data contamination in LLMs.
- Segments are provided in context, allowing for document-level evaluation.

3.2 Creation of Reference Translations

The data acquisition process was structured into three steps to ensure high quality, consistency, and adherence to idiom-specific conventions.

1. **Translation**: We hired language professionals who are native speakers of both German and the respective Romansh idiom.
2. **Review**: Two expert linguists of Lia Rumantscha reviewed a sample of translations for a representative selection of varieties, and formulated feedback that was communicated to all translators.

↓ pred	gold → RG	Surs.	Suts.	Surm.	Puter	Vall.
RG	764	83	23	43	29	35
Surs.	98	810	67	46	55	54
Suts.	8	12	809	20	6	10
Surm.	19	9	32	811	8	6
Puter	10	12	12	17	648	30
Vall.	61	34	17	23	214	825

Table 2: Confusion matrix of a Romansh language variety classifier when applied to the reference translations.

↓ sys	ref → RG	Surs.	Suts.	Surm.	Puter	Vall.

Vall.	49.3	42.4	38.4	42.4	58.4	

Table 3: Pairwise ChrF scores between the reference translations for the different varieties.

3. **Revision**: The translators incorporated the feedback into the reference translations.

We provided the translators with a guidelines document, inspired by the WMT24 translator brief (Kocmi et al., 2024). The key points of the guidelines, which we provide in Appendix D, are:

- The German text is the main source for the translation into Romansh, while the English text can be used as an additional reference in case of ambiguity.
- No AI tools should be used for the translation.

The translators and reviewers had access to the complete context of each segment, including a link to the original website from which the segment was extracted (e.g., for segments from the Speech domain, the original YouTube video).

3.3 Challenges in the Data Acquisition

A challenge we encountered in the translation process was that the degree of standardization can vary across text domains. The Romansh idioms are well-standardized, which is reflected in the formal domains *News* and (partially) *Literary*. However, in the *Social* and *Speech* domains, there is more room for individual variation based on the translator's style or regional background. Therefore, while we consider the reference translations suitable for their intended use of evaluating idiom-aware MT, the dataset does not aim to represent the full spectrum of variation present in the Romansh idioms.

4 Validation Experiments

We perform two automatic validation experiments to confirm that the reference translations are suitable for variety-specific evaluation:

Language Classification We use a fastText classifier (Joulin et al., 2017) trained on a corpus of Romansh newspaper articles that were manually labeled with their variety. Table 2 shows that when applied to our reference translations, the classifier predicts the expected variety for the majority of segments, indicating that the reference translations exhibit variety-specific features.

Cross-Variety Scores We calculate pairwise ChrF scores (Popović, 2015) between the sets of references, which are reported in Table 3. The maximum ChrF score across varieties is 60.7 (for Sursilvan–Rumantsch Grischun), which confirms that the sets of reference translations are distinct from each other even for related varieties, allowing for variety-specific evaluation. At the same time, the cross-variety scores are high enough to rule out serious data quality issues, such as a systematic misalignment of segments.

5 Evaluation of MT Systems and LLMs on Translation from and into Romansh

We use our benchmark to evaluate the following machine translation systems and LLMs:

- **MADLAD-400** (Kudugunta et al., 2023), a family of open-source MT models trained on parallel data in more than 450 languages, including Romansh. We report results for the largest, 10.7B-parameter model, using sentence segmentation with SpaCy to translate sentences individually, with a beam size of 5.
- **Supertext**, a commercial MT system that supports German and Romansh, among other languages.[3] We use the website of Supertext to translate the segments in an Excel file.
- **Translatur-ia**, a closed, early prototype of an MT system that translates from German into

[3] https://supertext.com/

System	Rumantsch Grischun	Sursilvan	Sutsilvan	Surmiran	Puter	Vallader
MADLAD-400 (10.7B)						
– direct	58.3 / 63.0	52.9 / 54.7	40.6 / 38.1	45.2 / 40.4	49.7 / 49.8	52.8 / 52.9

Table 4: **Romansh as source language:** ChrF / xCOMET scores of MT systems and LLMs for translation into German from six varieties of Romansh.

System	Rumantsch Grischun	Sursilvan	Sutsilvan	Surmiran	Puter	Vallader
MADLAD-400 (10.7B)						
– direct	48.0	40.7	34.6	37.1	37.0	38.5
– pivoting via English	50.7	43.0	36.1	38.7	38.6	40.1
Translatur-ia	19.7	18.1	16.7	17.4	17.3	17.6
Supertext	**68.9**	53.2	43.5	47.8	46.7	49.0
Llama 3.3 (70B)	52.1	43.9	36.6	39.3	40.3	42.6
GPT-4o	64.8	**60.1**	41.4	46.4	52.3	55.9
Gemini 2.5 Flash	66.0	58.7	**43.7**	**50.1**	**53.8**	**57.2**

Table 5: **Romansh as target language:** ChrF scores of MT systems and LLMs for translation from German into Romansh. Results in gray are based on translations into Rumantsch Grischun, which is the only target variety officially supported by these systems.

Rumantsch Grischun.[4]

- **Llama 3.3** (Grattafiori et al., 2024), an open-source LLM released in November 2024. We use the 70B-parameter version.
- **GPT-4o** (OpenAI et al., 2024), a commercial LLM that was released in May 2024 and was billed at $2.50 per million input tokens and $10 per million output tokens.
- **Gemini 2.5 Flash** (Comanici et al., 2025), a commercial LLM that was released in June 2025 and was billed at $0.30 per million input tokens and $2.50 per million output tokens. We turn off the 'thinking' mode to enable a direct comparison with the other systems.

