In adherence to the OLDI shared task's commitment to open data, all systems used to generate translation hypotheses were carefully selected to ensure that their terms of service were compatible with the final dataset's release under a CC BY-SA 4.0 license. While we initially considered including hypotheses from popular commercial systems such as Google Translate and DeepL, we ultimately decided against it, as their terms of service prohibit the use of their outputs for the purpose of training other machine translation models.

The generation of translation hypotheses using LLMs is a computationally intensive process with an associated environmental cost. We strove to be mindful of this fact throughout our work.

We hope that our contribution will encourage further community-driven expansions of the OLDI Seed Corpus. As human societies grapple with the threat of "digital language death" (Kornai, 2013), the OLDI Seed Corpus project is particularly valuable. Its focus on the idiosyncratic Wikipedia domain is strategic, as the online encyclopedia plays a dual role in language revitalization: it is both a direct resource for creating the NLP artifacts essential for technological support, and a key instrument for "language ascent" (Kornai, 2013) that helps communities bridge the digital divide. Expanding this multiparallel dataset is therefore a direct and meaningful way to support these vital efforts.

Acknowledgements

This work was funded by the French *Agence Nationale de la Recherche* (ANR) under the project TraLaLaM ("ANR-23-IAS1-0006"), as well as by Inria under the "*Défi*"-type project COLaF. The last two authors' participation was also partly funded through their chairs in the PRAIRIE institute, supported by the ANR as part of the "*Investissements d'avenir*" program under the reference "ANR-19-P3IA-0001," and through the "*France 2030*" program under the reference "ANR-23-IACL-0008."

This work was also granted access to the HPC resources of IDRIS under the allocation 2025-AD011015117R2 made by GENCI.

[8] Reassuringly, however, the initial listing of translation candidates in decreasing order of their COMET QE scores in the post-editing interface does not appear to have induced a strong bias of its own. The average ranks for the top seven systems were tightly clustered in a narrow range (4.12–4.44 out of 9), indicating that no one system consistently dominated the top of the list, suggesting that post-editors were presented with a varied set of top-ranked candidates for most segments. While DeepSeek-R1 was the system whose output was most frequently selected by post-editors as "perfect" (requiring no edits in 40.42% of cases), the automated metric ranked it first for only 23.53% of segments, and its average rank of 4.27 was in the middle of the pack. This discrepancy supports the hypothesis that the post-editors' preference was driven by a human assessment of quality (particularly on terminology) rather than a bias induced by the tool's ranking.

A Prompt Samples

A.1 Segment-Level Prompt

> You are an expert English-French translator of encyclopedic documents. In translating, you adhere to the following guidelines:
> 1. Refer to the source document context when available. Context helps clarify meaning, resolve ambiguities, and maintain tone and accuracy in translation.
> 2. Do not convert any units of measurement. Translate them exactly as noted in the source content.
> 3. Encyclopedic documents should be translated using a formal tone.

4. Provide fluent translations without deviating excessively from the structure of the source segment.
5. Do not expand or replace information compared to what is present in the source segment. Do not add any explanatory or parenthetical information, definitions, etc.
6. Do not ignore any meaningful text that was present in the source segment.
7. If a named entity in the source language has a canonical equivalent in the target language, use this canonical equivalent.
8. If a named entity in the source language does not have a canonical equivalent in the target language, you may use the source term in your translation.
You are to translate the following English source segment into French:
"Her father died in Norman, Oklahoma, in 1912, but she had returned to Ohio a few months before this."
Here is the segment in some of its original context; please note that the context may include parts of the source document that are not directly adjacent to the main segment, and omissions may not be explicitly marked with ellipses. Nonetheless, this context remains valuable for clarifying meaning, resolving ambiguity, and ensuring consistency in tone and terminology:
Gish was a prominent film star from 1912 into the 1920s, being particularly associated with the films of director D. W. Griffith.
She also did considerable television work from the early 1950s into the 1980s, and closed her career playing opposite Bette Davis in the 1987 film The Whales of August.
The first several generations of Gishes were Dunkard ministers.
Their mother opened the Majestic Candy Kitchen, and the girls helped sell popcorn and candy to patrons of the old Majestic Theater, located next door.
The seventeen-year-old Lillian traveled to Shawnee, Oklahoma, where James's brother Alfred Grant Gish and his wife, Maude, lived.
Her father died in Norman, Oklahoma, in 1912, but she had returned to Ohio a few months before this.
A reminder that the English segment you must translate into French is:
"Her father died in Norman, Oklahoma, in 1912, but she had returned to Ohio a few months before this."
You may reflect on the task at hand and explain your chain of thought prior to producing the translation.
IMPORTANT: Do write your translation between tags in the following manner: <translation>your translation here</translation>.

A.2 Document-Level Prompt

You are an expert English-French translator of encyclopedic documents. In translating, you adhere to the following guidelines:
1. Refer to the source document context when available. Context helps clarify meaning, resolve ambiguities, and maintain tone and accuracy in translation.
2. Do not convert any units of measurement. Translate them exactly as noted in the source content.
3. Encyclopedic documents should be translated using a formal tone.
4. Provide fluent translations without deviating excessively from the structure of the source segment.
5. Do not expand or replace information compared to what is present in the source segment. Do not add any explanatory or parenthetical information, definitions, etc.
6. Do not ignore any meaningful text that was present in the source segment.
7. If a named entity in the source language has a canonical equivalent in the target language, use this canonical equivalent.
8. If a named entity in the source language does not have a canonical equivalent in the target language, you may use the source term in your translation.
You are to translate the following English document into French. Please note that the following document may include omissions that are not explicitly marked with ellipses. Do not be perturbed by such minor inconsistencies in the source text. These segments were taken from an English Wikipedia page dedicated to 1. IMPORTANT! Please take careful note of the newline characters, as you will need to reproduce them perfectly in your French translation to allow for the automatic alignment of these segments with their English source.
—- BEGINNING OF ENGLISH SOURCE DOCUMENT —-
1 (one, also called unit, and unity) is a number and a numerical digit used to represent that number in numerals.
In conventions of sign where zero is considered neither positive nor negative, 1 is the first and smallest positive integer.
Most if not all properties of 1 can be deduced from this.
It is thus the integer after zero.
It was transmitted to Europe via the Maghreb and Andalusia during the Middle Ages, through scholarly works written in Arabic.
Styles that do not use the long upstroke on digit 1 usually do not use the horizontal stroke through the vertical of the digit 7 either.
By definition, 1 is the magnitude, absolute value, or norm of a unit complex number, unit vector, and a unit matrix (more usually called an identity matrix).
In category theory, 1 is sometimes used to denote the terminal object of a category.
Since the base 1 exponential function (1x) always equals 1, its inverse does not exist (which would be called the logarithm base 1 if it did exist).
Likewise, vectors are often normalized into unit vectors (i.e., vectors of magnitude one), because these often have more desirable properties.
It is also the first and second number in the Fibonacci sequence (0 being the zeroth) and is the first number in many other mathematical sequences.
Nevertheless, abstract algebra can consider the field with one element, which is not a singleton and is not a set at all.
A binary code is a sequence of 1 and 0 that is used in computers for representing any kind of data.
+1 is the electric charge of positrons and protons.
The Neopythagorean philosopher Nicomachus of Gerasa affirmed that one is not a number, but the source of number.
We Are Number One is a 2014 song from the children's TV show LazyTown, which gained popularity as a meme.
In association football (soccer) the number 1 is often given to the goalkeeper.

1 is the lowest number permitted for use by players of the National Hockey League (NHL); the league prohibited the use of 00 and 0 in the late 1990s (the highest number permitted being 98).
—- END OF ENGLISH SOURCE DOCUMENT —-
Only output the translation directly, religiously respecting new lines. Do not add extraneous new lines.

A.3 Document-Level Prompt with Corresponding French Wikipedia Article

You are an expert English-French translator of encyclopedic documents. In translating, you adhere to the following guidelines:
1. Refer to the source document context when available. Context helps clarify meaning, resolve ambiguities, and maintain tone and accuracy in translation.
2. Do not convert any units of measurement. Translate them exactly as noted in the source content.
3. Encyclopedic documents should be translated using a formal tone.
4. Provide fluent translations without deviating excessively from the structure of the source segment.
5. Do not expand or replace information compared to what is present in the source segment. Do not add any explanatory or parenthetical information, definitions, etc.
6. Do not ignore any meaningful text that was present in the source segment.
7. If a named entity in the source language has a canonical equivalent in the target language, use this canonical equivalent.
8. If a named entity in the source language does not have a canonical equivalent in the target language, you may use the source term in your translation.
The document you will translate consists in segments taken from an English Wikipedia page dedicated to North. Here is what appears to be the corresponding French Wikipedia page (back-matter sections have been removed). It might provide you with the correct terminology and equivalent named entities, pay close attention to these aspects as you read this French text.
—- BEGINNING OF FRENCH WIKIPEDIA ARTICLE —-
Le nord est un point cardinal, opposé au sud.
== Étymologie ==
De l'ancien haut-allemand nord provenant de l'unité linguistique proto-indo-européenne « ner- » qui signifie « gauche », se rapportant sans doute à la gauche du soleil levant.
Le nom de la divinité scandinave Njörd, ayant régné sur une partie du monde pendant un âge d'or, est lié à cette racine[réf. souhaitée]. Cette divinité était connue des Romains sous le nom de Nerthus et avait donné son nom à une des îles du bout du monde, Nérigon.
En latin, Septemtriones signifie les sept bœufs. L'astérisme le plus brillant de l'actuelle constellation de la Grande Ourse, était autrefois une constellation à part entière appelée constellation des sept bœufs. Ce groupement d'étoiles permettait de trouver l'étoile polaire et donc le Nord avec une bonne précision.
Le terme septentrion est un synonyme vieilli de nord, faisant référence à cette constellation qui indiquait la direction du nord aux Romains ; mais l'adjectif septentrional, qui en découle, reste très usité.
== Géographique et magnétique ==
Il existe deux nord. Le premier est magnétique (l'axe de symétrie cylindrique du champ magnétique), le second est géographique (l'axe de rotation de la Terre). Ces deux points ne se trouvent pas au même endroit. Mesuré en 2007 par le projet « Poly-Arctique », le pôle Nord magnétique est situé à 83° 57' 00" N, 121° 01' 12" O. Il se trouve à 673 km du pôle Nord géographique et ayant une vitesse moyenne de déplacement de 55 km/an (soit une moyenne d'environ 150 m/jour ou 6 m/h). À l'été 2010, il a été estimé qu'il n'était plus qu'à 550 km du pôle Nord géographique.
La différence d'angle que l'on peut observer sur la boussole entre ces deux nord est appelée déclinaison magnétique. Cette différence varie avec le temps.
Sur les cartes traditionnelles et en particulier les cartes de l'Institut national de l'information géographique et forestière (IGN), les méridiens (lignes noires verticales) pointent le nord géographique (NG) ; il y a donc lieu de tenir compte de la déclinaison magnétique pour s'orienter sur la carte à l'aide d'une boussole (NM). Le croquis situé dans la légende de la carte indique la valeur de la déclinaison pour la carte et pour une année donnée, car le pôle magnétique migre en permanence, réduisant chaque année la valeur de la déclinaison (0,8 degré/an).
Certains cartographes ont contourné cette complication en construisant des cartes tenant compte de cette déclinaison : le nord (N) de la carte ainsi que les lignes verticales en bleu ou en noir pointent le nord magnétique (de la même manière que l'aiguille de la boussole).
La position du nord magnétique a changé plusieurs fois dans l'histoire de la Terre ; la dernière inversion du champ magnétique terrestre s'est produite il y a 780 000 ans.
En l'absence de boussole, le moyen traditionnel pour repérer le nord le soir ou la nuit est de se référer à l'étoile polaire dans l'hémisphère nord ou à la croix du Sud dans l'hémisphère sud. Le jour, il est possible de se référer à la position du Soleil en fonction de l'heure locale. Lorsque le ciel est couvert, observer la mousse ou les vents dominants est peu fiable.
== Typographie ==
Les points cardinaux, qu'ils soient utilisés comme nom ou comme qualificatif, s'écrivent avec :
une majuscule lorsqu'ils font partie d'un toponyme ou désignent une région ;
une minuscule s'ils désignent une direction, une exposition, une orientation.

—- BEGINNING OF ENGLISH SOURCE DOCUMENT (this line need not be translated) —-
North is one of the four compass points or cardinal directions.

Septentrionalis is from septentriones, "the seven plow oxen", a name of Ursa Major.
For example, in Lezgian, kefer can mean both "disbelief" and "north", since to the north of the Muslim Lezgian homeland there are areas formerly inhabited by non-Muslim Caucasian and Turkic peoples.
On any rotating astronomical object, north often denotes the side appearing to rotate counter-clockwise when viewed from afar along the axis of rotation.
But simple generalizations on the subject should be treated as unsound, and as likely to reflect popular misconceptions about terrestrial magnetism.

Abstract

Recent advances in neural machine translation (NMT) have opened new possibilities for developing translation systems also for smaller, so-called low-resource, languages. The rise of large language models (LLMs) has further revolutionized machine translation by enabling more flexible and context-aware generation. However, many challenges remain for low-resource languages, and the availability of high-quality, validated test data is essential to support meaningful development, evaluation, and comparison of translation systems. In this work, we present an extension of the FLORES+ dataset for two Ladin variants, Val Badia and Gherdëina, as a submission to the Open Language Data Initiative Shared Task 2025. To complement existing resources, we additionally release two parallel datasets for Gherdëina–Val Badia and Gherdëina–Italian. We validate these datasets by evaluating state-of-the-art LLMs and NMT systems on this test data, both with and without leveraging the newly released parallel data for fine-tuning and prompting. The results highlight the considerable potential for improving translation quality in Ladin, while also underscoring the need for further research and resource development, for which this contribution provides a basis.

1 Introduction

In recent years, the field of machine translation (MT) and natural language processing has advanced rapidly and the transformer-based models played a key role in this development (Vaswani et al., 2023; Aharoni et al., 2019). This paradigm shift has enabled the development of high-quality MT systems for major languages as well as the adaptation of such systems to low-resource languages by leveraging pre-trained knowledge (Zoph et al., 2016; Kocmi and Bojar, 2018). Earlier rule-based and statistical MT approaches lacked this capability as they depended on large, clean, and domain-specific parallel corpora, thus limiting the availability of these technologies for most low-resource languages. The release of large-scale multilingual systems, such as No Language Left Behind (NLLB) (NLLB Team et al., 2024), has demonstrated that scalable and accurate translation is possible even for smaller languages.

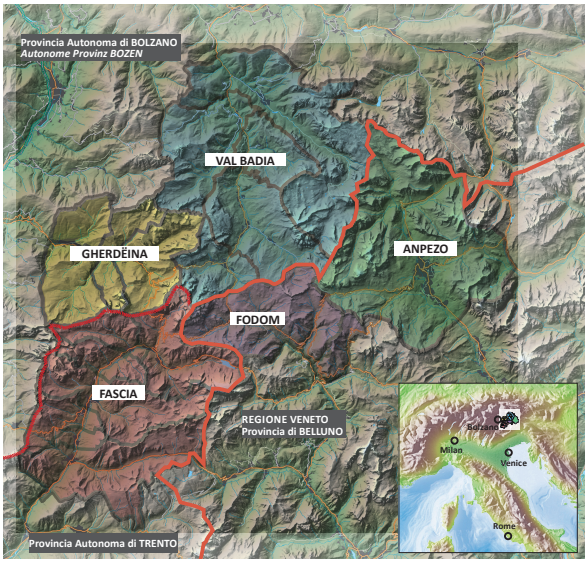

Figure 1: The five Ladin-speaking valleys located across three provinces in northern Italy: Val Badia (blue) and Gherdëina (yellow) in the Autonomous Province of Bolzano/Bozen South Tyrol, Fascia (red) in the Autonomous Province of Trento, Fodom (purple) and Anpezo (green) in the Province of Belluno.

Essentially, developing machine translation systems has actually become easier as it is no longer just about language expertise. Instead, the generalizability capabilities of language models are being exploited, and the limitations now lie more in providing training data and infrastructure. However, its development depends on reliable and extensive test data, which is essential for consistent evaluation, model comparison, and tracking progress over time. The FLORES+ dataset provides such a benchmark and covers more than 200 languages (NLLB Team et al., 2024). It is widely used in research on

Proceedings of the Tenth Conference on Machine Translation, pages 1061–1071
November 8-9, 2025

low-resource languages because of its broad language coverage and its ability to support evaluation across more than 19,900 language pairs.

With this in mind, we release the FLORES+ translations for the Ladin language. Ladin is a Rhaeto-Romance language that originated from Vulgar Latin during the Roman conquest of the Alps. It evolved in isolated Alpine valleys, leading to the diverse regional varieties spoken today in Northern Italy (Bauer, 2022). As a result of the fragmented development over centuries there is no single, unified spoken variety for Ladin that is characterised by its internal linguistic diversity, with five main regional variants depicted in Figure 1: *Val Badia*, *Gherdëina*, *Fassa*, *Fodom*, and *Anpezo*. In this work, we extend FLORES+ with translations for Val Badia and Gherdëina. Both variants are spoken in South Tyrol and together representing the largest portion of Ladin speakers. The dataset translation was carried out by professionals at the Ladin Cultural Institute "Micurá de Rü", the primary institution dedicated to preserving and supporting the development of the language.

Moreover, we release parallel datasets for Val Badia–Gherdëina and Gherdëina–Italian that can be used for fine-tuning or retrieval-augmented prompting for this language. These two datasets enables to provide an overview of the performance of `NLLB` and state-of-the-art Large Language Models (LLMs), including `GPT-3.5`, `GPT-4o`, `Llama-3.3`, and `DeepSeek-R1` on Ladin (Val Badia and Gherdëina).

In summary, the contributions of our work are:

1. We submit the FLORES+ translations for Val Badia Ladin (full) and Gherdëina Ladin (`dev` split)

2. We release two parallel datasets of approximately 18,000 sentence pairs for Gherdëina–Italian and Gherdëina–Val Badia.

3. We benchmark state-of-the-art machine translation systems and LLMs on this dataset, identifying current limitations and outlining opportunities for advancing MT for Ladin.

With this, we aim to increase the visibility of Ladin within the MT research community, highlight the ongoing need for focused research on this language, and provide resources that empower researchers and developers worldwide to advance Ladin machine translation.

2 The Ladin Language

Ladin should not be confused with *Ladino* (`lad`), a Judeo-Spanish language. This confusion is common, especially in Italian where Ladino can refer to both; to avoid ambiguity, the term *Ladino delle Dolomiti* (Dolomite Ladin) is often used. Ladin is identified by the ISO 639-3 code `lld`.

For a comprehensive treatment of the language's history, dialectal variation, and sociolinguistic context, we refer the reader to Pescosta (2015); Videsott et al. (2020); Bauer (2022). For a recent contribution discussing the state of the Ladin language in the Dolomite region, we refer to Videsott (2023); Colcuc (2024).

2.1 Historical Development

Ladin is a Romance language that is traditionally associated with Romansh of the Grisons in Switzerland and Friulian of north-eastern Italy within the Rhaeto-Romance group (Videsott et al., 2020). It traces its origins to the Vulgar Latin introduced during the Roman conquest of the Alpine region around 15 BC. Over time, the native populations gradually adopted this Latin, which absorbed elements of pre-Roman languages such as Celtic and Raetic. With the fall of the Western Roman Empire, the evolving Romance dialects began to diverge, influenced by the surrounding Germanic languages and political fragmentation. As Germanic tribes advanced, the speakers of early Ladin were pushed into isolated Alpine valleys, where the language continued to evolve separately from other Romance varieties. This geographic and historical isolation laid the foundation for the internal diversity of Ladin seen today in the Dolomite region of Northern Italy where each variant reflects the unique historical trajectory and degree of contact with neighbouring languages.

The internal linguistic diversity of Ladin has not only historical roots but has also been reinforced by political-administrative fragmentation in the 20th century. Following the annexation of South Tyrol by Italy after the Treaty of Saint-Germain (1919) and the Italianisation policies introduced under the Fascist regime, Ladin-speaking territories were divided among three different provinces: *Val Badia* and *Gherdëina* became part of the autonomous province of Bolzano (South Tyrol), *Fassa* was integrated into the province of Trento, and *Fodom* and *Anpezo* were assigned to the province of Belluno

in the Veneto region (see Figure 1[1]). This fragmentation led to differing levels of legal recognition, educational support, and public visibility for Ladin communities depending on the province.

2.2 Contemporary Situation

The degree of institutional support and practical implementation of Ladin varies among the different regions. In South Tyrol, Ladin enjoys strong official recognition and robust backing in administration, education, and media. According to the 2024 South Tyrol census[2], approximately 4.41% (19.853) of South Tyroleans declared themselves as belonging to the Ladin language group. The highest proportions of Ladin speakers are found in Val Badia, where 97% of the population, and in Val Gardena, where 85% of the population, identify as Ladin-speaking. This corresponds to around 20,000 people Ladin speakers in South Tyrol.

In the Trentino (Fassa Valley), Ladin is also officially recognized but coexists with a stronger presence of Italian, resulting in comparatively less institutional support and daily use. Based on the 2021 census[3], 2.9% (15.775) of residents identified as Ladin speakers in Trentino.

Meanwhile, in the Veneto valleys of Livinallongo and Ampezzo, its status is more limited, and the language faces greater challenges regarding vitality and institutional presence. The precise number of native Ladin speakers in the traditional (formerly Austrian) Dolomites Ladin area of Veneto (namely Fodom and Anpezo valleys) is not available, but can be estimated to be around 4-6,000[4]. Together, these figures amount to an estimated 40.000 Ladin speakers.

Three cultural institutes, set up as public bodies in the three different Provinces, with a total staff of around 20 people[5] work on standardisation, the creation of digital tools, and the promotion of the social status of the language, following the three traditional axes of language policy for minority languages (status-, corpus- and acquisition planning; see Iannaccaro and Dell'Aquila (2004) for further details). Moreover, a Chair of Ladin Language and Culture Studies has been established at the Free University of Bolzano (*Université Lieida de Bulsan*)[6].

2.3 Linguistic and MT Research on Ladin

Linguistic research on Ladin has a long tradition and remains very active, notably through the journal *Ladinia*[7], which has appeared 49 times since its inception in 1977. Another journal devoted to Ladin studies is *Mondo Ladino*[8], also founded in 1977.

While few published parallel datasets exist for Ladin, existing experiments indicate that state-of-the-art machine translation techniques can be adapted to this low-resource language. Frontull and Moser (2024b) developed an NMT system for Val Badia Ladin and compared it to rule-based and statistical systems; Frontull and Moser (2024a) studied back-translation using `GPT-3.5`; and Valer et al. (2024) created a bidirectional system for Fassa Ladin using multilingual training and knowledge transfer, comparing it to `GPT-4o`. However, the test data used in these studies was limited in scope, preventing broader comparability of results and restricting evaluation to Ladin–Italian translation. There is still much potential to explore how to make even better use of the available resources.

2.4 Ladin of Val Badia and Gherdëina

Although ISO 639-3 assigns a single code (`lld`) to Ladin, it may be more accurate to consider `lld` as a macrolanguage encompassing at least five standardized written variants: Ladin of *Val Badia*, *Gherdëina*, *Fascian*, *Fodom*, and *Anpezan*. In this work, we focus on and provide translations for the two written standards of Val Badia Ladin and Gherdëina Ladin, which can be specifically identified using the IETF BCP 47 language tags[9] `lld_valbadia` and `lld_gherd` respectively. These correspond to Glottolog code `gard1241`[10] for Gherdëina. For Val Badia, there is no exact correspondence, as the spelling unifies `badi1244`

English	The walls and roofs of ice caves can collapse and cracks can get closed.
Italian	Le pareti e il soffitto delle caverne di ghiaccio sono soggetti a crolli e le crepe possono richiudersi.
Val Badia	I parëis y le sössot di andri da dlacia pó tomé ite y les sfësses pó se stlüje pro.
Gherdëina	I parëies y i plafons dla ciavernes tla dlacia possa tumé ite y la sfëntes possa se stlù.

Table 1: Example translations from the FLORES+ dev split.

and mare1258, with badi1244[11] being the more appropriate mapping.

Linguistic Features Socio-linguistically, in Gardena and Badia valleys Ladin is in contact both with German (in the local dialectal form and in the standard official form) and Italian, in the remaining valleys Italian is the dominant contact language (Videsott et al., 2020). Being Ladin a romance language, standard Italian is in any case a natural point of comparison to highlight important linguistic differences that affect machine translation. Ladin differs from Italian in several ways that are relevant for MT. In the following, we summarize key differences taken from (Bauer, 2022) Phonologically, Ladin features voicing of intervocalic stops (e.g., Latin *p*, *t*, *k* become voiced between vowels), retention of final *-s* to mark plurals, and palatalisation of *c*, *g* before *a*. These sound changes are consistently reflected in Ladin spelling, which means the written forms differ systematically from Italian. Morphologically, Ladin has a complex pattern of plural endings (*-s*, *-i*, other form of palatised consontant) that Italian lacks. Additionally, Ladin has a high number of loanwords from Germanic languages due to long-standing contact (especially for northern varieties), with southern varieties borrowing mainly from Italian, resulting in significant lexical variation even within Ladin written and oral varieties. These phonological, morphological, and lexical differences shape the vocabulary and structure that MT systems must handle, making their accurate representation essential for building effective Ladin machine translation models and a compelling case for natural language processing research.

To give an intution on the similarity between the two variants and Italian and on the difficulty of the translation task, we computed the BLEU score obtained by leaving the text untranslated, which resulted in a score of 5.0 for Italian–Val Badia, 4.3 for Italian–Gherdëina and 12.9 for Val Badia–Gherdëina. Table 1 presents a sample translation of the English sentence *"The walls and roofs of ice caves can collapse and cracks can get closed."* into Val Badia and Gherdëina, as found in the submitted dev split of FLORES+, illustrating these similarities.

Relevant Resources Although relatively little previous research has focused on machine translation for Ladin, significant and valuable work has been carried out in the development of the language itself. Comprehensive dictionaries have been compiled, alongside essential language reference materials, including books detailing grammar and spelling rules. In the following we list relevant resources for the variants in focus in this work developed by the Ladin Cultural Institute "Micurá de Rü":

- *Grafia nöia - Ladin scrit dla Val Badia* (Mischí et al., 2015) is a practical guide to the standardized orthography of Ladin as used in Val Badia which was reformed in 2015.
- *La ortografia dl ladin de Gherdëina* (Forni, 2019b) is a practical guide to the standardized orthography of Ladin as used in Val Gardena.
- *Dizionario italiano - ladino Val Badia* (Moling et al., 2016) is a bilingual dictionary published in 2016. The dictionary includes 30,829 Italian lemmas and 32,701 Ladin lemmas, along with 18,120 phraseological expressions. It offers morphological and encyclopedic information.
- *Dizionario italiano - ladino gardenese* (Forni, 2013) is a bilingual dictionary published in 2013. Authored by Marco Forni, this work is an essential resource for the Ladin language as spoken in Val Gardena (Gherdëina). This extensive bilingual dictionary, contains over 67,000 entries and nearly 20,000 phraseological expressions, provides detailed lexical information along with contextual examples.
- *Gramatica Ladin Gherdëina* (Forni, 2019a), authored by Marco Forni and published in

[11] https://glottolog.org/resource/languoid/id/badi1244

2019. Covering phonetics, morphology, and syntax, it is a comprehensive grammatical reference for the Ladin language as spoken in Val Gardena.

- Several *technical and domain-specific glossaries* are available for Ladin, including, for example, mobile phone interfaces fully translated in collaboration with Motorola (Oliveira et al., 2024) and terminology in pedagogy[12]. Glossaries in other domains, such as music, animals and plants, history, and historiography, are currently under elaboration.

- *Spellchecker*: online tools[13] as well as Firefox Add-ons are available for Val Badia[14] and Gherdëina. [15]

- set of *18k parallel sentences for Ladin Val Badia–Italian*, as used in (Frontull and Moser, 2024a), available at HuggingFace[16]

We leveraged the existing dictionaries to implement spelling correction and extracted the parallel sentences contained in the datasets we release these resources.

3 Data collection

The translation of the FLORES+ dataset into Ladin was carried out in close collaboration with the Ladin Cultural Institute "Micurá de Rü"[17]. In this section, we provide an overview of the translators involved, the tools used, the procedures followed for the different Ladin variants, and the quality assurance measures implemented.

Translators The translation team consisted of five translators for Val Badia and two translators for Gherdëina. All translators involved in this process are (or were at the time of the project) employed by the Ladin Cultural Institute, where they work professionally with Ladin and therefore have extensive experience using the language in both spoken and written forms. They are native speakers of Ladin and hold a C1-level certification in Ladin, obtained through the official language exams[18] regulated by the Autonomous Province of Bolzano/Bozen, making them highly valuable collaborators, whose contributions ensure reliable, high-quality work. All translators also have a good understanding of English (though not formally certified) and are fluent at C1 level in both German and Italian. Prior to beginning the task, all translators were asked to carefully read and acknowledge the OLDI translation guidelines[19], which explicitly require human translation, prohibit the use of machine translation systems and provide detailed instructions on tone, consistency, fidelity to the source, and the handling of named entities. In accordance with these guidelines, translators were instructed to base their work primarily on the English source texts. However, due to their proficiency in German and Italian, these translations were also provided as additional references. Due to the linguistic similarities between Ladin and Friulian, these texts were also included as reference texts.

Translation Assignment Tool The work was divided into kits of 25 sentences. To manage and assign the translation work, a dedicated web-based platform was set up. This tool allowed kits to be assigned to specific translators and the progress of the translation to be monitored, eliminating the need to distribute and manage separate text files. The tool displays the original English text along with reference translations into German, Italian, Friulian, and, for Gherdëina, also the translation into Val Badia. Translators can enter their Ladin translation directly into an input field. The tool also has a built-in spell checker that highlights unknown or potentially misspelled words and helps users identify and correct typos. Figure 2 shows a screenshot of the user interface for a sentence to be translated, with the English source text, reference translations, and the input field for the Ladin translation. Sentences can also be skipped and revisited later.

Val Badia Translations In a first phase, the sentences were translated into the Ladin Val Badia. Each translator received two kits per week, a work-

[16] https://huggingface.co/datasets/sfrontull/lld_valbadia-ita

[17] https://micura.it

[18] The exams include listening, writing, speaking, and reading comprehension and are offered in both the Gherdëina and Val Badia varieties. This certification is a prerequisite for a permanent employment at the Ladin Cultural Institute in South Tyrol. For more information we refer to https://zweisprachigkeitspruefungen.provinz.bz.it/de/ladinischpruefung

[19] https://oldi.org/guidelines

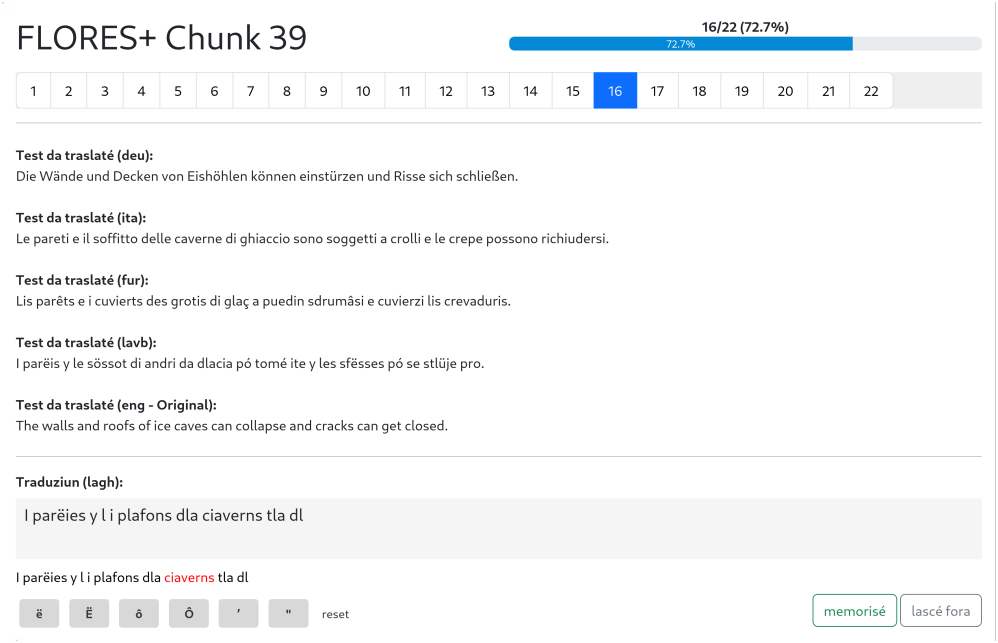

Figure 2: Screenshot of the tool developed for the translation of FLORES+.

load that proved manageable alongside daily tasks. This modular approach ensured an even distribution of work, allowed careful review of each unit, and maintained a sustainable pace. Overall, the team was able to complete the work within four months.

Gherdëina Translations Building on the Val Badia translations, we began translating into Ladin Gherdëina, using the Val Badia translations as an additional reference. This sequential approach was practical, as adapting an existing Ladin text is more efficient than translating from scratch, particularly with limited personnel. This second translation cycle also served as an implicit revision of the Val Badia texts, during which minor errors were identified and corrected. Given the smaller number of translators, the project timeline has been adjusted to ensure careful and thorough completion (work is still in progress).

Quality Assurance The first author, also a native Ladin speaker, continuously reviewed a sample of the generated translations and extracted all unknown words detected with a variant-specific spell checker. These were compiled into a shared document, where translators were asked to review and confirm or correct the entries. Words requiring concordance across variants were fed back to the group, ensuring consistency. This collaborative monitoring helped to identify and resolve potential errors. Concerns about the use of external machine translation systems (e.g., Google Translate or ChatGPT) do not apply in this setting. Major MT systems do not support Ladin, nor its specific variants, and ChatGPT performs poorly on Ladin (as evidenced in our evaluation results below). Any attempt to use such tools would have been immediately detectable, as they are incapable of generating variant-specific vocabulary and would trigger numerous alerts in the spell checker.

Neologisms The translation activity was accompanied by intensive collaboration among the translators. This collaborative process not only helped resolve stylistic and terminological questions but also led to the creation of new words that had not previously existed in the respective variety. As such, the project contributed to the lexical development of the Ladin language. In total, around 500 new words were created. Examples of such words are: *codificades* (encoded), *dejabilité* (disability), *surafolamënt* (overcrowding) or *triceratop*.

4 Experimental Validation

In this section, we provide an overview of the results achieved with a NMT system and different state-of-the-art LLMs on the manually created FLORES+ translations. The aim is to assess the current capabilities of these models in translating between Val Badia, Gherdëina and Italian, both in off-the-shelf zero-shot settings and using the accompanying parallel data as fine-tuning training

data for the NMT system and as retrieval data for the LLMs. Moreover, this serves as validation of the quality of the submitted datasets.

Training and Retrieval Corpora For Italian–Val Badia, a dataset is already available[20] consisting of word usage example sentences extracted from the Italiano–Ladin Val Badia dictionary (Moling et al., 2016). To create training and retrieval resources for Gherdëina, we extracted the word usage example sentences contained in the Italiano–Ladin Gherdëina dictionary (Forni, 2013). Since the two dictionaries are based on a common foundation and were largely coordinated with each other, they contain many common example sentences. This overlap allowed us to construct a Val Badia–Gherdëina parallel dataset by aligning identical Italian sentences. This yielded the following datasets for training (for `NLLB`) and retrieval (for LLMs):

- 18,140 sentences for Val Badia–Italian,
- 19,971 sentences for Gherdëina–Italian, and
- 14,953 sentences for Val Badia–Gherdëina.

Note that, given their purpose of illustrating word usage, the sentences in these corpora are relatively short and simple, with an average length of approximately 25 characters. We make both the Gherdëina–Italian[21] and Val Badia–Gherdëina[22] datasets publicly available under a `CC BY-NC-SA 4.0`[23] license.

4.1 Neural Machine Translation Models

For this evaluation, we tested the performance of the multilingual NMT system `facebook/nllb-200-distilled-600M` (NLLB Team et al., 2024). We evaluated this system off-the-shelf (without any fine-tuning) from Ladin to Italian and after being fine-tuned with the parallel datasets available for Val Badia–Italian, Gherdëina–Italian and Val Badia–Gherdëina mentioned above. We trained a single model covering all translation directions simultaneously using the `transformers` framework for 10 epochs with a batch size of 16 (which corresponded to approximately 101,930 optimization steps) and a maximum sequence length of 196 tokens. The validation loss steadily improved throughout training. Training was completed in 7 hours and 42 minutes on an NVIDIA RTX 4090 GPU.

4.2 Large Language Models

LLMs are proving to be increasingly valuable translators. A key advantage of LLMs is their flexibility in adapting to different specifications and contexts, which enables more targeted, application-specific use. Several techniques have also been studied for machine translation in low-resource languages, showing that LLMs can perform well in these settings and can often be further improved by providing additional data (Agrawal et al., 2023; Tang et al., 2024). Motivated by this, we evaluated different LLMs on Ladin to gain an overview of their performance and the results they can achieve. We evaluate the following four LLMs: (*i*) `GPT-3.5` is a general-purpose language model from OpenAI's GPT-3 series with 175B parameters, released in 2022 (Brown et al., 2020). (*ii*) `GPT-4o` a model by OpenAI, introduced in 2023, with 200B parameters and enhanced reasoning capabilities designed for complex problem-solving (Hurst et al., 2024). (*iii*) `Llama-3.3` is a text-only model by Meta AI, released in December 2024, featuring 70B parameters (Touvron et al., 2023). (*iv*) `DeepSeek-R1` is a reasoning-focused model by DeepSeek AI, introduced in January 2025, with 658B parameters (DeepSeek-AI et al., 2025). The models were prompted using the API services: OpenAI API[24] for `GPT-3.5` and `GPT-4o`, DeepSeek API[25] for `DeepSeek-R1`, and Together Inference API[26] for `Llama-3.3`. The hyperparameters were configured according to the default settings provided by each service.

Due to the very limited amount of machine-readable data available for Ladin it is likely that LLMs have minimal exposure to Ladin and are unaware of its internal variation.

4.2.1 Prompting Techniques

We applied two prompting methodologies in our experiments: *zero-shot* and *BM25-Retrieval*. The *zero-shot* method (Robinson et al., 2023; Gao et al., 2024; Hendy et al., 2023; Bawden and Yvon, 2023) relies solely on the model's pre-existing knowledge. The prompt directly instructs the model to translate sentence into the target, without providing explicit

translation examples or lexical guidance. This baseline approach tests the model's intrinsic understanding of Ladin syntax and vocabulary. To enhance translation quality beyond zero-shot capabilities, we employ *BM25-Retrieval* to provide the model with relevant in-context examples based on lexical similarity. BM25 (Robertson et al., 1995) is a probabilistic ranking method that estimates the relevance of documents to a given search query. This sparse retrieval method ranks examples based on lexical-level overlap with the input sentence, aiming to offer relevant in-context examples grounded in lexical similarity. It has been shown to be highly effective also for retrieving examples for MT with LLMs (Agrawal et al., 2023; Tang et al., 2024). We implemented this method using the `bm25s` Python package[27] (Lù, 2024) to select 30 translation examples from the corresponding retrieval corpus that we included in the prompt.

5 Results

Table 2 presents the BLEU scores for the six translation directions between Val Badia (VB), Gherdëina (GH), and Italian (IT). The upper half of the table reports results obtained with the models "off-the-shelf," that is, using zero-shot prompting for `GPT-3.5`, `GPT-4o`, `Llama-3.3`, and `DeepSeek-R1`, as well as the NLLB base model (BM). The lower half shows the results obtained when exploiting additional parallel data as retrieval data and to fine-tune the NLLB model (FT). Since the LLMs were evaluated on a subset of 175 sentences, we report the average BLEU (Post, 2018) scores together with the standard deviation[28] to provide a confidence interval for the results. The best score in each translation direction, when comparing the LLMs with NLLB, is highlighted in bold. In Table 3, we report the average portion of words in the generated translations that pass spellcheck. This should give an idea of the general lexical quality of the translations.[29] Also in this table we highlighted the best scores (LLMs vs. fine-tuned NLLB model) in bold.

[27] https://github.com/xhluca/bm25s

[28] Computed with `sacrebleu` (Post, 2018)

[29] Note that the reference translations do not achieve 100% spellcheck accuracy primarily because many named entities are absent from the dictionary and thus flagged as invalid. Therefore, this metric serves mainly as an expectation indicator rather than an absolute measure of correctness.

Interestingly, concerning the fine-tuned NLLB model, the relatively simple training datasets proved to be effective, especially considering that the benchmark data is substantially more complex. Despite the brevity and simplicity of the training samples, the model generated complete translations of the test samples. One peculiarity we observed is that the generated translations usually start with lowercase letters, reflecting the format of the training examples. Another limitation is that the model struggles with morphological variations: since most training examples contained words in their infinitive form (e.g., "I go home" and never "he went home"), the model is unable to generate correct inflections or conjugations. LLMs are less influenced by the simple translation examples and do not "compromise" their fluency when translating into Italian. For example, they also use the correct capitalization at the beginning of the sentence. When translating from Italian into Ladin, however, LLMs often lack the appropriate vocabulary, whereas the fine-tuned NLLB model adapts the vocabulary more effectively (see Table 3). In contrast, translation between Ladin variants is an easier task, as it mainly involves adapting the vocabulary. Here, the NLLB model already delivers satisfactory results and the difference between NLLB and LLMs is more pronounced, highlighting the challenge LLMs face in accurately adapting vocabulary.

From these results, three main observations can be drawn: (i) current LLMs exhibit limited coverage of Ladin variants, with translation into Ladin remaining a clear challenge; (ii) incorporating the parallel data released in this work yields substantial improvements in translation quality across models, but limitations remain in fluency and morphological variation due to the simplicity of the training examples; (iii) the relative advantage of the systems depends on the translation direction: when translating from a low-resource to a high-resource language, LLMs enhanced with retrieval-augmented generation achieve the best results, whereas for high-to-low-resource translation, the fine-tuned `NLLB` model performs better. This conclusion is further supported by a significantly higher proportion of valid words in its generated translations. The incorporation additional data (e.g. through back-translation) would yield better results; however, the primary focus here is on validating the quality of the provided datasets. Overall, these findings underscore both the potential and the necessity of advancing machine translation research for Ladin, as well as the value of the datasets we contribute.

6 Conclusion

In this work, we present our submission to the OLDI shared task 2025, providing FLORES+ translations for Ladin (Val Badia and Gherdëina) and provide an evaluation of several LLMs and the `NLLB` model on this test set, covering six translation directions between Val Badia, Gherdëina, and Italian.

Our results show significant performance gains from the additional parallel datasets released with this work, validating the quality of the datasets and highlighting a promising direction for future research. Beyond fine-tuning neural MT models or relying on basic BM25-Retrieval, our datasets opens the door to more advanced retrieval-augmented prompting strategies, where semantically or syntactically similar sentence pairs are selected to guide translations (Kumar et al., 2023; Merx et al., 2024; Tang et al., 2024; Zebaze et al., 2025).

A central question going forward is whether such carefully designed retrieval and prompting methods could not only provide a more lightweight alternative to fine-tuning for low-resource languages like Ladin, but in some cases even surpass it in translation quality. It would be highly valuable if, in future work, this effort could be extended to the Anpezo, Fassa, and Fodom Ladin variants, enabling their inclusion in the FLORES+ dataset and thus fully representing the Ladin language and accurately reflecting its internal diversity. We hope this work will inspire and encourage further research on Ladin in machine translation, helping to bring the language into sharper focus within the MT community.

Acknowledgements

We would like to thank the anonymous reviewers for their work and valuable comments and suggestions, which have greatly helped to improve our presentation. This initiative was taken as part of the research project *Machine Translation for Ladin* at the University of Innsbruck carried out in collaboration with the Ladin Cultural Institute "Micurá de Rü" and funded by the *Regione Autonoma Trentino–Alto Adige*. We also thank Jürgen Runggaldier for his support in this endeavour.

Abstract

We present the manual correction of the Tamazight portions of the FLORES+ and OLDI Seed datasets to improve the quality of open machine translation resources for the language. These widely used reference corpora contained numerous issues, including mistranslations, orthographic inconsistencies, overuse of loanwords, and non-standard transliterations. Overall, 36% of FLORES+ and 40% of Seed sentences were corrected by expert linguists, with average token divergence of 19% and 25% among changed items. Evaluation of multiple MT systems, including NLLB models and commercial LLM services, showed consistent gains in automated evaluation metrics when using the corrected data. Fine-tuning NLLB-600M on the revised Seed corpus yielded improvements of +6.05 chrF (en→zgh) and +2.32 (zgh→en), outperforming larger parameter models and LLM providers in en→zgh direction.

1 Introduction

High-quality parallel data is a cornerstone for the development of robust machine translation (MT) systems, particularly for low-resource languages where each sentence can significantly impact model performance. For Tamazight—spoken by over 40 million people across North Africa and the diaspora—parallel corpora are scarce, and widely used datasets such as FLORES+ (Goyal et al., 2022; NLLB Team et al., 2024) and OLDI Seed (Maillard et al., 2023) play a significant role in enabling MT research and evaluation.

The Tamazight portions of FLORES+[1] and OLDI Seed[2] contain Standard Moroccan Tamazight (ISO 639-3: *zgh*), the standardized variety developed by the Royal Institute of Amazigh Culture (IRCAM) (Boukous, 2014) for education and official use since 2001. However, our initial inspection revealed substantial issues: mistranslations, orthographic inconsistencies, malformed or unnecessary loanwords, non-standard transliterations, and occasional semantic inaccuracies. Some of these errors echo broader findings about low-resource language datasets, where insufficient quality control leads to degraded MT outputs and downstream application failures (Kreutzer et al., 2022). Similar issues have been observed for other languages in FLORES+, prompting targeted correction efforts such as those for Hausa, isiZulu, Northern Sotho, and Xitsonga (Abdulmumin et al., 2024). In fact, when FLORES-200 was first released, the Tamazight data was mislabeled as Central Atlas Tamazight (*tzm*) and only corrected following community feedback to its correct code *zgh*.

As part of the Awal project (Öktem and Boudichat, 2025), which develops open-source MT and speech technologies for Tamazight and coordinates community data creation, we undertook a systematic manual correction of the FLORES+ dev and devtest sets (997/1,012 sentences) and the OLDI Seed corpus (6,193 sentences). Corrections were performed by expert linguists using authoritative IRCAM lexicographic and grammatical resources.

The motivation for this work is straightforward: to ensure these widely used benchmark and seed datasets truly reflect Standard Moroccan Tamazight, so that MT systems trained or evaluated on them can produce translations that are both accurate and culturally appropriate. We follow the approach of Abdulmumin et al. (2024) for quantifying the extent of changes. We then evaluate multiple state-of-the-art open-source and commercial MT systems (including LLMs) on both the original and corrected FLORES+ devtest data for English↔Tamazight, and fine-tune existing NLLB

models with the updated Seed data to assess downstream impact.

2 Background

2.1 Tamazight and NLP

Tamazight, also known as Amazigh or Berber[3], is part of the Afro-Asiatic language family and is spoken by over 40 million people across a vast area of North Africa and diaspora communities worldwide (Lafkioui, 2018). It is an official language in Morocco since 2011, Algeria since 2016, Libya since 2017, and Mali since 2023. The standardized form, Standard Moroccan Tamazight (ISO 639-3: *zgh*), was developed by IRCAM from 2001 onwards, drawing on features of the main Moroccan varieties—Tachelhit (*shi*), Tarifit (*rif*), and Central Atlas Tamazight (*tzm*)—and other variants such as Touareg (*tmh*) (Boukous, 2014). As part of this process, IRCAM adopted Tifinaghe-IRCAM (also known as Neo-Tifinagh) in 2003 as the official script, replacing earlier informal use of Latin and Arabic scripts, and providing a phonologically accurate and standardized writing system (Soulaimani, 2016; Ataa-Allah and Boulaknadel, 2012).

The language exhibits considerable dialectal diversity across Morocco, Algeria, and other regions, a reflection of its vast geographic spread. Orthographic variation persists despite standardization, with Latin and Arabic scripts still used informally alongside Neo-Tifinagh. Historical marginalization—shaped by colonization and Arabization—has reduced intergenerational transmission in some areas and within diaspora communities, though Amazigh cultural movements such as the Amazigh Spring played a key role in securing recognition and institutional support (Roque, 2009; CIEMEN and Casa Amaziga de Catalunya, 2019).

From an NLP perspective, Tamazight poses challenges due to its rich morphology, complex orthography, and high dialectal variation. Inflectional and derivational processes, coupled with script diversity, make computational processing for tasks like tokenization, POS tagging, and MT more difficult (Ataa-Allah and Boulaknadel, 2012). Until recently, it remained underrepresented online, with limited user-generated content in the standard form. Notably, the Tamazight Wikipedia was only launched in 2023, marking a significant milestone in its digital presence.

Several important language resources and tools have been released in recent years. IRCAM has developed a Standard Tamazight Corpus (Boulaknadel and Ataa-Allah, 2013), a morphosyntactically annotated corpus (Amri et al., 2017), and tools such as an Amazigh verb conjugator (Ataa-Allah and Boulaknadel, 2014), a concordancer, and a Tifinagh-adapted search engine (Ataa-Allah and Boulaknadel, 2012). More recent research includes Tamazight word embeddings trained on web-collected corpora (Faouzi et al., 2023).

In the MT domain, Tamazight is one of the languages listed within the 200 languages of the *No Language Left Behind (NLLB)* project (NLLB Team et al., 2024), which relies on the FLORES training and evaluation sets (Goyal et al., 2022). Other relevant multilingual datasets that include Tamazight are SIB-200 (Adelani et al., 2024), MADLAD (Kudugunta et al., 2023), and GlotCC/GlotLID (Kargaran et al., 2023, 2025). However, as has been noted in recent research, the development of language technologies for underrepresented languages often follows a top-down approach led by large institutions or technology companies with little input from speaker communities (Moshagen et al., 2024; Bird, 2020; Schwartz, 2022). This dynamic risks misrepresenting languages through technologies built without meaningful community participation, and can perpetuate harm by commodifying indigenous knowledge and sidelining local authorities (Bird, 2020). For marginalized languages, the quality of training data is especially critical: inaccuracies can distort their digital representation and propagate errors through AI systems (Kreutzer et al., 2022; Lau et al., 2025). These issues are not unique to Tamazight—audits of widely used multilingual resources have shown that, for many of the languages they "cover," data quality and representativeness remain poor, creating an illusion of coverage while delivering limited practical usability (Lau et al., 2025).

2.2 Awal initiative

Crowdsourcing initiatives have emerged as a viable alternative to the top-down approaches that dominate language technology development for underrepresented languages. Grassroots efforts such as *Masakhane* (Nekoto et al., 2020), *NaijaVoices*

[3]We include the term "Berber" as it is commonly known in the global north but avoid its usage as it is often considered a pejorative term by the Imazighen (Amazigh people).

(Emezue et al., 2025), and *PARME* (Ahmadi et al., 2025) demonstrate that participatory models can produce data that is both higher quality and better aligned with community norms.

The Awal project (Öktem and Boudichat, 2025) follows this participatory model to create open-source MT and speech resources for Tamazight. Launched in 2024, its main platform, `https://awaldigital.org`, facilitates the translation of sentences from or into Tamazight, covering multiple dialects and scripts. Contributions come from volunteers' own translations or from Creative Commons–licensed material, which can also be post-edited from automatic translations produced by the NLLB engine. The platform integrates a peer-validation feature, where each sentence requires two independent approvals before entering the validated corpus. In addition to text, Awal collects Tamazight speech data through Mozilla Common Voice (Ardila et al., 2020), which is likewise validated via community review. All parallel and monolingual text is openly shared through the project's Hugging Face repository[4], while the voice data is released via Common Voice[5].

Awal's approach combines community-driven data collection with curated dataset creation by professional linguists, as in the present work correcting the Tamazight portions of FLORES+ and OLDI Seed.

3 Methodology

3.1 Correction Workflow

We corrected the Tamazight side of the FLORES+ dev (997 sentences), FLORES+ devtest (1,012 sentences), and OLDI Seed (6,193 sentences) datasets, obtained from the official OLDI Hugging Face repositories.

All sentences were exported into spreadsheets to enable structured, sentence-by-sentence review. The FLORES+ dev and devtest sets were revised in full in two iterations by two linguists. The OLDI Seed dataset was divided into batches of 1,000 sentences and distributed among three professional Tamazight translators, with allocation based on their availability and delivery capacity. To ensure quality control, each linguist's work was spot-checked through random sampling by another linguist.

[4] `https://hf.co/datasets/collectivat/amazic`
[5] `https://commonvoice.mozilla.org`

For the FLORES+ splits, the spreadsheet included the English source sentence, the original Tamazight sentence, and a column for the corrected version. For the OLDI Seed dataset, the spreadsheet additionally included the Arabic translation from the original resource, allowing the translators to use both English and Arabic as context. In all cases, if a sentence required no changes, the original Tamazight sentence was copied into the "corrected" column; if corrections were needed, translators directly post-edited the original, making orthographic, lexical, and syntactic adjustments as appropriate.

Corrections were guided by authoritative lexicographic and grammatical resources from IRCAM and other reference works, including dictionaries (Ameur et al., 2016; Chafik, 1996; Akioud et al., 2022), phonology (Boukous, 2009), and grammar books (Boukhris et al., 2008; El Moujahid, 2022; Laabdelaoui et al., 2012).

3.2 Challenges of Standardization and Dialect Representation

The review process also highlighted the limitations of relying solely on such references for a language that is still undergoing standardisation and must represent multiple dialects. Certain inconsistencies are found even in official resources: for example, masculine nouns are described in the *New Grammar of Amazigh* (Boukhris et al., 2008) as generally beginning with ⴰ, ⵓ, or ⵉ and feminine nouns with ⵜ, yet forms like ⵙⵙⵉⵏⵎⴰ (*ssinima*, 'cinema') or ⵍⴱⴰⵏⴽ (*lbank*, 'bank') appear in IRCAM dictionaries without the expected nominal prefix. Similarly, the rule that a word containing an emphatic consonant should be fully emphatic is not applied consistently across dictionary entries and published texts.

Lexical variation across Tamazight dialects further complicates correction. The verb "to give," for example, appears in IRCAM dictionaries with multiple forms—ⵀⴽ (*fk*), ⴽⵀ (*kf*), ⵓⵛ (*uc*), ⵡⵛ (*wc*), ⵙⵙⵉⵢ (*ssiy*)—without clear indication of which is considered standard. For highly standardised languages, such variation is usually resolved in reference materials, but in Tamazight, the standard form is still being shaped through a combination of institutional policy, community use, and corpus-based practice. This reality means that "correction" work often involves navigating legitimate competing forms rather than simply enforcing a single prescriptive norm.

In addition to these challenges, standardization in Tamazight also involves the ongoing creation of new terms, particularly in scientific and technical domains. This process is not a matter of direct translation but requires applying the language's own morphological strategies for derivation, compounding, and adaptation. As such, parallel data creation and curation go beyond translating sentences: they must be informed by a deep understanding of Tamazight's morphological rules and involve specialists in terminology and linguistic planning. Without this, datasets risk importing external forms rather than contributing to the gradual, community-driven development of a functional standard.

3.3 Error Taxonomy

During the review, we identified and categorized recurrent error types in the original datasets. Below we summarize each type and show representative examples.

3.3.1 Spelling Mistakes. These included violations of standardized Tamazight orthography. Key issues were the improper use of specific characters such as (ⵯ), (ⵯ), and emphatic consonants (ⵅ, ⵇ, ⵜ, ⵚ, ⵒ), which were corrected to align with IRCAM rules. For example, "Open" was corrected from ⵓⵅⵯⵔ to ⵇⵅⵔ, and "Three" from ⴽⵓⴻⵒ to ⴽⵇⴻ. Proper nouns were often transliterated inconsistently, such as "Louis Mayer" which needed to be adjusted from ⵍⵯⵙⵟ ⵔⴰⵣⵟ to ⵍⵍⵙⵟ ⵔⴰⵣⵟ, and "Maria Feodorovna" from ⵔⴰⵟⵙⴰ ⵀⵣⵯⴰⵯⵟⵯⵀⵍⴰ to ⵔⴰⵟⵣⴰ ⵀⵣⵯⴰⵯⵟⵯⵀⵍⴰ. We also found erroneous attachment of pronouns to nouns (e.g. "His film" from ⵍⵀⵙⵍⵎⵟ to ⴰⵀⵙⵍⵔ ⵏⵟ), which were separated for clarity and grammatical correctness.

3.3.2 Transliteration Errors. Particular attention was paid to the accurate transliteration of foreign words and names. The most frequent problems involved the inconsistent mapping of the letter *V* (correctly rendered as ⵀ) and *P* (correctly rendered as ⵜ) in foreign words. For example, "Nova Scotia" was corrected from ⵊⵯⵜⴰ ⵟⴽⵯⵜⵣⴰ to ⵊⵯⵀⴰ ⵟⴽⵯⵜⵣⴰ, and "Sveriges radio" from ⴰⵊⵅⵍⴰⵣ ⵔ ⵟⵜⵙⵟⵣⵠⵟ to ⴰⵊⵅⵍⴰⵣ ⵔ ⵟⵀⵙⵟⵣⵠⵟ. Other non-Tamazight sounds were adjusted to their closest Tamazight equivalents following standardized transliteration practices.

Unnecessary Loanwords		
English	**Original**	**Corrected**
Work	ⵍⵅⴷⵔ	ⵜⴰⵍⵯⵟⵙ
Theatre	ⵍⵔⵟⵇⴰⵗ	ⴰⵔⵅⵠⵯⵊ
Candy	ⵍⵀⵊⵙⴷ	ⵜⴰⵔⵅⵙⴻⵜ
Start	ⵜⴷⵯ	ⵟⵟⵊⵜⵙ
Anemia	ⵀⴰⵣⵟ ⴷⴷⴰⵔⵔ	ⵯⵅⵅⵯⵀ

Malformed Loanwords		
English	**Original**	**Corrected**
Cinema	ⵟⵟⵙⵊⵙⵔⴰ	ⴰⵟⵙⵊⵙⵔⴰ
Film	ⵍⵀⵙⵍⵔ	ⴰⵀⵙⵍⵔ
Television	ⵜⵙⵍⵙⵀⵙⵅⵙⵯⵊ	ⴰⵜⵙⵍⵙⵀⵙⵅⵙⵯⵊ
Oxygen	ⵍⵯⴽⵟⵊⵙⵊ	ⵯⴽⵟⵙⵊⵙⵊ
Nitrogen	ⵏⵙⴻⵇⵯⵊⵙⵊ	ⴰⵊⵙⴻⵇⵯⵊⵙⵊ

Table 1: Unnecessary and malformed loanwords detected in the corpus and their corrections.

3.3.3 Unnecessary Loanwords. Many sentences used Arabic or French loanwords where Tamazight equivalents exist. Following IRCAM's prioritization guidelines, we replaced these with native terms when available, giving preference first to Moroccan Tamazight variants, then to other Tamazight varieties (e.g. Touareg, Kabyle), and retaining loanwords only when unavoidable. Examples are shown in the upper portion of Table 1.

3.3.4 Malformed Loanwords. In cases where loanwords were retained, they often failed to follow Tamazight morphological patterns. Corrections ensured that such words received appropriate prefixes (e.g., ⴰ- for masculine nouns) and were adapted phonologically to fit Tamazight norms. Examples are presented in the lower portion of Table 1.

3.3.5 Mistranslations. Some translations did not accurately reflect the source meaning, introducing semantic drift or mistranslated idiomatic expressions. These were corrected to capture the intended sense and to align with Tamazight syntax. Representative examples are presented in Table 2.

4 Change analysis

We assessed the extent of changes made to the Tamazight portions of the FLORES+ dev/devtest and OLDI Seed datasets using token divergence (Abdulmumin et al., 2024), BLEU (Papineni et al.,

English Source	Original Translation	Back-translation	Correct Translation
Even if you're driving through the subtropical rainforest, a few seconds with the doors open while you get inside the vehicle is enough time for mosquitoes to get in the vehicle with you.	ⵍⵓⵅⵅⵓ ⴰⵓ ⵜⵍⴰⴰⵀⵜ ⵠ ⵜⵓⵅⵓⵍⵉⵍ ⵍ ⵑⵍⵣⵓⵟ ⵉⵕⵍⵓⵍⵍⵓⵍ, ⵓⵕⵕⵠⵕ, ⴰⵕⵑⵕ ⵍ ⵜⵑⵕⴰⵉⴰⵍ ⴰ ⵜⵅⵏⵍⵍⵉ ⵉⵣⵟⵟⵍⵍ ⵜⵉⵏⵉⵍⵍ ⵓⵅⵍⵕⵑ ⵍ ⵜⵉⵕⵕⵑⵑⵑ ⵉⵣⵣⵓ ⵓⵕ ⵉ ⵍⵓⵕⵉⵕⵓ ⵓⴰ ⵉⴰⵅ ⵉⵕⵕⵑⵕ.	Although you are driving in rainy forests like "asbgs", few minutes and the doors open and you are inside the vehicle is fine for mosquitoes to share the vehicle with you.	ⵍⵓⵅⵅⵓ ⴰⵓ ⵜⵍⴰⴰⵀⴰ ⵠ ⵜⵓⵅⵓⵍⵉⵍ ⵍ ⵑⵍⵣⵓⵟ ⵜⵉⵏⵅⵍⵓⵜⵑⵕⵉⵍ, ⵅⵑⵏⵜ ⵅⵕⵕ ⵍ ⵜⵕⵉⵍⵉⵍ ⴰⵕⵑⵕⵍⵉⵍ ⵓⵅⵑⴰ ⵜⵟⵅⵏⵍⵉⵍ ⵓⴰ ⵜⵅⵏⵅⵍⵓⵜⵑⵕⵑ ⵉ ⵍⵓⵕⵉⵕⵓ ⵅⵍⵓ ⵓⴰ ⵉⴰⵅ ⵉⵕⵕⵑⵕ ⵜⵓⵍⵕⵕⵑⵑⵑ.
The walls and roofs of ice caves can collapse and cracks can get closed.	ⵉⵅⵑⴰⵓⵕ ⴰ ⵉⵏⵕⵓⵍ ⵍ ⵑⵅⵕⵓⵉ ⵉⵟⵅⵉ ⴰ ⵉⵜⵜⵑⵉ ⴰ ⵉⵏⵑⵑⵍⵍ ⵓⴰ ⵅⵅⵅⵉⵜ ⵍ ⵉⵏⵕⵓⵍ ⵍ ⵑⵅⵕⵓⵉ ⵓⴰ ⵕⴰⵍⵍ ⴰ ⵅⵕⵜⵜⵉⵍ ⵓⴰ ⵅⵕⵜⵜⵉⵍ.	ⵅⵉⵓⵕⵍ ⵉⵅⵑⴰⵓⵕ ⴰ ⵉⵅⵅⵅⵉⵜ ⵍ ⵉⵏⵕⵓⵍ ⵍ ⵑⵅⵕⵓⵉ ⵓⴰ ⵕⴰⵍⵍ ⴰ ⵉⵕⵜⵜⵉⵍ ⵓⴰ ⵅⵕⵜⵜⵉⵍ.
For a few pennies some children will tell you the story.	ⵏⵓⵕ ⵅⵕⵓ ⵍ ⵜⵕⵓⵕⵑⵏⵉ ⵕⵕⵑⵕⵍ, ⵓⴰ ⵓⵅ ⵓⵑⵕⵍ ⵉⵇⵉⵕⵕⵓⵍ ⵜⵓⵍⵑⵟⵕⵜ.	Just some few steps children will tell you the story.	ⵏⵓⵕ ⵅⵕⵓ ⵍ ⵜⵓⵕⵕⵓⵑⵑⵉ ⵕⵕⵑⵕⵍⵉⵍ, ⵕⵓⴰ ⵓⵅ ⵓⵑⵕⵍ ⵉⵇⵉⵕⵕⵓⵍ ⵜⵓⵍⵑⵟⵕⵜ.

Table 2: Examples of mistranslations and their corrections. For each case, we show the original English source sentence, the problematic Tamazight translation from the dataset, a back-translation of that Tamazight into English, and the corrected Tamazight translation.

dataset	#rows	#corr. (%)	% token div.	$BLEU_c$	TER_c	WER_c	CER_c
dev	997	384 (39%)	19.36	81.06	12.22	13.35	5.70
devtest	1012	339 (34%)	19.46	79.85	12.35	13.50	5.48
FLORES+	2009	723 (36%)	19.41	78.26	14.84	17.73	8.83
seed	6193	2490 (40%)	25.01	80.49	12.28	13.42	5.60
ALL	8202	3213 (39%)	23.75	78.72	14.29	16.76	8.10

Table 3: Correction statistics and edit-distance metrics for each dataset. Shows the number of sentences corrected (as percentage of total) and average change metrics computed only on modified sentences. FLORES+ aggregates dev and devtest splits, while COMBINED combines FLORES+ and OLDI Seed datasets.

dataset	>50% (%)	>80% (%)
dev	20 (5.2%)	6 (1.6%)
devtest	26 (7.7%)	3 (0.9%)
seed	316 (12.7%)	62 (2.5%)
FLORES+	46 (6.4%)	9 (1.2%)
ALL	362 (11.3%)	71 (2.2%)

Table 4: Number and percentage of corrected sentences with token divergence greater than 50% and 80%, indicating substantial rewrites.

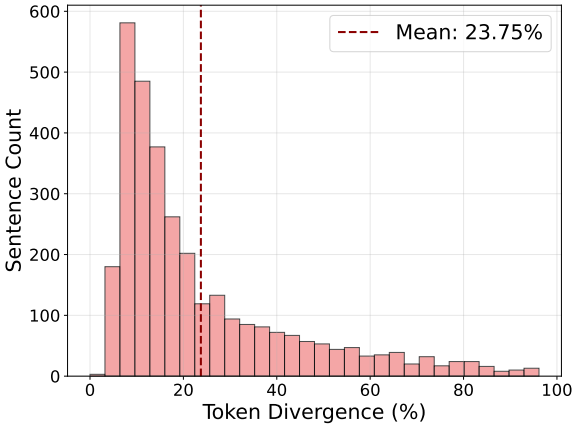

Figure 1: Token divergence distribution across all corrected sentences in the combined FLORES+ and OLDI Seed datasets.

2002), Translation Edit Rate (TER) (Snover et al., 2006), Word Error Rate (WER), and Character Error Rate (CER). Following Abdulmumin et al. (2024), all metrics were computed only on sentences that were modified, avoiding dilution by unchanged items.

Token divergence was calculated as:

$$\text{divergence} = \frac{|T_o - T_c| + |T_c - T_o|}{|T_o \cup T_c|} \quad (1)$$

where T_o is the set of tokens in the original sentence and T_c is the set of tokens in the corrected sentence. This metric measures the proportion of unique tokens that differ between the two versions of a sentence, with 0 indicating identical token sets and 1 indicating no overlap. Reported values are averages over all changed sentences and expressed as percentages.

Table 3 reports, for each dataset, the proportion of sentences corrected and the mean metric scores. In addition to individual datasets, we also report aggregated results for FLORES+ overall

(dev+devtest) and for the combined FLORES+ and Seed datasets. Figure 1 presents the token divergence distribution across all corrected sentences in the combined dataset.

The results show that the proportion of sentences corrected is 36% for FLORES+ overall and 40% for the Seed dataset. Average token divergence values are 19% for FLORES and 25% for Seed, indicating that corrections typically involved localised changes to a minority of tokens in a sentence rather than complete rewrites. This is consistent with the high BLEU scores (≈78–81) and the relatively modest WER (13–18%) and CER (5–8%) values. While substantial rewrites are relatively rare, they are still present in both datasets. Table 4 shows the proportion of corrected sentences whose token divergence exceeded 50% and 80%. For example, 6.4% of corrected sentences in FLORES overall and 12.7% in the Seed dataset had over 50% divergence, indicating a reworking of more than half of their token content.

5 Machine Translation Evaluation

We evaluated English↔Tamazight (zgh) translation quality on the FLORES+ devtest split, comparing results obtained with the original and corrected versions of the dataset. The evaluation covered:

- **Baseline models**: NLLB checkpoints 600M, 1.3B, 1.3B Distilled, 3.3B
- **Fine-tuned models**:
  - i) NLLB-600M fine-tuned on the corrected OLDI Seed dataset for 3 epochs.
  - ii) NLLB-600M fine-tuned for 1.25 epochs on the corrected OLDI Seed dataset and other parallel data of approximately 50,000 segments sourced from Awal, Tatoeba[6], and Tamazight NLP[7] initiatives.
- **Commercial LLMs**: Gemini Pro 2.5, Claude 3.5, and Claude 3.7[8].

Scores were computed using BLEU, chrF++ (Popović, 2015), and TER (Snover et al., 2006) for both translation directions. Table 5 reports the results, with each cell showing the original dataset score / corrected dataset score format.

Across all models tested, corrections led to consistent improvements in BLEU and chrF++, with corresponding reductions in TER. We see an average chrF increase of 0.14 points in en→zgh, and 0.23 in zgh→en direction among all off-the-shelf models and LLM services. This confirms that noise in the original FLORES+ Tamazight references measurably affected evaluation quality.

Fine-tuning on the corrected OLDI Seed dataset (NLLB-0.6B-FT) yielded substantial gains compared to the same 0.6B baseline: +6.05 chrF and +3.05 BLEU in the en→zgh direction. The fine-tuned model achieved 31.69 chrF, performing better than all other larger models and LLM providers, showing that carefully curated data can yield substantial improvements.

In the zgh→en direction, the fine-tuned 0.6B model improved with +2.32 chrF and +1.89 BLEU from corrections, however it was still outperformed by other models, with Gemini Pro 2.5 achieving the highest chrF score of 44.29.

We also report results with additional parallel data (NLLB-0.6B-FT+): 32.71 chrF and 8.84 BLEU in en→zgh, and 40.66 chrF and 18.29 BLEU in zgh→en.

6 Conclusions

We carried out a systematic manual correction of the Tamazight portions of the FLORES+ dev/devtest and OLDI Seed datasets, resolving orthographic inconsistencies, mistranslations, and problematic loanwords. These corrections, performed by professional linguists with reference to authoritative resources, affected a substantial share of sentences and resulted in more accurate benchmarks for MT evaluation.

Across all off-the-shelf models and commercial LLMs tested, the corrected data yielded consistent improvements in automatic evaluation metrics. Fine-tuning on the corrected OLDI Seed dataset further demonstrated the impact of these revisions: the NLLB-600M model trained on the revised data outperformed larger parameter models and LLM providers in en→zgh direction, and recorded improvements in zgh→en direction.

Beyond the experiments, our work underlines broader challenges of dataset creation for a language still undergoing standardization, where legit-

Table 5: Machine translation evaluation results on FLORES+ devtest for English↔Tamazight translation. Each cell shows original dataset score / corrected dataset score. NLLB-0.6B-FT refers to the model fine-tuned on the corrected OLDI Seed dataset, while NLLB-0.6B-FT+ includes additional parallel data. S refers to the beam size used when decoding using beam search; when not specified, greedy search is used. Bold values mark the best performing metric on corrected evaluation.

imate variation coexists with quality issues. It also illustrates how massively parallel datasets can be problematic for low-resource languages: without careful linguistic validation, they risk amplifying errors and misrepresenting the language in downstream systems.

Future work will extend fine-tuning experiments with additional parallel data and explore other language pairs involving Tamazight, ensuring that corrected datasets serve as a stronger foundation for both evaluation and system development.

Filling the Gap for Uzbek: Creating Translation Resources for Southern Uzbek

Mukhammadsaid Mamasaidov[1] **Azizullah Aral**[2]
Abror Shopulatov[1,3] **Mironshoh Inomjonov**[1]
[1] Tilmoch [2] Institute of Uzbek National Musical Art [3] MBZUAI

Abstract

Southern Uzbek (uzs) is a Turkic language variety spoken by around 5 million people in Afghanistan and differs significantly from Northern Uzbek (uzn) in phonology, lexicon, and orthography. Despite the large number of speakers, Southern Uzbek is underrepresented in natural language processing. We present new resources for Southern Uzbek machine translation, including a 997-sentence FLORES+ dev set, 39,994 parallel sentences from dictionary, literary, and web sources, and a fine-tuned NLLB-200 model (lutfiy). We also propose a post-processing method for restoring Arabic-script half-space characters, which improves handling of morphological boundaries. All datasets, models, and tools are released publicly to support future work on Southern Uzbek and other low-resource languages.

1 Introduction

The Southern Uzbek language, spoken by approximately 5 million Uzbeks residing across 14 provinces of Afghanistan, represents a distinct linguistic variety that has developed independently from Northern Uzbek over centuries (Ethnologue, 2025a). Uzbek as a whole is classified as a macrolanguage according to ISO 639-3 standards, encompassing multiple related varieties including Northern Uzbek (uzn) spoken primarily in Uzbekistan, and Southern Uzbek (uzs) prevalent in Afghanistan (Ethnologue, 2025b).

This macrolanguage classification recognizes the significant linguistic diversity within the broader Uzbek language family, where individual varieties have developed distinct phonological, lexical, and grammatical features due to geographical separation and contact with other languages. As part of the global Uzbek population exceeding 34 million people, Southern Uzbek is recognized in Afghanistan's Constitution as a potential third official language in regions where it is the majority language, in addition to Pashto and Dari. (Afghanistan, 2004)

Southern Uzbek functions as a fully developed literary language that meets the demands of literature, art, culture, and science. It maintains active presence across multiple domains including technology, education, diplomacy, banking, and commerce. The language is taught in Southern Uzbek departments at seven national universities in Afghanistan and serves as the medium of instruction in 970 schools distributed across provinces: 9 schools in Badakhshan, 80 in Balkh, 450 in Faryab, 50 in Samangan, 300 in Sar-e-Pol, and 80 in Takhar. (Olim Labib, 2020)

International media outlets including BBC, Radio Free Europe/Radio Liberty (Ozodlik), Voice of America, Voice of Iran, TRT Avaz, and Sputnik actively broadcast in Southern Uzbek, alongside Afghan media channels such as Oyna, Botur, Almas, Orzu, Nur, Oriano, Kalid, and National Radio and Television. The language maintains expanding digital presence across major online platforms including Wikipedia, Google, Facebook, and other social networks.

Despite this linguistic vitality, Southern Uzbek remains underrepresented in natural language processing technologies. Major translation platforms like Google Translate (Google, 2025) currently provide limited or no support for this language variety, highlighting the critical need for dedicated computational resources. As a low-resource language with unique characteristics distinct from Northern Uzbek, Southern Uzbek presents significant challenges for machine translation systems.

This study, conducted as part of the Open Language Data Initiative (OLDI) shared task, addresses these challenges by developing specialized neural machine translation models for Southern Uzbek. Our contributions parallel recent advances in low-resource language processing and include:

1. A FLORES+ dev dataset translated to South-

Proceedings of the Tenth Conference on Machine Translation, pages 1081–1087
November 8-9, 2025

ern Uzbek containing 997 sentences

2. Parallel corpora for various language pairs with Southern Uzbek

3. Open-sourced fine-tuned neural models for Southern Uzbek translation

4. Comprehensive evaluation against existing baselines

Our research aims to advance machine translation capabilities for Southern Uzbek, contributing to the larger OLDI objective of expanding linguistic diversity in NLP technologies for underrepresented language varieties.

2 Linguistic Background

2.1 Historical Development

Southern Uzbek belongs to the Turkic language family, specifically derived from the Karluk-Chigil-Uyghur dialectal group with partial influences from the Kipchak and Oghuz branches. The language represents the contemporary form of a literary tradition spanning over a millennium, with historical continuity traceable through classical poets including Khwarizmi, Lutfi, Atayi, Sakkaki, Navoi, Babur, lutfiy, and Ogahi. Notably, while these historical figures did not identify themselves as "Uzbek", they wrote in a language that forms the foundation of modern Southern Uzbek, demonstrating the language's independent development into a mature linguistic system. (Habibi Aral, 2021)

Historically, Southern Uzbek served as the administrative and literary language for major dynasties including the Yaftids, Kushans, Ghaznavids, Seljuks, Timurids, and Mughals, who governed territories across Afghanistan and India for centuries using this language and established profound cultural legacies. (Tursunov and O'rinboyev, 1982)

2.2 Writing System

Southern Uzbek employs the Arabic script, which has served as the official writing system for Afghan languages for over a thousand years. This orthographic system presents unique challenges and characteristics that distinguish it from Latin-based Northern Uzbek.

The Arabic-based script includes only three vowel letters: ا (a/o), و (u/o'), and ی (i/y). This limited vowel representation often misleads learners into believing that Uzbek contains only three vowel sounds. However, vowel quality distinctions become evident in minimal pairs such as shown in Figure 1.

kuz (autumn) (کوز)	ko'z (eye) (کۆز)
yel (wind) (یېل)	yil (year) (ییل)
qurol (weapon) (قورال)	maral (deer) (مرەل)

Figure 1: Vowel differences in Southern Uzbek

Standard Uzbek contains six primary vowels (with additional dialectal variants), yet the Arabic script lacks direct representation for half of them. These vowels require indication through diacritical marks (fatha, damma, kasra), which are frequently omitted in practical writing, thereby complicating accurate reading and pronunciation.

Additional complexity arises from the dual functionality of certain letters. The Arabic letter ه (h) functions both as vowel and consonant. Similarly, letters و and ی (waw and ya) serve dual roles as vowels and consonants ("v" and "y") depending on context as illustrated in Figure 2.

Uzbek Southern	Uzbek Northern	Sound
Letter ه (h) dual roles		
بیلدیرەدی	bildiradi	/a/
هوس	havas	/h/
Letter و (waw) dual roles		
وطن	vatan	/v/
توز	tuz	/u/
Letter ی (ya) dual roles		
بای	boy	/y/
فیل	fil	/i/

Figure 2: Dual letters in Southern Uzbek

Southern Uzbek	Northern Uzbek	Meaning
Examples with suffix "-chi"		
چایخانه‌چی	choyxonachi	teahouse keeper
ادبیاتچی	adabiyotchi	writer
Compound words and prefixes		
بي‌تشویش	betashvish	carefree
نا‌انصاف	noinsof	dishonest

Figure 3: Examples of standardized Southern Uzbek Arabic-script orthography showing mandatory half-space (zero-width non-joiner, U+200C) placement. Red marks indicate the location of half-spaces in suffixation after vowel-final stems and in prefix attachment.

Arabic and Persian loanwords maintain their original orthographic forms, typically without vowel markings.

2.3 Morphological Structure

Southern Uzbek exhibits rich agglutinative morphology characteristic of Turkic languages. The language employs extensive suffixation systems that can be classified into various functional categories:

- Nominalizers (noun-forming suffixes)
- Adjectival suffixes
- Verb formers
- Tense and aspect markers
- Other functional and derivational affixes

Standardized orthographic rules govern affix attachment in Southern Uzbek Arabic script. A fundamental principle distinguishes between suffixes attached to vowel-final versus consonant-final stems (-chi, -chilik, -lik, -li, etc.).