LLM Prompting When using LLMs for translation, we use the same prompting setup as the WMT24 General Machine Translation Shared Task (Kocmi et al., 2024).[5] Specifically, we use 3-shot prompting with temperature set to zero. The prompt template is listed in Appendix B.[6] As few-shot examples, we use typical example sentences from the fable *The Fox and the Crow* (Gross, 2004), which we list in Appendix C.

Quality Metrics For evaluating translation quality, we use ChrF (Popović, 2015), a metric based on character n-grams that does not require word segmentation, via SacreBLEU (Post, 2018).[7]

For evaluating translations from Romansh into German, we additionally use xCOMET (Guerreiro et al., 2024), a neural metric that was ranked highly in the WMT24 Metrics Shared Task (Freitag et al., 2024). We use model version `XCOMET-XL`[8] in the *reference-only* mode, i.e., we do not provide the Romansh source sequence to the metric, a language it

[4] https://translaturia.fhgr.ch/

[5] https://github.com/wmt-conference/wmt-collect-translations

[6] A limitation of this prompt template is that it does not provide the LLM with context beyond the segment that is currently being translated. We opt to keep the setup similar to WMT24 and leave document-level evaluation to future work.

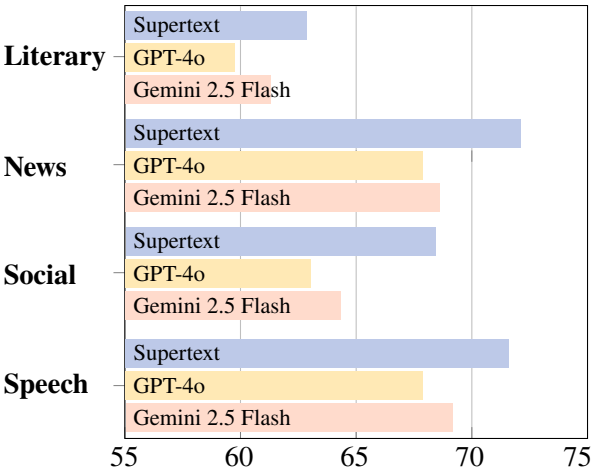

Figure 2: Domain-specific ChrF scores of systems translating from German into Rumantsch Grischun.

↓ **tgt**	**ref** → RG	Surs.	Suts.	Surm.	Puter	Vall.
RG	66.0	51.6	42.6	46.7	46.2	48.5
Surs.	57.0	58.7	42.6	44.8	43.7	45.1
Suts.	56.7	50.3	43.7	46.6	44.1	45.8
Surm.	52.3	46.5	42.5	50.1	43.8	44.5
Puter	47.5	42.1	38.0	41.2	53.8	54.6
Vall.	49.9	43.2	38.6	41.9	52.7	57.2

Figure 3: "Confusion matrix" of Gemini 2.5 Flash when translating into specific Romansh varieties. To visualize the degree to which the LLM output matches the requested variety (**tgt**), we evaluate the outputs with each set of reference translations (**ref**). A system that adheres to the requested target variety will achieve higher ChrF scores in the diagonal cells than in the off-diagonal cells.

has not seen during training. While xCOMET is designed to support such monolingual, *reference-only* evaluation, this mode has not been as extensively validated as other modes. Thus, xCOMET complements ChrF but should be interpreted with some caution. Following Kocmi et al. (2024), we report xCOMET as the macro-average over domains to control for different segment granularities.

6 Results

6.1 Comparison of Translation Directions

Table 4 shows the results for translation from Romansh into German, while Table 5 shows the results for translation from German into Romansh. The former performs consistently better than the latter; this is observed both for the supervised MT systems (MADLAD, Supertext) and for the LLMs.

Comparing performance across the six varieties of Romansh, we find that translation out of Romansh into German is relatively robust to linguistic variation: For Gemini, the gap in terms of ChrF between the minimum and maximum is $77.7 - 68.5$. In contrast, for translation into Romansh, the gap is $66.0 - 43.7$. Future work could exploit this asymmetry by using back-translation (Sennrich et al., 2016) for augmenting monolingual Romansh text with synthetic German translations.

6.2 Ranking of Models

For translation from Romansh into German, we report both ChrF and xCOMET scores in Table 4. We find that the system rankings are largely consistent between the two metrics, on average over the four domains, with Gemini 2.5 Flash achieving the highest scores according to both metrics. MADLAD-400 underperforms the other systems, likely due to the limited Romansh training data and the massively multilingual nature of the model.

In the German–Romansh direction, where ChrF is the only available metric (Table 5), we find that Gemini 2.5 Flash again achieves the highest scores for four out of six varieties. Supertext is the highest-ranked system for translation into Rumantsch Grischun, which is the officially supported target variety of this product.

6.3 Domain Difficulty

Figure 2 compares ChrF scores for German–Rumantsch Grischun translation for the four domains covered by the WMT24++ benchmark. The figure indicates that the *News* domain is the least challenging for all systems, which is consistent with findings of the WMT24 task for other languages (Kocmi et al., 2024). Surprisingly, lowest ChrF scores are achieved in the *Literary* domain, while the human evaluation of the WMT24 task did not find a systematic difference between the *Literary* and *News* domains in terms of difficulty. The *Speech* domain yields similar scores to *News*, and *Social* is slightly more challenging. Detailed results for each domain and variety (Appendices E and F) indicate that this pattern is consistent across varieties.

6.4 Target Variety Adherence of LLMs

While MADLAD and Supertext are limited to Rumantsch Grischun as the target variety, the LLMs can be prompted to produce translations in any of the six varieties. This raises the question of

whether the LLMs actually adhere to the requested target variety. Figure 3 shows a "confusion matrix" for Gemini 2.5 Flash, where we evaluate the system output not only with the reference translations for the requested target variety, but also with contrastive reference translations for the other varieties. The results suggest that state-of-the-art LLMs already have some degree of idiom awareness, but gravitate towards the higher-resource varieties (Rumantsch Grischun, Sursilvan, and Vallader).

7 Conclusion

This work fills a long-standing gap in the evaluation of machine translation for the Romansh language: the creation of a benchmark for the six main varieties of Romansh, and the provision of baseline results for existing MT systems and LLMs that cover Romansh.

B Prompt Template for LLMs

The below example is parameterized as follows:

- Source language: German
- Target language: Romansh
- Target variety: Rumantsch Grischun
- Source sentence: *"Sisos Darstellungen von Land und Wasser in neuer Ausstellung"*

````
Translate the following segment surrounded in triple backticks into Romansh
(Rumantsch Grischun variety). The German segment:

```Sisos Darstellungen von Land und Wasser in neuer Ausstellung```
````
````

C Few-shot Examples for LLM Prompting

German:

Der Fuchs war wieder einmal hungrig.

Da sah er auf einer Tanne einen Raben, der ein Stück Käse in seinem Schnabel hielt.

Das würde mir schmecken, dachte er, und rief dem Raben zu: «Wie schön du bist! Wenn dein Gesang ebenso schön ist wie dein Aussehen, dann bist du der Schönste von allen Vögeln».

English:

The fox was hungry yet again.

There, he saw a raven upon a fir holding a piece of cheese in its beak.

This I would like, he thought, and shouted at the raven: "You are so beautiful! If your singing is as beautiful as your looks, then you are the most beautiful of all birds."

Rumantsch Grischun:

La vulp era puspè ina giada fomentada.

Qua ha ella vis sin in pign in corv che tegneva in toc chaschiel en ses pichel.

Quai ma gustass, ha ella pensà, ed ha clamà al corv: «Tge bel che ti es! Sche tes chant è uschè bel sco tia parita, lur es ti il pli bel utschè da tuts».

Sursilvan:

L'uolp era puspei inagada fomentada.

Cheu ha ella viu sin in pegn in tgaper che teneva in toc caschiel en siu bec.

Quei gustass a mi, ha ella tertgau, ed ha clamau al tgaper: «Tgei bi che ti eis! Sche tiu cant ei aschi bials sco tia cumparsa, lu eis ti il pli bi utschi da tuts».

Sutsilvan:

La gualp eara puspe egn'eada fumantada.

Qua â ella vieu sen egn pegn egn corv ca taneva egn toc caschiel ainten sieus pecel.

Quegl gustass a mei, â ella tartgieu, ed ha clamo agli corv: «Tge beal ca tei es! Scha tieus tgànt e aschi beal sco tia pareta, alura es tei igl ple beal utschi da tuts».

Surmiran:

La golp era puspe eneda famantada.

Co ò ella via sen en pegn en corv tgi tigniva en toc caschiel an sies pecal.

Chegl am gustess, ò ella panso, ed ò clamo agl corv: «Tge bel tgi te ist! Schi ties cant è schi bel scu tia parentscha, alloura ist te igl pi bel utschel da tots».

Puter:

La vuolp d'eira darcho üna vouta famanteda.

Co ho'la vis sün ün pin ün corv chi tgnaiva ün töch chaschöl in sieu pical.

Que am gustess, ho'la penso, ed ho clamo al corv: «Che bel cha tü est! Scha tieu chaunt es uschè bel scu tia apparentscha, alura est tü il pü bel utschè da tuots».

Vallader:

La vuolp d'eira darcheu üna jada fomantada.

Qua ha'la vis sün ün pin ün corv chi tgnaiva ün toc chaschöl in seis pical.

Quai am gustess, ha'la pensà, ed ha clomà al corv: «Che bel cha tü est! Scha teis chant es uschè bel sco tia apparentscha, lura est tü il plü bel utschè da tuots».

D Translation Guidelines (in German)

1. Wofür werden die Übersetzungen benötigt?

Wir verwenden die von Ihnen erstellen Übersetzungen für die Evaluierung von maschinellen Übersetzungssystemen. Der Output der Übersetzungssysteme wird mit Ihrer Übersetzung verglichen – je ähnlicher der Output, desto besser das Übersetzungssystem.

Die Referenzübersetzungen werden nicht für das Training der Übersetzungssysteme verwendet.

2. Wie wurden die Texte ausgewählt?

Die Texte stammen aus einem bestehenden Datensatz («WMT24»), der zuvor bereits aus dem Englischen in 55 verschiedene Sprachen übersetzt worden ist, darunter Deutsch.

Der Datensatz setzt sich aus vier Textsorten zusammen:

- **literary:** Fan-Fiction, welche auf der Website «Archive of Our Own» veröffentlicht wurde.
- **news:** Zufällig ausgewählte Online-News vom Januar 2024.
- **social:** Zufällig ausgewählte Threads aus dem Sozialen Netzwerk «Mastodon».
- **speech:** Transkripte zufällig ausgewählter YouTube-Videos.

3. Wie ist die Excel-Datei aufgebaut?

Wir erstellen für jedes Idiom eine eigene Excel-Datei. Die Datei enthält vier Tabellen für die vier Textsorten, und jede Zeile in der Tabelle entspricht einem Textsegment. Mehrere Textsegmente setzen sich zu zusammenhängenden Dokumenten zusammen, welche durch graue Leerzeilen voneinander abgetrennt sind.

Die Tabellen sind wie folgt aufgebaut:

- **English:** Originaler Text auf Englisch.
- **document_id:** ID des Dokuments.
- **segment_id:** ID des Segments.
- **url:** Webseite, von welcher das Dokument ursprünglich bezogen wurde. Kann optional aufgerufen werden, um den Kontext des Dokuments nachzuvollziehen.
- **German:** Referenzübersetzung auf Deutsch.
- **translation:** Hier soll die Übersetzung auf Rätoromanisch eingetragen werden.
- **comment:** Kann von Ihnen optional benutzt werden, um uns einen wichtigen Kommentar zu hinterlassen.