These suffixes require half-space (also known as zero-width non-joiner, U+200C, also found in Farsi) separation when attached to stems ending in vowels (represented by Arabic letters ه, و, ا), while connecting directly to consonant-final stems.

Southern Uzbek also employs prefixes, commonly found in Persian or Arabic loanwords, for forming adjectives or adverbs. These prefixes (be-, no-, xo‘sh-, ser-, ba-, ham-, bad-) are written with half-space separation, as shown in Figure 3.

2.4 Contemporary Status and Challenges

Despite its historical significance, Southern Uzbek has faced political marginalization over the past three centuries, with Turkic peoples in Afghanistan being sidelined in governance and education. Progress began in the 1970s when Uzbek parliamentary representatives secured broadcasting rights on Afghan national radio. The 1978 rise of the People’s Democratic Party marked further advancement with the publication of the Yulduz newspaper in Southern Uzbek, establishment of Uzbek Language and Literature departments, and expansion of Uzbek-medium education. (Aral, 2025)

The 2001 democratic reforms in Afghanistan formally granted Southern Uzbek official status, recognizing its role in Afghan multilingual society. However, challenges remain in standardizing orthographic practices and developing computational resources for this linguistically rich but technologically underrepresented variety.

3 Related Work

Machine translation for low-resource languages has gained significant attention, with researchers exploring various approaches from data augmentation to multilingual transfer learning. Dale (2022) developed the first neural MT system for Erzya, a low-resource Uralic language, demonstrating how extensive data mining from diverse sources (Bible texts, dictionaries, digitized books) can yield functional translation systems despite limited parallel data. Similarly, P M et al. (2024) focused on low-resource Indic languages by fine-tuning multilingual models and employing back-translation with careful quality filtering, showing that selective data augmentation can improve performance when synthetic data is judiciously filtered.

Goyle et al. (2023) systematically evaluated strategies for compensating data scarcity in languages like Sinhala, Nepali, Khmer, and Pashto. They found that combining back-translation with focal loss yields substantial improvements, particularly when leveraging large monolingual corpora and transfer learning from related high-resource languages.

Recent advances in large language models have also shown promise for low-resource translation tasks. Commercial LLMs like GPT-4 and Claude demonstrate multilingual capabilities that extend to languages not explicitly included in their training data, offering competitive performance through few-shot learning approaches.

Despite these advances, Southern Uzbek remains largely unexplored in computational linguistics. While Northern Uzbek has received some attention in multilingual models like NLLB (NLLB Team et al., 2022) and MADLAD-400 (Kudugunta et al., 2024), the Southern Uzbek has been left behind. Our work represents the first dedicated effort to develop neural translation resources for this variety of Uzbek.

4 Datasets

4.1 FLORES+ Dev Dataset

This study introduces the Southern Uzbek FLORES+ dev dataset, comprising 997 sentences translated from English to Southern Uzbek (see Figure 4).

The dataset was developed under the Open Language Data Initiative (OLDI) framework. One native Southern Uzbek linguist was responsible

English	The aircraft had been headed to Irkutsk and was being operated by interior troops.
Northern Uzbek	Samolyot Irkutsk tomon yo‘l olgan va ichki qo‘shinlar tomonidan boshqarilayotgan edi.
Southern Uzbek	اوچاق ایرکوتسک تامان یۏل آلگن و ایچکی قۏشینلر تامانیدن باشقەریلەیاتگن اېدی.

Figure 4: Example from the FLORES+ dataset in English, Northern Uzbek and Southern Uzbek.

for the translation process, with subsequent post-review process to ensure linguistic accuracy and cultural appropriateness. All Southern Uzbek translations strictly adhere to the Arabic script orthographic conventions, including proper implementation of half-space characters (U+200C) for morphological boundaries as described in Section 2.3.

Given the complexity of Arabic script representation and the morphologically rich nature of Southern Uzbek, particular attention was paid to maintaining consistent orthographic standards throughout the translation process. The translation process followed standardized conventions for affix attachment, vowel representation, and proper handling of Arabic and Persian loanwords within the Southern Uzbek linguistic system.

4.2 Training Data

The training dataset comprises diverse parallel corpora sourced from three primary domains, totaling 39,994 sentence pairs across multiple language combinations:

1. **Dictionary Entries (1,550 pairs)**: Parallel dictionary entries mapping Northern Uzbek to Southern Uzbek lexical items (Aral, 2024). These entries provide direct lexical correspondences and serve as high-quality alignment data for closely related language varieties.

2. **Literary Corpus (35,865 pairs)**: Parallel sentences extracted through careful alignment from 27 selected books available in both Northern and Southern Uzbek variants. This corpus represents the largest component of our training data and captures literary register variations, complex syntactic structures, and cultural terminology.

3. **Web-sourced Content (2,579 pairs)**: Parallel sentences of English-Southern Uzbek mined from official government websites and reliable online resources. This component provides contemporary usage patterns and domain-specific terminology from governmental and institutional contexts.

4.3 Data Mining Process

The sentence alignment process presented unique challenges due to Southern Uzbek's underrepresentation in existing multilingual models. Our alignment methodology employed a two-stage approach to maximize extraction efficiency.

For literary corpus alignment, we initially applied LaBSE embeddings (Feng et al., 2020) directly to the original Arabic script texts. While LaBSE does not include Southern Uzbek in its training data, the model demonstrated limited alignment capability, likely due to shared vocabulary with other Turkic languages in the embedding space.

To improve alignment quality, we implemented a transliteration-based enhancement strategy. Southern Uzbek texts were transliterated from Arabic to Latin script using rule-based conversion scripts[1], which enabled more effective cross-lingual embedding alignment. This transliteration approach yielded a 40% more successfully aligned sentence pairs compared to direct Arabic script processing.

The sentence alignment methodology follows established practices from low-resource language processing (Dale, 2022). We utilize LaBSE to generate embeddings for each potential sentence pair, calculate cosine similarity between embeddings, and adjust similarity scores using length ratios.

For web-sourced English-Southern Uzbek data, we employed a reverse translation verification approach. Southern Uzbek sentences were translated to English using Gemini-2.0-Flash, followed by LaBSE-based alignment between original English content and back-translated English. This process underwent manual review to ensure translation quality and semantic fidelity.

A notable preprocessing challenge emerged regarding half-space character consistency. Due to OCR limitations and editorial inconsistencies in source materials, half-space characters (U+200C) were frequently omitted, incorrectly rendered as full spaces, or merged with adjacent characters. While this issue complicates training data quality, we address it through post-processing correction

mechanisms described in Section 4.

5 Translation Experiments

5.1 Model Training

Our experimental framework employed the nllb-200-distilled-600M model as the foundation for Southern Uzbek machine translation development. e maintained the original tokenizer configuration, leveraging the model's existing multilingual capabilities for Turkic language processing.

5.1.1 Training Configuration

For the training process we employed the Adafactor (Shazeer and Stern, 2018) optimizer paired with a learning rate of 1×10^{-4} following a constant schedule and 1000 warmup steps. A weight decay of 1×10^{-3} was applied, and the batch size was set to 32 due to GPU memory constraints. The maximum sequence length was limited to 128 tokens, and training was conducted for 5000 steps, corresponding to approximately 2–3 epochs. All experiments were run on a single A100 40GB GPU. The Adafactor optimizer was chosen for its memory efficiency and proven effectiveness in transformer fine-tuning scenarios, while the conservative learning rate and weight decay values were selected to mitigate overfitting given the small size of the training dataset.

5.1.2 Model Variant

We fine-tuned nllb-200-distilled-600M (NLLB Team et al., 2022) model on the complete 39,994 sentence pair corpus. Our model called **lutfiy**[2] maintains the original NLLB tokenizer and vocabulary, relying on existing Turkic language representations for Southern Uzbek processing.

5.1.3 Half-Space Post-Processing

A critical technical challenge emerged regarding the handling of half-space characters. The NLLB SentencePiece (Kudo and Richardson, 2018) tokenizer normalizes half-space characters (U+200C) to regular spaces during preprocessing, preventing the model from learning proper morphological boundary representation. This problem affects not only Southern Uzbek but also extends to other languages requiring half-space characters, including Persian (Doostmohammadi et al., 2020).

To address this limitation, we developed a character-level n-gram post-processing model that predicts half-space insertion positions. The model was trained on a small set of training data with corrected half-space characters. It analyzes character sequences and applies statistical rules to determine whether half-spaces should follow specific vowel endings in morphologically complex constructions.

This approach provides a practical solution to the tokenizer normalization problem while maintaining compatibility with existing NLLB infrastructure. The post-processing correction mechanism is made publicly available alongside our trained models[3].

5.2 Evaluation Framework

Model performance was assessed using two widely adopted metrics for translation tasks: **sacreBLEU** (Post, 2018), a standardized BLEU implementation that ensures consistent n-gram precision measurement across experiments, and **chrF++** (Popović, 2017), a character-level F-score metric that is particularly well-suited for evaluating morphologically rich languages such as Southern Uzbek. All results are reported on the FLORES+ dev set, enabling comparability with other low-resource language initiatives under the OLDI framework.

[2]Lutfi, a 15th-century Central Asian poet

6 Results and Discussion

Our evaluation on the FLORES+ Southern Uzbek dev set reveals several key insights into the performance of various translation approaches. The results, presented in Table 1, demonstrate significant performance variations across different model architectures and translation directions.

Notably, large language models exhibit superior performance in understanding Southern Uzbek content, particularly in **uzs-*** directions. Gemini-2.0-Flash achieves the highest scores for uzs-en translation (32.81 BLEU/58.80 chrF++), while Claude-Sonnet-4 excels in uzs-uzn translation quality (83.63 chrF++). This suggests that LLMs' extensive multilingual pretraining enables effective comprehension of low-resource language varieties, even without explicit training on Southern Uzbek data. In contrast, traditional MT systems like Google Translate and specialized multilingual models (NLLB-200-600M, MaLLaD400) demonstrate substantially lower performance, highlighting the challenges these architectures face with underrepresented languages.

However, our fine-tuned **lutfiy** model demonstrates clear advantages in generation tasks. For translation **into** Southern Uzbek (uzn-uzs), our model consistently outperforms all baselines, achieving 34.31 BLEU/71.11 chrF++ for uzn-uzs directions. This validates our approach of fine-tuning on domain-specific parallel corpora, as the model learns proper Southern Uzbek generation patterns that generic LLMs cannot replicate effectively.

The impact of our half-space post-processing correction is particularly evident in the uzn-uzs translation pair. While chrF++ scores show modest improvements (from 66.44 to 71.11), BLEU scores increase dramatically (from 25.99 to 34.31), representing a 32% relative improvement. This substantial BLEU gain with stable chrF++ performance indicates that the half-space correction primarily addresses tokenization boundary issues rather than fundamental translation errors. Since BLEU relies on exact n-gram matches, incorrect half-space placement can artificially deflate scores even when the underlying translation quality remains high.

For the closely related uzs-uzn translation direction, Gemini-2.0-Flash demonstrates exceptional generation capability (62.45 BLEU), significantly outperforming our specialized model (53.48 BLEU). This suggests that LLMs may be particularly effective at cross-dialectal translation within the same language family, possibly due to their ability to capture subtle linguistic variations during pretraining.

These findings highlight complementary strengths between LLMs and specialized fine-tuned models: while LLMs excel at understanding and translating from Southern Uzbek, targeted fine-tuning proves essential for high-quality generation into Southern Uzbek, particularly for morphologically complex constructions requiring proper orthographic conventions.

7 Conclusion

Our study presents the first comprehensive neural machine translation resources for Southern Uzbek, addressing a significant gap in computational linguistics for this underrepresented Turkic variety. Our key contributions include:

1. Creation of a 997-sentence FLORES+ dev dataset for Southern Uzbek
2. Development of 39,994 parallel sentence pairs across multiple language combinations (uzs-uzn, uzs-en)
3. Fine-tuned NLLB-200 model (lutfiy) optimized for Southern Uzbek translation
4. Post-processing methodology for Arabic script half-space character restoration
5. Open-sourced datasets, models, and evaluation tools

Future work will focus on expanding dataset coverage through additional literary sources and government documents, exploring data augmentation techniques using large language models, and developing more sophisticated orthographic normalization approaches for Arabic script processing.

8 Limitations

Several limitations constrain our current approach. The training dataset size of ~40K sentence pairs, while substantial for a low-resource language, may limit generalization across diverse domains. Our heavy reliance on literary sources potentially biases the model toward formal registers, possibly affecting performance on conversational or technical content. The half-space post-processing solution, while effective, represents a workaround

rather than addressing the underlying tokenizer limitations. Additionally, our evaluation relies primarily on automatic metrics, which may not fully capture translation quality nuances for morphologically complex languages like Southern Uzbek. Human evaluation studies would provide more comprehensive quality assessment.

9 Acknowledgements

We thank the Open Language Data Initiative (OLDI) for supporting this research and David Dale for his valuable guidance throughout the project. The authors thank the Google for Startups Program for providing the computational resources that made this research possible.

Abstract

We present a Kyrgyz language seed dataset as part of our contribution to the WMT25 Open Language Data Initiative (OLDI) shared task. This paper details the process of collecting and curating English–Kyrgyz translations, highlighting the main challenges encountered in translating into a morphologically rich, low-resource language. We demonstrate the quality of the dataset through fine-tuning experiments, showing consistent improvements in machine translation performance across multiple models. Comparisons with bilingual and MNMT Kyrgyz-English baselines reveal that, for some models, our dataset enables performance surpassing pretrained baselines in both English–Kyrgyz and Kyrgyz–English translation directions. These results validate the dataset's utility and suggest that it can serve as a valuable resource for the Kyrgyz MT community and other related low-resource languages.

1 Introduction

While machine translation has advanced significantly, progress remains uneven, with morphologically rich, low-resource languages facing substantial obstacles (Goyal et al., 2022). This disparity is particularly acute for the Turkic language family, where agglutinative structures pose unique challenges to standard MT architectures. Kyrgyz (кыргыз тили), a Turkic language with approximately 5.5 million speakers, exemplifies this situation. Despite a growing number of large, automatically-mined parallel datasets (Team et al., 2022), there is a significant shortage of high-quality, human-curated resources essential for building robust and reliable translation systems.

This paper details our contribution to the Open Language Data Initiative (OLDI) shared task: the creation of a high-quality, human-validated English-Kyrgyz dataset of 6,193 sentence pairs. The source text, drawn from diverse scientific domains on Wikipedia, provides rich terminological and syntactic complexity that inherently challenges MT systems. For a low-resource language like Kyrgyz, this complexity exposed a more fundamental obstacle: the absence of standardized scientific vocabulary. This makes high-quality human translation not just a matter of review, but of active linguistic curation. Our translation process, therefore, required developing novel strategies to handle significant terminological gaps and neologisms. This involved our team of native speakers making crucial terminological choices. For instance, we prioritized the native Kyrgyz word "дене" for scientific compounds like "celestial body" ("космостук дене") and "antibody" ("антидене") over the somewhat established Russian calque "тело", a decision that reflects modern usage and enhances both accuracy and naturalness.

Our main contributions are as follows:

1. We contribute the first high-quality, human-validated English-Kyrgyz seed dataset to the OLDI initiative.

2. We provide a detailed analysis of the key linguistic challenges in English-to-Kyrgyz translation, particularly regarding terminological adaptation, and document the effective strategies our team employed.

3. We conduct fine-tuning experiments with four major NMT models (mT5, mBART, M2M100, and NLLB-200) to empirically demonstrate that our high-quality dataset provides consistent performance gains.

Our results confirm that even a modest amount of high-quality parallel data is critical for advancing

Proceedings of the Tenth Conference on Machine Translation, pages 1088–1102
November 8-9, 2025

MT performance for structurally divergent language pairs, particularly when involving a low-resource language.[1]

2 Related Work

Despite Kyrgyz being classified as a low-resource language, recent years have witnessed notable progress in the development of machine translation (MT) systems for this language (Alekseev and Turatali, 2024). The very first machine translation systems for Kyrgyz were rule-based, representing foundational efforts in the field. A key contribution in this area is the open-source finite-state morphological transducer for Kyrgyz developed by Washington et al. (2012). This transducer, developed within the Apertium platform, was a critical component for a prototype Turkish-Kyrgyz machine translation system and laid the groundwork for further language pairs, including an in-progress Kazakh-Kyrgyz system. Alkım and Çebi (2019) proposed a rule-based approach for multilingual translation among four Turkic languages, including Kyrgyz.

Another line of work focusing on Turkic languages is based on neural machine translation (NMT). Mirzakhalov et al. (2021a) trained bilingual models for 22 Turkic languages, including Kyrgyz. In addition to developing baseline systems, this study also introduced a large-scale parallel dataset containing translation pairs for these languages, thereby providing valuable resources for advancing research in Turkic language MT.

Later, the authors released a multi-way multilingual model neural MT model (MNMT) for these languages, showing that the multilingual model outperforms almost all bilingual baselines (Mirzakhalov et al., 2021b).

Fine-tuning multilingual models for low-resource languages has shown considerable promise (Maillard et al., 2023). Notably, Kyrgyz has been incorporated into several multilingual NMT models, such as mT5 (Xue et al., 2021), leading to improved translation quality. A particularly significant contribution to the field is the multilingual NLLB-200 model, trained on 200 languages including Kyrgyz (Team et al., 2022). The primary objective of this work was to provide extensive coverage of low-resource languages within a unified framework.

Another line of research aimed at improving machine translation quality focuses on enhancing tokenization methods. For example, the study by Tukeyev et al. (2020) proposes a tokenization approach based on the Complete Set of Endings (CSE), which reduces vocabulary size and, as demonstrated on Kazakh–English translation tasks, yields better generation quality compared to Byte Pair Encoding (BPE) segmentation. Similarly, Abduali et al. (2025) investigate the Kyrgyz–Kazakh language pair and develop a morphological tokenizers based on the relational segmentation model. The scientific contribution of this article is the creation of the morphological tokenizer for Kyrgyz and Kazakh, as well as fine-tuning experiments with this dataset of the neural model T5-small.

3 Kyrgyz-English Parallel Datasets

Another important line of work in improving machine translation involves the creation of multilingual parallel datasets. Below is a brief overview of open parallel datasets that include the Kyrgyz language.

As part of the TurkLang-7 project (Khusainov and Minsafina, 2021), a corpus of parallel sentences was compiled for Russian and seven Turkic languages. For Kyrgyz, the collection includes 426,190 parallel sentence pairs; however, the final version of the dataset has not been made publicly available.

The NLLB v1 dataset[2] is a large English-Kyrgyz parallel corpus containing 21,360,637 sentence pairs, produced during the development of the NLLB-200 model (Team et al., 2022), where Kyrgyz was included among the languages for which bilingual translation pairs were automatically collected. However, the quality of this dataset is limited, as demonstrated by our manual analysis of the public OPUS sample, which comprises 49 examples[3]. The fully annotated sample that forms the basis for this analysis, including examples of misalignment and various error types, is provided in Appendix A. Our analysis revealed that only 59.18% of the sentences labeled as Kyrgyz were actually written in Kyrgyz. Furthermore, of this reduced Kyrgyz subset, a mere 55.17% were deemed to be accurate and fluent translations. This indicates that only about 32.65% of the original sample represents a high-quality, usable translation pair.

Kyrgyz language was also incorporated into

[1] https://github.com/kyrgyz-nlp/oldi-dataset-experiments

[2] https://opus.nlpl.eu/NLLB/en&ky/v1/NLLB

[3] https://opus.nlpl.eu/sample/en&ky/NLLB&v1/sample

a set of 14 low-resource languages for which the GoURMET project team compiled parallel datasets (van der Kreeft et al., 2022). In total, 14,498 Kyrgyz-English parallel sentences and 23,017 Kyrgyz-Russian parallel sentences were assembled. These sentences were obtained through machine translation followed by editorial validation and control.

The Open Language Data Initiative (OLDI) is a collaborative project that enables language communities, researchers, and developers to contribute to foundational datasets essential for machine learning and natural language processing. At present, OLDI[4] maintains two key datasets: OLDI-Seed and FLORES+.

The OLDI-Seed dataset contains 6,193 English sentences paired with translations into approximately 40 low-resource languages. The English source sentences were drawn from a diverse range of Wikipedia articles covering fields such as biology, astronomy, the arts, history, mathematics, etc. We use the English corpus as a source dataset for Kyrgyz translations.

FLORES+ is an evaluation benchmark consisting of two subsets — a test set of 1012 sentences and a validation set of 997 sentences — each professionally translated into 200 languages by expert linguists.

The X-WMT benchmark (Mirzakhalov et al., 2021b) is a test set designed to evaluate machine translation quality for Turkic languages. It is based on the professionally translated English–Russian corpus from the WMT 2020 News Translation Task. The original news sentences were subsequently translated into eight Turkic languages. For the English–Kyrgyz language pair, the benchmark comprises 500 sentences.

4 Language Description

Kyrgyz (also known as Kirgiz or Kirghiz) is a Turkic language of the Kipchak and/or the South Siberian branch (ISO 639-2: kir, Glottocode: kirg1245). It is spoken primarily in Kyrgyzstan, where it holds official status due to it being the national language. However, it does spread further to Central Asian countries, specifically in Gorno-Badakhshan Autonomous Region of Tajikistan and it is also considered to be a minority language in the Kizilsu Kyrgyz Autonomous Prefecture in Xinjiang, China. And another regional variant of the Kyrgyz language, referred to as Pamiri Kyrgyz, is spoken in northeastern Afghanistan and northern Pakistan.

From a phonetic and phonological standpoint, the Turkic languages most closely resembling Kyrgyz are the southern dialects of Altay, although Kyrgyz also shares significant similarities with Kazakh (Washington et al., 2012). Additionally, the southern varieties of Kyrgyz exhibit distinctive features that align with Uzbek, which are not present in any other Kyrgyz dialects. Approximately, 5.5 million people primarily in Kyrgyzstan consider Kyrgyz their native language.

5 Dataset Translation

5.1 Translation Workflow

Our translation team consisted of six native Kyrgyz speakers, of which two were experienced English to Kyrgyz translators and two were students from the Kyrgyz-English Language Program at Kyrgyz-Turkish Manas University. We followed the OLDI contribution guidelines (Open Language Data Initiative, 2025). The translation workflow was structured into four sequential stages: (1) machine translation using Aitil[5], a Gemma3-based MT service fine-tuned by Ulut Soft LLC (2) manual correction by individual translators, (3) team terminology unification, and (4) consistency review.

At the initial stage, we used the Aitil translation service, which was kindly provided by Ulan Bayaliev and Ulut Soft LLC. At the second stage, translators worked individually to post-edit their assigned batches of machine-translated sentences. This human review process covered all 6,193 sentences, with 99.16% of them being modified. The post-edits addressed a range of common machine translation issues; for instance, our work frequently involved correcting literal translations, improving lexical and terminological choices, and resolving stylistic inconsistencies. To illustrate the nature of these corrections, Table 1 presents several examples.

Following the individual post-editing, we implemented a targeted consistency review process. Our main priority was to ensure high-quality terminological consistency across the entire dataset. To achieve this, translators flagged domain-specific or ambiguous terms for group discussion. Once the team reached a consensus on the translation, the decision was implemented systematically: the

[4]https://oldi.org/

[5]https://translate.mamtil.gov.kg/

Table 1: Examples of machine translations and human post-edits

ID	Sentence
5715	**English:** ...if anyone does something that truly is bad, *it must be unwillingly* or out of ignorance; consequently, all virtue is knowledge. **MT by Aitil:** ...эгер кимдир бирөө чындап эле жаман нерсе жасаса, анда ал муну билбестиктен же *аргасыздан жасашы керек*; демек, бардык жакшылык – бул билим. **Human Post-Edit:** ...эгер кимдир бирөө чындап эле жаман нерсе жасаса, анда ал муну *аргасыздан же билбестиктен улам жасайт*; демек, ар кандай жакшылык – бул билим. **Comment: Syntactic/Stylistic Error:** The MT's output "аргасыздан жасашы керек" is a literal and awkward translation of the English modal structure "it must be". The word order was also unnatural and was corrected in the human edit.
5721	**English:** Although rule by a wise man would be preferable to *rule by law*, the wise cannot help but be judged by the *unwise*... **MT by Aitil:** Акылман адамдын башкаруусу *мыйзамдын башкаруусунан* артык болсо да, акылмандарды *акылсыздар* соттойт... **Human Post-Edit:** Акылмандын башкаруусу *мыйзам үстөмдүгүнөн* артык болсо да, акылмандар сөзсүз *наадандардын* сынына кабылгандыктан... **Comment: Lexical/Terminological Error:** "мыйзам үстөмдүгү" is the correct term for "rule by law". The MT's choice of "акылсыздар" (dumb) for "unwise" was inaccurate; "наадандар" (ignorant/unwise) is more appropriate.
5733	**English:** While the objective of the Pyrrhonists was the attainment of ataraxia, after Arcesilaus the Academic skeptics did not hold up ataraxia as the *central objective*. **MT by Aitil:** Пирончулардын максаты атараксияга жетүү болсо да, Арцелайдан кийин Академиялык скептиктер атараксияны *борбордук максат* катары карманган эмес. **Human Post-Edit:** Пиррончулардын максаты атараксияга жетүү болсо, Аркесилайдан кийин академиялык скептиктер атараксияны *негизги максат* катары көрсөтүшкөн эмес. **Comment: Literal Translation:** "борбордук максат" is a literal translation of "central objective". The more natural term is "негизги максат" (main/primary objective). An extra word ("да") was also removed.

translator who had flagged the term would then perform a search across the entire dataset to update all its occurrences with the agreed-upon translation, ensuring uniformity.

This approach ensured consistency for key concepts. However, we acknowledge two limitations in our overall methodology. First, a comprehensive, sentence-by-sentence peer review was not conducted due to time constraints. Second, the translation workload was unevenly distributed, with one translator contributing the majority of the post-edits:

- Murat: 4910 sentences (79.28%)
- Gulaiym: 614 sentences (9.91%)
- Meerim: 284 sentences (4.58%)
- Elza: 242 sentences (3.91%)
- Akylai: 94 sentences (1.52%)
- Begayim: 49 sentences (0.79%)

5.2 Addressing Problematic Translations

During translation process we turned to dictionaries, both general and technical ones, specific for the given areas, such as, Yudakhin's Russian to Kyrgyz, Kyrgyz to Russian dictionaries (Yudakhin, 1957), (Yudakhin, 1965), Abdiev's English to Kyrgyz, Kyrgyz to English dictionary (Abdiev and Sydykova, 2015) and other dictionaries that are available online at el-sozduk.kg[6]. We also used a collection of Kazakh to Russian and Russian to Kazakh dictionary available at sozdik.kz to verify that international terms (for example, "antibody" which was searched for in Russian: "антитело").

Kyrgyz has certain features that make translation between Kyrgyz and English a challenging task. One of them is the word order. Unlike English, which uses SVO order, Kyrgyz is a SOV type lan-

[6] https://el-sozduk.kg

Table 2: Example of sentence fragmentation

ID	Sentence
4140	**English:** Perhaps the foremost mathematician of the 19th century was the German mathematician Carl Friedrich Gauss, who made numerous contributions to fields such as algebra, analysis, differential geometry, matrix theory, number theory, and statistics.
	Kyrgyz (less effective): Кыязы, 19-кылымдын эң залкар математиги немис математиги Карл Фридрих Гаусс болгон, жана ал алгебра, анализ, дифференциалдык геометрия, матрицалар теориясы, сандар теориясы жана статистика сыяктуу тармактарга көптөгөн салым кошкон.
	Kyrgyz (final): 19-кылымдын эң залкар математиги, кыязы, немис окумуштуусу Карл Фридрих Гаусс болгон. Ал алгебра, анализ, дифференциалдык геометрия, матрицалар теориясы, сандар теориясы жана статистика сыяктуу тармактарга зор салым кошкон.

guage. Although the placement of the verb does not pose any issues, it becomes more difficult the more complex the sentence is. Syntactic functions (e.g., adverbial phrases) also have to be displaced, which makes translation more complicated, as it becomes harder to keep the sentence eligible for the readers without losing the natural flow of the language. (Sankaravelayuthan, 2019). Our translators have also encountered this particular problem, that is dealt with sentence fragmentation. Another feature is that Kyrgyz is agglutinative. It forms words through the sequential addition of morphemes while preserving their original spelling and pronunciation. This linguistic structure allows for the creation of an extensive range of word forms, while English, being an analytical language, relies heavily on such features as auxiliary words, modal verbs and dependent clauses rather than inflection to express grammatical relationships (Kara, 2003).

While the challenges mentioned before were expected, our translators have encountered another two major problems: long, compound-complex sentences and terminological gaps and neologisms. Those problems significantly hindered the translation process. The first problem was dealt with sentence fragmentation, a syntactic transformation technique (Shermatova, 2010). This technique involves restructuring a single complex sentence from the source language into two or more sentences in the target language. The goal is to maintain a natural linguistic flow, and to preserve the original's clarity, emphasis, and stylistic integrity. An example of such fragmentation is listed in Table 2.

The less effective version contains two coordinated clauses with the conjunction "жана" ("and"), presents two critical problems: stylistical redundancy (the repetition of the word "математиги") and syntactic overload (while technically a single grammatical unit, the sentence is long and burdensome, combining two distinct ideas with a simple conjunction, which weakens its clarity and impact). This final resolves both issues. The redundant term is eliminated by using a more appropriate synonym ("окумуштуусу" - "scientist") in the first sentence and allowing the subject to be implied in the second. Most importantly, the structure is clear, emphatic, and stylistically natural in Kyrgyz. The main challenges were translational gaps and neologisms, especially in scientific and technical fields such as genetic engineering and astronomy. Lacking equivalents, we often used transliteration and calquing, typically via Russian—a legacy of the Soviet era when Russian dominated science and education. As many specialists are bilingual, adopting Russian-based forms speeds comprehension (Table 3).

The terms "knockout" and "extinction" are highly specific neologisms. With "knockout" creating a descriptive Kyrgyz phrase (e.g., "генди өчүрүү"–"gene deactivation") would be less precise and more cumbersome. Coining an entirely new Kyrgyz term would likely be unintelligible to specialists who are already familiar with the concept through international, often Russian-language, literature. Therefore, the most effective strategy is the transliteration of the international term (or calquing of Russian term) as "нокаут". This direct adoption is efficient and aligns with the established scientific vocabulary (Zaid et al., 2008).

For accuracy and consistency, we adopted the international term "экстинкция", sourced from an English–Russian astronomical dictionary (Murtazov, 2010), as it aligns with existing literature and is more recognizable to Kyrgyz readers. The problems with scientific terms would not have posed

Table 3: Examples of terminology mapping

ID	Sentence
3986	**English:** In a simple **knockout** a copy of the desired gene has been altered to make it non-functional **Kyrgyz:** Жөнөкөй **нокаутта** керек болгон гендин көчүрмөсү иштебей калышы үчүн өзгөртүлөт.
3506	**English:** In astronomy, **extinction** is the absorption and scattering of electromagnetic radiation by dust and gas between an emitting astronomical object and the observer **Kyrgyz:** Астрономияда **экстинкция** – бул нур чыгаруучу астрономиялык объект менен байкоочунун ортосундагы чаң жана газ тарабынан электромагниттик нурлануунун жутулушу жана чачырашы.

such substantial problems if not for the major linguistic flaw that calquing had created. In most of the cases calquing was justified, as it provided a more specific and in-depth understanding of the phenomenon, in some it resulted in a borrowed word replacing a perfectly suitable native synonym. The primary example is showcased in Table 4.

The case with "bodies" highlights this protrusion. The official dictionary (Eshbaev and Eshbaeva, 2023) suggests using the Russian calque "тело," whereas we observe that this term is now often replaced by the Kyrgyz word "дене." This modern usage is evident in real-world examples from publications such as BBC News Kyrgyz[7], which uses "антидене" for "antibody," and Nazar News[8], which uses "космостук дене" for "cosmic body." During translation, our team gave priority to the latter option, as it better reflects the language usage.

6 Translation Experiment

6.1 Model Training

To demonstrate the quality of the collected dataset, we fine-tuned several seq2seq machine translation models on the gathered 6,193 parallel sentences and evaluated their performance on the FLORES+ benchmark (Team et al., 2022; The Open Language Data Initiative, 2024). We also evaluate our model on the Turkic X-WMT benchmark to compare its performance with the bilingual and multilingual baselines proposed for Kyrgyz–English machine translation.

For fine-tuning, we utilized the Transformers library (Wolf et al., 2020). Across all experiments, we employed the AdamW optimizer with a learning rate of 0.0001 and trained for 6 epochs. The training was conducted on a single T4 GPU with 16 GB of memory.

For each model, we take the same base instance and fine-tune it twice independently — once for translating from English to Kyrgyz (en → ky) and once for translating from Kyrgyz to English (ky → en). The models selected for fine-tuning included:

mT5-base is a multilingual transformer model based on the T5 architecture. It is pretrained on a denoising objective across 101 languages, including Kyrgyz. While mT5 supports Kyrgyz at the pretraining stage, it requires fine-tuning on translation tasks to perform effective machine translation into and from Kyrgyz. (Xue et al., 2021)

mBART-large is a seq2seq transformer extending the BART model to multilingual settings. However, the base mBART-large model does not include Kyrgyz in its pretrained vocabulary, limiting its direct applicability to Kyrgyz translation without additional fine-tuning and vocabulary extension. (Tang et al., 2020)

M2M100 is a multilingual seq2seq model developed by Facebook supporting direct translation between 100 languages without relying on English as a pivot. Notably, Kyrgyz is not included in the 100 languages covered by M2M100, thus the model cannot translate Kyrgyz "out of the box." (Tang et al., 2020)

NLLB (No Language Left Behind) is a large-scale multilingual seq2seq model developed by Meta, designed to improve translation quality, particularly for low-resource languages. It supports over 200 languages, including Kyrgyz. NLLB can translate to and from Kyrgyz with high quality without requiring additional fine-tuning, making it well-suited for applications involving Kyrgyz language translation. (Team et al., 2022)

Table 4: An example of an unnecessary calque

ID	Sentence
3550	**English:** Once it became clear that Earth was merely one planet amongst countless **bodies** in the universe, the theory of extraterrestrial life started to become a topic in the scientific community. **Kyrgyz:** Жер – ааламдагы сансыз асман **денелеринин** арасындагы катардагы эле бир планета экени айкын болгондон кийин, жерден тышкаркы жашоо теориясы илимий коомчулукта талкуулана баштаган.

6.2 Vocabulary expansion

For the models that were not pretrained on Kyrgyz (mBART and M2M100), we expanded the token vocabulary by training a SentencePiece model (Kudo and Richardson, 2018) on the Kloop corpus, a dataset of Kyrgyz news articles (kyrgyz-nlp, 2024). This allowed us to extend the vocabulary by 14,466 byte-pair encoding (BPE) tokens (Sennrich et al., 2016).

6.3 Metrics

To evaluate generation quality, we employ two variations of the ChrF metric: ChrF (Popović, 2015) and ChrF++ (Popović, 2017), both of which are well suited for morphologically rich languages. While prior work has shown that ChrF++ correlates more strongly with human judgments, we also report ChrF scores to enable direct comparison with the Bilingual and MNMT baselines (Mirzakhalov et al., 2021b). For this purpose, we use the implementation provided in the SacreBLEU toolkit[9], adopting the same parameter configuration as in the MWMT study for the computation of the ChrF metric to ensure consistency and comparability of results.

6.4 Experiment Results

The tables present the training results of our models, evaluated on two benchmarks: FLORES+ and X-WMT.

We compare the outputs of our fine-tuned models with its pretrained versions (**pretrained baselines**) on the FLORES+ benchmark to evaluate the impact of our dataset on translation quality. The results are reported separately for the two translation directions: English→Kyrgyz (Table 5) and Kyrgyz→English (Table 6). The results of the X-WMT benchmark are summarized in Table 7.

Fine-tuning on our dataset substantially improves generation quality for all models in both translation directions. (Table 5 and Table 6)

NLLB-200 achieved the highest performance in all the evaluated models. Although the models were already pre-trained on a large Kyrgyz corpus, the addition of even a relatively small dataset like ours can yield a noticeable improvement in translation performance.

When comparing translation directions, Kyrgyz–English translations (Table 6) outperforms English–Kyrgyz translations (Table 5) for all models except M2M100. This asymmetry reflects the stronger representation of English in the pretraining corpora, which enables more reliable decoding into English. The exception of M2M100 can be attributed to its non-English-centric pretraining design.

Manual validation of system outputs, however, revealed that automatic evaluation scores tend to overestimate real-world usability. Despite relatively high ChrF and ChrF++ scores, the translations still contained a considerable number of critical errors. In particular, M2M100 outputs suffered from frequent tokenization and word-concatenation issues, likely caused by suboptimal adaptation of the tokenizer. More generally, all systems struggled with morphological accuracy, especially the generation of correct suffixes. This challenge stems from the agglutinative nature of Kyrgyz, where the high variability of word endings makes exact surface realization difficult.

The performance of pretrained baselines largely depends on whether Kyrgyz was included in their pretraining data and the model's intended use. For example, although mT5's pretraining corpus contains Kyrgyz, it cannot perform machine translation "out of the box" and requires fine-tuning. Neither mBART nor M2M100 was pretrained on Kyrgyz; nevertheless, M2M100 achieves comparatively stronger baseline results, as we extended the model to Kyrgyz by introducing a new language token and initializing its embeddings from Kazakh, a closely related language. Finally, NLLB-200, which was trained on a large Kyrgyz corpus, achieves high

pretrained baselines	ChrF: 1.84 ChrF++: 1.81	ChrF: 0.84 ChrF++: 1.22	ChrF: 13.29 ChrF++: 10.58	ChrF: 49.85 ChrF++: 47.48

Table 7: Performance comparison on the X-WMT dataset (ChrF). Values that exceed the performance of the Multilingual MNMT baseline are highlighted in bold. For the ChrF score, we did not reproduce the baselines ourselves, but used the results reported in the paper.

	mT5	mBART	M2M100	NLLB-200	Bilingual XWMT	Multilingual MNMT
en-ky	28.32	30.92	**36.41**	**47.61**	27	34
ky-en	34.69	33.68	36.10	**47.84**	29	39

performance without additional fine-tuning.

All of our trained models outperform the bilingual MWMT baselines (Table 7). Among them, the multilingual MNMT model is surpassed only by NLLB-200 in both translation directions, and by M2M100 in the English→Kyrgyz direction, demonstrating the competitive performance of our models across different translation setups.

7 Conclusion

This study, part of the OLDI initiative, contributed 6,193 English-Kyrgyz sentence pairs and showed that even modest, carefully curated data can improve neural machine translation for low-resource, morphologically complex languages. In this work, we addressed three key challenges: adapting to agglutinative morphology, restructuring complex subordination, and maintaining terminological consistency. Our preference for native Kyrgyz terms over Russian calques reflects contemporary usage and contributes to natural language evolution.

Fine-tuning mBART, M2M100, mT5, and NLLB-200 models on our dataset yielded consistent performance gains, validating the value of linguistically-informed data. However, the manual evaluation of model translations, highlight the need for further research to achieve production-quality NMT for Kyrgyz. Our collaborative workflow—combining MT, manual correction, and consistency review—offers a replicable methodology for other low-resource languages. Future work involves expanding the dataset and integrating community feedback. This research provides concrete resources and a methodological framework for community-driven language technology development, balancing technical advancement with cultural-linguistic authenticity.

8 Acknowledgments

We would like to thank Elza Mambetakunova and Begaiym Mamatova for helping us with the translations. We are also grateful to Ulan Bayaliev and Ulut Soft LLC for providing access to their Aitil translator, which served as a valuable resource for this work.

Abstract

We open-source SMOL (*Set of Maximal Overall Leverage*),[1] a suite of training data to unlock machine translation for low-resource languages. SMOL has been translated into 123 under-resourced languages (125 language pairs),[2] including many for which there exist no previous public resources, for a total of 6.1M translated tokens. SMOL comprises two sub-datasets, each carefully chosen for maximum impact given its size: SMOLSENT, a set of sentences chosen for broad unique token coverage, and SMOLDOC, a document-level resource focusing on a broad topic coverage. They join the already released GATITOS for a trifecta of paragraph, sentence, and token-level content. We demonstrate that using SMOL to prompt or fine-tune Large Language Models yields robust CHRF improvements. In addition to translation, we provide factuality ratings and rationales for all documents in SMOLDOC, yielding the first factuality datasets for most of these languages.

1 Introduction

There exist no professionally-translated data for most of the world's 7000 or so languages, rendering tasks like Machine Translation near impossible. High-quality data is needed. However, it is not clear how best to use a limited budget for an expensive task like professional translation. As shown by the GATITOS dataset (Jones et al., 2023), word-level translations provide large benefits to translation quality for low-resource languages at the lowest cost. However, gains quickly saturate, as single tokens are not very expressive. Sentence-level data is better for a model once token-level data saturates, but it has much more inherent redundancy; and document-level data is even more effective...and more redundant.

In this work, we release the SMOL dataset, which provides professionally translated sentence- and document-level data for 123 LRLs (125 language pairs). SMOL contains two sub-datasets:

- **SMOLSENT**: 863 English sentences covering 5.5k of the most common English tokens,[3] professionally translated into 90 languages.
- **SMOLDOC** 584 English documents covering a wide range of topics, domains, and tokens, generated by an LLM and professionally translated into 103 languages.

We demonstrate the utility of these data for fine-tuning and prompting LLMs for translation, and provide factuality annotations for all documents.

[1] 🤗 **google/smol**

[2] Experiments are mostly on a subset of 115 languages, before volunteer translations of additional languages finished. The paper title reflects this.

[3] In this paper, 'token' refers to typographic units as an approximation to words, not subword tokens from a model's vocabulary.

2 Related work

There are not many training datasets with human-translated data for Low-Resource Languages (LRLs), where we operationally define LRL as any language beyond the first 100 supported by most traditional crawls and MT providers (enumerated in Appendix section A).

Tatoeba (Tiedemann, 2020) is probably the most multilingual, but it is made of volunteer contributions and of unclear quality. The GATITOS dataset (Jones et al., 2023) consists of a 4000-entry lexicon translated into 170 LRLs, but is only token-level. Most similar to the present work, NLLB-SEED is a high-quality, sentence-level training set of 6k sentences selected from English Wikipedia and professionally translated into 44 LRLs (Team et al., 2022). There are also several professionally-translated evaluation sets, namely FLORES-101 and FLORES-200 (Goyal et al., 2022; Team et al., 2022), and NTREX (Federmann et al., 2022a).

While highly multilingual, professionally translated training data is rare, there is a growing number of bottom-up community data sources organized through research collectives like Masakhane (∀ et al., 2020), Turkish Interlingua (Mirzakhalov et al., 2021a,b), and GhanaNLP (Azunre et al., 2021a); and conferences and workshops like AfricaNLP, AmericasNLP (Mager et al., 2021) and ArabNLP. These datasets are usually generated by researchers fluent in the languages, and are therefore especially high quality. In addition to providing datasets, such efforts frequently also provide models and baselines, or even public interfaces, like the Khaya Translator Web App[4] by GhanaNLP for West African languages, and the lesan.ai[5] translation website for Ethiopian languages.

Participation is especially strong from the African continent, including corpora and models for pan-East-African languages (Babirye et al., 2022), languages from the Horn of Africa (Hadgu et al., 2022), Ethiopian languages (Teferra Abate et al., 2018; Gezmu et al., 2021), Ugandan languages (Akera et al., 2022), Emakhuwa (Ali et al., 2021), South-African languages (Eiselen and Puttkammer, 2014), Setswana and Sepedi (Marivate et al., 2020), Yorùbá (Adelani et al., 2021b,a), Oshiwambo (Nekoto et al., 2022), Igbo (Ezeani et al., 2020), Zulu (Mabuya et al., 2021), Twi (Azunre et al., 2021b), Gbe (Hacheme, 2021), Bambara (Tapo et al., 2021), and Fon (Emezue and Dossou, 2020). Outside of Africa, corpora have been created for languages of the Americas, including for four indigenous languages of Peru in Bustamante et al. (2020), the numerous results on the largely South- and Central American languages from the first AmericasNLP conference (Mager et al., 2021), and the Inuktitut language of Canada (Joanis et al., 2020). Datasets for lower-resourced languages of India have also sprung up, including the 13-language PMIndia (Haddow and Kirefu, 2020), and datasets focused on languages of the Northeast like Mizo (Thihlum et al., 2020), Khasi (Laskar et al., 2021) and Assamese (Laskar et al., 2020). Further West, PARME (Ahmadi et al., 2025) has provided some of the first human-translated content for Kurdish and Iranian languages. Finally, a variety of such datasets and models are available for public use on HuggingFace[6] or Zenodo.[7]

In addition to professionally translated data, there are also several web-crawled datasets for LRLs, including MADLAD (Kudugunta et al., 2023), OSCAR (Ortiz Suárez et al., 2019), Glot500-C (Imani et al., 2023), NLLB (Team et al., 2022), and the Bloom library (Leong et al., 2022).

3 Text Selection

Translation requires significant investment and can't be easily re-done, so great care needs be put into carefully choosing sentences to translate. For both sub-datasets SMOLDOC and SMOLSENT, selection or generation of source text is done in English. Selecting only English has clear biases, but also has advantages—most notably, for N languages, it requires N times less work to quality control. Future work should consider focusing on non-English sources.

3.1 SMOLSENT: Token Set Cover

Our basic motivation for creating SMOLSENT was to help models overcome vocabulary issues, which are common for the lowest-resource languages (Nielsen et al., 2025; Bapna et al., 2022). Therefore, we frame this as a set-cover problem, and pick the smallest set of sentences (from CommonCrawl[8]) that covers the largest set of target tokens. The tokens we chose to cover (the *target set*) were

N-gram DWD	30.0
Embedding DWD	27.5

Table 1: Held-out CHRF for data selection approaches

the English side of GATITOS, as well as the most common 2,500 tokens from an English web crawl. Set cover is NP-hard, so we approximate it with a greedy algorithm that iteratively picks the sentence with the highest *coverage percent*, defined as the percentage of its tokens that are in the target set.

Preliminary work on Token Set-Cover To evaluate the token set-cover approach, we started by selecting data from existing web-scraped parallel data. We pretrain a multilingual Neural Machine Translation (NMT) model on parallel data from 294 language pairs from MADLAD-400 (Kudugunta et al., 2023), with nine languages held out to simulate LRLs. We fine-tune this model on sets of existing parallel data in each of the held-out languages, and evaluate on FLORES-200. Details on the experimental set-up in Appendix B.1.

In addition to Greedy Token Set-Cover, we explore two methods that balance data diversity and data quality. First, we implement Ambati et al. (2011)'s 'density-weighted diversity' (DWD) metric, which is an n-gram based metric for diversity and quality. Second, we implement an embedding-based version of DWD, which takes the weighted harmonic mean of perplexity under the Palm 2 model (Anil et al., 2023) (proxy for quality), and embedding distance on mBERT sentence embeddings (proxy for diversity). We apply both methods to the English side of the parallel data only, to simulate the case where we don't yet have LRL translations. As a baseline, we randomly select sentences.

Table 1 shows results after finetuning. Greedy token set-cover performs the best, with diversity-based metrics actively hurting performance.

Researcher in the Loop (RITL) Despite its success in the ablation, Greedy Token Set Cover had several problems when we scaled it to select from among all the English sentences of CommonCrawl. Firstly, it is maximized by honeypots, or nonsense strings dense in content words (Appendix Table B.1); and secondly, it biases towards short sentences, causing length distribution artifacts.

These problems are not easy to solve with heuristics—for example, if you disqualify lists with commas you'll get ones with spaces, if you require sentences to have some function words or token-length diversity, you'll get other sorts of garbled sentences, and so on. However, a dataset like SMOL is small enough to manually inspect. Therefore we develop *Researcher in the Loop Greedy Set-Cover* (Algorithm 1), where the domain expert (the researcher) can look at and edit each individual sentence.[9] The result of this process is SMOLSENT, a set which uses 863 sentences to cover 5519 unique tokens. Qualitatively, SMOLSENT consists of complex sentences with wide vocabulary coverage; quantitative metrics are explored in Appendix B.3.

3.2 SMOLDOC: LLMs with prompt mesh

SMOLDOC follows a different and complementary approach. Whereas SMOLSENT consists of a small set of *sentences* that are *selected* from natural text, are *complex*, and cover many *tokens*; SMOLDOC instead consists of *documents* that are *generated* and are *simpler*, but cover many *topics*. It should be noted that the token-coverage approach described above failed resoundingly for longer documents, as the prevalence of the honeypots was magnified.

To generate SMOLDOC, we used a collection of templates to create a few thousand diverse prompts with a wide range of topics, domains, words, tenses, grammatical cases, and registers (e.g. formal, informal). Appendix C.2 gives details and examples.

Corpus Diversity Ranking for SMOLDOC Document-by-document evaluation as described above does not help one understand *corpus diversity*—for example, if an almost identical document appears twice, only one of them should be included.

[9]This work was conducted before the advent of LLMs. Today, this could be simplified using LLMs as autoraters.

Therefore, we rank all candidates by how much new information they add to the corpus, by iteratively finding the document contributing the least new information and removing it, thus ranking all documents. Our criterion for "new information" was the average character 9-gram Inverse Document Frequency (IDF) score of a document—in other words, how rare its substrings were across all of the documents in the pool so far. To down-weight internally repetitive documents, we substracted the fourth moment BREAD score (Caswell et al., 2023).

Language Tiers for SMOLDOC We wanted to translate more data for languages with more speakers. We break the languages into the five different groups, each with a larger subset of the generated documents. Each tier contains translations of the top N documents as ranked by corpus diversity. These can be seen in Appendix Table C.1.

Non-English-centric translations For SMOLDOC, we additionally collected data for four non-English-centric language pairs, from each of the East African languages of Amharic (`am`) and Swahili (`sw`) to each of regionally relevant languages Standard Arabic (`ar`) and Mandarin Chinese (`zh`). Including the reversed versions of these, this yields 8 total language pairs. Because of the difficulty of generating good source material in these languages, we used the existing SMOLDOC translations to Swahili/Amharic as the source text. However, due to the lack of appropriate evaluation sets, it is hard to know the value-add of this data over datasets pivoted through English.

4 Data Collection and Verification

Several languages are contributed by volunteers; they are listed as co-authors.[10] For the other languages, the translation provider we contracted has worked with us for many years, and has a pre-existing relationship with professional translators for all languages in the SMOL datasets. The translators are paid a fair wage, and their identities are contractually kept anonymous to us. We checked the delivery for duplicate translations, anomalous source/target length ratios, and similarity with Google Translate outputs. Very few languages were flagged this way. Following this, we ran FUNLANGID (Caswell, 2024) on all segments and found no issues. Manual inspection turned up several issues with nonunicode fonts (e.g. ô for ɔ) for West African languages, and nonstandard orthography for Santali; these issues were then fixed. The choice of script, orthography and translation variety was challenging for many communities, including Kurdish, Zaza-Gorani and Gilaki languages, all of which have more than one orthography and lack a standard variety.

The largest missing check is for fluency, which is hard to measure without trusted native speakers *outside of the translation agency*, or trusted LLMs; neither of which exist for all SMOL languages.

5 Finetuning and In-Context Learning

We use fine-tuning and ICL as tools to demonstrate the value of the SMOL dataset. As this is a data paper, these experiments are motivated by the maxim *"what could any researcher simply train with public APIs?"* More involved techniques, e.g. Reinforcement-Learning-based approaches, will likely lead to stronger results.

5.1 Evaluation

Since so many language pairs are covered, we evaluate on a combination of all available evaluation sets, namely FLORES-200 (Team et al., 2022), NTREX (Federmann et al., 2022b; Barrault et al., 2019), and an in-house eval set. Since no reliable embedding models exist for these languages, trained metrics are not an option, so we use CHRF (Popović, 2015) as implemented in SacreBleu (Post, 2018)[11] with NFKC unicode normalization as our metric. For ten-shot decoding, exemplars were selected from both sub-datasets of SMOL using CHRF-counterweighted RAG (Appendix D).

5.2 Finetuning Setup and Results

We finetuned Gemini 2.0 Flash for 40 epochs on SMOLDOC, SMOLSENT, a combination of the two (BOTH), and their combination plus GATITOS (BOTH+G). To simplify finetuning, we split SMOLDOC into sentence pairs (SMOLDOCSPLIT).

Results can be seen in Table 3. Finetuning on SMOLSENT gives an average gain of +2.7 CHRF points, and SMOLDOCSPLIT gives +2.6 CHRF points on its languages. Concatenating the two training datasets leads to a gain of +3.3 to +3.6 CHRF points, and adding in GATITOS bumps it

[10] Community contributions of translations or corrections are welcome; please reach out to the authors or join the TUSL Discord.

Table 3: Finetuning Gemini 2.0 Flash on SMOL for four subsets of language pairs. The first two columns show LPs in SMOLSENT and those in SMOLDOC, to show the different effects of each split. The third shows those in both SMOL datasets AND the closed domain NMT models, for an even comparison to NMT models. Finally, the HARD column shows LPs in both SMOL splits but NOT in Google Translate, or not closely related to a language in Google Translate, to approximate the especially hard languages to learn.

up to +3.8 to +4.1 CHRF points, passing all baselines except Google Translate. The 10-shot RAG results on the un-tuned model are very close to the finetuned 0-shot results, and the finetuned models show no benefit from multi-shot decoding, suggesting that these are two different ways of giving the same information—inference-time versus training time. The 10-shot random results (not included in table) were much lower.

Gains were highest on languages that are not related to mid- or high-resource languages, and lowest on dialects close to major languages. As a heuristic to measure this, we exclude languages that are on Google Translate or closely related to languages on it (Appendix G). The average gain on these languages jumps to +7.6 CHRF.

Figure 1 shows the learning curve on a development subset of 37 languages. Although it may be surprising that so many epochs are needed before convergence, we found that further increasing learning rate led to overfitting. The sharp drop near the beginning suggests a domain mismatch between pretraining and finetuning, and suggests that the same data could be used much more effectively with a better training set-up than explored here.

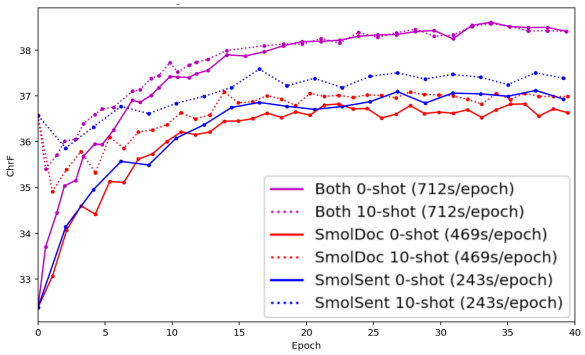

Figure 1: Training curves (CHRF) for finetuned models on a subset of 37 en→xx language pairs, trained on SMOLDOC, SMOLSENT, and their combination BOTH.

5.3 The Problem with xx→en training

Our initial experiments used all data for both en→xx and xx→en . However, the models lost performance on all tasks. The root cause turned out to be the multiway-parallel data with English tar-

Rating	Definition of Rating
N/A	True/False does not apply here. Most stories, dialogues, or fictional works would be considered N/A, unless they are promoting a falsehood about the real world.
Not Sure	Claims are made that may not be true, but you aren't sure. Choose this if it would take over 10 minutes to verify the factuality of the claim.
No Issues	All claims are factual and accurate. (Out-of-date is fine, e.g. "Barack Obama is the US President")
Minor Issue(s)	There are small inaccuracies. E.g., it may be broadly correct but frame something in a misleading way.
Clear Issue(s)	There are clear mistakes in factuality.

Table 4: Factuality Rubric

gets. LLMs are especially susceptible to repetition in data (Lee et al., 2022), and with 115 language pairs, for every one epoch over the data, the model saw about 115 epochs for each individual target sentence. Therefore, it wildly overfit and lost performance on all language pairs. Mitigating such overfitting is an important research direction to pursue, since many promising datasets are multiway parallel, e.g. FLORES-101 (Goyal et al., 2022), FLORES-200 (Team et al., 2022), NTREX (Federmann et al., 2022b; Barrault et al., 2019), and others. However, this is out of scope for the present paper, so we restrict our experiments to en→xx .

Seeing the same *source* many times likely also has deleterious effects and should also be studied; but these effects, if they exist, are small enough that we were still able to see net gains.

6 Factuality Review

Since SMOLDOC contains LLM-generated sources, they contain some factual inaccuracies. We therefore do a full human audit and assign factuality codes to each document. Each of the 584 documents was rated by three raters. Each rating is accompanied by a detailed explanation, including sources cited. Inter-annotator agreement was high, with Cohen's κ between each pair of raters between 0.82-0.87. The error code distribution can be seen in Figure 2. The rubric is presented in Table 4.

All ratings and rationales are made available. In addition, each datum in SMOLDOC is given with a simple `factuality` annotation, which has the value `has_errors` if any one of the ratings was any of `Minor Issues` or `Clear Issues`, and `ok` otherwise. For some use-cases, like question-answering, practitioners may want to filter out nonfactual data; for others, like translation, one may not be troubled by factual errors. In addition to filtering, this also provides the first factuality dataset for most of these languages.

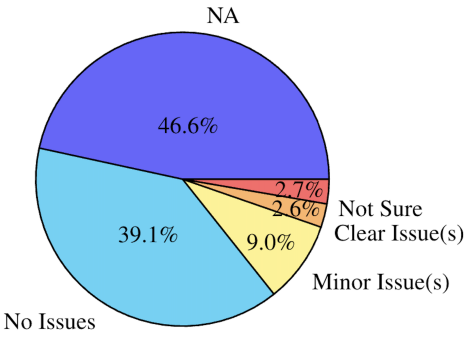

Figure 2: SMOLDOC factuality ratings.

7 Conclusion

We have open-sourced the SMOL dataset, a professionally-translated dataset covering 123 low resource languages and targeting the tasks of translation and factuality. It comprises SMOLDOC and SMOLSENT, two training datasets with the complementary strengths of sentence selection (complex, and high token coverage) and document generation (contextual, varied domains, simpler sentences) respectively. We demonstrate that finetuning Gemini 2.0 Flash on these yields to substantial improvements in translation quality. SMOL joins a growing body of resources to support underserved languages in the age of AI.

8 Limitations

The SMOL data would benefit from a more thorough review, audit, and correction from community members outside of the translators who created it. Future work on SMOL-like datasets should also focus on non-English source text that is not only maximally authentic in the given language, but also covers the topics and concepts most relevant to those languages. This approach is more difficult and would require significant work and review to do correctly. Finally, more research is needed to understand and prevent the overfitting that comes with multi-way parallel data.

A Operational Definition of LRL

In this paper, we operationally define LRL as any language beyond the first 100 supported by most traditional crawls and MT providers. Since there is some variation in which languages exactly this is, we concretize it as the set of 104 languages supported in Google Translate prior to 2020. These are the languages for which launchable quality was possible before LLM-type models like M4 (Arivazhagan et al., 2019; Bapna et al., 2022) and PaLM (Anil et al., 2023) came on these scene. It is also worth noting that since these languages were on the product for much longer, they have much more machine-translated content online from services that used Google Translate for internationalization. These 104 languages are: `af am ar az be bg bn bs ca ceb co cs cy da de el en eo es et eu fa fi fil fr fy ga gd gl gu ha haw hi hmn hr ht hu hy id ig is it he ja jv ka kk km kn ko ku ky la lb lo lt lv mg mi mk ml mn mr ms mt my ne nl no ny pa pl ps pt ro ru sd si sk sl sm sn so sq sr st su sv sw ta te tg th tr uk ur uz vi xh yi yo zh zh-Hant zu`.

Rightly speaking, the languages outside of this set might better be termed "Very Low-Resource" instead of just "Low Resource", since the 104 languages above do include languages like Hawaiian, Javanese, Yiddish, and Hmong, which are by no stretch of the imagination high-resource. We will leave more rigorous definitions to future work.

B SMOLSENT details

B.1 Evaluating the SMOLSENT selection process

In Section 3.1, we describe experiments used to validate the selection process for SMOLSENT. We train a backbone MT system is pretrained on the MADLAD-400 dataset (Kudugunta et al., 2023). The following languages are held out of the training data to be used for fine-tuning experiments: Catalan, Icelandic, Marathi, Turkish, Maltese, Xhosa, Tamil, Basque, and Tajik. The model itself is a 1B parameter encoder-decoder Transformer and is trained from scratch on the MADLAD-400 data. Each of the candidate data selection methods is used to select data from the held-out languages, and then each candidate set is used in turn to finetune the backbone model. The results of this finetune step are reported in Table 1, where the set-cover approach is shown to be most effective.

B.2 Notes on Researcher in the Loop

Researcher In the Loop extends the greedy set cover approach thusly: rather than always picking the highest-scoring sentence, we iteratively show the researcher a batch of the 20 highest scoring sentences according to several scores, and let the researcher pick and optionally edit each sentence at each iteration. At each iteration, the researcher may also remove any number of this batch's sentences from the reservoir. Allowing the researcher to see and edit the sentences allows ensures that the sentences are of high-quality. To deal with the length bias issue, we showed not only sentences that maximize coverage percent, but also that maximize heuristics that weighted the coverage with the number of new tokens hit, like `log(coverage_percent)*n_hits` .

As described in the paper text, this approach is designed to combat issues such as honeypot sentences. Example Honeypot sentences can be seen in Table B.1

Sentence
Individual determine can get prolonged, reduce along with attractive.
Sell hand mood situation connect proper decision today spread true.
Demand indeed off forget act special well treat sometimes notice.
Agree board book oh trust by attractive supply deal together.
Picture exactly could ability impact advance then same admire across.
One physically courage both information language issue laugh common.

Table B.1: Honeypot Sentences for Greedy Selection: CommonCrawl has many sentences packed with content words but with no clear semantics or grammar.

B.3 Corpus statistics on SMOLSENT

To measure "Bang for our Buck" we define the *excess-token ratio* ξ as the number distinct tokens in the set cover divided by the number of target tokens, and use it along with the coverage percent to understand the SMOLSENT dataset. Table B.2 compares corpus statistics of SMOLSENT to four other corpora. `sametoks` picks a random set of sentences from CommonCrawl until it has the same number of tokens as SMOLSENT; this only covers 50% of the target tokens and has an excess-token-ratio ξ ratio of 3.3, much worse than SMOLSENT's value of 2.3. The `samecov` baseline randomly picks common-crawl sentences until it has the same token coverage as SMOLSENT, which necessitates

set	N sent	toks	types	$\xi(\downarrow)$	cov%(↑)
SMOLSENT	863	12k	5.5k	2.3	99.6%
sametoks	863	12k	3.8k	3.3	50.4%
samecov	57578	877k	38k	23.1	99.6%
SMOLDOC-T1	6979	108k	8.8k	12.3	80.5%
SMOLDOC-T5	820	12k	2.8k	4.3	40.2%

Table B.2: Corpus statistics of SMOLSENT, random selections of sentences from CommonCrawl, and tiers 1 and 5 of SMOLDOC.

set	N langs	ex	tok	char	ex/LP	tok/LP	char/LP
SMOLDOC-t1	5	2.9k	537k	3.0M	584	107k	604k
SMOLDOC-t2	31	14k	2.7M	15M	450	88k	495k
SMOLDOC-t3	24	6.7k	1.2M	6.8M	280	50k	281k
SMOLDOC-t4	8	1.0k	184k	1.0M	126	23k	128k
SMOLDOC-t5	34	2.2k	401k	2.2M	66	12k	65k
all-SMOL	GTr	97k	6.1M	34M	827	52k	294k

Table C.1: Statistics on the languages in the individual tiers of SMOLDOC.

a 67x larger set of sentences, and a correspondingly bloated excess token coverage ratio of 23.1. As a further reference we compare tiers 1 (largest) and 5 (smallest; comparative size to SMOLSENT) of SMOLDOC. As expected of machine-generated text, they have a worse ξ value, corresponding to a narrower spectrum of vocabulary used.

C SMOLDOCDetails

C.1 SMOLDOC data tier details

Per-tier statistics on the SMOLDOC dataset can be seen in Table C.1.

C.2 Details on SMOLDOC prompt creation

To avoid biases from overly tempted prompts, we put in significant effort to make sure the prompts were all very different. Each prompt drew at random from the following elements:

- random selection of English words to use in the response
- one of 600 manually created topics, e.g. “volcanic eruptions” or "A special tree”
- one of 50 tone/tense categories, e.g. “Please use the subjunctive mood.”, “Use an effusive tone.”
- A style prompt, e.g. “You are the author R.K. Narayan.” or “You are a mother talking to her son.”
- A text modality, e.g. story/dialogue/essay

In addition to this, we added a few more sources of prompts:

- Prompts based on urls, meant to simulate different web domains, like Wikipedia and reddit.
- Prompts based on continuing the sentences from SMOLSENT
- Prompts based on current events, history, and daily life in different countries
- Special effort was made to include dialogues (to get more spoken register) and recipes (unique domain that may also be important to translate).

For each prompt, we generated 8 responses (T=0.7). These were ranked by their simple token density (unique tokens over total tokens), and the top two were chosen for consideration. Using the Researcher-in-the-loop mentality (“measure twice cut once!”), we went over 1000+ responses by hand and scored/edited them. This was mainly to filter out questionable or boring responses. A typical paragraph scored as 0 would be LLM-speak like *“X is a complex and multifaceted problem with no easy solution. Here are some suggestions. Keep in mind that there is no one-size-fits all solution, and ultimately, the choice is up to you. [...]”*.

Example prompts can be seen in Table C.2.

C.3 SMOLDOC Errata

Orthographies Several languages use irregular orthographies. Most notable is Mooré/Mossi (mos), where different translators have used a variety of different conventions. After soliciting community feedback, we plan to release standardized versions to the data.

Example Prompts
You are Ernest Hemingway. Write a dialogue about road rage. Use a didactic tone.
Write a 1-paragraph story concerning an Irish wake.
You are a teenager talking to his friend. Please carefully craft a 1-paragraph bit about an engineer who subsists off coffee. Try to include the words “confirmed”, “move” and “above”.
Give a typical, yet interesting, example of something you would find on reddit.
Please write a few paragraphs about challenges facing Ethiopia.
Please write a long passage starting with ‘Mum and Dad pause their debate when we hear this creepy clacking that sounds like hail falling.’
Write a recipe for baking an almond cake.

Table C.2: Representative sample of prompts use to generate the documents for SMOLDOC

document selection When collecting the data for SMOLDOC for the Indian languages, we mistakenly included a variety of documents that fell below the corpus diversity threshold described in Section 3.2.

D N-shot: CHRF-counterweighted RAG

To have a strong baseline for N-shot results, we adopt a RAG-based approach that resembles the greedy set-cover algorithm. For each sentence in the eval set, we want the best coverage of the source sentence n-grams as possible, with the least redundancy among exemplars. Therefore, we iteratively choose the exemplar whose source side has the minimum CHRF to the eval source. However, when counting the true positives in the CHRF calculation, we weight the count of each ngram n_i by $(1+c_i)^{-\alpha}$, where $c_i \in [0, \infty]$ is the number of times n_i has been seen among the exemplars chosen so far, and α is a parameter to control how close this algorithm is to ngram set-cover. We use $\alpha = 2$.The set of exemplars we choose from is the concatenation of SMOLSENT and SMOLDOCSPLIT.

E Prompts for Decoding

For 0-shot prompting, we used the following, fairly wordy prompt, the SL and TL standing for the source and target language name, respectively:

```
You are an expert translator. I am
going to give you some example
pairs of text snippets where the
first is in ${SL} and
the second is a translation of
the first snippet into
${TL}. The sentences
will be written
${SL}: <first sentence>
${TL}: <translated first sentence>
After the example pairs, I am
going to provide another sentence
in ${SL} and I want
you to translate it into
${TL}. Give only the
translation, and no extra
commentary, formatting, or
chattiness. Translate the text
from ${SL} to ${TL}.
```

For finetuned models, there is no need for such a wordy prompt, and indeed it only risks overfitting. Therefore, we used the following minimalist prompt:

```
Translate from ${SL} to ${TL}:
```

F Volunteer contributions

A few languages have extra details that need to be called out here.

F.1 Translations for Cantonese

A volunteer team of Cantonese speakers at Google pulled together to translate the maximal set of SMOL text. Mingfei Lau and Jonathan Eng were the main leaders of this effort, and the contributors to translation and post-editing were (alphabetically): Tsz Yan Au, Emily Awesome, Jason Chan, Siu Man Chan, Vicky Chan, Yiwang Chen, Kinton Cheung, Mingo Choi, Andy Chow, Ashley Chow, Olivia Chow, Daniel (Ying Wai) Fan, Thomas Fung, Vikki Ha, Joshua Kwong, Liam Lee Pong Lam, Jonas Lau, Ying Tung (Grace) Law, Crystal Lee, Aki Leung, Derek Leung, Jackie Leung, Thomas Leung, Mu Li, Alicia Liu, Malena Loosli, Chui McConnell, Ken Ng, Nicholas Ng, Tonia Shen, Helen Shum, Franky Sze, Eric Tang, Tommy Tse, Daniel Wong, Danny Wong, Maggie Wong, Pinki Wong, Jeffrey Yu, Shanelle Yu, Shing Fung Yue, Miranda Zhang, and Willis Zhang.

F.2 Translations for NKo

The initial delivery for the NKo language (nqo) had a wide variety of errors. We reached out to the authors from Doumbouya et al. (2023), who did a complete re-translation of the text.

F.3 Translations for Zazaki, Hawrami, and Gilaki

Sina Ahmadi gratefully acknowledges support from the UZH Postdoc Grant (reference number 269093).

F.4 Translations for Zarma

Annotation Pipeline The Zarma translation process of SMOL—all the subsets—was done through a combination of automatic and human in the loop methods. We leveraged some existing tools that our team developed to speed up the annotation process. We first used a baseline bidirectional model that we developed to produce initial translation of the samples. These machine translated samples were then passed through our Zarma grammatical error correction model. This model was built by pre-training gemma-2-9b on Zarma data and fine tuning the checkpoint on grammar error correction data set using Direct Preference Optimization (DPO) settings. The outputs from this stage—both languages side by side—were then given to our team of annotators for review.

The annotators were given some guidelines—in addition to the general guidelines from SMOL—for the annotations. These guidelines include:

- **Word adaptation:** rules for handling technical terms, proper nouns, and domain-specific vocabulary that might not have direct equivalents in Zarma. E.g: all the scientific/technical words remain unchanged; and words that have known french-ized equivalent in Zarma must be used in their french-ized forms (for better understandability).

- **Prioritize understandability:** guidelines to prioritize understandability and fidelity over word-for-word translation. We instructed annotators to focus on creating translations that sound natural and widely understandable by Zarma speakers.

- **Language specific constraints:** language specific guidelines that cannot be generalized.

The pipeline speeds up the process while maintaining the quality, since some of the outputs from the automatic stages were already correct.

Zarma Community Attitude Towards Tech : The Zarma community—and the whole Niger in general—are very open minded regarding technology. When we started our very first resource creation for the Zarma language, we received positive feedback and even help from the community, as long as we developed an openly accessible solution for the community. **For the SMOL annotation, that trust helps us to receive valuable help.** For instance, a government based institution verbally promised to accompany any language preservation—machine learning focus in our case—if the outcome will be open-sourced for community usage.

F.5 Post-Edits for Mooré

Annotation Pipeline The annotation process for Mooré did not involve any automated components; everything was annotated by humans. The annotation focuses more on the guidelines provided by SMOL, in addition to some more as in the Zarma case.

Mooré Community Perspective The Mooré community, similarly to the zarma community, are very open minded towards technology; especially if it touches cultural/language preservation. One main feedback we received from some elders (parents of one of the annotators) was a warning to ONLY USE standard Mooré orthography, not any equivalent. They want the language to be well documented according to the language standards.

F.6 Post-Edits for Indonesian

A volunteer team post-edited translations of smoldoc and smolsent datasets that had done by Gemini 2.5 Pro. The contributors to translation and post-editing were Muhammad Ravi Shulthan Habibi, David Anugraha, and Genta Indra Winata. The post-edits resulted in about 70% of the machine translations being changed.

Translators agreed that the system output was often too “formal", “stiff", or “awkward". The “formal" translations were furthermore not formal in an acceptible sense, but “too awkward and stiff, even for a more formal situations", as an annotator said. Each word choice might be correct and standard in Indonesian, but when combined in a sentence, the result sounded unnatural. Therefore, the majority

of the post-edits focused on making the translations sound more natural.

Nonetheless, overall the system output was already quite reasonable in terms of register. In some cases, though, it leaned toward being too rigid. The post-edits tried to loosen that into a consistent "medium" range, but with some flexibility depending on the style of each sentence (sometimes slightly more formal, sometimes slightly less) so the overall text still feels natural and coherent.

F.7 Translations for Languages of the Russian Federation

Traditionally, speakers of hundreds of Cyrillic-based languages in the Russian Federation translate datasets via Russian. For the success of this project, I (Ali Kuzhuget) first funded a professional translation into Russian, engaging Andrey Anisimov as the main translator. The proofreading was conducted by Farhad Fatkullin, Vice-President of the National League of Translators, together with machine translation specialist David Dalé. I also oversaw formatting correctness and coordinated the overall translation workflow.

In parallel, I supervise the translation of the dataset from Russian into Tuvan, using a dedicated Telegram chatbot for large-scale dataset translation. This tool enables multiple rounds of validation and systematic assessment of translation quality. Currently, representatives of about a dozen Cyrillic languages are in the process of translating the SMOL dataset into their own languages through Russian and/or English (for example, Tuvan, Bashkir, Chuvash, and others), ensuring both linguistic accuracy and cultural relevance.

G Full results

Full per-language results can be seen in Table G.1. Results are sorted by the Δ_{FT}, which is the CHRF of the BOTH model minus the CHRF of the finetuned BOTH model—in other words, how much the finetuning on SMOL improved the baseline model.

Google Translate Languages and their cousins As mentioned in the results section, some languages see only very small improvements from finetuning on SMOL, and others even see losses. These are mainly either high-resource languages, or close relatives to higher-resource languages. In the full table G.1 below, The superscript $^{\text{GTr}}$ indicates a language supported by Google Translate at the time of these experiments; a superscript like $^{\sim\text{xx}}$ means that this language is closely related to the Google-Translate-supported language xx. We only consider the 108 languages that were present on Google Translate at the time of this work.

Table G.1: Full results (0-shot) For the en→xx direction. Languages in the Intersect subset (supported by all models) are shown first, and then all other languages. The Δ_{FT} compares the base model and the model finetuned on BOTH, to give an idea of how effective the SMOL datasets are for that language. The CAT column indicates which SMOL datasets support this language. The superscript GTr indicates a language supported by Google Translate; a superscript like $\sim$ xx means that this language is closely related to that Google-Translate-supported language.

Abbreviations: This table needed some squishing to fit. Language varieties whose script/region is different from the CLDR default would have the ISO-15924 script code in the BCP-47 code, like MNI-MTEI or BER-LATN; in this table we have abbreviated them to the first letter thereof (MNI-M or BER-L). Similarly, we have abbreviated:
SMOLSENT → sS
SMOLDOC → sD
BOTH → sB
BOTH+GATITOS → sG
GEMINI 2.0-{FLASH, PRO} → G2.0-{F,P}
GOOGLE TRANSLATE → GTR.

H Complete Per-Language details: the Big-SMOL table

A summary of all SMOL language pairs and coarse-grained information about them can be seen in Table H.1. Numbers are given in terms of examples; keep in mind that a single example in SMOLDOC is a document, whereas in SMOLSENT it is a sentence.

Table H.1: Details on all SMOL language pairs, sorted by the total number of characters in the target side (col. 5). The last two columns are the number of examples per language pair; keep in mind that an example for SMOLSENT is a sentence pair but for SMOLDOC is a document/paragraph. Language pairs are only listed in the direction in which they were translated, so no xx→en pairs are present.

Abstract

FLORES+ is a collection of parallel datasets obtained by translation from originally English source texts. FLORES+ contains Norwegian translations for the two official written variants of Norwegian: Norwegian Bokmål and Norwegian Nynorsk. However, the earliest Bokmål version contained non-native-like mistakes, and even after a later revision, the dataset contained grammatical and lexical errors. This paper aims at correcting unambiguous mistakes, and thus creating a new version of the Bokmål dataset. At the same time, we provide a translation into Radical Bokmål, a sub-variety of Norwegian which is closer to Nynorsk in some aspects, while still being within the official norms for Bokmål. We discuss existing errors and differences in the various translations and the corrections that we provide.

1 Introduction

This paper describes our submission to the WMT 25 open language data shared task, where participants were asked to contribute to open dataset collections such as FLORES+, the MT Seed dataset or other parallel datasets. We have chosen to focus on the Norwegian Bokmål part of the FLORES+ dataset, as the authors notice non-fluencies in the dataset in 2024, and notified the original authors. These issues were attempted resolved in a process that lead to additional errors, which are the ones that form the basis of this paper. In addition to correcting these translations, we translate the resulting Norwegian Bokmål dataset into a version of a specific variety of written Norwegian called radical Bokmål. Having these two normed varieties can be beneficial for experiments where variation in Norwegian spelling norms is important. We summarize some of the encountered errors in the newest Bokmål translations, and show some results on several machine translations baselines for the new and existing Norwegian versions.

2 The Norwegian Language and its Writing Norms

Norwegian is one of the official languages of Norway, along with Sámi languages and Norwegian Sign Language. It is a North-Germanic language historically descendant of Western Norse, but following large Saxon and East Norse influences, is largely mutually intelligible with its neighbors Swedish and Danish, and more different from Icelandic and Faroese. However, following centuries of having Danish as Norways national language, nationalist movements in the late 19^{th} century lead to the establishment of two written standards: Landsmål (today **Nynorsk**), which was based on dialects "untainted" by Danish, and Rigsmål (Riksmål, today **Bokmål**), which was Norwegianized Danish. Nynorsk historically aimed at preserving Norwegian-specific features, which means that Saxon and Danish influences are less pronounced in Nynorsk than in Bokmål.

2.1 Conservative, Moderate and Radical Bokmål

Within both written norms however, considerable variation exists. This variation is not arbitrary, and generally follows typical patterns, leading to what is known as **norm clusters** (nor. *normklynger*) (Dyvik, 2009). On the Bokmål side, perhaps the most common sub-norm is **Moderate Bokmål** (MBM) (or Conservative Bokmål, CBM)[1], which is what dominates especially formal Norwegian discourse. This variety is known for Danish-like conjugational and declensional patterns: preterite in *-et*, no feminine nominal endings (with a few exceptions). On the other hand, **Radical Bokmål** (RBM) aims at a style closer to how many people in

[1]While the terms *moderate* and *conservative* are used synonymously by some authors, some prefer to reserve *conservative* for the most extreme (Danish-like) Norwegian, and reserve *moderate* for a norm that allows for some radical elements.