4. Welche Anforderungen gelten an die Übersetzungen?

- Die Referenzübersetzungen repräsentieren Ihre Erwartungen an den Output eines guten maschinellen Übersetzungssystems. Überlegen Sie sich: Was für eine Übersetzung würde ein gutes Übersetzungssystem (im Stil von DeepL oder Google Translate) für das entsprechende romanische Idiom erzeugen?
- Massgeblich für Ihre Übersetzung sollte der Text auf Deutsch sein. Der englische Text kann optional zu Rate gezogen werden, falls der deutsche Text mehrdeutig ist.
- Weil wir Ihre Referenzübersetzungen für die Evaluierung verwenden möchten, bitten wir Sie, keine AI-Tools zu verwenden. Bitte erstellen Sie die Übersetzungen von Grund auf in Ihren eigenen Worten.

  - Erlaubte Hilfsmittel: Wörterbücher, Translation Memories, ...
  - Nicht erlaubte Hilfsmittel: ChatGPT, Copilot, Supertext/Textshuttle, DeepL, ...

  Wir können den Übersetzungen ansehen, wenn sie mit AI-Unterstützung erstellt wurden, und wir müssten im schlimmsten Fall die Übersetzungen noch einmal neu erstellen lassen (dies ist leider in der Vergangenheit schon vorgekommen).

- Bitte fügen Sie keine Übersetzungsalternativen oder Erklärungen in Klammern in die Übersetzungen ein.
- Bitte übersetzen Sie die Information in den Texten vollständig.
- Lehnwörter, Eigennamen etc. dürfen gerne auf Englisch oder Deutsch belassen werden, falls ein gutes rätoromanisches Übersetzungssystem das gleiche machen sollte.
- Betreffend die Textsorte «social»:
  - Viele Posts enthalten Fachbegriffe, Slang, Abkürzungen. Durch die Übersetzung vom Englischen ins Deutsche dürfte vieles schon weniger kryptisch geworden sein. Falls dennoch bei einem Post Unsicherheit besteht, können Ihnen diese Notizen weiterhelfen: https://github.com/wmt-conference/wmt24-news-systems/blob/main/README-social-domain-translation-notes.pdf
  - Nutzernamen wurden anonymisiert (z.B. @user1, @user2). Bitte übernehmen Sie die Nutzernamen eins zu eins, d.h. Sie müssen diese nicht übersetzen.
  - Hingegen dürfen #Hashtags gerne übersetzt werden, falls dies im Kontext Sinn macht.

E Detailed Results for RM–DE

A French Version of the OLDI Seed Corpus

Malik Marmonier **Benoît Sagot** **Rachel Bawden**
Inria, Paris, France
{firstname.lastname}@inria.fr

Abstract

We present the first French partition of the OLDI Seed Corpus, our submission to the WMT 2025 Open Language Data Initiative (OLDI) shared task. We detail its creation process, which involved using multiple machine translation systems and a custom-built interface for post-editing by qualified native speakers. We also highlight the unique translation challenges presented by the source data, which combines highly technical, encyclopedic terminology with the stylistic irregularities characteristic of user-generated content taken from Wikipedia. This French corpus is not an end in itself, but is intended as a crucial pivot resource to facilitate the collection of parallel corpora for the under-resourced regional languages of France.

1 Introduction

While state-of-the-art machine translation (MT) has made significant strides, progress has largely been concentrated on a handful of high-resource languages (Haddow et al., 2022). For many of the world's languages, development is hindered by a lack of reliable training data (Joshi et al., 2020). Techniques like backtranslation (Bertoldi and Federico, 2009; Bojar and Tamchyna, 2011; Sennrich et al., 2016) can help bridge this gap, but they typically require an initial high-quality parallel corpus to "kickstart" the process. To address this, the OLDI Seed Corpus was created (originally as the NLLB Seed Dataset) to provide a small but high-quality, professionally translated dataset for dozens of low-resource languages (NLLB Team et al., 2022; Maillard et al., 2023). The source material consists of approximately 6,000 English sentences sampled from a curated list of core Wikipedia articles, ensuring broad topic coverage (NLLB Team et al., 2022).

The WMT 2025 Open Language Data Initiative (OLDI) shared task builds directly on this effort, inviting the research community to expand these foundational open-source datasets to more languages. Our work answers this call by adding a French partition to the OLDI Seed Corpus. While French is a high-resource language, its selection as a pivot is strategic for our ultimate goal: facilitating the creation of parallel corpora for under-resourced regional languages of France (e.g., Francoprovençal, Occitan, Picard). Translators for these languages are overwhelmingly more likely to have a native command of French than of English. Most importantly, many of these languages exist in a diglossic relationship with French, which serves as the dominant language for most technical and formal domains. A French source text would, therefore, greatly simplify the complex terminological work inherent in translating the encyclopedic content found in the OLDI Seed Corpus, enabling the creation of direct calques and other word-formation strategies that are linguistically and culturally more congruent than those derived from English. With that in mind, we went to great lengths to rigorously verify the French technical terminology throughout the data creation process. By providing this carefully curated French corpus, we aim to establish a solid foundation for future translation efforts.

In addition to the final French partition, we also contribute a supplementary dataset containing the full set of translation hypotheses generated by the nine different MT systems and prompting techniques used in our workflow. This resource, which pairs multiple machine-generated outputs with a final, human-post-edited reference for each source segment, may be of particular use for research on preference optimization and quality estimation in the Wikipedia domain.[1]

We hope that our contribution will encourage further community-driven expansions of the OLDI Seed Corpus.

November 8-9, 2025

2 Linguistic Overview

French is a Romance language that evolved from the Vulgar Latin spoken by the inhabitants of northern Gaul after the Roman conquest. Its development was significantly shaped by the Germanic invasions of the 5th century, particularly by the Franks, whose linguistic habits profoundly influenced the phonology and vocabulary of the emerging Gallo-Romance vernacular (Rickard, 2014). The earliest extant text, the Strasbourg Oaths, dates to 842. Over the subsequent centuries, the dialect of the Île-de-France region, known as Francien, gradually gained prestige due to the political and cultural centrality of Paris. This Parisian variety formed the basis of a standardized literary and administrative language that was progressively imposed throughout the kingdom, through a process legally enforced by the Ordinance of Villers-Cotterêts in 1539. This history of internal linguistic unification through political centralization later provided a model for its imposition as the language of administration and education throughout France's colonial empire.

Today, with over 321 million speakers, French is the fifth most spoken language in the world (OIF, 2022). However, this numerical strength, driven almost entirely by African demography, masks a more complex reality. Recent independent assessments point to a rebalancing, with French losing ground to English in several symbolic and high-value domains. In parts of West Africa, its constitutional standing has weakened, with countries like Mali and Burkina Faso downgrading it from an "official" to a "working" language in 2023–2024. In North Africa, educational policies increasingly favor English, while in major Anglophone countries, like the United Kingdom and the United States, learner numbers have seen long-term declines (Collen and Duff, 2025; Lusin et al., 2023). Furthermore, English overwhelmingly dominates high-prestige domains such as scientific publishing even within France's own research output (OST, 2024). While the language's global landscape is in flux, the variety used in this corpus, standard French as spoken in France, remains the most widely recognized norm for formal written communication.

3 Data Collection

The shared task guidelines for Seed data contributions permit the use of post-edited machine translation (MTPE). Given the high quality of modern MT systems for the English-French language pair, we adopted this workflow. A full professional translation from scratch was deemed prohibitively expensive. Counterintuitively perhaps for a "seed" corpus, the source text represents a non-trivial amount of written content; at 136,656 total words, its length is comparable to that of a novel, falling between Jane Austen's *Pride and Prejudice* and Charles Dickens' *A Tale of Two Cities*. We estimated that a professional translation would have required a substantial budget—around €50,000, not accounting for the added complexity of the varied and often highly technical terminology found in the source segments—that we felt would be more strategically allocated to future translation efforts into the low-resource regional languages of France. The MTPE approach therefore allowed us to produce a highly adequate French corpus while preserving resources for our long-term goals.

3.1 Machine translation

The source text was the English partition of the OLDI Seed Corpus. To generate a diverse set of initial translation hypotheses for post-editing, we made use of nine different MT systems and/or prompting techniques. Among these were four "traditional" sequence-to-sequence Transformer models (Vaswani et al., 2017). We used a standard bilingual OPUS-MT model (Tiedemann and Thottingal, 2020) trained on a large collection of open parallel corpora. We also used three larger multilingual models: two from the NLLB family, namely the 3.3B-parameter model and the 600M distilled version (NLLB Team et al., 2022), and the 3B-parameter model from the MADLAD-400 project (Kudugunta et al., 2023). For all four of these systems, translations were generated at the sentence level using beam search with a beam size of 4.

The remaining five translation hypotheses were generated using Large Language Models (LLMs).

Four hypotheses were generated using Llama 4 Scout, a recently released 109B-parameter Mixture-of-Experts model (Meta AI, 2025) with a remarkable 10M-token context window. The first and most straightforward approach was to translate each segment individually, though in a context-informed way. For this, we designed a detailed prompt that instructed the model to act as an expert translator of encyclopedic documents and provided it with a set of guidelines adapted from the official OLDI trans-

lation instructions.[2] A crucial aspect of the OLDI Seed corpus is that, while its segments are sourced from a limited number of Wikipedia articles, they are not necessarily contiguous. To account for this, the prompt supplied the model with preceding text from the source article as context (up to five segments), while explicitly stating that this context might not be directly adjacent to the segment being translated. We also prompted the model to use a chain-of-thought process before producing the final translation, which was to be enclosed in specific XML tags (<translation>...</translation>) for automatic retrieval (see Appendix A.1).

To take advantage of the model's large context window, the other three hypotheses from Llama 4 Scout were generated by translating at the document level. We reconstructed the source documents by grouping all segments from the OLDI Seed corpus that shared the same source URL in their metadata, ordering them by their numerical ID. This full-document text was then translated in a single prompt under three different conditions, with the model explicitly instructed to produce only the final translation without any preceding chain-of-thought. The first setting was identical to the segment-level approach, including the full set of translation guidelines (see Appendix A.2). The second was a contrastive ablation where we removed the OLDI guidelines from the prompt, in order to test the model's ability to follow a detailed translator's brief. For the third setting, we again used the full set of instructions, but also provided the model with the complete text of the corresponding French Wikipedia article as additional, in-domain context to inform its translation (see Appendix A.3).

The last translation hypothesis was produced by DeepSeek-R1 (DeepSeek-AI et al., 2025) via its web interface, at the document level, with prompts identical to the first document-level setting used with Llama 4 (guidelines, no corresponding French Wikipedia page; see Appendix A.2). Due to the model's safety filters, it refused to translate a handful of documents pertaining to religion, racism, or politics.

A final processing step was required for all document-level translations. The single block of translated text produced by the LLMs had to be segmented and re-aligned with the original source segments. While this process was largely automated, manual intervention was required for approximately 5% of the documents to correct errors typically resulting from skipped or hallucinated segments, or from the addition of extraneous newlines.