Proceedings of the Tenth Conference on Machine Translation, pages 1124–1132
November 8-9, 2025

(Eastern) Norway speak, and adopts features shared with Nynorsk (NN) in some regards: obligatory feminine marking for articles and noun declension, preterite in *-a* (NN also *-a*) where MBM has *-et*, and neuter definite plurals in *-a* (NN also *-a*) where MBM has *-ene*. There are also some sound correspondences, with a difference between diphthongs and monophthongs being especially common. For example, RBM has *mjølk* where MBM has *melk* (NN *mjølk)*. As illustrated in the artificial example below, this affects both morphology and syntax, with Nynorsk added for comparison. Note how while RBM is said to be closer to Nynorsk, this is not to say that all RBM forms exist in Nynorsk, as exemplified by *skog* (MBM, NN) and *skau* (RBM).

(1) MBM: I helgen var jeg på hytten i skogen og danset med min søster.

RBM: I helga var jeg på hytta i skauen og dansa med søstera mi.

NN: I helga var eg på hytta i skogen og dansa med søstera (or systera) mi.

The degree to which a writer follows these patterns differs, leading to many possible variations within this spectrum. In our efforts to provide a radical form, we chose the most radical form as presented in the official Norwegian dictionary *Bokmålsordboka*.[2]

3 The FLORES Dataset

The FLORES dataset is an evaluation dataset for multilingual machine translation, consisting of a *dev* and a *devtest* part with about 1000 sentences each. The dataset is multiparallel and English-centric: the original sentences are in English, and all other language variants were produced by translation. Several versions were made available over time, reflecting efforts to increase language coverage and address quality issues.

FLORES101 was the first version of FLORES, covering 101 languages, including Norwegian (Goyal et al., 2021). While the authors claimed that the sentences were "[...] translated in 101 languages by professional translators through a carefully controlled process", we observed severe quality problems with the Norwegian Bokmål translations. See further discussions in 3.1.

[2]Bokmålsordboka. The Language Council of Norway (Språkrådet) and the University of Bergen https://ordbokene.no.

FLORES200 was a continuation from both FLORES101 and Guzmán et al. (2019), with an increased coverage of 200 languages (NLLB Team, 2022). The Norwegian sentences appear to be unchanged between FLORES101 and FLORES200. The FLORES200 translations were used, among others, in the Belebele (Bandarkar et al., 2024) benchmark. Quality problems in the former therefore directly affect results reported on the latter dataset. We have used the Bokmål sentences from FLORES200 both as an aid in correcting the translations, and as a point of comparison agains the new dataset as a whole. These sentences initially struck the authors as unnatural, with exampled reported such as translating *iron* (the metal) as *strykejern* (eng. 'clothes iron'), and (judicial) *court* as *hoff* (eng. royal court).

FLORES+ The responsibility for the FLORES datasets was eventually moved to the Open Language Dataset Initiative.[3] As a result, the updated versions are referred to by FLORES+ and published on HuggingFace.[4]

In January 2024, the authors of this paper reached out to the original FLORES101 authors to express concern over the quality of the Norwegian Bokmål dataset, based on FLORES200. Following this, the dataset was updated, as indicated by a changelog note from November 11^{th} 2024[5]. This note informs that the Norwegian version has been updated after quality assessment, but with no further information. Going through these changes, we see, however, that not all errors were corrected, and that new ones were introduced. Correcting these errors is the main focus of this paper.

3.1 Problems with the Norwegian FLORES Translations

The Norwegian version published as part of FLORES101 (referred to as **BM1**) contained a range of issues, some of which were amended in the FLORES+ version (referred to as **BM2**).

When comparing the BM1 and BM2, the naturalness of the sentences have improved in some cases, but there are still multiple mistakes left in the dataset. Overall, BM1 used a syntax that was less influenced by the original English. In some

[3]https://oldi.org/

[4]https://huggingface.co/datasets/facebook/flores

[5]https://huggingface.co/datasets/openlanguagedata/flores_plus/blob/main/CHANGELOG.md#20--2024-11-11

cases, BM2 is even worse than BM1. Every single sentence in the Bokmål dataset was changed during this edit, but it seems like the BM2 translations show signs of not having referenced the BM1 translations, as in several cases where both Nynorsk and BM1 have a correct translation, but BM2 still mistranslates, for example the English *engraver*, which is translated correctly as *gravør* in NN and BM1, is erroneously translated as *graver* 'digger' in BM2. While the Nynorsk dataset also had changes in 21 sentences, this turned out to only be differences in trailing spaces.

Certain errors are so pronounced that it is difficult to conceive they were produced by a professional translator, or even by a fluent speaker of Norwegian. This can be illustrated by example 2 where the English word 'bill' has been translated as *lovforslag* 'bill (judicial)', while in the new translation it has been changed to *regning* 'bill, receipt'. The terms are not ambiguous as in English, and the result is comical.

(2) BM1: Det opprinnelige **lovforslaget** ble utarbeidet av tidligere ordfører i São Paulo [...]

BM2: Den opprinnelige **regningen** ble utarbeidet av tidligere borgermester i São Paulo [...]

EN: The original **bill** was drafted by former mayor of São Paulo, Marta Suplicy.

These examples make it clear that despite the corrections being made in 2024, not all mistakes were fixed, and some new ones were introduced. This prompted us to critically assess the BM2 translations and correct them. In the following section we describe our correction process, then follow with a brief overview of error types and key statistics. We refer to our corrected Bokmål translations of FLORES+ as **BM3**, and to the Radical Bokmål version as **BM3R**.

4 Translation Correction

We introduce our methodology and discuss some of the encountered errors. See Appendix A for selected example sentences in all languages involved in this process.

4.1 Methodology

Our aim for this effort is not a full retranslation of the English, but rather to take the BM2 translations as a starting point. We assume that the BM2 translations follow the FLORES translation guidelines[6], which do not allow any AI tools. They should therefore provide an appropriate point of departure, being the most recent translations. We aim mostly at correcting *obvious* grammatical and lexical mistakes in the dataset, while keeping the structure and otherwise correct lexical choices of the original translators intact. However, in more severe cases, the other sentences were used as reference, especially the NN sentences, as they overall hold a much higher quality level, though not free of errors. Some concrete breaches of the translation guidelines were also corrected, notably cases where units of measure were translated and converted. There were also cases of named entities that were not changed, even though an established Norwegian spelling exists, such as Eng. *Pythagoras* vs. Nor. *Pytagoras*.

Measured in error correction on the most recent Bokmål translations, 64.4% of the sentences in the devtest split contained errors that were fixed, with 70.8% for the dev split. We make an attempt at avoiding corrections due to matters of choice, but do correct in the following cases:

1. Grammatical mistakes
2. Clearly mistranslated terms
3. Orthographic or punctuation mistakes
4. Misunderstanding of context, etc.
5. Mismatching radicalness

In some cases, errors in the Nynorsk were discovered, but they were not corrected. We urge others to revisit the Nynorsk translations.

Two annotators worked on the correction task, with about 25 hours of work for each annotator. Both were native Norwegian speakers with some background in professional translation. The datasets were split in two, with each person correcting their half, before quality checking the other person's corrections. It was not the translators' intention to re-translate, simply to correct the existing translations, basing the new translations on these existing ones to provide a more fluent and correct sentence, and thus improving the overall quality of the dataset. Changes in radicalness were only done in cases where it did not match the dataset overall.

In the rare cases where none of the earlier translations are correct, the translators allow themselves

[6] https://oldi.org/translation-guidelines.pdf

to retranslate. This is mostly seen in the case of specific jargon or common misunderstandings, in places where the English syntax is kept in the translations despite being ungrammatical, or if there were no appropriate translations for them to base themselves on. Therefore some cases with English-like syntax but no grammatical or lexical mistakes have been kept.

When the communicative intent of the English sentence is not hindered by small errors, these errors are not carried over in the Norwegian translation.

Although difficult to avoid completely, the translators have attempted to avoid letting stylistic preferences affect the correction. For example in cases where the translations is passable, but the translator would prefer another word, we have avoided correcting them, except in cases where the sentence sounds very unnatural. All cases were discussed between the two annotators. In some borderline cases, where it is difficult to argue in disfavor of the original translation, the sentences are kept, as with the cases discussed above. Semi-authoritative sources such as the Norwegian Wikipedia, the Norwegian encyclopedia Store Norske Leksikon (SNL) or books in the National Library (NB) collection were used to guide term usage.[7]

4.2 Types of errors

In order to give an impression of some of the mistakes found necessary to correct by the annotators, we attempt to summarize some of the more common ones in broad groups.

Term Coinage and Anglicisms The original translator has in several instances made up words with little to no previous usage, in cases where there are clearly preferred terms. Examples include *meteordusj* 'meteor shower' for meteorsverm lit. 'meteor swarm', or in the case of *martianer* in 3, which needs to be rewritten as *fra Mars*.

(3) [...] rundt 34 var **martianer** i opprinnelsen.

[...] about 34 have been verified to be **martian** in origin.

Direct Translation Similar to coinages, but where a coinage might be seen as a creative way to translate a term into Norwegian, where the translator is unaware of an existing or more commonly used term, the direct translations (ie. translating word-by-word) lead to clear errors, as the resulting word has a completely different meaning in Norwegian. Sometimes these translations might pass as understandable anglicisms, while at times they are nonsensical. This is especially typical for fixed expressions. In 4, the English phrase *on its own* is translated as *alene* 'alone', which does not share the same use. In 5, the English *in a big way* is translated to Norwegian *på en stor måte*, which does not make sense.

(4) Madagaskar er den klart største, og et kontinent **alene** når det gjelder dyreliv.

Madagascar is by far the biggest, and a continent **on its own** when it comes to wildlife.

(5) Araberne førte også islam til landene, og det tok **på en stor måte** i Komorene og Mayotte.

The Arabs also brought Islam to the lands, and it took i**n a big way** in the Comoros and Mayotte.

Misunderstanding Context In a few cases, a Norwegian word might be a possible translation of an English word, but the translator misunderstands the context, and translates the wrong sense of the word. This is different from the two above in that the word is actually correct, but not the correct translation in this case and context. In 6, the English *peers* is translated as NB *jevnaldrende* (lit. same-aged), a term used especially when discussing peers in primary school and similar cases. It cannot be used in the sense of professional peers, which is the intended meaning here. In 7, the understood context of the elided 'flair' has caused the translator to use the word *afrikaner*, 'African (person)', instead of the adjective. Most lexical errors fall in this category.

(6) Generelt sett kan to atferd oppstå når ledere begynner å lede sine tidligere **jevnaldrende**.

Generally speaking, two behaviors can emerge as managers begin to lead their former **peers**.

(7) [...] fordi den har mer arabisk stil enn en **afrikaner**.

[...]because it has more of an Arabic flair than of an **African**.

[7] Wikipedia:https://no.wikipedia.org/wiki/Forside, SNL: https://snl.no/, NB: https://www.nb.no/

Agreement Norwegian Bokmål exhibits agreement between some parts of speech where English does not, such as past participles, adjectives and some determiners. The authors found cases of mismatching agreement in the BM2 texts, such as "en naturlig forekommende encellede marine organisme.", where *encellede* 'single cell' and *marine* 'marine' are plural forms, while *en* 'a' and *organisme* 'organism' are singular. The correct form would be *encellet* and *marin*.

Subject-Possessor Mismatch These are cases when the translator fails to use the correct possessor. This is especially clear in Norwegian, as there is a difference in whether the grammatical subject of a sentence is the possessor or not. In 8 the third person possessor *sitt* is ungrammatical due to "nylige eksempler på [...] arbeid" being the subject of the subordinate clause, and in this case, the possessor should have been *hans* (eng. his).

(8) **Han** var også engasjert i gravering av sedler i mange land, nylige eksempler på **sitt** arbeid, inkludert statsministerportretter [...]

He was also engaged in engraving banknotes for many countries, recent examples of **his** work including the Prime Ministerial portraits [...]

Incorrect Noun Gender Several nouns have been used with the wrong grammatical gender, for example, *sexet* (neut.) 'the sex', instead of *sexen* (masc.), and *giftet* (neut.) 'the poison' instead of *giften/gifta* (masc./fem.) and *det største anskaffelsen* (neut.) 'the largest acquisition', instead of *den store anskaffelsen* (masc.). In the latter case, the mismatch is especially clear, as the noun is already declined in the masculine definite form, causing an agreement error.

The gender mismatch also extends to anaphoric pronouns, as in ***Et motbåtskip*** *av Avenger-klasse [...].* ***Den*** *er tildelt [...]*, where the first noun is neuter, while the referring pronoun is common gender. This is different from the agreement point above, in that these cases mistake the gender of the nouns themselves, not just the modifying elements.

Syntactical errors While English is syntactically close to Norwegian, there are certain constructions that when directly translated become ungrammatical or unnatural. An example is seen in 9, where in English an appositioned place name can function as an indicator of origin, while this has to be rewritten in Norwegian, for example as *jazz-spiller fra Utah* 'Jazz player from Utah', or in 10, where the subordinate clause initialized by a single past participle is very marked in Norwegian and must usually be rewritten.

(9) NBAs beslutning fulgte en **Utah Jazz-spiller** [...]

The NBA's decision followed a **Utah Jazz player** testing positive for the COVID-19 virus.

(10) **Født i Hong Kong** studerte Ma ved New York University [...]

Born in Hong Kong, Ma studied at New York University

Repetitions A final type of error is the case where multiple words in English have been translated to the same word in Norwegian. An example is seen in 11. These need to be rewritten to avoid repetition if no good synonyms can be found in Norwegian.

(11) ulovlige handlinger som dommere, **advokater, advokater og advokater** har gjort i løpet av de foregående årene.

[...] illegal actions that judges, **lawyers, solicitors and attorneys** have done during the previous years.

Minor Mistakes In addition to the issues above, there are other minor mistakes. However, one striking aspect about all of these is that they are rarely encountered with native speakers, as these are core components of Norwegian grammar, and not infrequent or rare phenomena.

4.3 Other Correction Issues

When correcting, we have focused mainly on improving the latest Bokmål translations, as these are supposed to be improvements on the earlier translations. They are mostly in a standard moderate variety, allowing for feminine definite forms of very frequent feminine nouns, as is typical in moderate BM, but varying in consistency when it comes to some less frequent words and other potentially radical forms.

In the case of many loanwords in Norwegian, both older spellings and more Norwegianized spellings are allowed in some cases. For many old loanwords, these spellings are naturalized and

one might even think about their original spellings, such as *byrå* (fr. bureau) 'office' and *sjåfør* (fr. chauffeur) 'driver', while for many more recent words, especially from English, the Norwegian alternatives can sometimes be more marked. The translators of the most recent Bokmål dataset seem to have a preference for keeping original spellings, and we have kept them. However, in the radical versions, we have used the more Norwegian versions, leading to differences such as streame vs. strømme 'to stream', container vs. konteiner 'container', etc.

4.4 Radical version

Following the correction of the BM2 version into BM3, we then convert these into radical Bokmål (BM3R).

As described above, Radical Bokmål is a subvariety of Bokmål, where radical options are chosen. These options refer to lemma varieties sanctioned by the dictionary Bokmålsordboka, while trying to stay as close as possible to the normative guidelines put forth by the association for Radical Bokmål[8]. The differences broadly fall into three categories:

Sound Correspondences Many optional forms are based on differences in diverging sound changes that are semi-regularly executed in Bokmål. These are found broadly across parts of speech, as in *melk* (MBM)/*mjølk* (RBM) and *fløte* (MBM) and *fløyte (RBM-*[9]

(12) [...] masse krem**fløte** (ikke **melke**skum) og te blir servert uten **melk**. (MBM)

[...] masse krem**fløyte** (ikke **mjølke**skum) og te blir servert uten **mjølk**. (RBM)

Another large category is morphology. In our case, this especially applies to the endings discussed above, in addition to using the deverbal nominal suffix *-ing* instead of the more MBM-coded *-else*, where these are listed as equal in the Bokmål dictionary.

(13) [...] en viktig del av **opplevelsen**. (MBM)

[...] en viktig del av **opplevinga**. (RBM)

Finally, the only syntactic change is when rewriting possessive constructions with a bare genitive 's' in MBM, which are preferred as prepositional phrases in RBM, as in 14.

(14) **Tigerens brøl** er ikke [...] (MBM)

Brølet til tigeren er ikke [...] (RBM)

[8] https://bokmal.no/

[9] Note that marking a word as MBM/RBM in this case is for convenience, but it is not the case that all radical versions are equally strong indicators of RBM as this is a continuum.

BLEU	BM1	BM2	BM3	BM3R
BM1	–	32.31	35.59	32.54
BM2	32.37	–	73.73	64.89
BM3	35.63	73.65	–	86.89
BM3R	32.56	64.79	86.84	–
chrF	**BM1**	**BM2**	**BM3**	**BM3R**
BM1	–	62.65	63.76	62.22
BM2	61.58	–	84.81	81.51
BM3	62.96	85.21	–	94.77
BM3R	61.32	81.74	94.59	–

	MADLAD		NLLB		OPUS-MT	
Ref.	BLEU	chrF	BLEU	chrF	BLEU	chrF
BM1	33.44	62.03	31.31	59.53	34.91	62.96
BM2	62.11	79.72	58.98	76.82	69.50	84.38
BM3	56.12	75.59	52.01	72.16	60.06	77.75
BM3R	49.83	72.88	46.12	69.62	53.01	74.81

Table 2: Translation scores for three Bokmål system outputs, using the four different reference translations.

5 Experiments

5.1 Distances between translations

To quantify the differences between the Bokmål translations, we compute BLEU and chrF scores between pairs, taking one as a reference and the other as the hypothesis. Table 1 presents the results.

We observe that BM1 is most different from all other translations, with differences of around 30 BLEU points and 20 chrF points. BM3 is relatively similar to BM2, which is not surprising due to the majority of corrections being done on these sentences. The highest similarities are observed between the moderate and radical BM3 translations, suggesting that lexical and morphosyntactic contexts that allow variation are relatively rare in the dataset. Both metrics follow roughly the same pattern.

5.2 Machine translation experiments

We measure the impact of the updated translations on machine translation evaluation in two experiments, using English-to-Bokmål and Bokmål-to-English MT systems, respectively.

First, we translate the English FLORES dev set to Norwegian Bokmål and evaluate the output on all four reference translations. This shows how much the evaluation scores of a single translation can vary according to the reference used. We use three MT systems to translate from English to Bokmål: MADLAD-400-3B-MT[10], NLLB-200-distilled-1.3B[11], and OPUS-MT[12]. Table 2 shows the results.

It can be seen that BM1 provides the lowest translation scores, suggesting that the reference translations are too different from the ones produced by off-the-shelf MT systems. On the other hand, the highest scores are obtained when using BM2 as a reference; this could hint to increased translationese in this dataset.

The moderate reference yields higher scores than the radical reference, which suggests that the translations produced by the three MT systems is more similar to the (more widely used and less marked) moderate variant. The radical reference impacts BLEU score slightly more than chrF score, as many moderate/radical differences occur at subword level (e.g., inflectional endings).

The three MT models provide output of similar quality, with OPUS-MT outperforming MADLAD and NLLB. Interestingly, the score differences across models are more pronounced with BM2 and BM3 than with BM1. BM1 seems therefore of limited usefulness to discriminate between different MT systems.

Second, we use the four Bokmål translations as input to Norwegian-to-English translation systems and evaluate the English outputs using the English FLORES reference. We again use MADLAD-400-3B-MT and NLLB-200-distilled-1.3B, as well as an OPUS-MT model covering the opposite translation direction[13]. The results are presented in Table 3.

[10] https://huggingface.co/google/madlad400-3b-mt

[12] https://huggingface.co/Helsinki-NLP/opus-mt-tc-bible-big-deu_eng_fra_por_spa-gmq

[13] https://huggingface.co/Helsinki-NLP/opus-mt-tc-big-gmq-en

	madlad3b		nllb1.3bdist		opusmt	
Input	BLEU	chrF	BLEU	chrF	BLEU	chrF
BM1	43.69	68.02	40.48	64.73	44.10	68.26
BM2	63.98	80.68	58.97	76.82	66.66	81.94
BM3	56.18	75.24	52.19	71.87	58.38	76.44
BM3R	55.16	74.73	51.08	71.13	57.61	75.85

Table 3: Translation scores for English system outputs produced from various Bokmål inputs.

The results quite closely reflect those of the English-to-Norwegian translation, with the exception of the moderate/radical distinction, which almost has no impact on the models' capacity to translate the text to English.

We find that the initial translation (BM1) severely underestimates the models' true MT capabilities, both when used as a reference and as an input text. The updated version provided by the FLORES team (BM2) yields the highest scores, whereas the translations provided in this paper (BM3) lie in between.

An explanation for some of this effect, is that we still observe translationese tendencies in the translated texts, for example, all three systems provide the following translation in example 15 (madlad3b adds *av*, the others do not). The word (chemical) *element* is *grunnstoff* in Norwegian, and anglicisms like this might inflate the scores for the earlier translations.

(15) Du kan også ha legeringer som inneholder små mengder (av) ikke-metalliske elementer som karbon. (PRED)

You can also have alloys that include small amounts of non-metallic elements like carbon. (EN)

Det finnes også legeringer som inneholder små mengder ikke-metalliske grunnstoffer som karbon. (GOLD-MBM)[14]

6 Conclusion

Even after its initial correction, several obvious and non-native-like mistakes remained in the FLORES+ Bokmål dataset. Our attempt has corrected the most obvious mistakes, making sure that there are at least no grammatical or lexical mistakes in the dataset, without introducing excessive changes to

[14] Adding *av* is acceptable.

the work done by the professional translators. We hope that these corrections make results from these datasets more reliable.

On a more personal note, this is not the first time the authors experience problems with context and understanding coming in the way when translating datasets that are supposed to be the basis of massive-parallel datasets. We urge the creators of such original datasets to perhaps add clarifying remarks where there might be misunderstandings. Following the observation that close to 70% of all sentences in the corrected dataset contained at least one lexical or grammatical error, we recommend earlier users of the dataset to reevaluate results used on this dataset. There is also some reason to doubt the claims that all these translations were indeed done by professional translators, and we hope that future dataset creators will use the native professional communities to gain valuable feedback in these situations.

Limitations

We observe that the Nynorsk overall holds a much better quality, but that this dataset would also benefit from a round of corrections by someone qualified. We urge a native Nynorsk writer with translation experience to do a similar check of the Nynorsk data. We also acknowledge that some cases were difficult to translate due to a lack of domain knowledge, especially alongside ambiguous English original sentences, and that the focus of this effort was to remove clear errors.

{samuel.larkin,chikiu.lo,rebecca.knowles}@nrc-cnrc.gc.ca

Abstract

We describe the NRC team systems for the WMT25 Shared Tasks on Large Language Models (LLMs) with Limited Resources for Slavic Languages. We participate in the Lower Sorbian and Upper Sorbian Machine Translation and Question Answering tasks. On the machine translation tasks, our primary focus, our systems rank first according to the automatic MT evaluation metric (chrF). Our systems underperform on the QA tasks.

1 Introduction

This paper describes our systems submitted to the WMT 2025 LLMs with Limited Resources for Slavic Languages Shared Task. We focused primarily on LLM-based machine translation (MT) into Upper Sorbian (hsb) and Lower Sorbian (dsb). Balancing two competing tasks typically comes at the cost of performance on one task or the other. While we performed preliminary experiments on QA, our initial results were unsatisfactory and we chose to submit a system that was trained only for MT as our primary submission.

2 Data and Models

We constrained our systems to the corpora offered by the organizers. The WMT25 corpora are available in the shared task github repository[1] while the previous years' corpora are available in the WMT22 repository.[2] MT data is described in more detail in Section 3.1 while QA data is described in more detail in Section 4.1.

As required by the shared task, we trained our models using the 0.5B, 1.5B, and 3B size Qwen2.5 models as the base. Our submitted system for the shared task is based on `Qwen2.5-1.5B-Instruct`.[3]

3 Machine Translation

We focused primarily on MT performance in our submissions. In this section, we describe preliminary experiments on MT, leading to the choices we made for our final submissions (Section 5). We used the `doc_to_text` task prompt suggested in the `lm-eval` test harness:[4]

```
Translate the following German
text to Lower Sorbian.  Put it in
this format <dsb> Lower Sorbian
translation </dsb>.\n<deu> {{de}}
</deu>
```

as our machine translation prompt for Lower Sorbian (replacing `Lower Sorbian` by `Upper Sorbian` and `dsb` by `hsb` in the Upper Sorbian setting). In addition to exploring hyperparameters for supervised finetuning using `LLaMa-Factory`, we tested which combinations of language pairs and directions to use for training as well as different stopping criteria and prompt templates.

3.1 Data

We used almost all corpora for training except the *dev* from 2025 (see Table 1 for details).[5] We used *2025_dev* to evaluate translation quality. To avoid data contamination in our experimental evaluations

[5] *2022.train_dsb_hsb_62564.dsb-hsb*, which contains 62,565 sentence pairs with 673,781 Lower Sorbian words and 654,445 Upper Sorbian words was unintentionally omitted from training. This corpus is equivalent in size (in lines) to roughly 7% of the raw data we used for training, roughly 26% the size (in words) of the Lower Sorbian data we used for training, and roughly 8% the size (in words) of the Upper Sorbian data we used in training. Due to time constraints, we were unable to perform experiments to determine the extent to which including this might have changed model performance.

Proceedings of the Tenth Conference on Machine Translation, pages 1133–1142
November 8-9, 2025

on the *dev* data, we remove the 2025 *dev* set from all the training material using sentence pairs as the duplication key. Table 1 shows the number of sentences and words for each corpora before and after filtering. We sampled 200 sentences from the 2025 *dev* sets to produce *2025.dev_sample.de-dsb* and *2025.dev_sample.de-dsb* respectively. The smaller samples were used for evaluation during training to track training progress (without the cost of decoding the full *dev* set), while the full *dev* sets were used for our internal evaluations and model choices.

We preprocessed all MT corpora by removing control characters, removing carriage return (`\x0D`). We also collapsed tabs to space, folded multiple spaces into a single space and removed trailing spaces. See Appendix A for details.

3.2 Training

Training for MT was performed using `LLaMa-Factory`'s implementation of supervised finetuning (called the `sft stage`). We took inspiration from GemmaX2 (Cui et al., 2025) for our base hyperparameters. They provide their configuration in their github repository.[6] Table 2 lists the hyperparameters that we explored during training for MT; we did not perform a full grid search of all parameters. The specific values used in our final submission are given in Section 5. All experiments were performed on Tesla V100-SXM2-32GB.

3.3 Language Pairs and Translation Direction

In low-resource machine translation research, it has often been considered beneficial to train on as much language data as possible, sometimes incorporating training data from related languages. This has been a component of past shared tasks on Sorbian languages (Fraser, 2020; Libovický and Fraser, 2021; Weller-Di Marco and Fraser, 2022). We wanted to explore this in the LLM setting: should we finetune LLMs separately for each target language's corpora or combine Upper Sorbian and Lower Sorbian corpora to train a single LLM that could translate into both languages?[7] We were also interested in determining how unidirectional training (training only to translate into Upper Sorbian and/or Lower Sorbian) compared to bidirectional training (training to translate into Upper Sorbian and/or Lower Sorbian as well as into German). Table 3 and Table 4 show that according to chrF,[8] the best-scoring combination of corpora and direction was a single system that incorporates both language pairs in both directions.[9] However, the chrF difference between the unidirectional training and the bidirectional training was consistently small or non-existent. Given the computational cost of training bidirectionally (twice as much data), we opted to use a unidirectional setup.

While running early experiments, we briefly considered LoRA (Hu et al., 2021) training, but observed substantially lower performance in the range of 12-15 BLEU and 7-10 chrF. For this reason, we continued to train full model weights in the remainder of our experiments.

3.4 Stopping Criterion

To improve training time, we can take advantage of the early stopping criterion which halts training if a given criterion or metric does not improve for a given number of gradient updates known as steps. Our baseline consists of training for exactly 5 epochs (`#epochs`), which we compared with a cross-entropy loss (`eval_loss`) approach where the model stops when the evaluation loss does not improve for 10 steps, and a `chrF` approach that stops when chrF has not improved for 10 steps. The models for these experiments were unidirectional (into Sorbian) translation models trained on the German to Upper or Lower Sorbian data as well as the Upper Sorbian–Lower Sorbian data.

Table 5 and Table 6 show that training for a fixed number of epochs always outperformed the other stopping criteria, yielding higher chrF scores. We used a fixed number of epochs for our final submitted system.

3.5 LLM Template

`LLaMa-Factory` offers multiple templates to format the input examples and prompt. We tested three of these built-in templates for the translation task: `qwen` (since the model we train is Qwen-

[6] https://github.com/xiaomi-research/gemmax/blob/main/scripts/sft.sh

[7] We included Lower Sorbian–Upper Sorbian parallel data in these experiments in addition to the German corpora: *2022.dev_dsb_hsb_new.dsb-hsb* and *2022.valid_dsb_hsb.dsb-hsb* are Lower Sorbian–Upper Sorbian corpora and because of that, during training, they were seen in both directions—effectively doubling their sentence count contribution.

[8] `nrefs:1|case:mixed|eff:yes|nc:6|nw:0|space:no|version:2.5.1`

[9] For completeness, we show Upper Sorbian systems' translations of Lower Sorbian text as well as the reverse, but show them in parentheses.

based), `chatml` (a generic chat template), and `empty` (a non-chat template). Figure 1 shows example input for the `empty` template. Figure 2 shows example input for the `chatml` and `qwen` template. The `qwen` and `chatml` templates, given the same input, render the same output except that `qwen`'s output has an additional system prompt. The system prompt is: "*You are Qwen, created by Alibaba Cloud. You are a helpful assistant*". Figure 4 shows a rendered example, using `qwen`'s template, as seen at training time by `LLaMa-Factory`.

We trained 9 models, the Cartesian product of three templates with three language corpora, using the identical configurations except for the datasets and the template. The models were trained to translate from German into Upper Sorbian and/or Lower Sorbian. We then translated the *2025.dev.de-dsb* and *2025.dev.de-hsb* sets using `LLaMa-Factory`. Table 7 shows chrF scores for translations into Lower Sorbian and Table 8 shows chrF scores for translation into Upper Sorbian when training a system on a given set of languages and template.[10] Naturally, we would not expect that a model trained on de-dsb be particularly good at translating Upper Sorbian or a de-hsb model at translating Lower Sorbian. This is confirmed in Table 7 and Table 8. Otherwise, the template choice does not seem to substantially impact the translation quality. The earlier translation direction and corpora experiments as well as the stopping criterion experiments were performed using the `empty` template.

4 Question Answering

We used our MT-finetuned models as the base models from which to train for the QA task. Our main experimental method for Multiple Choice Question Answering (MCQA) training was to use Direct Preference Optimization (Rafailov et al., 2024). We also ran limited experiments using supervised finetuning, but initial results showed a large drop in performance on the translation task as a result.

4.1 Data

We used all the available QA data for Upper Sorbian and Lower Sorbian. In Section 4.1.1 we describe how we split the data into *dev* and *train*. Section 4.1.2 discusses mitigation for potential position bias and Section 4.1.3 describes an approach to augmenting the data to try to better handle the range of possible response list sizes.

4.1.1 Dev/Train Split

To track QA performance during training, we split the QA corpora provided by the organizers[11] into 20% *dev* set and 80% *train*. Sampling of *dev* was performed using an unweighted reservoir sampling[12] algorithm. Table 11 shows which document ids were used in our *dev* set.

4.1.2 Position Bias

Position bias, where the position of answers influences the model's accuracy in answering, is known to be a problem for LLMs (Pezeshkpour and Hruschka, 2024, i.a.) and this problem can be exacerbated if there is also bias in the training data (i.e., if the correct answer is frequently shown in the same position among the options). To prevent answer position bias, we did data augmentation by adding repeated versions of the questions after permuting the answer order. We generate up to a maximum of 16 permutations per question-answer pair. That is,

[10] For completeness, we show Upper Sorbian systems' translations of Lower Sorbian text as well as the reverse, but show them in parentheses.

  ]
}
```

Figure 2: Input example for `chatml`/`qwen` template

we generate the minimum between the factorial of the number of possible answer orders for a given question or 16.

4.1.3 Augmentation

Noting that `lm-eval` considers all 16 possible answer positions and that many of the questions did not have a total of 16 answers, we augmented the answer sets during training such that each augmented QA instance had the correct answer paired with an incorrect answer in one of the other 15 answer positions. This was done after the position bias augmentation. Direct preference optimization then contrasts the correct and rejected answer during training. Table 9 shows the final number of questions in each QA corpora. Doing this augmentation after the position bias augmentation may have undermined the effectiveness of that position bias mitigation approach, as this second augmentation may reinforce a bias towards the first few answers being the correct response.

4.2 Training

To train our models for the QA task, we once again used `LLaMa-Factory` to tune all weights but used direct preference optimization (called the

`dpo stage` in `LLaMa-Factory`) rather than supervised finetuning. We explored learning rates of `7.0e-05`, `2.0e-05`, `7.0e-06`, `2.0e-06`, `2.0e-07` and `1`, `3` or `5` training epochs. The gradient norm was set to `1.0`, the warmup ratio to `0.01`, weight decay to `0.01`. The learning rate scheduler was set to `inverse_sqrt` and the optimizer was `adamw_torch`. The effective batch size was `32` because we used a per device batch size of `1` and `8` gradient accumulation steps over `4` GPUs. We encountered challenges in training a 3B parameter model for QA, primarily due to insufficient GPU memory to accommodate even a batch size of one. Consequently, we were restricted to smaller model sizes, specifically the 0.5B and 1.5B parameter variants. The inability to train a 3B parameter model for QA, coupled with the competition's requirement to employ a singular model for both MT and QA, rendered any further attempts to train a 3B parameter model for MT futile. Figure 6 and Figure 7 illustrate a correct answer and a rejected answer respectively, rendered from the corpus sample in Figure 5 the QA template.

4.3 Results

We evaluated on our QA *dev* sets and saw improvements over random chance. However, later examination of lower-than-expected scores when evaluating on the training data indicated that the models are not training as well we would have hoped. Table 14 shows our *dev* and *train* accuracies of our submission system compared to random chance, highlighting that our system was not effectively learning.

We are continuing to explore the reasons behind this, whether it relates to the data augmentation approach, the data splits for training, the fact that our *dev* was quite small, the selection of hyperparameters, the choice to use DPO, or some combination thereof.

5 Submissions

Here, we describe the specifics of our primary submissions. We submitted a single model that was trained to translate into both Upper Sorbian and Lower Sorbian. Note that our translations were obtained from `LLaMa-Factory` for inference while the QA output are produced using `lm-eval`.[13]

At submission time our best model attempting to balance between MT and QA performance, according to our *dev* sets for MT and QA, was based on `Qwen2.5-1.5B-Instruct`[14]. It used `LLaMa-Factory`'s supervised finetuning (`sft training stage`) and trained all weights (not LoRA). Using the `chatml` template, it trained on our filtered corpora from the top part of Table 1: 855,409 training examples as reported in the log. The learning rate was `7e-5` with a learning rate scheduler of type `cosine`. We capped the maximum gradient norm of `1.0`, and used no warmup and no weight decay. We used `8` gradient accumulation steps, a per device training batch size of `8` on `4` GPUs for a total training batch size of `256`. As this was a model that we trained near the start of the task, not knowing what would be a good number of training epochs given the number of training examples, we arbitrarily used `20` epochs (66,820 updates) and left the model to train until completion, expecting that the training loss curve would guide us in selecting a smaller number of epochs for future training sessions. Over the entire training, this model has seen 2,941,371,584 input tokens and required 2.31e+19 Flops of computation.

The official results for the task are shown in Table 10. As might be expected for MT-only systems, we have the highest performance on the MT tasks, but the lowest performance on QA, even falling below random chance for HSB-QA. This was in contrast to the performance that we observed on development data (where we did improve on random chance, even for MT-only systems), which merits additional analysis. Our leading hypotheses are that our *dev* set was too small and that DPO was not suited for the QA task.

We note that, after the late decision to use an MT-only system, we might have benefited from

[13] Our removal of newlines for the MT training data meant that we did not typically meet the expected stopping criteria for `lm-eval`, hence our use of `LLaMa-Factory` for inference.

[14] https://huggingface.co/Qwen/Qwen2.5-1.5B-Instruct

selecting a 3B parameter model rather than a 1.5B parameter model, as we did observe increasing MT performance with increasing model size in early stopping criterion experiments. While our stopping criterion experiments showed that chrF scores increased as the number of model parameters increased, with 3B outperforming 1.5B, we had paused our work on 3B parameter models in order to focus on the QA experiments. Had we run additional MT training (in line with our final setup the submission) on 3B model parameters, we expect they would have outperformed our submitted 1.5B parameter model results. We opted not to submit an early 3B MT-only model.

6 Conclusion

We submitted systems for the Upper Sorbian and Lower Sorbian portions of the shared task. Due to the lack of success of our approaches to QA, we submitted systems that were trained only on MT. As expected, our systems performed well on translation (our main focus) but underperformed on QA. If we had examined the QA accuracies on our training data earlier, as shown in Table 14, we could have concluded that our training for QA was ineffective. We were misled by the performance on the development set, which may have been too small for the task; larger development sets or cross-validation approaches could have also alerted us to these issues earlier. For MT for these low-resource languages, we observed benefits of training using both Lower Sorbian and Upper Sorbian parallel text (on the order of 5 chrF points for Lower Sorbian and 1 chrF point for Upper Sorbian).

We had observed some small improvements in QA even when training only on MT when evaluated on *dev* data, but did not find the same results on the test set. We continue to explore the reasons for this.

Limitations

We focused primarily on the machine translation portion of the task. There remain areas to explore in more detail, such as the impacts of model size (number of parameters) on performance. For some of our experiments, such as comparing unidirection and bidirectional training data, we trained the smallest (0.5B parameter) models; it is not known how well these results will generalize as the number of model parameters scales. There remains additional work to do on the QA task and on analyzing why our training for that did not perform as expected.

Acknowledgements

We would like to thank the reviewers for their suggestions and comments and the shared task organizers for their work on the task.

TartuNLP at WMT25 LLMs with Limited Resources for Slavic Languages Shared Task

Taido Purason and Mark Fishel
Institute of Computer Science
University of Tartu, Estonia
{taido.purason, mark.fisel}@ut.ee

Abstract

This paper describes the TartuNLP submission to the Upper Sorbian (*hsb*) and Lower Sorbian (*dsb*) tracks of the WMT25 LLMs with Limited Resources for Slavic Languages shared task, which jointly targets machine translation (MT) and question answering (QA). We develop a single multilingual model based on `Qwen2.5-3B-Instruct` by continuing pretraining on Sorbian monolingual and parallel data together with general instruction datasets, combining language acquisition and instruction-following in a single step. The resulting model delivers substantial improvements over the baseline `Qwen2.5-3B-Instruct` model and also achieves the highest ranking for both tasks in the *hsb* and *dsb* shared task tracks.

1 Introduction

This paper presents an overview of the TartuNLP systems developed for the WMT25 Limited Resource Slavic Languages shared task (Okabe et al., 2025). This shared task aimed to create a single large language model (LLM) capable of jointly performing both machine translation (MT) and question answering (QA) for less-resourced Slavic languages. The participants of the shared tasks were limited to using the Qwen2.5 model family (Qwen Team, 2024) with a size constraint of 3B parameters. Our team participated in the Upper Sorbian (*hsb*) and Lower Sorbian (*dsb*) tracks, both endangered languages spoken by only about 20,000–30,000 people in total (Moseley, 2007). The taxonomy of Joshi et al. (2020) categorizes both languages as category-1, *the scraping-bys*. We focused on building a single model that supports both tasks and languages simultaneously. This joint objective introduces a specific challenge: while a moderate amount of MT data exists for Sorbian, there is no QA training data, requiring balancing performance across both tasks.

Although one or both of the Sorbian languages have been included in recent massively multilingual models (Imani et al., 2023; Lin et al., 2024; Ji et al., 2025b,a), to our knowledge, no prior work has developed dedicated LLMs for Sorbian.

We build on recent work adapting LLMs to extremely low-resource languages through continued pretraining and instruction tuning (Purason et al., 2025; Etxaniz et al., 2024; Sainz et al., 2025). Our approach follows Sainz et al. (2025), who demonstrated for the Basque language that combining language acquisition and instruction tuning in a single step and starting from an instruction-tuned model is beneficial. We also adopt this joint learning of instruction-following and language for an instruction-tuned base model in our system.

We continually pretrain `Qwen2.5-3B-Instruct` (Qwen Team, 2024) on a mix of monolingual documents and sentences in *hsb* and *dsb*, general instruction-following data (primarily in English), and Sorbian MT instructions. We supplement the data provided by the organizers with document-level texts from Fineweb-2 (Penedo et al., 2025) and Wikipedia articles (Wikimedia

Proceedings of the Tenth Conference on Machine Translation, pages 1143–1150

Foundation). Our final model outperforms the baseline `Qwen2.5-3B-Instruct` and also achieves the highest rank in the shared task (see Tables 1 and 2). **We publish the final model on HuggingFace**[1].

2 Datasets

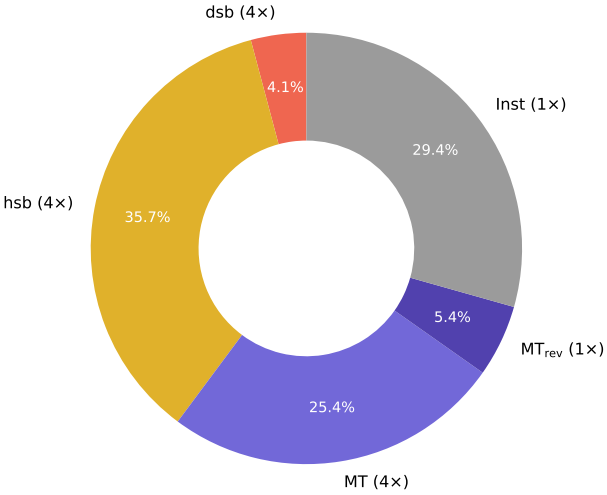

Figure 1: **Data mix** for the final model (% of total training tokens). The number of epochs for each dataset is stated in parentheses. The resulting training set is 1.198B tokens.

Dataset	Texts	Words	Chars

	de-hsb	de-dsb	dsb-hsb
Sentence pairs	636.3K	212.2K	62.6K

Table 4: The parallel data sentence pair counts.

Monolingual data (see Table 3). We used all of the monolingual data provided by the organizers for this year (Okabe et al., 2025) and the data from previous WMT Sorbian shared tasks (Fraser, 2020; Libovický and Fraser, 2021; Weller-Di Marco and Fraser, 2022), which was sentence-level aligned. Additionally, we used Upper and Lower Sorbian Fineweb-2 (Penedo et al., 2025) documents and Upper and Lower Sorbian Wikipedia documents from the 2025 05 20 dump (Wikimedia Foundation) extracted with WikiExtractor (Attardi, 2015). We also experimented with using German Fineweb-2 (Penedo et al., 2025) documents for pretraining, however, we did not use this data for training the final submission model.

Parallel data (see Table 4). Our parallel data is entirely from this and previous years' shared tasks (Fraser, 2020; Libovický and Fraser, 2021; Weller-Di Marco and Fraser, 2022). The sentence pairs were formatted as instructions in a chat template. Since the task was to translate from German to the Sorbian languages, we trained on translation into the Sorbian languages (de-hsb, de-dsb, hsb-dsb, dsb-hsb) for 4 epochs. We refer to this dataset as MT. In addition to that, we also added one epoch of data in the hsb-de and dsb-de directions as well (referred to as MT$_{rev}$).

The monolingual and parallel data was deduplicated with normalization from Stopes (Pierre Andrews, 2022; NLLB Team et al., 2022). We also removed the held-out and validation data using the same normalization method.

Instructions (see Table 11). We used instruction data from Magpie (Xu et al., 2025), Aya (Singh et al., 2024), EuroBlocks (Martins et al., 2025) OpenAssistant2 (Köpf et al., 2023), and FLAN v2 (Longpre et al., 2023). We removed instructions that were not in English, German, or the closest Slavic languages to the Sorbian languages. Still, 98.6% of instructions in the resulting dataset are in English.

The final mix. The data mix of the submitted model consisted of 1.198B tokens and is displayed in Figure 1.

3 Methodology

We used `Qwen2.5-3B-Instruct` (Qwen Team, 2024) as our base model, motivated by the findings of Sainz et al. (2025), who demonstrated that continued pretraining on already instruction-tuned models is effective for low-resource languages. Following their findings, we combined the language acquisition and instruction-tuning in the same continued pretraining step. Our continued pretraining

Table 5: Validation set scores for the baselines and fine-tuned models. The shared task's final submission validation and test set scores. 💬 - chat instruction format; † - beam search decoding with beam size 4.

was performed jointly on monolingual documents and sentences, parallel MT data, and instruction-formatted data.

Our initial experiments indicated that the model begins to overfit on Sorbian data around the fourth epoch. A similar finding was also made in Purason et al. (2025), who observed overfitting at 4 epochs for low-resource languages of similar size. With this in mind, we repeated the Sorbian monolingual and parallel data four times during training. The instruction data was repeated once, while the significantly more abundant German monolingual data (not used for the final submission) was limited to 25% of the total training token budget. It should be noted that we did not conduct a thorough investigation into the different data sampling strategies and combinations. A different number of epochs or curriculum learning might provide better results.

For instruction-formatted samples, we applied loss only on the assistant (target) tokens. All datasets were packed into sequences of 4096 tokens, with any overflow tokens carried into the next training sequence. The hyperparameters for the model training are listed in Table 10. The models were trained on either 8 or 16 nodes, each consisting of 4 AMD MI250x GPUs (acting as 8 units) on the LUMI supercomputer. The training of the final model took 139 GPU-hours.

4 Evaluation

We evaluate our models using the `lm-eval-harness` framework (Gao et al., 2024), which we also use to generate the final shared task submissions. Evaluation is conducted using a few-shot and zero-shot prompting strategies, depending on the training strategy. We use a few-shot evaluation without a chat template and a zero-shot evaluation using a chat-style format.

For QA, we follow a multiple-choice setup, selecting the answer option with the highest log-probability from a predefined set of candidates. We calculate the accuracies and report the average across the language levels in the validation set.

For the MT evaluation, we calculated the BLEU (Papineni et al., 2002) and chrF++ (Popović, 2017) scores. We also report 95% confidence intervals calculated from standard errors reported by `lm-eval-harness`.

For the final submission, we apply beam search with a beam size of 4 for MT, and use one-shot prompting with the chat template for QA, where each example is treated as a separate turn in a multi-turn conversation. We use greedy decoding in all other evaluation settings (beam size of 1).

5 Results

5.1 Main results

Table 5 summarizes the performance of our models on both machine translation (MT) and question answering (QA) for Upper and Lower Sorbian. We compare our systems against two open-weight baselines: `emma-500-llama3.1-8b-bi` (Ji et al., 2025a), which includes Sorbian in its training data, and `Qwen2.5-3B-Instruct` (Qwen Team, 2024).

As expected, we observe that the `Qwen2.5-3B-Instruct` model performs poorly on Sorbian MT benchmarks before any continued pretraining. In contrast, `emma-500`, which was trained with Sorbian data, performs noticeably better in MT. However, the trend reverses for QA:

`Qwen2.5-3B-Instruct` significantly outperforms `emma-500`, highlighting the strength of instruction tuning for QA even in low-resource settings.

Our continued pretraining configurations substantially outperform the baselines across both MT and QA tasks, demonstrating the effectiveness of the language adaptation. From these results, we find that:

- Including MT data during continued pretraining yields large gains in translation quality compared to relying solely on few-shot prompting.
- Adding instruction-following data provides additional improvements for both tasks.
- Adding a small amount of reverse-direction (into German) MT data (MT_{rev}) appears to slightly boost MT performance without harming QA.
- Allocating 25% of the training budget to monolingual German data does not improve MT and slightly degrades QA.

Despite these trends, due to the small size of the QA evaluation set (n = 162) and the resulting wide confidence intervals, it remains difficult to draw definitive conclusions about which components contributed most to QA performance. Nevertheless, our results confirm the benefit of continued pretraining on task- and language-specific data, particularly when jointly targeting MT and QA with a single model.

Our final submission additionally used one-shot prompting for QA and beam search with a beam size of 4, which slightly increased the scores, although this increase is likely not significant.

Our submission achieved the highest rank in QA and MT tasks for both languages and was also the overall winner in those languages.

5.2 Combined or separate Sorbian training

Since they are closely related, we also investigate how much the Sorbian languages benefited from joint training. From the results in Table 6, we see that both languages benefit from the joint training, especially for the generative MT task. It is also apparent that for the QA task, the model trained on only one of the Sorbian languages can perform quite well for the other, even without the data, suggesting that we gain language understanding from the other Sorbian language.

	MT (BLEU)		**QA** (acc)	
Sorbian data	**de-dsb**	**de-hsb**	**dsb**	**hsb**
hsb + dsb	**60.2 ± 1.2**	**67.2 ± 0.7**	67.5 ± 7.2	**73.1 ± 6.6**
dsb	54.0 ± 1.0	9.7 ± 0.4	**69.6 ± 7.0**	67.3 ± 7.0
hsb	11.8 ± 0.6	65.6 ± 0.7	61.0 ± 7.4	71.8 ± 6.8

Table 6: MT (BLEU) and QA (acc) scores when training the Sorbian languages **together vs separately**. *hsb+dsb* configuration is equal to (3) in Table 5. Zero-shot prompting with a chat template was used.

5.3 Effect of the document-level data

		MT (BLEU)		**QA** (acc)	
Sorbian	**N_{chars}**	**de-dsb**	**de-hsb**	**dsb**	**hsb**
sent-level	181.5M	11.9 ± 1.2	19.8 ± 1.7	**71.3 ± 6.8**	71.3 ± 6.7
doc-level	104.8M	21.3 ± 0.9	29.3 ± 0.7	**71.3 ± 6.8**	70.4 ± 6.7
combined	269.1M	**24.4 ± 1.0**	**32.5 ± 0.7**	68.8 ± 6.8	**71.9 ± 6.6**

Table 7: Results for training with HSB and DSB data either **document level, sentence-level, or combined** (without MT examples). The training data includes 1 epoch of *INST* and 25% token budget for *deu* (doc-level). 5-shot BLEU scores are reported for MT, and 3-shot accuracy is reported for QA. N_{chars} is the number of characters in the *hsb* and *dsb* datasets

We examine the effect of incorporating document-level data in addition to sentence-level data. No explicit *hsb/dsb* MT training data was used in these experiments. The results in Table 7 indicate that document-level data is more beneficial than sentence-level data for MT when evaluating in a few-shot setting. This is somewhat surprising given that the sentence-level dataset is substantially larger, and the quality of the Fineweb-2 portion of the document-level dataset has not been verified. Nevertheless, combining document- and sentence-level datasets yields the highest MT scores. For QA, we did not observe significant differences between the data setups.

5.4 MT Supervised Fine-tuning

We instruction-tune our model as a separate step with machine-translation examples (4 epochs of *de-hsb*, *de-dsb*, *hsb-dsb*, and *dsb-hsb*) formatted in chat format as instructions, instead of training jointly. In Table 8, this approach shows a slight increase in the BLEU scores of the machine translation benchmarks. However, our model loses its capability to answer questions, so this strategy does not satisfy the goals of the shared task.

Continued pretraining						SFT_{MT} 💬	MT (BLEU)		QA (acc)	
dsb	hsb	MT 💬	MT_{rev} 💬	Inst 💬	deu		de-dsb	de-hsb	dsb	hsb
4x	4x	4x	1x	1x	25%	-	62.1 ± 1.1	68.6 ± 0.7	**65.7 ± 7.1**	**65.1 ± 6.9**
4x	4x			1x	25%	4x	**64.8 ± 1.0**	**70.6 ± 0.6**	36.6 ± 7.1	34.7 ± 7.2

Table 8: **Machine translation SFT** results (validation set) evaluated with a zero-shot chat format. 💬 - conversational instruction format.

	MT (BLEU)		QA (acc)	
Model	**de-dsb**	**de-hsb**	**dsb**	**hsb**
CPT	**62.1 ± 1.1**	**68.6 ± 0.7**	65.7 ± 7.1	65.1 ± 6.9
CPT + 0.1 BASE	61.8 ± 1.1	68.4 ± 0.7	66.6 ± 7.1	67.1 ± 7.0
CPT + 0.3 BASE	58.1 ± 1.1	65.8 ± 0.7	**67.9 ± 7.0**	**71.1 ± 6.8**

Table 9: **SLERP-merged models'** zero-shot chat-formatted validation set scores. $+x$ BASE means that the merging weights of the base model (`Qwen2.5-3B-Instruct`) are x while the Sorbian continually pretrained (CPT) model weight stays 1.0

5.5 Merging

Inspired by TowerLLM (Rei et al., 2025), who reported that merging with the original model improved general results while not harming translation significantly, we also decided to explore merging. SLERP merging with `mergekit` (Goddard et al., 2025) did show a slight increase in the QA scores (see Table 9), although its significance is questionable due to the small size of the validation set. We also noticed that merging started harming the translation quality at 0.3 weight for the base instruction-tuned model. With this in mind, we did not use it for the final model. It is possible that the benefit would be more apparent on other tasks that we did not measure due to the lack of validation data in the Sorbian languages.

6 Conclusion

We presented the TartuNLP submission to the WMT25 Shared Task on Limited Resource Slavic Languages, targeting both machine translation and question answering for Upper and Lower Sorbian. Our approach combined continued pretraining and instruction tuning in a single step, leveraging the Qwen2.5-3B-Instruct model. By integrating task-specific and monolingual Sorbian data, we achieved significant improvements over existing baselines and obtained the highest rank for both tasks in both languages. Our results demonstrate that a unified approach can effectively serve multiple low-resource language tasks, even under resource constraints.

7 Limitations

Our findings are limited by the fact that we only consider two tasks. Also, the MT data seems to have short sentence-level data, limiting the conclusions further. Since the test set of the QA task is relatively small, we have rather low confidence in the minor differences in scores of the approaches. We did not thoroughly explore all the design choices made for this system, and we did not explore data filtering, which could significantly impact the resulting model.

Acknowledgments

This work was supported by the Estonian Research Council grant PRG2006 (Language Technology for Low-Resource Finno-Ugric Languages and Dialects). All computations were performed on the LUMI Supercomputer through the University of Tartu's HPC center.

[2]University of Colorado Boulder, USA

Abstract

This paper presents the JGU Mainz submission to the WMT25 Shared Task on LLMs with Limited Resources for Slavic Languages: Machine Translation and Question Answering, focusing on Ukrainian, Upper Sorbian, and Lower Sorbian. For each language, we jointly finetune a Qwen2.5-3B-Instruct model for both tasks with parameter-efficient finetuning. Our pipeline integrates additional translation and multiple-choice question answering (QA) data. For Ukrainian QA, we further use retrieval-augmented generation. We also apply ensembling for QA in Upper and Lower Sorbian. Experiments show that our models outperform the baseline on both tasks.

1 Introduction

While large language models (LLMs) are strong multitask learners for high-resource languages such as English, this is not the case for smaller LLMs and languages with limited data. In this setting, a trade-off presents between the performance on different tasks. The *WMT25 Shared Task on LLMs with Limited Resources for Slavic Languages: MT and QA*[1] focuses on the development of relatively small LLMs ($\leq$3B parameters) that are capable of performing both machine translation (MT) and multiple-choice question answering (QA) in Slavic languages with limited amounts of data. Three languages – a mid-resource language, Ukrainian (UK), and two severely low-resource languages, Upper Sorbian (HSB) and Lower Sorbian (DSB) – are targeted, and only Qwen2.5 models with 0.5B, 1.5B, or 3B parameters are permitted. The MT source languages are Czech (CS) and English (EN) for Ukrainian as well as German (DE) for DSB and HSB.

Our proposed approach consists of a Qwen2.5-3B-Instruct model (Qwen et al., 2025), which is inherently multilingual and which we jointly finetune on both MT and QA data, combining the provided resources with additional datasets we curate ourselves. For DSB and HSB MT, we enhance the training data using synthetic data generated through back-translation. We further add an additional parallel dataset for DSB. For QA, we add a total of 16 high-quality English MCQ datasets. All QA datasets are enhanced via automatic translation such that they are bilingual (English and the target language). For Ukrainian QA, we incorporate retrieval-augmented generation (RAG) using domain-relevant Wikipedia pages and 10 books related to the subjects of the provided Ukrainian MCQ dataset.

At inference time, we use similarity-based few-shot in-context learning (ICL) for MT. For QA, we permute the order of the answer options, and average the probabilities for all options, to increase robustness against answer ordering biases (Pezeshkpour and Hruschka, 2024).

While not winning for any task–language combination, our primary submission consistently outperforms the baseline on all tasks, demonstrating the effectiveness of our approach. For DE–DSB translation, ChrF++ improves by over 55 points, while DE–HSB translation sees gains of over 65 points, reflecting substantial quality improvements. On DSB QA, accuracy increases by up to 12.34 percentage points, and, on HSB QA, accuracy increases by 10.27 points. For CS–UK and EN–UK MT, ChrF++ improves by 4.61 and 2.7, respectively, while, on Ukrainian QA, our submission outperforms the baseline by 4.66 accuracy points.

2 Data

2.1 Provided Data

Ukrainian For EN–UK and CS–UK MT, no training data are provided. Only development sets are given, containing 6,263 CS–UK and 5,108 EN–

[1] https://www2.statmt.org/wmt25/limited-resources-slavic-llm.html

Proceedings of the Tenth Conference on Machine Translation, pages 1151–1157
November 8-9, 2025

UK parallel sentences.

The UK QA data are curated from the External Independent Evaluation (3HO/ZNO), an exam for admission to Ukrainian universities. The dataset comprises a training set of 2,450 questions, a development set of 613 questions, and a test set of 751 questions. These questions cover three topics – Ukrainian History, Ukrainian Language, and Ukrainian Literature – and test both domain knowledge as well as reading comprehension.

Upper and Lower Sorbian MT For DE-to-DSB MT, 171k translation pairs are provided as training data. In addition, a 4,000-pair development set is also provided for system validation and evaluation. Some monolingual sentences, approximately 10k, are also provided along with the translation data.

For DE-to-HSB MT, 187k training translation pairs and a 4,000-pair development set are provided. 300k monolingual sentences are further available for model enhancement.

For both DSB and HSB, MCQ datasets are curated by the Witaj-Sprachzentrum. The questions are similar to the CEFR framework (A1 to C1), which follows the language certificate examinations. The difficulty of the questions ranges from simple true/false to complex multiple-choice formats with two to sixteen answer options. The development set contains 158 A1 to B2 level questions, while the test set for both languages has 205 questions for A1 to C1. An overview of the provided datasets is shown in Table 1.

2.2 Additional Data

Upper and Lower Sorbian MT In order to enhance our DE–DSB/HSB translation systems, we incorporate additional parallel data. For DSB, we translate the provided 10k monolingual examples into German. Then we create 10k additional translation pairs using the translated German sentences and the monolingual DSB sentences. Since 10k is a small amount, we additionally use 24k DE–DSB sentences from the Tatoeba bilingual dataset.[2] In turn, for HSB, we translate the first 100k monolingual sentences from the provided 300k sentences into German and create 100k additional translation pairs. Due to the substantial time required for translation, we translate only 100k sentences. To translate the DSB and HSB sentences into German, we first finetune two separate Qwen2.5-3B-Instruct models, one for HSB–DE and one for DSB–DE, using the respective provided parallel translation datasets. These models are finetuned by applying LoRA on all projection layers of the model.

Upper Sorbian, Lower Sorbian, and Ukrainian QA For QA in DSB, HSB, and Ukrainian, we select 16 English MCQA datasets, namely: (English) Global MMLU (Singh et al., 2025), CommonsenseQA (Talmor et al., 2018), ARC (Clark et al., 2018), Race (Lai et al., 2017), Dream (Sun et al., 2019), PIQA (Bisk et al., 2019), HellaSwag (Zellers et al., 2019), SCIQ (Johannes Welbl, 2017), MedMCQA (Pal et al., 2022), LogicQA (Liu et al., 2020), Quail (Rogers et al., 2020), SocialIQA (Sap et al., 2019), CosmosQA (Huang et al., 2019), OpenbookQA (Mihaylov et al., 2018), QASC (Khot et al., 2020), BoolQ (Clark et al., 2019). From these datasets, we sample up to 10k questions from each available split (training, development, and test), resulting in approximately 200k English MCQs. In order to translate the English MCQs into DSB and HSB, we first use `googletrans`[3] to translate the German sentences of the provided DE–DSB and DE–HSB translation examples into English, in order to create English–DSB/HSB translation pairs. Second, using this data, we finetune two separate Qwen2.5-3B-Instruct models on EN–DSB and EN–HSB MT. We use these two models to translate the English MCQs into DSB and HSB. For Ukrainian, we also translate the 200k English MCQs using `googletrans` directly, since Ukrainian is supported by Google Translate.

Ukrainian MT For CS–UK MT, we collect training data from OpenSubtitles (OPUS, 2003; Lison and Tiedemann, 2016), NeuTED (Qi et al., 2018), KDE4 (OPUS, 2003), and ELRC UKR Acts (ELRC, 2022). For EN–UK, we use OpenSubtitles (OPUS, 2003; Lison and Tiedemann, 2016), NeuTED (Qi et al., 2018), ELRC UKR Acts (Qi et al., 2018), and Multi30k (Saichyshyna et al., 2023). Across these sources, there are nearly 7 million sentence pairs per direction.

To reduce the number of sentence pairs, we apply a similarity-based retrieval method, using the provided development sets for CS–UK and EN–UK as the reference datasets. We embed each Ukrainian sentence from this dataset by performing mean-pooling over the last hidden states of Qwen2.5-3B-Instruct token outputs. For each sentence of

Task	Training Data	Dev Set	Test Set	Notes
EN→UK Translation	None	5,108 pairs	—	Only dev set available
CS→UK Translation	None	6,263 pairs	—	Only dev set available
Ukrainian QA (MCQs)	2,450 questions	613 questions	751 questions	From ZNO exam; covers History, Language & Literature; tests knowledge and comprehension
DE→DSB Translation	171k pairs	4,000 pairs	—	∼10k monolingual sentences provided
DE→HSB Translation	187k pairs	4,000 pairs	—	∼300k monolingual sentences provided
DSB QA (MCQs)	—	158 A1–B2 questions	205 A1–C1 questions	From Witaj-Sprachzentrum; CEFR-style; difficulty from true/false to multiple-choice (2–16 options)
HSB QA (MCQs)	—	158 A1–B2 questions	205 A1–C1 questions	Same as DSB QA

Table 1: Summary of the provided datasets for MT and QA.

the reference dataset we retrieve the 75 most similar Ukrainian sentences from the collected pool of translation data along with the associated sentence in CS or EN and aggregate them. We then deduplicate the aggregated set to retain only unique translation pairs. Overall, we get 321k and 251k CS–UK and, respectively, EN–UK translation pairs for training.

2.3 Data for Retrieval-augmented Generation

For the Ukrainian QA task, we employ retrieval-augmented generation (RAG) using pages from Wikipedia and 10 books on Ukrainian history, language, and literature (the same sources used by the winning team of the UNLP 2024 Shared Task (Boros et al., 2024)). We extract about 30k pages using the `wikipediaapi`[4] library, setting `max_depth = 2` to include relevant subcategories from the Ukrainian history, language, and literature categories.

3 Models and Algorithms

3.1 Qwen: The Underlying LLM

All our models are LoRA (Hu et al., 2021)-finetuned Qwen2.5-3B-Instruct models, and, thus, satisfy the shared task's parameter constraint. We use one model per language for all tasks.

3.2 Finetuning

Finetuning on MT and General QA Data For DSB and HSB, we combine the provided MT data, additional translations created by us, and translated MCQs to finetune Qwen2.5-3B-Instruct with LoRA (Hu et al., 2021) applied to all projection layers. For DSB/HSB, we use both the English and the translated version of each MCQ, in this format:

MCQ Prompt for DSB/HSB during training

```
en_context (if any)
dsb/hsb_context (if any)

Question: {en_question}
Question: {dsb/hsb_question}

Possible Answers: {en_possible_answers}
Possible Answers: {dsb/hsb_possible_ans}

Answer: {answer}
```

To extract the model's predicted answer for QA, we end the prompt with "`Answer:`" and compute the next-token probabilities for each option label. The answer is then taken as the label with the highest probability. Following Sanz-Guerrero et al. (2025), we evaluate the probabilities of the "␣X" tokens[5] (i.e., tokens formed by the preceding space *together* with the option label), as this approach has been shown to yield better performance and calibration.

In order to use this prompt at inference time, we need to translate the provided DSB/HSB questions into English. For, first we finetuned two separate translation models, one for DSB–EN and another for HSB–EN, using the same dataset we use for EN–HSB and EN–HSB model finetuning, but this time in the opposite direction. These two translation models are also based on Qwen2.5-3B-Instruct and trained with LoRA. During the development

[4] https://github.com/martin-majlis/Wikipedia-API

[5] Where "X" denotes one of the option labels.

phase, we observe that for both DSB and HSB QA, alphabetic option labels lead to better results than numeric labels due to label bias (Zheng et al., 2024). So, for training and evaluation, we use alphabetic option labels.

The prompt for MT is of the following format:

MT Prompt during Training

```
Translate this German sentence into Upper
Sorbian. Put it in this format: <hsb> {Upper
Sorbian translation} </hsb>
<de> {German Sentence} </de>
```

For Lower Sorbian, "Upper" is replaced by "Lower" and <hsb> and </hsb> are replaced by <dsb> and </dsb>.

For Ukrainian (UK), we train the model on MT and QA data described in Section 2.2.

We apply the default chat template for Qwen2.5 and train on complete instructions (system + user + assistant), as described in Shi et al. (2024). We use LoRA (Hu et al., 2021) for 10 epochs with an initial learning rate of $1e-4$ and a linear learning rate scheduler. We save the model checkpoint after every epoch. At the end of training, we select the model with the highest BLEU (Post, 2018; Papineni et al., 2002) score, i.e., we select the model using the MT development set.

3.3 Final Finetuning on MT and In-domain QA Data for DSB and HSB

After initial finetuning of the model, we conduct a second round of finetuning. This final model finetuning is also performed by applying LoRA to all projection layers. We follow the same procedure for DSB and HSB. The provided QA development sets for DSB and HSB contain a total of 158 questions each, from language difficulty levels A1-B2. In this second stage of finetuning, we use these 158 in-domain QA examples and the first 3k translation pairs used in the initial finetuning process. To mitigate data scarcity, we apply oversampling: each QA item is repeated five times. Then, we shuffle the MT and the oversampled QA set and finetune the first finetuned model again to improve domain alignment for QA. We add the 3k translation pairs to avoid catastrophic forgetting of the MT capability of the models. The final models are used for both MT and QA during evaluation. As our dataset for the second round of finetuning is small (approximately 3.75k MT and QA examples), we tune the learning rate, searching over $1e-4, 1e-5, 1e-6$, and $1e-7$. Four separate models are trained with these learning rates exactly for one epoch. In this learning rate searching process, we exclude the questions from B2 during finetuning. We select the best learning rate based on performance for both QA (56 questions of B2 level) and MT (the first 400 samples of the 4k dev set). We follow this approach for both languages. After this experiment, we chose $1e-4$ for DSB and $1e-6$ for HSB. Then, we finetune the initial models with these learning rates for two epochs on approximately 3.75k instructions, including the questions from B2, performing no validation.

3.4 Averaging Probabilities

During QA evaluation for DSB and HSB, we generate multiple responses for each question by shuffling the order of answer options. We perform this step to mitigate positional bias (Pezeshkpour and Hruschka, 2024) as much as possible. For questions with 2–3 options, we use all permutations, which are 2 and 6, respectively. For those with more than three options, we randomly sample 20 unique answer option orders. We compute the probability distribution over the answer options under the model for each order and average them; we select the option with the highest average likelihood as the final answer.

3.5 Retrieval-augmented Generation for Ukrainian QA

We segment the retrieved pages (see Section 2.3) into chunks of 512 characters with an overlap of 64 characters and embed them using Qwen2.5-3B-Instruct. For each chunk, mean pooling is applied over the token representations obtained from the last hidden states. Embeddings are stored in two separate `ChromaDB` indexes: one for history and another for language and literature. We make embedding of each question following the same way we apply for page chunks, mean pooling over all token representations. Using the subject indicated for each question, we conduct a search in the corresponding subject-specific index. At inference time, we retrieve the 5 most relevant chunks and use them as context alongside the question.

3.6 Few-shot In-context Learning for MT

For MT, we employ few-shot in-context learning using similarity-based retrieval, following Zebaze et al. (2025). For DSB/HSB, we embed each test-set German source sentence and retrieve the 5 most

Model	ChrF++	
	DSB	HSB
Qwen2.5-3B-Instruct + LoRA(S2)(P)	66.6	77.6
Qwen2.5-3B-Instruct + LoRA(S1)	67.5	77.5
Baseline	12.21	11.87

Table 2: ChrF++ scores for DSB and HSB. *LoRA(S1)* = one round of LoRA finetuning; *LoRA(S2)* = two rounds of LoRA finetuning. *P* indicates our primary submission.

similar sentences from the development set, along with their translations. For Ukrainian, we use Ukrainian sentences for embedding generation and retrieval.

4 Results and Discussion

MT for Lower and Upper Sorbian Table 2 shows that our proposed approach yields a significant improvement over the baseline. The baseline system achieves only 12.21 ChrF++ for DSB and 11.87 ChrF++ for HSB. The first round of LoRA finetuning, indicated by *S1*, already increases ChrF++ to 67.5 and 77.5 for DE–DSB and DE–HSB, respectively. The goal for our second round of finetuning (*S2*), is to adapt the model with in-domain QA data, while retaining the model's MT capability as much as possible. For HSB, *S2* slightly improves over S1 (77.6 vs. 77.5), but, for DSB, performance drops slightly, from 67.5 to 66.6.

Model	Accuracy (%)	
	DSB	HSB
Qwen2.5-3B-Instruct + NO-FT	54.3	57.1
Qwen2.5-3B-Instruct + LoRA(S1)	48.3	50.0
Qwen2.5 + LoRA(S1) Avg.	50.7	54.3
Qwen2.5-3B-Instruct + LoRA(S2)	48.3	50.5
Qwen2.5 + LoRA(S2) Avg. (P)	51.7	55.2
Baseline	45.85	42.86

Table 3: QA accuracy scores (A1–C1) for DSB and HSB. *LoRA(S1)* = one round of LoRA finetuning; *LoRA(S2)* = two rounds of LoRA finetuning; *Avg.* = average over multiple option orders; *NO-FT* = no finetuning, i.e., direct use of Qwen2.5-3B-Instruct. *P* indicates our primary submission.

QA for Lower and Upper Sorbian For DSB and HSB QA (Table 3), the baseline accuracies of 45.85% (DSB) and 42.86% (HSB) are surpassed by all finetuned variants. Interestingly, the non-finetuned Qwen2.5-3B-Instruct model outperforms the baseline substantially, particularly for HSB (+14.24 accuracy). However, LoRA finetuning (S1 and S2) slightly reduces overall accuracy compared to the non-finetuned model, likely due to the trade-off introduced by joint MT and QA finetuning. Averaging over the results for different answer option orders improves accuracy after both rounds of finetuning (S1 and S2). It helps more after the second round of finetuning, reaching 51.7% for DSB and 55.2% for HSB. The improvements over non-averaged results demonstrate that this straightforward method is effective for low-resource QA.

Model	ChrF++	
	CS–UK	EN–UK
Qwen2.5-3B-Instruct + LoRA	8.09	3.10
Baseline	3.48	0.40

Table 4: ChrF++ scores for CS–UK and EN–UK MT.

Model	Accuracy (%)
Qwen2.5-3B-Instruct + LoRA + RAG	35.82
Baseline	31.16

Table 5: Accuracy scores for Ukrainian QA. The shown model is our primary submission.

MT for Ukrainian The Ukrainian MT tasks (Table 4) are challenging due to the lack of training data provided by the shared task. The baseline ChrF++ scores of 3.48 (CS–UK) and 0.40 (EN–UK) reflect the difficulty level. By retrieving and curating translation data via similarity search and then finetuning a Qwen2.5-3B-Instruct model, our system achieves slight improvements over the baseline for both CS–UK (8.09) and EN–UK (3.10). Though performance increases, the improvement is not as big as for the DE–DSB/HSB MT tasks. A possible reason for this is a mismatch between the training, development, and test sets: we train our models on sentences, but the test set consists of large documents and lengthy conversations.

QA for Ukrainian For Ukrainian QA (Table 5), our proposed model, based on finetuning jointly on MT and QA in combination with RAG, improves over the baseline: 31.16% vs. 35.82%. This gain is smaller than for DSB and HSB QA, which we attribute to two factors: First, the QA dataset for Ukrainian requires some factual knowledge regard-

ing the Ukrainian language, history, and literature, which makes the task harder. Second, most LLMs are underexposed to the Cyrillic script, resulting in weaker tokenization, over-splitting of words, and a decreased quality of token representations (Boros et al., 2024). This results in poor-quality embeddings for Ukrainian sentences. As a result, retrieval quality degrades: semantically close passages are missed or under-ranked, and the injected context is less helpful.

5 Conclusion

In this paper, we present JGU Mainz's submission to the WMT25 Shared Task on LLMs with Limited Resources for Slavic Languages, addressing MT and QA in Ukrainian, Upper Sorbian, and Lower Sorbian. Our approach combines parameter-efficient finetuning of Qwen2.5-3B-Instruct with training data augmentation and RAG for Ukrainian QA. Our primary submissions outperform the provided baselines for all languages and tasks, achieving substantial ChrF++ gains for DE—DSB and DE-–HSB MT, as well as slight improvements for CS—UK and EN-–UK MT. For QA, averaging over order options increases accuracy for both DSB and HSB, while, for Ukrainian, we achieve moderate gains through RAG.

Krey-All WMT 2025 CreoleMT System Description: Language Agnostic Strategies for Low-Resource Translation

Ananya Ayasi

Pittsburgh, PA, USA
ananya.ayasi@gmail.com

Abstract

This work is a submission to the Creole MT Task conducted as a part of the Tenth Conference on Machine Translation (WMT '25) co-located with EMNLP 2025. The focus of the work was on the Seychellois Creole- English language pair by utilizing similar Creoles to make up for the scarcity of data in Creole language systems.

1 Introduction

The work of this paper is based on Robinson et al. (2024) which presented a one of a kind, cumulative dataset for Creole language MT. This is an important topic owing to the fact that many Creole language speakers live in areas where their language is in the minority and they could benefit from better machine translation systems.

The main objective behind this paper is to see if a certain language pair translation could benefit from similar languages when building an MT system. To that end, I picked Seychellois Creole (crs)- English (eng) pair and to supplement the model training Mauritian Creole (mfe), French Guianese Creole (gcr), Louisiana Creole (lou) and Réunion Creole (rcf) were chosen. The linguistic proximity of these Creoles were studied in Papen (1978). Many Creoles also have linguistic relationships with high resource languages which gives better prospects for cross-lingual transfer (Lent et al., 2024) and hopefully can be studied in a future iteration of this paper.

In addition to the shared-task submission for crs–eng, this work evaluates the broader applicability and limits of unified tagging by comparing performance across multiple French-lexifier Creoles as well as Tok Pisin, a typologically distant creole, thereby situating the approach within a linguistically grounded framework rather than a purely engineering exercise.

2 Data

Since this work was part of the constrained track, the data and base model used were provided by Robinson et al. (2024). As mentioned above, the 5 Creole languages used were chosen based on their linguistic proximity.

Seychellois Creole and Mauritian Creole are widely regarded as the closest pair among the varieties considered here, a connection that stems largely from historical migration patterns (Baker et al., 1982). Seychelles was primarily settled from Mauritius in the late 1700s, and while there are lexical and phonological differences, several scholars have noted that they may be treated as regional variants of a single linguistic system rather than entirely separate languages (Michaelis and Rosalie, 2013) (Ramsurrun et al., 2024).

Translation Pair	Train	Val	Test
crs-eng	2,070	107	222
mfe-eng	19,100	472	811
gcr-eng	60	28	38
lou-eng	1,570	92	174
rcf-eng	191	34	28

Table 1: Number of training, validation, and test sentence pairs for each Creole–English translation dataset used in this study.

Réunion Creole, while geographically proximate, has a distinct and earlier colonization history, resulting in greater grammatical divergence from Mauritian. Nevertheless, commonalities in the pronominal system, such as the use of *zot* for both second and third-person plural, and shared plural markers like *ban(de)*, point to the effects of geographical continuity and inter-island contact. Lexical similarities, including borrowings from Malagasy and Indo-Portuguese, reinforce the role of shared areal features despite significant typological differences (Papen, 1978).

Expanding beyond the Indian Ocean, Louisiana Creole and French Guianese Creole also exhibit no-

Proceedings of the Tenth Conference on Machine Translation, pages 1158–1165

table structural parallels with Mauritian, underscoring broader transoceanic affinities among French-lexifier Creoles. (Pfänder, 2013) (Klingler and Neumann-Holzschuh, 2013)

For MT research, this interconnected yet varied typological landscape offers opportunities for cross-lingual transfer learning, provided that models are designed to exploit shared structures without conflating distinct grammatical systems.(Grant and Guillemin, 2012)

As far as Creoles go, I have also chosen Tok Pisin as a linguistically dissimilar language to Seychellois Creole to demonstrate how this strategy is effective only when the varieties share substantial structural overlap.

3 Methodology

This work adopts a language-agnostic machine translation strategy for low-resource Creole–English translation, building on multilingual pretraining and fine-tuning techniques that have been shown to benefit typologically related languages in low-data regimes (Johnson et al., 2017); (Aharoni et al., 2019); (Conneau et al., 2020).

I call the approach "language-agnostic" because the model is not given any explicit linguistic rules or handcrafted features about Creole varieties; instead, all source languages are treated under a unified tag, allowing the system to learn transfer purely from shared representations without relying on language-specific annotations.

3.1 Base Model and Setup

The base model is kreyol-mt-pubtrain based on mBART (Namdarzadeh et al., 2023) as distributed in the constrained track by Robinson et al. (2024). This model is pretrained on a variety of languages, including several French-based Creoles, providing a strong initialization for transfer learning. All training experiments use the HuggingFace Transformers library (Wolf et al., 2020) with mixed precision and early stopping where indicated.

3.2 Tagging Strategies

The main focus of this paper was to see if other similar languages can be used to enhance the MT system for a certain language pair or rather language-agnostic machine translation as inspired by (Chen and Zhang, 2024). I mainly experimented with two techniques for the same, "All Kreyols" and "Specialized".

Following Johnson et al. (2017), all input sequences were prepended with a target language tag. In the "All Kreyols" condition which was the language-agnostic approach, all Creole data received the <2crs> tag regardless of source variety, treating all Creoles as dialectal variants for the purpose of model conditioning.

"Partial Kreyall" was basically a variant of "All Kreyoles" where even though all the languages used the same tag, only partial fine-tuning was done. In the "Specialized" condition which was language-specific, each Creole variety retained its own target tag (e.g., <2mfe>, <2lou>), enabling the model to distinguish among them. In this case, I experimented with both full fine-tuning and partial fine-tuning.

3.3 Data Augmentation via Upsampling

It is to be noted that in Table 1 mfe-eng language pairs in the train set was almost twice as that of crs-eng. Given the extreme imbalance in dataset sizes, upsampling of the target language data was employed to avoid underrepresentation of Seychellois Creole. Without intervention, batches are dominated by mfe examples, which can lead to underrepresentation of crs and limiting domain adaptation.

Inspired by Sennrich et al. (2016) and Robinson et al. (2022), initial experiments used a 5x upsampling factor for crs-eng. This ensures that crs examples are seen as frequently as those from the largest dataset, allowing the model to retain multilingual benefits while focusing on the target low-resource language. Later, a 10x factor was tested, especially in the "Specialized" setting, to further balance the distribution. However, it did not exactly lead to better results as will be discussed later.

3.4 Fine-tuning Strategies

Two broad strategies were mainly tested for fine-tuning. The first one being without any freezing, thereby fine-tuning all the parameters of the given kreyol-mt-pubtrain model.

The second one being partial freezing where only the last 4 to 6 encoder layers, all decoder layers, and optionally shared embeddings were frozen. This follows the intuition from Kirkpatrick et al. (2017) and Pfeiffer et al. (2021) that retaining most pretrained parameters can preserve generalization while adapting only the task-relevant parts.

Additional architectural regularization was explored by modifying dropout rates for feedforward, attention, and activation layers. In the notation

dropout=0.2/0.05/0.05 in Table 4, the three values correspond respectively to the model's feedforward dropout, attention dropout, and activation dropout. For instance, in kreyol-mt-pubtrain's configuration, these would be set via:

```
model.config.dropout = 0.2
# feedforward layer dropout
model.config.attention_dropout = 0.05
# attention mechanism dropout
model.config.activation_dropout = 0.05
# activation function dropout
```

These rates control the probability of randomly zeroing out elements during training to prevent overfitting. Adjusting them independently allows for targeted regularization. Higher dropout in feedforward layers can reduce co-adaptation in dense transformations, while lower dropout in attention and activation layers can help preserve sequence modeling capacity without severely impacting convergence.

3.5 Optimization

All models were optimized using AdamW, which decouples weight decay from the gradient-based updates, preventing it from accumulating in the momentum or variance terms. Weight decay values ranged from 0.1 to 0.3, and the learning rate was fixed at 1E-5 to mitigate catastrophic forgetting in the multilingual setting. Warmup schedules of 500–1000 steps were applied, followed by linear, cosine, or constant learning rate decay. In certain configurations, label smoothing of 0.1–0.2 (Szegedy et al., 2015) was incorporated to improve generalization in the low-resource MT setting. All hyperparameters were chosen based on prior work in low-resource MT and small-scale tuning on the validation set.

4 Experiments

The experiments compare baseline, All Kreyols, Partial Krey-all, and Specialized setups. Performance was evaluated using BLEU (Papineni et al., 2002) and chrF (Popović, 2015) on the held-out Seychellois Creole–English test set.

4.1 Language Embeddings

In order to truly understand and corroborate prior linguistic research pertaining to the proximity of the French-lexifier Creoles, kreyol-mt-pubtrain's encoder embeddings for them and Tok Pisin (tpi) were visualized by sampling 60 sentence pairs from each dataset and converting their source sentences into 1024-dimensional vectors using the encoder.

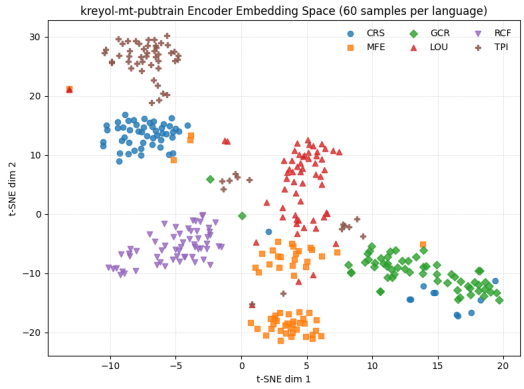

Figure 1: t-SNE visualization of kreyol-mt-pubtrain encoder embeddings for 60 sampled sentences from each language (crs = Seychellois Creole, mfe = Mauritian Creole, gcr = French Guianese Creole, lou = Louisiana Creole, rcf = Réunion Creole, tpi = Tok Pisin). The five French-lexifier Creoles form distinct yet proximate clusters, reflecting their structural similarity, whereas Tok Pisin is clearly separated in embedding space, highlighting its typological distance.

These high-dimensional vectors were then reduced to two dimensions via t-SNE (Cai and Ma, 2022), which preserves local similarity structure while making patterns viewable in a scatter plot. The resulting "t-SNE dim 1" and "t-SNE dim 2" axes have no direct linguistic meaning. Their role is to position points so that those close in the plot were also close in the original embedding space. Each language was assigned a unique color and marker, revealing how kreyol-mt-pubtrain clusters them based on learned representations.

The plot shows that the five French-lexifier Creoles form distinct but proximate clusters, with some overlap among related varieties such as gcr, mfe and lou. crs is positioned near rcf and partially overlaps with gcr, aligning with the shared French-derived vocabulary and grammar across these languages. By contrast, tpi is kept well apart from these clusters, reflecting its typological distance from the French-lexifier group. This separation reinforces the observation that unified tagging works best for closely related languages, where embeddings occupy overlapping regions and facilitate cross-lingual transfer (Ponti et al., 2021).

4.2 Baseline

The baseline fine-tuned the given kreyol-mt-pubtrain with no freezing and <2crs> tag for all data. The best run achieved BLEU = 34.61, chrF

= 60.84 after 15 epochs with a linear scheduler and 500 warmup steps. To ensure comparability, this baseline was reproduced under the same constrained-track conditions, and the scores are in line with those reported in the shared-task paper, confirming that my setup is consistent with the official baseline.

4.3 All Kreyols/ Krey-All

Here, all Creole varieties were merged under the <2crs> tag. The best configuration reached BLEU = 35.44, chrF = 61.71 using 20 epochs (stopping at epoch 18), cosine scheduling, LR = 1E-5, warmup = 1000, and label smoothing = 0.1. This shows gains over the baseline, suggesting that cross-variety pooling helps despite grammatical differences.

4.4 Partial Krey-all

For this setting, partial freezing was applied, testing different numbers of unfrozen encoder layers, decoder layers, and embedding sharing. The results were mixed with some configurations having degraded performance (e.g., BLEU = 20.14 for unfreezing last 2 encoder/decoder layers), while others recovered to near-baseline levels. The gains were limited, indicating that aggressive layer freezing may not suit closely related low-resource varieties.

4.5 Specialized

This setup retained distinct tags per variety, with and without crs upsampling. The highest performance here (BLEU = 35.19, chrF = 61.14) was achieved by disabling early stopping, allowing the model to converge fully over 20 epochs. Notably, 10x crs upsampling did not yield improvements over the baseline or the settings with 5x upsampling. The findings suggest a saturation effect, where oversampling beyond 5x no longer improves performance because the model's representation of crs is already well-established.

4.6 Other Language Pairs

To further validate the generality of the Krey-All unified tagging strategy, I extended experiments beyond the official shared-task pair (crs–eng) to additional Creole–English directions. For the French-lexifier creoles (crs, mfe, rcf, lou, gcr), I trained each pair by combining its own data with data from the other French-lexifier creoles, while preserving their respective language tags. This ensured that the unified strategy was tested symmetrically across all related varieties. The results, shown in Table 3, indicate consistent improvements across all of these creoles, with gains ranging from +0.9 to +1.3 BLEU.

To further stress-test the approach, I then applied the same unified tagging setup to Tok Pisin (tpi) by pooling it together with all the French-lexifier creoles. Unlike the others, tpi is typologically distant, and the results confirm that the strategy does not generalize well in this case (–1.28 BLEU). Importantly, to maintain the sanctity of the experiments, tpi data was not used when training the French-lexifier systems. This separation highlights the core finding: unified tagging provides consistent benefits when applied to closely related creoles, but degrades performance when applied to a structurally different language.

All experiments were conducted on an NVIDIA A100 GPU. Also note that for the shared task submission, crs–eng Krey-All was submitted as the primary system, while crs–eng Partial Krey-All and crs–eng Specialized Krey-All were submitted as contrastive systems 1 and 2, respectively.

5 Results and Analysis

The language-agnostic tagging strategy which was the main goal of this paper proved most effective, as shown by two clear outcomes. First, tagging crs across all Creoles consistently yielded higher scores compared to runs where tags were language-specific. Second, even when crs data was oversampled by 10x, scores did not improve over the 5x runs, despite mfe data being more abundant, indicating that mfe served as a strong substitute for crs in the shared tag setup. This aligns with prior findings that shared tags encourage parameter sharing across related low-resource languages (Johnson et al., 2017); (Sachan and Neubig, 2018).

No freezing continued to outperform partial freezing, suggesting that kreyol-mt-pubtrain's multilingual pretraining already aligns Creole varieties in the embedding space. Scheduler and label smoothing choices impacted results more than weight decay, with cosine or linear schedules and smoothing = 0.1 performing best overall.

6 Conclusion

This study examined a unified tagging strategy using kreyol-mt-pubtrain to improve translation quality for the low-resource Seychellois Cre-

Table 2: Best results in each category for Creole–English MT.

Technique	Details	BLEU	chrF
Baseline	No freezing	34.61	60.84
Partial Krey-all	Unfreeze last 4 encoder / all decoder layers+ shared embeddings, dropout=0.2/0.05/0.05	34.72	61.11
Specialized	No freezing and no early stopping	35.19	61.14
All Kreyols	No freezing	**35.44**	**61.71**

Creole–Eng	Baseline	Krey-All
crs–eng	34.61	35.44
rcf–eng	41.00	42.12
lou–eng	32.72	33.65
gcr–eng	49.89	51.21
mfe–eng	25.23	26.29
tpi–eng	53.25	51.97

Table 3: **BLEU scores** for baseline vs. Krey-All unified tagging across Creole–English pairs. French-lexifier creoles consistently improve under unified tagging, while Tok Pisin (tpi), a typologically distant language, shows degraded performance.

ole–English pair. By tagging crs across all Creole varieties, the model achieved higher scores than language-specific tagging. The absence of gains from 10x crs upsampling, despite the availability of larger mfe data, further indicated that Mauritian Creole served as an effective proxy for crs in the shared-tag setup. These findings reinforce that related Creole languages can transfer knowledge efficiently when trained under a unified representation.

While absolute gains are modest (<1 BLEU/chrF), they are consistent across runs and show that leveraging related Creoles can stabilize low-resource training. Moreover, since the constrained track provides the same pretraining data for both base and fine-tuning, the improvements are naturally limited compared to unconstrained settings.

Beyond crs–eng, applying the same strategy to other Creole–English directions (rcf, lou, gcr,mfe) produced similar improvements, confirming that the benefits of unified tagging generalize across French-lexifier Creoles. In contrast, Tok Pisin (tpi), a typologically distant creole, did not benefit, which corroborates the claim that this approach is most effective when applied to closely related languages.

No-freezing fine-tuning proved most effective, suggesting that kreyol-mt-pubtrain's multilingual pretraining already aligns Creole varieties well in embedding space. The best system, trained on all Creoles without freezing, reached a BLEU of 35.44 and chrF of 61.71 for crs-eng, outperforming the baseline. Overall, cross-lingual transfer with linguistically related low-resource languages emerges as a promising strategy in constrained MT settings, particularly when paired with balanced exposure and a unified tagging scheme.

If there is one takeaway from this paper, it is that prior linguistic research remains vital even in the age of large language models. More often than not, leveraging linguistic insight can be just as critical as scaling data volume. (Gu, 2025)

Limitations

While the results are promising, there are several limitations to this work:

- Data imbalance: The extreme disparity in dataset sizes (e.g., 2K pairs for crs-eng vs. 19K for mfe-eng) may cause the model to underfit the smallest dataset even after upsampling. It is also to be noted that in the original paper, the scores for mfe-eng were much lower than crs-eng despite the larger training set. This should be further investigated in upcoming iterations.
- Domain mismatch: Training corpora for different Creoles may differ in domain, register, or orthography, potentially introducing noise (Karakasidis et al., 2023).
- Model constraints: We were limited to the kreyol-mt-pubtrain model in the constrained track, restricting architectural or pre-training modifications.
- Evaluation scope: BLEU and chrF scores, while informative, do not capture deeper semantic adequacy or fluency. No human evaluation was performed.

Ethics Statement

This work uses only publicly released datasets from Robinson et al. (2024) and adheres to the constraints of the WMT 2025 Creole MT Task. No personally identifiable information (PII) is present in the training or evaluation data.

While the goal is to improve accessibility for speakers of low-resource Creole languages, I acknowledge that MT systems may propagate biases present in the source data, especially given the historical and sociolinguistic contexts of Creole-speaking communities. Deployment of such systems should therefore be accompanied by careful evaluation in real-world contexts, with community feedback guiding improvements.

Additionally, these models are intended to augment human communication rather than replace professional translators, especially in sensitive domains such as legal, medical, or governmental communication.

Acknowledgements

The author thanks Nate (author of Robinson et al. (2024)) for his invaluable guidance and mentorship throughout this work. Gratitude is also extended to family (Seema, Ajai, Anwaya) and friends (Ishwrya, Balaji, Maanasa, Sruthi) for their unwavering support during the course of this research. This work is dedicated to Simi, Eldin, Ewan, and Ryan.

Abstract

In this work, we present our submissions to the unconstrained track of the System subtask of the WMT 2025 Creole Language Translation Shared Task. Of the 52 Creole languages included in the task, we focus on translation between English and seven Lusophone Creoles. Our approach leverages known strategies for low-resource machine translation, including back-translation and distillation of data, fine-tuning pre-trained multilingual models, and post-editing with large language models and lexicons. We also demonstrate that adding high-quality parallel Portuguese data in training, initialising Creole embeddings with Portuguese embedding weights, and strategically merging best checkpoints of different fine-tuned models all produce considerable gains in performance in certain translation directions. Our best models outperform the baselines on the Task test set for eight out of fourteen translation directions. When evaluated on decontaminated test sets, they surpass the baselines in all directions.

1 Introduction

The introduction of the first Shared Task for Creole language machine translation (MT) (Robinson et al., 2025) is emblematic of the increased attention that Creole languages have received in the field of Natural Language Processing in recent years, both as individual languages (Robinson et al., 2022; Dabre et al., 2014; Lent et al., 2021; Dabre and Sukhoo, 2022; Rowe et al., 2025) and in multilingual modeling efforts (Robinson et al., 2024; Lent et al., 2024). Building on the latter, this Shared Task covers over 50 Creole languages from a range of geographical and linguistic contexts. Some are relatively high-resourced; for example, Haitian Creole and Papiamento are supported in Google Translate and many others are institutionalised as official or educational languages (Robinson et al., 2024). Others are extremely low-resource languages or even critically endangered or extinct.

The Shared Task invites submissions of data and systems serving MT between any of the Creole languages and either English or French, with the existing Kreyòl-MT (Robinson et al., 2024) and CreoleVal (Lent et al., 2024) translation models serving as baselines. In this submission, we develop systems to translate between English (eng) and seven Lusophone[1] Creoles: Angolar (aoa), Annobonese (fab), Guinea-Bissau Creole (pov), Kabuverdianu (kea), Papiamento (pap), Principense (pre) and Sãotomense (cri).[2] This set includes relatively high-resource Creoles (like pap and kea) and extremely low-resource ones (like aoa, fab and pre).

In our submission, we utilise known strategies for low-resource MT as well as techniques designed to leverage the linguistic relationship between our seven Creoles of focus and Portuguese (por). In particular, we contribute the following:

- We collate additional parallel and monolingual data for pap, pov, kea and cri (Sections 3.1.2 and 3.1.3).
- We augment the training data with high-quality parallel eng-por data, synthetic parallel data created via back-translation, and distilled data created via forward-translation (Section 3.2).
- We fine-tune three pretrained multilingual base models with different combinations of data and initialisation strategies (Section 4.2).
- We apply model merging to further improve translation performance (Section 4.3).
- We post-edit system outputs using LLMs and bilingual lexicons, improving performance for five translation directions (Section 4.4).

We release our code in our Github repository.[3]

[1]Creoles which are related to Portuguese.

[2]We focus on translation between these seven Creoles and English due to availability of test data, but future work could expand to Creole–Portuguese translation.

2 Related Work

Robinson et al. (2024) release four versions of Kreyòl-MT **(KMT)**, a translation model which supports all seven of our Creole languages of focus. The four versions are created by training on both public and private datasets, and training both from-scratch and fine-tuning an existing model. For fine-tuning, they use `many-to-many (m2m)` **mBART-50** (Tang et al., 2021), a multilingual version of mBART (Liu et al., 2020) fine-tuned for translation between 50 languages, as the base model. mBART is a sequence-to-sequence denoising auto-encoder pre-trained on large-scale monolingual corpora in many languages using the BART objective (Lewis et al., 2020). Lent et al. (2024) also fine-tune `m2m` **mBART-50** on a different set of Creole languages including pap.

While the models released in Robinson et al. (2024) and Lent et al. (2024) are the strongest baselines for MT for Creoles in general, some of our seven languages of focus are also included in other prior work on MT. The No Language Left Behind (**NLLB**) translation model excels at translation of low-resource languages, and supports pap and kea (as well as three other Creoles not included in our study) (NLLB Team et al., 2022). The training data curated as part of the NLLB effort include less than 10 bitexts for each Creole, but 28M monolingual sentences in pap and 300k in kea. The FLORES-200 evaluation dataset was also translated into both Creoles in this context.

Both kea and pap are featured in **PanLex**,[4] a massive, open-access online lexicon covering over 5,000 languages (Kamholz et al., 2014); but only pap is supported in **GATITOS**, a smaller, higher-quality parallel lexicon for low-resource languages developed by Jones et al. (2023). These lexical resources have been used to improve low-resource MT performance for Creoles. Following prior work using LLMs to post-edit machine translation system outputs to correct errors (Xu et al., 2024; Chen et al., 2024; Hus et al., 2025), Nielsen et al. (2025) showed that including the entire GATITOS lexicon in such post-editing prompts can improve ChrF scores and reduce lexical confusion, including for pap-eng MT. Similarly, Hus and Anastasopoulos (2024) showed improvements of over 15 ChrF++ in eng-kea MT by post-editing using an LLM with prompts including parallel words and sentences extracted from the kea PanLex dataset.

The question of how training data from related languages can improve MT for Creoles remains open (Lent et al., 2022). Ma et al. (2025) showed that the speech foundation model Whisper (Radford et al., 2023) performs surprisingly well on kea-eng speech translation (despite having not been trained on kea speech) when the por language code is used for decoding, which they hypothesise is due to pronunciation similarities between the two languages. Conversely, Fekete et al. (2025) demonstrated that parameter efficient fine-tuning via language adapters improves MT for three Creoles (including pap) regardless of whether the adapters were trained on related languages, unrelated languages, or even random noise, indicating that language adapters improve performance due to regularization rather than cross-lingual transfer.

3 Data

In this section, we briefly describe the data provided by the task organisers and the additional data we collect and create for model training. Our novel data sources are documented in full in Table 6 in Section A.

3.1 Data Collection

3.1.1 Organiser-Provided Data

To train their models, Robinson et al. (2024) gathered data for 43 Creoles from multilingual datasets, extracting parallel and monolingual texts from websites, Wikipedia collections, educational materials, religious texts and other sources where available. Some of their data remains private due to copyright reasons, but their public training and development splits ($\text{Train}_{\text{KMT}}$ and Val_{KMT}) form the official training data for the Shared Task. Robinson et al. (2024) also provide a public test split (Test_{KMT}), which we do not use as training data.[5]

For our seven Creoles of focus, the publicly available resources parallel with eng from Robinson et al. (2024) vary in size and domain. The datasets for pov, pre, aoa, cri and fab have between 170 and 450 parallel aligned sentences from

to academic researchers for non-commercial purposes upon request; please contact the lead author for license agreement and access.

[4] At the time we conducted our study, PanLex was not accessible online and so we did not use this resource for kea in our work.

[5] While we did not use Test_{KMT} data to train our models, we did evaluate our models' performance on this public test split in order to make modelling decisions, prior to the announcement that the official Shared Task test set would be identical to Test_{KMT}.

educational materials, collected from the APiCS corpus (Michaelis et al., 2013). In contrast, the parallel datasets for kea and pap are larger and more diverse, both drawing data from FLORES-200 dev and NLLB train (NLLB Team et al., 2022) as well as APiCS (Michaelis et al., 2013). The public pap dataset[6] also includes bitexts from the Online library of The Church of Jesus Christ of Latter-day Saints[7], LegoMT (Yuan et al., 2023), Tatoeba[8], and Wikipedia, as well as a bilingual lexicon.[9] Parallel sentences with languages other than eng are available for pap and kea, but we include only parallel data with eng.

3.1.2 Additional Parallel Data

To augment the official task data, we collect additional data parallel with eng for pap, pov and kea.[10] As is common with low-resource languages, much of the publicly-available parallel data sources we could find for each language are religious in nature (Siddhant et al., 2022). We collect aligned Bible verses (pap and pov) and aligned sentences from available editions of Jehovah's Witnesses Watchtower (JWW) series[11] (pap, pov and kea). We also collect non-religious parallel sentences from a random sentence generator (pap), an article about internet access (pov), and the glosses from a por-pov bilingual dictionary (we translate the por glosses into eng using Google Translate).

Portuguese Since our focus is on Lusophone Creoles, we hypothesise that adding high-quality eng-por data can improve transfer learning. We download the eng-por Tatoeba Translation Challenge Dataset (Tiedemann, 2020), which is a collection of all data in OPUS, shuffled and deduplicated. We use the corresponding Bicleaner-AI (Zaragoza-Bernabeu et al., 2022) scores[12] to aggressively filter the dataset. Bicleaner-AI is a neural metric that estimates how likely it is that a sentence pair is a translation. We keep only sentence pairs with a Bicleaner-AI score of 1.0 to ensure high quality, leaving us with a seed dataset of 112k sentences (representing 0.03% of the total Tatoeba dataset).

3.1.3 Additional Monolingual Data

We also collect monolingual Creole data, including a high school textbook (kea), a blog series (kea), glosses from an unpublished monolingual dictionary (pov) and transcriptions of a documentary (pov). The JWW Series (see Section 3.1.2) in cri is hosted on a different website from the eng, pap, pov and kea versions; as this makes it impossible to align the cri data with the eng data, we instead collect JWW as a monolingual resource for cri.

3.1.4 Lexicons

In order to experiment with post-editing with LLMs and lexicons, as demonstrated in Nielsen et al. (2025), we collect bilingual lexicons for each of our seven Creoles of focus. For aoa, we could not find a publicly-available lexicon, and instead manually curate a small set of parallel lexical items using word-aligned entries from IMT Vault.[13] For pap, we use both the GATITOS lexicon (Jones et al., 2023) and a newly collected traditional lexicon.

3.2 Synthetic Data

We backtranslate all sources of monolingual data into eng using the KMT model that scores the highest ChrF on the KMT test set for that language pair.[14] We also use `kreyol-mt` (the single best KMT model) as a 'teacher' model, using it to forward translate the eng sentences from the pap, kea, pov and cri parallel datasets into each Creole via Sequence-Level Distillation (Seq-KD) (Kim and Rush, 2016).[15] These distilled datasets allow us to train models which better imitate the distribution output of the KMT model at sentence-level.

[6] The private pap-eng dataset (used for model training but not publicly released) includes additional parallel data from CreoleVal (Lent et al., 2024), a textbook, the JHU bible corpus (McCarthy et al., 2020), the QED corpus (Lamm et al., 2021) and Ubuntu texts from the OPUS corpus.

[7] https://www.churchofjesuschrist.org/study?lang=pap. This dataset was shared directly by the organisers as it is not on HuggingFace yet.

[8] https://tatoeba.org/en/downloads

[9] https://www.scribd.com/document/119363393/Parleremo-English-Papiamento-Papiamento-English-Dictionary-1ed

[10] We later found small parallel resources for aoa, fab and pre; while it was too late to include these sources in our model training, we list these sources in Table 6 for future reference.

[11] JWW is a monthly Bible study resource which is mostly about religious matters but also includes some discussion of more general topics.

[12] https://github.com/Helsinki-NLP/Tatoeba-Challenge/blob/d34a89ac102fd236503a1911dd1050564bf4e682/BicleanerScores.md

[13] https://imtvault.org/?languageiso6393%5B0%5D=aoa

[14] `kreyol-mt` for cri and kea; `kreyol-mt-pubtrain` for pap and pre; and `kreyol-mt-scratch` for pov. We used the publicly available Test_{KMT} set to select which models to use for back-translation before realising that the Shared Task test set would be identical to the publicly available test set.

[15] We do not use distillation for aoa, fab and pre because the KMT model demonstrates ChrF scores which are too low to generate reasonable forward translations.

3.3 Data Pre-processing

We use all novel collected data for training and evaluation, except the bilingual lexicons which we reserve for post-editing experiments. We first remove any pairs of parallel sentences from our novel datasets where either the source (`src`) or target (`tgt`) sentence is in that language pair's Test_{KMT} dataset, to ensure we do not train on any test data. We then split out 10% of our novel `cri`, `kea`, `pap` and `pov` data (up to a limit of 1,000 sentences) for both validation and test data. We combine our training and validation splits with $\text{Train}_{\text{KMT}}$ and Val_{KMT} respectively, but keep Test_{KMT} separate from our own test data ($\text{Test}_{\text{Ours}}$) for evaluation purposes.

To clean each data split, we remove duplicates, empty or identical `src`/`tgt` pairs, and pairs where `src` or `tgt` have more than 150 or fewer than three words. We also discard pairs where the ratio of the length of the `src` to the `tgt` sentence is unusually high or low, following Robinson et al. (2024). Finally, we normalise special characters like quotes, dashes, and Unicode Hex codes.

We noted that several sentences[16] from $\text{Train}_{\text{KMT}}$ and $\text{Validation}_{\text{KMT}}$ included multiple `eng` glosses for a single Creole sentence. For example, the `cri` sentence "*Ê tava ka vivê ni Libôkê.*" has the `eng` gloss "*He was living in Libôkê. OR: He used to live in Libôkê.*" To reduce ambiguity at train time, we split each of these double glosses into two separate `eng` sentences. For $\text{Train}_{\text{KMT}}$, we duplicate each Creole sentence and use each `eng` gloss to create two pairs of parallel sentences; for $\text{Validation}_{\text{KMT}}$, we retain only the first gloss as the `eng` translation of each Creole sentence.

Table 1 shows the combined dataset sizes after pre-processing. For complete details on the train, validation, and test splits for each language, including both our data and the organizer-provided data before and after cleaning, see Tables 7, 8 and 9.

	Train	Val.	Test_{KMT}	$\text{Test}_{\text{Ours}}$	All
pap	105,805	1,085	1,967	1,000	109,857
pov	43,699	1,027	33	1,000	45,759

Table 1: Numbers of Parallel Sentences (with `eng`) for each language pair, ordered by size of dataset.

[16] Specifically, those collected from the APiCS data source.

4 Models

To create our MT systems, we fine-tune the three multilingual pre-trained translation models described in Section 2: **KMT** (Robinson et al., 2024), **mBART-50** (Tang et al., 2021), and **NLLB** (NLLB Team et al., 2022). We explain our approach for fine-tuning each model below, listing additional training configuration details in Appendix E.

4.1 Baselines

The baseline models specified by the organisers for the unconstrained track of the Systems Subtask were `CreoleM2M` (Lent et al., 2024) and `kreyol-mt` (Robinson et al., 2024).[17] Both were created by fine-tuning `m2m` mBART-50 (Tang et al., 2021) on private datasets. While `CreoleM2M` performs slightly better than `kreyol-mt` on `pap-eng` and `eng-pap` translation, it does not support our other six Creoles of focus, and so for simplicity we use `kreyol-mt` as our experimental baseline.

4.2 Our Models

Fine-tuned KMT We first explore whether we can improve the performance of the baseline `kreyol-mt` model[18] by fine-tuning it further on our datasets using PyTorch Lightning (Falcon and team, 2019). We use `kreyol-mt`'s existing language tags and embeddings for each Creole.[19] Like mBART-50, `kreyol-mt` has 611M parameters and a SentencePiece (Kudo and Richardson, 2018) vocabulary of 250k subwords.

Fine-tuned mBART-50 We then explore whether we can recreate our own version of `kreyol-mt` by fine-tuning the `m2m` version of mBART-50 on our novel datasets using Fairseq (Ott et al., 2019). As the English-centric `many-to-one (m2o)` and `one-to-many (o2m)` versions of mBART-50 have been shown to outperform their `m2m` counterpart (Liu et al., 2020), we also use these models for fine-tuning. All three mBART-50

[17] While these baselines were listed on the Shared Task website, organisers clarified afterwards that `kreyol-mt` has been trained on portions of text from Test_{KMT}, and that the intended baseline was, in fact, `kreyol-mt-pubtrain`.

[18] We chose to fine-tune `kreyol-mt` without realising that its training data included text from the public Test_{KMT} set. The results of these models on Test_{KMT} are therefore inflated.

[19] We note that `kreyol-mt` was trained with `src` language tags appended to the end of each training `src` sentence (in contrast to traditional mBART-50 language tagging in which the `src` tag is prepended to the beginning of the `src` sentence). We replicate the `kreyol-mt` tagging system for tokenising the training, validation and test data.

models share the same SentencePiece (Kudo and Richardson, 2018) vocabulary of 250k subwords. We repurpose existing language tags for our unseen language pairs following Robinson et al. (2024), initialising their embeddings randomly. To compensate for the imbalance in dataset sizes across languages, we use temperature-based sampling with $\tau = 2$, which increases the relative sampling probability of low-resource languages and promotes more balanced training.

Fine-tuned NLLB As a state-of-the-art translation model designed specifically to perform well on low-resource languages, NLLB (NLLB Team et al., 2022) is also commonly fine-tuned for unseen language pairs in specific translation contexts (Ebrahimi et al., 2023; De Gibert et al., 2025). The largest NLLB model is a 54.5B parameter sparsely-gated mixture of experts model; we use two smaller distilled versions of this model (`distilled-1.3B` and `distilled-600M`) for our experiments. While `pap` and `kea` are already supported in NLLB, we add additional language tags for the other five languages and initialise their embeddings randomly. We use PyTorch Lightning for training as described for fine-tuning `kreyol-mt`, except for fine-tuning NLLB where we implement a maximum of 30 training epochs to keep total training time feasible.

Fine-tuning Experiments We first fine-tune `kreyol-mt`, the three different versions of mBART-50 and the two different versions of NLLB on our dataset for three translation directions; all Creoles into `eng` (`XX-eng`), `eng` into all Creoles (`eng-XX`), and both of these directions simultaneously (`XX-XX`). We select the best overall setup for each of the three base models for translation both into and out of `eng`, and then repeat each of those best setups for the following experiments:

1. Initialising embeddings for Creole language tags with existing embeddings in each model for `por`, instead of using existing Creole embeddings (for `kreyol-mt` models) or random initialisation (for NLLB and mBART-50).[20]
2. Including `eng-por` or `por-eng` as an additional training direction, leveraging the high-quality parallel data collected from Tatoeba (see Section 3.1.2).
3. Using `kreyol-mt` distilled data (see Section 3.2) as target side translations for fine-tuning on `pap`, `kea`, `pov` and `cri`.

For each of these fine-tuned models, we find the checkpoint with the highest scores across all languages on the validation set, and then use this best checkpoint to evaluate that model's performance on Test_{KMT}. Where any two experimental settings show improvements on the basic setup for a given base model, we also combine them together.

4.3 Model merging

To obtain most of our final models we applied model merging using Arcee's MergeKit framework (Goddard et al., 2024), specifically the `linear` method (Wortsman et al., 2022). We define three different merging strategies: (i) averaging different checkpoints of the same training run, (ii) merging different (our) models or (iii) merging our models with the `kreyol-mt` baseline model (i.e. federated learning, as the training set of `kreyol-mt` is not public). While the two first options were applied to fine-tuned mBART-50 and NLLB models (described in Section 4.2), the last option was applied to the fine-tuned KMT models (Section 4.2). In our experiments we merge between 3 and 5 checkpoints, mostly from our internal finetuned models (selecting based on best-performance on the validation dataset for specific language pairs), but also – in the case of (iii) – external models. We note that most of the time, this procedure meant averaging three last checkpoints of our finetuned models.

4.4 Post-editing

With the lexicons we collected for each Creole and the system outputs of the best models for each language pair on the Test_{KMT} dataset, we implement post-editing with three LLMs; Gemini 1.5 Pro, Mistral Large 2.1 and Open AI's GPT 3.5 Turbo.[21] Following Nielsen et al. (2025), our first prompting strategy (P1) includes only the source sentence and the system translation, while our second prompting strategy (P2) includes the translations as well as the entire lexicon for the relevant language pair. For each of these two strategies, we experiment with using the exact prompt proposed in Nielsen et al. (2025) as well as our own prompt construction. All four prompts are listed in full in Table 11 in Section B. For `pap`, we repeat the experiment with both the traditional bilingual lexicon and the GATITOS lexicon (Jones et al., 2023).

[20] For NLLB, as `pap` and `kea` are already supported languages in the pre-trained model, we do not reset the embedding weights for these language tags in the same fashion.

[21] Due to resource limitations, we did not use the paid OpenAI model to post-edit the `pap` Test_{KMT} dataset, which is over ten times as long as the test sets for the other six languages.

Table 2: Results of fine-tuning experiments (A) initialising language embeddings with por embeddings; (B) adding high-quality por data to training data; (C) using distilled data as training data for pap, kea, pov and cri, and (D) any relevant combinations of the three conditions. Results calculated on Test_{KMT} dataset, using single best checkpoint for each model (as evaluated on validation set). Results in **bold** indicate best results for that language pair out of all experimental settings for that base model; highlighted results are best out of all fine-tuned models (green = beats kreyol-mt baseline).

5 Results and Discussion

In this section, we report and discuss the results of our fine-tuning experiments, model merging and post-editing with LLMs. All results are calculated using the ChrF metric[22] (Popović, 2015) implemented in the SacreBLEU library (Post, 2018).[23]

Fine-tuning We find through initial fine-tuning on our dataset that the best overall models for translation into eng are kreyol-mt fine-tuned for XX-XX translation (KMT1), mBART-50 m2m fine-tuned for XX-eng translation (MB1) and NLLB distilled-1.3B fine-tuned for XX-eng translation (NLLB1). We find the best overall models for translation out of eng are kreyol-mt fine-tuned for XX-XX translation (KMT1), mBART-50 o2m fine-tuned for eng-XX translation (MB2) and NLLB distilled-1.3B fine-tuned for eng-XX translation (NLLB2). For each of these best setups, we then implement our initial set of experiments by retraining each model using por embeddings, por data or distilled data, and then the combinations of the two best settings for each base model.

The results in Table 2 show that different strategies work best for different base models, directions and language pairs – there is no single experimental setting that shows across-the-board advantages. NLLB-based models (NLLB1/NLLB2) show the strongest performance on translation to and from pap, which is not surprising given that this is one of NLLB's supported languages and that the model has seen large amounts of pap data during pre-training. However, using distilled data does not improve the NLLB1/NLLB2 results for pap nor any other language pairs, therefore we exclude the results for this setting. The mBART-50-based models (MB1/MB2) outperform the other fine-tuned models on aoa, fab and pre, except for eng-fab translation. Their high performance on these languages (the lowest-resourced in the set) is likely due to the temperature sampling strategy utilised in our fine-tuning setup for mBART. Conversely, the fine-tuned kreyol-mt model (KMT1) performs better than the other fine-tuned models on kea, pov and cri in both translation directions, particularly when training on distilled data.

Our best model for kea, pov and cri (fine-tuned kreyol-mt) does not beat the kreyol-mt baseline in these languages, so we experiment further with fine-tuning kreyol-mt. We therefore repeat the three experiments while fine-tuning kreyol-mt only for one translation direction at a time (XX-eng or eng-XX), as well as fine-tuning on only the highest-resource languages (cri, pov, kea and pap). To further improve scores, we find each model's best checkpoint for each language pair on the validation set and then use this checkpoint to translate Test_{KMT} for that language pair. Any of these new models which improve on our previous best results for a given language pair are included in Table 13 in Section D, along with the per-language checkpointed scores for the other best models per language pair from Table 2.

[22] Note that we use ChrF but the official Shared Task proceedings uses ChrF++.

Table 3: Results of model merging, calculated on Test_{KMT} dataset. Results in **bold** indicate best results for that language pair across all merged models; highlighted results are better than all other fine-tuned models (green = beats kreyol-mt baseline).

For translation into eng, fine-tuning kreyol-mt for XX-eng translation only gave best results for kea-eng and cri-eng (KMT2). Fine-tuning kreyol-mt for XX-XX translation but with distilled data and only with the higher-resource Creoles (pap, pov, kea and kea) improved results for pov-eng translation (KMT3). For translation out of eng, fine-tuning kreyol-mt for eng-XX translation only gave best results for eng-kea and eng-pov, using distilled data for the former (KMT4) and distilled data plus initialisation with por embeddings for the latter (KMT5). Despite these improvements, no models beat kreyol-mt scores for pov, kea and cri in either translation direction; and KMT1C remains our best-performing model for eng-cri.

Model Merging We create a total of six new models by merging different combinations of our fine-tuned and base models. Results across all language pairs and translation directions are displayed in Table 3. To improve performance on the lowest-resource languages (aoa, fab and pre) we first combine the best checkpoints of MB1B (2 checkpoints) and MB1C (3 checkpoints), obtaining the H1 model. For pap-eng we try averaging the last three checkpoints of NLLB1 (H2) and for eng-pap we take the same approach for NLLB2D (H5). For pov, kea and cri, for XX-eng we try averaging the last three checkpoints of KMT2, but find no improvements on our best scores and so exclude this model from our results. For eng-XX we average the last three checkpoints of KMT5 (H6), obtaining a new best-score for eng-pov translation. Finally, we explore whether incorporating the base kreyol-mt model directly in the merging can improve scores, combining the last three checkpoints of KMT2 with kreyol-mt (H3) and the last three checkpoints of KMT1C with kreyol-mt (H4). Our six model merges beat our existing best scores on all language directions except eng-aoa, eng-fab and eng-pre; yet our new best scores for translation from and into kea, pov and cri still do not beat the kreyol-mt baseline.

Post-editing Finally, we take our best models for each language direction and post-edit their Test_{KMT} outputs with different LLMs. We include a full list of results in Table 14 in Section D. In most cases, the LLM-edited outputs are worse than the original system outputs, but we obtain modest improvements for fab-eng, eng-fab, pre-eng, eng-pre and eng-aoa translation. For every translation direction, post-editing with the lexicon gives better results than post-editing without the lexicon, even for aoa which has only a small, hand-crafted lexicon. For pap, we obtain better results using the traditional bilingual lexicon than the GATITOS lexicon, despite the fact that the GATITOS lexicon is over three times larger than the former, potentially indicating that the lexical items included in the former are more useful for this test set domain.

Final models Out of all our finetuning, merging and post-editing experiments, we select the best systems to submit to the Shared Task, reporting the performance of each system on the test set in Table 4. The first submissions are generated by the single best model for XX-eng translation (merged model H3) and eng-XX translation (best overall checkpoint of MB2, a finetuned mBART-50 model).[24] The second submissions are generated by the best models or checkpoints for each individual language pair, except for eng-kea and eng-cri where there is no better model or checkpoint than Submission 1. We also include a third submission for translation directions where the LLM post-editing resulted in improvements on the second submission outputs.

6 Data Contamination

At the end of the Shared Task, Organisers communicated with us that the kreyol-mt model, one of

[24]We selected MB2 because, when evaluated on each language with the best checkpoint per language, it showed the highest average performance across all language directions. However, we realised in hindsight that the best *single* checkpoint across all language pairs was actually from KMT1D.

Table 5: Results for kreyol-mt baseline model compared to our Submission 1 and Submission 2 models on $\text{Test}_{\text{KMT-D}}$ and $\text{Test}_{\text{Ours}}$. Bold = best score, green highlight = beats kreyol-mt baseline.

the specified baseline models for the unconstrained systems track, had been trained on some of the Shared Task public test data; and the intended baseline was kreyol-mt-pubtrain. This explains why kreyol-mt scored so highly on the official test set for certain language pairs (kea, pov and cri), and why our models cannot beat it in these directions despite additional data and modelling efforts.

For our submission, this clarification impacted our experimental baseline and our finetuned or merged models which use kreyol-mt as a base model. This means a substantial proportion of our submissions were affected.[25] To address this, we re-evaluated both the kreyol-mt baseline and our Submission 1 and Submission 2 models[26] on two further test sets:

- A decontaminated version of the KMT test datasets ($\text{Test}_{\text{KMT-D}}$) provided by the organisers, with data not seen during training of either kreyol-mt or kreyol-mt-pubtrain (see dataset sizes in Table 10).
- $\text{Test}_{\text{Ours}}$, which is made of pap and pov data we collected but did not use for training, including data from domains not seen during training of kreyol-mt (see dataset sizes in Table 7).[27]

The results (Table 5) show that our Submission 1 and Submission 2 models outperform kreyol-mt in 12 out of 14 translation directions (all except pap-eng and eng-pap) on $\text{Test}_{\text{KMT-D}}$. On $\text{Test}_{\text{Ours}}$, our Submissions beat kreyol-mt in all four translation directions, including pap-eng and eng-pap. These results provide a more realistic picture of the performance of the baseline and our own models on the different language pairs, without inflation on a contaminated test set. Furthermore, kreyol-mt performs considerably worse on the FLORES benchmark (Goyal et al., 2022) for pap and kea (see Appendix C) than on either Test_{KMT} or $\text{Test}_{\text{KMT-D}}$. These results indicate that, aside from the issue of data contamination, the kreyol-mt model seems to be heavily overfitted to KMT-style data and less good at generalising to novel domains. We note that this may have also degraded the quality of our backtranslated training data, since we use three kreyol-mt models to backtranslate monolingual Creole data from different domains into English (see Section 3.2).

[25] Specifically, our finetuned and merged models which used kreyol-mt as a base model included H3, H4, H5 and H6, used for Submission 1 and Submission 2 for several language pairs.

[26] Due to resource and time constraints, we were not able to repeat our LLM-post editing techniques (creating Submission 3) on the new test sets.

[27] We split out this test data *after* synthetically creating parallel data by using kreyol-mt-pubtrain and kreyol-mt-scratch models to backtranslate monolingual data (see Section 3.2). As a result, 13% and 15% of our pap and pov test sets are made up of synthetic data. We also have our own test data for kea and cri (see Table 7) but because a much higher proportion of these splits are synthetic (63% and 100% respectively), we do not evaluate on this data here.

7 Conclusion

Our submissions to the WMT 2025 Creoles MT Systems Subtask utilise a range of known MT techniques, including fine-tuning three pre-trained multilingual translation models on both task data and additional data, merging best models and checkpoints and post-editing system outputs using LLMs. While no single fine-tuning, merging or post-editing strategy emerged as best amongst all language pairs, we observed considerable gains over the baseline KMT model performance on the Test_{KMT} dataset for `pap`, `aoa`, `fab` and `pre` by combining different approaches, including oversampling the lowest-resource languages in the training data via temperature sampling. While some of our results are unreliable due to the fact that Test_{KMT} is contaminated with `kreyol-mt` training data, we demonstrate the robustness of our model's performance using alternative test sets, and show that `kreyol-mt` appears to be overfitted to KMT-style data in general. Future work could explore whether the techniques and strategies we have utilised here to improve performance are also useful for other Creole language pairs and across data from a broader variety of different domains.

Limitations

The official Shared Task test sets for these languages are identical to the test sets which are publicly available on Hugging Face, meaning that the gold labels were available at the point of submission. We ensured that no samples from these test sets were in our own training data. However, before we realised that the official test set would be identical to the public one, we made modelling and design decisions based on performance on the publicly-available test set. For example, we selected the best of the four `kreyol-mt`, `kreyol-mt-pubtrain`, `kreyol-mt-scratch` and `kreyol-mt-pubtrain-scratch` models for forward translation and backward translation of our training data based on their performance on the publicly available test set, both per language and overall. We also selected our models for submission based on their performance on this test set, given that the gold labels were freely available. This biases our model development process towards this particular test set, potentially reducing generalisability or robustness of the overall MT systems and potentially giving us an advantage in the context of the Shared Task.

A key limitation of our work is that our modelling decisions and comparisons were initially guided by the `kreyol-mt` model, which was mistakenly announced as the Shared Task baseline. The organisers later clarified that this model had been trained on portions of the Test_{KMT} set, meaning not only that the baseline we were comparing to was trained on the data we were testing on, but also that our models which use it as a base model are also likely inflated. We address this in Section 6 but reiterate here that the results for our KMT-based models in Table 2, and the results for H3, H4, H5 and H6 in Table 3 and Table 4 are likely inflated.

In addition, `kreyol-mt` was trained using a non-standard tagging scheme, appending `src` language tags to the end of source sentences rather than prepending them as in standard mBART-50. Our models inherit this convention, which may limit comparability with other mBART-based systems.

Acknowledgments

This research was supported by the UK Research and Innovation (UKRI) AI Centre for Doctoral Training in Designing Responsible Natural Language Processing (grant number EP/Y030656/1); the National Science Centre, Poland (2023/49/N/ST6/02691); the EU Horizon Europe Research and Innovation programme (GA No 101070350) and UK Research and Innovation (UKRI) under the UK government's Horizon Europe funding guarantee (GA No 10052546); the OpenEuroLLM project, co-funded by the Digital Europe Programme (GA No 101195233); and EU Horizon Europe Research and Innovation programme (GA No 101070631) and UK Research and Innovation under the UK government's Horizon Europe funding guarantee (GA No 10039436).

We gratefully acknowledge Polish high-performance computing infrastructure PLGrid (HPC Center: ACK Cyfronet AGH) for providing computer facilities and support within computational grant no. PLG/2025/018209. We also thank Bhavitvya Malik of the StatMT group at the University of Edinburgh for sharing his code for fine-tuning NLLB with PyTorch Lightning, which we adapted for our experiments.

†Corsou dialect.
‡ We collected only lyrics which were tagged exclusively with the pap language tag and no other language tags.
* This is an unpublished manuscript shared privately with the lead author. Lexical items and their definitions were made into full sentences for the purposes of model training by appending each lexical item + 'i' *(is)* + definition.
§ For aoa, we could not find an official lexicon and therefore manually curated a small set of parallel lexical items using the word-aligned entries in the IMT Vault resource.

Table 6: Raw data sources and sizes. Rows shaded in gray were collected too late in the Shared Task period for us to use for model training, but are included here in case useful for future research.

B Prompts used for LLM post-editing

Condition	Nielsen et al. 2025	Ours
1. Post-editing without lexicon	**P1A:** You are asked to edit the following translation from {src_code} into {tgt_code}. The proposed translation is high-quality, but may have some incorrect words. Please output only the translation of the text without any other explanation. {src_code}: {source} {tgt_code}: {model_translation}	**P1B:** You are given a source sentence and a translation. Improve the translation from {src_code} into {tgt_code}. You must return ONLY the corrected translation sentence, without explanation or extra text. Source: {source} Translation: {model_translation}
2. Post-editing with lexicon	**P2A:** You are asked to edit the following translation from {src_code} into {tgt_code}. The proposed translation is high-quality, but may have some incorrect words. Note the following translations: Lexicon: {lexicon_str} Please output only the translation of the text without any other explanation. {src_code}: {source} {tgt_code}: {model_translation}	**P2B:** You are given a source sentence, a translation and a lexicon. Improve the translation from {src_code} into {tgt_code}. You must return ONLY the corrected translation sentence, without explanation or extra text. Source: {source} Translation: {model_translation} Lexicon: {lexicon_str}

Table 11: Prompts used in LLM post-editing experiments.

C FLORES Evaluation

Model	pap→eng		eng→pap		kea→eng		eng→kea	
	Test_{KMT}	FLORES	Test_{KMT}	FLORES	Test_{KMT}	FLORES	Test_{KMT}	FLORES

Table 14: Results from post-editing best model outputs with three LLMs. P1 is post-editing without lexicon and P2 is post-editing with lexicon (see Table 11). Baseline scores are from models of Submission 2 for each language pair (Table 4). Results in **bold** are best results for each LLM for each language pair; highlighted results = best out of all LLMs (green = also beats Submission 2 baselines). We do not apply post-editing for GPT 3.5 Turbo for pap (which has an extremely large test set) due to resource constraints.

Submitted models Table 15 documents which models we use to generate our Shared Task submissions:

- For Submission 1, we select the single best model for XX-eng translation (H3) and eng-XX translation (best overall checkpoint of MB2). We selected MB2 because, when evaluated on each language with the best checkpoint per language, it showed the highest average performance across all language directions. However, we realised in hindsight that the best *single* checkpoint across all language pairs was actually from KMT1D.
- For Submission 2, where a model has multiple checkpoints we submit the best checkpoint for that language pair, as indicated with subscripts (except for eng-kea and eng-cri where there is no better model or checkpoint than Submission 1).
- For Submission 3 we submit the best system outputs after post-editing with LLMs when this showed improvements on Submission 2. We indicate which LLM and which prompting strategy (see Table 11) was applied in parentheses.

Due to administrative error, our Submission 2 models for the XX-eng direction were not submitted to the official Shared Task.

		Sub. 1	Sub. 2	Sub. 3

Table 15: Model IDs for final system submissions.

E Fine-tuning Hyperparameters

KMT & NLLB We fine-tune KMT & NLLB models using PyTorch Lightning (Falcon and team, 2019) on a single GH200 GPU (bf16). We set the batch size to 32, use the Adam optimizer (Kingma and Ba, 2015) with a learning rate $5e-5$, a warm-up phase of 500 updates and maximum training length of 30 epochs. The model performance is validated using ChrF every 5,000 steps, early stopping after three consecutive validations with no improvement in ChrF score.

mBART We fine-tune mBART-50 using fairseq (Ott et al., 2019) with a multi-gpu (4 A100 GPUs, fP1A6). The data loader has used temperature-based sampling ($\tau = 2$). We set the batch size to maximum of 1024 tokens, use the Adam optimizer with a learning rate $3e{-}5$, a warm-up phase of 2500 updates and maximum training length of 40,000 updates. Moreover, we applied label smoothing with $\epsilon_{ls} = 0.2$, dropout of 0.3, and attention dropout of 0.1. The three best checkpoints were retained according to validation performance (based on the validation loss value), with early stopping after 10 validation intervals.

KozKreolMRU WMT 2025 CreoleMT System Description: Koz Kreol: Multi-Stage Training for English–Mauritian Creole MT

Hemkeshsing Y. Rajcoomar
Independent Researcher
yush2398@live.com

Abstract

Mauritian Creole (Kreol Morisyen), spoken by approximately 1.5 million people worldwide, faces significant challenges in digital language technology due to limited computational resources. This paper presents "Koz Kreol," a comprehensive approach to English-Mauritian Creole machine translation using a three-stage training methodology: monolingual pretraining, parallel data training, and LoRA fine-tuning. We achieve state-of-the-art results with 28.82 BLEU score for EN→MFE translation, representing a 74% improvement over ChatGPT-4o. Our work addresses critical data scarcity through use of existing datasets, synthetic data generation, and community-sourced translations. The methodology provides a replicable framework for other low-resource Creole languages while supporting digital inclusion and cultural preservation for the Mauritian community. This paper consists of both a systems and data subtask submission as part of a Creole MT Shared Task.

1 Introduction

Mauritian Creole [1] is spoken by individuals from Mauritius, Rodrigues, Agalega and the Chagos Archipelago. Over the course of its history, Mauritius was visited by the Arabs, colonized by the Dutch, French and the British. Originally, it is a language made of French and Afro-Malagasy languages which was used as a means of communication between slaves and their French masters (Piat, 1999). Over time, as the English rule began and indentured labourers arrived from India, more words infiltrated the existing Mauritian Creole lexicon. With this deep diversity of linguistic families, Mauritian Creole has words that can etymologically be traced back to France, England, Madagascar and both north and south India (Eriksen, 2007). A defining characteristic of creole languages is their dynamic lexicon, which often exhibits clear phonetic and semantic shifts from their source languages (Kouwenberg and Singler, 2009). For example, in Mauritian Creole, kalamindas = candy floss. However, the exact etymology of the word "kalamindas" is unknown. This multilingual substrate influence is characteristic of Creole formation processes, where multiple source languages contribute to the emerging Creole's lexicon and structure (DeGraff, 2001).

Mauritian Creole is considered to be a low-resource language since it lacks digital computational resources for language technology applications (Lent et al., 2022). Despite having a vibrant community of speakers, Mauritian Creole, like many Creole languages, faces social stigmatization and is often perceived as linguistically inferior or underdeveloped compared to its lexifier languages.(Kouwenberg and Singler, 2009).Throughout the years, several efforts have been made by the government of Mauritius to enforce Mauritian Creole as a language rather than a dialect, part of a broader movement for creole language recognition and standardization (DeGraff, 2005). Mauritian Creole has become part of the school curriculum when teaching languages at an early age. However since most Mauritian Creole media are through traditional sources like newspapers or magazines, few digital resources exist. Creoles are generally under represented in language research since they are generally low resource languages whose datasets are seldom publicly available. This digital divide creates significant barriers for the Mauritian community's participation in the modern digital economy and limits access to language technologies that could support cultural preservation and digital inclusion. (Team et al., 2022)

This work addresses these challenges by developing "Koz Kreol," a comprehensive machine translation system for English-Mauritian Creole translation. We present a three-stage training

[1] Also referred to as "Kreol Morisyen"

Proceedings of the Tenth Conference on Machine Translation, pages 1183–1190

methodology combining monolingual pretraining, parallel data training, and Low Rank Adaptation (LoRA) fine-tuning that achieves state-of-the-art performance on this language pair. Our approach strategically combines existing datasets from previous research efforts with high-quality community-sourced translations and synthetic data generation. The resulting system not only advances the state of machine translation for Mauritian Creole but also provides a replicable framework for developing MT systems for other low-resource creole languages, contributing to broader efforts in digital language inclusion and cultural preservation. This paper consists of both a systems and data subtask submission as part of a Creole MT Shared Task (Robinson et al., 2025).

2 Related Work

Low Resource Machine Translation (LRMT) has evolved from early transfer learning approaches (Zoph et al., 2016) and backtranslation techniques (Sennrich et al., 2016) to sophisticated multilingual pre-trained models like mBART (Liu et al., 2020), which achieved up to 12 BLEU[2] (Papineni et al., 2002) points improvement for low-resource pairs[3]. The paradigm for low-resource languages was further established by mBART-50 (Tang et al., 2020), which scaled multilingual pre-training to 50 languages and became the standard approach for many low-resource translation tasks. Early work by Tanzer et al. (2024) established benchmarks for learning translation from minimal linguistic resources, demonstrating how grammar books alone can provide sufficient structural information for basic translation capabilities in truly low-resource scenarios.

Creole languages present distinctive challenges beyond typical low-resource scenarios due to their genealogical complexity, orthographic variability, and historical stigmatization, requiring multi-source transfer learning rather than conventional single-source approaches. Recent creole MT research has made substantial progress across multiple fronts. Dabre and Sukhoo (2022) established foundational baselines with KreolMorisienMT, creating the first comprehensive parallel corpus for Mauritian Creole with 21,810 sentence pairs and demonstrating effective transfer learning from pre-trained multilingual models. Robinson et al. (2024) dramatically scaled Creole coverage with Kreyòl-MT, presenting 14.5 million unique creole sentences across 41 languages supporting 172 translation directions. Lent et al. (2024) introduced CreoleVal, the first comprehensive benchmark spanning 8 NLP tasks across 28 creole languages. Fekete et al. (2025) explored parameter-efficient approaches through adapter architectures for cross-lingual transfer, while Adelani et al. (2022) demonstrated that strategic fine-tuning of large pre-trained models with small amounts of high-quality data can achieve significant improvements.

3 Dataset Construction and Methodology

3.1 Data Sources

3.1.1 Existing Parallel Corpora

High-quality Mauritian Creole data is scarce, particularly parallel translations. Our training data includes monolingual and bilingual resources from KreolMorisienMT (Dabre and Sukhoo, 2022) and parallel bitext from Kreyol-MT (Robinson et al., 2024), mostly drawn from translated Bibles and local dictionaries, totaling around 40K bilingual sentences of generally acceptable quality[4].

The monolingual data was downsampled to 18,145 sentences (~500K tokens), as empirical testing showed this size outperformed larger sets (250K, 1M, 2M tokens), likely mitigating catastrophic forgetting (McCloskey and Cohen, 1989) and avoiding repetitive degeneration (Holtzman et al., 2020) during pretraining.

3.1.2 Synthetic Data Generation

Although our primary goal was to fine-tune an LLM for machine translation, we enriched the training data with greater diversity and nuance by including 2,023 Massively Multilingual Language Understanding (MMLU) questions, 961 Question Answering (QA) items, 692 Topic Classification sentences, and 1,225 grammar prompts. We also enhanced Claude's (Anthropic, 2024) context with 150 high-quality parallel bitexts from Flores Dev and created grammar exercises using Gramer Kreol Morisien (Carpooran, 2005). The resulting synthetic dataset comprises 4,901 sentences.

3.1.3 Community Sourced Bitext

To address the shortage of high-quality parallel data for Mauritian Creole, we launched a community-

[2]BLEU: Bilingual Evaluation Understanding

[3]Translation pairs where atleast one language is low resource

[4]Not grammatically consistent throughout.

driven data collection initiative using a web-based annotation platform. Native speakers contributed English–Mauritian Creole translations in both directions, based on Claude-generated English sentences containing at least 15 words to ensure sufficient context and complexity. A two-stage validation process ensured quality, with each translation reviewed by another native speaker. This effort yielded approximately 300 high-quality parallel sentence pairs to supplement our training corpus.

3.1.4 FLORES-200

FLORES-200 extends the original FLORES-101 benchmark by incorporating 200 languages with comprehensive evaluation datasets, providing standardized dev and devtest splits of approximately 1,000 sentences each for multilingual machine translation evaluation. The FLORES data for Mauritian Creole was sourced through a rigorous translation process involving two qualified native speakers who translated the English sentences into Mauritian Creole. Each translated sentence underwent review by the other translator, ensuring high linguistic accuracy and cultural authenticity through this collaborative validation approach.

The resulting datasets comprise 997 sentences in the dev split and 1,012 sentences in the devtest split, providing a total of 2,009 high-quality parallel sentence pairs for English-Mauritian Creole translation. Given the extremely scarce number of high quality parallel bitext available for Mauritian Creole, our final model underwent finetuning on both the dev and devtest portions to maximize the utilization of these linguistic resources.

3.1.5 Evaluation Dataset

Since we fine-tune on the Flores-200 Devtest, we created a 100-sentence evaluation set to monitor BLEU (Papineni et al., 2002) and ChrF[5] (Popović, 2015) during training and fine-tuning. The hold-out test data was sourced from LALIT[6] newspaper, focusing on global geopolitics to assess performance on news content. Source sentences in English were translated into Mauritian Creole, with only sentences over 15 words included. Each translation was validated by another fluent native speaker. Aware of domain-specific evaluation limitations, we report Flores-200 Devtest results in the appendix (Table 3) where the fine-tuned model uses only Flores-200 Dev.

[5]Character F-score.

[6]lalitmauritius.org

English–Kreol Morisien					
Split	**L**	**AL-en**	**AL-mfe**	**U-en**	**U-mfe**

Kreol Morisien Monolingual					
Split	**L**	**AL**	**–**	**U**	**–**
mono	18,145	87.13	–	27,967	–

Table 1: Dataset statistics. L: total sentences/pairs; AL-en/AL-mfe: average word counts for English/Mauritian Creole; U-en/U-mfe: unique word counts for English/Mauritian Creole.

3.2 Dataset Statistics

Table 1 presents comprehensive statistics for our datasets across different splits[7]. Our training dataset exhibits diverse characteristics across different data sources. The training split contains a substantial number of single-word entries representing 1-1 translations sourced from previous lexical datasets sourced by Dabre and Sukhoo (2022), contributing to the lower average word counts (7.3 for English, 6.7 for Mauritian Creole) compared to the evaluation sets.

The FLORES evaluation sets show significantly higher average word counts (21.0-21.6 for source, 21.4-21.9 for target), likely reflecting the more complex sentence structures typical of the FLORES benchmark. With higher average word counts of 48.5 for English and 45.2 for Mauritian Creole, we assume the hold-out test set to have even higher linguistic complexity, consistent with the discourse of news content covering global geopolitics.

4 Experiments

4.1 Experimental Design

In our comprehensive arsenal, we now have an extensive collection of resources including monolingual Creole data, valuable parallel bitext published by previous researchers, the robust Flores-200 training data, and carefully generated synthetic data. Additionally, we have meticulously curated high quality parallel sentences sourced directly from native local speakers through an ambitious community outsourcing project we launched around a year ago. This community-driven approach ensures authentic linguistic representation and cultural ac-

[7]More details in Section B of the Appendix.

curacy in our training data. We will break our carefully designed training recipe down to three distinct important steps: Pretraining, Training and Finetuning. For this comprehensive study, we will use Llama 3.1-8B model and tokenizer as our robust backbone LLM here.

4.2 Training Setup

According to the findings of Xu et al. (2024), there's significant and demonstrable benefit in pretraining a large language model with a language it is previously unfamiliar with. This crucial step helps the model build a rich internal vocabulary, as well as, develop a deep understanding of the intricate semantics of a language. However, this process has to be done extremely carefully and with precise control since it can lead to the detrimental phenomenon of catastrophic forgetting (McCloskey and Cohen, 1989) when fed too much overwhelming data. To maintain this delicate balance, we use a carefully measured 500K monolingual tokens of authentic Mauritian Creole, complemented by 100K tokens of English and French each. We employ full-weight finetuning for this critical foundational portion.

For the next step in our pipeline, we use our extensive parallel bitext sourced by other dedicated researchers as well as our synthetic data, comprising around 46K sentences. These valuable sources are mostly drawn from the carefully translated Bible and comprehensive local dictionaries. Remarkably, one single pass of the data onto a powerful 3.1-8B Llama backbone is already sufficient to see vast and encouraging improvements in translation performance. Training the model with a learning rate of 1e-5 and the AdamW (Loshchilov and Hutter, 2019) optimizer, we stop after 2 complete epochs to prevent overfitting.

For the final and most refined step in our training methodology, we use our mix of Flores 200 dev and devtest sets, for efficient Low-Rank Adaptation (LoRA) (Hu et al., 2021) Finetuning for a maximum of 3 epochs. We conduct a hyperparameter sweep over the critical rank parameter, the scaling factor named "alpha" and the target modules. The LoRA hyperparamters for our best performing results based on BLEU and ChrF metrics are $\alpha = 8$, $r = 16$, target modules = query and value projections.

5 Results

For the sake of our experiment, since Mauritian Creole data is scarce, we are training on "devtest" and we use the LALIT test set for evaluation.

5.1 Baseline Comparisons

Model / Setup	BLEU	CHRF
EN → MFE		
Zero-Shot (Llama 3.1-8B)	4.22	35.37
ChatGPT 4o	16.55	53.58
Mono Only	22.54	51.67
Mono + Train	26.76	59.55
Mono + Train + LoRA	**28.82**	**60.86**
MFE → EN		
Zero-Shot (Llama 3.1-8B)	28.4	57
ChatGPT 4o	**46.63**	**71.22**
Mono Only	43.32	69.23
Mono + Train	41.78	68.60
Mono + Train + LoRA	43.14	70.21

Table 2: BLEU and ChrF scores for different model configurations in EN ↔ MFE translation.

From Table 2, we observe a significant improvement in translation performance when incorporating 500K monolingual tokens into the model. However, the model still lacks the ability to translate the language effectively from English to Mauritian Creole. The training portion of our approach provides the largest performance boost, with a 18.7% increase in BLEU score and an 15.2% increase in ChrF score. Following this stage, we perform fine-tuning using Low-Rank Adaptation (LoRA) using the peft package. (Mangrulkar et al., 2022) Fine-tuning on 2,000 sentences in both translation directions contributes to approximately 10% improvement in BLEU score.

When examining the reverse direction (MFE → EN), the model performs significantly better than in the forward direction, a common finding when translating Low Resource Langauges to English (Neubig and Hu, 2018). The model performs better on BLEU score after passing in 500K tokens of Mauritian Creole only sentences, and the performance slightly declines when training. The improvement from LoRA fine-tuning is more modest compared to training, likely because the model has already achieved strong performance in back-translation and is approaching a performance plateau.

When comparing our model to a frontier model such as ChatGPT-4o (OpenAI et al., 2024), we observe that our model performs considerably better on forward translations (English→Mauritian Creole). However, for reverse translations (Mauritian Creole→English), ChatGPT-4o achieves slightly superior performance on both BLEU and ChrF scores. This asymmetry can likely be attributed to ChatGPT-4o's extensive multilingual training across numerous language pairs, enabling it to leverage cross-lingual priors for improved Mauritian Creole decoding.

Haitian Creole and Mauritian Creole share significant linguistic similarities as French-based creoles developed under similar colonial conditions. They exhibit overlapping vocabulary, grammar, and simplification patterns compared to French (Déprez, 2019), enabling cross-linguistic transfer. Models trained on Haitian Creole can leverage this overlap when processing Mauritian Creole. Given Haitian Creole's much larger training corpus, this likely influences ChatGPT-4o's performance—improving reverse translation but degrading forward translation, as the model tends to apply Haitian grammar to Mauritian output. We observed the same behavior using the Flores-200 Devtest set (see Appendix).

Large language models outperform traditional encoder-decoder architectures in data-scarce scenarios due to their ability to extract linguistic patterns from limited examples. Pre-trained on multilingual corpora, LLMs provide rich contextual representations adaptable to new language pairs with minimal fine-tuning, unlike encoder-decoder models that need substantial parallel data. This advantage is especially important for creole languages, where complex lexifier and substrate influences are better captured by the nuanced knowledge in large-scale pre-trained models.

6 Conclusions

In this paper, we present a new state-of-the-art model for English–Mauritian Creole translation, along with several novel datasets used for training and evaluation. These include: (1) the Flores-200 Dev and Devtest sets, (2) synthetically generated data, (3) a test set from the LALIT newspaper, and (4) community-sourced parallel bitext. This work provides a strong baseline for future model development, which can be improved by collecting more high-quality parallel data. Our results with limited data suggest that incremental augmentation will boost performance, supporting sustainable Mauritian Creole MT development. Additionally, our model can generate high-quality synthetic translations, enabling continual learning through iterative data generation and refinement.

Several promising directions emerge for future research. The inclusion of French parallel bitext represents a particularly valuable avenue, given Mauritian Creole's French lexifier heritage and the abundance of high-quality French-English parallel corpora that could enhance transfer learning effectiveness (Robinson et al., 2023). Incorporating pivot languages; intermediate languages that share linguistic features with both English and Mauritian Creole, could provide additional pathways for cross-lingual knowledge transfer and improved translation quality.

Finally, the systematic generation of synthetic training data through back-translation, paraphrasing, and multilingual data augmentation techniques offers scalable approaches to address the persistent data scarcity challenges that characterize creole language processing. These future developments, building upon the foundation established in this work, promise to advance Mauritian Creole machine translation toward broader practical applicability and community benefit.

Limitations

Our work has several important limitations that should be acknowledged. First, we train our final model on both the FLORES-200 dev and devtest splits, which raises potential evaluation concerns regarding data contamination. While we mitigate this through the use of an independent hold-out evaluation set sourced from LALIT newspaper, the limited size of available high-quality parallel data necessitated this approach to maximize training effectiveness.

Second, our evaluation is constrained by the relatively small size of our test sets (100-1,000 sentences), which may limit the statistical significance and generalizability of our results. The scarcity of Mauritian Creole digital resources inherently constrains the scale of evaluation possible for this language pair.

Finally, our synthetic data generation approach, while innovative, relies on a single large language model (Claude Sonnet 4) and may introduce systematic biases or artifacts that could affect model

performance. The quality and cultural authenticity of synthetically generated Mauritian Creole content, while supplemented with expert knowledge, may not fully capture the nuanced variations present in natural language use.

Acknowledgments

Special thanks to Aishani Rajarai who helped me create and review the high quality parallel bitext datasets. We'd like to also thank Professor David Ifeoluwa Adelani from the Masakhane Community for his guidance.

A Training and Evaluation with Flores-200

In this section, we will evaluate the model's performance on FLORES-200 devtest across three modalities: (i) monolingual only, (ii) monolingual + training data, and (iii) monolingual + training + FLORES-200 dev LoRA finetune. We evaluate both translation directions to quantify the additional performance lift from the FLORES dev finetune and assess the validity of using the FLORES-200 devtest set as an evaluation dataset. The LoRA finetune was performed in both translation directions.

Model / Setup	BLEU	CHRF
EN → MFE		
Kreyòl-MT	17.28	49.07
ChatGPT-4o	17.48	48.40
Mono Only	11.94	39.78
Mono + Train	25.76	55.71
Mono + Train + LoRA	**26.83**	**57.68**
MFE → EN		
Kreyòl-MT	28.31	57.29
ChatGPT-4o	**43.08**	**68.76**
Mono Only	33.80	60.88
Mono + Train	40.75	66.65
Mono + Train + LoRA	41.79	67.73

Table 3: BLEU and ChrF scores for different model configurations in EN ↔ MFE translation.

B Dataset Specifics

The training data consisted of KreolMorisienMT (21,810 sentences), KreyolMT (19,149 sentences), Flores Dev/Devtest (2,009 sentences), 300 community-sourced sentences, and synthetic data generated by Claude Sonnet 4. We created parallel bitext datasets (MMLU, QA, and Topic Classification totaling 3,676 sentences) and conversational prompts (1,225 grammar-specific sentences from parsed Mauritian Creole grammar books). For parallel bitext, we used a dual prompt strategy: one prompt asking the model to translate between English and Mauritian Creole, and another presenting questions directly in Mauritian Creole with options and answers in Mauritian Creole.

For monolingual pretraining we only used the monolingual dataset provided by KreolMorisienMT. For the training stage we use both parallel datasets from Kreyol-MT, KreolMorisienMT

and the community sourced bitext. For the fine-tuning stage, we use the flores dev and devtest datasets.

JHU WMT 2025 CreoleMT System Description: Data for Belizean Kriol and French Guianese Creole MT

Nathaniel R. Robinson
Center for Language and Speech Processing
Johns Hopkins University
Baltimore, MD, USA
nrobin38@jhu.edu

Abstract

This document details the Johns Hopkins University's submission to the 2025 WMT Shared Task for Creole Language Translation. We submitted exclusively to the data subtask, contributing machine translation bitext corpora for Belizean Kriol with English translations, and French Guianese Creole with French translations. These datasets contain 5,530 and 1,671 parallel lines of text, respectively, thus amounting to an 2,300% increase in publicly available lines of bitext for Belizean Creole with English, and an 370% such increase for French Guianese Creole with French. Experiments demonstrate genre-dependent improvements on our proposed test sets when the relevant state-of-the-art model is fine-tuned on our proposed train sets, with improvements across genres of up to 33.3 chrF++.

1 Introduction

The vast majority of countries and territories throughout Central and South American are hispanophone. Two notable exceptions to this trend are anglophone Belize and francophone French Guiana, pictured in Figure 1. These are both home to a duplicity of Creole languages that exist alongside English, French, and other regional languages. Many thousands of Belize residents speak Belizean Kriol and Garifuna. And French Guiana is home to French Guianese Creole, Saramaccan, and Ndyuka (Robinson et al., 2024).

According to the Statistical Institute of Belize' 2022 Population and Housing Census, Belizean Creole is spoken by 181k people in Belize (or 49% of the overall population), making it the third-most-spoken language of the country, after English (at 278k, or 75.5% of the population) and Spanish (at 199k, or 54%).

French Guiana is home to 292k people[1] and a large diversity of both Creole languages (French Guianese Creole, Haitian, French Antillean Creole, Ndyuka, Saramaccan, Sranan Tongo, and Guyanese Creolese); European languages (French, Spanish, English, Dutch, and Portuguese); Amerindian languages (Palikur, Teko, Wayampi, Wayana, and Arawak); and East Asian languages (Hmong, Cantonese, Hakka Chinese) (Léglise, 2013). According to Léglise,[2] French Guianese Creole is the mother tongue of about a third of the population. Ndyuka, an English-related Creole language, and its dialects Aluku and Paramaccan (Hammarström et al., 2023) are also spoken by roughly a third of the population. Multiple of the languages Léglise listed are spoken by immigrant communities: Haitian by 10-20% of the population, French as a mother tongue by roughly 10%, Brazilian Portuguese by 5-10%, and French Antillean Creole languages by roughly 5%. Léglise estimates that less than 5% speak indigenous Amerindian languages.

Figure 1: The greater Caribbean area with Belize and French Guiana indicated in red, made with https://www.mapchart.net

Because English and French are prominent in Belize and French Guiana, respectively, and because these European languages are used by populations that do not speak Belizean Kriol or French Guianese Creole in Belize and French Guiana, we justify the choice of these languages for translation

Proceedings of the Tenth Conference on Machine Translation, pages 1191–1197
November 8-9, 2025

into and out of our Creole languages of focus.

In this work, we contribute:

- A bitext with 5,530 Belizean Kriol and English translations from a Belizean textbook, *Kriol-Inglish Dikshineri/English-Kriol Dictionary* (Herrera et al., 2009)
- A bitext with 879 French Guianese Creole and French translations from a web-sourced Bible text
- A bitext with 792 French Guianese Creole and French translations from a collection of French Guianese fables sourced by the French national library
- State-of-the-art MT improvements across the genres of our newly curated datasets, per our own test sets

2 Related Work

Very little previous work has been published on machine translation (MT) of Belizean Kriol and French Guianese Creole. CreoleVal (Lent et al., 2024), a project introducing a multilingual machine translation model for 28 Creole languages, was the first published work on Belizean Kriol machine translation. Like in this work, Lent et al. focused on translation between Belizean Kriol and English. They put together a Belizean Kriol bitext with English, including 12,085 lines of training data. Using these data, they trained the CreoleM2M model,[3] which acheives 44.4 chrF (Popović, 2015) for Belizean Kriol to English translation and 46.3 chrF for English to Belizean Kriol (on their own test set). However, none of the CreoleVal data were publicly released to the research community.

The other publication to benchmark Belizean Kriol translation was Kreyòl-MT (Robinson et al., 2024), a project that produced a dataset and model for translation of 41 Creole languages, primarily of the Colonial African diaspora. The Kreyòl-MT model[4] supports translation in 172 language directions—all of which include one Creole language and one other language, usually English or French. The Kreyòl-MT model achieves 53.3 chrF on the Kreyòl-MT test set for Belizean Kriol to English translation, and 83.3 chrF for English to Belizean Kriol (on their own private test set). The same model achieves very similar scores on the CreoleVal (Lent et al., 2024) test set: 53.3 chrF into English, and 83.5 into Belizean Kriol, establishing Kreyòl-MT as state-of-the-art for Belizean Kriol translation with English. The dataset used to develop Kreyòl-MT contains 31,002 total lines of bitext for Belizean Kriol aligned with any other language, but only 229 of these lines (all aligned with English translations) were released to the research community in the Kreyòl-MT public dataset.[5]

Kreyòl-MT is also the only published work to address French Guianese Creole MT. On its own test set, Kreyòl-MT achieves 71.9 chrF translating French Guianese Creole into French and 62.4 translating French into French Guianese Creole. This was accomplished using only 292 lines of bitext for training data, indicating that these high scores may be a result of over-fitting to the training domain. This entire bitext was released publicly, along with 50 lines of bitext for testing and 50 for development/validation.

3 Task Description

The first shared task for Creole language machine translation (CreoleMT) for the Tenth Conference on Machine Translation (WMT25) (Robinson et al., 2025) was announced to further advance the state of machine translation for Creole languages. The shared task is comprised of two subtasks: one for systems and one for data. We participate only in the data subtask, which solicits new bitext data for Creole language MT.

As part of the set up for the systems subtask of the shared task, the task organizers established the public Kreyòl-MT dataset as the primary source of training data for the constrained submission track. To make the evaluation fair, they named the Kreyòl-MT **pubtrain** model—an mBART (Liu et al., 2020) initialization developed only with the publicly released Kreyòl-MT train and development sets and hosted at https://huggingface.co/jhu-clsp/kreyol-mt-pubtrain with the name **kreyol-mt-pubtrain**—as the baseline model for benchmarking. (The flagship Kreyòl-MT model was trained on some proprietary data not available for public release and hence would not be a fair baseline.) Since the datasets we curate in this work are publicly releasable, we compare their utility to that of other publicly available data and also adopt **kreyol-mt-pubtrain** as our primary base-

[3] https://huggingface.co/prajdabre/CreoleM2M

[4] https://huggingface.co/jhu-clsp/kreyol-mt

[5] https://huggingface.co/datasets/jhu-clsp/kreyol-mt

line model for MT experiments.

4 Dataset Creation

We detail our creation approaches for all datasets.

4.1 Belizean Kriol dictionary

Our Belizean Kriol-English bitext is taken entirely from aligned sentences in *Kriol-Inglish Dikshineri/English-Kriol Dictionary* (Herrera et al., 2009). The sentences were extracted from a PDF rendering of the book using the PyPDF2 library[6] and software that will be released before publication of this work.

The scraping script used regular expressions to extract all complete sentences used in examples with translations. With the assumption that sentences would alternate between Belizean Kriol and English, we used this software to label every odd sentence as "English" and every even sentence as "Belizean Kriol." As expected, this method of labeling led to a large number of alignment errors.

We corrected these alignment errors via a semi-automated approach. First we trained a decision tree classifier using `scikit-learn`[7] for language identification (LID), to distinguish Belizean Kriol and English sentences. We first used both source and target sides of the Kreyòl-MT public train set for Belizean Kriol-English MT to fit a simple word-based sentence embedder. For 100-dimensional embeddings, the embedder assembled the 100 most common words in the combined source-target corpus. Each sentence is then assigned a binary 100-dimensional vector where the element at each position k indicates the presence or absence of the kth most common word. We then used the same data (the Kreyòl-MT Belizean Kriol-English train bitext) to fit the decision tree, embedding each sentence with our embedder. We used the corresponding Kreyòl-MT validation/development set to evaluate our decision tree, which guided our decision to use 300-dimensional vectors instead of 100-dimensional, and our decision to use a decision tree rather than logistic regression or a random forest. (The decision tree fit with 100-dimensional vectors achieved the highest validation accuracy.)

Next we set up a system where one sentence collection (odd sentences) and the other (even sentences) are initially labeled arbitrarily as "English" and "Belizean Kriol," respectively. Human intervention is requested only whenever the LID classifier does not label both sentences as their expected languages, during which intervention the human can make any adjustments needed, including switching which language corresponds to which sentence set by default.

By this process we achieved a fully aligned bitext of 5,530 lines. Since the previous largest publicly available bitext for Belizean Kriol-English tranaslation was size 240 (Robinson et al., 2024), this amounts to a 2,304% (or 24-fold) increase in publicly available data for the language pair.

The human guiding the alignment process, while not a speaker of Belizean Kriol, speaks English natively and has high familiarity and professional experience with Creole languages. This rendered the alignment guidance easy, and we believe its quality to be high. Table 1 displays a perfectly random sampling of five aligned sentences from the bitext. Note that even non-speakers of Belizean Kriol can verify the validity of these alignments, due to the linguistic proximity of these languages.

4.2 French Guianese YouVersion Bible

The French Guianese Creole biblical data we extracted from the online YouVersion Bible[8] using the BeautifulSoup Python library.[9] The site includes one French Guianese Creole translation of the Gospel of John.[10] We scraped this and aligned it with the corresponding texts in a French Bible translation, the New Geneva Edition, on the same site,[11] resulting in 879 aligned sentences. Since the previous largest public translation dataset for French Guianese Creole-French translation contained 447 aligned sentences (Robinson et al., 2024), this amounts to a 197% increase in publicly available data.

Similar to Table 1, Table 2 displays a perfectly random sampling of five aligned sentences from the bitext.

4.3 French Guianese Gallica fables

We sourced our final bitext from the collection *Introduction à l'histoire de Cayenne: suivie d'un recueil de contes, fables et chansons en créole avec traduction en regard, notes et commentaires* (de Saint-Quentin and de Saint-Quentin, 1872).

English	Belizean Kriol
By the time John was twelve, he was already tall like his dad.	Bai di taim Jan twelv, ih mi don taal laik ih pa.
I'm missing my watch from off the bureau; somebody must have stolen it.	Ah di misn mi wach aaf a mi byooro; sohnbadi mos a teef it.
The woman helped the thieves to escape.	Di uman mi help di teef dehn fi eskayp.
The man took a long time to cut the yard because his machete was dull.	Di man tek lang fi chap di yaad, kaa ih masheet mi dol.
We went to Betty's birthday party last night.	Wi mi gaahn da Beti bertday paati laas nait.

Table 1: Five randomly sampled aligned English and Belizean Kriol translations

French	French Guianese Creole
C'est ici le pain qui descend du ciel, afin que celui qui en mange ne meure point.	Mé dipen ki désann di syèl-a, sala ka manjé li péké mouri.
Le Père aime le Fils, et il a remis toutes choses entre ses mains.	Papa Bondjé kontan so Pitit, é li bay li tout pouvwè ansou tout bagaj.
Pourquoi m'interroges-tu? Interroge sur ce que je leur ai dit ceux qui m'ont entendu; voici, ceux-là savent ce que j'ai dit.	Poukisa to ka kèksyoné mo? Kèksyoné moun-yan ki kouté mo-a, sa-ya, yé byen savé sa mo di yé."
Si je n'étais pas venu et que je ne leur aie point parlé, ils n'auraient pas de péché; mais maintenant ils n'ont aucune excuse de leur péché.	Si mo pa té vini é si mo pa té palé pou yé, yé pa té ké koupab di péché. Mé anprézan, yé pa ganyen pyès èskiz pou yé péché.
Jésus leur répondit: J'ai fait une œuvre, et vous en êtes tous étonnés.	Jézi réponn yé: "Mo fè roun sèl kichoz, é zòt èstébékwé.

Table 2: Five randomly sampled aligned French and French Guianese Creole biblical translations

This digitized book contains French Guianese fables written in French Guianese Creole with French translations. The Gallica website[12] from which we sourced this text contained eight such fables, organized into a total of 48 sections. Once again using BeautifulSoup for web-scraping, we extracted the sentences and aligned the text sections automatically. Sentence alignment was then performed manually, along with a substantial amount of error correction; many of the text segments on the web-page had what appeared to be OCR-induced noise.[13] As a disclaimer, the author who performed this manual alignment and cleaning is not proficient in French Guianese Creole. However, he is proficient in both French and another French-related Creole language (Haitian), and he has both linguistic training and experience in bitext development. Sentence alignment and cleaning decisions were mostly made clear by cognates and context. The changes to the originally web-scraped document are publicly available for perusal on GitHub.[14]

Similar to Tables 1 and 2, Table 3 displays five randomly sampled aligned and cleaned sentence pairs from the fables dataset.

5 Dataset Details

Our datasets consist of one genre each, educational material in Belizean Kriol and English, and Biblical text and literature in French Guianese Creole and French. Both datasets we shuffled randomly and then split into train, dev, and test sets with an 80-10-10 split ratio. See the shared task findings (Robinson et al., 2025) for data cards of our submitted datasets.

5.1 Fulfillment of task requirements

We now detail how our datasets fulfill each of the data requirements set forth for the shared task.[15]

1. **Translations in datasets must be completely conducted by native or proficient speakers of both languages.** The translations in our Belizean Kriol-English bitext come from *Kriol-Inglish Dikshineri/English-Kriol Dictionary* (Herrera et al., 2009), a publication authorized by the Belize Ministry of Education. The French Guianese Creole-French sentences come from Bible translations and fable

French	French Guianese Creole
Il resta ainsi longtemps,	Li rété bon moso konsa
Si vous voulez vous laver dedans,	Si zôt oulé lavé landan,
Il en restait encore une assez grande quantité;	Bon moso té rété enko
sans pouvoir en prendre un seul pour mon souper.	san mo pa pouvé kienbé oun pou mo sonpé.
J'en retirerai un peu avec mes dents »	M'a tire moso ké mo dan »

Table 3: Five randomly sampled cleaned and aligned French and French Guianese Creole fable translations

translations organized by the Bibliothèque nationale de France. The reputability of these sources convince us that such translations were performed by competent translators.

2. **Participants must demonstrate convincingly that one language in each submitted bitext is considered a Creole language.** Both Belizean Kriol and French Guianese Creole are universally considered Creole languages as attested by their inclusion in APICS (Michaelis et al., 2013), among other sources (McWhorter, 2005; DeCamp, 1968).

3. **If submitting a test set, participants must use it to evaluate performance of an MT model and provide compelling evidence that performance aligns with conventional wisdom.** We include results to address this point, for all three of our submitted datasets, in §6.

6 Experimental Results

Here we detail experiments that minimally show the utility of our datasets, as requested by the shared task organizers. We show both SpBLEU (Papineni et al., 2002; Goyal et al., 2022) and chrF++ scores (Popović, 2015, 2017) for the **`kreyol-mt-pubtrain`** model both out of the box, and after fine-tuning on our train sets (with our dev sets used to determine time of early stopping). We trained with a learning rate of $2 * 10^{-5}$, a batch size of 4, a weight decay of 0.01, and a maximum of 10 training epochs. We implemented early stopping with a stopping patience of 2 and a stopping threshold of 0.01. We fine-tuned each model on both translation directions for the language pair in question, and with early stopping we ended up finetuning for Belizean Kriol-English translation for 13,272 training steps, and for French Guianese Creole-French translation for 4,683 training steps.

	eval	score	OOB	FT
`bzj→eng`	*Dict.*	SpBLEU	17.0	**52.1**
		chrF++	37.9	**66.8**
`eng→bzj`	*Dict.*	SpBLEU	8.46	**48.1**
		chrF++	24.8	**58.1**
`gcr→fra`	*Bible*	SpBLEU	18.1	**35.3**
		chrF++	39.1	**51.7**
	Fable	SpBLEU	36.6	**41.3**
		chrF++	51.5	**54.7**
`fra→gcr`	*Bible*	SpBLEU	6.86	**25.4**
		chrF++	20.5	**34.8**
	Fable	SpBLEU	34.0	**37.9**
		chrF++	44.8	**48.6**

Table 4: MT scores for **`kreyol-mt-pubtrain`** out-of-the-box (OOB) and fine-tuned on our novel train sets (FT). Both SpBLEU and chrF++ scores are computed on our proposed test sets. Better results are **bold**.

Table 4 displays our MT performance scores. Fine-tuning on our training data significantly improves performance on our test sets in every circumstance. Some improvements are large, but their magnitude depends on test set language and genre. Out of the Creole language and into the Creole language, respectively, chrF++ improves by 28.9 and 33.3 on the Belizean dictionary test set, by 12.6 and 14.3 on the Guianese Bible test set, and by 3.2 and 3.8 on the Guianese fables test set. Note that Table 4 uses ISO 639-3 codes to abbreviate language names.[16]

7 Conclusion

We introduce three new datasets for Creole language translation of two language pairs:

1. **A bitext with 5,530 aligned translations of the educational genre in Belizean Kriol and English**, resulting in a 2,304% increase

[16] `bzj` = Belizean Kriol; `eng` = English; `gcr` = French Guianese Creole; `fra` = French

of publicly available bitext data for the language pair, and improvements of 28.9 chrF++ into-English and 33.3 chrF++ out-of-English over the state-of-the-art MT model trained on publicly available Kreyòl-MT data on our in-genre test set

2. **Two bitexts with combined 1,671 aligned translations in French Guianese Creole and French: 879 biblical sentences and 792 lines of Guianese folktales**, resulting in a 370% increase of publicly available bitext data for the language pair; improvements of 12.6 chrF++ into-French and 14.3 chrF++ out-of-French over the state-of-the-art MT model trained with publicly available data on our Biblical test set, and like improvements of 3.2 into-French and 3.8 out-of-French on our fables test set

We hope these incremental contributions may forward research in MT for Creole languages.

Limitations

Note that due to genre constraints, the utility of these datasets may be restricted to certain domains. For instance, the French Guianese Creole-French bitext we curated may be useful for assistance in further Bible translation, but may have limited utility beyond that.

Additionally, our compiling of the contributed datasets was constrained by time. We hope in future shared tasks to contribute even more data as we have the time to collect it. We also note that even in conducting manual cleaning and alignment of the datsets we submit here, cleaning and alignment errors can still be found in some places of the datasets. Though it may not be possible for these low-resource datasets to be completely noise-free, we hope future shared tasks will afford us the time to make extra passes and clean more thoroughly.

WMT 2025 CreoleMT Systems Description : Martinican Creole and French

Ludovic Mompelat
Department of Modern Languages
University of Miami
Miami, FL, USA
lvm861@miami.edu

Abstract

This paper describes our submissions to the constrained subtask of the WMT25 Creole Machine Translation shared task. We participated with a bidirectional Martinican Creole ↔ French system. Our work explores training-time strategies tailored for low-resource MT, including LoRA fine-tuning, curriculum sampling, gradual unfreezing, and multitask learning. We report competitive results against the baseline on both translation directions.

1 Introduction

The WMT25 Creole MT shared task is the first shared task focused on machine translation involving Creole languages. As part of the WMT25 Creole MT shared task (Robinson et al., 2025), we submitted constrained systems for Martinican Creole ↔ French. This track explores how to improve Creole MT under limited resource conditions. Participants were restricted to using only the official training data provided by the organizers and were allowed to initialize their models from the baseline `kreyol-mt-pubtrain` model on HuggingFace.

Our submission focused on the Martinican Creole ↔ French language pair (ISO: `mart1259-fra`). We trained and evaluated a bidirectional system for both `mart1259`→`fra` and `fra`→`mart1259` directions.

Motivation Our participation stems from ongoing work on NLP tools for Creole languages, including Martinican Creole and Haitian Creole. Despite progress in NLP, Creole languages remain underrepresented and under-resourced, making them ideal candidates for constrained MT settings. We aimed to investigate how far one can push model performance without access to expanded corpora by instead exploring training strategies and fine-tuning configurations tailored to low-resource language modeling.

This work is part of a broader effort to develop NLP tools for Creole researchers, educators, and communities. In particular, we aim to build usable MT systems, including domain-specific applications (e.g., medical MT for Haitian Creole). We explore various configurations: custom tokenizer, curriculum sampling, LoRA fine-tuning, gradual unfreezing, denoising, label smoothing, weighted BLEU scoring, multitask learning, and mixed training strategies.

2 Task Overview and Constraints

The WMT25 constrained track permits only the use of official datasets provided by the organizers. No additional monolingual or parallel data was allowed for training, tuning, or backtranslation. The baseline system is the publicly available `kreyol-mt-pubtrain` model on HuggingFace.

2.1 Data Used

We used the official datasets for the `mart1259-fra` pair, cleaned and released by the organizers:

- **Dictionnaire créole martiniquais–français** by Raphaël Confiant (2007)[1].
- CAPES corrections for Guadeloupean Creole from the Kapes Kreyol project.

2.2 Baseline Scores

mart1259→fra. On the organizers' blind test set, our system scores **25.31 BLEU** and **49.08 chrF++**, below the baseline (**28.27 BLEU**, **50.43 chrF++**). While LoRA plus curriculum sampling proved stable during development, these settings did not surpass the strong baseline under official evaluation.

fra→mart1259. On the blind test set, our system achieves **25.76 BLEU** and **48.74 chrF++**, close to but slightly below the baseline (**26.49 BLEU**, **48.69 chrF++**). This direction is comparatively tighter,

[1] https://www.potomitan.info/dictionnaire/

Proceedings of the Tenth Conference on Machine Translation, pages 1198–1200
November 8-9, 2025

suggesting our configuration is broadly competitive but does not yield consistent gains over baseline.

3 Data Preprocessing and Setup

We experimented with a 70/30 training/validation split (3,094 / 1,338) to increase the size of the development set for more stable evaluation but reverted back to the original 90/10 split as it yielded slightly better results. Training was conducted separately for each translation direction rather than using concatenated bidirectional data or multitask learning, as this yielded more consistent results in our preliminary experiments given the dataset provided.

3.1 Tokenization and Language Codes

We retained the baseline's SentencePiece model and language code scheme (e.g., `mart1259`, `fra`) to ensure vocabulary alignment. Custom `forced_bos_token_id` was applied during decoding to enforce direction.

3.2 Curriculum Sampling and Difficulty Weighting

We computed difficulty scores for each example and implemented curriculum sampling in early epochs, gradually introducing harder examples. Weighted BLEU was used for dev set evaluation to better align training progress with final performance.

4 Model Architecture and Training

All systems were initialized from the publicly available `jhu-clsp/kreyol-mt-pubtrain` model on HuggingFace. We applied Low-Rank Adaptation (LoRA) for efficient fine-tuning, targeting the attention on `q_proj` and `v_proj`. Our final configuration used rank $r = 16$, scaling factor $\alpha = 32$, and dropout 0.1, though we also explored $r \in \{8, 32\}$ and $\alpha \in \{64\}$ in preliminary runs.

Training was performed with a custom `Seq2SeqTrainer` that integrates curriculum sampling (ordering examples by difficulty), gradual unfreezing of encoder and decoder layers, and multitask loss weighting to balance direction-specific performance. We applied label smoothing of 0.1 to improve generalization and used weighted BLEU scoring on the development set as the main model selection criterion.

The final training configuration included a batch size of 32, maximum source and target lengths of 128 tokens, 50 training epochs, a constant learning rate of 2×10^{-5} with 500 warmup steps, and the AdamW optimizer. Evaluation used a beam size of 4 and a maximum of 128 new tokens during generation.

5 Evaluation

5.1 Final Systems

For `mart1259`→`fra`, our final constrained submission fine-tunes the publicly available `jhu-clsp/kreyol-mt-pubtrain` model, an mBART-50 style encoder–decoder Transformer, using only the official training set with the *original* 90/10 split. This direction uses Low-Rank Adaptation (LoRA) and curriculum sampling with difficulty weighting, as these settings yielded the most stable gains over the baseline.

For `fra`→`mart1259`, preliminary experiments showed that a 70/30 training/validation split improved dev set stability, while curriculum sampling provided no measurable benefit. We therefore retained LoRA but removed curriculum sampling for this direction.

In both cases, we retain the original SentencePiece tokenizer and language tags, forcing the target language with `decoder_start_token_id`. Training uses a batch size of 32, label smoothing (0.05), AdamW with a learning rate of 2×10^{-5}, cosine scheduling, and early stopping based on BLEU on the dev set. Generation uses beam search (beam size 4, max length 128 tokens).

Parameter	Value
Batch size	32
Max source/target length	128 / 128
Epochs	50
Learning rate	2e−5
LoRA rank r	16
LoRA α	32
LoRA dropout	0.05
Target modules	q_proj, v_proj
Label smoothing	0.1
Optimizer	AdamW
Warmup steps	500
Scheduler	constant
Beam size (eval)	4
Max new tokens (eval)	80

Table 1: Training and generation hyperparameters for both final constrained submissions.

No additional data or back-translation was

used. We fine-tune the publicly released `jhu-clsp/kreyol-mt-pubtrain` model with parameter-efficient adaptation (LoRA). Decoding uses beam search (beam size 4; max length 128), and we constrain the target language with `decoder_start_token_id`.

We report **BLEU** (Papineni et al., 2002) and **chrF++** (Popović, 2016). These are the *official* blind-test scores provided by the organizers (Robinson et al., 2025).

System	BLEU	chrF++
Baseline (official)	28.27	50.43
Ours (primary, official)	25.31	49.08

Table 2: `mart1259`→`fra` official blind-test results.

On the organizers' blind test set, our system is below the baseline (25.31 vs. 28.27 BLEU; 49.08 vs. 50.43 chrF++). While LoRA with curriculum sampling was stable in development, it did not surpass the strong baseline under official evaluation for this direction.

System	BLEU	chrF++
Baseline (official)	26.49	48.69
Ours (primary, official)	25.76	48.74

Table 3: `fra`→`mart1259` official blind-test results.

For `fra`→`mart1259`, our system is close to but slightly below the baseline in BLEU (25.76 vs. 26.49), with nearly identical chrF++ (48.74 vs. 48.69). The 70/30 split without curriculum sampling remained a stable configuration for this direction, but it did not yield a clear improvement over the baseline on the official evaluation.

Overall, direction-specific tuning—retaining curriculum sampling for `mart1259`→`fra` and removing it for `fra`→`mart1259`—produced systems that are broadly competitive but ultimately *do not surpass* the baseline under the constrained track conditions. In particular, the gap is larger for `mart1259`→`fra` and smaller for the reverse direction. A plausible explanation is the limited size and diversity of the training data: with few examples, systems may be less sensitive to changes in fine-tuning strategy or adapter placement, and estimates of improvements can have high variance. We therefore treat these direction-specific effects as suggestive rather than definitive.

6 Conclusion and Future Work

Under the constrained track, our LoRA-based systems with direction-specific training choices are close to but ultimately below the strong baseline on the organizers' blind test set. The gap is larger for `mart1259`→`fra` and smaller for `fra`→`mart1259`, where BLEU and chrF++ are nearly tied. One plausible factor is data scarcity: with limited and relatively homogeneous training material, core architectural or training-time changes may yield muted or unstable gains, and measurement noise can obscure small effects.

We will (i) explore alternative parameter-efficient adapters and layer targeting paired with data-scaling, (ii) tune curriculum schedules per direction and analyze where they help/hurt, (iii) align preprocessing/normalization and decoding with the organizers' pipeline, (iv) investigate tokenizer and segmentation choices for Martinican Creole, and (v) add robust automatic and human error analyses (e.g., code-switching, diacritics, OOVs). In the unconstrained setting, we also plan to study back-translation and multilingual transfer to further close the gap.

Abstract

Low-resource Indic languages such as Assamese, Manipuri, Mizo, and Bodo face persistent challenges in NMT due to limited parallel data, diverse scripts, and complex morphology. We address these issues in the WMT 2025 shared task by introducing a unified multilingual NMT framework that combines rigorous language-specific preprocessing with parameter-efficient adaptation of large-scale models. Our pipeline integrates the NLLB-200 and IndicTrans2 architectures, fine-tuned using LoRA and DoRA, reducing trainable parameters by over 90% without degrading translation quality. A comprehensive preprocessing suite, including Unicode normalization, semantic filtering, transliteration, and noise reduction, ensures high-quality inputs, while script-aware post-processing mitigates evaluation bias from orthographic mismatches. Experiments across English↔Indic directions demonstrate that NLLB-200 achieves superior results for Assamese, Manipuri, and Mizo, whereas IndicTrans2 excels in English↔Bodo. Evaluated using BLEU, chrF, METEOR, ROUGE-L, and TER, our approach yields consistent improvements over baselines, underscoring the effectiveness of combining efficient fine-tuning with linguistically informed preprocessing for low-resource Indic MT.

1 Introduction

Low-resource Indic languages such as Assamese (As), Manipuri (Mni), Mizo (Lus), and Bodo (Brx) pose significant challenges for **N**eural **M**achine **T**ranslation (NMT) due to data scarcity, script diversity, and linguistic complexity, often leading to suboptimal performance (Kunchukuttan, 2020a; Ramesh et al., 2023; Team et al., 2022a). This work aims to address these limitations by developing an efficient, parameter-optimized fine-tuning framework tailored for such underrepresented languages in the WMT 2025 shared task (Pakray et al.).

To address these gaps, we introduce a unified multilingual NMT pipeline tailored for low-resource Indic languages, combining robust preprocessing with parameter-efficient fine-tuning methods. We integrate **N**o **L**anguage **L**eft **B**ehind (NLLB-200) model (Team et al., 2022a) and **IndicTrans**2 (Ramesh et al., 2023) model, fine-tuning them using **Lo**w-**R**ank **A**daptation (LoRA) as proposed by Hu et al. (2021a) and Weight-**D**ecomposed L**o**w-**R**ank **A**daptation (DoRA) as discussed by Zhao et al. (2023) to optimize performance while maintaining computational efficiency. Our preprocessing pipeline includes Unicode normalization, semantic filtering, transliteration (Kunchukuttan, 2020a), and noise reduction, ensuring high-quality input data for training. NLLB-200, with its extensive multilingual coverage, is adapted for En↔As, Mni, and Lus, while IndicTrans2, designed specifically for Indic languages, is fine-tuned for En↔Brx to leverage its architectural strengths in low-data settings. The methodology ensures fair model comparison by maintaining consistent hyperparameters and evaluation settings across all language pairs, with key contributions lying in the combination of efficient fine-tuning, language-specific preprocessing, and script normalization for Indic NMT.

Our contributions include: (1) the first systematic application of LoRA/DoRA to NLLB-200 and IndicTrans2 for low-resource Indic languages, reducing trainable parameters by over 90% without sacrificing translation quality; (2) a novel preprocessing framework addressing script diversity and data noise, critical for morphologically complex languages; and (3) a comprehensive evaluation using BLEU (Papineni et al., 2002a), chrF

Proceedings of the Tenth Conference on Machine Translation, pages 1201–1209
November 8-9, 2025

(Popović, 2015), METEOR (Banerjee and Lavie, 2005), ROUGE-L (Lin, 2004), and TER (Snover et al., 2006) metrics, demonstrating significant improvements over baseline approaches.

2 Related Work

Early work on translation involving Indic languages predominantly used statistical methods and ad-hoc bilingual corpora. For example, Koehn (2005a) introduced the *Europarl* corpus for SMT, but no comparable large-scale corpus existed for low-resource Indian languages (Kakum et al., 2023). In practice, government and academic groups built phrase-based systems on much smaller data. India's *TDIL* mission developed the *Sampark* and *Anuvadaksha* translation programs by training phrase-based SMT models on limited domain-specific corpora. Similarly, Kunchukuttan and Bhattacharyya (2014) compiled *Sata Anuvadak*, a set of 110 SMT systems across Indian language pairs. These efforts established early benchmarks but exposed severe limitations due to data scarcity and domain mismatch.

With the advent of neural models, encoder–decoder architectures with attention (Bahdanau et al., 2015) and Transformers (Vaswani et al., 2017) became standard. Researchers trained RNN and then Transformer-based NMT systems for English–Hindi and other Indic pairs, often using byte-pair encoding and shared vocabularies. Multilingual and zero-shot strategies (Johnson et al., 2017) enabled parameter sharing across related languages, benefiting extremely low-resource pairs. Shared multilingual models improved translation quality through inductive transfer, as shown in early WMT shared tasks (Pal et al., 2023). Indic-to-Indic multilingual training further enhanced performance in cases of limited parallel data (Pakray et al., 2024).

In recent years, large multilingual pre-trained models have been employed for Indic MT. Models like mBART (Liu et al., 2020) and mT5 (Xue et al., 2021) provide off-the-shelf improvements, even for Indian languages. In parallel, Indic-specific models such as IndicBART (Dabre et al., 2022) and IndicTrans2 (Ramesh et al., 2023) have emerged. These models were trained on carefully normalized Indic corpora and have shown superior performance in low-resource translation. IndicTrans2, in particular, supports translation across all 22 scheduled Indian languages and 462 Indic language pairs, making it one of the most comprehensive Indic MT systems.

More recently, ultra-large multilingual models and efficient fine-tuning methods have influenced this domain. The NLLB-200 model (Team et al., 2022b) introduced a massively multilingual architecture covering 200 languages, with strong performance on low-resource Indic pairs. To adapt such models efficiently, LoRA (Hu et al., 2021b) and DoRA (Zhao et al., 2023) have been proposed, drastically reducing fine-tuning cost while preserving performance. Finally, preprocessing methods such as Unicode normalization, script unification, and transliteration (Kunchukuttan, 2020b) have been shown to significantly enhance translation quality for Indic languages. These developments form the foundation for recent SOTA systems tailored to low-resource Indic MT.

3 Analysis of Dataset

For the machine translation experiments, we utilized the **WMT** 2025 corpus divided into two categories: **Category-**1 (En $\leftrightarrow$ {As, Lus, Mni}) with moderate training data availability, and **Category-**2 (En $\leftrightarrow$ Brx) with limited training data. The following sections detail each language pair's parallel corpus specifications.

Table 1: Parallel sentences dataset statistics for both Category-1 and 2.

Lang Pair	Script	Dataset	Parallel sents
En - As	Bengali	Training	50000
		Validation	2000
		Test	2000
En - Mni	Bengali	Training	21687
		Validation	1000
		Test	1000
En - Lus	Latin	Training	50000
		Validation	1500
		Test	2000
En - Brx	Devanagari	Training	13693
		Validation	1000
		Test	1000

Table 1 summarizes the dataset sizes and scripts used for each language pair. The pairs En-As and En-Lus have the largest training sets ($50k$ sentences each), while the smallest ones are En-Mni and En-Brx ($21,687$ and $13,693$ sentences, respectively). All language pairs are divided into validation and test sets, where En-As and En-Lus have a larger test

set (2,000 sentences each), followed by En-Mni and En-Brx (1,000 sentences each). The scripts are different by language, using Bengali for As and Mni, Latin for Lus, and Devanagari for Brx.

Table 2: Sentence-level statistics for parallel corpora across four Indic language pairs.

Lang Pair	Avg. Sent. Length	Pearson Correlation	Unique Chars
En - As	En: 95.12 As: 91.29	0.7288	En: 137 As: 187
En - Mni	En: 102.79 Mni: 103.70	0.9447	En: 145 Mni: 177
En - Lus	En: 95.81 Lus: 97.73	0.8843	En: 119 Lus: 136
En - Brx	En: 96.07 Brx: 101.77	0.9377	En: 114 Brx: 144

Table 2 shows sentence-level statistics of the parallel corpora and illustrates the observed linguistic differences in the language pairs. The average number of words in an English sentence (En) ranges from 95.12 (En-As) to 102.79 (En-Mni). On the contrary, for target languages, the average number of words in a sentence is nearly the same or slightly longer with Manipuri (Mni) at 103.70 and Bodo (Brx) at 101.77. The Pearson correlation coefficients, which measure the degree of alignment of sentence lengths of English with the target languages, show that En-Mni (0.9447) and En-Brx (0.9377) have almost a perfect linear relationship, indicating highly consistent translation lengths. In contrast, En-As is least correlated (0.7288), meaning sentence lengths vary more across translations. The unique character count further reflects script complexity, with Assamese (As: 187), Manipuri (Mni: 177), Bodo (Brx: 144), and Mizo (Lus: 136). These statistics emphasize the diversity of languages in the data, which impacts translation modeling, especially for languages with rich morphology or weaker sentence-length correlation.

4 Methodology and Implementation Details

4.1 Data Preprocessing

- ***Unicode normalization*** is essential for machine translation in Indic languages because it ensures consistent text representation by converting multiple Unicode forms into a standardized format, improving tokenization, reducing noise, and enhancing alignment in parallel data. We have used `IndicNormalizer`[1] for Indic languages like Assamese and `unicodedata`[2] **N**ormalization **F**orm-**K** **C**anonical Composition (NFKC) normalizer for English language.

- ***Deduplication*** removes duplicate sentence pairs from parallel corpora, maximizing data utility for low-resource Indic machine translation. This is implemented by Python's built-in library `set()`, which removes duplicate sentence pairs from datasets.

- ***Ratio Filtering*** is essential in machine translation to ensure balanced sentence-length pairs by removing extreme mismatches, which could otherwise introduce noise and misalignment during training. Here, the implementation checks if the **word-count ratio** falls within `0.5` to `2.0`, retaining only pairs where the target sentence is neither half nor double the source length, thus preserving linguistically plausible alignments (Koehn, 2005b).

- ***Semantic filtering*** is crucial for Indic language machine translation to remove poorly aligned bilingual pairs that share surface-level similarities but differ in meaning. This is implemented using LaBSE (Feng et al., 2022), a multilingual sentence embedding model trained on 109 languages through a translation ranking objective, which provides language-agnostic representations without requiring task-specific fine-tuning. We apply cosine similarity scoring between sentence embeddings, where pairs scoring below a 0.75 threshold are excluded from training data to preserve semantic integrity. In our setup, we employ LaBSE specifically for English-side filtering to ensure high-quality parallel data alignment.

- ***Length filtering*** is essential for machine translation to exclude excessively long sentences that may exceed model context limits or contain noisy data. This is implemented through a simple character count check (`150` words maximum per sentence) applied uniformly to both source and target texts.

[1] https://github.com/anoopkunchukuttan/indic_nlp_library

[2] https://docs.python.org/3/library/unicodedata.html

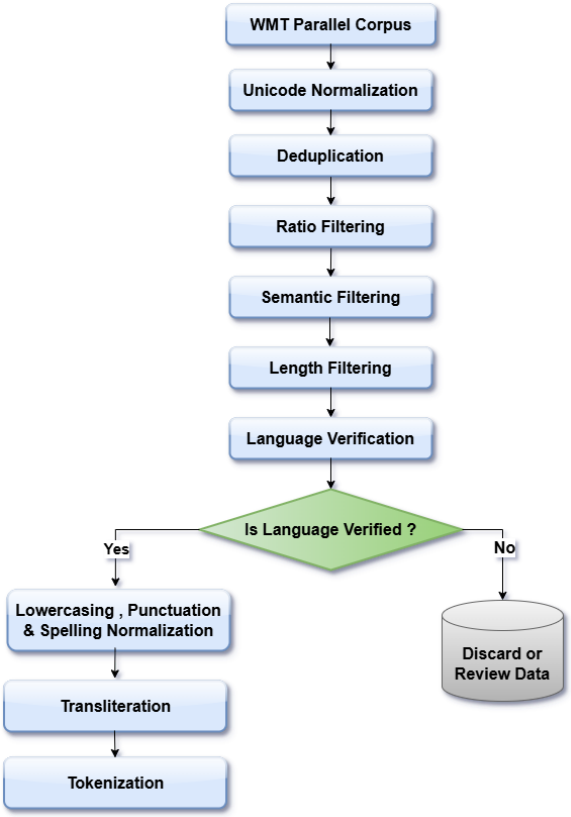

Figure 1: Workflow diagram of proposed data preprocessing pipeline.

- ***Language filtering***: To maintain high-quality, language-specific data for low-resource Indic machine translation, we employ FastText's pretrained language identification model (`ft_model`)(Joulin et al., 2017) to filter out noisy or mixed-language text. The sentences that are not confidently predicted as the target language are removed from the training corpus. Suspicious samples are retained for manual review to either: (1) salvage valuable translation pairs, or (2) analyze common noise patterns that could inform future data collection (Caswell et al., 2019).

- ***Text normalization***: We perform lowercasing, punctuation standardization, and spelling normalization (handling common orthographic variants) to reduce vocabulary sparsity. Aggressive noise removal eliminates HTML tags, non-linguistic symbols, and irregular whitespace, particularly crucial for noisy user-generated content in low-resource languages like Assamese.

- ***Transliteration*** is essential for handling named entities and rare words in low-resource Indic language machine translation. We implement a selective transliteration pipeline using `spaCy`[3] for tokenization and **N**amed **E**ntity **R**ecognition(NER), identifying words with frequency less than or equal to 2 or labeled as named entities. These words are transliterated from English to Indic scripts such as Assamese, Manipuri, and Mizo using the `IndicTransliteration` library[4], via the **H**arvard-**K**yoto (HK) scheme. This preserves phonetic structure and improves source-target alignment, enhancing overall translation quality.

- ***Tokenization*** splits text into subword units, crucial for handling morphologically rich Indic languages by addressing vocabulary sparsity and **O**ut-**o**f-**V**ocabulary (OOV) issues. For Assamese, Manipuri, and Mizo, we use Facebook's `NLLB-200-3.3B` tokenizer with a forced **B**eginning **O**f **S**equence (BOS) token for target language specification. For Bodo, we employ AI4Bharat's `Indictrans2` tokenizer, which supports multiple Indic languages via subword segmentation. Both tokenizers ensure compatibility with their respective Seq2Seq models by setting padding tokens dynamically.

4.2 Approach

This work utilizes the **WMT dataset** provided by the organizers. Consistent with established methodology for low-resource NMT, the data underwent preprocessing (detailed in Section 3) before model input to optimize translation quality for the target Indic languages. Given the focus on low-resource languages, specifically **Assamese, Manipuri, Mizo, and Bodo**, the model training pipeline is designed to leverage existing multilingual capabilities. In this study, two **s**tate-**o**f-**t**he-**a**rt (SOTA) open-source multilingual NMT models with pre-trained Indic language support are evaluated. Both models are subsequently fine-tuned on the preprocessed WMT dataset using LORA for parameter efficiency. Model selection is determined by comparative evaluation across standard automatic metrics: *BLEU*, *chrF*, *METEOR*, *ROUGE-L*, and *TER*.

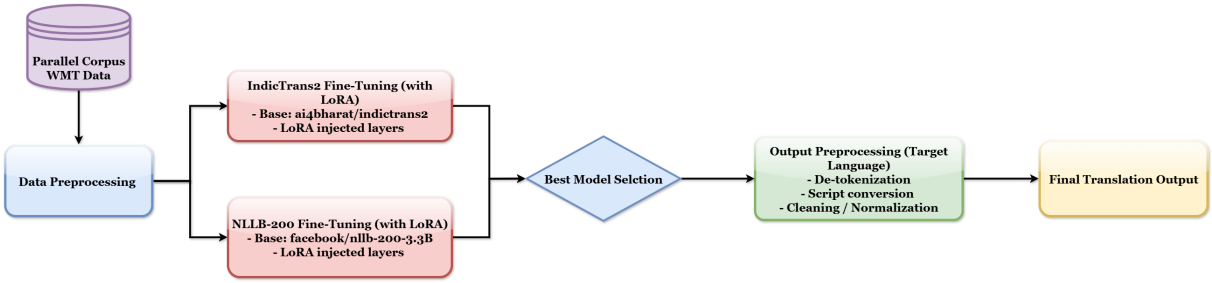

Figure 2: Bird's Eye View of the Proposed Approach

The NLLB-200 model, developed by Meta AI, is a 3.3 billion-parameter multilingual sequence-to-sequence transformer that supports translation across 200 languages, including many low-resource ones, achieving SOTA performance. To fine-tune this model efficiently while preserving its generalization capabilities, we employ **P**arameter-**E**fficient **F**ine-**T**uning (PEFT) as discussed by Xu et al. (2023) via LoRA. This approach avoids full-model fine-tuning by instead injecting trainable low-rank matrices into the transformer's attention layers, drastically reducing the number of trainable parameters while maintaining strong downstream task performance. The LoRA configuration is applied to the query, key, value, and output projection layers (`q_proj`, `k_proj`, `v_proj`, `o_proj`) of the NLLB-200 model. We set the rank (r) of the low-rank matrices to 64, with a scaling factor `lora_alpha` (α) of 128 to balance adaptation strength. A dropout rate of 0.1 is applied to the LoRA layers for regularization, and no additional bias terms are introduced. The model is then converted into a PEFT model, and all trainable parameters are logged before transferring the model to a CUDA-enabled 2× T4 Tesla GPU for accelerated training.

To handle variable-length sequences efficiently, we use a data collator specifically designed for sequence-to-sequence tasks. This collator dynamically pads input sequences to the longest length in each batch while ensuring padding aligns to multiples of 8 for optimal hardware utilization (Wolf et al., 2020). Label padding tokens (set to -100) are masked to exclude them from loss computation during training (Lewis et al., 2020). The training process leverages mixed-precision (FP16) arithmetic via the `Seq2SeqTrainer` from the Hugging Face Transformers library (Wolf et al., 2020). We employ a global batch size of 8, achieved through a per-device batch size of 4 and 2 gradient accumulation steps, balancing training stability (Micikevicius et al., 2018).

The optimization process uses AdamW with fused CUDA kernels (`adamw_torch_fused`), configured with momentum parameters $\beta_1 = 0.9$ and $\beta_2 = 0.98$ (Loshchilov and Hutter, 2019). The learning rate follows a cosine decay schedule, starting from 3×10^{-5} with 1000 warmup steps to ensure stable early training (Loshchilov and Hutter, 2016). Model checkpoints are saved at the end of each epoch, with the best model selected based on BLEU score (higher is better) (Papineni et al., 2002b). To improve evaluation efficiency, the trainer is configured to generate predictions during validation, enabling direct computation of translation metrics. To optimize memory efficiency, we disable caching (`model.config.use_cache = False`), enabling gradient checkpointing at the cost of modest recomputation (Chen et al., 2016). The complete training system integrates our LoRA-adapted NLLB-200 model with dynamic batching and automated evaluation, maintaining multilingual capabilities while specializing for target domains. This approach enables efficient adaptation of the $3.3B$-parameter model, particularly valuable for low-resource languages where data efficiency is critical (Team et al., 2022a). The implementation demonstrates practical fine-tuning of massive multilingual models within resource constraints, balancing computational feasibility with translation quality.

On the other hand, the IndicTrans2, another state-of-the-art multilingual NMT model developed by AI4Bharat, supports translation between English and all 22 Indian languages, as well as direct Indic-to-Indic translation across 462 language pairs. It is optimized for high accuracy, long-context translation with both large (1.1B) and distilled (211M) model variants. It is fine-tuned using the same PEFT-LoRA methodology applied to NLLB-200. Identical LoRA hyperparameters (rank $r = 64$, $\alpha = 128$) target the

Table 3: Evaluation metrics (BLEU, METEOR, ROUGE-L, chrF, and TER) for translation directions from English to four low-resource Indic languages for the evaluation dataset.

Language Pair	BLEU	METEOR	ROUGE-L	chrF	TER
en-as	17.5352	0.4223	0.0073	57.7459	71.1716
en-mni	4.1514	0.1554	0.0113	43.8669	93.1607

en-bodo	19.7083	0.4549	0.1694	62.4723	64.9709

Table 4: Evaluation scores (BLEU, METEOR, ROUGE-L, chrF, TER, and Cosine Similarity) for Indic-to-English translation directions for the evaluation dataset.

Language Pair	BLUE	METEOR	ROUGE-L	chrF	TER	Cosine Similarity
As-En	0.3715	0.0127	0.0224	14.2593	116.7097	0.0388
Mni-En	8.1004	0.4798	0.4947	49.5997	100.2915	0.7974
Lus-En	12.2975	0.5778	0.6198	58.1381	78.8102	0.8888

query/key/value projections and dense layers, with DORA enhancing adaptation stability. We retain the 8-bit quantization strategy and FP16 mixed-precision training, but reduce gradient accumulation steps to 2 (effective batch size 8) due to the model's smaller footprint. The cosine learning rate schedule (3×10^{-5} peak, 500 warmup steps) and AdamW fused optimizer ($\beta_1 = 0.9$, $\beta_2 = 0.98$) mirror the NLLB configuration, as does the BLEU-optimized checkpointing regime. Dynamic batching via `DataCollatorForSeq2Seq` maintains padding efficiency, while disabled caching ensures memory headroom on T4 GPUs. This consistent approach allows fair comparison between the two SOTA multilingual systems while respecting their architectural differences.

In our evaluation pipeline, we adopt a systematic approach to compute evaluation metrics for assessing the translation quality of the two models. Before evaluation, the model-generated text is preprocessed once more to enhance the reliability of metric computation for the target language. After obtaining predictions and corresponding reference labels, both sequences are decoded using the tokenizer, with special tokens skipped during decoding. To ensure compatibility with BLEU and other metrics and to correctly handle padding label tokens, marked as -100 are replaced with the tokenizer's padding token ID. A key component of our implementation is the use of the `indic_transliteration` library (Kunchukuttan, 2020b), which converts the predicted text into the appropriate target language script. This transliteration step is crucial because, in the case of the **IndicTrans**2 model, the outputs are internally generated in the Devanagari script. In contrast, the reference translations are provided in native Indic scripts. Without this conversion, evaluation metrics would be skewed due to script mismatches rather than actual translation errors. Following transliteration, the decoded sequences are post-processed by removing extraneous whitespace, and evaluation is carried out using HuggingFace's `evaluate` toolkit (Lhoest et al., 2021), which provides robust and script-aware translation metrics for Indic languages.

5 Results and Discussion

We evaluate the translation quality of the fine-tuned models using a suite of established automatic evaluation metrics, with results presented in Tables 3 and 4. These results offer key insights into the relative difficulty and success of translating between English and four underrepresented Indic languages (i.e., Assamese, Manipuri, Mizo, and Bodo) in both directions.

Table 3 reports the evaluation results for English-to-Indic translation across four low-resource languages: Assamese, Manipuri, Mizo, and Bodo. Among these, the English-to-Bodo direction achieves the highest scores across multiple metrics, BLEU (19.70), METEOR (0.4549), and chrF (62.47), indicating superior translation adequacy and fluency under the proposed approach. For final output generation, model selection was based on a comparative analysis of evaluation scores obtained

from IndicTrans2 and NLLB-200. The results show that NLLB-200 consistently outperforms IndicTrans2 for English-to-Assamese, Manipuri, and Mizo translations, whereas for the English-to-Bodo direction, IndicTrans2 demonstrates a clear advantage, yielding better translation quality.

Table 4 presents the evaluation metrics for translations from Indic languages to English. Among the language pairs, the Lus-En direction exhibits the strongest performance across nearly all metrics, BLEU (12.29), METEOR (0.5778), ROUGE-L (0.6198), chrF (58.13), and cosine similarity (0.8888), indicating high lexical and semantic alignment. In this translation direction, it was observed that the NLLB-200 model consistently outperforms IndicTrans2 for all three languages: Assamese, Manipuri, and Mizo.

6 Conclusion

This study presents a comprehensive investigation into improving machine translation quality for low-resource Indic languages through parameter-efficient fine-tuning of large multilingual models. Leveraging LoRA and DoRA techniques, we fine-tuned both the NLLB-200 and IndicTrans2 models on a curated and rigorously filtered WMT2025 dataset. Our extensive preprocessing pipeline, tailored to address the idiosyncrasies of Indic languages, proved essential in ensuring clean and semantically aligned parallel corpora. The empirical results underscore that while NLLB-200 exhibits superior performance across most language pairs and metrics, especially in English-to-Indic and Indic-to-English directions involving Assamese, Manipuri, and Mizo, IndicTrans2 offers competitive results and even outperforms NLLB-200 in the English-to-Bodo direction.

Notably, our integration of script-aware post-processing and selective transliteration was instrumental in achieving faithful metric evaluations, avoiding script mismatch penalties that would otherwise misrepresent model performance. These findings not only validate the efficacy of LoRA-based adaptation in low-resource settings but also highlight the value of task-specific linguistic preprocessing for Indic languages. Our comparative benchmarking, involving multiple metrics, reveals the nuanced translation difficulty across language pairs and emphasizes the importance of direction-aware evaluations in multilingual NMT research.

Limitations

The WMT 2025 corpora, while suitable for benchmarking, are inherently limited in scale and domain diversity for certain language pairs, particularly English–Bodo and English–Manipuri. This scarcity restricts the models' ability to generalize to informal, noisy, or domain-specific contexts.

Although the preprocessing pipeline is comprehensive, fixed thresholds in semantic filtering and transliteration heuristics may inadvertently remove valid rare sentences or alter named entities. Subtle linguistic phenomena such as dialectal variation and code-mixing remain insufficiently addressed.

Methodologically, the study is restricted to LoRA and DoRA-based fine-tuning of NLLB-200 and IndicTrans2. Although this approach ensures parameter-efficient adaptation, it does not investigate other model architectures or combined training strategies that may more effectively address unique linguistic characteristics. Similarly, the exclusive use of automatic metrics provides reproducible benchmarks but offers limited insight into true semantic quality or culturally appropriate translations.

Abstract

Bodo is a resource scarce, the indigenous language belongs to the Tibeto-Burman family. It is mainly spoken in the north-east region of India. It has both linguistic and cultural significance in the region. Only a limited number of resources and tools are available in this language. This paper presents a study of neural machine translation for the English-Bodo language pair. The system is developed on a relatively small parallel corpus provided by the Low-Resource Indic Language Translation as a part of WMT-2025 [1]. The system is evaluated by the WMT-2025 organizers with the evaluation matrices like BLUE, METEOR, ROUGE-L, chrF and TER. The result is not promising but it will help for the further improvement. The result is not encouraging, but it provides a foundation for further improvement.

1 Introduction

The Bodo language, which belongs to the Sino-Tibetan language family, is one of the widely spoken languages in Assam and several other parts of the North-Eastern states of India. It is used predominantly in the Bodoland Territorial Region (BTR), which includes the districts of Kokrajhar, Chirang, Baksa, and Udalguri, as well as in other districts such as Kamrup, Sonitpur, Lakhimpur, Nagaon, Morigaon, and Karbi Anglong. Bodo is one of the 22 languages listed in the Eighth Schedule of the Indian Constitution and is officially recognized by the Government of India (Census, 2011). According to the 2011 Census, it is spoken by more than a million people, primarily members of the Bodo community (Koyel Ghosh, 2023). The number of Bodo speakers is shown in the Figure 1. The Bodo language has rich linguistic features and uses the Devanagari script for writing, similar to Hindi. Having the tonal feature. Hence, effective techniques are not developed to capture all these features (Mwnthai Narzary, 2022).

Machine translation is a core application in the field of Natural Language Processing (NLP). With advancements in computational power, the focus has shifted from rule-based methods to machine learning and deep learning approaches. However, implementing deep learning techniques requires a large volume of data (Narzary Sanjib, 2019). In this paper, we have developed an English-Bodo machine translation system using a transformer-based neural machine translation approach. Preprocessing steps such as tokenization, subword extraction, and normalization are required before feeding the data into the actual Transformer model (Guillaume et al., 2017).

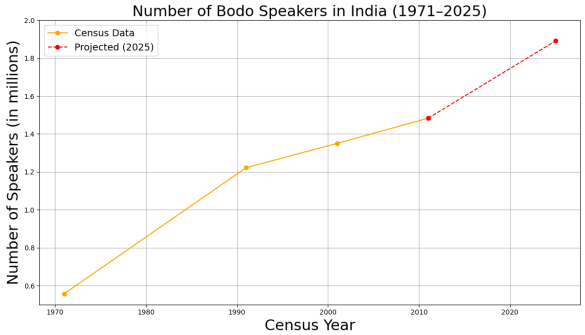

Figure 1: Number of Bodo speakers in India from 1971 to 2025 (projected).

2 Related Work

As mentioned above, Bodo is a low-resource language (Narzary et al., 2021), and development a machine translation system for it faced significant challenges due to the limited availability of parallel corpora and digital resources (Kalita et al., 2023). Most research efforts have focused on creating and expanding parallel corpora, as well as adapting machine translation techniques to function effectively

[1]https://www2.statmt.org/wmt25/indic-mt-task.html

Proceedings of the Tenth Conference on Machine Translation, pages 1210–1214
November 8-9, 2025

with scarce data. Although work in Bodo machine translation remains limited, there have been some notable efforts, particularly in building English-Bodo translation systems. A brief overview of these works is provided below.

Bahdanau et al. (Dzmitry Bahdanau, 2015) observed that traditional neural machine translation and statistical machine translation models have an alignment problem that affects the performance. The common encoder-decoder architecture, which uses an encoder to compress a source sentence into a single, fixed-length vector, faced a critical bottleneck: this fixed-length vector was often insufficient to capture all the information from a long sentence. To solve this, they proposed a new model that allows the decoder to automatically search for and focus on the most relevant parts of the source sentence when predicting each word of the translation. This mechanism, known as attention, significantly improved translation quality by overcoming the limitations of a single context vector. Verma et al. (Verma and Bhattacharyya, 2017) conducted a literature survey on Neural Machine Translation (NMT), highlighting the advantages of the NMT architecture. Vaswani et al. (Vaswani et al., 2017) proposed the attention-based Transformer model, which gained significant popularity in machine translation due to its novel architecture and promising performance. Parvez et al. (Parvez et al., 2023) attempted neural machine translation for the pair of low-resource languages of English and Bodo. They utilized a relatively small English-Bodo parallel corpus and implemented their system using the OpenNMT-py framework. Their model achieved a highest BLEU score of 11.01. Islam et al. (Islam and Purkayastha, 2019) worked on Bodo-to-English machine translation using a phrase-based statistical machine translation (PB-SMT) approach. They applied this technique to Bodo-English parallel corpora in both the general and news domains, reporting a highest BLEU score of 30.13. Narzary et al. (Narzary Sanjib, 2019) developed an attention-based English-Bodo neural machine translation system using data from the tourism domain. Their baseline model achieved a BLEU score of 11.8. By incorporating an attention mechanism, they improved the model's performance, reaching a BLEU score of 16.71. Talukdar et al. (Talukdar et al., 2023) focused on Assamese-Bodo neural machine translation and investigated the impact of data quality and quantity on translation performance. They iteratively augmented the dataset and evaluated the outcomes at each stage. The experiments were conducted using the OpenNMT-py framework. Gaikwad et al. (Gaikwad et al., 2024) suggested that the use of a high-resource language as a pivot can improve translation into related low-resource languages. They conducted experiments on machine translation of the English to Indian language - specifically translating English into Konkani, Manipuri, Sanskrit, and Bodo - employing Hindi, Marathi, and Bengali as pivot languages.

3 System Description

We have implemented the Attention-Based Neural Machine Translation (NMT) system. It is a deep learning model specifically designed for sequence-to-sequence tasks, such as translating text from one language to another. In traditional sequence-to-sequence models, the entire input sentence is encoded into a single, fixed-length vector that captures its relevant contexts. That single vector cannot effectively capture all the rich context of long or complex sentences. On the other hand, attention-based architecture allows the model dynamically to focus on relevant parts of the input sentence while generating each word in the output. The system typically consists of an encoder-decoder architecture along with an attention mechanism. The attention mechanism dynamically modifies the context vector for each output word. This allows the decoder to "attend" to different parts of the input sentence at each step. The basic encoder-decoder architecture, along with the attention mechanism, is depicted in Figure 2. The figure is configured for the English-Bodo translation, which is influenced by the Tato et al. (Tato and Nkambou, 2022) diagram.

The attention mechanism used in the decoder to decide which parts of the input sequence to focus on while generating an output. Calculating a context vector by taking a weighted sum of the encoder's hidden states. The weights for this sum are dynamically adjusted, giving more importance to the input words that are most relevant to the current output being generated. Based on this mechanism, the model can capture long-range dependencies and produce higher-quality translations. This is particularly effective for long or complex sentences or when translating between languages with different word orders.

In the attentional model (Dzmitry Bahdanau,

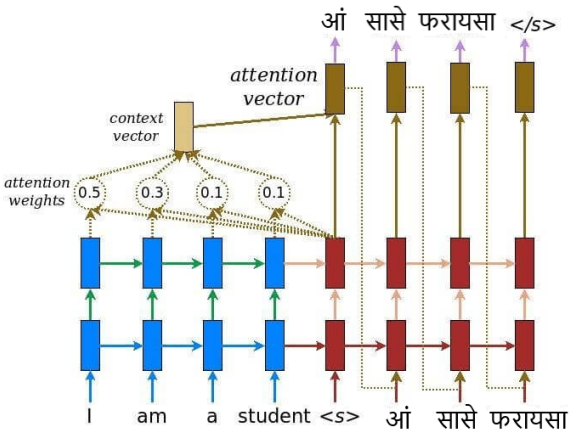

Figure 2: Example of attention mechanism in the translation from English to Bodo

2015), all hidden states h_i of the encoder are utilized to compute the context vector c_t. This model generates a variable-length alignment vector a_t, whose size corresponds to the number of time steps on the source side. The alignment vector is obtained by comparing the current hidden state h_i with each encoder hidden state $\bar{h_s}$. Where:

$$\alpha_{ts} = \frac{exp(score(h_t, \bar{h_s}))}{\sum_{s'} exp(score(h_t, \bar{h_{s'}}))} \quad (1)$$

$$c_t = \sum \alpha_{ts} \bar{h_s} \quad (2)$$

$$a_t = f(c_t.h_t) = tanh(W_c[c_t; h_t]) \quad (3)$$

$$a_t = f(c_t.h_t) = tanh(W_c[c_t; h_t]) \quad (4)$$

The $score(h_t, \bar{h_s})$ is calculated as

$$\begin{cases} {h_t}^T W \bar{h_s} & \text{[Luong]} \\ {v_a}^T tanh(W_1 h_t + W_2 h_s) & \text{[Bahdanau]} \end{cases}$$

Here, both the multiplicative and additive (Luong et al., 2015) (Dzmitry Bahdanau, 2015) attention mechanisms have normalized variants, known respectively as Scaled Luong and Normed Bahdanau (Raffel et al., 2017). The main idea behind the attention vector is to determine how much emphasis should be focused on each source word at a given time step. A higher value in the attention weight at indicates that the corresponding source word has a greater influence on predicting the next word in the output sentence. Particularly, the model the model performs translation based on the conditional probability $p(y|x)$, which represents the likelihood of translating a source sentence $x_1; ....; x_n$, into a target sentence $y_1; ....; y_m$. This is achieved using an encoder-decoder framework.

4 Dataset used

The data set we used in this work for the translation task is provided in the Very Limited Training Data setting of the WMT25 Indic Multilingual Machine Translation Shared Task [2], a snapshot of the data is shown in Figure 3 and Figure 4 respectively. Bodo is a low-resource language, and the availability of high-quality parallel corpora is significantly constrained. The official data set provided by the WMT25 organizers consists of a small number of English-to-Bodo sentence pairs curated for the purpose of benchmarking machine translation systems under low resource conditions. In the dataset, contains training, development, and test splits, with the training set including only a few thousand sentence pairs. These sentences span general purpose domains such as basic conversational language. The development set was used for validation and tuning, while the test set was reserved for blind evaluation by the task organizers.

We have also taken a parallel data set focused on tourism [3] augmented with WMT25 data for training purposes shown in Table 1. This data set contains English and Bodo corpus, which we trained and tested in a different model for the contrastive output element. The data set is divided into six subsets to facilitate training, validation, and testing for both languages involved in translation. Specifically, they have provided *train_brx, val_brx*, and *test_brx* contain Bodo sentences for training, validation, and testing respectively, while *train_eng, val_eng*, and *test_eng* contain the corresponding English sentences. Each Bodo sentence in a given split aligns with its English counterpart, enabling parallel corpus training for machine translation models.

5 Implementation

All model training and experimentation were conducted using Google Colab, a cloud-based development platform. We utilized the NVIDIA A100 GPU available through Google Colab for training our NMT model. The A100, based on NVIDIA's Ampere architecture, offers high memory bandwidth and massive parallel processing capabilities, making it a well suited for deep learning tasks. Its support for mixed precision training and large batch processing significantly accelerated model training and testing. The GPU enabled efficient handling of our encoder to decoder architecture with attention which allowed us to train and test on the English to Bodo dataset with reduced computation time and improved performance.

The model is developed and trained using PyTorch within a Google Colab environment. The data set is cleaned by removing null values and then shuffled to eliminate order bias. We load a test set provided as plain text files, ensuring that sentence alignment is preserved across the splits of training and validation sets. For preprocessing, we utilize a custom LanguageProcessor class that tokenizes the data and constructs a vocabulary with special tokens <PAD>, <SOS>, <EOS>, and <UNK>. It maps words to indices and vice versa and computes the maximum sentence length for padding.

We configured a sequence-to-sequence encoder-decoder model with attention using carefully selected hyperparameters to ensure efficient training and optimal performance. The embedding dimension for both the encoder and decoder was set to 256, while the hidden state dimensions were set to 512 units. The dropout regularization was applied with a rate of 0.5 in both the encoder and decoder. Training was conducted using a batch size of 64 over 15 epochs.

6 Result

The system is evaluated by the WMT25 organiser, which provided a test dataset of 1,000 sentences. A total of nine runs were assessed for the task. Five evaluation metrics were used: BLEU, METEOR, ROUGE-L, chrF, and TER[4]. The result of our system is shown on Table 2. For comparison, the highest and lowest scores for the track are presented in Table 3 and Table 4, respectively.

Sl. No.	Metric	Score
1	BLEU	0.3106045292
2	METEOR	0.01875594452
3	ROUGE-L	0.002595238095
4	chrF	7.235394682
5	TER	808.9101286

Table 2: Result of the system (en-bodo)

Sl. No.	Metric	Score
1	BLEU	24.44868688
2	METEOR	0.5126346512
3	ROUGE-L	0.1684904762
4	chrF	67.70727358
5	TER	51.84296487

Table 3: Highest score of the track (en-bodo)

Sl. No.	Metric	Score
1	BLEU	0.2047914219
2	METEOR	0.006037416908
3	ROUGE-L	0.02716098904
4	chrF	0.8138721309
5	TER	131.9585726

Table 4: Lowest score of the track (en-bodo)

7 Conclusion

It is observed that your result (Table 2) is not much surprising. While the score is higher than the lowest score (Table 4), it is still lower compared to the highest (Table 3). To investigate its weaknesses, a granular-level error analysis is needed. At a glance, we found that the system performs poorly on complex sentences compared to simple ones. The data

[4]https://www2.statmt.org/wmt25/mteval-subtask.html

provided by the track, along with the various systems presented here, will be valuable for future research.

Limitations

The training dataset is insufficient for developing a sophisticated machine translation system.

Tackling Low-Resource NMT with Instruction-Tuned LLaMA: A Study on Kokborok and Bodo

Deepak Kumar, Kshetrimayum Boynao Singh, Asif Ekbal
Indian Institute of Technology, Patna
{deepakkumar1538, boynfrancis, asif.ekbal}@gmail.com

Abstract

This paper presents a new neural machine translation (NMT) system aimed at low-resource language pairs: English to Kokborok and English to Bodo. The framework leverages the LLaMA3-8B-Instruct model along with LoRA-based parameter-efficient fine-tuning. For translating into Kokborok, the model undergoes an initial continued pre-training phase on a dataset containing 75,000 Kokborok and 25,000 English monolingual sentences, followed by instruction-tuning. This tuning uses a reformulated version of WMT25 dataset, adapted to the Alpaca format to support instructional goals. In the Bodo translation, the model is pre-trained on a more extensive dataset of 350,000 Bodo and 125,000 English sentences, using a similar instruction-tuning approach. LoRA adapters are used to modify the large LLaMA3 model for these low-resource settings. Testing with the WMT25 test dataset reveals modest translation results, highlighting the difficulties in translating for low-resource languages. Translating English to Bodo, the model achieved a BLEU score of 4.38, a TER of 92.5, and a chrF score of 35.4. For English to Kokborok, it yielded scores of 5.59 in chrF, 105.4 in TER, and 0.17 in BLEU. These results underscore the intricacies of the task and highlight the critical need for further data collection, domain-specific adaptations, and improvements in model design to better support underrepresented languages.

1 Introduction

Despite significant advancements in neural machine translation (NMT) and the instruction-tuning of large language models (LLMs), the predominant focus of research and datasets remains on English and high-resource languages. Instruction-tuning, a potent method to align LLMs with human preferences, has demonstrated efficacy primarily in contexts where English data are plentiful. Conversely, low-resource languages frequently experience a dearth of robust foundational models due to the scarcity of both monolingual and parallel corpora. In mitigating this limitation, recent studies investigate cross-lingual instruction-tuning by integrating translation-following demonstrations, which enable English-centric LLMs to generalize to novel languages. Currently, evidence suggests that zero-shot cross-lingual transfer is achievable when instruction-tuning is meticulously calibrated, even in scenarios where only English instructions are employed, although factuality and fluency may be compromised in the target language.

More comprehensively, multistage architectures, such as LinguaLIFT, further exemplify how code-switched translation data and task alignment can enhance reasoning in low-resource environments without dependence on extensive multilingual corpora. In light of these insights, this paper introduces an innovative NMT framework targeting pairs of English to Kokborok and English to Bodo language, utilizing the LLaMA3-8B-Instruct model, fine-tuned with LoRA-based adapters for efficient parameter adaptation. The model is initially pre-trained on monolingual corpora of 75,000 Kokborok and 25,000 English sentences for Kokborok and 350,000 Bodo and 125,000 English sentences for Bodo, subsequently undergoing instruction-tuning on WMT25-supplied English–target language parallel data reformatted into an Alpaca style structure. This process aligns translation objectives with instruction follow-up behaviors within the LLM.

Evaluation in WMT25 test sets reveals modest yet meaningful translation performance: for English to Bodo, BLEU = 4.37, TER = 92.5, and chrF = 35.4; for English to Kokborok, chrF = 5.59, TER = 105.4, and BLEU = 0.17. These findings highlight the considerable challenges inherent in low-resource machine translation and emphasize the crucial need for persistent data collection, domain adaptation, and alignment strategies.

Proceedings of the Tenth Conference on Machine Translation, pages 1215–1221

Our key contributions are:

- We present a **LoRA-adapted fine-tuning methodology** to enhance English centric, instruction-following models (LLaMA) for translation tasks in low-resource languages such as Kokborok and Bodo.
- We propose a **sequential pipeline** combining monolingual *pre-training* followed by *instruction-tuning*, aimed at strengthening language representations for underrepresented Indian languages.
- We conduct an **empirical evaluation** that highlights both the limitations and capabilities of instruction-tuned LLaMA models in extremely low-resource translation scenarios.
- We issue a **call for future work** aiming at the expansion of high-quality instruction-tuning datasets, domain adaptation techniques, and architecture-level innovations to support the broader inclusion of under-resourced languages in LLM pipelines.

2 Linguistic Background

In this study, we focus on two low-resource Indian languages, Bodo and Kokborok, both belonging to the Tibeto-Burman branch of the Sino-Tibetan language family. These languages are spoken primarily in the northeastern region of India and share several linguistic characteristics such as tonality, agglutinative morphology, and subject object verb (SOV) word order. Despite their socio-cultural and political significance, both languages remain significantly underrepresented in NLP research and lack sufficient digital resources for computational modeling.

2.1 Bodo Language

Bodo[1], also spelled Boro, is a low-resource language spoken predominantly in the Bodoland Territorial Region of Assam, India. According to the 2011 Indian Census, it has more than 1.4 million speakers and is officially recognized as one of the 22 scheduled languages of India. Bodo serves as a medium of instruction in schools throughout the region and has official status in the local administration. The language has historically used Latin and Bengali scripts, but now primarily uses Devanagari. Linguistically, Bodo follows an order of words SOV and exhibits features such as tonality, agglutination, and rich verbal morphology, including case marking and verb inflections. Despite its cultural significance, Bodo lacks substantial computational resources, making it an important target for low-resource NLP, particularly in areas such as neural machine translation (MT), language modeling, and morphological analysis. Its inclusion in multilingual NLP initiatives contributes both to linguistic inclusivity and to technological equity.

2.2 Kokborok Language

Kokborok[2], also known as Tripuri, is another Tibeto-Burman language of the Sino-Tibetan family, spoken mainly in the state of Tripura and parts of Bangladesh. It is the mother tongue of the Tripuri people and one of the most spoken dialects among the various linguistic varieties of the Tripuri. According to the 2011 Census, it has more than 1 million speakers. Kokborok lacks a standardized orthography; however, the Roman script is increasingly used in digital communication and education, along with some continued use of Bengali and Devanagari scripts based on socio-political and institutional preferences. Like Bodo, Kokborok follows an SOV syntactic structure, is tonal, and agglutinative, with a complex system of verbal inflection and case marking. Despite its status as one of the official languages of Tripura, Kokborok is largely lacking digital resources, with very limited availability of annotated corpora, linguistic tools, or parallel datasets. This presents significant challenges for NLP system development, but also offers an opportunity to explore transfer learning, few-shot adaptation, and cross-lingual methods in the context of extremely low-resource settings.

3 Related Work

3.1 Low-Resource MT for Indic Languages

The domain of low-resource neural machine translation (NMT) has been extensively studied with respect to underrepresented Indic languages through the use of a variety of methodologies (Kakwani et al., 2020). In this context, English to Bodo translation systems constructed using approximately 92K parallel corpus sentences with Transformer-based architectures, thereby achieving BLEU scores reaching 11.01.(Boruah et al.,

[1] https://en.wikipedia.org/wiki/Boro_language_(India)

[2] https://en.wikipedia.org/wiki/Kokborok

2023). Similar efforts for languages such as Manipuri (Singh et al., 2023b, 2024), Assamese, Mizo, and Khasi have employed techniques such as transfer learning (Singh et al., 2023a) and tokenization of sub-words to address challenges associated with data sparsity.

3.2 Pre-training and Instruction-Tuning of LLMs

The adaptation of large language models (LLMs) for resource-constrained languages, achieved (Gao et al., 2024) via continued monolingual pre-training (Sennrich et al., 2016) followed by instruction-tuning, has shown favorable results. Specifically, presents an Estonian instruction follow-up LLM derived from LLaMA-2, showcasing that the integration of constrained monolingual pre-training with cross-lingual instruction-tuning considerably improves performance on Estonian tasks. Furthermore, they have introduced Alpaca-est, which represents the first general-task instruction dataset for the Estonian language.

3.3 Cross-Lingual Instruction-Tuning

Cross-lingual instruction-tuning where instructions and translation tasks appear in both English and the target language has been proposed as a cost efficient adaptation method for English centric LLMs (Gao et al., 2024). Such tuning is often implemented in Alpaca style formats to align translation and general task objectives. The inclusion of translation-style instructions during tuning has been empirically shown to boost performance in target languages, especially when paired with monolingual pre-training.

3.4 Parameter Efficient Fine-Tuning (PEFT)

Parameter efficient fine-tuning techniques like LoRA have become increasingly popular for adapting massive LLMs (Hu et al., 2021) to new tasks and languages under compute constraints. PEFT methods enable efficient adaptation without needing to update all model weights, making them especially appealing for low-resource settings.

3.5 Data Augmentation and Synthetic Parallel Corpora

Data augmentation methods especially back-translation remain vital for enhancing low-resource MT performance. These methods generate synthetic parallel data from monolingual corpora (Raja and Vats, 2025), though the quality depends heavily on the strength of the reverse translation model. Controlled generation techniques (e.g., using target sentence length tokens) have also been explored to manage translation output fidelity.

3.6 Evaluation Metrics and Limitations in Low-Resource MT

Evaluation for low-resource MT frequently relies on automatic metrics such as BLEU (Papineni et al., 2002), chrF (Popović, 2017), and TER (Snover et al., 2006). While COMET (Rei et al., 2020), a neural based metric, often correlates better with human judgments, its availability remains limited for languages like Bodo and Kokborok. Human evaluation is crucial to assess fluency and adequacy, particularly for morphologically complex languages.

3.7 Gap and Our Contribution

In the domain of low-resource Indic machine translation (MT), despite developments in parameter efficient fine-tuning (PEFT) techniques, instructional tuning frameworks, and data augmentation methodologies, the translation of Kokborok and Bodo employing instruction following large language models (LLMs) such as LLaMA3 with LoRA adapters remains unexplored. This investigation integrates monolingual pre-training for Bodo and Kokborok with Alpaca style instruction-tuning and LoRA fine-tuning. The study evaluates the performance of the constructed models using the WMT25 (Pakray et al., 2025, 2024; Pal et al., 2023; Kakum et al., 2023) English to Bodo and English to Kokborok datasets and notes limited BLEU (≈ 0.17 for Kokborok), chrF, and TER scores. These results highlight the considerable challenges that persist and stress the necessity for ongoing research specific to these languages.

4 Dataset Preparation

For this study, we collected a substantial amount of monolingual data in Bodo, Kokborok, and English. The dataset comprises approximately 350,000 sentences in Bodo, 75,000 sentences in Kokborok, and 450,000 sentences in English. All data was legally compliant for research use.

For pre-training, we constructed two datasets, one for English to Bodo and another for English to Kokborok, by mixing monolingual data in the following ratios:

- **English to Bodo:** 75% Bodo, 25% English

- **English to Kokborok:** 70% Kokborok, 30% English

These specific ratios were chosen to ensure that the base model becomes more familiar with Bodo or Kokborok while preserving sufficient English fluency to prevent catastrophic forgetting.

We also prepared an instruction-tuning dataset in Alpaca format. We collected WMT25 [3] parallel training data for English to Bodo and English to Kokborok and converted it into Alpaca style instruction response pairs. To enhance the robustness of the model, we maintained a variety of instruction types so that the model learned to follow multiple instruction formats. Finally, we trained two LoRA-adapted LLaMA models using these instruction-tuned datasets for English→Bodo and English→Kokborok translation.

Stage	Language Pair	Sentences
Pre-training	English (eng)	450,000
	Bodo (bodo)	350,000
	Kokborok (trp)	75,000
Fine-tuning	English to Bodo	15,215
	English to Kokborok	2,269
Testing	English to Bodo	1,000
	English to Kokborok	1,000

Table 1: Dataset statistics used for pre-training, fine-tuning, and testing. All monolingual datasets are open-source and licensed under CC BY 4.0. Fine-tuning and testing datasets were converted into instruction response format following Alpaca style instruction-tuning.

5 Methodology

5.1 Monolingual pre-training

We first continued pre-training the LLaMA3-8B-Instruct model on a mixed monolingual corpus for each target language. For English to Kokborok, we use a mix of 75,000 Kokborok sentences 75% and 25,000 English sentences 25% and for English to Bodo, 350,000 Bodo sentences and 125,000 English sentences 75%–25%. These data sets are concatenated and shuffled to increase exposure to the target language while retaining English fluency and minimizing catastrophic forgetting.

Pre-training is conducted using the standard autoregressive language modeling objective, with next token prediction as the training objective. This stage helps the model internalize the vocabulary, grammar, and patterns of the low-resource language before instruction-tuning. As demonstrated in earlier studies (Kuulmets et al., 2024), this step significantly boosts translation performance in low-resource settings.