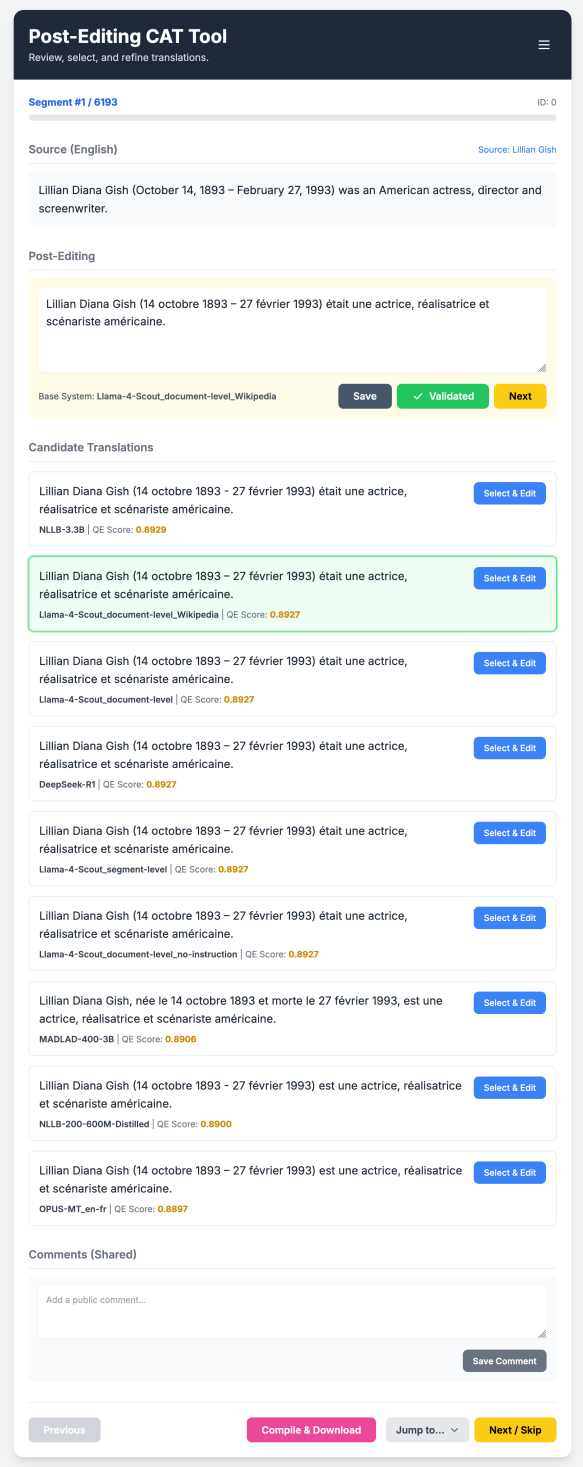

Figure 1: Our custom post-editing interface.

3.2 Human post-edition

The core of our contribution lies in a meticulous post-editing process, which was performed by two

[2] https://oldi.org/translation-guidelines.pdf

native French speakers with C2-level proficiency in English (the first and second authors). A native British English speaker with C2 proficiency in French (the third author) was also available for consultation to resolve ambiguities in the source text.

To facilitate this work, we developed a custom post-editing interface[3] (see Figure 1). For each source segment, the interface presents the user with all nine machine-generated hypotheses, sorted in descending order of their COMET[4] quality estimation (QE) scores (Rei et al., 2022). The post-editor can then select the most promising candidate, which populates a text area for refinement. This process allowed for an efficient workflow focused on two primary goals:

Fluency. Improving the naturalness and readability of the French text. A significant challenge throughout the post-editing process was dealing with various types of errors and disfluencies present in the English source text. These issues, likely stemming from the nature of user-generated content and the automated extraction process used to create the corpus, required careful interpretation and, at times, consultation with other language versions of the Seed corpus to resolve ambiguities. The problems ranged from simple typographical errors and ungrammatical constructions to more complex issues like garden-path sentences and segmentation errors that rendered segments nonsensical. Table 1 provides several examples of these challenges and our resulting post-edited translations.

Accuracy. Rigorously verifying and correcting the translation of technical terminology. Given the encyclopedic nature of the content, this required systematic external research. The corpus covers a dizzying array of technical topics, from cartography and bionanotechnology to Gothic architecture and Hilbert's problems, and verifying the correct terminology for each was a significant undertaking. Official resources like FranceTerme[5] were often of limited use. We therefore relied on extensive documentary research to find correct or acceptable equivalents in French, a crucial step to ensure the corpus can effectively serve as a pivot for the complex neology that will likely be required for translation into the regional languages of France. This task was made more difficult by the increasing prevalence of low-quality, machine-generated content on the web, or "AI slop," which degrades its utility as a reliable concordancer for the translator. In a handful of cases, we consulted with domain experts to resolve particularly challenging terminological issues. Table 2 provides examples of such challenging segments.

3.3 Human validation

After post-editing, all segments were processed through the Grammalecte[6] grammar checker interface (see Figure 2) for a final validation pass, correcting any residual spelling or grammatical errors.

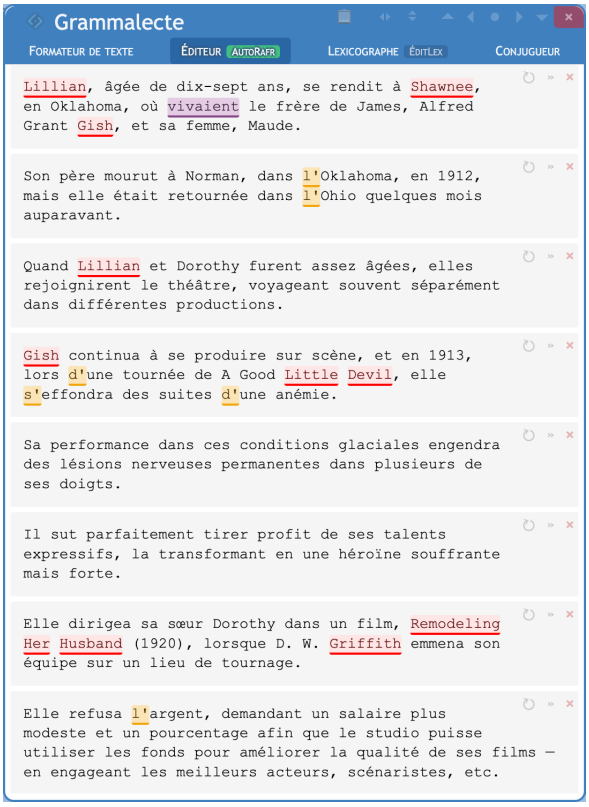

Figure 2: Grammalecte interface used for validation.

As per the shared task guidelines for Seed data, we have ensured that the terms of service for all MT models used allow for the reuse of their outputs. The final dataset is released under the same CC BY-SA 4.0 license as the source corpus.

4 Discussion

While we were initially tempted to follow the validation approach of Cols (2024) by training separate neural MT models on our final corpus and on each set of hypotheses, we ultimately judged that for a

[3]The interface was developed using Vue.js and styled with Tailwind CSS.

ID	English Source & Issue Description
2129	**Source:** "Carleton University and the University of Western Ontario, 1945 and 1946 prospectively, created Journalism specific programs or schools." **Issue:** Typographical, lexical and grammatical errors ("prospectively" for "respectively", missing preposition, capitalization). **Post-edited:** "*L'Université Carleton et l'Université Western Ontario ont créé des programmes ou des écoles spécifiques de journalisme, respectivement en 1945 et 1946.*"
2244	**Source:** "Without social capital in the area of education, teachers and parents who play a responsibility in a students learning, the significant impacts on their child's academic learning can rely on these factors." **Issue:** Ungrammatical and confusing sentence structure (garden path, unclear pronoun reference). Resolved in part by soliciting the opinion of a native English speaker, and by following the interpretation of the Spanish version of the corpus. **Post-edited:** "*Sans capital social dans le domaine de l'éducation, et sans des enseignants et des parents qui jouent un rôle essentiel dans l'apprentissage de l'élève, les impacts significatifs sur l'apprentissage scolaire de leur enfant peuvent dépendre de ces facteurs.*"
3881	**Source:** "The first genetically modified ornamentals commercialized altered color." **Issue:** Garden-path sentence structure. Resolved by following the interpretation of the Italian version of the corpus. (We note that the Spanish version of the OLDI Seed has a different analysis of the segment.) **Post-edited:** "*Les premières plantes ornementales génétiquement modifiées commercialisées changeaient de couleur.*"
4326	**Source:** "When interest rates are very low, the number 0 is included if the interest rate is less than 1%, e.g. "% Treasury Stock", not "% Treasury Stock".)" **Issue:** Apparent error in the source text, likely from faulty extraction of a mathematical or financial example. The error was preserved as per the guidelines. **Post-edited:** "*Lorsque les taux d'intérêt sont très bas, le nombre 0 est inclus si le taux d'intérêt est inférieur à 1 %, par ex. « % Treasury Stock », et non « % Treasury Stock ».)*"
4539	**Source:** "Another early globe, the Hunt–Lenox Globe, ca." **Issue:** Sentence segmentation error; the segment is incomplete. **Post-edited:** "*Un autre des premiers globes, le globe Hunt–Lenox, env.*"

Table 1: Examples of challenges encountered in the source text during post-editing.

ID	English Source & Terminological Field
4044	**Source (Nanotechnology):** "Another group of nanotechnological techniques include those used for fabrication of nanotubes and nanowires, those used in semiconductor fabrication such as deep ultraviolet lithography, electron beam lithography, focused ion beam machining, nanoimprint lithography, atomic layer deposition, and molecular vapor deposition, and further including molecular self-assembly techniques such as those employing di-block copolymers." **Post-edited:** "*Un autre groupe de techniques nanotechnologiques comprend celles utilisées pour la fabrication de nanotubes et de nanofils, celles utilisées dans la fabrication de semi-conducteurs telles que la lithographie ultraviolette profonde, la lithographie par faisceau d'électrons, l'usinage par faisceau d'ions focalisés, la lithographie par nano-impression, le dépôt en couches atomiques et le dépôt moléculaire en phase vapeur, et incluant en outre des techniques d'auto-assemblage moléculaire telles que celles employant des copolymères à diblocs.*"
4845	**Source (Gothic Architecture):** "Lancet windows were supplanted by multiple lights separated by geometrical bar-tracery." **Post-edited:** "*Les fenêtres en lancette furent supplantées par des baies multiples séparées par des remplages géométriques.*"

Table 2: Examples of segments requiring specialized terminological research.

well-resourced language pair like English-French, and given that the initial MT hypotheses were already of a high standard—failing mostly on specific terminological choices and disfluencies inherited from the source—quality estimation using a state-of-the-art metric would provide a more telling as well as a more environmentally responsible validation of our data.

Although we had used a COMET-based QE model in our post-editing interface, we had observed certain limitations, such as insensitivity to terminological accuracy and a tendency to reward superficial trivial features (like hyphen or apostrophe type) at the expense of more essential features in the candidate translations. For our final validation, we therefore chose MetricX-24[7] (Juraska et al., 2024), a top-performing hybrid reference-based and reference-free metric. MetricX-24 is trained on human judgements (MQM and DA ratings; cf. Lommel et al. 2013; Graham et al. 2013) and predicts an error score, where lower scores indicate higher quality. This allows for a direct comparison of our final, human post-edited translations against the raw machine-generated hypotheses, thereby quantifying the value added by our human-in-the-loop process.