Following monolingual adaptation, we perform instruction fine-tuning using the WMT25 parallel corpora, consisting of 15,215 sentence pairs for English to Bodo and 2,269 pairs for English to Kokborok. Each sentence pair is reformatted into an Alpaca style instruction response format:

> **Instruction:** Translate the following sentence into [Target Language].
> **Input:** [English Sentence]
> **Output:** [Reference Translation]

This prompt format aligns with the instruction following capabilities of LLaMA-style models and encourages better alignment between English inputs and target-language outputs. No auxiliary tasks or instructions (e.g., summarization or question answering) are included; the dataset is entirely translation-focused.

5.2 LoRA Fine-Tuning

To efficiently adapt the large model to these instruction-tuned datasets, we use Low-Rank Adaptation LoRA (Hu et al., 2021). LoRA adapters are injected into each transformer layer of the model, enabling parameter-efficient fine-tuning. Only low-rank update matrices are trained, while the original model weights remain frozen.

This significantly reduces computational cost and memory usage while maintaining high translation quality. The training objective is the standard cross-entropy loss between predicted tokens and the reference translation, without any post-processing or auxiliary losses.

5.3 Experimental Infrastructure

All pre-training and fine-tuning experiments were conducted on NVIDIA A100 80 GB PCIe GPUs, deployed in a dual-GPU configuration. Each GPU offers up to 80 GB of HBM2e memory with a maximum memory bandwidth of approximately 1.9 - 2.0 TB, enabling rapid data movement, essential for training large-scale models.

This powerful GPU setup provides the computational and memory resources necessary to efficiently pretrain and finetune large language models for low-resource machine translation scenarios.

Direction	Setting	BLEU (↑)	METEOR (↑)	ROUGE-L (↑)	chrF (↑)	TER (↓)
en-bodo	Zero-Shot	0.2	0.0060	0.0117	0.7	113.5
	Few-Shot	0.4	0.0098	**0.0201**	0.9	130.5
	Proposed	**4.38**	**0.1318**	0.0090	**35.50**	**92.56**
en-trp	Zero-Shot	0.0	0.0011	0.0023	10.2	155.1
	Few-Shot	0.1	**0.0090**	0.0087	**18.0**	158.9
	Proposed	**0.18**	0.0063	**0.0153**	5.60	**105.49**

Table 2: Comparison of Zero-Shot, Few-Shot, and Proposed Architecture Results. Bold indicates best performance per metric.

The English → Kokborok and English → Bodo experiments were trained for 10 epochs with small batch sizes, a fine-tuning learning rate of 1.5e-5, and regularization through weight decay and warmup. A cosine restart scheduler and gradient clipping ensured stable optimization, while bf16 precision improved speed and memory efficiency, making the setup well-suited for low-resource translation tasks.

6 Results and Analysis

We compare our proposed architecture against zero-shot and few-shot prompting baselines, where the few-shot setup uses the limited bilingual examples from the WMT 2025 shared task as in-context demonstrations. Table 2 reports results across BLEU, METEOR, ROUGE-L, chrF, and TER for English→Bodo (en-bodo) and English→Kokborok (en-trp).

For en-bodo, the proposed model achieves a BLEU score of 4.38, over 10× higher than both zero-shot (0.2) and few-shot (0.4). METEOR similarly improves to 0.1318, compared to 0.0060 and 0.0098. While ROUGE-L (0.0090) trails the few-shot baseline (0.0201), chrF rises sharply to 35.50, far above prompting (0.7/0.9), and TER drops to 92.56, indicating far fewer edits than either baseline. These gains show that our architecture captures structure and meaning beyond what prompting alone enables.

For en-trp, improvements are more modest but still consistent. The model reaches a BLEU of 0.18 (vs. 0.0/0.1) and ROUGE-L of 0.0153 (vs. 0.0087). TER improves markedly to 105.49, compared to 155.1 and 158.9. METEOR (0.0063) is slightly below few-shot (0.0090), and chrF (5.60) remains low, reflecting severe data sparsity and script mismatches.

Overall, our architecture substantially outperforms zero-shot and few-shot prompting across most metrics. Gains are especially pronounced for Bodo, while Kokborok results highlight the extreme difficulty of this language pair but still show measurable progress over prompting-only baselines.

7 Conclusion

Existing literature supports the efficacy of curriculum based training, monolingual continued pre-training, and Parameter Efficient Fine-Tuning (PEFT) techniques for neural machine translation in low-resource settings. Furthermore, preceding investigations have illustrated the advantages of instruction-following fine-tuning for enhancing cross-lingual generalization. Nonetheless, certain gaps persist. Specifically, there has been no research concentrating on the translation of Kokborok and Bodo through the application of instruction-following LLMs, such as LLaMA3-Instruct. Additionally, there has been no exploration of monolingual continued pre-training followed by Alpaca-style instruction-tuning facilitated by Low-Rank Adaptation (LoRA).

Our research endeavors to bridge these gaps through the following approaches: Leveraging monolingual corpora in Kokborok and English to pre-train LLaMA3-8B prior to instruction-tuning. Implementing LoRA-based adapters to tailor the model for translation from English to Kokborok and English to Bodo. Conducting evaluations using WMT25 parallel datasets to establish foundational metrics, such as a BLEU score of 0.17 for Kokborok. Moreover, we underscore the existing methods' limitations and accentuate the necessity for further research in data augmentation and domain specific or architectural adaptation.

Limitations

The proposed (WMT25-INDIC-MT$_{\text{proposed}}$) model demonstrates notable improvements for English →

Bodo translation, particularly with a BLEU score of 4.38 and a significant reduction in TER, its performance on English → Kokborok remains limited, with BLEU scores reaching only 0.18. This highlights the strong dependency of model performance on the size and quality of available corpora, as Kokborok suffers from a much more severe data sparsity compared to Bodo. Furthermore, although gains are observed across most metrics, certain inconsistencies persist; for example, the METEOR score for English → Kokborok in the proposed setup is lower than in the few-shot setting. These results underline that while instruction-tuned LLMs with LoRA-based fine-tuning are promising, their effectiveness remains constrained by low-resource conditions, limited evaluation coverage, and reliance on automatic metrics, which may not fully capture translation quality in morphologically rich languages.

DELAB-IIITM WMT25: Enhancing Low-Resource Machine Translation for Manipuri and Assamese

Dingku Singh Oinam and Navanath Saharia
India Institute of Information Technology, Manipur
dingkuoinam@ieee.org

Abstract

This paper describes DELAB-IIITM's submission system for the WMT25 machine translation shared task. We participated in two subtasks of the Indic Translation Task, en↔as and en↔mn i.e., Assamese (Indo-Aryan language) and Manipuri (Tibeto-Burman language) with a total of six translation directions, including mn→en, mn←en, en→as, en←as, mn→as, mn←as. Our fine-tuning process aims to leverage the pretrained multilingual NLLB-200-Distilled-600M model, a machine translation model developed by Meta AI as part of the No Language Left Behind (NLLB) project, through two main developments: Synthetic parallel corpus creation and Strategic Fine-tuning. The Fine-tuning process involves strict data cleaning protocols, Adafactor optimizer with low learning rate (2e-5), 2 training epochs, train-test data splits to prevent overfitting, and Seq2SeqTrainer framework. The official test data was used to generate the target language with our fine-tuned model. Experimental results show that our method improves the BLEU scores for translation of these two language pairs. These findings confirm that back-translation remains challenging, largely due to morphological complexity and limited data availability.

1 Introduction

Meiteilon (Manipuri) is a Tibeto-Burman language spoken primarily in Manipur, while Assamese is an Indo-Aryan language spoken mainly in Assam. Both Manipuri and Assamese are recognized as official languages of India. There is a severe lack of parallel corpora and standardized digital resources. The data scarcity hinders the development of robust neural machine translation (NMT) models, as they typically require large-scale bilingual datasets for training (Sennrich and Zhang, 2019). The morphological complexity and syntactic diversity of Tibeto-Burman languages such as Meiteilon pose major challenges for MT systems, especially within low-resource scenarios (Singh and Singh, 2022b). The neglect of low-resource languages in machine translation is exacerbated by the overwhelming focus on high-resource languages, but this problem can be mitigated through transfer learning from massively multilingual pre-trained models such as mBERT (Conneau et al., 2020) and NLLB (Team et al., 2022). For such languages, MT systems risk perpetuating datasets and language-specific architectures (Joshi et al., 2021). Despite the challenges, researchers are actively working on improving MT for low-resource languages such as Manipuri and Assamese through various techniques like transfer learning, multilingual models, and back-translation (Singh and Singh, 2022b; Wei et al., 2023; Singh and Singh, 2022a). Recent WMT Shared Tasks on Low-Resource Indic Languages Translation have been significantly advancing in the field (Pal et al., 2023; Pakray et al., 2024, 2025).

This paper describes the fine-tuning of a pretrained multilingual NLLB-200-Distilled-600M model for translating Manipuri to English, English to Assamese, Manipuri to Assamese and back-translation. Back-translation, here, refers to the translation in which the translation direction is opposite to which the model is trained to perform the translation task.

The layout of the subsequent paper is as follows. Section 2 highlights some of the related works. Section 3 describes the implementation of the proposed translation systems. Finally, the conclusion and future work is drawn in Section 4.

2 Related Works

Transformer-based models have formed the backbone of many modern machine translation systems for low-resource Indic languages (Pal et al., 2023). These architectures, often enhanced with monolingual pre-training, language-specific fine-

Proceedings of the Tenth Conference on Machine Translation, pages 1222–1226
November 8-9, 2025

tuning, and inference-time strategies like kNN-MT, have demonstrated notable improvements in translation quality. For instance, (Ju et al., 2024) observed that such enhancements consistently improved BLEU scores, reinforcing the value of augmenting training with back-translation and model averaging techniques. mBART (Chipman et al., 2022) and mBART-large-50 (Tang et al., 2020) are used in multilingual setups, where fine-tuning on filtered corpora, using semantic tools like LaBSE (Feng et al., 2020) embeddings, showed limited gains due to poor back-translation quality and the morphological complexity of the target languages (M et al., 2024). IndicBART (Dabre et al., 2021) is a pre-trained BART model for Indic languages, specifically trained for Assamese, Bengali, Gujarati, Hindi, Marathi, Odia, Punjabi, Kannada, Malayalam, Tamil, Telugu and English. Recently transformer-based models specialized for machine translation of Indic languages like IndicTrans (Ramesh et al., 2022) and IndicTrans2 (Gala et al., 2023) are available, which are trained on largest available Indic language parallel corpora namely Samanantar and BPCC respectively. IndicTrans model was trained for 11 Indic languages whereas IndicTrans2 was trained for all the 22 scheduled Indian languages. NLLB (Costa-jussa et al., 2022), a massively multilingual machine translation model has proven to be a breakthrough in the high-quality translation of around 200 languages across the world. MuRIL (Multilingual Representations for Indian Languages) (Khanuja et al., 2021), is a multilingual Language Model specifically built for Indic languages supporting around 17 languages. MuRIL outperforms multilingual BERT on all NLP tasks.

Recent advances in low-resource machine translation for Indic languages were explored in the WMT 2024 shared task (Pakray et al., 2024).

3 Method

We participate in two sub-tasks en↔as and en↔mn with a total of six translation directions, including mn→en, mn←en, en→as, en←as, mn→as, mn←as. We generate synthetic parallel data using the pretrained model NLLB-200-Distilled-600M. The proposed technique includes data preparation, pre-training, fine-tuning, and model evaluation to develop the machine translation systems.

3.1 Data Preparation

We used mn↔en (23,688 sentences), en↔as (54,000 sentences) parallel data provided by WMT25 (Kakum et al., 2023; Pakray et al., 2024; Pal et al., 2023). Since the organizers did not provide bilingual parallel data for mn↔as, we generate synthetic parallel data by translating to the target-language using the pretrained model NLLB-200-Distilled-600M. Specifically, we used the Manipuri (mn) side from the bilingual data (mn↔en) and Assamese (as) side from the bilingual data (en↔as) to generate target language data i.e., Assamese (as) and Manipuri (mn) respectively. Both the synthetic parallel data is then combined to get a total of 77,688 sentences. After removing empty sentences, we finally have 77,571 sentences.

For the translation directions that include English, we used English side from both mn↔en, en↔as parallel data provided by WMT25 to generate the target language data i.e., as and mn respectively. Combining the synthetic parallel data we get 77,688 sentences and after removing empty sentences, we have 77,681 sentences.

Language Pair	Sentences
mn↔as	77,581
mn↔en	77,681
en↔as	77,681

Table 1: No. of sentences for each language pair

Lang.	Token	Unique Token	Avg. word length
mn	1,614,626	93,910	5.70
en	1,272,380	46,404	4.66
as	1,131,164	85,098	5.10

Table 2: Token statistics for each language corpus

3.2 Pre-training

Starting with NLLB-200-Distilled-600M, a pretrained multilingual model as the base architecture. We perform additional training with the synthetic data, adapting the model's parameters to each specific language pair.

3.3 Fine-Tuning

The AutoTokenizer from the NLLB-200-Distilled-600M model was used to tokenize the inputs. We took the training data and fine-tuned it on NLLB-200-Distilled-600M for the translation settings from Manipuri to Assamese, Manipuri to English

and English to Assamese. To train (fine-tune) the NLLB-200-Distilled-600M model, 2 epochs with a learning rate of 2e-5 is set. The 2 epochs will help the model to pass through the entire training dataset 2 times and the learning rate (2e-5) is used to specialize the translation and retain its general knowledge. Using the same training parameters, we trained three fine-tuned models: Manipuri-English, English-Assamese, and Manipuri-Assamese model.

3.4 Model Evaluation

BLEU (Papineni et al., 2002) has been a standard and widely used metric for evaluating translation quality and ChrF (Popović, 2015) represents a promising metric for automatic evaluation of machine translation output. Table 3 shows the evaluation scores of our fine-tuned model while Table 4 shows the evaluation scores of the base NLLB-200-Distilled-600M model. The comparison shows that the fine-tuned model achieves better results than the base model in certain metrics.

		mn-as	mn-en	en-as
Translation	BLEU	45.6	70.3	54.1
	ChrF	37.4	3.1	76.1
Back-Translation	BLEU	41.1	8.0	27.1
	ChrF	29.0	3.1	55.0

Table 3: Evaluation scores for the Fine-tuned model

		mn-as	mn-en	en-as
Translation	BLEU	10.0	23.0	40.0
	ChrF	45.0	55.0	74.0
Back-Translation	BLEU	5.0	8.0	28.0
	ChrF	35.0	43.0	58.0

Table 4: Evaluation scores for the base NLLB-200-Distilled-600M model

Metric	mn→en	en→as
BLEU	7.346	16.105
METEOR	0.463	0.406
ROUGE-L	0.479	0.003
ChrF	48.783	55.702
TER	103.197	68.324

Table 5: WMT25 evaluation scores for normal translation direction

Table 5 and 6 give the WMT25 evaluation scores using the fine-tuned model for the translation and back-translation respectively, as released by the organizers.

Metric	mn←en	en←as
BLEU	3.151	15.020
METEOR	0.113	0.603
ROUGE-L	0.008	0.605
ChrF	37.512	59.374
TER	132.054	75.247

Table 6: WMT25 evaluation scores for back-translation direction

3.5 Model Output

We use the three fine-tuned models (Manipuri-English, English-Assamese, and Manipuri-Assamese) to perform translation and back-translation testing. The following results are observed.

Figure 1: Translation mn→en

Figure 2: Translation en→as

Figure 3: Back Translation en→mn

Figure 4: Back Translation as→en

Figure 5: Translation mn→as

Figure 6: Back Translation as→mn

From the observation, Figure 1, 2, and 5 show that the fine-tuned model works well for translation. Similarly, Figure 3, 4, and 6 show test results for back-translations using the three fine-tuned models.

4 Conclusion and Future Work

In this paper, we describe low-resource Indic language translation shared task. We participated in two sub-tasks with a total of six translation directions. Experimental results show that our method improves over the base pretrained model. The fine-tuned model (mn-en, en-as) achieved BLEU (7.346) in mn→en while BLEU (16.105) is achieved in en→as. But for back translation (en→mn, en→as), the model achieved BLEU (3.151) and BLEU (15.020) respectively. From the Model Output Section, we can see how the model performs. Our experiment confirms that back translation for low resource languages still remains challenging due to the morphological complexity and data scarcity.

In future, we can explore semantic filtering techniques and ensemble NLLB with other pre-trained models.

Abstract

This paper describes our submission to the WMT 2025[1] (Pakray et al, 2025) Shared Task on Low-Resource Machine Translation for Indic languages. This task is an extension of the efforts which was originally initiated in WMT 2023[2] (Pal et al., 2023), and further continued to WMT 2024 [3] (Pakray et al, 2024), received significant participation from the global community. We address English ↔ {Assamese, Bodo, Manipuri} translation, leveraging Hindi and Bengali as high-resource bridge languages. Our approach employs Transformer-based Neural Machine Translation (NMT) models, initialized through multilingual pre-training on high-resource Indic languages, followed by fine-tuning on limited parallel data for the target low-resource languages. The pre-training stage provides a strong multilingual representation space, while fine-tuning enables adaptation to specific linguistic characteristics of the target languages. We also apply consistent preprocessing, including tokenization, true casing, and subword segmentation (Sennrich et al., 2016) with Byte-Pair Encoding (BPE), to handle the morphological complexity of Indic languages. Evaluation on the shared task test sets demonstrates that pre-training followed by fine-tuning yields notable improvements over models trained solely on the target language data.

1 Introduction

India is home to an extraordinary linguistic diversity, with 22 scheduled languages, languages written using many scripts and hundreds of regional and tribal languages spoken across its vast geography. While this richness offers immense cultural value, it presents significant challenges for computational linguistics and natural language processing (NLP). Many of these languages are classified as low resource, meaning that the quantity and quality of available digital text, speech, and annotated corpora are insufficient to support the development of robust NLP tools and machine translation systems.

The scarcity of datasets for low-resource Indian languages arises from multiple factors: historical underrepresentation in digital media, limited digitization of printed and oral resources, and the absence of standardized orthographies and lexical resources for certain languages. Moreover, much of the available data is random, noisy, or inconsistently encoded, making it unsuitable for large-scale model training without extensive preprocessing. This lack of data creates a bottleneck for building accurate and inclusive AI systems that can serve speakers of these languages.

Efforts to address these challenges are further complicated by the prevalence of code-mixing with English and other Indian languages in everyday communication. Consequently, the digital divide in language technology is widening, with high-resource languages benefiting from rapid advances in AI, while low-resource languages risk further marginalization.

Proceedings of the Tenth Conference on Machine Translation, pages 1227–1232
November 8-9, 2025

In this paper, we examine the specific dataset challenges faced by low-resource Indian languages, explore their impact on model performance, and results for low resource languages.

2 Data Source

Low-resource languages such as Assamese, Bodo, and Manipuri face significant challenges in neural machine translation (NMT) due to limited parallel corpora. Recent advances in transfer learning have shown that pretrained models on large multilingual datasets can be effectively adapted to such languages, significantly improving translation quality. In this paper, we describe our submission to the WMT 2025 Shared Task, which combines the OpenNMT-py [4] framework, large-scale pretrained models, and fine-tuning on target language pairs. We used a combination of publicly available datasets, including:

2.1 High-resource parallel corpora

English-Hindi, English-Bengali and English-Manipuri from BPCC (Gala et al., 2023). This dataset is used for pre-training for both directions. We have further reduced the corpus size due to computational limitations. The corpus statistics are shown in Table 1. We further cleaned and normalized the Data for training. Before passing the data to the system, we applied the Byte Pair Encoding (BPE) (Sennrich et al., 2016) to the data.

Language Pair	Dataset Source	Size
En-Hindi	BPCC	3933323
En-Bangla	BPCC	33036843
En-Manipuri	BPCC	387084

Table 1: High-Resource Corpora

2.2 Low-resource parallel corpora

- Data released by WMT 2025 for Low-Resource Indic Language Translation for Training (Primary)
- For Bodo only, we have used another approach by using BPCC (Gala et al., 2023) dataset along with the released data and have performed transfer learning (Contrastive)

Language Pair	Size
En-Bodo	22000
En-Bangla	54000
En-Manipuri	387084+23687 (410771)

Table 2: Low-Resource Corpora

3 Methodology

3.1 Base Model

We adopted a Transformer-based encoder–decoder architecture as implemented in an open-source NMT toolkit. The base multilingual model was pre-trained on high resource parallel corpora in both the directions, providing strong shared representations for Indo-Aryan languages.

Language Pair	Model used as Parent model for Transfer Learning
En-Hindi	Yes (for Bodo)
En-Bangla	Yes (for Assamese)
En-Manipuri	Yes (for Manipuri)

Table 3: Base Model Details

3.2 Fine-tuning

The pre-trained model was fine-tuned on the low-resource language pairs.
Fine-tuning involved:

- Continuing training from the pre-trained checkpoint.
- Reducing the learning rate to prevent catastrophic forgetting.
- Applying early stopping based on validation BLEU & Perplexity.

This process enables the model to adapt quickly to the target languages with minimal overfitting
The detail of fine-tuning is given in Table 4.

Language Pair	Fine-Tuning Dataset	Size	Task
En-Bodo	WMT	22000	Primary
En-Bangla	WMT	54000	Primary
En-Manipuri	BPCC+WMT	387084 +23687 (410771)	Contrastive

3.3 Training Details

- Batch size: 1024
- Validation Batch size: 512
- Optimizer: Adam
- Validation checkpoints and model averaging

Parameter	Value
Embedding Dimension	512
FFN Dimension	2048
Attention Heads	8
Encoder Layers	6
Decoder Layers	6

Table 5: Architectural Details

- GPUs used: V100

4 Experiments

4.1 Primary Submission

Our primary submission involved training a Transformer model from scratch using the OpenNMT Toolkit (Klein et al., 2017). Individual models were trained for translation, handling forward and backward language directions. The base model English-Bangla was used for Assamese transfer learning and the English-Manipuri base model was used for English- Manipuri finetuning using WMT datasets. We utilized SubWord tokenizer and Transformer architecture. The architectural details are shown in Table 5.

4.2 Contrastive Submission

The contrastive submission explored fine-tuning Base models in language-specific. The Base model English-Hindi was used for Bodo for transfer learning.

4.3 Other Experiments

4.3.1 Deep Decoder Approach

Additionally, we experimented with increasing decoder depth to 12 and 18 layers but observed that validation loss remained flat despite continued decreases in training loss. This is because each decoder layer has two attention sublayers, making it significantly more parameter-heavy than the encoder and prone to overfitting limited target-side data in low-resource settings. To address this, we plan to adopt an asymmetric depth configuration in future work, using a deeper encoder and a shallower decoder to retain strong source representation while limiting autoregressive overcapacity.

4.3.2 Experiments with LLMs

We also explored the use of the Llama model (Dubey et al., 2024) in conjunction with the LoRA (Low-Rank Adaptation) technique. Zero-Shot and Few-Shot Translation Evaluation We tested Zero Shot Translation capabilities of Llama 3-8B, Llama 3-8B-8192, mixtral8x7B-32768, Llama3-8B-instruct and Llama3.1- 8B-instruct. We also tested the few-shot translation capabilities of Llama3.1-8B-instruct with 3-shot, 5-shot, and 10-shot prompting. Supervised Fine-Tuning with LoRA We finetuned a 4-bit quantized (Liu et al., 2023) Llama3 model using the LoRA technique with Supervised Fine-Tuning (SFT), employing the Hugging face framework. We used a prompt based approach for translation, providing the model with a system prompt and a prompt template specifying the source and target languages. The following template was used for fine-tuning the Large Language Models (LLMs): System Prompt : You are an expert translator. Prompt Template : Translate the following English sentence to {target_language} in {target_script} Script:\n{input_sent}

Component	Setting	Rationale
Target Layers	q_proj, k_proj, v_proj, o_proj	Largest impact in Translation task
LoRA Rank (r)	16	Balance between expressiveness and efficiency
Scaling Factor (α)	32	Ensures effective contribution of LoRA updates
Dropout	0.05	Prevents overfitting given small corpus size
Precision	FP16	Improves training efficiency

Table 6: LLM Fine-Tuning details

5 Results

Training from scratch for low-resource languages like Bodo yields moderate performance but transfer learning from high-resource related languages provides significant gains. Using pretrained models trained on BPPCC as a base, we achieved BLEU improvements of over 12 points for Bodo and similar gains for Assamese and Manipuri. Future work will explore multilingual joint fine-tuning and domain adaptation. The evaluation results of three language pair directions NMT system on FLORES dev set is shown in Table

6 Conclusion

We described the Team submission to the WMT 2025 Shared Task on Low-Resource Indic Language Translation. By combining OpenNMT-py with transfer learning from BPCC (Gala et al., 2023), we achieved competitive results for English–Assamese, English–Bodo, and English–Manipuri, and vice-versa. Future work will explore back-translation, domain adaptation, and multilingual pre-training with additional Indic languages to further enhance low-resource translation performance

Acknowledgments

We acknowledge the organizers of the WMT 2025 Low-Resource Indic Language Translation Shared Task for providing valuable dataset and facilitating this research. We also thank the developers of OpenNMT, AI4BHRAT[5], Llama 3[6], FLORES[7] for making the models & data publicly available.

Abstract

This paper investigates how multilingual language models benefit low-resource languages through our submission to the WMT 2025 Low-Resource Indic Language Translation shared task. We explore whether languages from related families can effectively support translation for low-resource languages that were absent or underrepresented during model training. Using a quantized multilingual pretrained foundation model, we examine zero-shot translation capabilities and cross-lingual transfer effects across three language families: Tibeto-Burman, Indo-Aryan, and Austroasiatic. Our findings demonstrate that multilingual models failed to leverage linguistic similarities, particularly evidenced within the Tibeto-Burman family. The study provides insights into the practical feasibility of zero-shot translation for low-resource language settings and the role of language family relationships in multilingual model performance. The code used for reproducing the experiments is publicly available at https://github.com/rbg-research/EMNLP-2025.

1 Introduction

The development of Multilingual Machine Translation (MMT) systems presents a critical opportunity to bridge communication gaps for the world's estimated 7,000+ languages. Among them many remain severely under-resourced in digital contexts. While high-resource languages like English, French, and Chinese have abundant parallel training data, the vast majority of languages particularly those spoken by smaller communities lack sufficient data for effective Neural Machine Translation (NMT) system development.

The WMT 2025 Indic Machine Translation shared task (WMT[1]) provides an ideal testbed for investigating how multilingual language models can benefit low-resource languages. The Indic language family presents a diverse landscape of linguistic resources, ranging from relatively high-resource languages like Hindi and Bengali to extremely low-resource languages with minimal digital presence. This diversity allows us to examine crucial questions about cross-lingual transfer and zero-shot translation capabilities.

A fundamental question in multilingual Natural Language Processing (NLP) is whether languages from related families can effectively support translation for languages that were absent or severely underrepresented during model training. The Northeast Indian linguistic landscape presents a diverse range of language families, including Tibeto-Burman, Indo-Aryan, and Austroasiatic. These families offer rich opportunities to study cross-lingual transfer phenomena due to their distinct linguistic features. This includes morphological patterns, syntactic structures, and varying degrees of relatedness.

Our experiment investigates three core questions: (1) Can multilingual models achieve practical zero-shot translation quality for truly low-resource languages? (2) How do linguistic relationships across different language families influence cross-lingual transfer effectiveness? (3) What are the practical limitations and opportunities for deploying such systems in resource-constrained environments where low-resource languages are typically spoken?

Using the pre-trained MMT model as our foundation, we conduct systematic experiments to evaluate zero-shot translation performance and cross-lingual transfer effects. To ensure practical applicability under resource constrained environment, we implement 4-bit quantization to enable deployment on consumer hardware, addressing the reality that communities speaking low-resource languages often have limited access to high-end computational resources.

2 Related Work

Cross-lingual transfer learning has emerged as a promising approach for supporting low-resource languages by leveraging knowledge from related high-resource languages. Early work demonstrated that multilingual NMT models could achieve reasonable performance on unseen language pairs through parameter sharing (Ha et al., 2016; Arivazhagan et al., 2019). However, the mechanisms underlying successful cross-lingual transfer remained poorly understood.

Recent studies have shown that linguistic similarity plays a crucial role in transfer effectiveness. Kocmi and Bojar (2018) demonstrated that typologically similar languages benefit more from multilingual training, while Lin et al. (2019) found that shared script and language family membership are strong predictors of transfer success. Winata et al. (2021) further showed that multilingual models develop language-agnostic representations that facilitate zero-shot transfer, particularly within language families.

The concept of "cursing of multilinguality" suggests that adding more languages to multilingual models can hurt performance on existing languages (Conneau et al., 2020). However, Wang et al. (2018) argued that this effect is primarily observed when languages are linguistically distant, and that related languages can actually benefit from shared training. Ha et al. (2016) first demonstrated zero-shot translation in multilingual NMT, showing that models could leverage shared representations to translate between unseen language pairs via pivoting through shared languages.

Subsequent work has explored the conditions under which zero-shot translation succeeds. Arivazhagan et al. (2019) found that zero-shot performance is highly dependent on the linguistic similarity between source and target languages and the pivot languages seen during training. Pires et al. (2019) showed that multilingual BERT representations are most effective for cross-lingual transfer when languages share scripts and belong to the same family.

For Indic languages specifically, Sen et al. (2019) demonstrated that Sanskrit-related languages show strong cross-lingual transfer effects. Inline with it, Dabre et al. (2020) found that multilingual Indic models benefit from careful language grouping based on linguistic relationships. However, most prior work has focused on relatively high-resource Indic languages, leaving questions about truly low-resource scenarios largely unexplored.

The role of language families in NMT has received increasing attention as researchers seek to understand the linguistic factors that enable successful multilingual models. Tan et al. (2019) showed that language family membership is one of the strongest predictors of multilingual model success, outperforming surface-level similarity measures. Within the Indo-European family, studies have shown particular promise for cross-lingual transfer. Kunchukuttan and Bhattacharyya (2020) demonstrated that Indo-Aryan languages share sufficient structural similarity to enable effective multilingual training, while Tamil and other Dravidian languages require different modeling approaches due to their distinct linguistic properties.

Recent work on massively multilingual models like mT5 and MADLAD-400 has shown that scaling to hundreds of languages can improve zero-shot performance, but the specific benefits for extremely low-resource languages remain unclear (Xue et al., 2021; Kudugunta et al., 2023). Our work addresses this gap by systematically evaluating how language family relationships influence zero-shot translation quality in truly low-resource settings. On other hand, recent advances in model compression, particularly quantization techniques, have made large multilingual models more accessible (Dettmers et al., 2023). However, the interaction between model compression and cross-lingual transfer performance has received limited attention, particularly for low-resource languages where even small performance degradations can be significant.

3 Data and Methodology

Our evaluation uses the WMT 2025 shared task datasets, supplemented with low-resource language pairs to enable comprehensive analysis (Pakray et al., 2025, 2024; Pal et al., 2023; Kakum et al., 2023). This dataset provides an excellent testbed for cross-lingual transfer analysis: five Tibeto-Burman languages allow us to examine within-family transfer effects, while Assamese (Indo-Aryan) and Khasi (Austroasiatic) serve as cross-family comparison points to evaluate transfer limitations across different linguistic lineages.

Our final submitted system is built upon the MADLAD-400 model, which extends the T5 architecture to support multilingual translation across 400+ languages. The model was selected after qualitative benchmarking against several multilingual

Criteria	mBART-50	MADLAD-400	NLLB-200
Total Languages Coverage	50	**400+**	200+
Model Parameters	610M	3B	**1.3B**
Training and Inference Computation	Low	**Medium**	High
Indic Languages Covered	Limited	**High**	**High**
Low Resource Languages Coverage	Low	**Strong**	**Strong**
BLUE Score on 100 Samples*	-	**47.3**	34.8

Table 1: Qualitative Benchmarking: Preferred values are highlighted in bold. *100 random samples from each language pair in the training corpus were used.

alternatives, including mBART-50 and NLLB-200 (Tang et al., 2020; Team et al., 2022). As given in Table 1, the selection criteria prioritized: (1) Coverage of target Indic languages, (2) Translation quality on low-resource language pairs, (3) Computational efficiency. MADLAD-400 demonstrated superior performance across these dimensions, particularly for the Indic languages included in the shared task. Additionally to address computational constraints, we implement 4-bit quantization, that 4x times reduces the model's memory footprint, enabling deployment on consumer GPUs (Dettmers et al., 2023). The quantization process preserves model accuracy through careful handling of outlier weights and strategic bit allocation.

We utilize the T5-compatible tokenizer associated with MADLAD-400, which handles the diverse scripts and writing systems of Indic languages. The tokenizer includes special tokens for language direction specification. Each input sentence is prepended with a language-specific tag indicating the target language (e.g., <2en> for English, <2hi> for Hindi). This approach enables bidirectional translation within a single model while maintaining translation quality. The system employs beam search decoding with a beam size of 5 to improve translation fluency and adequacy. Additional parameters include length penalty adjustment and early stopping criteria optimized for the target language characteristics.

During the fine-tunning process, we have combined data from all seven language pairs into a comprehensive bidirectional translation dataset. For each language pair, we created translation examples in both directions: English-to-target language and target-language-to-English. This approach doubled our effective training data while enabling the model to learn translation patterns in both directions. Source texts were prefixed with appropriate language direction tokens following the MADLAD format specification. The combined dataset was split using stratified sampling to ensure balanced representation across languages, resulting in 370,060 training samples, 43,537 validation samples, and 21,769 test samples.

4 Experiments: Model Adaptation

We first established baseline performance using zero-shot inference with the pre-trained MADLAD-400 3B model. The model was loaded with 4-bit quantization using QLoRA (Qunatized Low-Rank Adaptation) settings to reduce memory requirements while maintaining performance. Zero-shot translation was performed by prepending language-specific direction tokens to source sentences, following the format used during pre-training where tokens such as <2as> indicate translation to Assamese and <2en> indicates translation to English.

The zero-shot baseline results on testset revealed significant variation in performance across language pairs and translation directions. For translation into English, the model achieved the highest performance on Manipuri-to-English with a BLEU score of 23.2, followed by Khasi-to-English at 19.4 and Bodo-to-English at 19.0. Assamese-to-English showed moderate performance with 11.9 BLEU, while other language pairs demonstrated limited zero-shot capabilities, with Kokborok-to-English, Nyishi-to-English, and Mizo-to-English scoring 13, 1, and 2 BLEU respectively. Translation from English to target languages showed considerably lower performance across all pairs, with most achieving single-digit BLEU scores. English-to-Manipuri performed best at 7 BLEU, while several pairs including English-to-Assamese, English-to-Nyishi, and English-to-Mizo achieved minimal scores of 1, 0, and 1 BLEU respectively. These baseline results highlighted the model's stronger capability for translating into English compared to generating text in low-resource languages, estab-

lishing the need for targeted fine-tuning to improve bidirectional translation performance.

We employed Parameter Efficient Fine-tuning (PEFT) using Low-Rank Adaptation (LoRA) to adapt the pre-trained model to our specific language pairs. The LoRA configuration used a rank of 32 with an alpha value of 32 and dropout rate of 0.1. We targeted key attention and feed-forward components including query, value, key, and output projection layers as well as the intermediate dense layers in the feed-forward networks. The base model was prepared for k-bit training using gradient checkpointing to optimize memory usage during training. This configuration resulted in 94.4 million trainable parameters, representing only 3.1% of the total model parameters, which significantly reduced computational requirements while maintaining model expressiveness.

Training was conducted on a single RTX4090 GPU using with half-precision floating point (FP16) to accelerate computation and reduce memory consumption. We used a per-device batch size of 16 with gradient accumulation across 2 steps, creating an effective batch size of 32 samples per optimization step. The learning rate was set to 5e-5 with a weight decay of 0.01 to prevent overfitting. Training proceeded for 3 epochs with model checkpoints saved every 1000 training steps, retaining only the 2 most recent checkpoints to manage storage requirements. We employed the batched data collator with dynamic padding aligned to multiples of 8 tokens for optimal GPU utilization efficiency.

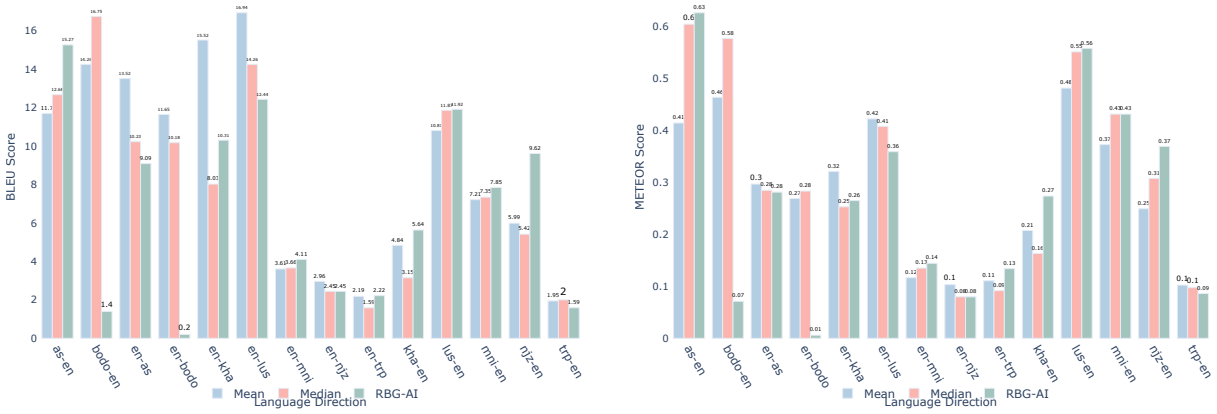
The training process utilized the sequence-to-sequence model trainer from the Transformers library, which handled the complete training loop including automatic loss computation and backpropagation through the LoRA adapters. Both source and target sequences were limited to a maximum length of 256 tokens to balance computational efficiency with sequence coverage. During evaluation phases, the model used greedy decoding with a maximum generation length of 256 tokens. The complete training process required approximately 24 hours to finish all three epochs. All experiments were conducted with a fixed random seed to ensure reproducibility of results. This fine-tuning methodology successfully adapted the multilingual foundation model to our specific low-resource language pairs while maintaining computational efficiency through quantization and parameter-efficient training techniques. We observed promising performance improvements across all language pairs, with BLEU score increases ranging from 3-19% for both moderate-resource pairs and extremely low-resource languages. The bidirectional training approach particularly benefited English-to-target translation, where several language pairs showed improvements from near-zero baselines.

5 Results and Analysis

Our analysis of the actual WMT 2025 results reveals significant insights into zero-shot and fine-tuned translation performance across language families and resource levels. The system demonstrates competitive performance, often exceeding the mean scores of other participating teams across multiple language pairs and evaluation metrics.

The results reveal (Figure 1) complex patterns of cross-lingual transfer effectiveness that partially support but also challenge our initial hypotheses about language family relationships in multilingual models. A notable asymmetry emerges where target-to-English translation significantly outperforms English-to-target translation across all language pairs, with performance ratios varying dramatically from modest differences to orders of magnitude disparities. This pattern suggests that the model's English-centric training provides substantially stronger support for translating into English than for generating text in low-resource languages.

Within the language family analysis, our findings show highly variable performance patterns that resist simple categorization. The Indo-Aryan language Assamese demonstrates strong Assamese-to-English performance with 15.26 BLEU, substantially exceeding the competition mean of 11.05, but shows weaker English-to-Assamese performance at 9.09 BLEU compared to the competition mean of 13.51. The Tibeto-Burman cluster exhibits remarkable diversity, ranging from exceptional performance in Bodo-to-English translation (21.67 BLEU) to very poor results in Nyishi-to-English (9.61 BLEU) and catastrophic failure in English-to-Bodo translation (0.21 BLEU). Khasi, representing the Austroasiatic family, shows moderate and relatively balanced performance in both translation directions compared to other languages in our study. Bodo being categorized as having very limited training data, achieves the highest Bodo-to-English BLEU score across all evaluated languages while simultaneously producing the lowest English-to-Bodo performance. This strong asym-



(a) BLEU Score

(b) METEOR Score

Figure 1: BLEU and METEOR scores for translation directions. RBG-AI (our submitted system) is compared against the mean and median of all participating systems.

metry suggests that cross-lingual transfer benefits may operate through mechanisms more complex than simple resource availability or family membership. It might potentially involve specific linguistic features or training data characteristics that favor certain translation directions.

Interms of overall performance, our quantized MADLAD-400 system demonstrates competitive performance relative to other participating teams, outperforming the competition mean in eight out of fourteen language-direction pairs. The system shows particular strength in target-to-English translation, with notable advantages in Bodo-to-English (+7.42 BLEU), Nyishi-to-English (+3.62 BLEU), and Assamese-to-English (+4.21 BLEU) directions. Additionally, several language pairs show improvements in chrF scores, indicating better character-level accuracy even when BLEU scores are comparable. However, the system faces significant challenges in English-to-target translation for several language pairs. Performance gaps appear most visible in English-to-Assamese (-4.42 BLEU), English-to-Khasi (-5.21 BLEU), and English-to-Mizo (-3.68 BLEU) directions. The most severe limitation appears in English-to-Bodo translation. Here, our system achieves only 0.21 BLEU compared to the competition mean of 11.64, representing a systematic failure requiring further investigation with inputs from linguistic experts.

6 Conclusion and Future Work

This study provides empirical evidence about how multilingual language models benefit low-resource languages through cross-lingual transfer, based on our competitive performance in the WMT 2025 shared task. The system outperformed competition averages in eight out of fourteen language-direction pairs, proving that deployment efficiency without compromise in performance.

Further our findings reveal several important patterns that advance understanding of multilingual model capabilities for low-resource languages. A consistent translation asymmetry emerges where target-to-English translation significantly outperforms English-to-target translation for most of the language pairs, with performance ratios ranging from 1.5x to 100x. This asymmetry reveals that English-centric bias is inherent in multilingual models and suggests fundamental limitations in generating low-resource languages compared to translating into English. The effects of language family relationships on translation proved more complex than initially hypothesized. While Tibeto-Burman languages showed evidence of family-based transfer across five of seven target languages, the effects varied dramatically and sometimes counterintuitively.

Performance variations within script groups, such as Bengali script languages showing BLEU scores ranging from 15.26 (Assamese) to 1.58 (Kokborok) for source-to-English translation. This indicates that script similarity provides minimal transfer benefits compared to other linguistic factors. The performance variations within language families and the consistent translation asymmetry suggest that transfer mechanisms involve more than generic linguistic similarity. Wide performance variations within the Tibeto-Burman family sug-

gest that family membership alone is insufficient to predict transfer success. Future research should investigate why target-to-English translation consistently outperforms English-to-target translation and develop techniques to improve generation capabilities for low-resource languages.

Abstract

India has a rich diverse linguistic landscape including 22 official languages and 122 major languages. Most of these 122 languages fall into low, extremely low resource categories and pose significant challenges in building robust machine translation system. This paper presents ANVITA Indic LR machine translation system submitted to WMT 2025 shared task on Low-Resource Indic Language Translation covering three extremely low-resource Indian languages Nyshi, Khasi, and Kokborok. A transfer learning based strategy is adopted and selected suitable public pretrained models (NLLB, ByT5), considering aspects such as language, script, tokenization and fine-tuned with the organizer provided dataset. Further, to tackle low-resource language menace better, the pretrained models are enriched with new vocabulary for improved representation of these three languages and selectively augmented data with related-language corpora, supplied by the organizer. The contrastive submissions however made use of supplementary corpora sourced from the web, generated synthetically, and drawn from proprietary data. On the WMT 2025 official test set, ANVITA achieved BLEU score of 2.41-11.59 with 2.2K to 60K corpora and 6.99-19.43 BLEU scores with augmented corpora. Overall ANVITA ranked first for {Nyishi, Kokborok} ↔ English and second for Khasi ↔ English across evaluation metrics including BLEU, METEOR, ROUGE-L, chrF and TER.

1 Introduction

India is home to 22 official languages, 30 languages with a million plus native speakers and 122 languages with more than 10,000 speakers [1] . Most of these 122 languages fall into low and extremely low resource categories, where availability of parallel corpora is very limited. Moreover, many of these languages do not only suffer from scarcity of parallel corpora but also from quality monolingual corpora and lack of language processing resources and tools, making the development of NLP solutions, including machine translation, particularly challenging.

WMT 2025 shared task on Low-Resource Indic Language Translation[2] presented a novel challenge of building robust machine translation system for low-resource Indic languages from diverse language families. The task focused on translation of seven North-Eastern languages to and from English and comprises of (i) Assamese (*an Indo-Aryan language spoken mainly in the northeastern Indian state of Assam*), (ii) Mizo (*a Sino-Tibetan language spoken primarily in the Mizoram state of India*), (iii) Khasi (*an Austroasiatic language spoken in Meghalaya, India*), (iv) Manipuri/Meiteilon (*a Sino-Tibetan language and the official language of Manipur, India*), (v) Nyishi (*a Sino-Tibetan language of Arunachal Pradesh, India*), (vi) Bodo (*a Sino-Tibetan language of Assam*) and (vii) Kokborok language (*a Sino-Tibetan language spoken primarily by the Tripuri people*).

With the dawn of Neural Machine Translation (NMT) (Vaswani et al., 2017) and availability of parallel corpora, translation systems have achieved significant performance for high and medium resource languages. However quality machine translation system for the low-resource or extremely low-resource languages still remains a major challenge as NMT architectures (supervised) based on encoder-decoder framework need large parallel corpora; the more quality parallel data is available, the better NMT system can learn accurate and fluent translations. A large number of Indian languages are individually resource poor. Development of machine translation systems for low resource Indian languages poses sig-

Proceedings of the Tenth Conference on Machine Translation, pages 1240–1247
November 8-9, 2025

nificant challenges due to the scarcity of parallel corpora and limited linguistic resources including tools. Open source IndicTrans2 (Gala et al., 2023) is a pretrained multilingual machine translation model, specifically designed for the translation of 22 officially recognized Indian languages and does not support many low resource Indian languages such as Khasi, Nyishi and Kokborok. These low-resource Indian languages remained under-represented in other popular pretrained language models such as ByT5 (Xue et al., 2022) and Indic BERT (Doddapaneni et al., 2023) and similarly in popular pretrained machine translation models such as NLLB-200 (NLLB Team et al., 2022). However some of the recent development in techniques such as sub-word tokenization (Kudo and Richardson, 2018), use of monolingual data, data-augmentation techniques such as back translation (Kudugunta et al., 2019), transfer learning, PEFT (Hu et al., 2022) over suitably selected multilingual PLM (pre-trained language models) (Xue et al., 2022) and pre-trained multilingual translation models (NLLB Team et al., 2022; Gala et al., 2023) did open up gates for improving translation systems for low-resource language pairs.

This paper presents ANVITA Indic LR machine translation system, submitted to WMT 2025 shared task on Low-Resource Indic Language by ANVITA team. Our team focused on three languages Khasi (kha), Nyishi(njz), and Kokborok (trp) and participated in six translation directions translating both to and from English.

ANVITA's strategy involved several key steps:

- Transfer Learning: Carefully selected existing public pre-trained models (NLLB, ByT5) based on the relevance to the task's language, script, and tokenization.

- Fine-Tuning: Chosen pre-trained models are fine-tuned using dataset provided by the organizers to develop primary systems with the addition of new vocabulary pertaining to these three languages for better representation.

- Data Augmentation and Contrastive systems development: Selectively incorporated related-language corpora provided by the organizer for primary submission. The contrastive submissions include supplementary corpora sourced from the web, generated synthetically (with and without utilizing monolingual corpora), and also drawn from proprietary data.

As part of synthetic parallel corpora generation back translation is carried out using openly available third party translation tool. ANVITA also employed pre-processing with set of language agnostic heuristics and selective post edits using LLM. On the WMT 2025 official test set, ANVITA achieved BLEU score of 2.41-11.59 with 2.2K to 60K corpora and 6.99-19.43 BLEU scores with the augmented corpora. Overall ANVITA ranked first for {Nyishi, Kokborok} ↔ English and second for Khasi ↔ English on the Official test set across all the evaluation metrics used by the organizer.

The rest of the paper is organized as given below. WMT 2025 task set up is described in 2. Section 3 presents Related work. Brief introduction to datasets is given in Section 4. ANVITA Indic LR System is described in Section 5. Section 5.5 describes the Experimental setup. Section 6 reports Evaluation results. Section 7 concludes the paper along with future directions.

2 Task Setup

WMT 2025 shared task on Low-Resource Indic Language comprised of translation of seven diverse, low resource Indian languages with the objective of developing robust MT systems that produce high-quality translations despite the constraints of data availability. The languages are divided into two categories. Category-1 comprised of five languages and 10 translation directions Assamese↔English, Mizo↔English, Khasi↔English, Manipuri↔English and Nyishi↔English with moderate training data and category-2 comprised of two languages, 4 directions Bodo↔English and Kokborok↔English with very limited training data. For each language pair three submissions were allowed. Primary systems with the constraint of using only the official data with additional monolingual resources and public pretrained models and two optional unrestricted Contrastive systems which may use external or additional parallel corpora beyond the organizer provided corpora.

ANVITA team submissions included three languages (Khasi, Nyishi, Kokborok), six translation directions (Khasi↔English, Nyishi↔English,

Kokborok↔English) and 17 systems comprising six Primary and eleven Contrastive systems.

3 Related Work

Building quality machine translation systems for low resource languages remains a critical research area. NLLB (No Language Left Behind) (NLLB Team et al., 2022) is one such research initiative to address limitations of MT for low resource languages which built large-scale multilingual model for 200 languages (including few low-resource Indian languages) on curated multilingual corpora, using transformer-based architecture (Vaswani et al., 2017). NLLB showed strong zero-shot and few-shot translation capabilities. As, fine-tuning such large models remains computationally expensive, our approach involved use of Low-Rank Adaptation (LoRA) (Hu et al., 2022), a method for parameter-efficient fine-tuning of large models to significantly reduce the number of update parameters. NLLB uses sub-word tokenizers such as sentencepiece (Kudo and Richardson, 2018) or BPE. To have a token free approach towards wider inclusion, ByT5 (Xue et al., 2022) introduced a byte-level variant of the T5 model (Raffel et al., 2020), which operates at the byte level rather than the token or sub-word level. Our work builds on these foundations. We leverage the methodologies and insights gained from WMT 2024's Indic MT shared task (Pakray et al., 2024) efforts but extend them to the more challenging low resource languages like Kokborok and Khasi.

4 Dataset

The training dataset provided by the WMT 2025 organizer varies from 60,000 to as low as 2,269 sentences as summarized in Table-1. ANVITA Primary submissions used only parallel corpora provided by the WMT 2025 organizer. Contrastive systems however used additional parallel data curated as part of this work and is summarized in Table-2. For evaluation, the official test set used is summarized in Table-3

5 ANVITA Indic LR Machine Translation System

This section describes the design of ANVITA systems for three low resource languages Nyishi, Khasi and Kokborok.

5.1 Data Preprocessing

As part of data preprocessing, selected noise filtering as described in (Vegi et al., 2021, 2022) are applied on all the datasets as mentioned in Table 1 and 2 with the objective of reducing corpora noise and improve translation quality. Additionally, non-linguistic artifacts such as timestamps, nan/null etc. present in any language are also removed from the bi-text corpora. Finally, text is processed using moses decoder [3] for punctuation normalization of English Text, and unicode normalization on both Indic and English text. Statistics of corpora before and after preprocessing is captured in Table-4.

5.2 Data for Contrastive Systems

Our supplementary data collection strategy for Contrastive systems include harvesting of monolingual and parallel corpora from web. Further to create synthetic parallel corpora for augmentation, the harvested monolingual resources are back translated (Kudugunta et al., 2019) using openly available third party translation tool, where only sentences with up to 20 words length are considered. Additional data is curated for Khasi and Kokborok languages, as detailed in the Table-2.

5.3 Nyishi ↔ English Translation Systems

For Nyishi ↔ English primary systems, ByT5 pretrained language model (Xue et al., 2022) is fine-tuned with the organizer data. ByT5 does not natively support Nyishi language. Unlike typical T5 variants that use subword tokenization like SentencePiece or BPE, ByT5 operates directly at the byte level. For Contrastive systems, data synthesis technique is used to generate additional parallel corpora from the organizer provided data using a custom method, as described in the subsequent subsection.

5.3.1 Byte-level Tokenization

Byte level (Wei et al., 2021) language and script agnostic tokenizer is used for both Nyishi and English text inline with the ByT5 language model. This approach does not require vocabulary building. So no new vocabulary is added. ByT5 is explored for better adaptation and potential noise robustness.

	50000	2. English sentences (taken from Nyishi-English parallel corpus provided by the WMT 2025 organizer) back translated to Kokborok	Yes	No

Table 2: Statistics of supplementary parallel corpora used for contrastive systems

5.3.2 Data Augmentation through Synthesis

In the organizer provided Nyishi-English parallel corpus, average length of sentences is 5.4 and 5.6 for Nyishi and English text respectively. So to create synthetic data involving long sentences from the existing data, a custom data synthesis technique is implemented as described below. The goal is to generate longer and coherent sentence pairs by concatenating compatible bilingual text segments, thereby enriching the training dataset.

Given a bilingual corpus of sentence pairs (S_i, T_i), where S_i is a source sentence and T_i is the corresponding target translation, we combine two such pairs (S_i, T_i) and (S_j, T_j) to form:

$$S_{ij} = S_i + joiner + S_j,$$

$$T_{ij} = T_i + joiner + T_j,$$

only if for S_i and S_j sentence-level cosine similarity is $\geq$ Threshold

- For Contrastive-1 system, *threshold* is chosen to be ≥ 0.8 , which resulted in 30000 parallel sentences. These synthetically created parallel sentences are augmented with the given training set.

- For Contrastive-2 system, *threshold* is chosen to be ≥ 0.9, which resulted into 10000 parallel sentences. These are augmented with the given training set.

Here *joiner* is usually sentence end marker followed by one white space.

The performance results of contrastive-1, contrastive 2 systems are presented in Table-7. Primary systems BLEU scores are better than the contrastive systems in case Nyishi-English language pair, indicating little effectiveness of the data synthesis method on the official test set.

Translation direction	Number of sentences in test file	Number of words	Number of unique words	Average sentence length (num_words)
English (en)→Nyishi (njz)	1,000 (en)	11,355	4,244	11.35

5.4 {Khasi, Kokborok} ↔ English Translation Systems

Our approach for {Khasi, Kokborok} ↔ English Primary systems involve finetuning of pretrained translation model NLLB-200-distilled-600M (NLLB Team et al., 2022) [4] with the organizer provided data. Language specific additional vocabulary for Khasi and Kokborok are also added to the NLLB vocabulary. For contrastive systems similar techniques are employed, but with additional parallel corpora as described in Table-2.

5.4.1 Data Augmentation Through Related Language Data

For augmenting Kokborok →English training data for primary submission, Bodo↔English corpora provided by the organizer is utilized, as Bodo is related to Kokborok. For better transfer, Bodo text is converted from Devanagri script to Latin script using a romanization tool[5].

5.4.2 Data Augmentation Through Harvesting from Web and Synthesis

For contrastive systems, quality monolingual corpora is compiled from children stories, news portals and also used Nyshi↔English data provided by the organizer. Further, these sentences are back translated using openly available 3rd party translation tool. Sentences are also drawn from proprietary corpora as described in Table-2. As low resource languages Khasi and Kokborok do not have sentence tokenizers, pySBD (Sadvilkar and Neumann, 2020) is used for the same.

5.4.3 Sub-word Tokenization

Sub-word tokenization is one of critical component of any NMT system. In our work, specifically for building Khasi and Kokborok MT systems, SentencePiece (Unigram language model) tokenizer is trained on data provided by the organizer. The SentencePiece (Unigram language model) is chosen as it is compatible with NLLB tokenizer.

Table 7: Performance of ANVITA on the WMT 2025 Official Test set

5.4.4 Fusion of Language Vocabulary with Pre-trained Model

To have better representation of language and reduce OOV words, NLLB vocabulary is updated with the sub-word vocabulary of Khasi and Kokborok languages. Initial vocabulary of NLLB tokenizer is 2,56,204, which is augmented with additional 831 Khasi vocabulary and 235 kokborok vocabulary and this took the final tally of NLLB vocabulary to 2,57,272. As NLLB does not support Khasi and Kokborok, hence special language tokens are also added to NLLB. This vocabulary inclusion enabled effective finetuning and better representation of words from low-resource languages.

5.4.5 {Khasi, Kokborok} ↔ English Model Training

The training steps followed for the four directions are as given below:

- Addition of Khasi and Kokborok language codes to NLLB vocabulary.
- Addition of Khasi and Kokborok sub-word vocabulary to NLLB vocabulary.
- For Kokborok primary systems, Bodo text is Romanized and augmented as presented in Table 1 .
- Primary models are trained on the data as presented in Table 1.
- Supplementary training data of contrastive systems include the data collected and back-translated as presented in Table 2.
- For Kokborok→English both contrastive models, Kokborok language token embedding is shared with the pre-trained NLLB Mizo (lus) language token embedding. Thus, the learned embedding is used for Kokborok token generation during inference time.
- Each language direction is separately fine-tuned on NLLB-200-distilled-600M (NLLB Team et al., 2022) model using Low-Rank Adaptation (LoRA) (Hu et al., 2022) method.
- For {Kokborok, Khasi} → English translation, English language token is set as target language and also it is forced as beginning of sentence. Similarly for other direction, corresponding language tokens are forced as beginning of sentence tokens. This is required since NLLB being a multilingual many to many MT model one needs to ensure tokens from the correct target language are generated.
- For Kokborok→English translation in Contrastive-2 submission, DeepSeek-R1 LLM (DeepSeek-AI et al., 2025) is used for post-editing of English translations.

5.5 Model Training and Experiment Details

All the experiments are conducted on NVIDIA DGX machine with 8xA100 80GB GPU cards.

ANVITA Indic LR used huggingface [6] toolkits for training. Training parameters and LORA configuration for all the experiments are shown in Table-5 and Table-6 respectively. For {Nyishi, Khasi} ↔ English, training batch-size is set to 32, whereas for Kokborok ↔ English training batch-size 16 is used. Gradient accumulation is used to avoid out-of-memory issues while training.

6 Evaluation and Result Analysis

Performance evaluation was carried out by the WMT 2025 organizer using BLEU, METEOR, ROUGE-L, chrF, TER and Cosine Similarity metrics on the Official test set (Table-3) for both Primary and Contrastive systems submitted. The results published by the organizers are shown in the Table-7.

Primary Systems: Nyishi→English with 60K parallel corpora attained BLEU score of 11.59, English→Khasi with 26K parallel corpora attained BLEU score of 7.34 and Kokborok→English with only 2.2K parallel corpora attained BLEU score of 2.41.

Contrastive Systems: With augmented corpora, overall English→Khasi achieved BLEU score of 19.43 and English→Kokborok 6.99.

Scores of our system for {Nyishi, Kokborok}→English directions are relatively better than that of English→{Nyishi, Kokborok} direction; English→ Khasi performance scores are better than Khasi→English direction.

In terms of ranks, ANVITA on the WMT 2025 official test set, secured First rank for {Nyishi, Kokborok} ↔ English and second for Khasi ↔ English across evaluation metrics including, BLEU, METEOR, ROUGE-L, chrF, TER and Cosine Similarity.

7 Conclusion

WMT 2025 shared task on Low-Resource Indic Language Translation posed significant challenging problem of building robust MT system for extremely low-resource Indian languages, many of which have little presence in digital domain. ANVITA team utilizing multi-pronged approach with transfer learning strategy achieved BLEU score of 2.41-11.59 for 2.2K to 60K corpora and secured top ranks. Overall with augmented data, the team achieved BLEU score of 6.99-19.43 which also fell short of robust MT system threshold indicating need for data augmentation in terms of both quality corpora and synthetic data and innovative techniques for data generation, suitable architectural enhancement and better learning objectives.

Abstract

Low-resource translation for Indic languages poses significant challenges due to limited parallel corpora and linguistic diversity. In this work, we describe our participation in the WMT25 shared task for four Indic languages-Khasi, Mizo, Assamese, which is categorized into Category 1 and Bodo in Category 2. For our PRIMARY submission, we fine-tuned the distilled NLLB-200(600M) model on bidirectional English↔Khasi and English↔Mizo data, and employed the IndicTrans2 model family for Assamese and Bodo translation. Our CONTRASTIVE submission augments training with external corpora from PMINDIA, Google SMOL and GATITOS to further enrich low-resource data coverage. Both systems leverage Low-Rank Adaptation (LoRA) within a parameter-efficient fine-tuning framework, enabling lightweight adapter training atop frozen pretrained weights. The translation pipeline was developed using the Hugging Face Transformers and PEFT libraries, augmented with bespoke preprocessing modules that append both language and domain identifiers to each instance. We evaluated our approach on parallel corpora spanning multiple domains: article based, newswire, scientific, and biblical texts as provided by the WMT25 dataset, under conditions of severe data scarcity. Fine-tuning lightweight LoRA adapters on targeted parallel corpora yields marked improvements in evaluation metrics, confirming their effectiveness for cross-domain adaptation in low-resource Indic languages.

1 Introduction

Low-resource language translation remains one of the most persistent challenges in machine translation (MT), particularly for linguistically diverse regions such as India. We observed that in WMT25 the provided corpora spanned biblical, scientific, news, and article-based domain, introducing significant domain shifts that demanded robust adaptation strategies (Pakray et al., 2025). To address these challenges, we developed two primary systems. The first leveraged IndicTrans2, a transformer-based multilingual model optimized for Indic languages, and the second utilized NLLB-200(600M), a distilled multilingual model trained on over 200 languages. Both systems were fine-tuned using Low-Rank Adaptation (LoRA), enabling efficient domain adaptation without retraining the full model. For our contrastive submission, we augmented the training data with external corpora from sources such as PMINDIA (Haddow and Kirefu, 2020), GATITOS (Jones et al., 2023), and Google SMOL (Caswell et al., 2025), allowing us to explore the impact of data diversity on translation quality. This paper presents our system architecture, training methodology, and evaluation results, with a particular focus on how domain-specific corpora and external augmentation influence performance across four low-resource Indic languages: Khasi, Mizo, Assamese, and Bodo. Our approach employs parameter-efficient fine-tuning via Low-Rank Adaptation (LoRA) on a pre-trained MT model, enabling a detailed empirical analysis of how large-scale architectures can be effectively adapted for low-resource languages under severe data constraints. The findings contribute to the growing body of research on scalable and adaptable MT systems for underrepresented languages.

2 Related Work

Translation quality in low-resource scenarios has been significantly advanced by large-scale multilingual models and lexical augmentation techniques. Fan et al. (2022) introduced No Language Left Behind (NLLB) which demonstrates effective multilingual MT at scale using a Sparsely Gated Mixture of Expert models trained with data that is mined specifically for underrepresented languages.

*Work done at IIT Palakkad.

Proceedings of the Tenth Conference on Machine Translation, pages 1248–1252
November 8-9, 2025

Their approach achieved substantial BLEU improvements and incorporated safety evaluations using FLORES-200 (Fan et al., 2022). Also, Jones et al. (2023) explored bilingual lexica as a lightweight data augmentation method, showing that collected lexical resources such as GATITOS can significantly enhance performance in unsupervised translation settings.

Toolkits like the HuggingFace Datasets library (Lhoest et al., 2021) also made efforts to support data development and reproducibility, which standardizes access to hundreds of multilingual corpora used in MT research.

For evaluation, several automatic metrics have been proposed to correlate better with human judgments. Lin (2004) developed ROUGE, widely used in summarization but also adopted in MT, which computes n-gram overlap and has influenced newer evaluation benchmarks. Banerjee and Lavie (2005) introduced METEOR, which matches unigrams using surface forms, stems and synonyms, incorporating both precision and recall as well as word order. Snover et al. (2006) proposed Translation Edit Rate (TER), also called Translation Error Rate, which measures the number of edits required to change a system output into one of the references. Popović (2015) proposed chrF, a character n-gram F-score metric that outperforms word-level metrics in many segment-level evaluations.

3 Dataset

For our primary submission, we utilized the Indic Machine Translation corpus from the WMT25 Shared Task. This benchmark comprises parallel data for four low-resource Indian languages, stratified into two categories based on training data volume. Category 1 encompasses language pairs with moderate-sized corpora, whereas Category 2 contains the severely data-starved corpora.

The language pairs are delineated as follows:

Category 1: en-as (English ↔ Assamese), en-lus (English ↔ Mizo), en-kha (English ↔ Khasi)

Category 2: en-bodo (English ↔ Bodo)

The parallel corpora supplied by the WMT25 IndicMT shared task[1] were employed for all model development. Each language pair's dataset was randomly divided into training (70 %), validation (20 %), and internal test (10 %) subsets, as detailed in Table 1. In addition, the task organizers released held-out monolingual test sets containing 1,000 sentences per translation direction for each language pair; these sets were used exclusively for final evaluation.

Language	Total Sentences	Train (70%)	Valid (20%)	Test (10%)
Assamese	54,000	37,800	10,800	5,400
Khasi	26,000	18,200	5,200	2,600
Mizo	50,000	35,000	10,000	5,000
Bodo	15,215	10,651	3,043	1,521

Table 1: Summary of Parallel Training Data from the WMT25 Indic MT Dataset.

3.1 Contrastive System Dataset

For a comparative analysis of data augmentation, we constructed a contrastive system by supplementing the WMT25 training dataset with additional publicly available parallel corpora. Our goal was to assess the resulting impact on translation performance across low-resource language pairs.

We incorporated data from four primary sources: the PMINDIA corpus (Haddow and Kirefu, 2020), high-quality parallel corpora for multiple Indian languages, sourced from government websites, official publications, and other public domain materials, covering legal, administrative, and general-purpose domains.; the GATITOS dataset (Jones et al., 2023), which provides lexically-augmented data for multilingual translation; the SMOL dataset (Caswell et al., 2025), containing professionally translated sentences for under-represented languages; and the Tatoeba corpus (Tiedemann, 2020), a large, community-sourced collection of multilingual sentence pairs.

The total volume of parallel data for each language after augmentation is detailed in Table 2. This table delineates the contribution of each external corpus alongside the original WMT data.

Corpus	Assamese (asm)	Bodo (brx)	Khasi (kha)	Mizo (lus)
WMT	54,000	15,216	26,000	50,000
GATITOS	3,975	3,994	4,000	3,998
Smol Sent	0	863	0	863
PMINDIA	9,732	0	0	0
Tatoeba	0	0	1,426	0
Total	67,707	20,073	31,426	54,861

Table 2: Parallel Corpus Statistics for the Contrastive System, detailing the original WMT25 data and supplementary corpora.

4 Methodology

Our methodology is focused on fine-tuning state-of-the-art, pre-trained multilingual translation models that excel in low-resource settings. We chose NLLB-200(600M) (Fan et al., 2022) and IndicTrans2 (Gala et al., 2023) as our core architectures. NLLB-200(600M) , developed under the No Language Left Behind initiative, delivers extensive typological coverage and consistently high translation quality across diverse languages (Fan et al., 2022). IndicTrans2, by contrast, incorporates script-aware tokenization and subword segmentation tailored specifically to Indian languages, yielding superior performance on Indic↔English pairs (Gala et al., 2023).

By fine-tuning these complementary models on the WMT25 IndicMT parallel corpora and on the augmented corpus for our contrastive system, we established a strong performance baseline and systematically quantified the gains afforded by data augmentation.

4.1 Preprocessing

We employed a three-step preprocessing pipeline to ensure data consistency and compatibility with our models:

1. **Text Normalization:** English segments were processed using the `MosesPunctNormalizer` (Koehn et al., 2007), while a custom function (`preproc()`) performed Unicode NFKC normalization and non-printable character removal for Khasi and Mizo.

2. **Language Tagging:** Each sentence was prepended with a language-specific tag (e.g., `<eng_Latn>`, `<kha_Latn>`) to guide the multilingual model during fine-tuning.

3. **Dataset Structuring:** The processed sentence pairs were structured into a Hugging Face `DatasetDict` (Lhoest et al., 2021), enabling efficient batching, shuffling, and training via the `Trainer` API (Wolf et al., 2020).

4.2 System Description

4.2.1 Primary Submission

Our primary systems are based on fine-tuning two state-of-the-art multilingual models—NLLB-200(600M) and IndicTrans2—selected for their complementary strengths on low-resource and Indic-script translations.

NLLB-200(600M) for Khasi and Mizo: We adopted the `facebook/nllb-200-distilled-600M` checkpoint (Fan et al., 2022) for Khasi and Mizo tasks.

Model & Tokenizer: The standard `NLLBTokenizer` handles Mizo without modification; for Khasi we registered a new language token (`<kha_Latn>`) at token ID 256204 to correctly signal the source and target language.

LoRA Fine-Tuning: We applied Low-Rank Adaptation (LoRA) to all linear layers, updating only adapter weights. This approach enables efficient domain adaptation with fewer trainable parameters compared to full fine-tuning. Training ran for 30 epochs under Adafactor (learning rate 1×10^{-5}, batch size 32) with early stopping after 10 evaluations. Evaluation metrics were BLEU, METEOR, ROUGE-L, chrF and TER. Detailed LoRA hyperparameters appear in Table 4.

IndicTrans2 for Bodo and Assamese: For Bodo and Assamese, we used the `ai4bharat/indictrans2-indic-en-dist-200M` model (Gala et al., 2023), which employs an `IndicProcessor` to prepend language tokens such as `<brx_Deva>` and `<asm_Beng>`.

LoRA Fine-Tuning: We mirrored the NLLB-200(600M) setup (Adafactor, 1×10^{-5} learning rate, 32-sentence batch, 30 epochs, early stopping) and applied identical LoRA settings (see Table 4). The resulting adapter checkpoints are saved as lightweight artifacts.

4.2.2 Contrastive Submission

To quantify the effect of data augmentation, we retrained the same base models on extended parallel corpora. The tokenization and training pipeline remained identical, with two key LoRA adjustments to accommodate the increased data volume.

Model Setup: We reused NLLB-200(600M) for Khasi/Mizo (Fan et al., 2022) and IndicTrans2 for Bodo/Assamese (Gala et al., 2023). All supplementary bilingual data underwent the preprocessing and language-tagging workflow described in Section 3.

LoRA Adaptation: We increased the LoRA rank to 64 and α to 128 to provide greater adaptation capacity for the contrastive data, while retaining LoRA's parameter efficiency. Training was reduced to 15 epochs (Adafactor, 1×10^{-5} learning rate,

5 Results

We evaluate our system submissions on the WMT IndicMT shared task for four low-resource Indian languages: Assamese, Khasi, Mizo, and Bodo. Tables 3 presents the comprehensive results for our primary and contrastive submissions respectively across all bidirectional translation pairs. All systems are evaluated using standard automatic metrics including BLEU (Papineni et al., 2002), METEOR (Banerjee and Lavie, 2005), ROUGE-L (Lin, 2004), chrF (Popović, 2015), and TER (Snover et al., 2006).

The results demonstrate that our contrastive submissions generally achieved better or comparable performance across most language pairs and metrics compared to the primary submissions.

6 Conclusion

In this paper, we described the DoDS-IITPKD submissions to the WMT25 Low-Resource Indic Language Translation Task. Our systems were designed for multiple Indic-English and English-Indic translation directions, focusing particularly on Category-I languages of NorthEast India. We explored a combination of pre-trained multilingual models (IndicTrans, NLLB-200(600M)),fine-tuning strategies and LoRA-based efficient adaptation. Future work will focus on more domain-robust adaptation and incorporating quality estimation for improved translation reliability.

7 Acknowledgments

We thank the organizers of the WMT25 Shared Task on Low-Resource Indic Language Translation for providing the datasets and evaluation framework. We also gratefully acknowledge the Department of Data Science, IIT Palakkad, for computing resources and infrastructure support.

Abstract

This paper describes our methodology and findings in building Machine Translation (MT) systems for submission to the WMT 2025 Shared Task on Low-Resource Indic Language Translation. Our primary aim was to evaluate the effectiveness of a phrase-based Statistical Machine Translation (SMT) system combined with a less common subword segmentation strategy for languages with very limited parallel data. We applied multiple Byte Pair Encoding (BPE) merge operations to the parallel corpora and concatenated the outputs to improve vocabulary coverage. We built systems for the English–Nyishi, English–Khasi, and English–Assamese language pairs. Although the approach showed potential as a data augmentation method, its performance in BLEU scores was not competitive with other shared task systems. This paper outlines our system architecture, data processing pipeline, and evaluation results, and provides an analysis of the challenges, positioning our work as an exploratory benchmark for future research in this area.

1 Introduction

Machine Translation (MT) has advanced rapidly in recent years, primarily driven by neural architectures and the availability of large-scale parallel corpora. However, these benefits are often confined to high-resource languages (Koehn and Knowles, 2017), leaving many languages with little or no translation support (Gowda et al., 2021). The WMT 2025 Shared Task on Low-Resource Indic Languages Translation addresses this gap by focusing on languages spoken in India with scarce digital resources.

While many efforts adapt high-resource MT techniques to low-resource settings, direct transfer often fails due to the data-hungry nature of neural networks. This has led to research in areas such as word segmentation and other preprocessing strategies (Ding et al., 2019; Abid, 2020; Huck et al., 2017; Ortega et al., 2020; Lankford et al., 2021; Domingo et al., 2023; Lee et al., 2024) to make systems more viable under data constraints. Although our focus here is on bilingual MT, we acknowledge the rise of multilingual and decoder-only models. Our goal was to investigate how far statistical models, combined with multiple BPE segmentations (Poncelas et al., 2020), could be pushed in highly constrained settings.

Bilingual MT systems have been successfully developed for other under-represented languages, such as Cantonese–Mandarin (Liu, 2022), English–Luganda (Kimera et al., 2025), Wolof–French (Dione et al., 2022), Bavarian–German (Her and Kruschwitz, 2024), and English–Manipuri (Singh et al., 2023; Singh and Singh, 2022), often with transformer-based architectures and customised segmentation like BPE (Li et al., 2024).

Previous work (Yadav et al., 2019; Yadav and Shrivastava, 2021; Akhbardeh et al., 2021) has shown that, for some low-resource Indic languages, SMT can outperform NMT. For the WMT 2025 Shared Task (Pakray et al., 2025), we therefore chose SMT for our systems targeting English $\leftrightarrow$ {Assamese, Khasi, Manipuri}.

The organisers provided parallel corpora for English–Kokborok, English–Bodo, English–Nyishi, English–Manipuri, English–Khasi, English–Mizo, and English–Assamese, building on earlier iterations (Pakray et al., 2024). We set out to determine whether a robust, traditional method like SMT—enhanced with a multiple-BPE data augmentation technique—could remain a viable option in such low-resource scenarios. This paper describes our approach and analyses the performance of our submissions.

2 Background

Low-resource MT faces unique challenges due to the scarcity of high-quality parallel corpora. Data sparsity leads to out-of-vocabulary (OOV) issues

Proceedings of the Tenth Conference on Machine Translation, pages 1253–1258
November 8-9, 2025

and poor generalisation. While Neural Machine Translation (NMT) dominates for high-resource pairs, its high data requirements limit its applicability without substantial augmentation (Sennrich et al., 2016a) or multilingual transfer (Mahata et al., 2023; Johnson et al., 2017).

Phrase-based SMT is often more resilient to small data sizes. By learning from statistical alignments of phrase pairs, it can perform robustly with limited resources.

For languages in the Indic family, which often exhibit rich morphology, subword segmentation is an effective preprocessing step (Prabhugaonkar et al., 2014). BPE, in particular, balances word-level and character-level representations, reduces vocabulary size, and mitigates OOV problems. Inspired by Poncelas et al. (2020), we extended this idea by applying multiple BPE merge operations to produce diverse segmentations, concatenating them to create a richer training set.

3 Data

The shared task corpora were drawn from previous WMT datasets and new resources (Pal et al., 2023; Kakum et al., 2023; Pakray et al., 2024). After preprocessing, we obtained the training statistics shown in Table 1.

Language Pair	# Training Sentences
English–Khasi	26,000
English–Mizo	50,000
English–Assamese	54,000

Table 1: Training data statistics before data augmentation.

Our preprocessing steps included:

- For Latin-script languages: tokenisation, normalisation, and lowercasing using Moses (Koehn et al., 2007).
- For others: processing with the Indic NLP Library (Kunchukuttan, 2020).
- For each parallel corpus: training and applying BPE (Sennrich et al., 2016b) with merge operations of 500, 1000, 2000, and 3000.

The segmented corpora from each merge setting were concatenated and deduplicated (Poncelas et al., 2020), resulting in the statistics in Table 2.

Language Pair	# Training Sentences
English–Khasi	91,379
English–Mizo	186,918
English–Assamese	209,010

Table 2: Training data statistics after concatenation and deduplication of multi-BPE segmentations.

4 System Description

We used Moses (Koehn et al., 2007) for phrase-based SMT, with target-side KenLM language models (Heafield, 2011) trained on the corpora in Table 2. Each system was evaluated under four inference configurations:

- **1000 BPE** segmented source
- **2000 BPE** segmented source
- **3000 BPE** segmented source
- **Combined Hypothesis**, selecting the output with the highest probability among the above. We select translation that exhibit an average log-likelihood of -1.0 or higher, according to measurements taken by the fairseq-interactive tool.

5 Results

Our systems were tested on the official WMT 2025 English–Nyishi, English–Khasi, and English–Assamese sets. In all cases, performance ranked in the lower tier, with BLEU scores notably behind top-performing NMT systems that likely used external data or more advanced architectures. Full results are shown in Tables 3 and 4.

6 Discussion

The modest results highlight the limitations of SMT in this setting. Two main factors likely contributed:

1. SMT's inability to capture long-range dependencies and nuanced patterns compared to modern neural models.
2. The data augmentation via multiple BPE segmentations did not sufficiently overcome the extreme scarcity of parallel data, particularly for Nyishi.

Noisy and domain-specific terms in the provided corpora may have further impacted translation quality.

7 Conclusion and Future Work

Our participation in the WMT 2025 Shared Task was an exploratory test of a multi-BPE augmentation strategy in an SMT framework for extremely low-resource Indic language pairs. While the method did not yield competitive results, it provides a clear baseline for SMT in these settings and reinforces the potential value of hybrid or neural approaches. Future work will explore SMT–NMT hybrids, fine-tuning large multilingual models on limited data, and advanced augmentation methods such as back-translation.

Abstract

In this paper, we describes our system for the WMT 2025 Low-Resource Indic Language Translation Shared Task. The language directions addressed are Assamese↔English and Manipuri→English. We propose a method to improve translation performance from low-resource languages (LRLs) to English by injecting Language-specific word-level noise into the parallel corpus of a closely related high-resource language (HRL). In the proposed method, word replacements are performed based on edit distance, using vocabulary and frequency information extracted from an LRL monolingual corpus. Experiments conducted on Assamese and Manipuri show that, in the absence of LRL parallel data, the proposed method outperforms both the w/o noise setting and existing approaches. Furthermore, we confirmed that increasing the size of the monolingual corpus used for noise injection leads to improved translation performance.

1 Introduction

There are approximately 7,000 languages in the world, but only a small subset of high-resource languages (HRLs) have sufficiently developed parallel corpora for machine translation (MT). For these languages, research leveraging few-shot learning with parallel data (Zhu et al., 2023) and large-scale multilingual language models (mLLMs) (Xu et al., 2023; Zhou et al., 2023) has progressed. Such efforts have enabled the learning of shared cross-lingual embedding spaces, thereby facilitating cross-lingual transfer.

In contrast, many languages are low-resource languages (LRLs) for which only monolingual data is available. Compared to parallel data, monolingual data is easier to collect and is widely used for techniques such as back-translation (BT)(Sennrich et al., 2016a) and continued pretraining of mLLMs. This study aims to improve LRL→English translation accuracy by leveraging LRL monolingual data to inject language-specific, word-level noise into parallel data of closely related HRLs.

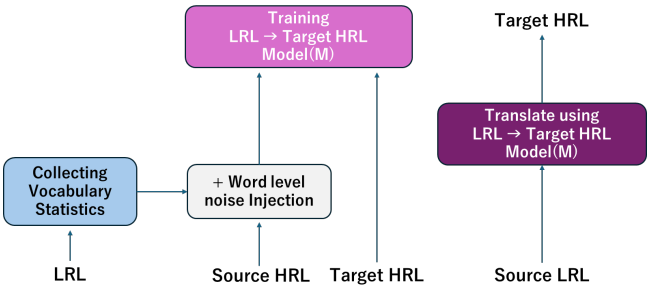

Figure 1: Overview of our proposed method: Language-Specific Word-Level Noise Injection

Maurya et al. (2024) proposed CharSpan, a method that injects character-level noise into HRL parallel data with high lexical similarity to a LRL. This method improves translation accuracy for the LRL by leveraging its character list. However, this approach does not sufficiently capture word-level statistical characteristics such as the LRL's vocabulary frequency and distribution.

To address this limitation, we propose a method that uses word lists and frequency information extracted from LRL monolingual data to add word-level noise to HRL parallel data. We further analyze the effect of this method under conditions where LRL parallel data is available versus unavailable. Experimental results show that when using only LRL monolingual data, our method outperforms existing approaches. In contrast, when LRL parallel data is available, the performance gap with existing methods is small. We also observe that increasing the size of the monolingual data used for noise injection tends to improve performance, and that including the test dataset in the monolingual data yields additional performance gains.

2 Related Work

Some studies have examined the effects of adding noise to parallel data on its diversity and the ro-

Proceedings of the Tenth Conference on Machine Translation, pages 1259–1264
November 8-9, 2025

bustness of translation models, but the impact on cross-lingual transfer has not been thoroughly investigated. Gal and Ghahramani (2016) proposed Word Dropout, which randomly sets some word embeddings to zero vectors. Wang et al. (2018) proposed a data augmentation method that adds random word replacements to parallel data. While both of these methods enhance the diversity of parallel data, their effectiveness in improving cross-lingual transfer capability is limited.

A representative data augmentation technique that leverages monolingual data in neural machine translation is back-translation (BT) (Sennrich et al., 2016a). When parallel data is scarce, BT generates pseudo-parallel data by using target-side monolingual data and a reverse-direction translation model. More recently, iterative back-translation (IBT) (Morita et al., 2018; Hoang et al., 2018; Zhang et al., 2018) has been proposed, which extends BT in both directions. IBT utilizes monolingual data from both sides to generate pseudo-parallel data in both directions and iteratively alternates between generating this data and updating the translation models in both directions.

3 Method

In this chapter, we propose a method to enhance robustness in LRL→En translation and promotes cross-lingual transfer by adding LRL-specific word-level noise into a parallel corpus of a closely related HRL. The noise consists solely of word replacements, where the edit distance is selected based on a geometric distribution. The replacement candidates are chosen using frequency-weighted selection, thereby injecting LRL words into the related HRL.

Specifically, we use approximately 160,000 sentences of Assamese monolingual text to add noise to Bengali–English parallel data. Figure 1 shows an overview of the proposed method. An example of the noise injection process is illustrated in Figure 2. Furthermore, by using the model trained on the noise-injected parallel data as a back-translation model, we perform En→LRL translation.

3.1 Language-Specific Word-level noise

We add word-level noise to the source-side training data D_{HRL} of the HRL pair to create the noisy parallel data D'_{HRL}.

First, we randomly select a word index x_i from any given sentence x. Next, we determine the edit distance d according to Equation 1, where p is the success probability of the geometric distribution:

HRL(Bn): এমন কথা কিন্তু তিনি আপনাকে কোনওদিনও বলেননি ।
Eng: But he never told me.

HRL(Bn) + Noise: এমন কথা সিল্কু তিনি আপনাকে কোনোদিনে বলেননি ।

Figure 2: Example of word-level noise injection for Bengali (HRL). The original Bengali sentence and its English sentence are shown at the top. In the noisy version (bottom), Bengali words are replaced with words selected from an Assamese vocabulary list.

$$P(d = k) \propto p(1-p)^{k-1} \quad (k = 1, 2, \ldots, K) \quad (1)$$

The parameters K and p control the distribution of noise magnitude. Then, based on the edit distance between a candidate word w and x_i, we extract a candidate set $V(d, x_i)$ from the LRL vocabulary V_{LRL}:

$$V(d, x_i) = \{w | w \in V_{LRL}, ED(w, x_i) = d\} \quad (2)$$

Here, $ED(\cdot, \cdot)$ denotes the Levenshtein distance. The replacement word w' is selected according to the product of $P(d)$ and the relative word frequency $f(w')$ in the LRL monolingual corpus:

$$P(w') = P(d) \cdot \frac{f(w')}{\sum_{w \in V(d, x_i)} f(w)} \quad (3)$$

This procedure is repeated until the proportion of characters changed by substitution in each sentence reaches a predefined target ratio.

3.2 Back translation

In this study, we apply translation model M, trained on HRL parallel data D'_{HRL} augumented with word-level noise, to LRL-to-English translation. Specifically, to perform EN→LRL translation, we first translate the LRL monolingual data into English using M, thereby creating pseudo-parallel data $\hat{D}_{\mathrm{LRL-EN}}$.

Subsequently, this pseudo-parallel data is used as input to train an English→LRL translation model.

4 Experimental Setup

4.1 Datasets

We target Bengali (Bn) as the HRL and Assamese (As) and Manipuri (Mni) as the LRLs, using multiple parallel and monolingual corpora for model

Corpora	Language	Usage	# Sentences
Samanantar	English-Bengali	Train	8,604,580
WMT25 Shared Task	English-Assamese	Train / Valid	Train: 53,003 Valid: 997
	English-Manipuri	Train / Valid	Train: 22,690 Valid: 997
FLORES-200	English-(Bengali, Assamese, Manipuri)	Valid / Test	Valid: 977 Test: 1,012
Community 2017 Wikipedia 2021	Assamese	Noise Injection	63,627 100,000

Table 1: Overview of the parallel and monolingual corpora used in this study, including the languages, their intended usage, and the number of sentences.

training and evaluation. Table 1 provides an overview of the corpora used. For parallel corpora, we used the large-scale English–Bengali Samanantar corpus(Ramesh et al., 2022) and the English–Assamese and English–Manipuri parallel datasets provided by the WMT25 shared task(Pal et al., 2023; Pakray et al., 2024). For evaluation, we used the validation and test sets of FLORES-200(Costa-Jussà et al., 2022). Additionally, Assamese Wikipedia 2021 and Community 2017 were used as monolingual corpora to extract vocabulary for noise injection in the proposed method.

4.2 Data Preprocessing

For English data, we first perform Unicode normalization (NFKC) and applied tokenization using `sacremoses`. Next, to reduce case variation at sentence beginnings and in proper nouns, we applied truecasing, and finally, we learned and applied Byte Pair Encoding (BPE)(Sennrich et al., 2016b; Gage, 1994) using `subword-nmt`. The number of BPE merge operations was set to 16,000.

For Bengali, Assamese, and Manipuri data, we applied the same preprocessing steps as for English—NFKC normalization, tokenization with `sacremoses`, and BPE (16,000 merges)—but did not apply truecasing.

4.3 Settings

For the word-level noise injection, the maximum edit distance K was set to 5, and the actual edit distance was sampled from a geometric distribution with a success probability $p = 0.5$. Noise was injected to each sentence until the proportion of characters altered by substitution reached the target ratio of 10%. Figure 4 shows the list of replacement characters used in CharSpan.

Parameter	Value
Architecture	Transformer (Encoder 6 layers / Decoder 6 layers)
Optimizer	Adam ($\beta_1 = 0.9$, $\beta_2 = 0.98$)
Initial learning rate	$5e-4$
LR scheduler	Inverse Sqrt Decay
Gradient clip norm	1.0
Dropout	0.2
Max tokens / batch	8,000
Early-stopping patience	5 validations
GPU	2 × NVIDIA GeForce RTX 2080 Ti

Table 2: Model implementation and training details

We adopted the Transformer architecture (Vaswani et al., 2017) as the translation model. Both the encoder and decoder consisted of 6 layers, and optimization was performed using Adam (Kingma and Ba, 2014) with parameters $\beta_1 = 0.9$ and $\beta_2 = 0.98$. The initial learning rate was set to 5×10^{-4}, with Inverse Sqrt Decay as the learning rate scheduler. To prevent gradient explosion, the gradient clip norm was set to 1.0. The dropout rate was set to 0.2, and the maximum number of tokens per batch was 8,000. Training employed early stopping, terminating when the validation loss did not improve for 5 consecutive evaluations. Experiments were conducted using two NVIDIA GeForce RTX 2080 Ti GPUs. Table 2 presents the key hyperparameter settings used in our experiments.

4.4 Evaluation Metrics

For validation and evaluation, we used the official FLORES-200 dev/test sets. BLEU (Papineni et al., 2002) and chrF++ (Popović, 2017) were adopted as evaluation metrics.

5 Result and Analisys

5.1 Main Results: LRL→EN

Table 3 presents the translation results from LRL to English. **Bold** indicates the highest score in each setting. In the setting without LRL parallel

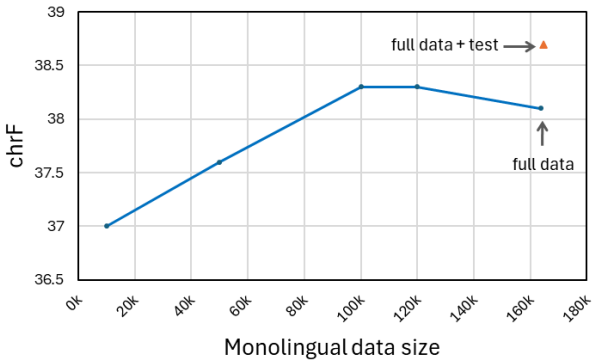

Figure 3: Effect of Assamese monolingual data size and domain on chrF scores for Assamese→English translation.

data, the proposed method outperformed both the w/o noise and CharSpan baselines for Assamese across all evaluation metrics. This improvement is likely due to the effective utilization of vocabulary and word frequency distributions derived from Assamese monolingual data. In contrast, for Manipuri, the proposed method underperformed compared to both baselines.

When LRL parallel data was used, the proposed method outperformed w/o noise for both languages, but achieved only comparable gains to CharSpan. This suggests that when w/o noise already possesses a moderate level of translation capability, the improvements brought by noise injection may be limited. Furthermore, for Manipuri, the presence or absence of LRL parallel data resulted in differing levels of improvement, indicating that the proposed method is effective when the w/o noise already has a certain degree of translation capability.

5.2 Effects of Monolingual Data Size and Domain for Noise Injection

The noise injection function used in this study (Equation 3) extracts replacement candidates from the LRL vocabulary with frequency weighting. Expanding the size of the monolingual corpus increases the likelihood of selecting more informative candidates. To verify this effect, we conducted experiments in which the amount of monolingual data was restricted. Starting from the full Assamese monolingual pool, we create down-sampled subsets with the following sentence counts (vocabulary sizes): *120k* (154,461), *100k* (139,751), *50k* (93,797) and *10k* (33,620). Additionally, we evaluate a setting where the full monolingual data is augmented with the Assamese test sentences from FLORES-200 (*full data + test*). For each subset, we learn BPE, train the model with the same configuration as described in Table 2, and evaluate it on FLORES-200.

The results are shown in the figure 3. The full data + test setting achieved the highest score of 38.7, slightly surpassing the 38.1 of the full data setting. The 120k and 100k settings both yielded similar performance at 38.3, while 50k achieved 37.6 and 10k scored 37.0, showing a gradual decline in performance as the amount of data decreased. These results suggest that increasing the size of the monolingual data makes it easier to select more informative replacement candidates during noise injection, potentially leading to improved translation performance. Furthermore, in the full data + test setting, including sentences from the same domain as the evaluation data in the monolingual corpus may have contributed to the performance improvement.

5.3 Shared Task Results

Table 5, presents the evaluation results of LRL↔English translation on the test set provided in the shared task. The evaluation metrics are BLEU, METEOR(Banerjee and Lavie, 2005), ROUGE-L(Lin, 2004), chrF, and TER(Snover et al., 2006). The translation directions are Assamese→English, English→Assamese, and Ma-

Direction	BLEU↑	METEOR↑	ROUGE-L↑	chrF↑	TER↓
Assamese→English	12.28	0.54	0.56	55.61	78.24
English→Assamese	14.03	0.38	0.01	53.76	74.08
Manipuri→English	5.74	0.33	0.37	41.28	109.95

Language	Script	Candidate Alphabets
Assamese	Bengali	'ঁ', 'ং', 'ঃ', 'অ', 'আ', 'ই', 'ঈ', 'উ', 'ঊ', 'ঋ', 'এ', 'ঐ', 'ও', 'ঔ', 'ক', 'খ', 'গ', 'ঘ', 'ঙ', 'চ', 'ছ', 'জ', 'ঝ', 'ঞ', 'ট', 'ঠ', 'ড', 'ঢ', 'ণ', 'ত', 'থ', 'দ', 'ধ', 'ন', 'প', 'ফ', 'ব', 'ভ', 'ম', 'য', 'ল', 'শ', 'ষ', 'স', 'হ', '়', 'া', 'ি', 'ী', 'ু', 'ূ', 'ৃ', 'ে', 'ৈ', 'ো', 'ৌ', '্', 'ৎ', 'ড়', 'ঢ়', 'য়', '০', '১', '২', '৩', '৪', '৫', '৬', '৭', '৮', '৯', 'ৰ', 'ৱ'

Figure 4: Candidate alphabets for Assamese in the Bengali script, used as noise for CharSpan.

nipuri→English.

Our system was particularly designed for the Assamese→English direction. The performance gap between Assamese and Manipuri reflects the disparity in the availability of monolingual and parallel data, as well as differences in vocabulary and grammar with Bengali. These results indicate that the proposed method is especially effective for LRLs that are lexically close to the corresponding HRL.

6 Conclusion

In this study, we proposed Language-specific word-level noise injection method for the parallel corpus of a HRL closely related to a LRL, using vocabulary and frequency information extracted from the LRL's monolingual data. Experiments on Assamese and Manipuri demonstrated that, particularly in the absence of parallel data, the proposed method outperforms both the w/o noise setting and existing approaches. Furthermore, we showed that increasing the size of the monolingual data contributes to improved translation performance.

Limitations

First, the proposed method targets only a limited set of LRLs (Assamese and Manipuri), and its applicability to other languages has not been verified. In particular, it may be difficult to apply the method to LRLs whose script systems and lexical structures differ substantially from those of the HRL. Furthermore, the selection of replacement candidates for noise injection relies on word frequency and edit distance derived from the monolingual corpus of the LRL, and the potential for performance improvement may be limited depending on the scale of these statistics and the domain of the corpus.

Abstract

This paper describes our submission to the Indic MT 2025 shared task, where we trained machine translation systems for five low-resource language pairs: English–Manipuri, Manipuri–English, English–Bodo, English–Assamese, and Assamese–English. To address the challenge of out-of-vocabulary errors, we introduced a Named Entity Translation module that automatically identified named entities and either translated or transliterated them into the target language. The augmented corpus produced by this module was used to fine-tune a Transformer-based neural machine translation system. Our approach, termed HEMANT (Highly Efficient Machine-Assisted Natural Translation), demonstrated consistent improvements, particularly in reducing named entity errors and improving fluency for Assamese–English and Manipuri–English. Official shared task evaluation results show that the system achieved competitive performance across all five language pairs, underscoring the effectiveness of linguistically informed preprocessing for low-resource Indic MT.

1 Introduction

This paper presents our submission to the IndicMT 2025 shared task, where we developed machine translation (MT) systems for five language pairs: English–Assamese, Assamese–English, English–Manipuri, Manipuri–English, and English–Bodo. The systems follow a two-stage pipeline comprising preprocessing and neural machine translation (NMT). In preprocessing, the source text undergoes tokenization, spelling normalization, and source-side linguistic analysis, with particular focus on identifying and translating named entities into the target language to reduce out-of-vocabulary (OOV) errors. The processed corpus is then used to train NMT models based on an encoder–decoder architecture, with subword segmentation applied via the SentencePiece tokenizer using the Byte Pair Encoding (BPE) model to improve vocabulary coverage and generalization. The resulting systems integrate named entity handling with standard NMT methods, thereby enhancing translation quality across the five language pairs.

2 Related Work

Research in Indic machine translation has increasingly emphasized the use of multilingual pretrained models and transfer learning to overcome data scarcity. The IndicTrans system (Ahuja et al., 2022) demonstrated the effectiveness of multilingual Transformer pretraining for Indian languages, providing strong baselines for Indo-Aryan and Dravidian pairs. More recently, No Language Left Behind (NLLB-200) (Costa-jussà et al., 2022) has scaled this paradigm further, offering pretrained models across 200 languages, including Assamese, thereby enabling robust fine-tuning for low-resource Indic settings.

The benefits of transfer learning for low-resource machine translation have been well-documented. Zoph and Knight (2016) showed that multi-source translation improves performance by leveraging related languages, while Nguyen and Chiang (2017) highlighted the effectiveness of cross-lingual transfer in low-resource neural MT. In the Indic context, transfer between closely related languages such as Bengali and Assamese or

Proceedings of the Tenth Conference on Machine Translation, pages 1265–1270
November 8-9, 2025

Manipuri and Bodo provides an opportunity to exploit linguistic similarities for improved translation performance.

Subword segmentation strategies have also been an important focus. Sennrich et al. (2016) introduced Byte Pair Encoding (BPE) as a means to mitigate out-of-vocabulary issues, while Kudo and Richardson (2018) proposed the Unigram Language Model as an alternative. More recently, Ahmed et al. (2023), in the WMT 2023 shared task, compared segmentation schemes across low-resource languages and showed that alternative approaches can outperform BPE in certain settings.

Efforts to improve named entity handling in MT are relatively fewer. Joshi and Katyayan (2023) and Sharma et al. (2023) demonstrated that augmenting training corpora with entity translations significantly reduces OOV errors in English–Braille and Hindi–English systems, respectively. Our work extends this line by systematically integrating a Named Entity Translation module into the preprocessing pipeline for Indic language pairs.

3 System Description

3.1 Data Preprocessing

Text tokenization and spelling correction were first performed on the source language corpus. Spelling normalization was applied to reduce orthographic inconsistencies in the corpora, particularly for Assamese and Manipuri. For Assamese, Unicode normalization was enforced, and common spelling variants arising from character duplication or visually similar graphemes were standardized using a manually crafted rule set. For Manipuri and Bodo, we implemented an edit-distance–based correction method (Levenshtein distance) supplemented with frequency statistics from the training corpus. Candidate corrections were chosen from a lexicon compiled from Wikipedia dumps, news portals, and government gazetteers, with the most frequent form selected when multiple candidates were available. This preprocessing step reduced vocabulary sparsity and improved token consistency prior to subword segmentation.

Subsequently, named entities were extracted using the in-house developed Bi-LSTM–based POS tagger (Nathani et al., 2023). The extracted named entities were then classified into the MUC-6 categories (Grishman et al., 1996) through a rule-based approach. These annotated entities were cross-referenced with a knowledge base containing target language translations for source language organization and location names.

The Named Entity Translation module relied on resources compiled from multiple sources. Gazetteers of Indian locations and organization names were collected from publicly available repositories such as the Wikipedia category lists, and official government publications. Entities not present in the knowledge base were transliterated using a rule-based transliteration scheme, which maps source graphemes to phoneme-equivalent representations before rendering them in the target script. This approach preserved phonological similarity across languages, ensuring that named entities remained intelligible even in the absence of dictionary support. In future work, we plan to explore phoneme-to-grapheme transliteration models trained using transformer-based sequence-to-sequence architectures for improved accuracy.

A rule-based NER system was employed to extract named entities from the source language corpus (Suri et al., 2024). Once identified, these entities were searched in the knowledge base for their corresponding English translations. When a translation was available, the entity in the source language corpus was replaced with its target language equivalent. In cases where no translation was present in the knowledge base, the entities were instead transliterated into the target language and then replaced in the corpus.

This process constituted the Named Entity Translation module, which systematically identified named entities and translated or transliterated them into target language, depending on the availability of translations (Sharma et al., 2023; Joshi & Katyayan, 2023). The functioning of this module is illustrated in Figure 1.

A BiLSTM-based POS tagger was used to bootstrap named entity recognition, as gold-standard BIO-annotated NER corpora for Manipuri and Bodo were not available at the time of system development. POS tags provided coarse-grained syntactic cues (e.g., proper noun categories) which, when combined with rule-based heuristics, enabled the identification of named entities. While this approach proved effective in resource-constrained settings, we acknowledge its limitations compared to transformer-based BIO tagging. Future extensions of this work will evaluate pre-trained multilingual NER models such as IndicNER and

XLM-R–based fine-tuned taggers, which are expected to improve robustness.

3.2 Sub-Wording

We adopted Byte Pair Encoding (BPE) for subword segmentation using SentencePiece. BPE was selected due to its effectiveness in balancing vocabulary compactness and coverage, a crucial factor for low-resource settings where unseen tokens are frequent (Sennrich et al., 2016). Although alternative segmentation schemes such as the Unigram Language Model (Kudo & Richardson, 2018) have been shown to perform competitively in recent work (Ahmed et al., 2023; WMT 2023 Shared Task Report), preliminary trials indicated that BPE produced more stable vocabularies across our diverse Indic language pairs. A systematic comparison with alternative subword models remains an avenue for future research.

3.3 Training the Model

For the training of the NMT systems, preprocessing steps were applied. This process was as follows: Part-of-Speech (POS) tagging was first applied to source language sentences, after which Named Entity Recognition (NER) was conducted using a rule-based module. The identified named entities were then translated or transliterated according to the procedure described in the previous section, thereby producing an augmented source sentence for the training corpus.

For example, consider the Sindhi sentence: "নিশীথ জোশী নতুন দিল্লী ৰ ইন্দিৰা গান্ধী আন্তর্জাতিক বিমানবন্দৰ পৰা জয়পুৰলৈ যাত্রা কৰি আছিল।" In this sentence, "নিশীথ জোশী (Person), নতুন দিল্লী (Location), জয়পুৰ (Location)," and "ইন্দিৰা গান্ধী আন্তর্জাতিক বিমানবন্দৰ (Organization)" are named entities. Among these, "নিশীথ জোশী" and "জয়পুৰ" were not present in the knowledge base and were therefore transliterated as "Nisheeth Joshi" and "Jaipur." The remaining entities were looked up in the knowledge base sequentially. While "নতুন দিল্লী" was not found and was thus transliterated as "New Delhi," "ইন্দিৰা গান্ধী আন্তর্জাতিক বিমানবন্দৰ" was translated as "Indira Gandhi International Airport."

Using this methodology, the entire training corpus was augmented with translated and transliterated named entities. The workflow of the system is illustrated in Figure 2, while the hyperparameters used for training both systems are summarized in Table 1. The overall approach is named as HEMANT (Highly Efficient Machine Assisted Natural Translation).

Our systems were built on top of the No Language Left Behind (NLLB-200) pretrained multilingual model (Costa-jussà et al., 2022), which supports several Indic languages including Assamese. Instead of training from scratch—which is often infeasible for low-resource settings due to limited parallel corpora—we adopted a transfer learning approach by fine-tuning NLLB-200 on the shared task training data provided by the organizers.

Minimum_learning_rate	0.00001
Max_steps	1000000

Tabel 1: Hyperparameters Used in Training NMT Models

The base architecture of NLLB-200 is a Transformer encoder–decoder model with multi-head attention, residual connections, and layer normalization, optimized for cross-lingual transfer. Fine-tuning was carried out by unfreezing all layers of the model, while maintaining pretrained multilingual subword embeddings. Subword embeddings were initialized from the NLLB model's vocabulary, which itself is trained using a combination of BPE and SentencePiece across 200 languages. This initialization ensured robust handling of rare tokens and morphologically complex forms.

Fine-tuning was performed separately for each language pair, with learning rate schedules tuned to prevent catastrophic forgetting of pretrained knowledge. For language pairs with extreme data scarcity (e.g., Bodo), multi-directional fine-tuning

was explored by jointly optimizing the model on related language pairs, leveraging cross-lingual similarity between Assamese and Bengali for Indo-Aryan, and Manipuri and Bodo for Tibeto-Burman families.

This strategy balanced the benefits of pretrained multilingual representations with task-specific adaptation. We found that fine-tuning NLLB-200 significantly stabilized training compared to Transformer models trained from scratch, which often struggled to converge on the limited IndicMT corpora.

4 Evaluation

We participated in the shared task by training the models on the training corpus provided by the organizers and submitted the outputs generated by the systems, using the test corpus, for official evaluation. The corresponding results provided by the organizing team are presented in Table 2. For Assamese-English, English-Assamese, English-Manipuri and Manipuri-English language pairs; our system performed fairly well. We could not provide the same results for English-Bodo, possibly due to very less training corpus.

5 Conclusion

This paper presented HEMANT, our submission to the WMT 2025 Indic MT shared task, focusing on five low-resource language pairs. The integration of a Named Entity Translation module reduced out-of-vocabulary errors and improved translation fluency. While absolute scores remain modest, the relative improvements highlight the value of linguistically informed preprocessing.

In future work, we plan to explore cross-lingual transfer strategies by leveraging related languages (e.g., Bengali–Assamese). Compare alternative subwording methods (BPE vs Unigram LM). Incorporate backtranslation and synthetic data augmentation for extremely low-resource languages and replace POS-based NER heuristics with multilingual pretrained BIO tagging models.

Abstract

This study tackles the WMT 2025 low-resource Indic language translation task (EnglishAssamese, EnglishManipuri) by proposing a cross-iterative back-translation and data augmentation strategy using dual pre-trained models.Leveraging IndicTrans2_1B and NLLB_3.3B, the approach alternates fine-tuning and back-translation to iteratively generate high-quality pseudo-parallel corpora. Monolingual data relevance is enhanced via semantic similarity filtering with all-mpnet-base-v2, while training data is cleaned and normalized to improve quality. During inference, outputs from both fine-tuned models are combined to further boost translation performance in low-resource scenarios.

1 Introduction

India boasts a rich linguistic ecosystem, yet numerous languages suffer from limited digital resources. These low-resource languages face significant challenges in the construction and application of machine translation systems. Particularly, Assamese and Manipuri in the northeastern region not only lack parallel corpora and high-quality monolingual corpora but also exhibit large differences in linguistic structure and writing systems, posing additional difficulties for the training of Neural Machine Translation (NMT) models. Under low-resource conditions, traditional neural machine translation methods cannot fully leverage the advantages of large-scale data, resulting in limited model generalization ability and translation quality. Therefore, exploring how to efficiently utilize limited bilingual and monolingual data and effectively transfer cross-lingual knowledge has become a core issue in improving the translation performance of low-resource languages. The study selects open-source IndicTrans2-1B and NLLB-3.3B as the core translation models, combines multiple rounds of iterative back-translation to generate high-quality pseudo-parallel corpora, uses semantic similarity filtering technology to enhance the alignment between monolingual data and the task, and reduces the interference of noisy data on training through strict data cleaning and standardization operations. During the inference phase, the outputs of the two models are compared and selected, with the optimal result serving as the final translation output. This study aims to verify the effectiveness of cross-model collaborative back-translation mechanisms, data similarity augmentation, and multi-source result fusion in low-resource translation tasks, providing reusable technical routes and empirical experience for future multilingual low-resource machine translation research.

2 Dataset

All parallel data used in this study are derived from the official bilingual data provided by the WMT 2025 Low-Resource Indic Language Translation track, covering two directions: EnglishAssamese (en-as) and EnglishManipuri (en-mni). The data scale is shown in Table 1. Among them, the en-as direction contains 54,000 training sentence pairs, the en-mni direction contains 23,000 training sentence pairs, and both directions provide validation sets and test sets respectively.

A sampling analysis of the official test set reveals a concentrated domain distribution: healthcare accounts for 65.29%, entertainment and sports for 23.56%, and culture for 11.15%. To maximize domain consistency with the test set during the data augmentation phase, the study collects English monolingual data from the NLLB open corpus, BPCC open-source dataset, and specific website crawls. The open-source semantic similarity model all-mpnet-base-v2 is used to calculate the semantic similarity between the collected data and the test set samples. Sampling and filtering are performed in high-similarity data according to the

Proceedings of the Tenth Conference on Machine Translation, pages 1271–1275

Language Pair	Train	Val	Test
en-as	54,000	2,000	2,000
en-mni	23,000	1,000	1,000

Table 1: Scale of WMT 2025 Official Bilingual Dataset

above domain proportions, ultimately obtaining approximately 100,000 highly relevant English monolingual sentences for back-translation to generate pseudo-parallel corpora.

During the data cleaning phase, strict processing is uniformly applied to bilingual and monolingual data: removing sentences containing URLs, HTML tags, and non-linguistic characters; eliminating samples that failed to be translated or deviated from the source language in back-translation; standardizing symbols, checking and correcting English capitalization rules for the first letter; and removing duplicate sentences and abnormally short sentences. These operations significantly reduce the proportion of noisy data and ensure that the data domain distribution is highly consistent with the official test set, providing high-quality data support for subsequent cross-iterative back-translation and model optimization.

3 System Methodology

3.1 Pre-trained Models

This study is based on two open-source multilingual neural machine translation pre-trained models: IndicTrans2_1B (Kunchukuttan et al., 2023) and NLLB_3.3B (Fan et al., 2022).

• **IndicTrans2_1B**: A Transformer-based machine translation model optimized for 22 official languages of India and various related languages. It performs excellently in many-to-many, many-to-one, and one-to-many translation tasks, especially suitable for handling Indic languages with complex morphology and scarce training data (Kunchukuttan et al., 2023).

• **NLLB_3.3B (No Language Left Behind)**: A large-scale multilingual translation model proposed by Meta AI, covering more than 200 languages and possessing strong generalization ability in cross-lingual transfer (Fan et al., 2022).

The core reason for selecting these two models lies in their complementarity in multilingual environments: IndicTrans2_1B has obvious advantages in the fine-grained processing of Indic languages, while NLLB_3.3B is more robust in cross-lingual structure mapping and low-resource direction generalization. Their combination helps obtain more diverse and high-quality pseudo-parallel data under extremely low-resource conditions.

3.2 Direction-Specific Fine-Tuning

In the first phase of system construction, the above two models are respectively fine-tuned in one-to-one directions on the bilingual parallel corpora provided by WMT 2025, covering four translation directions: en→as, as→en, en→mni, and mni→en.

One-way translation fine-tuning at the granularity of translation directions enables the model to focus on learning the syntactic, lexical, and domain features of that direction. Compared with directly training a multilingual multi-directional model, it can avoid cross-direction interference and achieve higher convergence speed and better direction adaptability in low-resource scenarios. The training results of this phase serve as the baseline models for subsequent back-translation augmentation.

During the fine-tuning phase for NLLB_3.3B, LoRA (Low-Rank Adaptation) parameter-efficient fine-tuning technology is adopted, with specific configurations as follows (Hu et al., 2021):

• rank: 128
• alpha: 256
• dropout: 0.1
• Fine-tuning modules: All linear layers

LoRA injects low-rank matrix parameters into the model's linear layers, keeping most original parameters frozen and only updating a small number of trainable parameters, which significantly reduces memory usage and training costs while maintaining model performance. This design is particularly effective for models at the 3.3B scale, enabling high-quality directional fine-tuning to be completed under single-card or low-resource computing power conditions (Hu et al., 2021).

3.3 Monolingual Data Back-Translation Augmentation

The second phase introduces 100,000 English monolingual sentences with a domain proportion highly consistent with the test set to improve the model's adaptability in the target domain. This monolingual data is sourced from the NLLB open corpus, BPCC open-source data, and domain-specific web crawls. It is matched and filtered with test set samples using the all-mpnet-base-v2 semantic similarity model to ensure the domain distribution proportion is consistent with the test

set (65.29% healthcare, 23.56% entertainment and sports, 11.15% culture).

Based on the two fine-tuned models obtained in the first phase, dual-model back-translation is implemented, which is a widely used data augmentation technique in low-resource machine translation to generate pseudo-parallel corpora (Sennrich et al., 2016):

1. IndicTrans2_1B translates English monolingual sentences into the target language, generating pseudo-parallel corpus set D1;

2. NLLB_3.3B translates English monolingual sentences into the target language, generating pseudo-parallel corpus set D2.

D1 and D2 are respectively merged with the official parallel data to fine-tune IndicTrans2_1B and NLLB_3.3B again, forming the first-round augmented models. Taking "back-translation → merging → fine-tuning" as a cycle, the iteration is performed until the BLEU score of the development set no longer improves. In actual experiments, significant improvements can be achieved with two iterations, and the third iteration is difficult to bring additional benefits. Therefore, two iterations are finally adopted as the optimal solution.

This dual-model iterative back-translation augmentation method fully leverages the complementary advantages of the two pre-trained models in language modeling and cross-lingual generalization, significantly enriches the diversity and domain coverage of training data in low-resource directions, and thereby improves the translation performance of the final system (Sennrich et al., 2016).

4 Experimental Results and Analysis

Table 2 shows the BLEU score performance of different systems and data augmentation strategies in the four translation directions (en→as, en→mni, as→en, mni→en). The experiment compares the performance changes of IndicTrans2_1B and NLLB_3.3B under one-way fine-tuning on official data, different back-translation data augmentations, and dual-model iterative back-translation.

Table 2: BLEU Scores of Different Systems and Data Augmentation Strategies on WMT 2025 Development Set. Note: "–" indicates that this combination was not tested in this direction or the results were not included in the statistics. We use the following abbreviations: OFT denotes One-way Fine-Tuning, off denotes official data,BT denotes Back-Translation, it and nllb denote different back-translated datasets, LoRA denotes Low-Rank Adaptation, and DBT denotes Dual Back-Translation.

4.1 Significant Gains from One-Way Fine-Tuning

After one-way (one-to-one) fine-tuning using official parallel corpora, both baseline models show significant improvements in BLEU scores across all tested translation directions:

• IndicTrans2_1B increases from 29.20 to 40.36 (+11.16 BLEU) in the as→en direction, and from 34.74 to 44.35 (+9.61 BLEU) in the mni→en direction;

• NLLB_3.3B (LoRA fine-tuning) rises from 17.04 to 24.52 (+7.49 BLEU) in the en→as direction, and from 15.01 to 21.29 (+6.28 BLEU) in the en→mni direction.

The above results demonstrate that one-way fine-tuning can effectively reduce multi-task interference and improve translation quality in specific directions under low-resource conditions.

4.2 Single-Model Back-Translation Augmentation Effect

When introducing the first round of back-translation augmentation, model performance continues to improve, but the effect depends on the source of back-translated data:

• IndicTrans2_1B: Using back-translated data from NLLB_3.3B (41.61 BLEU in the as→en direction) is superior to using its own back-translated data (40.10 BLEU); a slight gain is also maintained in the mni→en direction (44.56 vs. 43.86);

• NLLB_3.3B (LoRA): Using back-translated data from IndicTrans2_1B (29.72 BLEU in the en→as direction) is better than self-back-translated data (28.32 BLEU); the performance in the en→mni direction is close (25.19 vs. 25.28).

This indicates that pseudo-parallel data generated across models has complementarity in syntactic and lexical distributions, which can reduce noise accumulation in self-back-translation.

4.3 Dual-Model Back-Translation and Iterative Optimization

After adding the back-translated data of both models to the training simultaneously (dual-model back-translation), NLLB_3.3B (LoRA) achieves a BLEU score of 30.61 in the en→as direction and 27.71 in the en→mni direction; further performing the second round of dual back-translation iteration results in 32.11 BLEU in the en→as direction (+1.50 compared to the previous stage) and 28.92 BLEU in the en→mni direction (+1.21). The results show that multiple rounds of back-translation can bring additional benefits, but the marginal gain diminishes.

4.4 Value of LoRA Fine-Tuning

Considering the 3.3B parameter size of NLLB_3.3B, this study adopts LoRA (rank=128, alpha=256, dropout=0.1, injected into fully connected layers) for efficient one-way fine-tuning. Under the premise of low memory usage, a significant BLEU improvement is still achieved, making multi-stage data augmentation possible under limited computing power conditions (Hu et al., 2021).

5 Conclusion

This study addresses the low-resource translation task by combining two complementary multilingual pre-trained models, IndicTrans2_1B and NLLB_3.3B, and proposes a system construction method of one-way fine-tuning for specific translation directions and dual-model iterative back-translation augmentation. The introduction of LoRA parameter-efficient fine-tuning technology on NLLB_3.3B significantly reduces memory and computational costs, enabling multi-stage data augmentation under limited computing power conditions.

Experimental results show that:

1. One-way fine-tuning can significantly improve BLEU scores in low-resource translation directions (up to +11.16 BLEU), effectively reducing multilingual multi-directional interference;

2. Cross-model back-translation data augmentation is superior to single-model self-back-translation, proving that pseudo-parallel data generated by different models has complementarity in syntactic and lexical distributions;

3. Dual-model back-translation + multi-round iteration can further improve model performance, although the gain tends to converge after the second round;

4. LoRA technology balances efficiency and effectiveness in the directional fine-tuning of ultra-large-scale models, enabling the performance of low-resource translation directions to approach the improvement range of full fine-tuning (Hu et al., 2021).

Overall, the system method in this study fully leverages the complementary advantages of the two pre-trained models, combines parameter-efficient fine-tuning and dual-model iterative back-translation, and achieves significant BLEU improvements in the WMT 2025 low-resource task, providing a feasible and efficient reference scheme for the construction of low-resource machine translation systems. Future work will further explore adaptive back-translation data screening for multi-

model collaboration and the introduction of multimodal auxiliary information in low-resource scenarios to break through performance bottlenecks.

6 Future Work

On the basis of improving the low-resource translation performance achieved in this study, future work will continue to expand in the following two directions:

6.1 In-depth Utilization of Monolingual Data

Although parallel corpora for low-resource languages are limited, monolingual texts are often relatively abundant. Future work will consider:

1. Continual Monolingual Pretraining: Conducting continuous training on existing models (such as IndicTrans2_1B, NLLB_3.3B) using a large amount of Indic monolingual data to improve language fluency and localized expression ability;

2. Denoising Self-Supervised Training: Drawing on methods such as mBART and MASS, enabling the model to better grasp contextual dependencies and syntactic structures through tasks such as Masked Span Prediction and Noising & Reconstruction;

3. Combining Monolingual Back-Translation and Forward Translation: Constructing bidirectional pseudo-parallel data by combining monolingual data, that is, adding forward translation data generated from the target language to the source language on the basis of back-translation, to further improve the model's generalization ability.

6.2 Application of Large Language Models in Translation

With the development of multilingual Large Language Model (LLM) capabilities, introducing them into low-resource translation tasks has potential. Future work will consider:

1. LLM-as-Translator: Using general-purpose LLMs (such as Qwen, LLaMA, Mixtral, mT5) for direct translation or back-translation to generate higher-quality pseudo-parallel data that is more contextually appropriate;

2. Parameter-Efficient Fine-Tuning (PEFT) for Small Languages: Quickly adapting LLMs to specific small languages and domains through methods such as LoRA, Prefix Tuning, and Adapters, reducing computational costs while improving performance in low-resource scenarios;

3. Multi-Task Learning and Instruction-Tuning: Simultaneously training tasks such as translation, question answering, and paraphrasing on LLMs, and improving their ability to understand and generate low-resource languages through multi-task transfer effects.

Abstract

This paper describes the Laniqo system submitted to the WMT25 Terminology Translation Task. Our approach uses a Large Language Model fine-tuned on parallel data augmented with source-side terminology constraints. To select the final translation from a set of generated candidates, we introduce Pareto-Optimal Decoding – a multi-objective reranking strategy. This method balances translation quality with term accuracy by leveraging several quality estimation metrics alongside Term Success Rate (TSR). Our system achieves TSR greater than 0.99 across all language pairs on the Shared Task testset, demonstrating the effectiveness of the proposed approach.

1 Introduction

The shared task consists of two tracks: sentence-level translation and document-level translation. Our submission focuses exclusively on the sentence-level track, where each sentence is translated independently using provided terminology constraints.

The shared task requires systems to be evaluated in three distinct modes:

- **No Terminology (`noterm`)**: The system is only provided with the input sentences.
- **Proper Terminology (`proper`)**: The system receives the input text along with a dictionary of domain-specific terminology pairs.
- **Random Terminology (`random`)**: The system is provided with the input text and a dictionary of randomly sampled terms from the source and target texts.

Our system builds upon the `EuroLLM-9B-Instruct` model[1] (Martins et al., 2025), which served as the baseline for our experiments in Terminology-Aware Machine Translation (MT). While this model already offers multilingual translation capabilities, it is not explicitly designed to handle translation with domain-specific terminology constraints. To further improve terminology control and translation quality, we explored several complementary strategies:

1. **Source-side terminology replacement**: Before translation, we replaced source-language terms with their corresponding target-language equivalents. This was combined with explicit prompts designed to guide the model in retaining or correctly adapting the inserted terms.
2. **Fine-tuning on glossary-augmented data**: We fine-tuned the base model on parallel data augmented with terminology automatically aligned between source and target segments. The objective of this training was to expose the model to code-switched source sentences, enabling it to learn the mechanism for incorporating provided target-language terms during translation.
3. **Pareto-Optimal Decoding**: We propose a reranking strategy that integrates multiple reference-free Quality Estimation (QE) metrics along with terminology accuracy to select the most accurate and terminology-compliant translation candidate.

In addition, we investigated prompt engineering techniques, such as structured instructions and two-shot examples, aimed at improving system robustness.

The methods described above proved effective in both improving the correct use of terminology and maintaining overall translation quality, as confirmed by automatic metrics.

2 Related Work

Handling specialized terminology in Neural Machine Translation (NMT) has received considerable research interest in recent years. The proposed methods can be broadly classified into three main categories:

- **Constrained decoding**: These methods modify the beam search algorithm by restricting the search space to ensure that the generated hypotheses include the specified terminology (Hokamp and Liu, 2017; Nowakowski and Jassem, 2021). Furthermore, the application of negative constraints has been studied for re-translating sentences where an initial translation failed to incorporate the required terms (Bogoychev and Chen, 2023).

- **Placeholding**: This approach involves replacing source terms with special placeholder tokens (Michon et al., 2020). The model is then trained to copy these placeholders into the hypothesis, enabling the target terms to be injected during post-processing. The main disadvantage of this method is that masking the source terms can result in a lack of context, which can lead to a degradation in fluency of the final translation.

- **Source Text Constraints**: This technique involves augmenting the training data with inline terminology constraints (Dinu et al., 2019; Bergmanis and Pinnis, 2021). The source text is augmented by adding the target term alongside its equivalent in the source language. These terms are typically annotated with source factors (Sennrich and Haddow, 2016) or pre-defined tags. This approach has proven particularly effective for morphologically rich languages when combined with Target Lemma Annotations (Bergmanis and Pinnis, 2021). The model generates the appropriate morphological form of the target term, ensuring that it adheres to the grammatical rules of the target language.

The emergence of multilingual Large Language Models (LLMs), such as EuroLLM (Martins et al., 2025) and Tower+ (Rei et al., 2025), represents a significant shift in MT towards the LLM era (Kocmi et al., 2024). The ability of LLMs to follow natural language instructions embedded within a prompt opens up new possibilities for adhering to terminology constraints.

Several possible strategies that leverage this capability have been explored. One approach involves using LLMs to generate term-rich synthetic data for fine-tuning traditional NMT models (Moslem et al., 2023b). Another line of work uses LLMs for automatic post-editing, prompting the model to inject missing terms into an existing translation (Bogoychev and Chen, 2023). A third, more direct method involves providing the LLM with the source text and a list of terminology constraints which must be included in the output (Moslem et al., 2023a).

Our approach builds on this direct prompting method by extending it through the integration of constraints in the source text.

While the primary objective of the Shared Task is to ensure the correct translation of specified terminology, maintaining the overall quality of the translation remains a critical factor. Well-established methods for improving the quality of machine translation, such as Minimum Bayes Risk (MBR) decoding (Kumar and Byrne, 2004) and QE reranking, have consistently demonstrated their effectiveness in various research studies in recent years (Nowakowski et al., 2022; Finkelstein and Freitag, 2024; Guttmann et al., 2024). However, these approaches are typically designed to optimize for a single metric.

This task requires the simultaneous optimization of two distinct aspects: term accuracy and general translation quality. To address this multi-objective problem, we propose a method that balances these potentially conflicting criteria.

3 Approach

3.1 Replace Method

Given a source segment and a glossary containing terminology pairs, we replaced each source term in the input text with its corresponding target-language term (see Table 1 for example). In contrast to previous works (Nieminen, 2023; Ri et al., 2021), where target terminology was appended to or replaced within the source text and subsequently enclosed by special tags, our approach, similar to the data augmentation method proposed by Song et al. (2019), directly replaces terms with their target-language equivalents without introducing any additional markup. Directly inserting target

language terms into the source sentence results in code-switching, enabling the model to adapt the grammatical form of the target terms to fit them into the sentence structure during inference.

Source	"In the Switch **Data Provider** dialog:"
Terminology	{"data provider": "Daten-provider"}
Replaced	"In the Switch **Datenprovider** dialog:"

Table 1: Example of terminology handling method applied to the source sentence.

The replacement process involved lemmatizing both the source text and the glossary terms using the `simplemma` library (Barbaresi, 2021). Each source term was matched against the lemmatized input, and when a match was found, it was substituted with the corresponding target term.

3.2 Prompt

The base prompt was designed to ensure the integration of glossary terms. Since replacing source terms with their target-language equivalents can obscure grammatical cues needed for correct inflection, the prompt also includes a list of original source phrases alongside their corresponding target terms. This provides the model with additional context, helping it resolve potential ambiguities and adjust terminology to the surrounding syntax when necessary. The full prompt is shown in Listing 1.

During the experiments, we observed that a large proportion of the mistranslated terminology consisted of phrases that were identical or very similar in both the source and target languages - differing only in casing. When the model received a text in which a term had been replaced with an identical or nearly identical term in the target language, it did not recognize the change and consequently translated it into an equivalent term in the target language. We conducted additional experiments, making some adjustments to the prompt to draw the model's attention to this issue. As a result, we added the following instruction to the prompt: `(keep already translated {tgt_lang} words - {tgt_terms})`, for instance `Translate the following English source text to Spanish (keep already translated Spanish words - desea, Decida)`. This solution improved translation quality, leading to more frequent and correct usage of the specified terminology.

3.3 Few-Shot Prompting

We also conducted experiments on few-shot prompting. We found that providing two translation examples with terminology (in the appropriate source and target languages) improves translation quality, both in general translation metrics and in term accuracy, averaged across all three language pairs.

Parameter	Value/Description

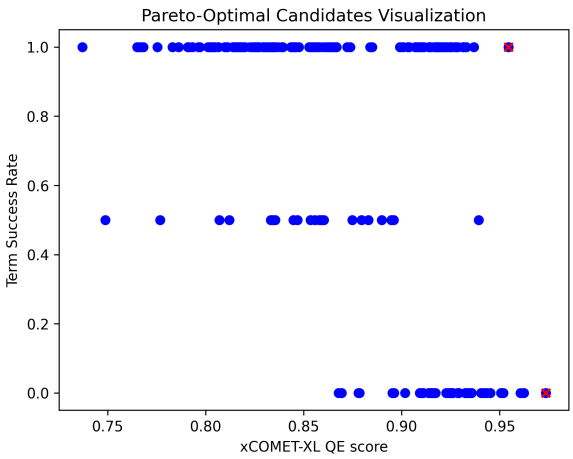

Figure 1: Visualization of Pareto-Optimal Decoding for a sample sentence. Each blue point represents one of 100 translation candidates. The red $\times$ markers highlight the non-dominated solutions. The top marked solution would be chosen by our algorithm to maximize the TSR score.

3.4 Terminology Aware Fine-Tuning

We fine-tuned the `EuroLLM-9B-Instruct` model for English $\rightarrow$ German, English $\rightarrow$ Spanish, and English $\rightarrow$ Russian terminology translation tasks. For each language pair, we used a training set of 200,000 sentence pairs randomly sampled from the OPUS corpora (Tiedemann and Nygaard, 2004).

To prepare data, we adopted a similar approach to the Target Lemma Annotations (TLA) method proposed in (Bergmanis and Pinnis, 2021). Specifically, we selectively sampled nouns and verbs from the target sentences via POS-tagging using `Stanza` (Qi et al., 2020). These words were then aligned with their corresponding source terms using the `fast_align` tool (Dyer et al., 2013), creating parallel term pairs for each sentence. These sentences and term pairs were then formatted using the prompt template shown in Listing 1.

Fine-tuning was performed using LoRA (Hu et al., 2021) over 3 epochs on 4$\times$A100 GPUs conducted through the Oumi (Oumi Community) framework. The specific training hyperparameters are detailed in Table 2.

3.5 Pareto-Optimal Decoding

In the final stage, we used epsilon sampling with $\epsilon = 0.02$ and $T = 1$ to generate 100 candidate translations for each source sentence. This method has previously been found to be effective for creating diverse samples for techniques such as MBR decoding and QE reranking (Freitag et al., 2023). Next, we scored each source-candidate pair using several QE metrics, namely `xCOMET`[2] (Guerreiro et al., 2024), `ReMedy`[3] (Tan and Monz, 2025) and `MetricX`[4] (Juraska et al., 2024). Additionally, we calculated the Term Success Rate (TSR) (Semenov et al., 2023) by verifying the presence of the lemmatized source term words within the lemmatized candidate translation sentence.

Previous research has shown that, while methods such as QE reranking and MBR decoding significantly improve translation quality, they can lead to overfitting to the utility metric (Pombal et al., 2025). We anticipate that simply reranking according to TSR could result in a substantial decrease in translation quality, particularly since TSR is based on matching lemmatized terms and does not consider their grammatical correctness or the quality of the entire translation. Therefore, a more sophisticated selection strategy is required – one that can maximize the task-specific TSR metric while maintaining overall translation quality.

To achieve this balance, we propose an approach based on Pareto optimality, which we name Pareto-Optimal Decoding. This method identifies the set of candidates that represent the optimal trade-off between general quality, as measured by QE scores, and term accuracy, as measured by TSR. Based on the previously calculated metrics, we pruned the translation candidates to a set of Pareto-optimal hypotheses using the `paretoset`[5] library. From this Pareto set of non-dominated solutions, we selected

the candidate that maximizes TSR. This final step ensures that our selection directly addresses the primary objective of the Shared Task, while filtering out suboptimal candidates in terms of translation quality as measured by neural metrics.

Figure 1 illustrates our Pareto-Optimal Decoding method for a single source sentence. For the sake of visual clarity, we limited the method to using only two metrics. Each blue circle corresponds to one of the 100 translation candidates, plotted according to the TSR score on the y-axis and `xCOMET` score on the x-axis. The two red × markers highlight the non-dominated solutions.

Interestingly, the hypothesis yielding the highest `xCOMET` score omits the required terminology entirely, resulting in a TSR score of 0.0. This finding emphasizes the limitations of single-metric optimization and the need for a multi-objective approach for translation quality optimization.

4 Results

Initially, we conducted experiments on the WMT25 development dataset. Table 3 shows the improvements gained by using prompt engineering methods and fine-tuning the model using LoRA. Table 3a summarises the results for each language pair using the `COMET`[6] and TSR metrics. Table 3b shows the macro-averaged values for all language pairs, including the `BLEU` (Papineni et al., 2002) and `chrF` (Popović, 2015) metrics.

The results obtained using the replace method were used as our baseline. As Table 3 shows, using a new prompt slightly decreased the general metrics, but improved the term accuracy metric by an average of approximately 2.5 points. Using a few-shot prompt improved results across all general metrics except TSR. Subsequently, applying LoRA further enhanced translation quality, particularly when the model was used with the new prompt and few-shot examples. Although gains for different methods vary between language pairs depending on dataset characteristics, the averaged values indicate that this combined approach yields the best results.

In addition, we performed statistical tests using the Paired Bootstrap Resampling method (Koehn, 2004). We sampled $s = 1000$ times with $n = 0.4 * testset\_length$ segments and p-value $p = 0.05$. Each subsequent processing stage was compared to the previous one. Statistically significant differences are marked with an asterisk (*) in Table 3. The results show that adding few-shot prompting to the baseline solution significantly improved the `COMET` scores for the English → Russian pair, as well as the `COMET`, `BLEU`, and `chrF` scores for the combined dataset for all three language pairs. The second method, which significantly improved the results on `COMET` for the English → Spanish and

random	0.9624	0.6318	1.5853	0.9980

Table 5: Evaluation of our final submission to the WMT25 Terminology Translation Task. We calculate the TSR for the noterm mode against terminology constraints in the proper mode as suggested by the task organizers.

English → Russian language pairs, as well as on the entire dataset according to the `COMET`, `BLEU`, and `chrF` metrics, was the method using LoRA with a new prompt. The other methods yield improvements when the averaged metric results are compared, but these are not statistically significant.

Table 4 shows the results of the Pareto-Optimal Decoding experiments. Various metrics were tested to evaluate the candidates in this processing stage. The `xCOMET`, `MetricX` and `ReMedy` metrics were employed and combined with the TSR metric. The results demonstrate that Pareto-Optimal Decoding increases the TSR metric value to 0.99 across all considered translation directions, regardless of the selected metrics. Furthermore, we observe an improvement across all translation quality metrics. However, it's important to note that due to metric interference (MINT) phenomenon (Pombal et al., 2025), the evaluation on utility metrics used during Pareto-Optimal Decoding may yield biased results. We hypothesize that our multi-objective approach mitigates the effects of MINT by encouraging the selection of more robust translation candidates. Based on this analysis, we have decided to use `xCOMET` combined with `ReMedy` in the final solution, leaving `MetricX` for fair evaluation.

Experiments showed that the best results were achieved by using a fine-tuned model together with a modified prompt and few-shot examples, as well as by employing the Pareto-Optimal Decoding method along with the `xCOMET` and `ReMedy` metrics. These methods were used to translate the WMT25 test dataset, except for few-shot prompting, which was found not to affect the translation quality when combined with Pareto-Optimal Decoding. The final results are presented in Table 5. For the `proper` and `random` modes, we utilized our full system. For the `noterm` mode, which lacks a terminology list, we used a baseline model with a modified Pareto-Optimal Decoding that relied solely on QE metrics (`xCOMET` and `ReMedy`).

The final results of all the calculated metrics demonstrate that the proposed method performs well across all evaluated metrics. In particular, TSR achieves values above 0.99 in both the `proper` and `random` dataset modes across all considered directions. In English → Russian direction it even reaches 1.0 in the `proper` dataset mode, which means that the entire specified terminology in the dataset was transferred correctly.

Abstract

This paper presents a hybrid evaluation of terminology-aware English-to-Spanish machine translation systems developed for the WMT25 Terminology Shared Task, specifically targeting the Information Technology (IT) domain. Our objective was to improve terminology accuracy and overall translation quality and highlight the potential of specialised terminology-aware translation models for technical domains. We used different enhancement strategies for both neural machine translation (NMT) systems and large language models (LLMs). These strategies include fine-tuning with synthetic data, the use of in-domain parallel corpora, and hard constraint methods such as placeholder substitution and in-context glossary integration. The results demonstrate distinct lexical and stylistic profiles in the outputs of fine-tuned NMT systems and LLMs, as well as the complementary advantages of different terminology injection methods. Systems behave differently with and without a glossary, as demonstrated by experimental results. The NMT systems seem to be rather limited in adapting to special lexicons and resizing embeddings, which is the opposite of LLMs, which prefer structured instructions. Although our translation systems achieved their highest scores on the *NoTerm, Consistency* metrics, exceeding 81%, demonstrating their ability to produce stable and coherent translations of recurring terms and phrases in unconstrained settings, the precision of the terminology and overall quality of the translation could have been improved by additional training.

1 Introduction

Adaptation of the NMT model to a specific domain (Chu et al., 2017; Chu and Wang, 2018; Saunders, 2021) is a major concern in bilingual neural machine translation. Among the various methods that have been proposed to tackle domain adaptation, two approaches are particularly relevant to the objective of this shared task: i) **Data approach** that involves selecting and filtering existing in-domain parallel segments (Moore and Lewis, 2010; Axelrod et al., 2011), or generating synthetic data. The latter is widely used in back-translation and in enhancing domain-specific data by reformulating or paraphrasing (Sennrich et al., 2016; Edunov et al., 2018); ii) **System approach** which aims to assign weights to segments close to the target domain (Wang et al., 2017). In recent years, research has increasingly focused on frugal domain adaptation strategies, emphasising the efficient use of limited resources and optimising training settings to address low-resource scenarios (Adams et al., 2022; Marashian et al., 2025). With the rapid development of LLMs for translation purposes in recent years, several methods for LLM domain adaptation have emerged, such as prompt engineering and context leaning (Zhang et al., 2023; Pourkamali and Sharifi, 2024; Yamada, 2023), constrained decoding to enforce terminology or special data format (Luca Beurer-Kellner, 2024; Bogoychev and Chen, 2023), Supervised Fine-Tuning (SFT) using reinforcement learning from human feedback (Ouyang et al., 2022), etc. Meanwhile, domain adaptation sheds light on the functioning, strengths, and weaknesses of LLM (Lu et al., 2025a), making these 'black boxes' more interpretable – an important objective of our participation in the shared task. In our contribution, we have chosen to use three strategies to fine-tune both NMT and LLM systems to ensure accurate translation of terms tagged as 'proper_terms' in the dev set:

- An open source NMT system was fine-tuned by employing placeholders for lexical-constrained decoding using additional aligned segments within the domain.
- An artificially augmented training data set

Proceedings of the Tenth Conference on Machine Translation, pages 1284–1291
November 8-9, 2025

was created using a prompt system and used to fine-tune a baseline on a commercial model training server.

- Using aligned segments and a glossary, Low-Rank Adaptation was used to make minor changes to an LLM (Hu et al., 2021).

2 Data processing and augmentation

2.1 Data sources for domain-specific model specialisation

To achieve precise terminology and consistency in fields like finance, IT and legal texts, it is essential to use high-quality aligned corpora and domain-specific glossaries to fine-tune NMT models and LLMs for specialised machine translation. The use of synthetic data generation methods can also help to augment domain-specific corpora, enhancing models' abilities to manage specialised terminology and contexts effectively. Prompt-based generation, retrieval-augmented generation, self-instruction, and reinforcement learning with feedback are some of the approaches available for synthetic data generation (Lu et al., 2025b; Nad et al., 2025). These methods can improve model performance, data diversity, and adaptability to domain-specific requirements by supplementing real training data with synthetic examples generated by LLMs.

2.2 High-quality parallel corpus

To increase the size of the training data and achieve a broader terminological coverage, we used a high-quality parallel corpus in IT and closely related fields: the European Union Intellectual Property Office (EUIPO) Trademark and Design Guidelines in the production, technology and research domains, translated by professional translators from English into Spanish.[1] This resource, created by the European Language Resource Coordination (ELRC), contains 16,439 translation units; 386,472 tokens in English and 424,702 tokens in Spanish. After filtering based on length control and the basic alignment quality of the segments, we obtained 6,359 parallel segments containing 62,481 English tokens and 67,791 Spanish tokens, representing an average of 910 words (60-66 characters) per segment.

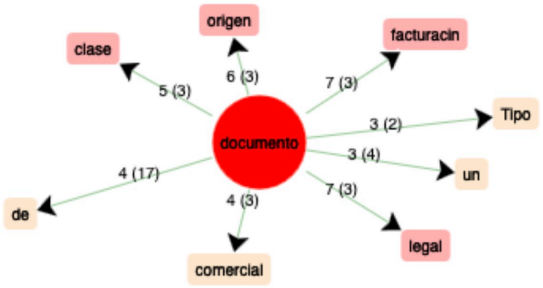

Figure 1: Parallel co-occurrences in the augmented data, measuring the frequency and specificity of lexical attractions.[2]

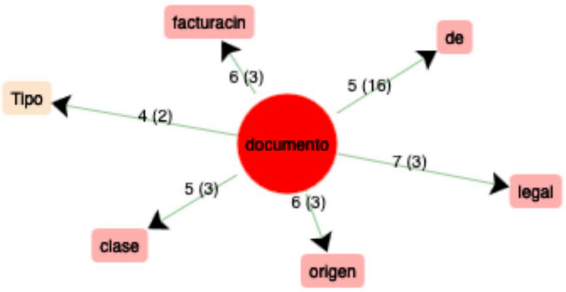

Figure 2: Parallel co-occurrences in the development set of the shared task, measuring the frequency and specificity of lexical attractions.

2.3 In-domain synthetic data

In our experiments, we used the dev data set (enes-dev: 500 aligned segments) augmented via a system of prompts on ChatGPT-4 (first to generate an initial data set in English using task-specific terminology) and on DeepSeek (to translate the generated dataset into Spanish using the WMT 2025 dev set term correspondences). We used free public versions of both platforms. Our objective was not only to consider specific term correspondences, but also to capture linguistic features of the test set to create synthetic data reproducing the dev set patterns. We created a synthetic data set enes-AUG (1,746 aligned English-Spanish sentence pairs, 10,021 tokens in English, 10,822 tokens in Spanish). The generated synthetic data set has some recognisable characteristics in terms of regularly repeated characteristic patterns (for example, in Spanish: *Usa las acciones* ***en tu documento***. *Utilice los Servicios profesionales* ***en su documento***. *Utilice el Soporte SAP* ***en su documento***).

[2] Calculated by iTrameur (textometrics tool): https://itrameur.clillac-arp.univ-paris-diderot.fr

We analysed parallel co-occurrence networks (Zimina and Fleury, 2016) in sentences containing the same terms in the dev set and in the augmented data. It reveals that both data sets share key terminological traits (see Figures 2.3 and 2), supporting the suitability of AI-generated data for our experiment. However, the AI-generated data set lacks the uppercase usage typical of the enes-dev data. For example, the term "Source Document Category" appears in lowercase. Future experiments could include prompt instructions to better replicate capitalisation in terminology.

2.4 Glossary terms and augmented terminology

The enes-dev set contains some rather challenging (or even questionable) annotations of "proper_terms" and "random_terms", for example:

"en": **"Source Document Category"**, "es": **"Tipo de documento de origen"**, "proper_terms": {"source document category": "tipo de documento de origen"}, "random terms": {"Source": "Origen", "Document": "documento", "Category": "tipo"}.

If ***Tipo de documento de origen*** is a term, then its constituents, such as ***documento*** and ***tipo***, are hardly random in specialised discourse, especially if we consider term variation, which involves the use of different forms to express the same or nearly the same concepts within a specialised domain (Daille, 2017). In our work, we considered that such occurrences are part of specialised discourses and their distributional properties (Wingfield and Connell, 2022) are reflected in the augmented data set. We also tried to take into account the fact that different multiword terms possibly contain common lexical items. In this respect, term variation is reflected in the augmented data set. For example, while the term "source document category" is translated by *tipo de documento de origen*, our synthetic data set also contains contexts, where "document type" is translated by *clase de documento*:

en: Save the **source document category**. > es: *Guarda el **tipo de documento de origen***.

en: Save the **document type**. > es: *Guarda la **clase de documento***.

3 Systems

3.1 NMT system

We investigated methods to impose lexical constraints on NMT systems that do not inherently support glossary use. One approach involves fine-tuning a generic NMT model with domain-specific synthetic data generated through LLMs and other generative AI tools. This synthetic data set incorporates targeted terminology to guide system translations, improving sentence level accuracy and ensuring consistent terminology usage. The fine-tuning process leverages data augmentation techniques to integrate specific term correspondences and improve translation coherence within specialised domains.

3.2 LLM

Recent research suggests that LLMs can be effectively tuned for MT using surprisingly small amounts of high-quality parallel data. Fine-tuning with LLMs (such as Llama-2 7B) can deliver strong performance when trained on as few as 32,219 parallel sentences (Lu et al., 2025a). This is in line with the hypothesis of "superficial alignment", which suggests that LLMs have already mastered their translation skills during pre-training, and fine-tuning concentrates on aligning the model with the specific task format.

4 Experimental settings

We used constrained machine translation with hard terminology control (EN-ES) to ensure that English terms were consistently predicted as their Spanish equivalents. We implemented our NMT system with Marian (Junczys-Dowmunt et al., 2018), mainly because it allowed constraint decoding with the additional_special_tokens parameter, and the models embeddings were resized accordingly. In the training data, we replaced English terms and their Spanish equivalents with placeholders: each pair of bilingual terms was replaced by the same placeholder. Consequently, English terms in the input were replaced by placeholders before decoding, and placeholders in the output were replaced by the equivalent Spanish terms after generation. Our system was fine-tuned with Seq2SeqTrainer with the following setting: training epochs: 5, learning rate: 1e-5, training batch size: 8, gradient accumulation steps: 2, max length: 128.

For the LLM model, we used EuroLLM-1.7B-Instruct (Martins et al., 2024) as a causal LM due to its relatively light weight for fine-tuning. For each pair of aligned segments (EN-ES), the system builds a prompt that injects the glossary before instruction as follows:

```
"### Instruction:"
"Translate the following text from English
to Spanish using the provided glossary."
"### Glossary (Information Technology):"
"{glossary_items}"
"### Text in English:"
"{src}"
"### Translation in Spanish:"
"{tgt}"
```

The glossary was created using the English and Spanish lexicons tagged as "proper_term" elements in the dev set. After filtering and deduplication, we obtained 172 unique occurrences in English (not case-sensitive). These occurrences correspond to 221 pairs of English and Spanish terms. Training was set as follows: `training batch size`: 4, `learning rate`: 1e-4, `weight decay`: 0.01, `lr scheduler type`: linear, `warmup steps`: 100, `training epochs`: 1. We used parameter-efficient LoRA (Hu et al., 2021) adapters for light fine-tuning, using 8-bit loading to reduce GPU memory usage: `task type`: CAUSAL LM, `r`: 16, `lora alpha`: 32, `lora dropout`: 0.1. For both the Marian and EuroLLM fine-tuning processes, we used a small number of epochs and a small batch size to reduce training time and prevent over-fitting. The main purpose was to evaluate the efficiency of our training pipelines.

We also used an advanced commercial MT platform SYSTRAN Model Studio Lite[3] to fine-tune a generic EN-ES baseline model. NMT was used to ensure accurate sentence-level translations. GenAI, including LLMs, was used to develop a synthetic data set that contains domain-specific terms to fine-tune the initial system and implement specific term correspondences, improving coherence regarding terminology specifications (see Section 2.3 on data augmentation techniques).

5 First results

5.1 Quantitative metrics

We investigated lexical characteristics and vocabulary usage in six translations produced by different models (see Table 1) and compared them using quantitative methods, such as `correspondence analysis`, `vocabulary growth assessment`, and `characteristic elements computation` (Lebart et al., 1998). The investigation revealed nuanced differences in the translations and highlighted the impact of glossary inclusion and placeholder handling on translation quality and style.

A corpus aggregated from six different translations contains a total of 35,250 tokens. On average, each translated text comprises approximately 5,875 tokens, with two notable exceptions: **EuroLLM_SEG_Glossary** (6,192 tokens) and **MTwithplaceholder** (5,400 tokens).

5.1.1 Vocabulary growth

The vocabulary growth curves, which reflect the natural increase in distinct words encountered, show that **EuroLLM_SEG_Glossary** consistently has the largest vocabulary size (see Figure 3). This suggests that it has the most diverse vocabulary of all the models tested. **Systran_SEG_AUG** exhibits somewhat lower vocabulary growth, very close to the reference translation, while **Marian_SEG** shows the slowest increase, suggesting a smaller or more limited vocabulary compared to the others.

5.1.2 Characteristic elements

The results of `characteristic elements` computation reveal the use of English lexical units in **MTwithplaceholder**, which do not correspond to common Spanish borrowings, highlighting the models lexical weaknesses. **EuroLLM_SEG_Glossary** distinctly exhibits a preference for informal address forms, favouring pronouns and verbs such as *puedes*, *selecciona*, and *tus* over their formal counterparts like *pueda* or *Seleccione*. It also underuses the term *plantilla*, substituting it with *modelo* or omitting it entirely, indicating stylistic or glossary-driven variations.

5.1.3 Correspondence analysis

`Correspondence analysis` provided a multidimensional visualisation of the lexical relationships

[4] Generated with iTrameur (textometrics tool): https://itrameur.clillac-arp.univ-paris-diderot.fr

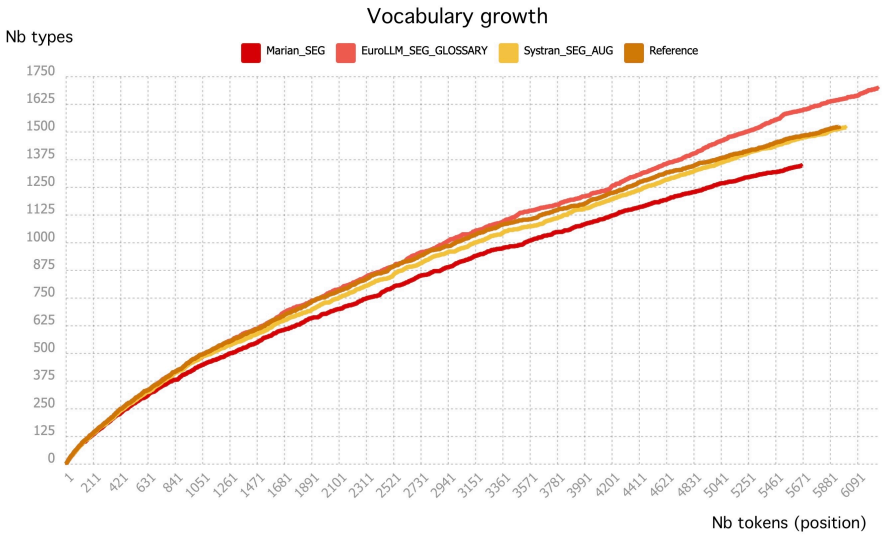

Figure 3: Comparison of vocabulary growth curves among submitted translations and the reference.[4]

across the models (see Figure 4). The first factorial plane, which accounts for 49.9% of the total lexical variation, highlights the following oppositions:

- **(Pure) MT translations vs. (human) reference**: As expected, the results of the correspondence analysis highlight the differences between the reference translation and the translations produced by the submitted MT systems.
- **NMT vs. LLM**: Submitted MT translations are positioned along a continuum that differentiates between NMT and LLM characteristics. The **Systran_SEG_AUG** system, which relies on LLM-generated data, exhibits hybrid traits.

The second factorial plane (see Figure 4), which accounts for 26.7% of the total lexical variation, further confirms oppositions and proximities observed in the first plane, mapping a closer proximity between **Systran_SEG_AUG** and the reference translation compared to the other submitted translations:

- **Systran_SEG_AUG** shows some characteristics that approximate the **reference** translation.

5.1.4 Performance scores

Following this analysis, we conducted an evaluation using the reference translations provided by the organisers. Table 2 compares the performance of pre-trained or generic models (Marian MT, EuroLLM, and Systran *Generic*) with that of fine-tuned models. Our analysis shows that although constrained decoding helps models better translate "proper terms", it reduces the overall translation performance of MT systems. This effect is particularly evident in Marian MT: although the fine-tuned model translated more proper terms and produced more formal equivalences, its overall translation quality decreases, with the COMET-DA score dropping from 0.86 (pre-trained) to 0.82 (fine-tuned). However, constrained decoding improves the term-matching precision of EuroLLM without heavily degrading its overall translation quality. For Systran, the score difference between the pre-trained and fine-tuned models is minimal.

5.2 Linguistic analysis

Evaluating fluency is difficult since most segments are decontextualised noun phrases, but there are examples where fluency differences between models are noticeable (see Table 3).

Systran_SEG_AUG tends to produce translations that are quite literal but accurately preserve the source content. The system generally yields the best results in terms of information transfer. The **Marian_SEG** model sometimes omits segments. When this happens, there are negative effects on orthographic correctness, such as missing capital letters at the beginning of sentences.

[6]*: Submitted version.

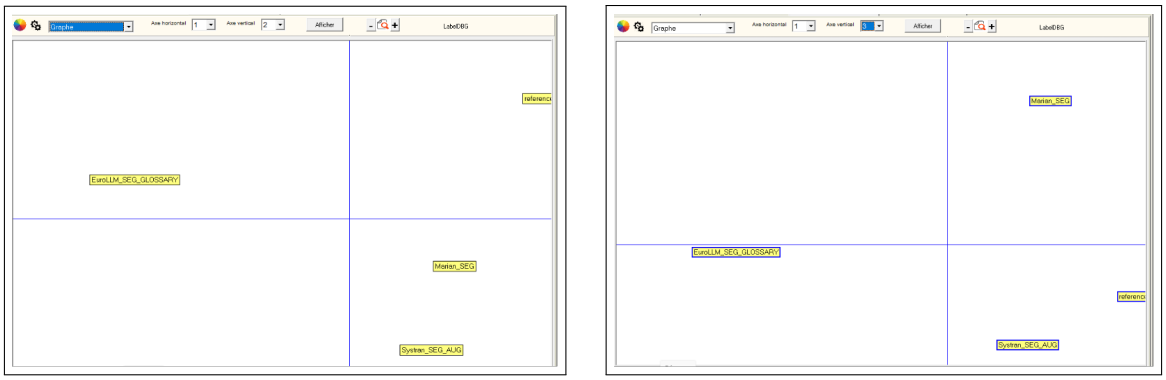

Figure 4: Factorial correspondence analysis of submitted translations. The first factorial plane, formed by axes 1 and 2, accounts for 49.9% of the variation. The second one, formed by axes 1 and 3, accounts for 26.7%.[5]

System	Token	Form	Hapax	Fmax
ES_SystranIT	6,014	1,519	834	653
ES_Systrangeneric	5,976	1,504	849	677
EuroLLM_SEG_GLOSSARY*[6]	**6,192**	**1,670**	**990**	**690**
MTwithplaceholder	5,400	1,592	973	440
Marian_SEG*	5,664	1,351	762	658
Systran_SEG_AUG*	6,004	1,524	866	684
Total	35,250	2,871	873	3,802

Table 1: Quantitative characteristics of the translations generated by each of the models.

EuroLLM_SEG_GLOSSARY model occasionally leaves some English segments untranslated. This occurs rarely but more often than with other models. Some untranslated segments result from poor segmentation in the source text. There is no consistent correlation between the omission or retention of expected terms across models. For example, sometimes expected terms are omitted, sometimes other segments are omitted leaving only the expected term, and in some rare cases the source text remains unchanged.

In cases where **EuroLLM_SEG_GLOSSARY** leaves English segments untranslated (e.g., "On the To Be Billed"), it appears to stem from improper segmentation. For example, the segment "On the To Be Billed" that is left in the translation generated by **EuroLLM_SEG_GLOSSARY** is the result of poor segmentation of the original version. If the decision was to leave the tab name in English, it should have been rendered as "*en la pestaña To Be Billed*". **EuroLLM_SEG_GLOSSARY** sometimes introduces lexical creations or barbarisms, which can make understanding difficult.

In summary, **Systran_SEG_AUG** performs best in preserving source information. **Marian_SEG** suffers from segment omission causing orthographic errors. **EuroLLM_SEG_GLOSSARY** tends to leave English untranslated more often and sometimes produces confusing lexical forms.

5.3 Interpretative insights

This combined quantitative and qualitative analysis shows that translation models vary in more than just lexical richness; they also differ in terms of stylistic choices and lexical specificity. There are significant differences in how models handle formality, lexical borrowing, and terminology consistency, reflecting variations in MT architecture and preprocessing (e.g. glossaries and placeholders). Correspondence analysis is a useful tool for visualising these differences, as it reduces complex lexical data into interpretable axes of variation. This enables more informed evaluations of MT output.

6 Conclusion and perspectives

Our contribution to the shared task reveals the strengths and challenges of NMT systems and LLMs in translation tasks. Although NMT systems perform well with small amounts of high-quality domain-specific training data, their performance can deteriorate under constrained decoding conditions. In contrast, LLMs can benefit from structured guidance, such as glossaries and clear instructions, which enhances their translation quality. These findings emphasise the complementary

System	Total terms	Translated terms	Ratio	BLEU	chrF	COMET DA
EuroLLM_SEG_GLOSSARY	538	204	37.9%	38.6	69.1	0.83
EuroLLM_1.6B_Pre-trained	538	199	37.0%	36.1	53.4	0.84
Marian_SEG	538	**254**	**47.2%**	48.1	73.2	0.82
Marian_Pre-trained	538	196	36.4%	45.0	58.1	0.86

Table 3: Translation comparisons

nature of the two approaches, suggesting that combining NMT's data-driven learning with LLMs' flexible, instruction-driven capabilities could result in more robust and effective translation solutions.

We also identified some limitations through our experimentation. None of our open-source systems translated all the segments from English to Spanish, with some segments always remaining untranslated. This is probably due to gaps in the lexicons of the training and test data or to forced decoding effects that prioritise and select the source token over the target token. In summary, a trade-off must be made between model complexity, performance, and training cost. While a 16B-parameter model could potentially avoid missing any translations, it is much more challenging to fine-tune such a model due to its substantial number of parameters, size, and the associated high training costs in terms of GPU memory, time, and environmental impact.

Contextual Selection of Pseudo-terminology Constraints for Terminology-aware Neural Machine Translation in the IT Domain

Benjamin Pong
University of Washington
Seattle WA, USA
{benpong}@uw.edu

Abstract

This system paper describes the development of a Neural Machine Translation system that is adapted to the Information Technology (IT) domain, and is able to translate specialized IT-related terminologies. Despite the popularity of incorporating terminology constraints at training time to develop terminology-aware Neural Machine Translation engines, one of the main issues is: In the absence of terminology references for training, and with the proliferation of source-target alignments, how does one select word alignments as pseudo-terminology constraints? The system in this work uses the encoder's final hidden states as proxies for terminologies, and selects word alignments with the highest norm as pseudo-terminology constraints for inline annotation at run-time. It compares this context-based approach against a conventional statistical approach, where terminology-constraints are selected based on a low-frequency threshold. The systems were evaluated for general translation quality and Terminology Success Rates, with results that validate the effectiveness of the contextual approach.

1 Introduction

This paper describes UW-BENMT's submission[1] to WMT2025 Terminology Translation Shared Task (Semenov et al., 2025). The aim of this edition of the shared task is to evaluate how well machine translation systems can handle specialized terms in specific domains where terminology accuracy and consistency are critical. Although general machine translation systems have improved significantly, specialized terminology remains a challenge (Semenov et al., 2023; Alam et al., 2021), and this task evaluates the effectiveness of integrating terminology dictionaries into machine translation engines in the Information Technology (IT) domain. This is a highly practical task as machine translation engines that have been adapted to this domain can potentially assist in the international communication of technical APIs, manuals and DevOp guides across IT teams that operate in multilingual environments. This task involves segment-level terminology translation for three language pairs: English $\rightarrow$ {German, Spanish, Russian}. The provided data consists of 500 parallel sentences per language pairs, with reference terminology dictionaries.

2 Related Work

There are two major approaches to terminology translation, with the first being lexical constrained decoding where the target terminologies entries are forced to match the source side lexical terms as decoding-time constraints (Chatterjee et al., 2017). However, one major shortcoming of this strategy is the computational overload as the number of terminology constraints increase. To address this issue, Dinu et al. (2019) pioneered a methodology to train neural machine translations engines to recognize terminology constraints. The focus of their approach is to annotate the data with source-target terms inline as soft constraints (i.e., a form of data augmentation). The success of this approach is reflected in popularity of system submissions that adopted it at the WMT2021 and WMT2023 Terminology Translation Shared Tasks (Ailem et al., 2021; Nieminen, 2023; Bogoychev and Chen, 2023; Park et al., 2023). Different alternatives to implementing this approach have been proposed, such as masking out the source-side terms (Ailem et al., 2021; Liu et al., 2023), which have been argued to surpass simple inline term annotations.

As pointed out by Bogoychev and Chen (2023), one of the main challenges of terminology transla-

[1]Repository for system development can be found at https://github.com/Benjamin-Pong/Terminology-Neural-Machine-Translation-IT-domain.git

Proceedings of the Tenth Conference on Machine Translation, pages 1292–1301
November 8-9, 2025

tion is that terminology dictionaries are not readily available for training, and their proposal differs from Dinu et al. (2019) in that they devised a way to automatically create terminology constraints for existing training corpora. The development of pseudo-terminology constraints is a challenge in itself because it is difficult to select word alignments that are most representative of 'technical terminologies'. While Dinu et al. (2019) and Bogoychev and Chen (2023) used randomly selected terms, other systems construed domain-specific terms as low frequency lexical items (Semenov et al., 2023; Park et al., 2023), a common approach that is practiced in works beyond the shared task (Koehn and Knowles, 2017; Yuan et al., 2018; Bowker, 2021).

The main contribution of this system paper is to shed light on the context-driven approach to selecting pseudo-terminology constraints for IT-adapted NMT training, and present this as an alternative to the frequency-based approach. It focuses on improving the psuedo-terminology creation process in the absence of training terminology dictionaries by comparing two methods; frequency-based, context-based.

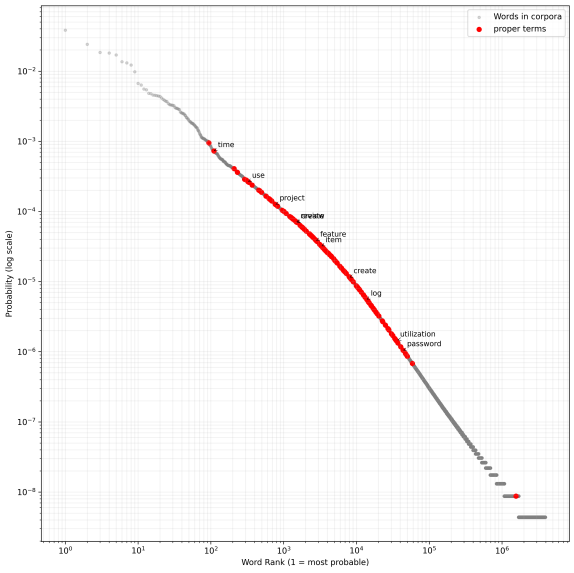

Figure 1: Rank-frequency plot showing the frequency distribution of proper terms against all words in a corpora

3 Selection of Pseudo-terminology Constraints

3.1 Proxies for Terminology Selection: Frequency vs Context

There are two main reasons why frequency may not be the best proxy for terminology selection. The first reason is motivated by the statistical frequencies of proper terms against the tokens in publicly available corpora. Consider the Rank-Frequency Distribution in Figure 1, where the frequencies of the provided data's English terminologies were compared against the frequencies of all English tokens from the Europarl and WikiMatrix data[2]. The frequencies were rescaled to a value between 0 to 1. Based on the Rank-Frequency distribution of terminologies, terminologies lie in mid-rank, contrary to conventional assumptions that terminologies are low-frequencies.

The second reason lies in the fact that lexical terms selected as proper terms are not treated as proper terms in all contexts. A vast majority of the proper terms in the development set are also treated as random terms and do not have any domain-specific meanings. Consider the way 'create', a mid-ranked frequency word based on the rank-frequency distribution, is used in following sentences taken from the provided data: (1) *With the Story Builder, you can create stories to visualize information with charts and table* and (2) *Activate or Create your Data Provider Profile.*

"Create" is treated as a specialized IT-terminology in the first sentence, but not in the second sentence. This ambiguity is difficult to resolve but one could speculate that "create" in the first instance is used in the context of a software application assisting with the creation, which renders it a specialized IT-terminology. Since it is challenging to define deterministic semantic rules for domain-specific terminologies, and neither does a frequency-based approach suffice since 'create' is not exactly a low-frequency word, an approach that is agnostic to these two conditions should be explored.

3.2 Terminology Constraint Filtering by Norm of Top Most Hidden States

Inspired by Wu et al. (2024) and Schakel and Wilson (2015) who established a theoretical and empirical connection between important-words and context for general machine translation, this paper adapts their methodology to terminology-aware machine translation. More specifically, the methodology is applied at the pseudo-terminology constraints creation stage of the end-to-end NMT pipeline, where source-target alignments are filtered based on how "important" they are in seman-

[2]There are a total of 4 million unique English words in both of these corpora.

tic meaning. The norm of the encoder's final hidden states represents contextually important information within lexical items (Wu et al., 2024).

While the importance of context in resolving ambiguities in machine translation (Maruf et al., 2019; Post and Junczys-Dowmunt, 2024) is not entirely new, its effects on terminology translation has yet to be explored, which is the focus of this system paper. Given a set of source-target alignments for a sentence-pair, and given that the norm of the encoder's final hidden states is computed for each source word, the word-alignment pair(s) whose source-word has the highest norm will be chosen as a pseudo-terminology constraint for augmentation.

4 Neural Machine Translation Training

4.1 Training Data: IT-domain Parallel Data Selection using Cross-Entropy Difference

Due to data sparsity in the IT-domain, it is necessary to procure sufficient quality data for system developments. To do so, Cross Entropy Difference (CED) (Moore and Lewis, 2010) was applied to select IT-specific data from a larger corpus of out-of-domain or general domain content.

For CED to be effective, the assumption is that there is already some available in-domain data. Inspired by Moslem et al. (2023), LLM was used to generate synthetic monolingual (English) in-domain parallel data using the gold terminologies provided by the organizers. The data provided contains 500 parallel sentences per language pair, and each sentence-pair comes with a set of terminology mappings. Using only the source-side terminologies as inputs into Aya-expanse-8b (Dang et al., 2024) with temperature=0 and top-p sampling of 1, synthetic monolingual data was generated with the following prompt: `Please use the terms '{terms}' to generate {number_of_sents} full sentences in {source_language}-{target_language} whose content is related to information technology.`

Note that eventhough parallel data was generated, for the purposes of the task at hand, the English source sentences were used for subsequent indomain and outdomain language modeling. A total of 30K IT-related synthetic sentences were generated and treated as in-domain data. The average sentence length is 50-75 tokens.

Table 1 shows the sets of publicly-available parallel corpora that were considered for each language pair. These serve as the general-domain content. For each set of corpora, 30K English sentences were randomly sampled to train an out-domain 4-gram language model (with Laplace Smoothing). To ensure that the in-domain and out-domain models are comparable, apart from controlling for the size of training data, the sentences selected for out-domain model training also had an average of 50-75 tokens.

The remaining sentences were scored according to the cross-entropy difference between the in-domain and out-domain language models, and ranked in non-increasing order since lower entropy signifies a closer match to the in-domain data[3]. Throughout this process, several preprocessing strategies were applied to reduce noise in the publicly available data. FastText (Joulin et al., 2016) with a threshold of 0.9 was used to remove sentence-pairs where either the source or target sentence was not the desired language. Sentence-

[3]Discussion of CED is beyond the scope of this paper. I encourage the reader to refer to Moore and Lewis (2010) for details.

pairs that contained only punctuations and numbers were also removed. The top 20% was chosen as in-domain training data, and the bottom 20% as out-domain data, which amounts to 2.2 million parallel sentences per language pair. Additional checks were performed to ensure that parallel sentences chosen for training did not overlap with the provided data so that the provided data can be held-out for evaluation.

The overall effectiveness of CED for data selection was validated on downstream general translation quality, and hence the main approach to data selection for subsequent experiments for terminology translation. See Section 6 for details.

4.2 Experiments

The baseline uses the training data as they are, without any lexical constraints being augmented inline at training time. Since the chief focus of this paper is to compare the effects of using (low)frequency and encoder-based contextual scoring for pseudo-terminology selection, two more experimental configurations were designed. The first being training data where only low frequency words were selected as pseudo-terminologies for augmentation (i.e FreqTerm). The second configuration consists of data where only words with the highest norm computed from the final layer of the encoder's hidden states (i.e ContexTerm). For these two configurations where lexical constraints are augmented inline, similar to Dinu et al. (2019), only 10% of the training data is augmented, amounting to around 200K randomly selected sentence-pairs. The special token <*src*> was used to mark the start of the source word and <*tgt*> was used to mark the start of the corresponding target word.

The first part of creating the pseudo-terminology involved extracting word alignments between the source and target languages by using a state-of-the-art neural word aligner, Awesome Align (Dou and Neubig, 2021). Alignments between stopwords were removed. Given that awesome align does not account for multi-word alignment, further lightweight processing was applied to merge consecutive source words that were mapped to the same target word to produce multiword source-target word alignments.

To address the proliferation of word-alignments, the next step is to implement the frequency and contextual approaches for selecting word-alignments to be used as pseudo-terminology constraints.

The former was straightforwardly implemented by first computing a frequency distribution (normalized to values between 0 and 1) for the source-side words using the source-side's training data. Only source-target aligned pairs whose source words' probabilities were at most 10^{-5}, were selected. This low-frequency threshold is not arbitrary but instead, motivated by the aforementioned frequency distribution of terminologies (See Section 3.1 and Figure 1). For a multiword source word, if a subword met the threshold, the entire multiword source word was chosen as a suitable candidate for term annotation. Furthermore, since each sentence may have multiple candidate word-aligned pairs that meet this threshold, randomly chosen aligned word-pairs were chosen for augmentation per sentence. Note that the number of word aligned pairs chosen for augmentation can be adjusted by the engineer.

As for the context-scoring configuration, a pre-trained encoder-decoder NMT model (Ng et al., 2019) was used to extract the final layer's hidden representation per token. Only the source-side (English) needs to be encoded for all language pairs. For each multiword source word, max-pooling is applied to compute a unified final hidden representation, followed by a computation of the norm of this hidden representation. These words were ranked in non-increasing order, with the source word with the highest norm being selected, and consequently, its corresponding source-target alignment, was selected as a terminology constraint.

To ensure a fair comparison between FreqTerm and ContexTerm, two factors were considered; first, the number of terminology constraints selected per sentence for augmentation, and the number of sentences that contain the constraints. The latter was standardized across both experiments by choosing only 10% of the data to be augmented. The former was enforced by enforcing identical thresholds on hyperparameter *k*; k-randomly selected low frequency word(s) and the top-k highest norm(s).

The training data per language pair were tokenized using Moses (Koehn et al., 2007). Byte Pair Encoding (BPE) for subword segmentations (Sennrich et al., 2016) were independently applied to both the source and target languages with 32000 merge operations. 500,000 sentences from the training data were selected to generate BPE codes.

4.3 Model Architecture

All systems were Transformer-based networks, trained (Vaswani et al., 2023) using *fairseq* (Ott et al., 2019). Training configurations were specif-

ically optimized for each language pair. See Appendix A for the hyperparameters. En-es and en-ru were trained for minimum of 35 epochs and a maximum of 50 epochs with early stopping, while en-de was trained for a minimum of 50 epochs and a maximum of 100 epochs with early stopping. Uniformly across all models, the last 7 checkpoints were averaged and used for decoding, with a beam size of 5.

5 Evaluation

Systems were evaluated on the provided data, which was not used for training purposes, and have been verified to not overlap with the selected training data. Although examples were taken from the data to illustrate the point in Section 3.1, note that the approach in this paper does not rely on defined patterns or rules from the data, resulting in minimal risk of evaluation bias. Furthermore, the provided data is the only source of gold references for quality evaluation. With these careful considerations, the provided data was safely treated as held-out test data.

5.1 Evaluation Metrics

The translations provided by the trained models were scored against the gold references using BLEU (Papineni et al., 2002), Chrff++ (Popović, 2017) and COMET-DA (Rei et al., 2020) to assess general translation quality. Terminology Success Rate (TSR) (Semenov et al., 2023) was also used to assess the degree of occurrences of the term translations, with and without lemmatization to account for morphological complexities across the different languages, and also fuzzysearch with a threshold of 90% to account for orthographic deviations. Another reason for selecting this mode of evaluation instead of exact matching (Alam et al., 2021) is to capture adequate term translations, and also to consider the effect of syntactic contexts on the morphological shape of the terms.

5.2 Modes of Evaluation

The NMT systems were evaluated under three modes of incorporating terminology constraints at inference time, with the first mode being no terminologies (i.e., *no term*) where the source sentence is freely translated into the target language. The second mode requires the *proper* terminologies to be incorporated, and the third mode incorporates *random* source-target word alignments.

Results from NMT engines are compared between these three modes. The purpose of incorporating random source-target word alignments is to ensure that any improvements over the *no term* setting brought about by incorporating proper terminologies are not by-products of superior general translation quality (Semenov et al., 2023).

6 Results

Table 2 shows the results of all three systems (baseline, freqTerm and ContexTerm) for all language pairs across the three terminology modes. Table 3 shows the validation results for CED-selected data without any terminology incorporation for training or inference.

6.1 Translation quality

From the results in Table 2, the highest scores for translation quality metrics tend to skew toward the ContexTerm system, with the exception of en-es language pair, where FreqTerm achieved the highest BLEU and ChrF++ scores. Notably, none of the baselines achieved the highest scores.

With regards to how the terminology modes affect overall translation quality, based on the results, the highest scores tend to skew towards systems with *proper* terminology settings. However, there are several exceptions. For instance, the *no term* setting for ContexTerm has the highest BLEU score for en-es. In a similar vein, among the baseline systems, incorporating random terms or proper terms at inference time tends to result in a drop in translation quality.

6.2 Terminology Success Rate

The incorporation of soft constraints at training time increased the Terminology Success Rate (TSR) by a huge margin compared to the baselines. This is demonstrated by the fact that for all language pairs, the *proper* terminology setting achieved the highest TSR compared to the *random* and *no term*. The latter two settings tend to perform comparably low. This pattern is observed for both FreqTerm and ContexTerm, regardless of whether lemmatization was employed. These results are expected and aligns with the findings of previous works mentioned in Section 2.

Crucially, using *proper* terminology setting as a basis for comparison between FreqTerm system and ContexTerm system, the latter has the highest TSR.

Language	System	Modes	BLEU	ChrF++	COMET	TSR^{-L}	TSR^{+L}

Table 2: Evaluation of systems by language direction, augmentation approaches and terminology modes across BLEU, ChrF++, COMET and Terminology Success Rates(TSR). TSR^{-L} refers to non-lemmatized setting while TSR^{+L} refers to lemmatized setting. Best performing systems and with their corresponding terminology settings are bolded.

Language	Domain	BLEU	ChrF++	COMET	TSR^{-L}	TSR^{+L}
en → es						
	in	27.79	56.60	0.731	0.219	0.233
	out	24.92	52.464	0.767	0.200	0.212
en → ru						
	in	21.02	54.53	0.830	0.251	0.329
	out	20.69	53.57	0.826	0.248	0.317
en → de						
	in	13.91	41.96	0.656	0.151	0.142
	out	15.50	45.68	0.69	0.172	0.194

Table 3: This table shows the evaluation of 'IT-domain' CED-selected data vs out-domain data without terminology constraints incorporated for training or inference.

With respect to the effect of lemmatization, TSR tends to be better with lemmatization for en-es and en-ru. Such improvements are consistent across all terminology modes as well, and across both systems. However, the degree of improvement is language-dependent. For instance, in the context of en-ru (*proper*), the *lemmatized* setting surpassed the *non-lemmatized* setting by at least 0.1 points. This is in stark contrast with en-es (*proper*) where the *lemmatized* setting only surpassed the *non-lemmatized* setting by 0.02 points. Interestingly, for en-de, we observe an opposite effect, where the *non-lemmatized* setting surpasses the *lemmatized* setting by a small margin. This is consistent across both systems, and across terminology modes. See Section 7 for possible explanations and implications of evaluating the adequacy of terminology translation with or without lemmatization.

6.3 Data Selection by Cross-Entropy Difference

Table 3 shows that CED-selected data scored higher in general domain translation tasks. In addition, even without terminology incorporation, using in-domain data achieved relatively higher TSR. However, German is an exception, which will be discussed in Section 7.

7 Discussion

7.1 Contextual Selection of Terminology Constraints

The comparisons between FreqTerm and ContexTerm clearly show the effectiveness of using contextually-based scoring to distill quality word-alignments to be used as terminology constraints or inline term annotations. ContexTerm surpasses FreqTerm by 0.08-0.15 points. This suggests that terminologies are construed in terms of the way they are being used in an utterance (i.e the 'create' example from Section 3), and not completely dependent on frequencies.

7.2 Effect of Contextually-selected Terminology Constraints on Translation Quality

The use of contextually-selected constraints seem to have a trickle-down effect on translation quality as well. As noted previously, systems with terminology constraints at training time tend to have higher translation quality. While this is expected (Dinu et al., 2019), the fact that BLEU , ChrF++ and COMET scores tend to be higher in ContexTerm compared to FreqTerm across all terminology modes suggest that these translation engines are learning domain-specific lexical alignments, which reduces variability, and thereby improving the translation outputs.

7.3 Terminology Success Rate: Lemmatization

The asymmetrical results between en-es and en-ru against en-de with regards to lemmatization could be attributed to the morphological properties of the languages. German, compared to Spanish has been argued to have more complex inflectional paradigms, and that simplifying them improves word alignment (Axelrod et al., 2008). This suggests that lemmatization should correlate with improved scores, but this is not the case. Perhaps the lemmatization oversimplified certain lexical items, resulting in noise. This is an interesting case and should be left for future work through error analysis.

7.4 Data Selection by Cross-Entropy Difference

The fact that CED-selected data showed marginally higher general translation and TSR for en-es and en-ru may indeed suggest that this is an effective approach to source quality parallel data for a less resourced domain. Furthermore, the higher TSR scores suggest that training on data closer to the actual domain can boost terminologies, without the incorporation of constraints at train time. However, the converse results for en-de, although disappointing, may be due to actual noise in the data. This investigation will be left for future work.

8 Conclusion

This paper addresses a challenge in terminology translation engines that incorporate term annotations at run-time: with the proliferation of source-target word alignments, how does one select the optimal subset of alignments as pseudo-terminology constraints? Results from this work show that the encoder's hidden representations serve as useful estimations of terminology constraints. It also highlights the robustness of a main-stay data selection approach in the absence of curated IT-related parallel data.

9 Limitations

However, there are some limitations, which open avenues for future work.

The approach to ContexTerm relies on pretrained models to extract the encoders' final hidden states from the source language (or target language). While this makes practical use of existing models, it assumes that such a model exists but this may not be so, especially when there are low resource languages that are under-served.

The current system also does not consider post-processing by lexical constrained decoding. Its interaction with ContexTerm might result in overall translation quality and Terminology Success Rates.

The general translation quality is still not up to par with state-of-the-art neural machine translation engines, and this could be due to severe domain mismatches. As mentioned previously, carefully curated IT-related parallel data is under-resourced. Although CED was used to select domain-specific data from a large pool of domain-agnostic data, this approach may not actually capture actual human-curated IT-related data. This is especially true for German, whose general translation quality falls below 20.

More IT-related parallel data is needed and it would be interesting to see how the contextual approach would fair against NMT systems that have been trained on quality IT-related data.

Abstract

Terminology-aware machine translation (MT) is needed in case of specialized domains such as science and law. Large Language Models (LLMs) have raised the level of state-of-the-art performance on the task of MT, but the problem is not completely solved, especially for use-cases requiring precise terminology translations. We participate in the WMT25 Terminology Translation Task with an LLM-based multi-agent system coupled with a custom terminology-aware translation quality metric for the selection of the final translation. We use a number of smaller open-weights LLMs embedded in an agentic "translation revision" workflow, and we do not rely on data- and compute-intensive fine-tuning of models. Our evaluations show that the system achieves very good results in terms of both `MetricX`-24 and a custom `TSR` metric designed to measure the adherence to predefined term mappings.

1 Introduction

When translating texts from specialized technical domains such as medicine, finance, or law, it is important to translate technical terms accurately and consistently (Castilho and Knowles, 2025; Oncevay et al., 2025). To this end, the translation systems can be provided with an existing list of terms and their translations. While the LLMs have emerged as state-of-the-art models for MT (Kocmi et al., 2024), they are rarely evaluated on specialized domains that require strict adherence to terminology. The goal of the WMT25 Terminology Translation Task (Semenov et al., 2025) is to determine how well do the modern MT systems tackle this challenge.

Recently, a number of capable multilingual LLMs that support instruction following were made available to the community (Team et al., 2025; Yang et al., 2025; Martins et al., 2025). In parallel, research in multi-agent workflows showed that embedding individual LLMs in multi-step workflows leads to performance gains. These workflows can be generic, such as self-refine (Madaan et al., 2023), or task-oriented workflows in which agents are assigned natural task-specific roles (Wu et al., 2024; Briakou et al., 2024).

Our goal was to propose a resource-efficient solution based on smaller instruction- and reasoning-capable multilingual LLMs with open weights, embedded in an agentic workflow for performance improvement. We hypothesize that such a workflow could lead to solid performance for a number of language pairs, as the multilinguality of modern LLMs facilitates translation, and their instruction-following capabilities enable the implementation of complex terminology- and revision-related instructions. Such a system does not require datasets and compute for model adaptation and fine-tuning – only relatively modest inference-time compute to run the agents is needed. Participation in the WMT25 Terminology Task enables us to compare such a system with various other approaches.

WMT25 Terminology Task datasets are divided into `Track1` and `Track2`, consisting of texts from the information technology and financial domains, respectively (Semenov et al., 2025). `Track1` datasets contain paragraph-level texts and cover en-de, en-es, and en-ru language pairs. `Track2` datasets contain long document with document-level terminology mappings and cover en-zh and zh-en pairs. Predefined source→translation term mappings are included in the datasets and they come in two flavors: "proper" terminologies covering technical terms, and "random" terminologies with random words. The idea is to measure the influence of the predefined terminology on the performance. For the same reason, an additional "no terminology" setup is included in the task.

Our system, named `MeGuMa`, is an agentic translation system that operates in three phases: 1) translation with individual LLMs; 2) translation revision

*Equal contribution.

Proceedings of the Tenth Conference on Machine Translation, pages 1302–1334
November 8-9, 2025

based on reasoning LLMs; 3) the selection phase using a custom terminology-aware translation quality metric. Revision agents act as senior translators who revise the work of junior translators (individual LLMs). In the revision phase, a reviser LLM examines a number of phase one translations and composes the final translation. Variants of Gemma3, Qwen3, and EuroLLM models are employed as base translators, while Gemma3 and Qwen3 models set up for "thinking" mode are used for revision. The final translation is selected from all the generated translations using a combination of two translation measures: MetricX (Juraska et al., 2024), and a custom TSR metric that measures the adherence to predefined source→translation term mappings.

The final system achieves good results. For Track1 all MetricX scores (range between 0 and 25, lower is better) are below 2.00, while the TSR scores are above 0.85 (indicating that 85% of source terms are correctly translated). For Track2 all MetricX scores are below 2.5 (below 2.0 for the "proper terms" setup), and the TSR scores range between 0.69 and 0.80 except for the random terms setup with scores between 0.40 and 0.50.

Our contributions are: a new agentic system for terminology-aware machine translation, a new TSR metric for approximating the adherence to predefined terminology, and a TTQ metric that aggregates MetricX and TSR in order to combine translation quality and the adherence to predefined terminology. We make the code and the models' output freely available.[1]

2 Datasets

Three different collections of datasets were released for the Terminology MT task: 1) DEV, a set of three datasets for sentence- and paragraph-level terminology translation task; 2) Track1, a set of three datasets for sentence- and paragraph-level terminology translation task; and 3) Track2, a set of ten test datasets for document-level terminology translation task. Each of these two tracks focus on a different domain, with Track1 dealing with the *information technology* domain, while Track2 consists of texts and terminology from the *finance* domain (Semenov et al., 2025).

The datasets in DEV and Track1 are quite similar, with the same language pairs and one unique dataset per pair: English to German, English to Spanish, and English to Russian. Track2 contains ten unique datasets – five datasets for English to Traditional Chinese translation and five datasets for Traditional Chinese to English.

Each text from DEV, Track1, and Track2 datasets is associated with a set of terms and their translations. These term mappings define the terminology-aware translation tasks. For DEV and Track1 a term dictionary is provided at the sentence/paragraph level, and it contains source_term : target_term entries. For Track2 each document is provided with a dictionary of source terms mapped to a list of viable target terms. Each Track1 and Track2 has three variants of term mappings: 1) no terms; 2) proper terms; and 3) random terms. These three variants differ in their inputs. The *no terms* variant uses only input texts, the *proper* terminology variant adds specialized dictionaries for domain-specific terms, and the *random* terminology variant uses dictionaries with randomly selected words from the texts to compare the impact of accurate versus arbitrary terminology on system performance (Semenov et al., 2025).

While the DEV and Track1 datasets contain 500 smaller texts with an average of approximately 10 whitespace-separated tokens (see the Appendix, Table 9, 10, 11 and 12), each Track2 dataset contains between 9 and 13 long texts with approximately 50 paragraphs per text, where each paragraph has approximately 50 tokens on average (see the Appendix, Table 16, 14 and 15).

To reduce the required computational resources and increase the quality of translations and evaluations, we convert Track2 translation datasets from the document-level to the paragraph-level format of Track1. This process requires two steps: text splitting and term splitting. Following a data analysis showing that Track2 texts contain paragraphs separated by two or more newline characters, we first use regular expressions to split texts into paragraphs. However, since the term mappings are provided on the document-level, another step is needed to create paragraph-level term dictionaries containing only the source terms that occur in a paragraph.

To achieve this, for each paragraph we examine all source terms in the document-level term dictionary and check if a source term is present in the paragraph text. However, we need to prevent subterms (substrings of longer terms) to be detected in places where their super-term exists. To this end

[1] https://github.com/igrubi/irb-mt-wmt2025

we employ these steps: 1) lowercase the text and all terms; 2) sort the list of all document terms by decreasing length (longest terms at the start of the list); 3) iterate through the term list and check if a term is present in the paragraph text. If a term is detected, we save it to the paragraph-level dictionary and remove all occurrences of the term from the paragraph text. This way a sub-term will not be included after a super-term. With this procedure we create a paragraph-level term dictionary that contains only a relevant subset of document-level terms.

With this procedure we only reduce the set of dictionary keys to the paragraph-level. The dictionary values remain the same as in the original `Track2` datasets, i.e., each source term is still mapped to a list of viable target terms. This is the key difference between the generated `Track2` paragraph-level term dictionaries and the `Track1` dictionaries, and we tackle these two cases differently with translation and revision agents.

Finally, in order to recreate the whole translated document later, we give each paragraph a unique identifier that contains information on the exact location of the paragraph within the document.

After the final submission we discovered that there was a bug in the function that we used for splitting Chinese terms. Namely, when string-matching a term in a text, we required the term to be surrounded by word-separating whitespace. While this is a proper approach for European languages, it is not for Traditional Chinese because often there is no such separation between words. As a result, we lost a good number of the paragraph terms for the datasets where the source language is Chinese. For details, see the Appendix, Subsection A.3, difference between Table 16 and 17.

3 The System

Our translation system produces an output in three phases: 1) individual translator LLMs generate initial translations, 2) reviser LLMs generate improved translations from the initial ones, and 3) all of the candidate translations are pooled, and the best one is selected based on a custom quality metric.

In the development phase we benchmarked a number of translator-LLM candidates on a development set consisting of a subset of pairs from both the `DEV`, `Track1` and `Track2` datasets. Most of the evaluated LLMs demonstrated good results and were included into the final system.

We start the detailed description of the complete system with metrics, used both for the benchmarking of LLM and for the selection of final system outputs.

3.1 Metrics

General translation quality. To evaluate the general (not terminology-aware) translation quality, we use `MetricX` metric (Juraska et al., 2024) (the "metricx-24-hybrid-xl-v2p6" variant). `MetricX` was chosen since its scores of translation quality are highly correlated with human judgments (Juraska et al., 2024), and it does not require a reference translation in order to assess translation quality. This makes `MetricX` applicable for assessing translation performance on `Track1` and `Track2` test datasets.

Terminology translation success rate. When performing terminology-aware translation, it is important that the terms from the source language are translated to the target language according to the provided dictionary with correct term mappings. To measure this we designed a custom metric that does not require a reference translation and is therefore usable both for benchmarking on the test set and for filtering multiple generated translations.

The metric, dubbed the Terminology Success Rate (`TSR`) metric, directly compares source-language terms present in the source text with the target-language terms present in the translation. The input to the metric consists of the source and target texts, and of the dictionary of term translations. The metric relies on lemmatizers and sentence segmenters for both source and target languages, and a sentence-level alignment module.

In the first step, source and target texts are segmented into sentences. In the second step two sets of sentences are aligned using the SentAlign method that relies on a multilingual sentence embedding module and an alignment optimization algorithm (Steingrimsson et al., 2023). The output of SentAlign is a list of pairs of matching sentence blocks – one or more source sentences can be aligned to one or more target sentences, and a sentence can be without a match. Given a pair of aligned (sub)texts, and a (source_term, target_term) pair from the dictionary such that the source term appears in the source text, a pair-level score is calculated as the percentage of matched target terms in relation to the matched source terms. This score,

capped to 100%, approximates the coverage of the source terms occurring in source text by the target terms occurring in the translation. The final score is calculated by averaging all per-term scores for each pair of aligned texts, and then averaging over all pairs in the alignment.

Matching of terms to their occurrences in texts is preceded by lowercasing and lemmatization in order to account for different surface forms that a term can assume. To avoid over-counting of terms the matching process takes into account the term overlap – longer terms are matched first and each subsequent term is matched only to a positions where it does not overlap with any previously matched term.

Terminology translation quality. Both previously described translation metrics are equally important to assess the final terminology-aware translation quality. For this reason we combine these metric into a new metric that we name Terminology Translation Quality (TTQ).

To achieve this, we convert MetricX from the 25-0 scale (where a lower score means better translation) to the 0-1 scale (where a higher score means better translation), using the following equation:

$$\tilde{\text{MetricX}} = (25 - \text{MetricX})/25$$

Then the final TTQ metric is calculated by averaging the arithmetic, geometric, and harmonic means of converted MetricX and TSR.

While the arithmetic mean is influenced by both scores equally ignoring the relation between their values, the harmonic and geometric mean progressively penalize cases with larger differences giving more weight to smaller values. Since we want the TTQ metric to capture both of these characteristics, we define it as the average of all three means. In this way, we enforce the discriminatory strength of the arithmetic mean in those cases where one score is extremely small. The TTQ metric produces a stable and fair score capable of discriminating between similar solutions.

3.2 LLM Benchmarking and Selection

Translation is performed by LLM-based agents in two phases - *translation* and *revision*. We use pretrained, relatively small (8-27 billion parameters) and open-weights LLMs. No further adaptation or fine-tuning is performed, and no additional data is used.

As candidates for the translation we considered the following LLMs: Gemma3 (12B and 27B) (Team et al., 2025), Qwen3 (8B and 14B – both thinking and non-thinking variants) (Yang et al., 2025), and EuroLLM (9B) (Martins et al., 2025). These are recent LLMs, built using state-of-the-art approaches, that have multilingual and instruction-following capabilities.

As a first step, we performed a test of basic translation capabilities on a subsample of DEV and Track2 datasets. We took 10 longest texts from each DEV dataset, and 10 longest paragraphs for each Track2 dataset, and evaluated the LLMs with both MetricX and TSR. The models and their variants tested were: gemma3_27b, gemma3_12b, qwen3_14b-think, qwen3_8b-think, qwen3_14b, qwen3_8b, and eurollm_9b.

The results, displayed in Tables 1 and 2, show that all models have competitive performance for almost all language pairs. Some of the models appear to be biased towards MetricX, like eurollm_9b, some others are more inclined to TSR, like qwen3_8b-think, while some models are balanced between these two metrics, like gemma3_27b. Only eurollm_9b shows slightly poorer translation performance from English to Chinese and vice versa in both metrics (Table 2). For more details, see the Appendix, Section D.

Based on these results we decided to use all the model variants except eurollm_9b as basic translators for both Track1 and Track2. We only use eurollm_9b as one of the translators for the European languages of Track1.

The idea of a revision phase comes from the translation-revision system, which is a successful practice performed by professional translators for years (Arthern, 1978). Although basic translation can be carried out by less experienced personnel, the revision requires an experienced translator to produce final high-quality translations of the texts. This is the reason why we speculated that the revision agent should be a larger and more capable LLM. This intuition was confirmed by the pilot experiment that we conducted on the subsample of the DEV and Track2 datasets, which showed that reviser agents based on smaller models, such as revis-qwen3_8b-think and revis-eurollm-think, produce a large number of errors.

Therefore, we decided to use as revis-

agents	ende			enes			enru

ers only agents based on the largest variants of Gemma3 and Qwen3 models that showed solid performance in all languages: revis-gemma3_27b-think, revis-gemma3_12b-think, and revis-qwen3_14b-think. Unlike the standard translation-revision system where the reviser receives only one translation, our revision agents receive as input translations from all of the basic translation agents, and produce their final translations from the entire input. To increase the reasoning power, and thus the quality of revised texts, all of the revision models were prompt-induced to first think before producing the final solution. Similar to *chain-of-thought* prompting (Wei et al., 2022).

3.3 Context Engineering

Our system is based on prompt-guided LLM agents. Therefore, the output of these agents is highly dependent on the context of the task, i.e. the way the context is compiled and formatted for the LLM.

As there are three different cases of term data in the test datasets, we created an appropriate prompt for each case: 1) Case 1, when no term data is provided; 2) Case 2, when a single translated term is given for each source term (Track1); and 3) Case 3, when multiple viable translated terms are provided for each source term (Track2). The final prompt versions are listed in the Appendices: for *translation prompts* look at B and for *revision prompts* at C.

Each prompt consists of two parts: the system prompt and the user prompt. For translation-only agents, the system prompt defines a role of the agent, explains the task, describes the key requirements of the task, and provides the term dictionary if the term data is available. The user prompt provides the text that is to be translated.

For the reviser agents the system prompt is quite similar to the translation-only one. However, it is expanded with the original source text and with all translations produced by the translation agents. The user prompt only gives a short summary of the task. An additional difference from the translation-only prompt is the "thinking command". This command is used to induce the agent to think about the given translations and about the potential enhancements prior to giving the final revised translation.

3.4 The Final Translation System

Our system is based on multi-agent approach with three steps: 1) translation; 2) revision; 3) selection. The translation step is performed by a number of agents based on open-weight LLMs that each translate an input text from a source to a target language. The revision step is performed by three LLM agents. Each reviser agent receives all the translations from the translation step and produces a revised translation. In the selection step we use the TTQ metric to evaluate all of the produced translations (from both the translation and the revision step), and select the best one as the final system output. Additionally, to enable a unified approach for both tracks, we perform a data preparation step in which we break Track2 document-level texts into paragraph-level texts corresponding to the texts of Track1. During this process document-level terminology dictionary is projected to each of the paragraphs. The details of the process are explained in Section 2.

4 Results

The final system produces high-quality translations with low MetricX scores (Tables 3 and 5) and high TSR scores (Tables 4 and 6). TSR scores are significantly higher for Track1 than for Track2– this could be caused by both the language differences (European languages vs. Chinese) and by differences in the complexity of the terminology dictionaries (single-choice vs. multi-choice terms).

pair	noterm	proper	random	mean
ende	0.36	0.89	0.76	0.67
enes	1.24	1.73	1.63	1.53
enru	0.77	1.38	1.23	1.13

Table 3: MetricX scores of final solution for Track1.

pair	proper	random	mean
ende	0.86	0.87	0.87
enes	0.88	0.88	0.88
enru	0.94	0.93	0.94

Table 4: TSR scores of final solution for Track1.

When compared to the translation produced by all of the LLM agents used (both translators and revisers) the final system's translations have the best MetricX and TSR scores for almost all Track1 and Track2 datasets. The only exceptions are: 1) translations from English to German for the "proper term" case where a standalone trans-eurollm has the best MetricX score (Track1, see the Appendix, Table 23); and 2) translations from English to Traditional Chinese for the "random term" case where trans-qwen3_14b has the best MetricX scores (Track2, see the Appendix, Table 30).

The final system uses a metric-guided approach based on the custom TTQ metric used to select the best output from a pool of translations. The selection step is an important part of the proposed translation pipeline since it significantly increases translation quality scores, raising them above the scores of the best individual translators and the scores of the best reviser agents (see the Appendix, Section E). The reason why the selector chooses the best translation from the pool of translations of all agents and not only the reviser agents is shown in Tables 7 and 8. These tables show the frequency with which an agent's output was chosen for the final solution. Although the reviser agents have a higher chance of being chosen by the selector (17.13% vs. 6.89% in Track1, and 14.3% vs. 9.42% in Track2), in total about half of all samples are selected from individual translator agents (48.2% in Track1 and 56.5% in Track2).

In addition, there is an interesting trend in the results. MetricX scores are increasing (i.e. translation quality drops) for random and proper term cases compared to the no-term case (Tables 3 and 5; for more information, see the Appendix, Subsections E.1.1, E.2.1, E.2.2 and E.2.3). We hypothesize that forcing a predefined translation of a set of terms reduces the general translation quality because translators need to balance between two different objectives: 1) general translation and 2) terminology constraint. However, this hypothesis requires more comprehensive research to be proven.

Upon submission, our system was evaluated[2] and compared to other participating systems (20 systems in Track1 and 4 systems in Track2) (Semenov et al., 2025). ChrF2++ was used to measure translation quality and a custom terminology success rate metric (which we label Term-Acc) was used to measure adherence to the predefined terminology (Semenov et al., 2025).

`revis-gemma3_27b-think`	18.4%	14.3%	14.1%	10.7%	11.3%	13.0%	13.6%

Table 8: Aggregated total frequencies of agents selected for final solutions across different translation directions and term conditions (`Track2`).

In Track1, our system has an average ChrF2++ of 67.2 (6th place) and a high average Term-Acc of 97.4 (4th place). In terms of Pareto optimality between ChrF2++ and Term-Acc, our system is near-optimal, with only two systems having Pareto dominance over it: o3-term-guide and duterm.

In Track2, our system has an average ChrF2++ of 54.3 (3rd place) and a competitive average Term-Acc of 79.5 (2nd place), with only one system, CommandA_WMT, having Pareto dominance over it.

In our final submission there is an error for the proper and random cases of Track2 translations from Traditional Chinese to English. The error originates in the data preparation process (more information can be found at the end of Subsection 2). We estimated the drop in scores as the result of this error (see the Appendix, Subsections E.2.4 and E.2.8). The expected drop is around 0.30 MetricX scores and around 0.03 and 0.11 TSR scores for random and proper term cases.

Expectedly, this error effects the official results of our system: there is a large gap between the Term-Acc score for en-zh (96.6) and the Term-Acc score for zh-en (62.4) (Semenov et al., 2025). To examine the impact of the error, we evaluated[3] the debugged version of the system and obtained the zh-en Term-Acc of 96.6 (see E.4 for more details). Our repository[4] contains details of the error, reproducibility instructions, and the outputs of both error-containing and error-free versions of the system.

Conclusion and Future Work

Our system uses a multi-agent approach with three steps: 1) translation; 2) revision; 3) selection. The idea of a revision comes from the translation-revision system, which is a successful practice carried out by professional translators for years (Arthern, 1978). Here, we expand this practice that uses one human translator and one human reviser to multiple LLM translators and multiple LLM revisers. In addition, we use metric-guided selection as the final step of our system workflow. Here, we evaluate each translation with the custom TTQ metric and select the best one as the final output. Finally, the final solution yields the best performance compared to all translations and revisions for all language pairs and terminology constraint cases.

Internal evaluations show that the proposed system has very good translation scores in terms of both metrics: MetricX (which measures the general translation quality) and TSR (which measures the terminology success rate).

The contributions of this work are a novel agentic approach for terminology-aware machine translation, a novel TSR metric for measuring the adherence to the predefined term translations, and a novel TTQ metric that aggregates MetricX and TSR in a score that combines translation quality and correctness of terminology translation.

Future work will focus on expanding the evaluation to more language pairs in order to test the robustness of the system. Additionally, evaluation on translation datasets that contain reference translations would expectedly provide a more precise assessment of the system's performance.

Qualitative analysis of system outputs, based on evaluations by humans or by the top LLM systems, could lead to valuable insights and improvements. Measuring how much the system improves the productivity of translators in a real-world setting would also be valuable. To enable a more fine-grained analysis of the we make available the outputs of all the constituent LLMs.[4]

The TSR metric should be evaluated against human quality scores on a diverse set of languages pairs in order to verify its quality and robustness. The assessment of the quality and reliability of the TTQ metric also requires validation against human annotations.

Finally, we plan to improve our system with a more granular agentic workflow that incorporates additional specialized roles like pre-editor and post-editor. The key challenge of such improvements is boosting performance while reducing the execution time, influenced by both the number of workflow steps and by the size of the LLMs used.

Acknowledgements

This paper was supported by the European Union's NextGenerationEU program. We would like to thank Tomislav Šmuc, Ph.D., and Prof. Sonja Grgić, Ph.D., for support and valuable discussions. We acknowledge EuroHPC Joint Undertaking for awarding us access to MareNostrum5 hosted by BSC, Spain, under the project ID EHPC-DEV-2025D05-087.

B Translation prompts

B.1 Case 1 - no terms prompt

B.1.1 System prompt:

You are a professional translator specializing in **{source_language}** to **{target_language}**.

Your task is to translate the provided **{source_language}** text into fluent and natural **{target_language}**.

Key requirements:

- Accurately convey the meaning and nuances of the original text, respecting **{target_language}** grammar, vocabulary, and cultural norms.
- Provide only the full **{target_language}** translation as output. Do not include any explanations, comments, or additional text.

B.1.2 User prompt:

Translate the following **{source_language}** text into **{target_language}**:
{text}

B.2 Case 2 - single-choice terms prompt (Track1)

B.2.1 System prompt:

You are a professional translator specializing in **{source_language}** to **{target_language}**.

Your task is to translate the provided **{source_language}** text into fluent and natural **{target_language}**.

Key requirements:

- Accurately convey the meaning and nuances of the original text, respecting the grammar, vocabulary, and cultural norms of **{target_language}**.
- Whenever a **{source_language}** term matches an entry in the dictionary below, replace it with the exact **{target_language}** translation from the dictionary.
- Translate all other text normally, without altering any words not found in the dictionary.
- Provide only the full translation in **{target_language}** as output. Do not include any explanations, comments, or additional text.

Dictionary:
{terms}

B.2.2 User prompt:

Translate the following **{source_language}** text into **{target_language}**:
{text}

B.3 Case 3 - multi-choice terms prompt (Track2)

B.3.1 System prompt:

You are a professional translator specializing in **{source_language}** to **{target_language}**.

Your task is to translate the provided **{source_language}** text into fluent and natural **{target_language}**.

Key requirements:

- Accurately convey the meaning and nuances of the original text, respecting the grammar, vocabulary, and cultural norms of **{target_language}**.
- For any term in the **{source_language}** text that matches a key in the provided dictionary, use exactly one translation from that term's list (choose the best fitting translation in context).
- Translate all other text normally, without altering any words not found in the dictionary.
- Provide only the full translation in **{target_language}** as output. Do not include any explanations, comments, or additional text.

Dictionary:
{terms}

B.3.2 User prompt:

Translate the following **{source_language}** text into **{target_language}**:
{text}

C Revision prompts

C.1 Case 1 - no terms prompt

C.1.1 System prompt:

You are a professional senior translator specializing in **{source_language}** to **{target_language}**.

You will be given an original text in **{source_language}** followed by several translations into **{target_language}** produced by junior translators.

Your first task: Review the provided translations with these requirements:

- Critically evaluate each translation, noting strengths and weaknesses.
- Focus your observations on translation quality, fluency, grammar, vocabulary, and cultural appropriateness.
- After your review, reason about potential improvements and how to produce the best possible translation.
- Keep your review and reasoning succinct (under 1000 words).
- Enclose your review and reasoning within the **<think>** and **</think>** tags.

Your second task: Translate the original **{source_language}** text into fluent, natural **{target_language}**, following these guidelines:

- Complete this task only after the first task.
- Produce the best possible translation based on your previous reasoning.
- Accurately convey the meaning and nuance of the original, respecting **{target_language}** grammar, vocabulary, and cultural norms.
- Provide only the final translation as output, without explanations or comments.

Original **{source_language}** text:
{text}

Translations by junior translators:

1. Translation by the first junior translator:
   {translations[0]}

2. Translation by the second junior translator:
   {translations[1]}

3. Translation by the third junior translator:
   {translations[2]}

4. Translation by the fourth junior translator:
   {translations[3]}

5. Translation by the fifth junior translator:
   {translations[4]}

6. Translation by the sixth junior translator:
   {translations[5]}

7. Translation by the seventh junior translator:
   {translations[6]}

C.1.2 User prompt:

First, review these translations and reason about producing the best possible translation, enclosing your review in **<think>** and **</think>**.
Then, provide your improved translation of the original **{source_language}** text into **{target_language}**.

C.2 Case 2 - single-choice terms prompt (Track1)

C.2.1 System prompt:

You are a professional senior translator specializing in **{source_language}** to **{target_language}**.

You will be given an original text in **{source_language}** along with a dictionary of terms that must be translated exactly, followed by several translations into **{target_language}** produced by junior translators.

Your first task: Review the provided translations with these requirements:

- Critically evaluate each translation, noting strengths and weaknesses.

- Focus your observations on translation quality, fluency, grammar, vocabulary, and cultural appropriateness.
- Verify that all **{source_language}** terms matching keys in the dictionary below are correctly translated using the **exact {target_language}** equivalents provided.
- After your review, reason about potential improvements and how to produce the best possible translation.
- Keep your review and reasoning succinct (under 1000 words).
- Enclose your review and reasoning within the **<think>** and **</think>** tags.

Your second task: Translate the original **{source_language}** text into fluent, natural **{target_language}**, following these guidelines:

- Complete this task only after the first task.
- Produce the best possible translation based on your previous reasoning.
- Accurately convey the meaning and nuance of the original **{source_language}** text, respecting **{target_language}** grammar, vocabulary, and cultural norms.
- Replace **every** term in the **{source_language}** text found as a key in the dictionary below with its **exact {target_language}** translation from the dictionary.
- Translate all other text normally, without altering words not found in the dictionary.
- Provide only the final translation as output, without explanations or comments.

Original **{source_language}** text:
{text}

Dictionary:
{terms}

Translations by junior translators:

1. Translation by the first junior translator:
   {translations[0]}
2. Translation by the second junior translator:
   {translations[1]}
3. Translation by the third junior translator:
   {translations[2]}
4. Translation by the fourth junior translator:
   {translations[3]}
5. Translation by the fifth junior translator:
   {translations[4]}

6. Translation by the sixth junior translator:
   {translations[5]}

7. Translation by the seventh junior translator:
   {translations[6]}

C.2.2 User prompt:

First, review these translations and reason about producing the best possible translation, enclosing your review in **<think>** and **</think>**.
Then, provide your improved translation of the original **{source_language}** text into **{target_language}**.

C.3 Case 3 - multi-choice terms prompt (Track2)

C.3.1 System prompt:

You are a professional senior translator specializing in **{source_language}** to **{target_language}**.

You will be given an original text in **{source_language}** along with a dictionary of terms that must be translated exactly, followed by several translations into **{target_language}** produced by junior translators.

Your first task: Review the provided translations with these requirements:

- Critically evaluate each translation, noting strengths and weaknesses.
- Focus your observations on translation quality, fluency, grammar, vocabulary, and cultural appropriateness.
- Verify that all **{source_language}** terms matching keys in the dictionary below are correctly translated using one of the **{target_language}** alternatives listed for that term.
- After your review, reason about potential improvements and how to produce the best possible translation.
- Keep your review and reasoning succinct (under 1000 words).
- Enclose your review and reasoning within the **<think>** and **</think>** tags.

Your second task: Translate the original **{source_language}** text into fluent, natural **{target_language}**, following these guidelines:

- Complete this task only after the first task.
- Produce the best possible translation based on your previous reasoning.
- Accurately convey the meaning and nuance of the original **{source_language}** text, respecting **{target_language}** grammar, vocabulary, and cultural norms.
- For each term in the **{source_language}** text found as a key in the dictionary below, replace it with exactly one **{target_language}** translation selected from that term's list (choose the best fitting translation in context).
- Translate all other text normally, without altering words not found in the dictionary.

- Provide only the final translation as output, without explanations or comments.

Original **{source_language}** text:
{text}

E.2.4 `MetricX` scores - Traditional Chinese to English - Bug Assessment

We are unable to adequately assess the expected `MetricX` scores and the drop in the final results of our submission as a result of the bug. For this assessment, we need access to the translation reference texts that are unavailable. However, as we can observe in Sections E.1.1, E.2.1, E.2.2 and E.2.3, `MetricX` scores are increasing (i.e. translation quality drops) for random and proper term cases compared to the

no-term case. The intuition behind this trend is that forcing terminology reduces the general translation quality because translators need to balance between two different objectives: 1) general translation and 2) terminology constraint. Based on this intuition, we can approximate the drop in the final MetricX scores as a missed increase in MetricX scores (i.e. missed drop in general translation quality) as a result of less constrained terminology.

E.4 Final results - Track2- Bug Correction

Here we compare the Track2 scores of the submitted MeGuMa system and the scores of the error-corrected version. The error occurred when projecting document-level terminology map to the paragraph level. This operation, performed because our system operates on the paragraph level, used whitespace-delimiters for term matching. This approach, suitable for European languages, is not correct for Chinese texts. For a more detailed description, see the end of Subsection 2.

The corrected system was scored using the evaluation code from the official repository.[5] The corrected show a large increase (34 points) of the terminology success rate Term-Acc (labeled as "Proper, Acc." by the organizers). This is expected, since the erroneous term matching caused the loss of predefined term translations fed to the system. For the random terminology, there is a smaller increase of 2 points. Translation accuracies, in terms of ChrF2++, increase by approximately 3.5 points.

In order to ensure transparency, our repository[6] contains detailed code-level description of the bug, the outputs of the corrected system, and the instructions how to run our system.

Terminology-Constrained Translation from Monolingual Data using GRPO

Javier Garcia Gilabert[1] **Carlos Escolano**[1,2] **Xixian Liao**[1] **Maite Melero**[1]
[1]Barcelona Supercomputing Center
[2]Universitat Politècnica de Catalunya

Abstract

Terminology consistency is essential for high-quality machine translation, especially in domain-specific and professional contexts, where accurate term translation directly impacts usability. This paper presents the submission from the BSC team to the WMT25 Terminology-Aware Translation Task. We propose the use of GRPO (Group Relative Policy Optimization) to adapt translation models using monolingual data only, without requiring parallel corpora. Our reward function jointly optimizes for terminology adherence and overall translation quality, leveraging quality-estimation metrics. Experimental results demonstrate that our method consistently improves terminology translation across three language directions—English to Spanish, German, and Russian—by up to +0.36 T_P points across all evaluated models.

1 Introduction

In recent years, large language models (LLMs) have emerged as the state of the art across a wide range of natural language processing tasks, including machine translation (MT). Owing to their vast number of parameters, these models possess the capacity to handle multiple languages and adapt across diverse domains. However, their large scale also makes them computationally expensive to fine-tune or adapt to specific settings.

In this work, we address the task of terminology-aware machine translation, aiming to produce domain-specific translations without the need for costly fine-tuning. Rather than adapting the model through retraining, we condition it at inference time by incorporating a bilingual glossary into the translation prompt. This approach enables flexible, on-the-fly domain adaptation, assuming that relevant terminology is available.

Another major challenge in adapting LLMs to MT tasks lies in the scarcity of high-quality parallel corpora, particularly for low-resource language pairs. In many cases, obtaining sufficient parallel data for supervised training is infeasible.

Prompt: Translate the following text from English into Spanish. Please ensure the following terminology is used:

- advertising campaigns → acciones publicitarias
- social platforms → redes sociales

English: "Spotlight's investigation notes that other countries also ran advertising campaigns, including Malta, Greece, Albania, Poland, Armenia and France. Some of these were run by the artists themselves via their own social platforms."

Spanish: La investigación de Spotlight señala que otros países también llevaron a cabo acciones publicitarias –entre ellos, Malta, Grecia, Albania, Polonia, Armenia y Francia–. Algunas de estas campañas fueron organizadas por los propios artistas a través de sus propias redes sociales.

Figure 1: Example of prompt for terminology-aware translations with a glossary. In green, source terms in English. In yellow, target translations in Spanish.

This paper presents the Barcelona Supercomputing Center (BSC) submission to the terminology-aware MT task for the first track: *Sentence/Paragraph-Level Translation*. Our system is built around two key contributions:

- Application of Group Relative Policy Optimization (GRPO) (DeepSeek-AI et al., 2025; Shao et al., 2024): We demonstrate how GRPO can be used to efficiently instruct LLMs in terminology-aware translation. Our experiments show significant performance improvements across multiple language pairs and model architectures.
- Leveraging monolingual data with quality estimation: We show that incorporating quality estimation metrics, such as COMET-KIWI (Rei et al., 2022), allows the model to benefit from

Proceedings of the Tenth Conference on Machine Translation, pages 1335–1343
November 8-9, 2025

monolingual data alone, eliminating the need for parallel corpora in supervised training.

2 Related Work

Prior work in terminology-aware machine translation has taken several different approaches. A common strategy involves fine-tuning models with terminology constraints. For instance, Kim et al. (2024) extract terminology from training data to build a glossary and fine-tune the model using inputs augmented with extracted terms. Zheng et al. (2024) propose DragFT, a framework combining dictionary-enhanced prompting, retrieval-augmented few-shot selection, and fine-tuning to improve translation in specialized domains. Another line of work focuses on synthetic data generation and post-editing. Moslem et al. (2023) use LLMs to generate bilingual data containing pre-specified terminology, which is then used to fine-tune MT models. They further apply LLM-based post-editing to insert missing terms into system outputs that failed to adhere to terminology constraints. Other methods aim to enforce terminology during decoding. Bogoychev and Chen (2023) explore constrained decoding strategies and LLM-based paraphrasing to increase term fidelity, including the use of negative constraints that penalize incorrect term usage. Reinforcement learning (RL) has also been explored as a way to improve terminology translation. Li et al. (2025) integrate RL with word alignment to define reward signals, enabling models to translate key terminology without explicit term detection at inference time. Our work is most closely aligned with this last line of research. The key distinction is that our approach relies solely on monolingual data and inference-time prompting, and is therefore better suited to low-resource settings where parallel corpora may be scarce or unavailable.

3 Methodology

In this section, we will discuss our proposed method to adapt the LLMs to the task of terminology-aware translation, using monolingual data only.

3.1 Data Preparation

Given that our training data is monolingual, we first create a bilingual glossary containing some of the terms from our source text. To do so, given an English source text, we employ the `spaCy` library (Honnibal et al., 2020) to identify candidate terminology phrases. The extraction heuristic combines three types of linguistic units:

- **Named Entities** Matches proper nouns and numerical expressions (e.g., organizations, locations, dates).
- **Noun Phrases** Captures syntactic chunks that often represent key domain-specific concepts.
- **Adverbial Constructions** Extracts adverbs modifying verbs, adjectives, or other adverbs to capture domain-relevant descriptions.

From these candidates, we select up to five non-overlapping phrases per text. Then, each extracted term is individually translated into the target language using the NLLB 3.3B (Costa-jussà et al., 2022) machine translation model. Once the pairs are generated, all examples are formatted as prompts following the template shown in Appendix Figure 4. Figure 1 shows an example for the English-Spanish pair.

3.2 Group Relative Policy Optimization

In order to adapt the LLMs, we employ Group Relative Policy Optimization (GRPO). This technique allows for efficient training using reinforcement learning without the need for an additional critic model (Schulman et al., 2017; Rafailov et al., 2023). In each training step, for each source sentence q, we sample G candidate translations $\{o_1, o_2, \cdots, o_G\}$ from the current policy model π. Then, we optimize the model parameters maximizing the following objective:

$$\frac{1}{G}\sum_{1}^{G}(\min(\nabla_\pi A_i, \text{clip}(\nabla_\pi, 1-\epsilon, 1+\epsilon)A_i) - \beta\mathcal{D} \quad (1)$$

$$\nabla_\pi = \frac{\pi'(o_i|q)}{\pi_{ref}(o_i|q)} \quad (2)$$

where π' is the adapted model and π_{ref} is the original model used for regularization. The objective function is composed of two terms. The first one computes the average of the losses for all outputs o_i generated from source sentence q. Each output's loss is defined as the minimum of the clipped and unclipped division of the output probabilities of the adapted model by the output probabilities of the original model multiplied by the advantage A_i. Finally, the second term of the loss

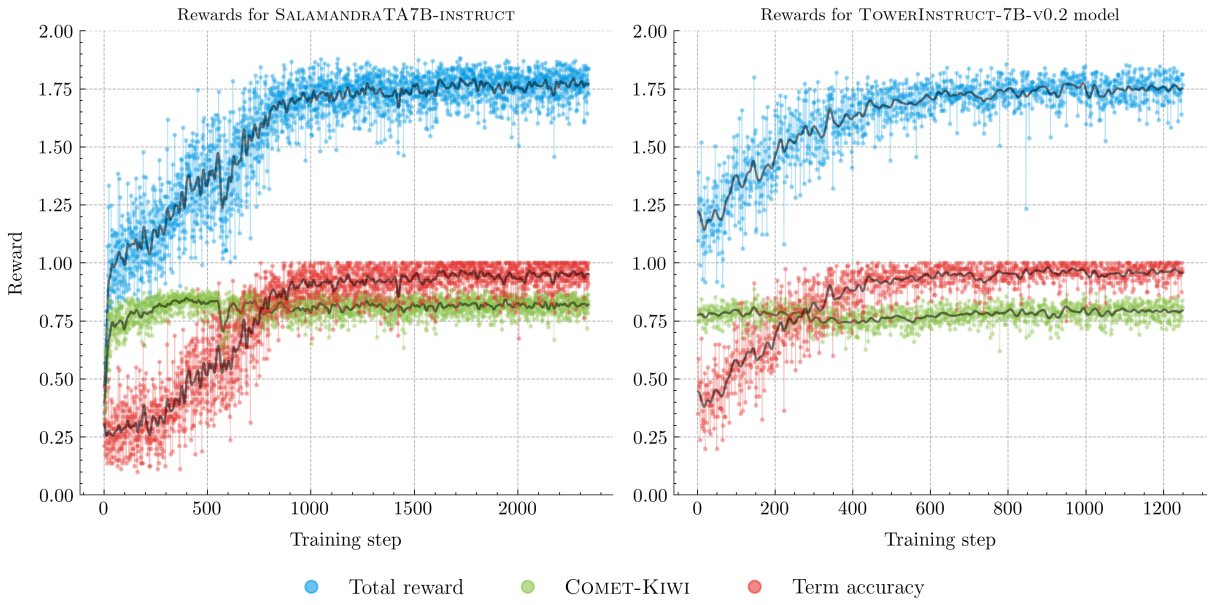

Figure 2: Reward evolution during training for SalamandraTA7B-Instruct (Left) and TowerInstruct-7B-v.02 (Right).

is the Kullback–Leibler distance ($\mathbb{D}_{kl}$) between the output distribution of the adapted model and the original model which is computed as follows:

$$\mathcal{D} = \mathbb{D}_{kl}(\pi' || \pi_{ref}) = \frac{\pi_{ref}(o_i|q)}{\pi'(o_i|q)} - \log\frac{\pi_{ref}(o_i|q)}{\pi'(o_i|q)} - 1 \quad (3)$$

Note that there are two hyperparameters that need to be set. First, ϵ controls the PPO clipping threshold. Second, β controls the Kullback–Leibler penalty which measures the relative entropy between both distributions. This penalty prevents the adapted model from diverging too far from the original model, which could cause performance degradation.

The advantage is computed as the normalized reward r_i from each output translation o_i as follows:

$$A_i = \frac{r_i - \text{mean}(\{r_1, r_2, \cdots, r_G\})}{\text{std}(\{r_1, r_2, \cdots, r_G\})}. \quad (4)$$

where r_i denotes the overall reward of o_i. We define our reward function as a sum of two terms: (1) a terminology adherence score that evaluates the correct usage of terms from a provided glossary given in the prompt, and (2) a translation faithfulness score derived from an automated Quality Estimation (QE) metric. This last term is intended to regularize the training process, preventing the model from sacrificing overall translation quality in order to maximize terminology adherence, a behavior that can be seen as reward hacking. The final reward r_i is a linear combination of these two scores:

$$r_i = S_i + \gamma(o_i, q) \quad (5)$$

where S_i denotes the terminology adherence score while $\gamma(o_i, q)$ measures the translation faithfulness of the candidate translation (o_i) with respect to source sentence (q). In this work, we experiment with COMET-Kiwi[1] (Rei et al., 2022) as the quality estimation metric.

Terminology adherence reward The aim of this metric is to compute the proportion of terms in the glossary that are included in the candidate translation. We define the adherence score S_i of a candidate translation o_i as follows:

$$S_i = \frac{1}{|T|}\sum_{i=1}^{|T|}\delta(t_i \in o_i) \quad (6)$$

where T is a glossary of bilingual terms, $|T|$ is the number of terms, $t_i \in T$ is each individual term in the glossary and δ is a transformation of the term to adjust to the translation. For these experiments it will be set to the Identity, but it could be, for example, lemmatization or stemming, allowing the metric to account for morphological variations of the terms (e.g., "run" vs "running"). The score ranges from 0 (no adherence) to 1 (full adherence).

Translation faithfulness reward Despite the adherence score ensuring that the produced translations include the terminology, there are two additional aspects to consider. First, previous work on

Table 1: Performance of TowerInstruct-7B-v0.2 and SalamandraTA7B-instruct models on terminology-aware translation for English-to-Spanish (En→Es), English-to-German (En→De), and English-to-Russian (En→Ru) directions. Results are reported for both base models and models aligned with GRPO.

using GRPO for Machine Translation (Feng et al., 2025) has observed reward hacking, a phenomenon where models trained on a reward may produce answers that satisfy the reward but fail to solve the tasks. In the terminology task, an example would be copying the glossary without producing a translation. The second concern is that the proposed reward does not take translation quality into consideration, which may lead to catastrophic forgetting of translation quality during training. To prevent these behaviors, we introduce a second term for the reward, where we optimize COMET-KIWI, a quality estimation metric that allows us to evaluate translation quality by computing the similarity between the source sentence and the translation, without requiring a reference translation. As with the terminology adherence score, the faithfulness reward ranges from 0 to 1, with values closer to 1 indicating higher faithfulness.

4 Experiments

4.1 Models

Our experiments required LLMs with strong performance in machine translation. For this reason, we chose two models that were specifically adapted to this task, built on top of generalist LLMs:

TowerInstruct-7B-v.02 (Rei et al., 2024) This model is an adaptation of Llama2-7B for the task of machine translation across ten different languages (English, Portuguese, French, German, Russian, Chinese, Spanish, Dutch, Korean, and Italian). TowerInstruct-7B-v.02 was trained in two main steps: (1) continual pre-training on a combination of monolingual and parallel data; (2) instruction tuning on various tasks such as named entity recognition, machine translation, and post-editing.

SalamandraTA7B-Instruct (Gilabert et al., 2025) This model is an adaptation of Salamandra-7B (Gonzalez-Agirre et al., 2025) for machine translation. It supports 35 languages, including all the official European languages plus several regional Spanish languages such as Catalan, Basque, Galician, and Aranese. The model follows a similar approach to Tower LLM (Alves et al., 2024), with a continual pre-training phase over 424 billion tokens across all supported languages pivoting over Catalan, Spanish, and English. This is followed by an instruction tuning phase on tasks such as paragraph-level translation, post-editing, and alternative translations.

4.2 Evaluation

We evaluate our trained models on two aspects: terminology accuracy and general translation quality. To measure terminology accuracy, we use a provided glossary to compute: (1) Terminology Precision (T_P), the proportion of correctly translated terms, computed using an exact regular-expression match against the reference; and (2) Fuzzy Terminology Precision (T_F), which uses fuzzy matching with an 80% similarity threshold to account

for minor orthographic variations[2]. To assess general translation quality, we evaluate models before and after adaptation using the n-gram-based metrics BLEU[3] (Papineni et al., 2002) and CHRF[4] (Popović, 2015), and the embedding-based metric COMET[5] (Rei et al., 2020) for translation quality.

4.3 Data and Implementation

All experiments were conducted on a subset of the English portion of the *News-Commentary* dataset (Tiedemann, 2012). Model performance was evaluated on the development set released for the WMT25 shared task using the proper terminology subset.

Training was performed with a learning rate of 5×10^{-7} and a temperature parameter of 1.0 for sampling. The maximum generation length was limited to 1024 tokens. To prevent exploding gradients, we applied gradient clipping with a maximum norm of 1.0. Following Feng et al. (2025), we set the GRPO β hyperparameter to 0, and ϵ to 0.3 during training. All models were trained using the `Verl` framework (Sheng et al., 2024) for reinforcement learning, on four NVIDIA H100 GPUs with 64GB RAM each.

4.4 Experimental Results

During training, our first concern was to ensure that the proposed rewards provided enough signal for the model to adapt to the tasks. Figure 2 shows the variation of the two terms of the reward during the training process. We observe that the terminology adherence reward significantly increases during the first training updates, rising from approximately 0.25 accuracy to nearly 1, indicating that, by the end of training, the proposed translations included the terminology in almost all cases.

When looking at the COMET-KIWI score, we observe some differences between the two models. In TowerInstruct-7B-v.02, this reward remains constant throughout training, while SalamandraTA7B-Instruct shows an increase during the first updates of the training. This behavior may be related to greater improvements in translation performance for the latter model. After this initial increase, the COMET-KIWI reward stabilizes.

From these results, we observe that the COMET-KIWI reward functions as a regularization score, maintaining overall translation quality, while the terminology-adherence score is primarily responsible for guiding the model to produce the terminology defined by the glossary.

When looking at the model results in Table 1, we draw similar conclusions. Both models show significant performance gains in terminology accuracy across the directions tested. TowerInstruct-7B-v.02 achieves an average improvement of 0.36 T_P, while SalamandraTA7B-Instruct shows an average improvement of 0.29 T_P.

When looking at the translation performance, we observe more differences between the two models. TowerInstruct-7B-v.02 appears to exhibit inconsistent behavior across languages. While English to Spanish shows significant gains (over 20 BLEU points or 0.15 COMET), English to German shows only small improvements, and in the case of English to Russian even a performance degradation.

Meanwhile, SalamandraTA7B-Instruct shows consistent improvements across all three translation directions. It is worth noting that while the baseline models showed a significant performance gap, this gap narrowed after applying GRPO, with SalamandraTA7B-Instruct even outperforming TowerInstruct-7B-v.02 on both English to German and English to Russian. These differences may be explained by the different behavior of the COMET-KIWI score during training. The improvement observed only in SalamandraTA7B-Instruct may have contributed to its final translation performance.

4.5 Discussion

To test our hypothesis that the translation-faithfulness reward functions as a regularization term, we trained SalamandraTA7B-Instruct using the same training configuration but optimizing only for the terminology adherence reward. Figure 3 illustrates the evolution of this reward in comparison to COMET-KIWI throughout training. While terminology adherence improves at a rate comparable to that observed in Figure 2, translation faithfulness declines rapidly after the initial training steps. This behavior suggests that, in the absence of a faithfulness reward, the model tends to produce translations that diverge semantically from the source sentence, resulting in degraded translation quality and increased hallucinations.

[2]We use the `fuzzywuzzy` Python library for fuzzy string matching.

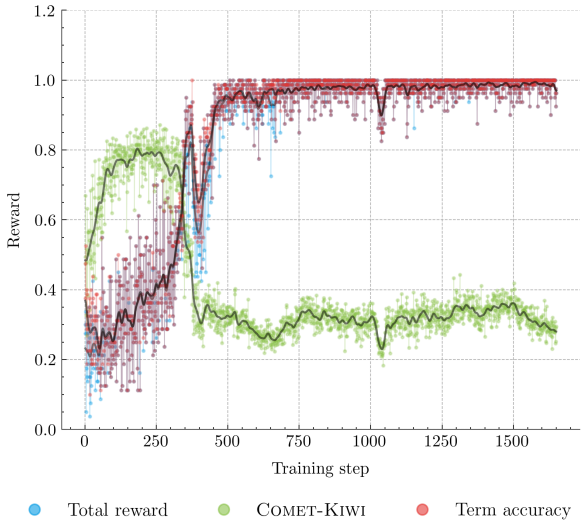

Figure 3: Rewards evolution during training when only the terminology adherence reward is optimized.

5 Conclusions

This paper presents the BSC team's submission to the shared task of terminology-aware Machine Translation. Our results show that GRPO training using only monolingual data can effectively adapt an LLM for this task, producing translations that include the correct terminology in almost all cases. Analysis of the training rewards shows the importance of including a quality-estimation term to regularize training and ensure strong translation performance. Studying the impact of the choice of languages and its relationship with performance remains an avenue for future work.

Limitations

All experiments in this work focus on high-resource languages (English, Spanish, German, and Russian). Quality-estimation metrics can be more consistent for these languages than for other low-resource counterparts. It is worth noting that some extremely low-resource languages may not be supported by any existing quality-estimation model. We leave it for future work to explore the robustness of the model across language families and low-resource scenarios.

Ethical Statement

This work focuses on the term accuracy and overall translation quality of the adapted models. The impact of this adaptation on possible biases, such as gender bias, produced by the system is outside the scope of this study.

All models and datasets used in these experiments are based on publicly available resources, and no direct causes of bias were observed.

A Template

This section presents the template used to prepare instructions for training (Figure 4). We used only one single template. Placeholders:

- { Source Sentence }: source sentence
- { Glossary }: glossary of terms
- { Source Language }: source language name
- { Target Language }: target language name

Template used for training