We scored our final post-edited translations and the raw outputs of the nine systems used to generate initial hypotheses. The results, including 95% confidence intervals and statistical significance groupings, are presented in Table 3.

As noted in Section 3.1, DeepSeek-R1 refused to translate a small number of documents due to its safety filters. To ensure a fair comparison of translation quality on the segments all systems were able to process, we also performed an analysis excluding these 165 segments. The results of this filtered evaluation are presented in Table 4.

Both analyses clearly validate the quality of our contributed dataset. The human post-edited text achieves the lowest average error score by a significant margin, placing it in a statistical group of its own (Group A), confirming the soundness and effectiveness of our manual post-editing and validation process. Among the machine-generated hypotheses, the results on the full dataset (Table 3) show a top tier (Group B) consisting of the larger sequence-to-sequence models and the segment-level Llama 4 Scout prompt. However, when excluding the segments DeepSeek-R1 refused to translate (Table 4), its relative performance improves significantly, moving it into this top tier of MT systems. This was not surprising, as we were consistently impressed during post-editing by DeepSeek-R1's knowledge of even the most arcane terminology, which we systematically verified through arduous external research ourselves. The remaining rankings are largely consistent across both analyses. Interestingly, all document-level prompting strategies for Llama 4 Scout were slightly less effective than the segment-level approach. The setting that ablated the specific OLDI guidelines ("no-instruction") performed on par with the standard document-level prompt from the point of view of MetricX-24; a direct comparison reveals that the specific OLDI guidelines had a limited impact on model generation, as these two settings produced identical translations in over 76% of cases, and for the minority of instances where they differed, the average Translation Edit Rate (TER; cf. Olive 2005; Snover et al. 2006) was a relatively low 9.48, indicating the variations were typically minor. Counter-intuitively, providing the model with the corresponding French Wikipedia article as additional context resulted in a statistically significant degradation in quality. Finally, the weakest-performing systems across all settings were the smaller distilled NLLB model and the bilingual OPUS-MT model.

Our post-editing logs offer another lens through which to evaluate the raw quality of the MT hypotheses. Of the 6,193 segments in the corpus, 3,043 (49.14%) had at least one machine-generated hypothesis that was deemed perfect by the post-editors and required no changes. A breakdown by system reveals that DeepSeek-R1 was by far the most reliable, providing the "perfect" translation in 2,503 instances, or 40.42% of all segments in the corpus. The other systems lagged considerably behind, with the various Llama 4 Scout prompting strategies and the larger NLLB and MADLAD models providing the perfect match in 7-9% of cases, while the smaller NLLB and OPUS-MT models did so less than 5% of the time.

5 Related Work

While data-driven approaches to MT have precedents as early as the 1950s (Edmundson and Hays, 1958), they did not truly come into their own until the late 1980s and early 1990s with the pioneering work on statistical machine translation (SMT) at

IBM (Brown et al. 1990; Berger et al. 1994). This early research was heavily reliant on the availability of large parallel corpora, and the French-English language pair played a central role, largely thanks to the Canadian Hansard, a bilingual record of parliamentary proceedings. So influential was this corpus that it established a lasting convention in SMT literature, where the letters f and e became the standard variables to denote source ($f$rench) and target ($e$nglish) language strings in equations, regardless of the actual languages involved. Our work builds on the modern legacy of these corpus-based approaches. Specifically, we contribute to the OLDI Seed Corpus (NLLB Team et al., 2022; Maillard et al., 2023), a resource designed to bootstrap translation capabilities for low-resource languages. The OLDI shared task has spurred several recent efforts to expand this dataset, including the creation of Spanish (Cols, 2024), Italian (Ferrante, 2024; Haberland et al., 2024), and Bangla (Ahmed et al., 2024) partitions, each contributing to this growing ecosystem of open, multiparallel data.

6 Conclusion

In this paper, we have presented our contribution to the WMT 2025 OLDI shared task: a high-quality, human-post-edited French partition of the OLDI Seed Corpus. We have detailed our data creation methodology, which relied on a diverse array of MT systems and approaches—from traditional NMT models to various LLM prompting strategies—and a custom-built interface to facilitate an efficient and robust post-editing workflow. Our experimental validation, using the state-of-the-art MetricX-24 QE metric, confirmed that our final, manually-refined corpus is of significantly higher quality than any of the individual machine-generated hypotheses. Our primary motivation for this work is to provide a reliable pivot resource to enable the future development of translation capabilities for the under-resourced regional languages of France. We hope that this dataset, along with the supplementary collection of raw MT outputs, will serve as a valuable contribution to the community and a stepping stone towards this long-term goal.

Limitations

Our discussion of relative system performance in Section 4 should be interpreted with one caveat. To enable qualitative observations during post-edition, we did not anonymize the MT systems in our interface (see Figure 1), a design choice that may have led to a "halo effect." The particular strength of one system (DeepSeek-R1) on challenging terminology, for instance, might have favorably influenced post-editor choice over time and slightly biased our logs.[8]

A key challenge in this work was navigating the tension between the OLDI translation guidelines, which tend to favor a more literal translation approach, and the need to resolve the stylistic and grammatical disfluencies often present in the source Wikipedia segments. While our post-editing process aimed to produce fluent French, a review of the final data in isolation from the source text reveals that some of these disfluencies, while corrected, may have still carried over into the target segments to some extent. This appears to be a common difficulty when working with this particular source corpus; indeed, a brief review of the recently released Italian (Ferrante, 2024; Haberland et al., 2024) and Spanish (Cols, 2024) partitions suggests that their respective translation teams grappled with similar issues. As this French corpus is intended primarily as a pivot resource, we plan to monitor its use in the translation into regional languages of France and will consider releasing future revisions should any significant issues be surfaced during this process.