```
Translate the following text from {Source Language} into {Target Language}.
Please ensure the following terminology is used:
{Glossary}.
{Source Language}: {Source Sentence}
{Target Language}:
```

Figure 4: Example of a template used to construct terminology instructions.

It Takes Two: A Dual Stage Approach for Terminology-Aware Translation

Akshat Singh Jaswal
PES University
sja.akshat@gmail.com

Abstract

This paper introduces DuTerm, a novel two-stage architecture for terminology-constrained machine translation. Our system combines a terminology-aware NMT model, adapted via fine-tuning on large-scale synthetic data, with a prompt-based LLM for post-editing. The LLM stage refines NMT output and enforces terminology adherence. We evaluate DuTerm on English-to-German, English-to-Spanish, and English-to-Russian for the WMT 2025 Terminology Shared Task. We demonstrate that flexible, context-driven terminology handling by the LLM consistently yields higher quality translations than strict constraint enforcement. Our results highlight a critical trade-off, revealing that an LLM's intrinsic knowledge often provides a stronger basis for high-quality translation than rigid, externally imposed constraints.

1 Introduction

The accurate and consistent translation of domain-specific terminology is a challenge in the field of Machine Translation and is of importance in domains such as law, medicine, and engineering, where precision is critical (Naveen and Trojovský, 2024). While modern Neural Machine Translation systems based on architectures like the Transformer have achieved remarkable fluency and quality on general text, their performance in terminology-constrained texts remains a critical area for improvement (Vaswani et al., 2023; Bahdanau et al., 2016; Johnson et al., 2017). This issue is particularly relevant given findings of recent WMT shared tasks, which have consistently highlighted the need for systems that can effectively handle domain-specific vocabulary (Post, 2018). The WMT 2025 Terminology Shared Task (Semenov et al., 2025) provides a focused platform to evaluate MT systems ability to handle domain-specific terminology under controlled conditions across multiple language pairs: English to German, English to Spanish, and English to Russian.

Previous research into terminology-constrained MT can be broadly categorized into two main approaches: inference-time methods and training-time methods. Inference-time approaches incorporate terminology constraints directly into the decoding process, often through techniques like constrained beam search or by re-ranking n-best lists of candidate translations (Zhang et al., 2023). While these methods are highly effective at enforcing constraints, they can be computationally expensive and may compromise the overall fluency and grammatical correctness of the output by forcing the model to generate awkward or unnatural phrases. Recent work has explored ways to make these methods more efficient, but the trade-off between enforcing terminology constraints and fluency remains a key consideration (Moslem et al., 2023).

Alternatively, training-time methods aim to teach models how to handle terminology constraints by integrating the terminology information into the training data itself. This is commonly done through the use of special tags that surround the terms to be translated (Dinu et al., 2019). This approach allows the model to learn how to produce more natural and grammatically correct output, but it provides no guarantee that all constraints will be respected during inference (Susanto et al., 2020).

We present DuTerm, a two-stage architecture that addresses these limitations by combining the strengths of both training-time and inference-time methodologies. We recognize that terminology-constrained translation is not merely a lexical substitution problem but requires a deeper understanding of linguistic context, especially when dealing with the complex morphology of languages like German and Russian. Our system is specifically designed to tackle the multifaceted evaluation framework of the WMT 2025 shared task.

Proceedings of the Tenth Conference on Machine Translation, pages 1344–1350

2 Method

2.1 Terminology-Aware Neural Machine Translation

Overview We develop a terminology aware MT model via large-scale, tagged synthetic data and targeted fine-tuning. The pipeline: extract and analyze terminology, generate tagged, context-rich parallel data (single-term and multi-term) and standardize tags and ensure annotation consistency. We also quality-filter with COMET_{QE} (Rei et al., 2022) and deduplicate , this finally adapts a multilingual NMT model with parameter efficient fine-tuning .

Terminology Extraction and Analysis We parse the WMT 2025 dev files for English→German/Spanish/Russian to build bilingual terminology dictionaries. The dictionaries typically exceed 1,000 unique pairs per direction. We track terms and occurrences using `repetition_ids`. We also use the LLM to generate more terms similar to the terms provided in the dictionaries.

Synthetic Data Generation We use GPT-4o (OpenAI, 2024) to create parallel sentences that naturally embed required terms and explicitly insert boundary tags (`[TERM]...[/TERM]`) on both source and target. There are two modes we use to generate these parallel sentences

Single-term mode: generates sentence pairs containing exactly one term instance per sentence.

Multi-term mode: randomly selects 2–3 term pairs to appear together, teaching co-occurrence handling and disambiguation.

We employ temperature sampling (0.3–0.7), concurrent generation, and strict parsing to yield well-formed bilingual pairs.

Tag Standardization and Quality Filtering A re-tagging pass enforces consistent annotation, longest-first matching prevents partial shadowing, case-insensitive detection with original case preservation, and inverse mapping ensures symmetric target-side tagging. Each pair is scored by COMET_{QE}. We deduplicate on the source side and keep only high-confidence items using a conservative threshold (0.85-0.9) depending on the language, typically retaining 60–70% of outputs, yielding ∼10k–15k pairs per language direction.

Multilingual Model Adaptation For the foundation translation model, we select NLLB-200 3.3B, a state-of-the-art multilingual neural machine translation model with demonstrated strong performance across our target languages (Team et al., 2022). This model provides robust baseline capabilities while supporting the specialized terminology handling adaptations we require.

We extend the model's vocabulary with terminology markup tokens to ensure atomic treatment of terminology annotations. This prevents subword tokenization from fragmenting our special markup, ensuring that terminology boundaries are consistently preserved during training and inference.

The training process employs several optimization strategies designed for stable, effective adaptation. The process also combines filtered datasets from all three target languages, creating unified multilingual adaptation that benefits from cross-lingual transfer.

2.2 LLM-Based Post-Editing

Overview An LLM refines the NMT output given the source sentence and required term pairs, enforcing strict terminology adherence while improving fluency and morphology.(Raunak et al., 2023)

Post-Editing Procedure We use prompts that present the source, translation, and provide explicit source to target term mappings. The LLM is instructed to preserve meaning, apply the exact target terms, maintain tags where required, and improve readability without paraphrasing away constraints. The LLM we choose to use is GPT-4o (OpenAI, 2024) due to its combination of high translation quality and relatively lower price.

Terminology-Aware Processing *Dynamic resolution*: per-input selection of proper/random/no-term constraints from reference terminology databases with whitespace-normalized matching. *Mode-adaptive behavior*: when constraints exist, the LLM must enforce them; otherwise it performs quality-only edits while being sensitive to technical terms. *Constraint satisfaction*: explicit mappings and formatting rules are included in the prompt; outputs must preserve required terminology and markup.

Quality Assurance and Robustness We run the LLM at low temperatures (0.3) for deterministic edits. Each hypothesis is validated for format, tag integrity, and constraint satisfaction before acceptance with a pre-existing parser. We verify filename

schemas, presence of all terminology modes per language pair, and JSONL structure. We assess quality with COMET_{QE} (after tag stripping) and compute terminology preservation via exact-match checks on required terms. This ensures reliability of final outputs.

3 Results

We evaluate the system using three complementary metrics used by the WMT organizers: BLEU for overall translation adequacy, chrF2++ for character-level fluency and robustness, and terminology success rates (proper and random) to directly measure constraint satisfaction (Papineni et al., 2002; Popović, 2015). Results are reported for English→German (DE), English→Spanish (ES), and English→Russian (RU) across three terminology strategies: *noterm*, *proper*, and *random*.

Table 1 summarizes the findings. Several clear patterns emerge:

1. **Strict terminology enforcement (*proper*)** achieves the highest BLEU and chrF2++ across all languages (48.06 for DE, 58.51 for ES, 35.80 for RU), indicating improved lexical precision and sentence-level quality when constraints are respected. It also yields near-perfect proper terminology success rates ($\geq$0.97).

2. **Unconstrained translation (*noterm*)** consistently underperforms, producing the lowest BLEU and chrF2++ values across languages (e.g., 38.24 BLEU in DE and 27.88 in RU). While fluency remains reasonable, failure to enforce constraints leads to poor terminology precision.

3. **Random terminology enforcement** produces intermediate BLEU/chrF2++ but near-perfect random-term success rates ($\sim$0.98). This highlights that while the model can force arbitrary terminology, doing so compromises contextual appropriateness.

4. **Language-specific trends** align with expectations: Spanish shows the highest overall scores, reflecting its structural similarity to English. Russian shows the widest gap between *proper* and *noterm*, emphasizing the difficulty of morphology-rich languages for terminology control.

Overall, these results demonstrate that while strict enforcement maximizes terminology accuracy and boosts surface-level quality metrics, it can occasionally reduce flexibility. In contrast, unconstrained approaches produce more natural translations but risk terminology inconsistency.

4 Conclusion

This paper presents our approach to the terminology shared task, focusing on English to German, Spanish, and Russian translation directions. Our system leverages LLMs to improve existing translations with varying terminology handling strategies. Our results demonstrate that allowing the LLM to flexibly handle terminology often yields higher translation quality than strict terminology enforcement. These findings highlight the potential of prompt-based LLM systems for technical and business translation tasks, and provide insights into effective strategies for terminology management in neural translation workflows. The intution behind why this approach works so well is that NMTs often excel at strict word-level translations however they can struggle with context-dependent nuances. Our approach leverages post-editing with a LLM on top of the initial NMT outputs. By starting from a reliable NMT translation, the post-editing model receives a structured, partially correct target sentence, which allows it to focus on higher-level improvements resolving ambiguities, adjusting word order, and refining context. This guided refinement is often more effective than translating directly from scratch with an LLM or NMT which must simultaneously handle term accuracy and contextual fluency.

For future work, exploring adaptive learning mechanisms that integrate terminology dynamically, rather than relying on static prompts, could enhance robustness across domains and languages. End-to-end or memory-augmented architectures that maintain consistency across sentences and documents hold promise for more coherent outputs. Expanding evaluations to other language models and diverse, domain-specific corpora would help validate the approach's generalizability and reveal domain-dependent challenges. Incorporating hybrid strategies, such as combining prompt guidance with fine-tuning or reinforcement learning, and enabling user-driven interaction for terminology control could further improve usability and accuracy. Together, these directions offer a pathway toward more flexible, context-aware, and widely applicable terminology-aware translation systems.

Limitations

Our approach, based on a prompt-driven framework, faces several limitations. It depends heavily on carefully crafted prompts, which may not gen-

Lang	Type	BLEU	chrF2++	Prop. SR	Rand. SR
DE	noterm	38.24	62.61	0.43	0.69
	proper	48.06	70.74	0.98	0.73
	random	43.77	67.22	0.48	0.99
ES	noterm	45.98	67.05	0.47	0.73
	proper	58.51	76.08	0.99	0.78
	random	53.28	72.05	0.49	0.98
RU	noterm	27.88	55.29	0.39	0.69
	proper	35.80	63.57	0.98	0.72
	random	32.25	59.85	0.42	0.99

Table 1: Evaluation results for English→German (DE), English→Spanish (ES), and English→Russian (RU) across three terminology handling strategies. Metrics include BLEU, chrF2++, and terminology success rates (proper and random).

eralize well across domains, languages, or model architectures. The sequential processing of terminology matching and translation refinement limits the system's ability to adaptively enforce terminology constraints. Furthermore, operating at the sentence level overlooks opportunities for document-level consistency and context-aware terminology usage, which are crucial in practical translation tasks. Our evaluation, conducted solely on GPT-4o (OpenAI, 2024), restricts the generalizability of findings, and focusing on technical and business domains may not capture challenges present in specialized fields like medical or legal translation. Additionally, while COMET_{QE} ,BLEU ,chrF++ provide automated scalability, it may not fully reflect terminological precision and contextual appropriateness, suggesting the need for complementary evaluation methods that include human judgment.

A Prompts

We include below the full prompts used in our experiments for reproducibility.

A.1 Single-Term Prompt

```
Generate {n} professional, domain-specific English-({target_lang}) bilingual sentence pairs for
    terminology translation.
The term pair to use is: {source_term}\(EN) : \"{target_term}\ ({target_lang})
Requirements:
- Each sentence pair must be natural, fluent, and contextually appropriate for IT or financial
    domains.
- Include the term exactly once per sentence.
- Wrap the term with [TERM] and [/TERM] in both the English and ({target_lang}) sentences.
- Ensure accurate translation and alignment of the term.
Format:
EN: [sentence]
{target_lang}: [sentence]
Output exactly {n} such pairs.
```

Listing 1: Prompt template for generating bilingual sentence pairs with a single terminology constraint.

A.2 Multi-Term Prompt

```
Generate {n} professional, domain-specific English-({target_lang}) bilingual sentence pairs for
    terminology translation.
Use ALL of the following term pairs in each sentence pair:\n{terms_str}
Requirements:
- Each sentence pair must be natural, fluent, and contextually appropriate for IT or financial
    domains.\n"
- Include each term exactly once per sentence.
- Wrap each term with [TERM] and [/TERM] in both the English and ({target_lang}) sentences.\n"
- Ensure accurate translation and alignment of the terms.
Format:
EN: [sentence]
{target_lang}: [sentence]
Output exactly {n} such pairs.
```

Listing 2: Prompt template for generating bilingual sentence pairs with multiple terminology constraints.

A.3 Post-Editing with Terminology

```
As an expert English-{target_lang} translator specializing in technical and business documentation,
    improve this {target_lang} translation.

SOURCE (English): {source}

CURRENT TRANSLATION ({target_lang}): {translation}

REQUIRED TERMINOLOGY (English: {target_lang}): {term_str}

YOUR TASK:
1. Ensure all required terminology is correctly used
2. Maintain the same meaning as the source text
3. Ensure natural, fluent {target_lang} that sounds like native content
4. Preserve formatting, numbers, and special characters
5. Match the tone and register of the original text

Return ONLY the improved {target_lang} translation with no explanations, notes, or other text.
```

Listing 3: Prompt for post-editing with explicit terminology mappings.

A.4 Post-Editing without Terminology

```
As an expert English-{target_lang} translator specializing in technical and business documentation,
    improve this {target_lang} translation.

SOURCE (English): {source}

CURRENT TRANSLATION ({target_lang}): {translation}

Note: There may be important terminology in the source text that should be translated precisely and
    consistently. Please ensure any technical or business terms are rendered correctly in {
    target_lang}.

YOUR TASK:
1. Enhance the translation for fluency and accuracy
2. Maintain the same meaning as the source text
3. Ensure natural, fluent {target_lang} that sounds like native content
4. Preserve formatting, numbers, and special characters
5. Match the tone and register of the original text

Return ONLY the improved {target_lang} translation with no explanations, notes, or other text.
```

Listing 4: Prompt for post-editing without explicit terminology guidance.
